Proof. (a)⇔(b): Set $X := \mathrm{Spec}\,A$, $Y := \mathrm{Spec}\,B$, and let $\pi : Y \times_X Y \to X$ be the projection. With this notation, $\mathrm{Spec}\,B \otimes_A B/I_f$ is the diagonal closed subset $\Delta_{Y/X} \subset Y \times_X Y$. Suppose then that (b) holds; it follows already that $\Delta_{Y/X} = Y \times_X Y$, so $\varphi := \mathrm{Spec}\,f : Y \to X$ is injective. Moreover, let $y \in Y$ be any point, set $x := \varphi(y)$, and let $\kappa(x)$ and $\kappa(y)$ be the residue fields of x and respectively y; then $Z(y) := \mathrm{Spec}\,\kappa(y) \otimes_{\kappa(x)} \kappa(y) = \pi^{-1}(y)$ consists of a unique point of $Y \times_X Y$, which means that the field extension $\kappa(x) \subset \kappa(y)$ is algebraic and purely inseparable, therefore (a) holds. Conversely, if (a) holds, then φ is injective, and $Z(y)$ consists of a unique point, so that $\Delta_{Y/X} = Y \times_X Y$, whence (b).

(b)⇔(c): Since the natural map $R^{\mathrm{perf}} \to (R_{\mathrm{red}})^{\mathrm{perf}}$ is an isomorphism for every $\mathbb{F}_p$-algebra R, and since f is radicial if and only if the same holds for the induced map $f_{\mathrm{red}} : A_{\mathrm{red}} \to B_{\mathrm{red}}$, *we may assume that A and B are reduced*, in which case (c) means that for every $b \in B$ there exists $n \in \mathbb{N}$ with $b^{p^n} \in A$. Now, let us write B as the filtered colimit of the system $(f_\lambda : A \to B_\lambda \mid \lambda \in \Lambda)$ of its finite A-subalgebras. It follows easily that (c) holds for f if and only if it holds for every f_λ. On the other hand, $\mathrm{Spec}\,f$ is the limit of the system of maps $(\mathrm{Spec}\,f_\lambda \mid \lambda \in \Lambda)$, and each $\mathrm{Spec}\,f_\lambda$ is surjective; it follows easily that $\mathrm{Spec}\,f$ is injective if and only if the same holds for each $\mathrm{Spec}\,f_\lambda$. Moreover, it is clear that for any field K, and any filtered system $E_\bullet := (E_\lambda \mid \lambda \in \Lambda)$ of field extension of K, the colimit of $E_\bullet$ is algebraic and purely inseparable over K if and only if the same holds for every E_λ; summing up, we see that f is radicial if and only if the same holds for every f_λ, hence, in view of (i), it suffices to show the equivalence (b)⇔(c) for each f_λ, and *we may assume that f is a finite ring homomorphism.*

Next, let $(A_\lambda \mid \lambda \in \Lambda)$ be the filtered system of all $\mathbb{Z}$-subalgebras of A of finite type; also, choose any finite subset $\Sigma \subset B$ such that $B = A[\Sigma]$. Notice that (c) holds if and only if for every $b \in \Sigma$ there exists $n \in \mathbb{N}$ such that $b^{p^n} \in A$; then the latter condition holds if and only if there exists $\lambda \in \Lambda$ and $n \in \mathbb{N}$ such that $b^{p^n} \in A_\lambda$ for every $b \in \Sigma$. Moreover, there exists a cofinal subset $\Lambda' \subset \Lambda$ such that the restriction $f_\lambda : A_\lambda \to B_\lambda := A_\lambda[\Sigma]$ is a finite ring homomorphism for every $\lambda \in \Lambda'$. Furthermore, recall that I_f is the ideal generated by $(b \otimes 1 - 1 \otimes b \mid b \in \Sigma)$, and likewise for the ideal I_{f_λ}, for every $\lambda \in \Lambda$. It follows that $I_f \subset \mathscr{N}_{B \otimes_A B}$ if and only if $I_{f_\lambda} \subset \mathscr{N}_{B_\lambda \otimes_{A_\lambda} B_\lambda}$ for some $\lambda \in \Lambda'$. Summing up, it then suffices to check the equivalence (b)$\Leftrightarrow$(c) for each map f_λ, and therefore *we may assume that* A *and* B *are noetherian*.

Next, pick a decomposition $f = f_1 \circ \cdots \circ f_n$ as in proposition 9.8.9; since $\mathrm{Spec}\, f_i$ is a surjection for every $i = 1, \dots, n$, clearly f is radicial if and only if the same holds for each f_i. Similarly, $f^{\mathrm{perf}} = f_1^{\mathrm{perf}} \circ \cdots \circ f_n^{\mathrm{perf}}$ is an isomorphism if and only if f_i^{perf} is an isomorphism for every $i = 1, \dots, n$. Thus, it suffices to show the equivalence (b)$\Leftrightarrow$(c) for each f_i, and therefore *we may assume that* $\mathrm{Spec}\, f$ *is an effective epimorphism of schemes*. Now, (b) says that for every $b \in B$ there exists $n \in \mathbb{N}$ with

$$(b \otimes 1 - 1 \otimes b)^{p^n} = b^{p^n} \otimes 1 - 1 \otimes b^{p^n} = 0.$$

By assumption, the latter holds if and only if $b^{p^n} \in A$, whence the contention. □

Remark 9.8.14. (i) Let $f : A \to B$ an injective ring homomorphism, and denote by $\mathscr{E}$ the set of all A-subalgebras $B' \subset B$ such that the induced map $f' : A \to B'$ is integral and radicial; recall that if $B' = A[\Sigma]$ for a subset $\Sigma \subset B'$, then $I_{f'}$ is generated by the system $(b \otimes 1 - 1 \otimes b \mid b \in \Sigma)$.

(ii) In view of corollary 9.8.13(i), it follows easily that if $B', B'' \in \mathscr{E}$, then also $B' \cdot B'' \in \mathscr{E}$.

(iii) Moreover, for every system $(B_\lambda \mid \lambda \in \Lambda)$ of elements of $\mathscr{E}$ filtered by inclusion, we have $\bigcup_{\lambda \in \Lambda} B_\lambda \in \mathscr{E}$.

(iv) Furthermore, if $B' \in \mathscr{E}$, and $B'' \subset B'$ is any A-subalgebra, then $B'' \in \mathscr{E}$ as well.

Definition 9.8.15. From remark (9.8.14)(ii,iii), it follows that $\mathscr{E}$ is a filtered set, and the subring $C := \bigcup_{B' \in \mathscr{E}} B'$ is the largest element of $\mathscr{E}$; we call C the *weak normalization* of A in B.

Remark 9.8.16. (i) Consider a commutative diagram of rings :

$$\begin{array}{ccc} A & \xrightarrow{i} & B \\ {\scriptstyle g_A}\downarrow & & \downarrow{\scriptstyle g_B} \\ A' & \xrightarrow{i'} & B' \end{array}$$

where i and i' are injective ring homomorphisms. Denote by C (resp. C') the weak normalization of A in B (resp. of A' in B'). Then $g_B(C) \subset C'$. Indeed, let $x \in C$; by remark 9.8.14(iv), the induced map $A \to A[x]$ is radicial, hence $x \otimes 1 - 1 \otimes x$ is nilpotent in $A[x] \otimes_A A[x]$, so that its image $g_B(x) \otimes 1 - 1 \otimes g_B(x)$ is nilpotent in $A'[x] \otimes_{A'} A'[x]$, and therefore the induced map $A' \to A'[x]$ is radicial, whence the claim.

(ii) Let $f : A \to B$ be an injective and integral ring homomorphism; let j_1 (resp. j_2) be the ring homomorphism $B \to B \otimes_A B$ given by the rule : $b \mapsto b \otimes 1$ (resp. $b \mapsto 1 \otimes b$) for every $b \in B$. For $i = 1, 2$ let also $j'_i : B \to (B \otimes_A B)_{\mathrm{red}}$ be the composition of j_i with the projection $B \otimes_A B \to (B \otimes_A B)_{\mathrm{red}}$. Then the weak normalization of A in B is the equalizer of j'_1 and j'_2. Indeed, if $b \in B$ and $A[b]$ is a radicial A-algebra, then $b \otimes 1 - 1 \otimes b$ is nilpotent in $A[b] \otimes_A A[b]$, hence also in $B \otimes_A B$, so $j'_1(b) = j'_2(b)$. Conversely, if the latter identity holds, $b \otimes 1 - 1 \otimes b$ is nilpotent in $B \otimes_A B$; but notice that the map $A[b] \to B$ is still injective and integral, so the kernel of the induced map $A[b] \otimes_A A[b] \to B \otimes_A B$ lies in the nilradical (lemma 9.8.8(iii)). It follows that $b \otimes 1 - 1 \otimes b$ is nilpotent in $A[b] \otimes_A A[b]$, so $A[b]$ is a radicial A-algebra, as required.

Lemma 9.8.17. *Let* $f_\bullet := (f_\lambda : A_\lambda \to B_\lambda \mid \lambda \in \Lambda)$ *be a filtered system of injective ring homomorphisms; denote by* $f : A \to B$ *the colimit of* $f_\bullet$*, and for every* $\lambda \in \Lambda$ *let* C_λ *be the weak normalization of* A_λ *in* B_λ*. Then, the system of rings* $(B_\lambda \mid \lambda \in \Lambda)$ *restricts to a filtered system of rings* $C_\bullet := (C_\lambda \mid \lambda \in \Lambda)$*, whose colimit* C *is the weak normalization of* A *in* B*.*

Proof. Let $f' : A \to C$ be the map induced by f, and for every $\lambda \in \Lambda$, let $f'_\lambda : A_\lambda \to C_\lambda$ be the map induced by f_λ. By corollary 9.8.13(i) we know that $I_{f'_\lambda} \subset \mathscr{N}_{C_\lambda \otimes_{A_\lambda} C_\lambda}$; on the other hand, it is easily seen that $I_{f'}$ is the colimit of the system of ideals $(I_{f'_\lambda} \mid \lambda \in \Lambda)$, hence $I_{f'} \subset \mathscr{N}_{C\otimes_A C}$. Moreover, since C_λ is an integral A_λ-algebra for every $\lambda \in \Lambda$, it is easily seen that C is an integral A-algebra. Invoking again corollary 9.8.13(i), we deduce that C lies in the weak normalization C' of A in B. Conversely, if $x \in C'$, then in particular x lies in the integral closure C'' of A in B, hence we find $\lambda \in \Lambda$ and $x_\lambda \in B_\lambda$ whose class in B agrees with x, and such that x_λ is integral over A_λ; by corollary 9.8.13(i), we have $x \otimes 1 - 1 \otimes x \in \mathscr{N}_{C'\otimes_A C'}$, and therefore $x \otimes 1 - 1 \otimes x \in \mathscr{N}_{C''\otimes_A C''}$ as well. Hence, after replacing λ by some $\lambda' \geq \lambda$, we may assume that $x_\lambda \otimes 1 - 1 \otimes x_\lambda \in \mathscr{N}_{C''_\lambda \otimes_{A_\lambda} C''_\lambda}$, where C''_λ denotes the integral closure of A_λ in B_λ. Now, the inclusion $A_\lambda[x] \to C''_\lambda$ is integral and injective, hence the kernel of the induced ring homomorphism $A_\lambda[x] \otimes_{A_\lambda} A_\lambda[x] \to C''_\lambda \otimes_{A_\lambda} C''_\lambda$ lies in the nilradical (lemma 9.8.8(iii)). Summing up, we conclude that $x_\lambda \otimes 1 - 1 \otimes x_\lambda$ is already nilpotent in $A_\lambda[x] \otimes_{A_\lambda} A_\lambda[x]$, so $x_\lambda \in C_\lambda$, and finally $x \in C$. This shows that $C' = C$, as required. □

Proposition 9.8.18. *Let $f : A \to B$ be an injective ring homomorphism, C the weak normalization of A in B, and A' a flat A-algebra such that the induced morphism* $\mathrm{Spec}\, A' \to \mathrm{Spec}\, A$ *has geometrically reduced fibres. Suppose that :*

- *either A' is a finitely presented A-algebra*
- *or else, A is noetherian.*

Then $A' \otimes_A f : A' \to B' := A' \otimes_A B$ is an injective ring homomorphism, and the weak normalization of A' in B' is $A' \otimes_A C$.

Proof. Since A' is a flat A-algebra, $A' \otimes_A f$ is still injective, as stated. Now, let A^ν (resp. A'^ν) be the integral closure of A in B (resp. of A' in B'); then $A'^\nu = A' \otimes_A A^\nu$ (proposition 9.8.3). We may then replace B by A^ν, and assume that B is an integral A-algebra. In this case, notice that for every A-algebra R we have $(A' \otimes_A R)_{\mathrm{red}} = A' \otimes_A R_{\mathrm{red}}$ (proposition 9.8.3); then the assertion follows easily from remark 9.8.16(ii). □

9.8.19. Let $f : A \to B$ be an integral and injective ring homomorphism, $I \subset A$ an ideal; set $X := \mathrm{Spec}\, A$, $Y := \mathrm{Spec}\, B$, $Z := \mathrm{Spec}\, A/I$, $U := X \setminus Z$, and notice that $\varphi := \mathrm{Spec}\, f : Y \to X$ is surjective by the going up theorem, hence the same holds for its restriction $\varphi^{-1}Z \to Z$, and therefore the kernel of $A/I \otimes_A f : A/I \to B/IB$ lies in the nilradical (lemma 9.8.8(ii)), *i.e.* the induced map $(A/I)_{\mathrm{red}} \to (B/IB)_{\mathrm{red}}$ is injective and integral as well.

Lemma 9.8.20. *In the situation of* (9.8.19)*, suppose that φ restricts to a radicial morphism of schemes $\varphi_{|U} : \varphi^{-1}U \to U$, and let C (resp. $\overline{C}$) be the weak normalization of A in B (resp. of $(A/I)_{\mathrm{red}}$ in $(B/IB)_{\mathrm{red}}$). Then we have :*

$$C = B \times_{(B/IB)_{\mathrm{red}}} \overline{C}.$$

Proof. By remark 9.8.16(i), the projection $B \to (B/IB)_{\mathrm{red}}$ maps C into $\overline{C}$, whence the inclusion $C \subset C' := B \times_{(B/IB)_{\mathrm{red}}} \overline{C}$. For the converse inclusion, we need to show that the induced map $g : A \to C'$ is radicial. To this aim, it suffices to check that the same holds for $A/I \otimes_A g : A/I \to C'/IC$ and for $A[a^{-1}] \otimes_A g : A[a^{-1}] \to C'[a^{-1}]$, for every $a \in I$. However, for any such a, the localization $C'[a^{-1}]$ is the fibre product $B[a^{-1}] \times_{(B/IB)_{\mathrm{red}}[a^{-1}]} \overline{C}[a^{-1}]$, and since $(B/IB)_{\mathrm{red}}[a^{-1}] = \overline{C}[a^{-1}] = 0$, we see that $C'[a^{-1}] = B[a^{-1}]$; but f induces a radicial map $A[a^{-1}] \to B[a^{-1}]$, since $\varphi_{|U}$ is radicial. It remains thus only to check that C/IC is a radicial A/I-algebra; to this aim, notice that the kernel of the surjection $B \to (B/IB)_{\mathrm{red}}$ is the radical J of the ideal $IB \subset B$. Then J is also the kernel of the surjection $C' \to \overline{C}$; on the other hand, since $IB \subset J \subset C$, we have $I^2B \subset IC \subset IB \subset J$, and clearly J is also the radical of the ideal I^2B of C. Hence, C/IC is a radicial A/I-algebra if and only if the same holds for the A/I-algebra C/J; but $C/J = \overline{C}$, whence the contention. □

Proposition 9.8.21. *Let B be a ring, $A \subset B$ a subring, and G a finite group of automorphisms of B such that $g(A) = A$ for every $g \in G$. Denote by C (resp. D) the integral closure (resp. the weak normalization) of A in B. Then we have :*

(i) *C^G is the integral closure of A^G in B^G.*
(ii) *D^G is the weak normalization of A^G in B^G.*

Proof. (i): Clearly $\mathrm{i.c.}(A^G, B^G) \subset C^G$. To show the reverse inclusion, let $x \in C^G$, so that $x \in B^G$, and x is integral over A; but since G is a finite group, A is integral over A^G (details left to the reader), hence x is integral over A^G, as required.

(ii): Let D' be the weak normalization of A^G in B^G; we have $D' \subset D$ by remark 9.8.16(i), and then obviously $D' \subset D^G$. For the reverse inclusion, we come down to checking that the inclusion map $A^G \to D^G$ is radicial. To this aim, notice first :

Claim 9.8.22. (i) $g(D) = D$ for every $g \in G$.

(ii) Let K be any algebraically closed field, and $E \subset B$ any subring such that $g(E) = E$ for every $g \in G$. Then the set $\mathrm{Hom}_{\mathbb{Z}\text{-}\mathsf{Alg}}(E, K)$ inherits from E a natural G-action, and the map $\mathrm{Hom}_{\mathbb{Z}\text{-}\mathsf{Alg}}(E, K) \to \mathrm{Hom}_{\mathbb{Z}\text{-}\mathsf{Alg}}(E^G, K) : \varphi \mapsto \varphi_{|A^G}$ factors through a bijection

$$\mathrm{Hom}_{\mathbb{Z}\text{-}\mathsf{Alg}}(E, K)/G \xrightarrow{\sim} \mathrm{Hom}_{\mathbb{Z}\text{-}\mathsf{Alg}}(E^G, K).$$

Proof of the claim. (i): We apply remark 9.8.16(i) with $A' := A$, $B' := B$, $g_B := g$, $g_A := g_{|A}$, and with i and i' the inclusion maps; then we get $g(D) \subset D$, and similarly $g^{-1}(D) \subset D$, whence the claim.

(ii): The injectivity follows easily from [34, Ch.5, §2, n.2, Cor. of Th.2], and the surjectivity is clear, since the inclusion map $E^G \to E$ is integral. ◊

Now, the radicial map $A \to D$ induces a bijection $\mathrm{Hom}_{\mathbb{Z}\text{-}\mathsf{Alg}}(D, K) \xrightarrow{\sim} \mathrm{Hom}_{\mathbb{Z}\text{-}\mathsf{Alg}}(A, D)$ for every algebraically closed field K; in view of claim 9.8.22(i), this map is obviously G-equivariant, hence it induces a bijection on the quotients by the respective G-actions. Then, claim 9.8.22(ii) implies that the map $A^G \to D^G$ also induces a bijection $\mathrm{Hom}_{\mathbb{Z}\text{-}\mathsf{Alg}}(D^G, K) \xrightarrow{\sim} \mathrm{Hom}_{\mathbb{Z}\text{-}\mathsf{Alg}}(A^G, D)$ for every such K, whence the contention. □

Proposition 9.8.23. *In the situation of remark* 9.8.16(i)*, let D (resp. D') be the integral closure of A in B (resp. of A' in B'), and suppose that we have norm maps $\nu_A : \Gamma^d_A A' \to A$ and $\nu_B : \Gamma^d_B B' \to B$ of some degree $d \in \mathbb{N}$, that make commute the induced diagram :*

$$\begin{array}{ccc} \Gamma^d_A A' & \longrightarrow & \Gamma^d_B B' \\ {\scriptstyle \nu_A}\downarrow & & \downarrow{\scriptstyle \nu_B} \\ A & \xrightarrow{\ i\ } & B \end{array}$$

(see definition 9.5.70*). Then there exist unique norm maps $\nu_C : \Gamma^d_C C' \to C$ and $\nu_D : \Gamma^d_D D' \to D$ of degree d, that make commute the resulting diagram :*

$$\begin{array}{ccccccc} \Gamma^d_A A' & \longrightarrow & \Gamma^d_C C' & \longrightarrow & \Gamma^d_D D' & \longrightarrow & \Gamma^d_B B' \\ {\scriptstyle \nu_A}\downarrow & & {\scriptstyle \nu_C}\downarrow & & \downarrow{\scriptstyle \nu_D} & & \downarrow{\scriptstyle \nu_B} \\ A & \longrightarrow & C & \longrightarrow & D & \longrightarrow & B. \end{array}$$

Moreover, if ν_B is Cayley-Hamilton, the same holds for ν_C and ν_D (see definition 9.5.74*).*

Proof. We need to show that that the image of the composition of ν_B with the natural map $\Gamma^d_D D' \to \Gamma^d_B B'$ lies in D; to this aim, it suffices to check that the natural map $\Gamma^d_A A' \to \Gamma^d_D D'$ is integral. However, the latter is the composition of the integral map $\Gamma^d_A A' \to D \otimes_A \Gamma^d_A D'$ (proposition 9.5.68(iv.a)), the isomorphism $D \otimes_A \Gamma^d_A D' \xrightarrow{\sim} \Gamma^d_D(D \otimes_A D')$ (proposition 9.5.68(i)) and the surjection $\Gamma^d_D(D \otimes_A D') \to \Gamma^d_D D'$ (corollary 9.5.22(iv)), whence the contention.

Likewise, we need to check that the image of the composition of ν_B with the natural map $\Gamma^d_C C' \to \Gamma^d_B B'$ lies in C. To this aim, notice that the natural map $\Gamma^d_A A' \to \Gamma^d_A C'$ is integral, radicial, and its kernel lies in the nilradical of $\Gamma^d_A A'$ (proposition 9.5.68(iv.b,iv.c)); the same holds for the natural map $\Gamma^d_A C' \to C \otimes_A \Gamma^d_A C' \xrightarrow{\sim} \Gamma^d_C(C \otimes_A C')$. By the same token, since the natural map $C \otimes_A C' \to C'$ is surjective, and its kernel lies in the nilradical of $C \otimes_A C'$, then the same holds for the induced map $\Gamma^d_C(C \otimes_A C') \to \Gamma^d_C C'$. Summing up, we conclude that the natural map $\Gamma^d_A A' \to \Gamma^d_C C'$ is integral, radicial, and its kernel J lies in the nilradical of $\Gamma^d_A A'$; we have therefore a commutative diagram of rings :

$$\begin{array}{ccc} \Gamma^d_A(A')/J & \longrightarrow & \Gamma^d_C C' \\ \downarrow & & \downarrow \\ A & \xrightarrow{\ i\ } & B \end{array}$$

whose top horizontal arrow is integral, radicial and injective. Then the contention follows from remark 9.8.16(i). Lastly, let $\chi^\dagger_B, \chi^\dagger_C, \chi^\dagger_D$ be the characteristic maps of ν_B, ν_C and ν_D (see (9.5.73)); by inspecting the definitions, we get a commutative diagram :

$$\begin{array}{ccccc} \Gamma^d_C C' & \longrightarrow & \Gamma^d_D D' & \longrightarrow & \Gamma^d_B B' \\ {\scriptstyle \chi^\dagger_C}\downarrow & & {\scriptstyle \chi^\dagger_D}\downarrow & & \downarrow{\scriptstyle \chi^\dagger_B} \\ C' & \longrightarrow & D' & \longrightarrow & B' \end{array}$$

whence the last assertion of the proposition. □

Definition 9.8.24. (i) Let R be a ring, $S \subset R$ a subring, and $p > 0$ a prime integer. We say that *S is p-root closed in R*, if for every $x \in R$ such that $x^p \in S$, we have $x \in S$.

(ii) Let R be a ring and $p > 0$ a prime integer; if $(S_\lambda \mid \lambda \in \Lambda)$ is any family of p-root closed subrings of R, then clearly $\bigcap_{\lambda \in \Lambda} S_\lambda$ is also p-root closed in R. Hence, for every subring $S \subset R$ there exists a smallest p-root closed subring S' of R containing S. We say that S' is the *p-root closure of S in R*.

Remark 9.8.25. (i) Let R be a ring, $S \subset R$ a subring; consider the increasing countable system $(S_n \mid n \in \mathbb{N})$ of subrings of R defined inductively as follows : $S_0 := S$, and $S_{n+1} := S_n[\Sigma_n]$ for every $n \in \mathbb{N}$, where $\Sigma_n := \{x \in R \mid x^p \in S_n\}$. Then it is easily seen that $\bigcup_{n \in \mathbb{N}} S_n$ is the p-root closure of S in R.

(ii) In the situation of remark 9.8.16(i), let D (resp. D') be the p-root closure of A in B (resp. of A' in B'). Define the system of subrings $(A_n \mid n \in \mathbb{N})$ of B (resp. $(A'_n \mid n \in \mathbb{N})$ of B') as in (i); a simple induction shows that $g_B(A_n) \subset A'_n$ for every $n \in \mathbb{N}$, so g_B restricts to a ring homomorphism $D \to D'$.

Lemma 9.8.26. (i) *Let R be a ring, $a \in R$ a regular element such that $pR \subset a^p R$. Then R is p-root closed in $R[a^{-1}]$ if and only if the Frobenius endomorphism of $R/a^p R$ induces an injective ring homomorphism $\overline{\Phi} : R/aR \to R/a^p R$.*

(ii) *Let R be a topological ring, $S \subset R$ an open subring, T the p-root closure of S in R; endow S and T with the topologies induced by R, and denote by $R^\wedge$, $S^\wedge$ and $T^\wedge$ the respective completions. Then $T^\wedge$ is the p-root closure in $R^\wedge$ of $S^\wedge$.*

(iii) *Let $R_\bullet := (R_\lambda \mid \lambda \in \Lambda)$ be a system of rings, with transition morphisms $f_{\lambda\mu} : R_\lambda \to R_\mu$ for every $\lambda, \mu \in \Lambda$ with $\mu \geq \lambda$. For every $\lambda \in \Lambda$, let also $S_\lambda \subset R_\lambda$ be a subring, such that $f_{\lambda\mu}(S_\lambda) \subset S_\mu$ for every such λ, μ. Denote by $D_\lambda \subset R_\lambda$ the p-root closure of S_λ in R_λ, for every $\lambda \in \Lambda$. The following holds :*

(a) *Let R and S be the limits of $R_\bullet$ and respectively of $S_\bullet := (S_\lambda \mid \lambda \in \Lambda)$. Then the limit of the induced system $D_\bullet := (D_\lambda \mid \lambda \in \Lambda)$ is the p-root closure of S in R.*

(b) *Suppose moreover that* Λ *is filtered, and let* R' *and* S' *be the colimits of* $R_\bullet$ *and respectively of* $S_\bullet$*. Then the colimit of* $D_\bullet$ *is the* p*-root closure of* S' *in* R'*.*

(iv) *Let* B *be a ring,* $A \subset B$ *a subring,* C *the* p*-root closure of* A *in* B*, and* $S \subset A$ *a multiplicative subset. Then* $S^{-1}C$ *is the* p*-root closure of* $S^{-1}A$ *in* $S^{-1}B$*.*

Proof. (i): Suppose first that $\overline{\Phi}$ is injective; let $x \in R[a^{-1}]$ be any element such that $x^p \in R$, and suppose, by way of contradiction, that $x \notin R$. There exists a smallest $m \in \mathbb{N}$ such that $y := a^m x \notin R$ and $a^{m+1}x \in R$. Hence, $y^p = a^{pm}x^p \in R$, and therefore $(a^{m+1}x)^p = a^p y^p \in a^p R$. Thus, the class of $a^{m+1}x$ lies in $\mathrm{Ker}\,\overline{\Phi}$, *i.e.* $a^{m+1}x = az$ for some $z \in R$; since a is regular, it follows that $z = a^m x \in R$, contradicting the choice of m.

Conversely, suppose that R is integrally closed in $R[a^{-1}]$, and let $x \in R$ be an element whose class $\overline{x} \in R/aR$ lies in $\mathrm{Ker}\,\overline{\Phi}$; this means that there exists $y \in R$ such that $x^p = a^p y$. Hence, $(x/a)^p \in R$, so that $x/a \in R$, and therefore $\overline{x} = 0$.

(ii): Notice that $S^\wedge \cdot T = T^\wedge$, hence $T^\wedge$ lies in the p-root closure of $S^\wedge$ in $R^\wedge$. Hence, we are reduced to checking that S is p-root closed in R if and only if $S^\wedge$ is p-root closed in $R^\wedge$. Suppose first that S is p-root closed in R, and let $x \in R^\wedge$ be any element such that $x^p \in S^\wedge$. Denote by $j : R \to R^\wedge$ the completion map. Pick a Cauchy net $(x_\lambda \mid \lambda \in \Lambda)$ in R whose limit is x; then $(x_\lambda^p \mid \lambda \in \Lambda)$ is a Cauchy net converging to x^p, and since $S^\wedge$ is open in $R^\wedge$ (corollary 8.2.17(i)), we may replace Λ by a cofinal subset, and assume that $j(x_\lambda)^p \in S^\wedge$ for every $\lambda \in \Lambda$. Then $x_\lambda^p \in S$ (corollary 8.2.17(ii)), whence $x_\lambda \in S$ for every $\lambda \in \Lambda$, and finally $x \in S^\wedge$, as required. Conversely, if $S^\wedge$ is p-root closed in $R^\wedge$, and $x \in R$ is any element with $x^p \in S$, we have $j(x)^p \in S^\wedge$, so $j(x) \in S$, whence $x \in S$, again by corollary 8.2.17(ii).

The proof of (iii) shall be left to the reader.

(iv): Let $b \in B, s \in S$ such that $(b/s)^p \in S^{-1}C$; it follows easily that $t^p b^p \in C$ for some $t \in S$, hence $tb \in C$, and consequently $b/s \in S^{-1}C$. This shows that $S^{-1}C$ is p-root closed in $S^{-1}B$, hence it contains the p-root closure C' of $S^{-1}A$ in $S^{-1}B$. On the other hand, by remark 9.8.25, the localization $B \to S^{-1}B$ restricts to a ring homomorphism $C \to C'$; since C' is an $S^{-1}A$-algebra, we must then have $S^{-1}C \subset C'$. □

9.8.27. Let X be a scheme, $\mathscr{A} \to \mathscr{B}$ a monomorphism of quasi-coherent $\mathscr{O}_X$-algebras; for every affine open subset $U \subset X$, let $\mathscr{C}(U)$ (resp. $\mathscr{D}(U)$) be the weak normalization (resp. the p-root closure) of $\mathscr{A}(U)$ in $\mathscr{B}(U)$; by remark 9.8.16(i), the rule : $U \mapsto \mathscr{C}(U)$ (resp. $U \mapsto \mathscr{D}(U)$) defines a subpresheaf of $\mathscr{O}_X$-algebras $\mathscr{C} \subset \mathscr{B}$ (resp. $\mathscr{D} \subset \mathscr{B}$) on the site of affine open subsets of X, and it follows easily from proposition 9.8.18 (resp. from lemma 9.8.26(iv)) that $\mathscr{C}$ (resp. $\mathscr{D}$) is a sheaf on this site, so it extends uniquely to a subsheaf of $\mathscr{B}$ on the Zariski site of X; moreover, $\mathscr{C}$ and $\mathscr{D}$ are quasi-coherent $\mathscr{O}_X$-algebras. We call $\mathscr{C}$ and $\mathscr{D}$ respectively the *weak normalization* and the *p-root closure* of $\mathscr{A}$ in $\mathscr{B}$.

Proposition 9.8.28. *Let* $f : A \to B$ *be an injective ring homomorphism,* $p \in \mathbb{N}$ *a prime integer, and suppose that* f *induces an isomorphism* $A[1/p] \xrightarrow{\sim} B[1/p]$*. Let* A^ν *(resp.* C_0*, resp.* C_1*) be the integral closure (resp. the weak normalization, resp. the* p*-root closure) of* A *in* B*; denote by* $(A/pA)_{\mathrm{red}} \xrightarrow{j} (A^\nu/pA^\nu)_{\mathrm{red}} \xleftarrow{\pi} A^\nu$ *the natural maps, and set*

$$C_2 := \{b \in B \mid \textit{there exists } n \in \mathbb{N} \textit{ such that } b^{p^n} \in A\}$$
$$D := \{x \in (A^\nu/pA^\nu)_{\mathrm{red}} \mid \textit{there exists } n \in \mathbb{N} \textit{ such that } x^{p^n} \in \mathrm{Im}(j)\}.$$

Then j *is injective, and* $C_0 = C_1 = C_2 = \pi^{-1}D$*.*

Proof. One argues as in (9.8.19) to see that j is injective.

Now, the inclusion $C_2 \subset C_1$ is obvious, and the identity $C_0 = \pi^{-1}D$ follows easily from lemma 9.8.20. By remark 9.8.25, we may write C_1 as the increasing union of the family $A_0 \subset A_1 \subset A_2 \subset \cdots$ of subrings of B, defined inductively by $A_0 := A$, and $A_{i+1} := A_i[\Sigma_i]$ for every

$i \in \mathbb{N}$, where $\Sigma_i := \{b \in B \mid b^p \in A_i\}$. By remark 9.8.14(iii), in order to check that $C_1 \subset C_0$, it will therefore suffice to show that the inclusion map $A_i \to A_{i+1}$ is radicial for every $i \in \mathbb{N}$. However, notice that $A_i[1/p] = A_{i+1}[1/p]$ for every such i, hence we are reduced to checking that the induced map $A_i/pA_i \to A_{i+1}/pA_{i+1}$ is radicial, which is clear by construction.

Lastly, let us show that $C_0 \subset C_2$. To this aim, let us write f as the colimit of a filtered system of injective ring homomorphisms $(f_\lambda : A_\lambda \to B_\lambda \mid \lambda \in \Lambda)$, where A_λ and B_λ are $\mathbb{Z}$-subalgebras of finite type of A and respectively B, for every $\lambda \in \Lambda$; since f induces an isomorphism $A[1/p] \xrightarrow{\sim} B[1/p]$, we may also assume that f_λ induces an isomorphism $A_\lambda[1/p] \xrightarrow{\sim} B_\lambda[1/p]$ for every $\lambda \in \Lambda$ (details left to the reader). For every such λ, let $C_{2,\lambda}$ be the subset of all $b \in B_\lambda$ such that $b^{p^n} \in A_\lambda$ for some $n \in \mathbb{N}$, and let $C_{0,\lambda}$ be the weak normalization of A_λ in B_λ. Clearly C_2 is the filtered union of the resulting system $(C_{2,\lambda} \mid \lambda \in \Lambda)$; on the other hand, C_0 is the colimit of the system of subrings $(C_{0,\lambda} \mid \lambda \in \Lambda)$, by lemma 9.8.17. Hence, we are reduced to checking that $C_{0,\lambda} \subset C_{2,\lambda}$ for every $\lambda \in \Lambda$, and *we may assume that A and B are noetherian*.

Let now $b \in C_0$, and set $B' := A[b]$; we have to check that $b^{p^n} \in A$ for some $n \in \mathbb{N}$, and obviously $A[1/p] = B'[1/p]$, so we may replace B by B' and *suppose that f is finite and radicial*. In this case, pick a decomposition $f = f_1 \circ \cdots \circ f_n$ as in proposition 9.8.9; again, it suffices to check the assertion for each f_i, hence *we may assume that* $\mathrm{Spec}\, f$ *is an effective epimorphism of schemes* (and still radicial). Thus, for every $b \in B$ the element $c := b \otimes 1 - 1 \otimes b$ is nilpotent in $B \otimes_A B$ (corollary 9.8.13(i)), and moreover notice that the two natural maps $B[1/p] \to B \otimes_A B[1/p]$ are isomorphisms, since $A[1/p] = B[1/p]$, hence the same holds for the multiplication law $B \otimes_A B[1/p] \to B[1/p]$, and the therefore image of c vanishes in $B \otimes_A B[1/p]$, *i.e.* $p^k c = 0$ in $B \otimes_A B$ for some $k \in \mathbb{N}$, and after replacing k by a larger integer, we may assume that $c^k = 0$ as well. We write

$$b^{p^n} \otimes 1 = 1 \otimes b^{p^n} + \sum_{j=1}^{p^n} \binom{p^n}{j} (1 \otimes b^{p^n - j}) \cdot c^j = 1 \otimes b^{p^n} + \sum_{j=1}^{k-1} \binom{p^n}{j} (1 \otimes b^{p^n - j}) \cdot c^j$$

and recall that the p-adic valuation of $\binom{p^n}{j}$ equals $n - v_p(j)$ for $j = 1, \dots, p^n$, where $v_p(j)$ denotes the p-adic valuation of j. In particular, with $n := 2k$, we see that $\binom{p^n}{j}$ is divisible by p^k for every $j = 1 \dots, k-1$, so finally $b^{p^n} \otimes 1 = 1 \otimes b^{p^n}$ in $B \otimes_A B$, and consequently $b^{p^n} \in A$, since $\mathrm{Spec}\, f$ is an effective epimorphism. □

Proposition 9.8.29. *Let us resume the situation of remark* 9.8.16(i)*, and let $a \in A$ be any element and $n \in \mathbb{N}$ any integer; also, denote by A^ν (resp. A'^ν) the integral closure of A in B (resp. of A' in B'). The following holds :*

(i) *If g_A and g_B are injective, $aB' \subset \mathrm{Im}\, g_B$ and $a^n A' \subset \mathrm{Im}\, g_A$, then :*

$$aA'^\nu \subset g_B(A^\nu) \qquad \textit{and} \qquad aC' \subset g_B(C).$$

(ii) *If g_A and g_B are surjective, and* $a\mathrm{Ker}\, g_B = 0$*, then :*

$$a \cdot g_B^{-1} A'^\nu \subset A^\nu \qquad \textit{and} \qquad a \cdot g_B^{-1} C' \subset C.$$

(iii) *If g_A and g_B are surjective, and* $\mathrm{Ker}\, g_B \subset \mathscr{N}_B$ *(notation of* (9.8.7)*), then :*

$$g_B^{-1} A'^\nu = A^\nu \qquad \textit{and} \qquad g_B^{-1} C' = C.$$

Proof. (i): Let $b \in A'^\nu$, and pick any monic polynomial $P := X^m + a'_1 X^{m-1} + \cdots + a'_m \in A'[X]$ such that $P(b^n) = 0$. Hence $a^{mn} \cdot P(b^n) = 0 = (ab)^{mn} + a^n a'_1 (ab)^{n(m-1)} + \cdots + a^{mn} a'_m = 0$, and by assumption $a^n a'_1, a^{2n} a'_2, \dots, a^{mn} a'_m \in g_A(A)$ and $ab \in g_B(B)$, so $ab \in g_B(A^\nu)$, whence the first stated inclusion. Next, set $C_0 := g_A(A) + aC'$; clearly C'_0 is an A-subalgebra of $g_B(B)$, and we need to check that the induced map $A \to C_0$ is radicial.

Claim 9.8.30. The kernel and cokernel of the induced map $C_0 \otimes_A C_0 \to C' \otimes_{A'} C'$ are annihilated by a^{n+2}.

Proof of the claim. By consruction, the cokernel of the inclusion $j : C_0 \to C'$ is annihilated by a; since the kernel of $C' \otimes_A j$ is a quotient of $\mathrm{Tor}_1^A(C', C'/C_0)$, it follows that both the kernel and cokernel of $C' \otimes_A j$ are annihilated by a. By the same token, the kernel and cokernel of $(C' \otimes_A C_0) \otimes_{C_0} j : C' \otimes_A C_0 \to C' \otimes_A C'$ are annihilated by a as well. Lastly, the natural map $\pi : C' \otimes_A C' \to C'' \otimes_{A'} C'$ is clearly surjective, and its kernel is generated by the elements of the form $a'x \otimes y - x \otimes a'y$, for all $a' \in A'$ and all $x, y \in C'$. By assumption, $a^n(a'x \otimes y - x \otimes a'y) = 0$ in $C' \otimes_A C'$, so $a^n \mathrm{Ker}\, \pi = 0$. The claim follows easily. ◊

Let $c \in aC'$ be any element; then $c \otimes 1 - 1 \otimes c$ is nilpotent in $C' \otimes_{A'} C'$ (corollary 9.8.13(i)); by claim 9.8.30, it follows that there exists $N \in \mathbb{N}$ with $a^{n+2}(c \otimes 1 - 1 \otimes c)^N = 0$ in $C_0 \otimes_A C_0$. Then, say that $c = ad$ for some $d \in C'$; it follows that $(c \otimes 1 - 1 \otimes c)^3 = a^3 d^3 \otimes 1 - 3a^2 d^2 \otimes ad + 3ad \otimes a^2 d^2 + 1 \otimes a^3 d^3$ is divisible by a in $C_0 \otimes_A C_0$, and finally $(c \otimes 1 - 1 \otimes c)^{N+3n+6} = 0$ in $C_0 \otimes_A C_0$, whence the contention.

(ii): Let b and P be as in the foregoing; suppose that $b = g_B(c)$ for some $c \in B$, and pick $a_1, \dots, a_m \in A$ with $g_A(a_i) = a'_i$ for $i = 1, \dots, m$. Set $Q := X^m + a_1 X^{m-1} + \cdots + a_m \in A[X]$; then $aQ(c) = 0$, and it follows easily that $ac \in A^\nu$, whence the first inclusion of (ii). Next, set $C_0 := A + a \cdot g_B^{-1} C'$; we need to show that the resulting ring homomorphism $A \to C_0$ is radicial. However, notice that the restriction $g_C : C_0 \to C$ of g_B has both kernel and cokernel annihilated by a; then by lemma 14.1.55 we find an A-linear map $h : C \to C_0$ with $h \circ g_C = a^2 \mathbf{1}_{C_0}$ and $g_C \circ h = a^2 \cdot \mathbf{1}_C$. Hence $(h \otimes_A h) \circ (g_C \otimes_A g_C) = a^4 \mathbf{1}_{C_0}$ and $(g_C \otimes_A g_C) \circ (h \otimes_A h) = a^4 \mathbf{1}_C$, so both the kernel and cokernel of $g_C \otimes_A g_C : C_0 \otimes_A C_0 \to C \otimes_A C = C \otimes_{A'} C$ are annihilated by a^4. We may now argue as in the proof of (i), to conclude that $c \otimes 1 - 1 \otimes c$ is nilpotent in $C_0 \otimes_A C_0$, for every $c \in a \cdot g_B^{-1} C'$, whence the contention.

(iii): Let b, c, P and Q be as in the proof of (ii); since $\mathrm{Ker}\, g_B \subset \mathscr{N}_B$, we have $Q(c)^n = 0$ for some $n \in \mathbb{N}$, so $c \in A^\nu$, whence the first identity of (iii). Next, set $C_0 := g_B^{-1} C'$; we need to check that the map $A \to C_0$ is radicial, or equivalently, that the same holds the induced map on reduced quotients $A_{\mathrm{red}} \to (C_0)_{\mathrm{red}}$. However, g_B induces an isomorphism $(C_0)_{\mathrm{red}} \xrightarrow{\sim} (C')_{\mathrm{red}}$, and by definition the map $A'_{\mathrm{red}} \to (C')_{\mathrm{red}}$ is radicial; since g_A induces a surjection $A_{\mathrm{red}} \to A'_{\mathrm{red}}$, the assertion follows easily. □

10. Cohomology and local cohomology of sheaves

10.1. Cohomology of topoi and topological spaces.

Definition 10.1.1. Let X be a topological space, $\mathscr{F}$ a sheaf on X.

(i) We say that $\mathscr{F}$ is *flabby* if the restriction map $\mathscr{F}(X) \to \mathscr{F}(U)$ is surjective for every open subset $U \subset X$.

(ii) We say that $\mathscr{F}$ is *qc-flabby* if the restriction map $\mathscr{F}(V) \to \mathscr{F}(U)$ is a surjection whenever $U \subset V$ are quasi-compact open subsets of X.

(iii) The *support* of $\mathscr{F}$ is the subset :

$$\mathrm{Supp}\, \mathscr{F} := \{x \in X \mid \mathscr{F}_x \neq \varnothing\} \subset X.$$

(iv) On the other hand, if $\mathscr{F}$ is an abelian sheaf, we define the *support* of $\mathscr{F}$ as the subset :

$$\mathrm{Supp}\, \mathscr{F} := \{x \in X \mid \mathscr{F}_x \neq 0\} \subset X.$$

Lemma 10.1.2. *Let X be a topological space, $(X_\lambda \mid \lambda \in \Lambda)$ a family of open subsets of X with $X = \bigcup_{\lambda \in \Lambda} X_\lambda$, and $\mathscr{F}$ a sheaf on X. For every $\lambda \in \Lambda$, let $\mathscr{F}_\lambda$ be the restriction of $\mathscr{F}$ to X_λ. Then $\mathscr{F}$ is flabby if and only if $\mathscr{F}_\lambda$ is flabby for every $\lambda \in \Lambda$.*

Proof. It is easily seen that if $\mathscr{F}$ is flabby, the same holds for every $\mathscr{F}_\lambda$. Conversely, suppose that $\mathscr{F}_\lambda$ is flabby for every $\lambda \in \Lambda$; let $U \subset X$ be any open subset, and $\sigma \in \mathscr{F}(U)$. For every subset $\Lambda' \subset \Lambda$ set $X_{\Lambda'} := \bigcup_{\lambda \in \Lambda'} X_\lambda$, and denote by $\mathscr{P}$ the set of all pairs (Λ', σ') where Λ' is a subset of Λ, and $\sigma' \in \mathscr{F}(U \cup X_{\Lambda'})$ is any section whose restriction to U agrees with

σ. We endow $\mathscr{P}$ with the partial order such that $(\Lambda', \sigma') \leq (\Lambda'', \sigma'')$ if and only if $\Lambda' \subset \Lambda''$ and the restriction of σ'' to $U \cup X_{\Lambda'}$ agrees with σ'. It is clear that if $((\Lambda_i, \sigma_i) \mid i \in I)$ is any totally ordered subset in $\mathscr{P}$, then there exists (Λ', σ') in $\mathscr{P}$ with $\Lambda' = \bigcup_{i \in I} \Lambda_i$ and such that $(\Lambda_i, \sigma_i) \leq (\Lambda', \sigma')$ for every $i \in I$. Also, $(\varnothing, \sigma) \in \mathscr{P}$. By Zorn's lemma, $\mathscr{P}$ admits then a maximal element (Λ', σ'), and it suffices to check that $\Lambda' = \Lambda$. Thus, suppose that $\lambda \in \Lambda \setminus \Lambda'$; set $\Lambda'' := \Lambda' \cup \{\lambda\}$, and let σ'' be the restriction of σ' to $U_\lambda := X_\lambda \cap (U \cup X_{\Lambda'})$. Since $\mathscr{F}_\lambda$ is flabby, there exists $\sigma_\lambda \in X_\lambda$ whose restriction to U_λ agrees with σ''. Then there exists $\tau \in \mathscr{F}(U \cup X_{\Lambda''})$ whose restriction to $U \cup X_{\Lambda'}$ agrees with σ' and whose restriction to X_λ agrees with σ_λ. By construction, we have $(\Lambda'', \tau) > (\Lambda', \sigma')$, a contradiction. □

10.1.3. Let X be a topological space, and consider a short exact sequence

$$\Sigma \qquad : \qquad 0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$$

of abelian sheaves on X. For every open subset $U \subset X$, the sequence Σ induces a complex :

$$\Sigma(U) \qquad : \qquad 0 \to \mathscr{F}'(U) \to \mathscr{F}(U) \to \mathscr{F}''(U) \to 0.$$

Lemma 10.1.4. *In the situation of* (10.1.3)*, the following holds :*

(i) *If $\mathscr{F}'$ is flabby, the sequence $\Sigma(U)$ is short exact.*
(ii) *If both $\mathscr{F}$ and $\mathscr{F}'$ are flabby, the same holds for $\mathscr{F}''$.*
(iii) *Suppose that X is locally coherent and quasi-separated. Then :*
   (a) *If $\mathscr{F}'$ is qc-flabby and U is quasi-compact, the sequence $\Sigma(U)$ is short exact.*
   (b) *If both $\mathscr{F}$ and $\mathscr{F}'$ are qc-flabby, the same holds for $\mathscr{F}''$.*

Proof. (i): Let $s'' \in \mathscr{F}''(U)$ be any section; we need to show that s'' is the image of an element of $\mathscr{F}(U)$. To this aim, let $\mathscr{P}$ be the set of all pairs (V, t), where $V \subset U$ is an open subset, and $t \in \mathscr{F}(V)$ is a section whose image in $\mathscr{F}''(V)$ agrees with the restriction of s''. Then $\mathscr{P}$ is partially ordered by declaring that $(V, t) \leq (V', t')$ if and only if $V \subset V'$ and t is the restriction of t' to V. Clearly, if $((V_\lambda, t_\lambda) \mid \lambda \in \Lambda)$ is a totally ordered subset of $\mathscr{P}$, then there exists a unique section t on $V := \bigcup_{\lambda \in \Lambda} V_\lambda$ such that $(V, t) \in \mathscr{P}$ and $(V_\lambda, t_\lambda) \leq (V, t)$ for every $\lambda \in \Lambda$. Moreover, $\mathscr{P} \neq \varnothing$, since $(\varnothing, 0) \in \mathscr{P}$. By Zorn's lemma, $\mathscr{P}$ admits therefore a maximal element (V, s), and it suffices to check that $V = U$. Thus, suppose that $x \in U \setminus V$; by assumption, we may find an open neighborhood V' of x in U, and $t \in \mathscr{F}(V')$ with $(V', t) \in \mathscr{P}$. Set $W := V \cap V'$, and let t_W (resp. s_W) be the restriction of t (resp. of s) to W; then $s_W - t_W \in \mathscr{F}'(W)$. Since $\mathscr{F}'$ is flabby, the same holds for its restriction $\mathscr{F}'_{|V}$ (lemma 10.1.2), hence we find $r \in \mathscr{F}'(V')$ whose restriction to W agrees with $s_W - t_W$; set $t' := r + t \in \mathscr{F}(V')$. Set $V'' := V \cup V'$; clearly the restriction of t' to W agrees with s_W, hence there exists $u \in \mathscr{F}(V'')$ whose restriction to V and V' agrees respectively with s and t'. By construction, we have $(V'', t') \in \mathscr{P}$ and $(V'', t') > (V, s)$, a contradiction.

(ii): In view of (i), we get a commutative ladder with short exact rows :

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathscr{F}'(X) & \longrightarrow & \mathscr{F}(X) & \longrightarrow & \mathscr{F}''(X) & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \rho'} & & \downarrow{\scriptstyle \rho} & & \downarrow{\scriptstyle \rho''} & & \\ 0 & \longrightarrow & \mathscr{F}'(U) & \longrightarrow & \mathscr{F}(U) & \longrightarrow & \mathscr{F}''(U) & \longrightarrow & 0 \end{array}$$

whence, by the snake lemma, a surjection : $\operatorname{Coker} \rho \to \operatorname{Coker} \rho''$. But $\operatorname{Coker} \rho = 0$, since $\mathscr{F}$ is flabby; so $\operatorname{Coker} \rho'' = 0$, whence the assertion.

The proof of (iii.a) is a variant of that of (i). Indeed, we may replace X by U, and thereby assume that X is quasi-compact. Then we have to check that every section $s'' \in \mathscr{F}''(X)$ is the image of an element of $\mathscr{F}(X)$. However, we can find a finite covering $(U_i \mid i = 1, \dots, n)$ of X, consisting of quasi-compact open subsets, such that $s''_{|U_i}$ is the image of a section $s_i \in \mathscr{F}(U_i)$. For every $k \leq n$, let $V_k := U_1 \cup \cdots \cup U_k$; we show by induction on k that $s''_{|V_k}$ is in the image of $\mathscr{F}(V_k)$; the lemma will follow for $k = n$. For $k = 1$ there is nothing to prove. Suppose that $k > 1$ and that the assertion is known for all $j < k$; hence we can find $t \in \mathscr{F}(V_{k-1})$ whose image is $s''_{|V_{k-1}}$. The difference $u := (t - s_k)_{|U_k \cap V_{k-1}}$ lies in the image of $\mathscr{F}'(U_k \cap V_{k-1})$; since $U_k \cap V_{k-1}$ is quasi-compact and $\mathscr{F}'$ is qc-flabby, u extends to a section of $\mathscr{F}'(U_k)$. We can then replace s_k by $s_k + u$, and assume that s_k and t agree on $U_k \cap V_{k-1}$, whence a section on $V_k = U_k \cup V_{k-1}$ with the sought property. Assertion (iii.b) is proved as (ii). □

Lemma 10.1.5. *Let $f : Y \to X$ be a continuous map of topological spaces, $\mathscr{F}$ a sheaf on X, and $\mathscr{G}$ a sheaf on Y. We have :*

- (i) *If f is an open immersion and $\mathscr{F}$ is qc-flabby on X, then $f^*\mathscr{F}$ is qc-flabby on Y.*
- (ii) *If $\mathscr{G}$ is flabby on Y, then $f_*\mathscr{G}$ is flabby on X, and $R^p f_*\mathscr{G} = 0$ for every $p > 0$.*
- (iii) *If f is quasi-compact and $\mathscr{G}$ is qc-flabby on Y, then $f_*\mathscr{G}$ is qc-flabby on X.*
- (iv) *If X and Y are locally coherent, f is quasi-compact and quasi-separated, and $\mathscr{G}$ is abelian and qc-flabby, then $R^p f_*\mathscr{G} = 0$ for every $p > 0$.*
- (v) *Let $\mathscr{A}$ be any sheaf of rings on X. Every injective $\mathscr{A}$-module is flabby.*
- (vi) *If X is locally noetherian, every qc-flabby sheaf on X is flabby.*

Proof. (i) and (iii) are trivial.

(ii): Clearly $f_*\mathscr{G}$ is flabby, and it remains to check that $R^p f_*\mathscr{G} = 0$ for every $p > 0$. To this aim, in view of remark 7.3.31(vi) and lemma 10.1.4(ii), it suffices to show that for every short exact sequence $0 \to \mathscr{G}' \to \mathscr{G} \to \mathscr{G}'' \to 0$ of flabby abelian sheaves on Y, the resulting sequence $0 \to f_*\mathscr{G}' \to f_*\mathscr{G} \to f_*\mathscr{G}'' \to 0$ is still short exact; the latter follows from 10.1.4(i).

(iv): The assertion is local on X, so we may assume that X is quasi-compact and quasi-separated, and then Y is also quasi-compact. Remark 7.3.31(vi) and lemma 10.1.4(iii.b) reduce to showing that, for every short exact sequence $0 \to \mathscr{G}' \to \mathscr{G} \to \mathscr{G}'' \to 0$ of qc-flabby abelian sheaves on Y, the resulting sequence $0 \to (f_*\mathscr{G}')_x \to (f_*\mathscr{G})_x \to (f_*\mathscr{G}'')_x \to 0$ is short exact, for every $x \in X$. However, every such x has a fundamental system of open neighborhoods consisting of coherent open subsets of X, so we come down to checking that the induced sequence $0 \to \mathscr{G}'(f^{-1}U) \to \mathscr{G}(f^{-1}U) \to \mathscr{G}''(f^{-1}U) \to 0$ is short exact, for every coherent open neighborhood U of x. But under the current assumptions, $f^{-1}U$ is quasi-compact and quasi-separated, so we conclude by lemma 10.1.4(iii.a).

(v): Let $j : U \to X$ be an open immersion, and $\mathscr{I}$ any injective $\mathscr{A}$-module; the counit of adjunction $j_!j^*\mathscr{A} \to \mathscr{A}$ is a monomorphism of $\mathscr{A}$-modules, so it induces a surjection

$$\varphi : \mathrm{Hom}_{\mathscr{A}}(\mathscr{A}, \mathscr{I}) \to \mathrm{Hom}_{\mathscr{A}}(j_!j^*\mathscr{A}, \mathscr{I}).$$

We have a natural identification : $\mathrm{Hom}_{\mathscr{A}}(\mathscr{A}, \mathscr{I}) \xrightarrow{\sim} \mathscr{I}(X)$; by adjunction, we have also a natural identification : $\mathrm{Hom}_{\mathscr{A}}(j_!j^*\mathscr{A}, \mathscr{I}) \xrightarrow{\sim} \mathrm{Hom}_{j^*\mathscr{A}}(j^*\mathscr{A}, j^*\mathscr{I}) \xrightarrow{\sim} \mathscr{I}(U)$. Under these identifications, φ corresponds to the restriction map $\mathscr{I}(X) \to \mathscr{I}(U)$, whence the contention.

(vi): Let $U \subset X$ be any open subset; we have to check that the restriction map $\mathscr{F}(X) \to \mathscr{F}(U)$ is surjective. To this aim, fix $s \in \mathscr{F}(U)$, and let S be the set of all pairs (V, s_V) where $V \subset X$ is an open subset containing U, and $s_V \in \mathscr{F}(V)$ is a section whose restriction to U agrees with s. We endow S with a partial ordering, by declaring that $(V, s_V) \leq (V', s_{V'})$ if $V \subset V'$ and the restriction of $s_{V'}$ to V agrees with s_V. A standard application of Zorn's lemma shows that S admits a maximal element (V, s_V), and it suffices to show that $V = X$. However, if the latter fails, there exists a noetherian open subset $U' \subset X$ which does not lie in V, and $U' \cap V$ is quasi-compact (remark 8.1.6(iv)); since $\mathscr{F}$ is qc-flabby, we may then find $s_{U'} \in \mathscr{F}(U')$ whose restriction to $U' \cap V$ agrees with the restriction of s_V. Then there exists a unique $s_{U' \cup V} \in \mathscr{F}(U' \cap V)$ whose restriction to U' and V agrees with $s_{U'}$ and respectively s_V; the pair $(U' \cup V, s_{U' \cup V})$ lies in S, contradicting the maximality of (V, s_V). □

10.1.6. Let Λ be a small cofiltered category. We call a *system of topological spaces indexed by* Λ, any functor (notation of (8.1.7))

$$X_\bullet : \Lambda \to \mathbf{Top} \qquad \lambda \mapsto X_u \qquad (\lambda \xrightarrow{u} \mu) \mapsto (\varphi_u : X_\lambda \to X_\mu)$$

We also call a *compatible system of sheaves on* $X_\bullet$ the datum of a family $(\mathscr{F}_\lambda \mid \lambda \in \mathrm{Ob}(\Lambda))$, where $\mathscr{F}_\lambda$ is a sheaf on X_λ for every $\lambda \in \mathrm{Ob}(\Lambda)$, together with *transition maps* :

$$\beta_u : \varphi_u^{-1}\mathscr{F}_\lambda \to \mathscr{F}_\mu \qquad \text{for every morphism } u : \mu \to \lambda \text{ in } \Lambda$$

such that $\beta_{\mathbf{1}_\lambda} = \mathbf{1}_{\mathscr{F}_\lambda}$ for every $\lambda \in \mathrm{Ob}(\Lambda)$, and for any two morphisms $\nu \xrightarrow{v} \mu \xrightarrow{u} \lambda$ of Λ, the following diagram commutes :

$$\begin{array}{ccc} \varphi_\nu^{-1} \circ \varphi_u^{-1}\mathscr{F}_\lambda & \xrightarrow{\sim} & \varphi_{u\circ v}^{-1}\mathscr{F}_\lambda \\ {\scriptstyle \varphi_\nu^{-1}\beta_u}\downarrow & & \downarrow{\scriptstyle \beta_{u\circ v}} \\ \varphi_\nu^{-1}\mathscr{F}_\mu & \xrightarrow{\beta_\nu} & \mathscr{F}_\nu. \end{array}$$

Lemma 10.1.7. *With the notation of* (10.1.6)*, let* X *be the limit of* $X_\bullet$*, and* $(\varphi_\lambda : X \to X_\lambda \mid \lambda \in \Lambda)$ *a universal cone. Suppose that either one of the following conditions holds :*

(a) $X_\bullet$ *is a constant functor with value* X *(so* $X_\lambda = X$ *for every* $\lambda \in \mathrm{Ob}(\Lambda)$*, and* $\varphi_u = \mathbf{1}_X$ *for every morphism* u *of* Λ*), and* X *is quasi-compact.*

(b) X_λ *is a sober and quasi-compact topological space, for every* $\lambda \in \Lambda$*.*

Then the natural map

$$\operatorname*{colim}_{\lambda\in\mathrm{Ob}(\Lambda^o)} \Gamma(X_\lambda, \mathscr{F}_\lambda) \to \Gamma(X, \mathscr{F}) \qquad \textit{with} \qquad \mathscr{F} := \operatorname*{colim}_{\lambda\in\mathrm{Ob}(\Lambda^o)} \varphi_\lambda^*\mathscr{F}_\lambda$$

is injective.

Proof. By virtue of proposition 1.5.21(ii), we may assume that Λ is a cofiltered partially ordered set, and we let $(\Lambda^o, \leq)$ be the opposite ordering on Λ (see example 1.1.6(iii)). We then come down to proving the following assertion. Let $\lambda \in \Lambda^o$ be any index, $s, s' \in \Gamma(X_\lambda, \mathscr{F}_\lambda)$ two sections whose images agree in $\Gamma(X, \mathscr{F})$, and for every $\mu \in \Lambda^o$ such that $\mu \geq \lambda$, denote by s_μ and s'_μ the images of s and s' in $\Gamma(X_\mu, \mathscr{F}_\mu)$; then there exists an index $\mu \geq \lambda$, such that $s_\mu = s'_\mu$. However, set

$$Z_\mu := \{x \in X_\mu \mid s_{\mu,x} \neq s'_{\mu,x}\} \qquad \text{for every } \mu \in \Lambda^o \text{ such that } \mu \geq \lambda$$

and endow Z_μ with the topology induced from X_μ. Now Z_μ is a closed subset of X_μ for every $\mu \geq \lambda$, and it is easily seen that $\psi_u(Z_\mu) \subset Z_\nu$ for every morphism $u : \mu \geq \nu$. Thus, $(Z_\mu \mid \mu \geq \lambda)$ is a cofiltered system of topological spaces, and the assumption on s and s' implies that the limit of this system is empty. If condition (a) holds, each Z_μ is a closed subset of the quasi-compact space X, so we deduce that $Z_\mu = \varnothing$ for some $\mu \geq \lambda$, whence $s_\mu = s'_\mu$ for such index μ. If (b) holds, each Z_μ is a sober space (lemma 8.1.3(iii)), and we conclude again that $Z_\mu = \varnothing$ for some $\mu \geq \lambda$, due to proposition 8.1.23(ii.a). □

10.1.8. Let Λ be a small cofiltered category; we consider the datum consisting of:

• Two systems $X_\bullet$ and $Y_\bullet$ of topological spaces indexed by Λ, such that X_λ and Y_λ are *locally spectral* for every $\lambda \in \Lambda$, with *quasi-compact and quasi-separated* transition maps :

$$(10.1.9) \qquad \varphi_u : X_\mu \to X_\lambda \qquad \psi_u : Y_\mu \to Y_\lambda \qquad \text{for every morphism } u : \mu \to \lambda \text{ in } \Lambda$$

• A compatible system of sheaves $\mathscr{F}_\bullet$ on $Y_\bullet$, as defined in (10.1.6).

• A natural transformation $g_\bullet : X_\bullet \Rightarrow Y_\bullet$, *i.e.* a system $g_\bullet := (g_\lambda : Y_\lambda \to X_\lambda \mid \lambda \in \mathrm{Ob}(\Lambda))$ of *quasi-compact and quasi-separated* continuous maps, such that

$$g_\lambda \circ \psi_u = \varphi_u \circ g_\mu \qquad \text{for every morphism } u : \mu \to \lambda.$$

The limits of $X_\bullet$, $Y_\bullet$ and $g_\bullet$ are representable by topological spaces and continuous maps

$$X := \lim_{\Lambda} X_\bullet \qquad Y := \lim_{\Lambda} Y_\bullet \qquad g := \lim_{\Lambda} g_\bullet : Y \to X$$

and the universal cones consist of *continuous spectral maps*

$$\varphi_\lambda : X \to X_\lambda \qquad \psi_\lambda : Y \to Y_\lambda \qquad \text{for every } \lambda \in \Lambda.$$

Proposition 10.1.10. *In the situation of* (10.1.8)*, the following holds :*

(i) *If Y_λ is spectral for every $\lambda \in \mathrm{Ob}(\Lambda)$, the natural map*

$$\operatorname*{colim}_{\lambda \in \mathrm{Ob}(\Lambda^o)} \Gamma(Y_\lambda, \mathscr{F}_\lambda) \to \Gamma(Y, \mathscr{F}) \qquad \textit{with} \qquad \mathscr{F} := \operatorname*{colim}_{\lambda \in \mathrm{Ob}(\Lambda^o)} \psi^*_\lambda \mathscr{F}_\lambda$$

is a bijection.

(ii) *If $\mathscr{F}_\bullet$ is a system of abelian sheaves, then the natural morphisms :*

$$\operatorname*{colim}_{\lambda \in \mathrm{Ob}(\Lambda^o)} \varphi^*_\lambda R^i g_{\lambda *} \mathscr{F}_\lambda \to R^i g_* \mathscr{F}$$

are isomorphisms for every $i \in \mathbb{N}$.

Proof. By virtue of proposition 1.5.21(ii), we may assume that Λ is a cofiltered partially ordered set, and we let $(\Lambda^o, \leq)$ be the opposite ordering on Λ (see example 1.1.6(iii)). The injectivity of the map in (i) is already known, by lemma 10.1.7. Let us then verify the surjectivity. In case $Y = \varnothing$, we know that $Y_\lambda = \varnothing$ for some $\lambda \in \Lambda^o$, so the assertion holds. Hence, we may assume that Y is not empty. Now, let $s \in \Gamma(Y, \mathscr{F})$ be any section; since

$$\mathscr{F}_y = \operatorname*{colim}_{\lambda \in \Lambda^o} \mathscr{F}_{\lambda, \psi_\lambda(y)} \qquad \text{for every } y \in Y$$

we may find, for every $y \in Y$, an index $\lambda(y) \in \Lambda^o$, a quasi-compact open neighborhood U_y of $\psi_{\lambda(y)}(y)$ in $Y_{\lambda,y}$ and a section $s(y) \in \Gamma(U_y, \mathscr{F}_\lambda)$ such that the image of $s(y)$ in $\mathscr{F}_y$ equals s_y. Then, for each $y \in Y$, we may find a quasi-compact open neighborhood U'_y of y in $\psi^{-1}_{\lambda(y)} U_y$ such that the image of $s(y)$ in U'_y agrees with the restriction of s. The family $(U'_y \mid y \in Y)$ is an open covering of Y, and since Y is quasi-compact (theorem 8.1.34(i)), we may find a finite (non-empty) subset $S \subset Y$ such that $(U'_y \mid y \in S)$ already covers Y. Then, for each $y \in S$ we may find an index $\mu(y) \geq \lambda(y)$ and a quasi-compact open subset U''_y of $\psi^{-1}_{\mu(y)\lambda(y)} U_{\lambda(y)}$ such that $\psi^{-1}_{\mu(y)} U''_y = U'_y$ (corollary 8.1.40(ii.a)). Next, since Λ is cofiltered, we may find $\mu \in \Lambda^o$ such that $\mu \geq \mu(y)$ for every $y \in S$, and after replacing U''_y by $\psi^{-1}_{\mu,\mu(y)} U''_y$, and $s(y)$ by its image in $\Gamma(\psi^{-1}_{\mu,\mu(y)} U''_y, \mathscr{F}_\mu)$ for every $y \in S$, we may assume that $\mu(y)$ is a single index μ, independent of $y \in S$. Now, since $\bigcup_{y \in S} \psi^{-1}_\mu U''_y = Y$, there exists $\nu \geq \mu$ such that $\bigcup_{y \in S} \psi^{-1}_{\nu\mu} U''_y = Y_\mu$ (corollary 8.1.40(ii.b)), so we may replace μ by ν, each U''_y by its preimage in Y_ν, and $s(y)$ by its image in $\Gamma(\psi^{-1}_{\nu\mu} U''_y, \mathscr{F}_\nu)$, and further assume that $(U''_y \mid y \in S)$ is a covering of Y_μ. Lastly, notice that – by construction – for every $y, y' \in S$, the images of $s(y)$ and $s(y')$ agree in $\Gamma(\psi^{-1}_\mu(U_y \cap U_{y'}), \mathscr{F})$. Since the injectivity of the map in (i) has already been established, we deduce that, for every $y, y' \in S$ there exists $\lambda(y, y') \geq \mu$ such that the images of $s(y)$ and $s(y')$ agree in $\Gamma(\psi^{-1}_{\lambda(y,y'),\mu}(U''_y \cap U''_{y'}), \mathscr{F}_{\lambda(y,y')})$. Since Λ is cofiltered, we may then find $\lambda \in \Lambda^o$ such that $\lambda \geq \lambda(y, y')$ for every $y, y' \in S$. Now, let $V_y := \psi^{-1}_{\lambda\mu} U''_y$ and denote by $s'(y)$ the image of $s(y)$ in $\Gamma(V_y, \mathscr{F}_\lambda)$, for every $y \in S$; by construction we have $s'(y)_{|V_y \cap V_{y'}} = s'(y)_{|V_y \cap V_{y'}}$ for every $y, y' \in S$, so the system $(s'(y) \mid y \in S)$ corresponds to a well defined section $s' \in \Gamma(Y_\lambda, \mathscr{F}_\lambda)$, whose image in $\Gamma(Y, \mathscr{F})$ is finally the original section s.

(ii): We notice :

Claim 10.1.11. Suppose that $\mathscr{F}_\lambda$ is qc-flabby for every $\lambda \in \Lambda^o$. Then the same holds for $\mathscr{F}$.

Proof of the claim. Indeed, let $U \subset V$ be any two quasi-compact open subsets of Y; we need to show that the restriction map

$$\Gamma(V, \mathscr{F}) \to \Gamma(U, \mathscr{F})$$

is onto. By corollary 8.1.40(ii) we can find $\lambda \in \Lambda^o$ and quasi-compact open subsets $U_\lambda \subset V_\lambda \subset Y_\lambda$ such that $U = \psi_\lambda^{-1} U_\lambda$, and likewise for V. Let us set $U_\mu := \psi_{\mu\lambda}^{-1} U_\lambda$ for every $\mu \in \Lambda^o$ such that $\mu \geq \lambda$, and likewise define V_μ. Then, up to replacing Λ^o by the cofinal subset $\{\mu \in \Lambda^o \mid \mu \geq \lambda\}$, we may assume that $U_\mu \subset V_\mu$ are defined for every $\mu \in \Lambda^o$. By (i) the natural map

$$\operatorname*{colim}_{\lambda \in \Lambda^o} \Gamma(U_\lambda, \mathscr{F}_\lambda) \to \Gamma(U, \mathscr{F})$$

is bijective for every $n \in \mathbb{N}$, and likewise for V, whence the claim. ◊

Now, we pick for each $\lambda \in \Lambda^o$ an injective resolution $\mathscr{F}_\lambda \to \mathscr{I}_\lambda^\bullet$, having care to construct $\mathscr{I}_\lambda^\bullet$ functorially, so that $\mathscr{F}_\bullet$ extends to a compatible system of complexes $(\mathscr{F}_\lambda \to \mathscr{I}_\lambda^\bullet \mid \lambda \in \Lambda^o)$. From claim 10.1.11, we know that $\mathscr{I}^\bullet := \operatorname{colim}_{\lambda \in \Lambda^o} \psi_\lambda^* \mathscr{I}_\lambda^\bullet$ is a complex of qc-flabby sheaves; then lemma 10.1.5(iv) and remark 7.3.31(vi) yield a natural isomorphism :

$$g_* \mathscr{I}^\bullet \xrightarrow{\sim} Rg_* \mathscr{F} \qquad \text{in } \mathsf{D}(\mathbb{Z}_X\text{-}\mathbf{Mod}).$$

To conclude, let $V \to X$ be any quasi-compact open immersion, which as usual we see as the limit of a system $(V_\lambda \to X_\lambda \mid \lambda \in \Lambda)$ of quasi-compact open immersions; we come down to checking that the natural map

$$\Gamma(V, \operatorname*{colim}_{\lambda \in \Lambda^o} \varphi_\lambda^* g_{\lambda *} \mathscr{I}_\lambda^\bullet) \to \Gamma(V, g_{\infty *} \mathscr{I}^\bullet) = \Gamma(g^{-1}V, \mathscr{I}^\bullet)$$

is an isomorphism of complexes. However, $g^{-1}V$ is the limit of the system $(g_\lambda^{-1} V_\lambda \mid \lambda \in \Lambda)$ of spectral topological spaces and quasi-compact quasi-separated maps, so (i) naturally identifies both complexes with

$$\operatorname*{colim}_{\lambda \in \Lambda^o} \Gamma(g_\lambda^{-1} V_\lambda, \mathscr{I}_\lambda^\bullet)$$

whence the contention. □

Remark 10.1.12. In the situation of (10.1.8), suppose that $X_\bullet$ and $Y_\bullet$ are two systems of *schemes*, that the systems $\varphi_\bullet$ and $\psi_\bullet$ of (10.1.9) consist of *affine* morphisms of schemes, and $g_\bullet$ is a system of *quasi-compact and quasi-separated* morphisms of schemes. By [65, Ch.IV, Prop.8.2.3] the limits (in the category of schemes) of the systems $X_\bullet$, $Y_\bullet$ (resp. $g_\bullet$) are representable by schemes (resp. by a morphism of schemes) whose underlying topological spaces (resp. continuous map) agrees with X and Y (resp. g), and the resulting φ_λ, ψ_λ are affine morphisms of schemes, for every $\lambda \in \mathrm{Ob}(\Lambda)$. Hence, proposition 10.1.10 applies especially to such inverse systems.

10.1.13. Let $(X, \mathscr{A})$ be a ringed space, and denote by $\mathbb{Z}_X$ the sheaf of rings associated with the constant presheaf with values $\mathbb{Z}$; then $\mathbb{Z}_X\text{-}\mathbf{Mod}$ is the category of abelian sheaves on X, and the natural morphism $\mathbb{Z}_X \to \mathscr{A}$ induces a forgetful functor

$$\varphi_{\mathscr{A}} : \mathsf{D}(\mathscr{A}\text{-}\mathbf{Mod}) \to \mathsf{D}(\mathbb{Z}_X\text{-}\mathbf{Mod}).$$

Furthermore, let $f : (Y, \mathscr{B}) \to (X, \mathscr{A})$ be a morphism of ringed spaces. For every $\mathscr{B}$-module $\mathscr{F}$, the direct image $f_* \mathscr{F}$ is naturally an $\mathscr{A}$-module, and we notice that the derived functor $Rf_* : \mathsf{D}^+(\mathscr{B}\text{-}\mathbf{Mod}) \to \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$ commutes with the forgetful functors $\varphi_{\mathscr{A}}, \varphi_{\mathscr{B}}$; indeed, every injective $\mathscr{B}$-module is a flabby $\mathbb{Z}_Y$-module (lemma 10.1.5(v)), and the latter are acyclic for the functor $f_* : \mathbb{Z}_Y\text{-}\mathbf{Mod} \to \mathbb{Z}_X\text{-}\mathbf{Mod}$ (lemma 10.1.5(ii)), so the assertion follows easily.

One defines as in example 7.1.16(v) a *total* Hom *cochain complex*, which is a functor :

$$\mathscr{H}om^\bullet_{\mathscr{A}} : \mathsf{C}(\mathscr{A}\text{-}\mathbf{Mod}) \times \mathsf{C}(\mathscr{A}\text{-}\mathbf{Mod})^o \to \mathsf{C}(\mathscr{A}\text{-}\mathbf{Mod})$$

on the category of complexes of $\mathscr{A}$-modules. Recall that, for any two complexes $M_\bullet$, $N^\bullet$, and any object U of X, the group of n-cocycles in $\mathscr{H}om^\bullet_{\mathscr{A}}(M_\bullet, N^\bullet)(U)$ is naturally isomorphic to $\mathrm{Hom}_{\mathsf{C}(\mathscr{A}_{|U}\text{-}\mathbf{Mod})}(M_{\bullet|U}, N^\bullet_{|U}[n])$, and $H^n\mathscr{H}om^\bullet_{\mathscr{A}}(M_\bullet, N^\bullet)(U)$ is naturally isomorphic to the group of homotopy classes of maps $M_{\bullet|U} \to N^\bullet_{|U}[n]$ (see example 7.1.15(i)). We also set :

$$(10.1.14)\qquad \mathrm{Hom}^\bullet_{\mathscr{A}} := \Gamma \circ \mathscr{H}om^\bullet_{\mathscr{A}} : \mathsf{C}(\mathscr{A}\text{-}\mathbf{Mod}) \times \mathsf{C}(\mathscr{A}\text{-}\mathbf{Mod})^o \to \mathsf{C}(\Gamma(\mathscr{A})\text{-}\mathbf{Mod}).$$

The bifunctor $\mathscr{H}om^\bullet_{\mathscr{A}}$ admits a right derived functor :

$$R\mathscr{H}om^\bullet_{\mathscr{A}} : \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}) \times \mathsf{D}(\mathscr{A}\text{-}\mathbf{Mod})^o \to \mathsf{D}(\mathscr{A}\text{-}\mathbf{Mod})$$

for whose construction we refer to [163, §10.7]. Likewise, one has a derived functor $R\mathrm{Hom}^\bullet_{\mathscr{A}}$ for (10.1.14), and there are natural isomorphisms of $\mathscr{A}$-modules :

$$(10.1.15)\qquad H^iR\mathrm{Hom}^\bullet_{\mathscr{A}}(M^\bullet, N^\bullet) \xrightarrow{\sim} \mathrm{Hom}_{\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})}(M^\bullet, N^\bullet[i])$$

for every $i \in \mathbb{Z}$, and every bounded below complexes $M^\bullet$ and $N^\bullet$ of $\mathscr{A}$-modules.

Lemma 10.1.16. *Let $(X, \mathscr{A})$ be a ringed space, $\mathscr{B}$ an $\mathscr{A}$-algebra. Then :*

(i) *If $\mathscr{I}$ is an injective $\mathscr{A}$-module, $\mathscr{H}om_{\mathscr{A}}(\mathscr{F}, \mathscr{I})$ is flabby for every $\mathscr{A}$-module $\mathscr{F}$, and $\mathscr{H}om_{\mathscr{A}}(\mathscr{B}, \mathscr{I})$ is an injective $\mathscr{B}$-module.*

(ii) *There is a natural isomorphism of bifunctors :*

$$R\Gamma \circ R\mathscr{H}om^\bullet_{\mathscr{A}} \xrightarrow{\sim} R\mathrm{Hom}^\bullet_{\mathscr{A}}.$$

(iii) *The forgetful functor $\mathsf{D}^+(\mathscr{B}\text{-}\mathbf{Mod}) \to \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$ admits the right adjoint :*

$$\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}) \to \mathsf{D}^+(\mathscr{B}\text{-}\mathbf{Mod}) \quad : \quad K^\bullet \mapsto R\mathscr{H}om^\bullet_{\mathscr{A}}(\mathscr{B}, K^\bullet).$$

Proof. (i) : Let $j : U \subset X$ be any open immersion; a section $s \in \mathscr{H}om_{\mathscr{A}}(\mathscr{F}, \mathscr{I})(U)$ is a map of $\mathscr{A}_{|U}$-modules $s : \mathscr{F}_{|U} \to \mathscr{I}_{|U}$. We deduce a map of $\mathscr{A}$-modules $j_!s : j_!\mathscr{F}_{|U} \to j_!\mathscr{I}_{|U} \to \mathscr{I}$; since $\mathscr{I}$ is injective, $j_!s$ extends to a map $\mathscr{F} \to \mathscr{I}$, as required. Next, let $\mathscr{B}$ be an $\mathscr{A}$-algebra; we recall the following :

Claim 10.1.17. The functor

$$\mathscr{A}\text{-}\mathbf{Mod} \to \mathscr{B}\text{-}\mathbf{Mod} \quad : \quad \mathscr{F} \mapsto \mathscr{H}om_{\mathscr{A}}(\mathscr{B}, \mathscr{F})$$

is right adjoint to the forgetful functor.

Proof of the claim. We have to exhibit a natural bijection

$$\mathrm{Hom}_{\mathscr{A}}(N, M) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{B}}(N, \mathrm{Hom}_{\mathscr{A}}(\mathscr{B}, M))$$

for every $\mathscr{A}$-module M and $\mathscr{B}$-module N. This is given by the following rule. To an $\mathscr{A}$-linear map $t : N \to M$ one assigns the $\mathscr{B}$-linear map $t' : N \to \mathrm{Hom}_{\mathscr{A}}(\mathscr{B}, M)$ such that $t'(x)(b) = t(x \cdot b)$ for every $x \in N(U)$ and $b \in \mathscr{B}(V)$, where $V \subset U$ are any two open subsets of X. To describe the inverse of this transformation, it suffices to remark that $t(x) = t'(x)(1)$ for every local section x of N. ◊

Since the forgetful functor is exact, the second assertion of (i) follows immediately from claim 10.1.17. Assertion (ii) follows from (i) and [163, Th.10.8.2].

(iii): Let $K^\bullet$ (resp. $L^\bullet$) be a bounded below complex of $\mathscr{B}$-modules (resp. of injective $\mathscr{A}$-modules); then :

$$\begin{aligned}\mathrm{Hom}_{\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})}(K^\bullet, L^\bullet) &= H^0\mathrm{Hom}^\bullet_{\mathsf{C}(\mathscr{A}\text{-}\mathbf{Mod})}(K^\bullet, L^\bullet)\\ &= H^0\mathrm{Hom}^\bullet_{\mathsf{C}(\mathscr{B}\text{-}\mathbf{Mod})}(K^\bullet, \mathscr{H}om_{\mathscr{A}}(\mathscr{B}, L^\bullet))\\ &= \mathrm{Hom}_{\mathsf{D}^+(\mathscr{B}\text{-}\mathbf{Mod})}(K^\bullet, \mathscr{H}om_{\mathscr{A}}(\mathscr{B}, L^\bullet))\end{aligned}$$

where the last identity follows from (i) and (10.1.15). □

Theorem 10.1.18 (Trivial duality)**.** *Let $f : (Y, \mathscr{B}) \to (X, \mathscr{A})$ be a morphism of ringed spaces. For every $M_\bullet \in \mathrm{Ob}(\mathsf{D}^-(\mathscr{A}\text{-}\mathbf{Mod}))$ and $N^\bullet \in \mathrm{Ob}(\mathsf{D}^+(\mathscr{B}\text{-}\mathbf{Mod}))$, there are natural isomorphisms :*

(i) $R\mathrm{Hom}^\bullet_{\mathscr{A}}(M_\bullet, Rf_*N^\bullet) \xrightarrow{\sim} R\mathrm{Hom}^\bullet_{\mathscr{B}}(Lf^*M_\bullet, N^\bullet)$ *in* $\mathsf{D}^+(\mathscr{A}(X)\text{-}\mathbf{Mod})$.

(ii) $R\mathscr{H}om^\bullet_{\mathscr{A}}(M_\bullet, Rf_*N^\bullet) \xrightarrow{\sim} Rf_*R\mathscr{H}om^\bullet_{\mathscr{B}}(Lf^*M_\bullet, N^\bullet)$ *in* $\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$.

Proof. One applies lemma 10.1.16(ii) to deduce (i) from (ii).

(ii) : By standard adjunctions, for any two complexes $M_\bullet$ and $N^\bullet$ as in the proposition, we have a natural isomorphism of total Hom cochain complexes :

$$\mathscr{H}om^\bullet_{\mathscr{A}}(M_\bullet, f_*N^\bullet) \xrightarrow{\sim} f_*\mathscr{H}om^\bullet_{\mathscr{B}}(f^*M_\bullet, N^\bullet). \tag{10.1.19}$$

Now, let us choose a flat resolution $P_\bullet \xrightarrow{\sim} M_\bullet$ of $\mathscr{A}$-modules, and an injective resolution $N^\bullet \xrightarrow{\sim} I^\bullet$ of $\mathscr{B}$-modules. In view of (10.1.19) and lemma 10.1.16(i) we have natural isomorphisms :

$$Rf_*R\mathscr{H}om^\bullet_{\mathscr{B}}(Lf^*M_\bullet, N^\bullet) \xrightarrow{\sim} f_*\mathscr{H}om^\bullet_{\mathscr{B}}(f^*P_\bullet, I^\bullet) \xleftarrow{\sim} \mathscr{H}om^\bullet_{\mathscr{A}}(P_\bullet, f_*I^\bullet)$$

in $\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$. It remains to show that the natural map

$$\mathscr{H}om^\bullet_{\mathscr{A}}(P_\bullet, f_*I^\bullet) \to R\mathscr{H}om^\bullet_{\mathscr{A}}(P_\bullet, f_*I^\bullet) \tag{10.1.20}$$

is an isomorphism. However, we have two spectral sequences :

$$E^1_{pq} := H_p\mathscr{H}om^\bullet_{\mathscr{A}}(P_q, f_*I^\bullet) \Rightarrow H_{p+q}\mathscr{H}om^\bullet_{\mathscr{A}}(P_\bullet, f_*I^\bullet)$$
$$F^1_{pq} := H_pR\mathscr{H}om^\bullet_{\mathscr{A}}(P_q, f_*I^\bullet) \Rightarrow H_{p+q}R\mathscr{H}om^\bullet_{\mathscr{A}}(P_\bullet, f_*I^\bullet)$$

and (10.1.20) induces a natural map of spectral sequences :

$$E^1_{pq} \to F^1_{pq} \tag{10.1.21}$$

Consequently, it suffices to show that (10.1.21) is an isomorphism for every $p, q \in \mathbb{N}$, and therefore we may assume that $P_\bullet$ consists of a single flat $\mathscr{A}$-module placed in degree zero. A similar argument reduces to the case where $I_\bullet$ consists of a single injective $\mathscr{B}$-module sitting in degree zero. To conclude, it suffices to show :

Claim 10.1.22. Let P be a flat $\mathscr{A}$-module, I an injective $\mathscr{B}$-module. Then the natural map :

$$\mathscr{H}om_{\mathscr{A}}(P, f_*I)[0] \to R\mathscr{H}om^\bullet_{\mathscr{A}}(P, f_*I)$$

is an isomorphism.

Proof of the claim. $R^i\mathscr{H}om^\bullet_{\mathscr{A}}(P, f_*I)$ is the sheaf associated with the presheaf on X :

$$U \mapsto R^i\mathrm{Hom}^\bullet_{\mathscr{A}_{|U}}(P_{|U}, f_*I_{|U}).$$

Since $I_{|U}$ is an injective $\mathscr{B}_{|U}$-module, it suffices therefore to show that $R^i\mathrm{Hom}^\bullet_{\mathscr{A}}(P, f_*I) = 0$ for $i > 0$. However, recall that there is a natural isomorphism :

$$R^i\mathrm{Hom}^\bullet_{\mathscr{A}}(P, f_*I) \simeq \mathrm{Hom}_{\mathsf{D}(\mathscr{A}\text{-}\mathbf{Mod})}(P, f_*I[-i]).$$

Since the homotopy category $\mathsf{Hot}(\mathscr{A}\text{-}\mathbf{Mod})$ admits a left calculus of fractions, we deduce a natural isomorphism :

$$R^i\mathrm{Hom}^\bullet_{\mathscr{A}}(P, f_*I) \simeq \operatorname*{colim}_{E_\bullet \to P} \mathrm{Hot}_{\mathscr{A}\text{-}\mathbf{Mod}}(E_\bullet, f_*I[-i]) \tag{10.1.23}$$

where the colimit ranges over the family of quasi-isomorphisms $E_\bullet \to P$. We may furthermore restrict the colimit in (10.1.23) to the subfamily of all such $E_\bullet \to P$ where $E_\bullet$ is a bounded above complex of flat $\mathscr{A}$-modules, since this subfamily is cofinal. Every such map $E_\bullet \to P$ induces a commutative diagram :

$$\begin{array}{ccc} \mathrm{Hom}_{\mathscr{A}}(P, f_*I[-i]) & \longrightarrow & \mathrm{Hot}_{\mathscr{A}\text{-}\mathbf{Mod}}(E_\bullet, f_*I[-i]) \\ \downarrow & & \downarrow \\ \mathrm{Hom}_{\mathscr{B}}(f^*P, I[-i]) & \longrightarrow & \mathrm{Hot}_{\mathscr{B}\text{-}\mathbf{Mod}}(f^*E_\bullet, I[-i]) \end{array}$$

whose vertical arrows are isomorphisms. Since $E_\bullet$ and P are complexes of flat $\mathscr{A}$-modules, the induced map $f^*E_\bullet \to f^*P$ is again a quasi-isomorphism; therefore, since I is injective, the bottom horizontal arrow is an isomorphism, hence the same holds for the top horizontal one, and the claim follows easily. □

10.1.24. Suppose that $\mathscr{F}$ is an abelian group object in a given topos X, and let $(\mathrm{Fil}^n\mathscr{F} \mid n \in \mathbb{N})$ be a descending filtration by abelian subobjects of $\mathscr{F}$, such that $\mathrm{Fil}^0\mathscr{F} = \mathscr{F}$. Set $\mathscr{F}^n := \mathscr{F}/\mathrm{Fil}^{n+1}\mathscr{F}$ for every $n \in \mathbb{N}$, and denote by $\mathrm{gr}^\bullet\mathscr{F}$ the graded abelian object associated with the filtered object $\mathrm{Fil}^\bullet\mathscr{F}$; then we have :

Lemma 10.1.25. *In the situation of* (10.1.24)*, fix $q \in \mathbb{N}$ and suppose that the natural map :*

$$\mathscr{F} \to R\lim_{k\in\mathbb{N}} \mathscr{F}^k$$

is an isomorphism in $\mathsf{D}(\mathbb{Z}_X\text{-}\mathbf{Mod})$. Then, the following conditions are equivalent :

(a) $H^q(X, \mathrm{Fil}^n\mathscr{F}) = 0$ *for every* $n \in \mathbb{N}$.

(b) *The natural map* $H^q(X, \mathrm{Fil}^n\mathscr{F}) \to H^q(X, \mathrm{gr}^n\mathscr{F})$ *vanishes for every* $n \in \mathbb{N}$.

Proof. Obviously we have only to show that (b) implies (a). Moreover, let us set :

$$(\mathrm{Fil}^n\mathscr{F})^k := \mathrm{Fil}^n\mathscr{F}/\mathrm{Fil}^{k+1}\mathscr{F} \qquad \text{for every } n, k \in \mathbb{N} \text{ with } k \geq n.$$

There follows, for every $n \in \mathbb{N}$, a short exact sequence of inverse systems of sheaves :

$$0 \to ((\mathrm{Fil}^n\mathscr{F})^k \mid k \geq n) \to (\mathscr{F}^k \mid k \geq n) \to \mathscr{F}^{n-1} \to 0$$

(where the right-most term is the constant inverse system which equals $\mathscr{F}^{n-1}$ in all degrees, with transition maps given by the identity morphisms); whence a distinguished triangle :

$$R\lim_{k\in\mathbb{N}} (\mathrm{Fil}^n\mathscr{F})^k \to R\lim_{k\in\mathbb{N}} \mathscr{F}^k \to \mathscr{F}^{n-1}[0] \to R\lim_{k\in\mathbb{N}} (\mathrm{Fil}^n\mathscr{F})^k[1]$$

which, together with our assumption on $\mathscr{F}$, easily implies that the natural map $\mathrm{Fil}^n\mathscr{F} \to R\lim_{k\in\mathbb{N}}(\mathrm{Fil}^n\mathscr{F})^k$ is an isomorphism in $\mathsf{D}(\mathbb{Z}_X\text{-}\mathbf{Mod})$. Summing up, we may replace the datum $(\mathscr{F}, \mathrm{Fil}^\bullet\mathscr{F})$ by $(\mathrm{Fil}^n\mathscr{F}, \mathrm{Fil}^{\bullet+n}\mathscr{F})$, and reduce to the case where $n = 0$.

The inverse system $(\mathscr{F}^n \mid n \in \mathbb{N})$ defines an abelian group object of the topos $X^{\mathbb{N}}$ (see [75, §7.3.4]); whence a spectral sequence:

$$E_2^{pq} := \lim_{n\in\mathbb{N}}{}^p\, H^q(X, \mathscr{F}^n) \Rightarrow H^{p+q}(X^{\mathbb{N}}, \mathscr{F}^\bullet) \simeq H^{p+q}(X, R\lim_{n\in\mathbb{N}} \mathscr{F}^n). \tag{10.1.26}$$

By [163, Cor.3.5.4] we have $E_2^{pq} = 0$ whenever $p > 1$, and, in view of our assumptions, (10.1.26) decomposes into short exact sequences :

$$0 \to \lim_{n\in\mathbb{N}}{}^1\, H^{q-1}(X, \mathscr{F}^n) \xrightarrow{\alpha_q} H^q(X, \mathscr{F}) \xrightarrow{\beta_q} \lim_{n\in\mathbb{N}} H^q(X, \mathscr{F}^n) \to 0 \qquad \text{for every } q \in \mathbb{N}$$

where β_q is induced by the natural system of maps $(\beta_{q,n} : H^q(X, \mathscr{F}) \to H^q(X, \mathscr{F}^n) \mid n \in \mathbb{N})$.

Claim 10.1.27. If (b) holds, then $\beta_q = 0$.

Proof of the claim. Suppose that (b) holds; we consider the long exact cohomology sequence associated with the short exact sequence :

$$0 \to \mathrm{Fil}^{n+1}\mathscr{F} \to \mathrm{Fil}^n\mathscr{F} \to \mathrm{gr}^n\mathscr{F} \to 0$$

to deduce that the natural map $H^q(X, \mathrm{Fil}^{n+1}\mathscr{F}) \to H^q(X, \mathrm{Fil}^n\mathscr{F})$ is onto for every $n \in \mathbb{N}$; hence the same holds for the natural map $H^q(X, \mathrm{Fil}^n\mathscr{F}) \to H^q(X, \mathscr{F})$. By considering the long exact cohomology sequence attached to the short exact sequence :

$$0 \to \mathrm{Fil}^n\mathscr{F} \to \mathscr{F} \to \mathscr{F}^n \to 0 \tag{10.1.28}$$

we then deduce that $\beta_{q,n}$ vanishes for every $n \in \mathbb{N}$, which implies the claim. ◊

Claim 10.1.29. If (b) holds, then the inverse system $(H^{q-1}(X, \mathscr{F}^n) \mid n \in \mathbb{N})$ has surjective transition maps.

Proof of the claim. By considering the long exact cohomology sequence associated with the short exact sequence : $0 \to \mathrm{gr}^n \mathscr{F} \to \mathscr{F}^{n+1} \to \mathscr{F}^n \to 0$, we are reduced to showing that the boundary map $\partial_{q-1} : H^{q-1}(X, \mathscr{F}^n) \to H^q(X, \mathrm{gr}^n \mathscr{F})$ vanishes for every $n \in \mathbb{N}$. However, comparing with (10.1.28), we find that ∂_{q-1} factors through the natural map $H^q(X, \mathrm{Fil}^n \mathscr{F}) \to H^q(X, \mathrm{gr}^n \mathscr{F})$, which vanishes if (b) holds. ◊

The lemma follows from claims 10.1.27 and 10.1.29, and [163, Lemma 3.5.3]. □

Our next result generalizes to arbitrary coherent spaces a classical theorem from [84], where it was stated only for noetherian spaces. We need first to introduce a general truncation construction for abelian sheaves, that shall be useful also in section 11.2.

10.1.30. Let $(X, \mathscr{A})$ be a ringed topological space, $\varphi : V \to X$ a locally closed immersion, denote by $\overline{V}$ the topological closure of V in X, and set $\partial V := \overline{V} \setminus V$, which is also a closed subset of X. Let also $i : \overline{V} \to X$ and $j : V \to \overline{V}$ be the induced closed and respectively open immersions. We set

$$\varphi_! := i_* \circ j_! : \varphi^* \mathscr{A}\text{-}\mathbf{Mod} \to \mathscr{A}\text{-}\mathbf{Mod} \qquad t_V := \varphi_! \circ \varphi^* : \mathscr{A}\text{-}\mathbf{Mod} \to \mathscr{A}\text{-}\mathbf{Mod}$$

and we call $\varphi_!$ (resp. t_V) the functor of *extension by zero from V to X* (resp. of *truncation outside V*). Notice that we have natural identifications

$$t_V \mathscr{F}_x \xrightarrow{\sim} \begin{cases} \mathscr{F}_x & \text{if } x \in V \\ 0 & \text{otherwise.} \end{cases} \tag{10.1.31}$$

Lemma 10.1.32. *In the situation of* (10.1.30)*, set $W := X \setminus V$, denote by $\psi : W \to X$ the resulting locally closed immersion, and let $\mathscr{F}$ be an $\mathscr{A}$-module such that $\psi^* \mathscr{F} = 0$. Then there exists a unique natural isomorphism*

$$f_{\mathscr{F}} : t_V \mathscr{F} \xrightarrow{\sim} \mathscr{F}$$

such that $f_{\mathscr{F},x}$ is the natural identification (10.1.31)*, for every $x \in V$.*

Proof. The uniqueness of $f_{\mathscr{F}}$ is clear. For the existence, set $\mathscr{G} := i^* \mathscr{F}$; it suffices to exhibit natural isomorphisms

$$\mathscr{F} \xrightarrow{\sim} i_* \mathscr{G} \qquad \text{and} \qquad j_! \varphi^* \mathscr{F} \xrightarrow{\sim} \mathscr{G}$$

which induce the corresponding natural identifications on the stalks. So we may assume that φ is either an open or closed immersion. In case φ is open, we obtain a natural map $f : \varphi_! \mathscr{F} \to \mathscr{F}$ as follows. Recall that $\varphi_! \mathscr{F}$ is the sheaf associated with the presheaf $\mathscr{H}$ such that $\mathscr{H}(U) = \mathscr{F}(U)$ for $U \subset V$, and $\mathscr{H}(U) = 0$ otherwise; then clearly there is a natural monomorphism $\mathscr{H} \to \mathscr{F}$ in the category of presheaves on X, and the latter factors uniquely through a map as sought. By construction, f_x is the identity endomorphism of $\mathscr{F}_x$, for every $x \in V$, and f_x is also trivially an isomorphism for $x \notin V$, since in this case the stalks of both source and target of f_x vanish. So f is indeed an isomorphism with the required properties.

Lastly, suppose φ is a closed immersion; for any open subset T of V, let C_T be the cofiltered set of all open subsets U of X such that $U \cap V = T$, and set

$$\varphi^{-1} \mathscr{H}(T) := \operatorname*{colim}_{U \in C_T^o} \mathscr{H}(U) \qquad \text{for every presheaf of abelian groups } \mathscr{H} \text{ on } X.$$

The rule $T \mapsto \varphi^{-1} \mathscr{H}(T)$ for every open subset T of V yields a well defined abelian presheaf on V, functorial in $\mathscr{H}$ (the resulting functor φ^{-1} from abelian presheaves on X to abelian presheaves on V is left adjoint to the direct image functor φ_* : cp. remark 1.3.6(i)). Now, suppose that $\mathscr{H}$ is a $\mathscr{A}$-module such that $\mathscr{H}_{|X \setminus V} = 0$; in this case, it is easily seen that $\varphi^{-1} \mathscr{H}$ is a $\varphi^* \mathscr{A}$-module, and moreover the transition map $\mathscr{H}(U) \to \mathscr{H}(U')$ is an isomorphism, for every $U, U' \in C_T$ such that $U' \subset U$. Especially, this applies with $\mathscr{H} := \mathscr{F}$, so we get a natural isomorphism

$$f_U : \mathscr{F}(U) \xrightarrow{\sim} i^{-1}\mathscr{F}(U \cap V) = i_* i^{-1}\mathscr{F}(U) \qquad \text{for every open subset } U \subset X$$

and the system of such maps f_U is the sought isomorphism $\mathscr{F} \xrightarrow{\sim} i_* i^* \mathscr{F}$. □

Proposition 10.1.33. *Let V and V' be two locally closed subsets of X. The following holds :*

(i) *We have a unique isomorphism of functors :*

$$\tau^{V,V'} : t_V \circ t_{V'} \xrightarrow{\sim} t_{V \cap V'}$$

which induces, for every $\mathscr{A}$-module $\mathscr{F}$ and every $x \in V \cap V'$ a commutative diagram

$$\begin{array}{ccc} t_V \circ t_{V'}\mathscr{F}_x & \xrightarrow{\tau_x^{V,V'}} & t_{V\cap V''}\mathscr{F}_x \\ \alpha\downarrow & & \downarrow\beta \\ t_{V'}\mathscr{F}_x & \xrightarrow{\gamma} & \mathscr{F}_x \end{array} \tag{10.1.34}$$

where α, β and γ are the natural identifications of (10.1.31).

(ii) *Let $V'' \subset X$ be a third locally closed subset. Then the diagram*

$$\begin{array}{ccc} t_V \circ t_{V'} \circ t_{V''} & \xrightarrow{t_V * \tau^{V',V''}} & t_V \circ t_{V'\cap V''} \\ \tau^{V,V'} * t_{V''}\downarrow & & \downarrow\tau^{V,V'\cap V''} \\ t_{V\cap V'} \circ t_{V''} & \xrightarrow{\tau^{V\cap V',V''}} & t_{V\cap V'\cap V''} \end{array}$$

commutes.

(iii) *Suppose that :*
  (a) *either $V \subset V'$ and the resulting immersion $V \to V'$ is closed*
  (b) *or else $V' \subset V$ and the resulting immersion $V' \to V$ is open.*

Then there exists a unique morphism of functors

$$c^{V,V'} : t_{V'} \to t_V$$

which induces, for every $\mathscr{A}$-module $\mathscr{F}$ and every $x \in V \cap V'$, a commutative diagram

$$\begin{array}{ccc} t_{V'}\mathscr{F}_x & \xrightarrow{c_x^{V,V'}} & t_V\mathscr{F}_x \\ & \searrow \quad \swarrow & \\ & \mathscr{F}_x & \end{array}$$

whose downward arrows are the natural identifications (10.1.31).

(iv) *In the situation of* (iii), *let V'' be a third locally closed subset of X. Then the resulting diagram*

$$\begin{array}{ccc} t_{V''} \circ t_{V'} & \xrightarrow{t_{V''} * c^{V,V'}} & t_{V''} \circ t_V \\ \tau^{V'',V'}\downarrow & & \downarrow\tau^{V'',V} \\ t_{V''\cap V'} & \xrightarrow{c^{V''\cap V,V''\cap V'}} & t_{V''\cap V} \end{array}$$

commutes.

(v) *Let $V \subset V' \subset V''$ (resp. $V'' \subset V' \subset V$) be a chain of closed (resp. open) immersions of locally closed subsets of X. Then*

$$c^{V,V'} \circ c^{V',V''} = c^{V,V''}.$$

Proof. (i): The uniqueness is clear. For the existence, set $W := V \cap V''$, and let $\varphi : W \to X$ and $\psi : X \setminus W \to X$ be the locally closed immersions; by inspecting the definition, we find natural isomorphisms

$$\varphi^* \circ t_V \circ t_{V'}\mathscr{F} \xrightarrow{\sim} \varphi^*\mathscr{F} \xleftarrow{\sim} \varphi^* t_W \mathscr{F} \qquad \text{for every } \mathscr{A}\text{-module } \mathscr{F}$$

which induce on stalks the isomorphisms $\varphi^*(\gamma \circ \alpha)$ and respectively $\varphi^*\beta$. There follows an isomorphism $\varphi_! f : t_W \circ t_V \circ t_{V'}\mathscr{F} \xrightarrow{\sim} t_{V''} \circ t_{V''}\mathscr{F}$. On the other hand, it is easily seen that $\psi^* \circ t_V \circ t_{V'}\mathscr{F}$ and $\psi^* \circ t_W \mathscr{F}$ both vanish, so lemma 10.1.32 naturally identifies $\varphi_! f$ with an isomorphism $t_V \circ t_{V'}\mathscr{F} \xrightarrow{\sim} t_W\mathscr{F}$ with the sought property.

(ii): The commutativity of the diagram can be checked on stalks, and then it follows easily from the commutativity of (10.1.34) : details left to the reader.

(iii): Again, the uniqueness of $c^{V,V'}$ is clear. For the existence, consider first case (a), and write $V = V' \cap Z$ for some closed immersion $\varphi : Z \to X$. The unit of the adjunction (φ^*, φ_*) yields a natural morphism $\eta : \mathscr{F} \to t_Z\mathscr{F}$, whence a morphism $t_{V'}\eta : t_{V'}\mathscr{F} \to t_{V'} \circ t_Z\mathscr{F}$, which, by (i) is naturally identified with a morphism $t_{V'}\mathscr{F} \to t_V\mathscr{F}$ fulfilling the stated condition. A similar argument works in case (b) : we write $V' = V \cap U$ for some open immersion $\psi : U \subset X$ and we consider the counit $\varepsilon : t_U\mathscr{F} \to \mathscr{F}$ of the adjunction $(\psi_!, \psi^*)$; then (i) naturally identifies $t_V\varepsilon$ with a morphism with the sought properties.

(iv) and (v) can be checked on the stalks : the details shall be left to the reader. □

Theorem 10.1.35. *Let X be any coherent space, $\mathscr{F}$ any abelian sheaf on X. Then :*

(i) $H^i(X, \mathscr{F}) = 0$ *for every* $i > \dim X$.

(ii) *If X is spectral, we have more precisely*

$$H^i(X, \mathscr{F}) = 0 \qquad \text{for every } i > d_{\mathscr{F}} := \sup(\dim \overline{\{x\}} \mid x \in \operatorname{Supp} \mathscr{F}).$$

Proof. (Here, for any subset $T \subset X$, we denote by $\overline{T}$ the topological closure of T in X).

Claim 10.1.36. Let $d \in \mathbb{N}$ be any integer, and suppose that (i) holds for every spectral space X of dimension $\leq d$. Then (ii) holds for every spectral space X and every $\mathbb{Z}_X$-module $\mathscr{F}$ such that $d_{\mathscr{F}} \leq d$.

Proof of the claim. Indeed, let $\mathscr{S}$ be the set consisting of all pairs (U, s), where $U \subset X$ is a quasi-compact open subset, and $s \in \mathscr{F}(U)$ is any element. For any $(U, s) \in \mathscr{S}$, let $\operatorname{Supp}(s) := \{x \in U \mid s_x \neq 0\}$, notice that $\operatorname{Supp}(s)$ is a closed subset of U, and denote by $i_s : \operatorname{Supp}(s) \to U$ and $j_U : U \to X$ the resulting closed and respectively open immersions; the section s is the same as a morphism of $\mathbb{Z}_U$-modules $\mathbb{Z}_U \to j_U^*\mathscr{F}$ which factors through the epimorphism $\mathbb{Z}_U \to i_{s*}\mathbb{Z}_{\operatorname{Supp}(s)}$. By adjunction, there follows a unique morphism of $\mathbb{Z}_X$-modules $\varphi_{U,s} : j_{U!}i_{s*}\mathbb{Z}_{\operatorname{Supp}(s)} \to \mathscr{F}$. For any finite subset $S \subset \mathscr{S}$, we let

$$\varphi_S : \bigoplus_{(U,s) \in S} j_{U!}i_{s*}\mathbb{Z}_{\operatorname{Supp}(s)} \to \mathscr{F}$$

be the unique map of $\mathbb{Z}_X$-modules whose restriction to $j_{U!}i_{s*}\mathbb{Z}_{\operatorname{Supp}(s)}$ agrees with $\varphi_{U,s}$, for every $(U, s) \in S$. It is easily seen that $\mathscr{F}$ is the colimit of the filtered system of its subsheaves $\mathscr{F}_S := \operatorname{Im} \varphi_S$, for S ranging over all finite subsets of $\mathscr{S}$. By proposition 10.1.10(i) we deduce that $H^i(X, \mathscr{F})$ is the filtered colimit of the system of abelian groups $(H^i(X, \mathscr{F}_S) \mid S \subset \mathscr{S})$; it then suffices to show the assertion for each subsheaf $\mathscr{F}_S$. Thus, we may assume from start that there exists a finite subset $S \subset \mathscr{S}$ with $\mathscr{F} = \mathscr{F}_S$. In this case, we set

$$Z := \overline{\operatorname{Supp} \mathscr{F}} = \bigcup_{(U,s) \in S} \overline{\operatorname{Supp}(s)}$$

and we let $i_Z : Z \to X$ be the closed immersion. Clearly we have a natural isomorphism

$$H^i(X, \mathscr{F}) \xrightarrow{\sim} H^i(Z, i_Z^*\mathscr{F}) \qquad \text{for every } i \in \mathbb{N}$$

and Z is still a spectral space, by corollary 8.1.42. Hence, we may replace X by Z and $\mathscr{F}$ by $i_Z^*\mathscr{F}$, and assume from start that $Z = X$ (and clearly, we still have $\mathscr{F} = \mathscr{F}_S$). In view of our assumption, it then suffices to show that

$$\dim Z = \sup\Big(\dim \overline{\{x\}} \mid x \in \bigcup_{(U,s)\in S} \mathrm{Supp}(s)\Big).$$

To this aim, in light of remark 8.1.2(v), we are reduced to checking that $\dim \overline{\mathrm{Supp}(s)} = \sup(\dim \overline{\{x\}} \mid x \in \mathrm{Supp}(s))$ for every $(U,s) \in S$. However, notice that $\mathrm{Supp}(s)$ is pro-constructible in X, hence $\overline{\mathrm{Supp}(s)}$ is the set of all specializations in X of the points of $\mathrm{Supp}(s)$ (proposition 8.1.47(i)). Now the contention follows from remark 8.1.45(iii). $\Diamond$

(i): Let S_X be the sober space associated with X, and $f_X : X \to S_X$ the unit of adjunction (proposition 8.1.8); by remark 8.1.11, the space S_X is spectral; moreover the functor

$$f_X^* : \mathbb{Z}_{S_X}\text{-}\mathbf{Mod} \to \mathbb{Z}_X\text{-}\mathbf{Mod}$$

is an equivalence of categories, and the induced map $\Gamma(S_X, \mathscr{F}) \to \Gamma(X, f_X^*\mathscr{F})$ is a bijection for every $\mathbb{Z}_{S_X}$-module $\mathscr{F}$. It follows easily that the induced map

$$H^i(S_X, \mathscr{F}) \to H^i(X, f_X^*\mathscr{F})$$

is an isomorphism as well; thus, we may replace X by S_X, and assume from start that X is spectral.

We argue by induction on $d := \dim X$. If $d = 0$, X is a boolean space (see example 8.1.48), so every sheaf on X is qc-flabby, and the assertion follows from lemma 10.1.5(iv). We may then assume that $d > 0$ and that (i) is already known for every spectral space of dimension $< d$. Suppose, by way of contradiction, that $H^{d+1}(X, \mathscr{F}) \neq 0$ for some $\mathbb{Z}_X$-module $\mathscr{F}$, and pick any element $c \neq 0$ in this cohomology group. For any closed subset $Z \subset X$, let $i_Z : Z \to X$ be the corresponding closed immersion, denote by $\mathscr{Z}$ the system of all closed subsets $Z \subset X$ such that the image of c does not vanish in $H^{d+1}(Z, i_Z^*\mathscr{F})$, and endow $\mathscr{Z}$ with the partial ordering given by inclusion. Notice that each $Z \in \mathscr{Z}$ is also a spectral space (corollary 8.1.42), so we must have $\dim Z = d$, by inductive assumption.

Claim 10.1.37. (i) The partially ordered set $\mathscr{Z}$ admits minimal elements.

(ii) Every minimal element of $\mathscr{Z}$ is an irreducible closed subset of X.

Proof of the claim. (i): Let $(Z_i \mid i \in I)$ be any totally ordered non-empty subset of $\mathscr{Z}$; by Zorn's lemma, it suffices to check that $\bigcap_{i\in I} Z_i \in \mathscr{Z}$. However, notice that the inclusion maps $Z_i \to Z_j$ are spectral for every $i, j \in I$ with $Z_i \subset Z_j$ (lemma 8.1.19(x.e) and remark 8.1.20(iv)), so the latter assertion follows directly from proposition 10.1.10(i).

(ii): Let Z be any minimal element of $\mathscr{Z}$, and suppose, by way of contradiction, that $Z = Z_1 \cup Z_2$ for two non-empty closed subsets Z_1, Z_2 strictly contained in Z; notice that Z_1 and Z_2 are also spectral spaces (corollary 8.1.42). Pick any non-empty quasi-compact open subset $U \subset Z \setminus Z_1$, and set $Z'_1 := Z \setminus U$, $Z'_2 := \overline{U}$. Since $U \subset Z_2$, we have $Z'_2 \subset Z_2$ and $Z_1 \subset Z'_1$. Moreover, both Z'_1 (resp. Z'_2) is the set of all specializations of the points of $Z \setminus U$ (resp. of U); it follows that $Z'_3 := Z'_1 \cap Z'_2$ has dimension $< d$: indeed, any totally ordered sequence $x_1 < \cdots < x_k$ of elements of $(Z'_3, \leq)$ (with ordering given by specialization) can be extended to a totally ordered sequence of $(Z'_2, \leq)$, by adding a generization x_{k+1} of x_k with $x_{k+1} \in U$.

On the other hand, consider the sequence

$$(10.1.38) \qquad 0 \to t_{Z'_3}\mathscr{F} \to t_{Z'_1}\mathscr{F} \oplus t_{Z'_2}\mathscr{F} \to t_Z\mathscr{F} \to 0.$$

whose second and third arrows are given by the natural transformations provided by proposition 10.1.33(iii); by considering the stalks over the points of Z, it is easily seen that (10.1.38) is short exact, whence an exact sequence of abelian groups

$$H^d(Z'_3, i^*_{Z'_3}\mathscr{F}) \to H^{d+1}(Z, i^*_Z\mathscr{F}) \xrightarrow{\beta} H^{d+1}(Z'_1, i^*_{Z'_1}\mathscr{F}) \oplus H^{d+1}(Z'_2, i^*_{Z'_2}\mathscr{F}). \tag{10.1.39}$$

However, the first term of (10.1.39) vanishes by inductive assumption, hence β is injective; especially the image of c cannot vanish in both $H^{d+1}(Z'_1, i^*_{Z'_1}\mathscr{F})$ and $H^{d+1}(Z'_2, i^*_{Z'_2}\mathscr{F})$, contradicting the minimality of Z. ♢

By claim 10.1.37, we may replace X by a minimal element of $\mathscr{X}$, and assume from start that X is irreducible. In this case, denote by $\eta \in X$ the maximal point, and let $j_\eta : \{\eta\} \to X$ be the inclusion map; there follows a natural map of $\mathbb{Z}_X$-modules $f : \mathscr{F} \to j_{\eta*}j^*_\eta\mathscr{F}$ such that f_η is an isomorphism. Since $j^*_\eta\mathscr{F}$ is obviously qc-flabby on $\{\eta\}$, lemma 10.1.5(iii,iv) implies that $H^i(X, j_{\eta*}j^*_\eta\mathscr{F}) = 0$ for every $i > 0$. We deduce an exact sequence of abelian groups

$$H^{d+1}(X, \mathrm{Ker}\, f) \to H^{d+1}(X, \mathscr{F}) \to H^{d+1}(X, \mathrm{Im}\, f) \tag{10.1.40}$$

as well as an isomorphism of abelian groups

$$H^d(X, \mathrm{Coker}\, f) \xrightarrow{\sim} H^{d+1}(X, \mathrm{Im}\, f)$$

and by construction we have $d_{\mathrm{Ker}, f}, d_{\mathrm{Coker}\, f} < d$. From the inductive assumption and claim 10.1.36, it follows that the first and third terms of (10.1.40) vanish, so the same holds for the middle one, and the proof is concluded. □

Remark 10.1.41. A different proof of (a slight improvement of) theorem 10.1.35 is found in [147]. See also proposition 10.4.7(ii). Alternative proofs for both theorem 10.1.35 and proposition 10.4.7(ii.b,ii.c) are also found in [107, Tag 0A3G].

10.2. **Čech cohomology.** This section is a review of the standard constructions of resolutions via Čech complexes, for general topoi. We also include two classical applications to the cohomology of quasi-coherent modules on a scheme.

10.2.1. Let T be a topos, and $\mathfrak{U} := (U_i \mid i \in I)$ a family of objects of T; pick any final object 1_T of T, and set as well (notation of example 4.7.8(iii))

$$Y := \coprod_{i\in I} U_i \qquad U := \bigcup_{i\in I} \mathrm{Im}(U_i \to 1_T) \qquad Z := \complement U.$$

According to example 4.7.8(i,iii) there exist natural morphisms of topoi

$$j_U : T/U \to T \qquad \pi : T/Y \to T \qquad i : Z \to T.$$

Moreover, the functor $\pi^* : T \to T/Y$ admits a left adjoint $\pi_! : T/Y \to T$. Furthermore, let $\mathbb{Z}_T$ (resp. $\mathbb{Z}_X$, for every object X of T) be the constant ring object of T (resp. of T/X) associated with the ring $\mathbb{Z}$. The functor $\pi^* : \mathbb{Z}_T\text{-}\mathbf{Mod} \to \mathbb{Z}_Y\text{-}\mathbf{Mod}$ admits a left adjoint

$$\pi_! : \mathbb{Z}_Y\text{-}\mathbf{Mod} \to \mathbb{Z}_T\text{-}\mathbf{Mod}.$$

Then, according to (7.10.3), the adjoint pair $(\pi_!, \pi^*)$ determines a cotriple $(\perp^{\mathfrak{U}}, \eta, \mu)$, which in turns yields a functor

$$\mathbb{Z}_T\text{-}\mathbf{Mod} \to \widehat{s}.\mathbb{Z}_T\text{-}\mathbf{Mod} \qquad \mathscr{F} \mapsto \perp^{\mathfrak{U}}_\bullet \mathscr{F}.$$

(notation of definition 7.4.1(iv)). This construction can be described explicitly as follows. We attach to I the simplicial set $I^\bullet$ which, in every degree $n \in \mathbb{N}$ consists of the set of all mappings $[n] \to I$, where $[n] := \{0, \dots, n\}$; *i.e.*, this is the cartesian power I^{n+1} of I, whose elements are all the ordered sequences $\underline{t} := (t_0, \dots, t_n)$ of elements of I. Every morphism $\varphi : [n] \to [m]$ in the simplicial category Δ induces a map $\varphi^* : I^{m+1} \to I^{n+1}$ by the rule :

$$\underline{t} \mapsto \underline{t} \circ \varphi := (t_{\varphi 0}, \dots, t_{\varphi n}) \qquad \text{for every } \underline{t} \in I^{m+1}$$

and it is clear that the rules : $[n] \mapsto I^{n+1}$ and $\varphi \mapsto \varphi^*$ yield a well defined functor $\Delta^o \to \mathbf{Set}$. For every $\underline{t} \in I^{n+1}$, we fix as well an object $U_{\underline{t}}$ of T that represents the product $U_{t_0} \times \cdots \times U_{t_n}$, and denote by $j_{\underline{t}} : T/U_{\underline{t}} \to T$ the induced morphism. Notice that every $\varphi : [n] \to [m]$ in Δ and every $\underline{t} \in I^{m+1}$ induces a well defined morphism in T :

$$\nu_\varphi^{(\underline{t})} : U_{\underline{t}} \to U_{\varphi^*(\underline{t})}$$

namely, the unique morphism whose composition with the projection on the i-th factor of $U_{\varphi^*(\underline{t})}$ agrees with the projection onto the $\varphi(i)$-th factor of $U_{\underline{t}}$, for every $i = 0, \dots, n$. Then $\nu_\varphi^{(\underline{t})}$ in turns induces a morphism

$$u_\varphi^{(\underline{t})} : j_{\underline{t}!} j_{\underline{t}}^* \mathscr{F} \to j_{\varphi^*(\underline{t})!} j_{\varphi^*(\underline{t})}^* \mathscr{F}.$$

With this notation, we have

$$\perp_n^{\mathfrak{U}} \mathscr{F} := \bigoplus_{\underline{t} \in I^{n+1}} j_{\underline{t}!} j_{\underline{t}}^* \mathscr{F} \qquad \text{for every } n \in \mathbb{N}$$

and every morphism $\varphi : [n] \to [m]$ in Δ corresponds to the unique morphism of $\mathbb{Z}_T$-modules $u_\varphi : \perp_m^{\mathfrak{U}} \mathscr{F} \to \perp_n^{\mathfrak{U}} \mathscr{F}$ that makes commute the diagram

$$\begin{array}{ccc} j_{\underline{t}!} j_{\underline{t}}^* \mathscr{F} & \xrightarrow{u_\varphi^{(\underline{t})}} & j_{\varphi^*(\underline{t})!} j_{\varphi^*(\underline{t})}^* \mathscr{F} \\ \downarrow & & \downarrow \\ \perp_m^{\mathfrak{U}} \mathscr{F} & \xrightarrow{u_\varphi} & \perp_n^{\mathfrak{U}} \mathscr{F} \end{array} \qquad \text{for every } \underline{t} \in I^{m+1}.$$

where the vertical arrows are the inclusion maps. Moreover, $\perp_{-1}^{\mathfrak{U}} \mathscr{F} = \mathscr{F}$, and the augmentation $\varepsilon : \perp_0^{\mathfrak{U}} \mathscr{F} \to \perp_{-1}^{\mathfrak{U}} (\mathfrak{U})$ is the sum of the natural morphisms $j_{i!} j_i^* \mathscr{F} \to \mathscr{F}$ given by the counit for the adjunction $(j_{i!}, j_i^*)$, for every $i \in I$.

Definition 10.2.2. (i) With the notation of (10.2.1), the *augmented Čech resolution* associated with $\mathfrak{U}$ and the $\mathbb{Z}_T$-module $\mathscr{F}$ is the unnormalized chain complex of $\mathbb{Z}_T$-modules

$$(R_\bullet(\mathfrak{U}, \mathscr{F}), d_\bullet)$$

obtained from the augmented simplicial complex $\perp_\bullet^{\mathfrak{U}} (\mathfrak{U}, \mathbb{Z}_T)$ (see definition 7.4.24(i)).

(ii) To ease notation, we shall set also

$$R_\bullet(\mathfrak{U}) := R_\bullet(\mathfrak{U}, \mathbb{Z}_T) \qquad \text{and} \qquad \overline{R}_\bullet(\mathfrak{U}) := \tau_{\leq 0} R_\bullet(\mathfrak{U}).$$

Then the *augmented Čech complex of $\mathscr{F}$ relative to the covering* $\mathfrak{U}$ of U is the cochain complex

$$C^\bullet(\mathfrak{U}_\bullet, \mathscr{F}) := \mathrm{Hom}^\bullet_{\mathbb{Z}_T}(R_\bullet(\mathfrak{U}), \mathscr{F}[0]).$$

Hence, $R_\bullet(\mathfrak{U})$ is an object of $\mathsf{C}^{\leq 1}(\mathbb{Z}_T\text{-}\mathbf{Mod})$, and $C^\bullet(\mathfrak{U}_\bullet, \mathscr{F})$ is an object of $\mathsf{C}^{\geq -1}(\mathbb{Z}\text{-}\mathbf{Mod})$.

Lemma 10.2.3. *With the notation of definition* 10.2.2*, we have :*

(i) *For every $\mathbb{Z}_T$-module $\mathscr{F}$, the complex of $\mathbb{Z}_U$-modules $j_U^* R_\bullet(\mathfrak{U}, \mathscr{F})$ is acyclic.*

(ii) *The natural projection $\mathbb{Z}_T \to i_* \mathbb{Z}_Z$ induces a quasi-isomorphism :*

$$R_\bullet(\mathfrak{U}) \xrightarrow{\sim} i_* \mathbb{Z}_Z[-1] \qquad \textit{in } \mathsf{C}^-(\mathbb{Z}_T\text{-}\mathbf{Mod}).$$

(iii) *Suppose that $\mathfrak{U}$ is a* covering *of T (*i.e. *that $U = 1_T$ and $Z = \varnothing_T$). Then the differential d_0 of $R_\bullet(\mathfrak{U})$ induces a quasi-isomorphism*

$$\overline{R}_\bullet(\mathfrak{U}) \xrightarrow{\sim} \mathbb{Z}_T[0] \qquad \textit{in } \mathsf{C}^-(\mathbb{Z}_T\text{-}\mathbf{Mod}).$$

Proof. (i): The natural morphism $Y \to U$ is an epimorphism, hence it is a covering in the canonical topology of T, and therefore it suffices to check that $\pi^* R_\bullet(\mathfrak{U}, \mathscr{F})$ is acyclic. But proposition 7.10.5(i) says that $\pi^*(\perp^{\mathfrak{U}}_\bullet \mathscr{F})$ is homotopically trivial. Then the assertion follows from corollary 7.4.67(ii).

Assertions (ii) and (iii) are immediate consequences of (i). □

10.2.4. Keep the notation of (10.2.1), and choose any total ordering on I. We let $I^{n+1}_{\mathrm{alt}} \subset I^{n+1}$ be the subset of all injective order-preserving mappings $[n] \to I$, for every $n \in \mathbb{N}$, and we set

$$R^{\mathrm{alt}}_{-1}(\mathfrak{U}, \mathscr{F}) := \mathscr{F} \qquad R^{\mathrm{alt}}_n(\mathfrak{U}, \mathscr{F}) := \bigoplus_{\underline{t} \in I^{n+1}_{\mathrm{alt}}} j_{\underline{t}!} j^*_{\underline{t}} \mathscr{F} \qquad \text{for every } n \in \mathbb{N}.$$

Obviously $\varphi^*(I^{m+1}_{\mathrm{alt}}) \subset I^{n+1}_{\mathrm{alt}}$ for every *injective* morphism $\varphi : [n] \to [m]$ of Δ, so the differential d_n of $R_\bullet(\mathfrak{U}, \mathscr{F})$ restricts to a well defined morphism of $\mathbb{Z}_T$-modules $R^{\mathrm{alt}}_n(\mathfrak{U}, \mathscr{F}) \to R^{\mathrm{alt}}_{n-1}(\mathfrak{U}, \mathscr{F})$ for every $n \in \mathbb{N}$, and we obtain therefore a subcomplex

$$(R^{\mathrm{alt}}_\bullet(\mathfrak{U}, \mathscr{F}), d_\bullet).$$

We set as well $R^{\mathrm{alt}}_\bullet(\mathfrak{U}) := R^{\mathrm{alt}}_\bullet(\mathfrak{U}, \mathbb{Z}_T)$, and to every $\mathbb{Z}_T$-module $\mathscr{F}$ we assign its *alternating augmented Čech complex relative to the covering* $\mathfrak{U}$ of U, which is the cochain complex

$$C^\bullet_{\mathrm{alt}}(\mathfrak{U}_\bullet, \mathscr{F}) := \mathrm{Hom}^\bullet_{\mathbb{Z}}(R^{\mathrm{alt}}_\bullet(\mathfrak{U}), \mathscr{F}[0]).$$

We shall also consider the alternating variant of the *Čech resolution*

$$\overline{R}^{\mathrm{alt}}_\bullet(\mathfrak{U}) := \tau_{\leq 0} R^{\mathrm{alt}}_\bullet(\mathfrak{U}).$$

10.2.5. For every $n \in \mathbb{N}$, denote by S_{n+1} the permutation group of $[n]$; then, for any $\underline{t} \in I^{n+1}_{\mathrm{alt}}$, and any $\sigma \in S_{n+1}$, the sequence $\underline{t} \circ \sigma$ is an element of I^{n+1} such that $U_{\underline{t}\circ\sigma} = U_{\underline{t}}$, and there exists a unique isomorphism $\mu_{\underline{t}} : U_{\underline{t}\circ\sigma} \xrightarrow{\sim} U_{\underline{t}}$ whose composition with the projection on the i-th factor of $U_{\underline{t}}$ agrees with the projection on the $\sigma(i)$-th factor of $U_{\underline{t}\circ\sigma}$, for every $i \in [n]$. We set

$$\mathrm{Alt}^{(\underline{t}\circ\sigma)} := \mathrm{sign}(\sigma) \cdot v_{\underline{t}} : j_{(\underline{t}\circ\sigma)!} \mathbb{Z}_{U_{\underline{t}\circ\sigma}} \to j_{\underline{t}!} \mathbb{Z}_{U_{\underline{t}}}$$

where $v_{\underline{t}}$ is the isomorphism induced by $\mu_{\underline{t}}$, and where $\mathrm{sign}(\sigma)$ denotes the signature of σ. Then, for every $n \in \mathbb{N}$ there exists a unique morphism of $\mathbb{Z}_T$-modules

$$\mathrm{Alt}^{\mathfrak{U}}_n : R_n(\mathfrak{U}) \to R^{\mathrm{alt}}_n(\mathfrak{U})$$

whose kernel contains the direct summands $j_{\underline{t}!} \mathbb{Z}_{U_{\underline{t}}}$ such that the mapping $\underline{t} : [n] \to I$ is not injective, and that makes commute the diagram

$$\begin{array}{ccc} j_{(\underline{t}\circ\sigma)!} \mathbb{Z}_{U_{\underline{t}\circ\sigma}} & \xrightarrow{\mathrm{Alt}^{(\underline{t}\circ\sigma)}} & j_{\underline{t}!} \mathbb{Z}_{U_{\underline{t}}} \\ \downarrow & & \downarrow \\ R_n(\mathfrak{U}) & \xrightarrow{\mathrm{Alt}^{\mathfrak{U}}_n} & R^{\mathrm{alt}}_n(\mathfrak{U}) \end{array} \qquad \text{for every } \underline{t} \in I^{\mathrm{alt}}_n$$

(where the vertical arrows are the inclusion maps).

Proposition 10.2.6. *In the situation of* (10.2.5)*, denote by* $\iota^{\mathfrak{U}}_\bullet : R^{\mathrm{alt}}_\bullet(\mathfrak{U}) \to R_\bullet(\mathfrak{U})$ *the inclusion map, and suppose that* U_i *is a subobject of* 1_T*, for every* $i \in I$*. Then the following holds :*

(i) *The system* $(\mathrm{Alt}^{\mathfrak{U}}_{n-1} \mid n \in \mathbb{N})$ *defines an epimorphism of chain complexes*

$$\mathrm{Alt}^{\mathfrak{U}}_\bullet : R_\bullet(\mathfrak{U}) \to R^{\mathrm{alt}}_\bullet(\mathfrak{U})$$

whose kernel is independent of the choice of ordering on I.

(ii) $\mathrm{Alt}^{\mathfrak{U}}_\bullet \circ \iota^{\mathfrak{U}}_\bullet = \mathbf{1}_{R^{\mathrm{alt}}_\bullet(\mathfrak{U})}$. *and* $\iota^{\mathfrak{U}}_\bullet \circ \mathrm{Alt}^{\mathfrak{U}}_\bullet$ *is homotopically equivalent to* $\mathbf{1}_{R_\bullet(\mathfrak{U})}$.

(iii) *Especially,* $\iota^{\mathfrak{U}}_\bullet$ *and* $\mathrm{Alt}^{\mathfrak{U}}_\bullet$ *are mutually inverse isomorphisms in* $\mathsf{D}(\mathbb{Z}_X\text{-}\mathbf{Mod})$.

(iv) *The natural projection* $\mathbb{Z}_T \to i_*\mathbb{Z}_Z$ *induces a quasi-isomorphism :*

$$R^{\mathrm{alt}}_\bullet(\mathfrak{U}) \stackrel{\sim}{\to} i_*\mathbb{Z}_Z[-1] \qquad \textit{in } \mathsf{C}^-(\mathbb{Z}_T\text{-}\mathbf{Mod}).$$

(v) *Suppose that* $\mathfrak{U}$ *is a* covering *of* T *(*i.e. *that* $U = 1_T$ *and* $Z = \varnothing_T$*). Then the differential* d_0 *of* $R^{\mathrm{alt}}_\bullet(\mathfrak{U})$ *induces a quasi-isomorphism*

$$\overline{R}^{\mathrm{alt}}_\bullet(\mathfrak{U}) \stackrel{\sim}{\to} \mathbb{Z}_T[0] \qquad \textit{in } \mathsf{C}^-(\mathbb{Z}_T\text{-}\mathbf{Mod}).$$

Proof. (i): Fix an integer $n > 0$, a sequence $\underline{s} \in I^{n+1}$, and let $c \leq n+1$ be the cardinality of $\{s_0, \dots, s_n\}$. It suffices to check that the compositions $d_n \circ \mathrm{Alt}^{\mathfrak{U}}_n$ and $\mathrm{Alt}^{\mathfrak{U}}_{n-1} \circ d_n$ agree on $j_{\underline{s}!}\mathbb{Z}_{U_{\underline{s}}}$. In case $c < n$, it is easily seen that both these compositions vanish on such direct summand. In case $c = 1$ and $n = 0$, the assertion follows by a direct inspection. In case $c = n+1 > 1$, we may find a unique permutation $\sigma \in S_{n+1}$ and a unique $\underline{t} \in I^{n+1}_{\mathrm{alt}}$ such that $\underline{s} = \underline{t} \circ \sigma$, and we have to show that we have a commutative diagram

$$\begin{array}{ccc} j_{(\underline{t}\circ\sigma)!}\mathbb{Z}_{U_{\underline{t}\circ\sigma}} & \xrightarrow{\mathrm{Alt}^{(\underline{t}\circ\sigma)}} & j_{\underline{t}!}\mathbb{Z}_{U_{\underline{t}}} \\ {\scriptstyle d_{\underline{t}\circ\sigma}}\downarrow & & \downarrow{\scriptstyle d_{\underline{t}}} \\ R_{n-1}(\mathfrak{U}) & \xrightarrow{\mathrm{Alt}^{\mathfrak{U}}_{n-1}} & R_{n-1}(\mathfrak{U}') \end{array}$$

where $d_{\underline{t}}$ and $d_{\underline{t}\circ\sigma}$ denote the restrictions of the differentials of $R^{\mathrm{alt}}_\bullet(\mathfrak{U})$ and respectively $R_\bullet(\mathfrak{U})$. To this aim, for every $i = 0, \dots, n$ denote by $\beta^{(i)}_1$ the unique permutation of $[n]$ such that

$$\beta^{(i)}_1(\sigma(i)) = \sigma(i) \qquad \text{and} \qquad \beta^{(i)}_1(\sigma(j)) < \beta^{(i)}_1(\sigma(k)) \quad \text{for every } j,k \in [n] \setminus \{i\} \text{ with } j < k.$$

Also, we define a third permutation as follows :

- If $\sigma(i) < i$, let $\beta^{(i)}_2$ be the cycle $(i, i-1, \dots, \sigma(i))$ of length $i - \beta(i) + 1$
- If $\sigma(i) > i$, let $\beta^{(i)}_2$ be the cycle $(i, i+1, \dots, \sigma(i))$ of length $\sigma(i) - i + 1$
- If $\sigma(i) = i$, let $\beta^{(i)}_2$ be the identity map of $[n]$.

It is easily seen that in either cases

$$\sigma^{-1} = \beta^{(i)}_2 \circ \beta^{(i)}_1 \qquad \text{and} \qquad \mathrm{sign}(\beta^{(i)}_2) = (-1)^{i-\sigma(i)} \qquad \text{for every } i = 0, \dots, n.$$

Now, for every $i = 0, \dots, n$ let $\varepsilon_i : [n-1] \to [n]$ be the i-th face map (see (7.4.6)); we compute:

$$\begin{aligned} \mathrm{Alt}^{\mathfrak{U}}_{n-1} \circ d_{\underline{t}\circ\sigma} &= \mathrm{Alt}^{\mathfrak{U}}_{n-1} \circ \Big(\sum_{i=0}^n (-1)^i \cdot u^{(\underline{t}\circ\sigma)}_{\varepsilon_i}\Big) \\ &= \sum_{i=0}^n (-1)^i \cdot \mathrm{sign}(\beta^{(i)}_1) \cdot u^{(\underline{t}\circ\sigma)}_{\varepsilon_i} \\ &= \sum_{i=0}^n (-1)^{\sigma(i)} \cdot \mathrm{sign}(\sigma) \cdot u^{(\underline{t}\circ\sigma)}_{\varepsilon_i} \\ &= \sum_{i=0}^n (-1)^i \cdot \mathrm{sign}(\sigma) \cdot u^{(\underline{t})}_{\varepsilon_i} \\ &= \mathrm{sign}(\sigma) \cdot d_{\underline{t}} \end{aligned}$$

as required. Lastly, if $c = n$, the morphism $d_n \circ \mathrm{Alt}^{(\underline{t}\circ\sigma)}$ vanishes, and it remains to check that $\mathrm{Alt}^{\mathfrak{U}}_{n-1} \circ d_{\underline{s}} = 0$ as well. However, in this situation there exist exactly two distinct indices $i, j \in [n]$ such that $s_i = s_j$, and it follows already that $\mathrm{Alt}^{\mathfrak{U}}_{n-1} \circ u^{(\underline{s})}_{\varepsilon_k} = 0$ for every $k \neq i, j$.

Moreover, clearly there exists a unique $\underline{t} \in I^n_{\mathrm{alt}}$ such that $\{t_0, \dots, t_{n-1}\} = \{s_0, \dots, s_n\}$, and notice that the diagram :

$$\begin{array}{ccc} U_{\underline{s}} & \xrightarrow{\nu^{(\underline{s})}_{\varepsilon_i}} & U_{\varepsilon^*_i(\underline{s})} \\ {\scriptstyle \nu^{(\underline{s})}_{\varepsilon_j}} \downarrow & & \downarrow {\scriptstyle \mu_{\varepsilon^*_i(\underline{s})}} \\ U_{\varepsilon^*_j(\underline{s})} & \xrightarrow{\mu_{\varepsilon^*_j(\underline{s})}} & U_{\underline{t}} \end{array}$$

commutes (this is the only place where we use our assumption on the objects U_i). There follows a commutative diagram

$$\begin{array}{ccc} j_{\underline{s}!}\mathbb{Z}_{U_{\underline{s}}} & \xrightarrow{u^{(\underline{s})}_{\varepsilon_i}} & j_{\varepsilon^*_i(\underline{s})!}\mathbb{Z}_{U_{\varepsilon^*_i(\underline{s})}} \\ {\scriptstyle u^{(\underline{s})}_{\varepsilon_j}} \downarrow & & \downarrow {\scriptstyle v_{\varepsilon^*_i(\underline{s})}} \\ j_{\varepsilon^*_j(\underline{s})!}\mathbb{Z}_{U_{\varepsilon^*_j(\underline{s})}} & \xrightarrow{v_{\varepsilon^*_j(\underline{s})}} & U_{\underline{t}} \end{array}$$

Now, let β_i (resp. β_j) be the unique permutation of $[n]$ that fixes i (resp. j) and such that $\underline{s} \circ \beta_i$ (resp. $\underline{s} \circ \beta_j$) restricts to an order-preserving map on $[n] \setminus \{i\}$ (resp. on $[n] \setminus \{j\}$). Arguing as in the foregoing, we see that $\beta_i = \gamma \circ \beta_j$ for a cyclic permutation γ of length $|j - i|$, so that

$$\rho := (-1)^i \cdot \mathrm{sign}(\beta_i) = (-1)^{j+1} \cdot \mathrm{sign}(\beta_j).$$

Denote by $\mathbf{1}_{\underline{t}}$ the identity automorphism of $j_{\underline{t}!}\mathbb{Z}_{U_{\underline{t}}}$. Summing up, we get

$$\begin{aligned} \mathrm{Alt}^{\mathfrak{U}}_{n-1} \circ d_{\underline{s}} &= (-1)^i \cdot \mathrm{Alt}^{\mathfrak{U}}_{n-1} \circ u^{(\underline{s})}_{\varepsilon_i} + (-1)^j \cdot \mathrm{Alt}^{\mathfrak{U}}_{n-1} \circ u^{(\underline{s})}_{\varepsilon_j} \\ &= (-1)^i \cdot \mathrm{sign}(\beta_i) \cdot v_{\varepsilon^*_i(\underline{s})} \circ u^{(\underline{s})}_{\varepsilon_i} + (-1)^j \cdot \mathrm{sign}(\beta_j) \cdot v_{\varepsilon^*_j(\underline{s})} \circ u^{(\underline{s})}_{\varepsilon_j} \\ &= \rho \cdot (v_{\varepsilon^*_i(\underline{s})} \circ u^{(\underline{s})}_{\varepsilon_i} - v_{\varepsilon^*_j(\underline{s})} \circ u^{(\underline{s})}_{\varepsilon_j}) \\ &= 0 \end{aligned}$$

and the proof of (i) is concluded.

(ii): Let V be a universe such that T is V-small, and set $T' := T^\wedge_{\mathsf{V}}$; also, let J be the canonical topology on T. Then T' is a V-topos, and the Yoneda imbedding $h : T \to T'$ factors through an equivalence $T \stackrel{\sim}{\to} (T, J)^\sim_{\mathsf{U}}$ and the inclusion functor $(T, J)^\sim_{\mathsf{U}} \to T'$. Set $U'_i := h_{U_i} \in \mathrm{Ob}(T')$ for every $i \in I$, $U' := \bigcup_{i \in I} \mathrm{Im}(U'_i \to 1_{T'})$, and $\mathfrak{U}' := (U'_i \mid i \in I)$. Hence U' is a presheaf on T whose associated sheaf is isomorphic to h_U. Let $j_{U'} : T'/U' \to T'$ be the induced morphism of topoi; according to lemma 10.2.3, the chain complex $j^*_{U'}R_\bullet(\mathfrak{U}')$ is acyclic, hence the same holds for $j_{U'!}j^*_{U'}R_\bullet(\mathfrak{U}')$, and there follows a commutative diagram of complexes of $\mathbb{Z}_{T'}$-modules :

$$\begin{array}{ccc} \overline{R}_\bullet(\mathfrak{U}') & \longrightarrow & j_{U'!}\mathbb{Z}_{U'}[0] \\ {\scriptstyle \tau_{\leq 0}(\iota^{\mathfrak{U}'}_\bullet \circ \mathrm{Alt}^{\mathfrak{U}'}_\bullet)} \downarrow & & \| \\ \overline{R}_\bullet(\mathfrak{U}') & \longrightarrow & j_{U'!}\mathbb{Z}_{U'}[0] \end{array}$$

whose horizontal arrows are induced by the differential d_0 of $R_\bullet(\mathfrak{U}')$, and therefore are isomorphisms in the category $\mathsf{D}(\mathbb{Z}_{T'}\text{-}\mathbf{Mod})$, so that

$$\tau_{\leq 0}(\iota^{\mathfrak{U}'}_\bullet \circ \mathrm{Alt}^{\mathfrak{U}'}_\bullet) = \mathbf{1}_{\overline{R}_\bullet(\mathfrak{U}')} \qquad \text{in } \mathsf{D}(\mathbb{Z}_{T'}\text{-}\mathbf{Mod}).$$

However, from the explicit description of (10.2.1) it is easily seen that $\overline{R}_\bullet(\mathfrak{U}')$ is a complex of projective $\mathbb{Z}_{T'}$-modules, hence we have as well $\tau_{\leq 0}(\iota^{\mathfrak{U}'}_\bullet \circ \mathrm{Alt}^{\mathfrak{U}'}_\bullet) = \mathbf{1}_{\overline{R}_\bullet(\mathfrak{U}')}$ in $\mathsf{Hot}(\mathbb{Z}_{T'}\text{-}\mathbf{Mod})$, by theorem 7.3.25(iii), and then it follows as well that $\iota^{\mathfrak{U}'}_\bullet \circ \mathrm{Alt}^{\mathfrak{U}'}_\bullet = \mathbf{1}_{R_\bullet(\mathfrak{U}')}$ in $\mathsf{Hot}(\mathbb{Z}_{T'}\text{-}\mathbf{Mod})$. Next, notice that $R_\bullet(\mathfrak{U}')$ is a complex of abelian presheaves on T, whose associated complex of sheaves agrees with $R_\bullet(\mathfrak{U})$, and likewise the morphism of abelian sheaves associated with $\iota_\bullet^{\mathfrak{U}'} \circ \mathrm{Alt}_\bullet^{\mathfrak{U}'}$ agrees with $\iota_\bullet^{\mathfrak{U}} \circ \mathrm{Alt}_\bullet^{\mathfrak{U}}$. The assertion follows.

(iii) follows directly from (ii). Likewise, (iv) and (v) are immediate from (iii) and lemma 10.2.3(ii,iii). □

Remark 10.2.7. (i) In light of proposition 10.2.6(iv) we shall call $R_\bullet^{\mathrm{alt}}(\mathfrak{U})$ the *alternating augmented Čech resolution* associated with $\mathfrak{U}$. This name can be justified as follows. Notice that for every $\mathbb{Z}_T$-module $\mathscr{F}$ we have natural identifications

$$C^n(\mathfrak{U},\mathscr{F}) \stackrel{\sim}{\to} \prod_{\underline{t}\in I^{n+1}} \mathscr{F}(U_{\underline{t}}) \qquad C^n_{\mathrm{alt}}(\mathfrak{U},\mathscr{F}) \stackrel{\sim}{\to} \prod_{\underline{t}\in I^{n+1}_{\mathrm{alt}}} \mathscr{F}(U_{\underline{t}}) \tag{10.2.8}$$

for every $n \in \mathbb{N}$ (notation of definition 10.2.2(ii)). Under these identifications, $C^\bullet(\mathfrak{U},\mathscr{F})$ becomes the cochain complex

$$0 \to \Gamma(\mathscr{F}) \to \prod_{t\in I} \mathscr{F}(U_t) \to \cdots \to \prod_{\underline{t}\in I^{n+1}} \mathscr{F}(U_{\underline{t}}) \to \cdots \tag{10.2.9}$$

whose differential d^n is given by the following rule. First, d^{-1} assigns to each global section $s \in \Gamma(\mathscr{F})$ the system of its restrictions $(s_{|U_t} \mid t \in I)$. In case $n \geq 0$, we have

$$d^n(s_\bullet)_{\underline{t}} := \sum_{k=0}^{n+1} (-1)^{k+n+1} \cdot (s_{\underline{t}\circ\varepsilon_k})_{|U_{\underline{t}}} \qquad \text{for every } \underline{t} \in I^{n+2} \text{ and every } s_\bullet \in C^n(\mathfrak{U},\mathscr{F}).$$

(ii) Likewise, under the natural identifications of (i), the alternating augmented Čech complex $C^\bullet_{\mathrm{alt}}(\mathfrak{U},\mathscr{F})$ becomes the cochain complex

$$0 \to \Gamma(\mathscr{F}) \to \prod_{t\in I} \mathscr{F}(U_t) \to \cdots \to \prod_{\underline{t}\in I^{n+1}_{\mathrm{alt}}} \mathscr{F}(U_{\underline{t}}) \to \cdots$$

whose differentials are given by the same expressions as in (i).

(iii) Under the identification of (i), the morphisms $R_n(\mathfrak{U}) \to \mathscr{F}$ that factor through $\mathrm{Alt}_n^{\mathfrak{U}}$ correspond to the system of sections $f_\bullet := (f_{\underline{t}} \mid \underline{t} \in I^{n+1})$ with the following properties :

- $f_{\underline{t}} = 0$ whenever the map $\underline{t} : [n] \to I$ is not injective.
- $f_{\underline{t}\circ\sigma} = \mathrm{sign}(\sigma) \cdot f_{\underline{t}}$ for every injective map $\underline{t} : [n] \to I$ and every $\sigma \in S_{n+1}$.

Thus, under the identification (10.2.8), the submodule $\mathrm{Hom}_{\mathbb{Z}_X}(R_n^{\mathrm{alt}}(\mathfrak{U}),\mathscr{F})$ corresponds to the subgroup of all *alternating systems* $f_\bullet$ *of sections of* $\mathscr{F}$.

10.2.10. In the situation of (10.2.1), consider another family $\mathfrak{U}' := (U'_{i'} \mid i' \in I')$ of objects of T, indexed by a totally ordered set I', and set $U' := \bigcup_{i'\in I'} \mathrm{Im}(U'_{i'} \to 1_T)$ and $Z' := \complement U'$. Also, for every $n \in \mathbb{N}$, and every $\underline{s} \in I'^{n+1}$ set as usual $U'_{\underline{s}} := U'_{s_0} \times \cdots \times U'_{s_n}$, and denote by $j'_{\underline{s}} : T/U'_{\underline{s}} \to T$ the induced functor. Suppose that $\mathfrak{U}$ is a *refinement* of $\mathfrak{U}'$, *i.e.* there exists a mapping (that does not necessarily respect the orderings)

$$\tau : I \to I' \qquad \text{such that} \qquad \mathrm{Hom}_T(U_i, U'_{\tau(i)}) \neq \varnothing \qquad \text{for every } i \in I$$

and pick a morphism $\vartheta_i : U_i \to U'_{\tau(i)}$ for every $i \in I$. Then, for every $n \in \mathbb{N}$ and every $\underline{t} := (t_0,\dots,t_n) \in I^{n+1}$, we set $\tau(\underline{t}) := (\tau(t_0),\dots,\tau(t_n)) \in I'^{n+1}$, and notice that the morphism $\vartheta_{\underline{t}} := \vartheta_{t_0} \times \cdots \times \vartheta_{t_n} : U_{\underline{t}} \to U'_{\tau(\underline{t})}$ induces a morphism of $\mathbb{Z}_T$-modules

$$\varphi_{\underline{t}} : j_{\underline{t}!}\mathbb{Z}_{U_{\underline{t}}} \to j'_{\tau(\underline{t})!}\mathbb{Z}_{U'_{\tau(\underline{t})}}.$$

For every $n \in \mathbb{N}$, denote by $\varphi_n : R_n(\mathfrak{U}) \to R_n(\mathfrak{U}')$ the unique morphism of $\mathbb{Z}_T$-modules that makes commute the diagram

$$\begin{array}{ccc} j_{\underline{t}!}\mathbb{Z}_{U_{\underline{t}}} & \xrightarrow{\varphi(\underline{t})} & j'_{\tau(\underline{t})!}\mathbb{Z}_{U'_{\tau(\underline{t})}} \\ \downarrow & & \downarrow \\ R_n(\mathfrak{U}) & \xrightarrow{\varphi_n} & R_n(\mathfrak{U}') \end{array} \qquad \text{for every } \underline{t} \in I^{n+1}.$$

whose vertical arrows are the inclusion maps. Let as well $\varphi_{-1} := \mathbf{1}_{\mathbb{Z}_T}$. With this notation, it is clear that the system $(\varphi_{n-1} \mid n \in \mathbb{N})$ is a morphism of augmented simplicial complexes $R_\bullet(\mathfrak{U}) \to R_\bullet(\mathfrak{U}')$, and we denote

$$\varphi_\bullet : R_\bullet(\mathfrak{U}) \to R_\bullet(\mathfrak{U}')$$

the associated morphism of chain complexes.

10.2.11. Suppose next that $U'_{i'}$ is a subobject of 1_T, for every $i' \in I'$; then, on account of proposition 10.2.6(i) we may define

$$\varphi^{\mathrm{alt}}_\bullet := \mathrm{Alt}^{\mathfrak{U}'}_\bullet \circ \varphi_\bullet \circ \iota^{\mathfrak{U}}_\bullet : R^{\mathrm{alt}}_\bullet(\mathfrak{U}) \to R^{\mathrm{alt}}_\bullet(\mathfrak{U}').$$

The terms φ^{alt}_n can be described explicitly : first, it is clear that $\varphi^{\mathrm{alt}}_{-1} := \mathbf{1}_{\mathbb{Z}_T}$. Next, if $n \in \mathbb{N}$ and $\underline{t} \in I^{n+1}_{\mathrm{alt}}$ is any sequence, let

$$\varphi^{\mathrm{alt}}_{\underline{t}} : j_{\underline{t}!}\mathbb{Z}_{U_{\underline{t}}} \to R^{\mathrm{alt}}_n(\mathfrak{U}')$$

be the map given by the following rule. If $\tau(\underline{t})$ is also an injective sequence $[n] \to I'$, let $\sigma \in S_{n+1}$ be the unique permutation such that $\tau(\underline{t}) \circ \sigma \in I'^{n+1}_{\mathrm{alt}}$, and set $\varphi^{\mathrm{alt}}_{\underline{t}} := \mathrm{sign}(\sigma) \cdot \varphi_{(\underline{t})} : j_{\underline{t}!}\mathbb{Z}_{U_{\underline{t}}} \to \mathbb{Z}_{U'_{\tau(\underline{t})\circ\sigma}} \subset R^{\mathrm{alt}}_n(\mathfrak{U}')$. In case $\tau(\underline{t})$ is not injective, we let $\varphi^{\mathrm{alt}}_{\underline{t}}$ be the zero morphism. Then φ^{alt}_n is the sum of the $\varphi^{\mathrm{alt}}_{\underline{t}}$, for $\underline{t}$ ranging over all elements of I^{n+1}_{alt}. In case also U_i is a subobject of 1_T for every $i \in I$, it is easily seen that we get a commutative diagram

$$\begin{array}{ccc} R_\bullet(\mathfrak{U}) & \xrightarrow{\mathrm{Alt}^{\mathfrak{U}}_\bullet} & R^{\mathrm{alt}}_\bullet(\mathfrak{U}) \\ {\scriptstyle\varphi_\bullet}\downarrow & & \downarrow{\scriptstyle\varphi^{\mathrm{alt}}_\bullet} \\ R_\bullet(\mathfrak{U}') & \xrightarrow{\mathrm{Alt}^{\mathfrak{U}'}_\bullet} & R^{\mathrm{alt}}_\bullet(\mathfrak{U}'). \end{array}$$

Lemma 10.2.12. *In the situation of* (10.2.10)*, suppose that $\tau' : I \to I'$ is another mapping with* $\mathrm{Hom}_T(U_i, U'_{\tau'(i)}) \neq \varnothing$ *for every $i \in I$. Pick a system of morphisms $(\vartheta'_i : U_i \to U'_{\tau'(i)} \mid i \in I)$, and denote by $\varphi'_\bullet : R_\bullet(\mathfrak{U}) \to R_\bullet(\mathfrak{U}')$ the associated morphisms of chain complexes. We have :*

(i) *There exists a homotopy from $\varphi_\bullet$ to $\varphi'_\bullet$.*
(ii) *If $U'_{i'}$ is a subobject of 1_T for every $i' \in I'$, there is also a homotopy from $\varphi^{\mathrm{alt}}_\bullet$ to $\varphi'^{\mathrm{alt}}_\bullet$.*

Proof. Clearly it suffices to show (i). To this aim, for every $i \in I$ let $(\vartheta_i, \vartheta'_i) : U_i \to U'_{\tau(i)} \times U'_{\tau'(i)}$ be the unique morphism whose composition with the projection on the first (resp. second) factor equals ϑ_i (resp. ϑ'_i), and for every $n \in \mathbb{N}$, every $k = 0, \dots, n$, and every $\underline{t} \in I^{n+1}$, set

$$\tau(k, \underline{t}) := (\tau(t_0), \dots, \tau(t_k), \tau'(t_k), \dots, \tau'(t_n)) \in I^{n+2}$$
$$\vartheta^{(k)}_{\underline{t}} := \vartheta_{t_0} \times \cdots \times \vartheta_{t_{k-1}} \times (\vartheta_{t_k}, \vartheta'_{t_k}) \times \vartheta'_{t_{k+1}} \times \cdots \times \vartheta'_{t_n} : U_{\underline{t}} \to U'_{\tau(k,\underline{t})}.$$

Then $\vartheta^{(k)}_{\underline{t}}$ induces a natural morphism $h^{(k)}_{\underline{t}} : j_{\underline{t}!}\mathbb{Z}_{U_{\underline{t}}} \to j_{\tau(k,\underline{t})!}\mathbb{Z}_{U'_{\tau(k,\underline{t})}}$ and we set

$$h_{\underline{t}} := \sum_{k=0}^{n} (-1)^k \cdot h^{(k)}_{\underline{t}} : j_{\underline{t}!}\mathbb{Z}_{U_{\underline{t}}} \to R_{n+1}(\mathfrak{U}').$$

Clearly there exists a unique morphism of $\mathbb{Z}_T$-modules $h_n : R_n(\mathfrak{U}) \to R_{n+1}(\mathfrak{U}')$ whose restriction to $j_{\underline{t}!}\mathbb{Z}_{U_{\underline{t}}}$ agrees with $h_{\underline{t}}$ for every $\underline{t} \in I^{n+1}$. Let also $h_{-1} : R_{-1}(\mathfrak{U}) \to R_0(\mathfrak{U}')$ be the zero morphism; a direct calculation shows that the system $(h_{n-1} \mid n \in \mathbb{N})$ yields the sought homotopy : the details shall be left to the reader. □

Remark 10.2.13. (i) In the situation of (10.2.11), consider the case where $U_{i_0} = 1_T$ for some $i_0 \in I$. Then $\mathfrak{U}$ can be refined by itself in two different ways : we may take for $\tau : I \to I$ the identity map (with $\vartheta_i := \mathbf{1}_{U_i}$ for every $i \in I$), and we have also the map $\tau' : I \to I$ such that $\tau'(i) = i_0$ for every $i \in I$ (and then there is a unique choice of ϑ_i). Obviously, the morphism $\varphi_\bullet : R^{\mathrm{alt}}_\bullet(\mathfrak{U}) \to R^{\mathrm{alt}}_\bullet(\mathfrak{U})$ associated with τ is the identity map. For the morphism $\varphi'_\bullet : R^{\mathrm{alt}}_\bullet(\mathfrak{U}) \to R^{\mathrm{alt}}_\bullet(\mathfrak{U})$ associated with τ' it is easily seen that

$$\varphi'_{-1} = \mathbf{1}_{\mathbb{Z}_T} \qquad \text{and} \qquad \varphi'_n = 0 \qquad \text{for every } n > 0$$

and φ'_0 is the sum of the natural morphisms $j_{t!}\mathbb{Z}_{U_t} \to j_{i_0!}\mathbb{Z}_{U_{i_0}} = \mathbb{Z}_T$. The homotopy $h_\bullet$ from $\varphi_\bullet$ to $\varphi'_\bullet$ furnished by lemma 10.2.12 can be described as follows. First, we may suppose that i_0 is the maximal element of I. A simple inspection shows that $h_{-1} : R^{\mathrm{alt}}_{-1}(\mathfrak{U}) \to R^{\mathrm{alt}}_0(\mathfrak{U})$ is the zero map. Next, for every $n \in \mathbb{N}$ and every $\underline{t} \in I^{n+1}_{\mathrm{alt}}$, notice that $U_{\underline{t}} = U_{(\underline{t},i_0)}$, where $(\underline{t}, i_0)$ denotes the sequence $(t_0, \dots, t_n, i_0)$; it follows that we may write

$$h_n = \sum_{\underline{t} \in I^{n+1}_{\mathrm{alt}}} \rho(\underline{t}) \cdot h_{\underline{t}}$$

where $h_{\underline{t}} : j_{\underline{t}}\mathbb{Z}_{U_{\underline{t}}} \to j_{(\underline{t},i_0)!}\mathbb{Z}_{U_{(\underline{t},i_0)}}$ is the identity map, and $\rho(\underline{t})$ equals 0 if $t_n = i_0$, and equals 1 otherwise.

(ii) In the situation of (i), we deduce a homotopy from $\mathbf{1}_{R^{\mathrm{alt}}_\bullet(\mathfrak{U})}$ to the zero map. Indeed, let $h'_{-1} : \mathbb{Z}_T \to R_0(\mathfrak{U})$ be the composition of the identity map $\mathbb{Z}_T \to j_{i_0!}\mathbb{Z}_{U_{i_0}}$ and the inclusion map $j_{i_0!}\mathbb{Z}_{U_{i_0}} \to R_0(\mathfrak{U})$. Let also $h'_n := h_n$ for every $n \in \mathbb{N}$. A simple inspection shows that

$$\varphi'_0 = h'_{-1} \circ d_0$$

(where $d_0 : R_0(\mathfrak{U}) \to \mathbb{Z}_T$ is the differential of $R_\bullet(\mathfrak{U})$). It follows easily that $(h'_{n-1} \mid n \in \mathbb{N})$ is the sought homotopy.

(iii) Let $\mathscr{F}$ be any $\mathbb{Z}_T$-module. The homotopy $h'_\bullet$ of (i) induces a homotopy from the identity automorphism of the augmented Čech complex $C^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F})$ to its zero endomorphism. Under the natural identifications of remark 10.2.7(ii), this homotopy $h^\bullet$ can be described as follows.

- $h^0 : C^0(\mathfrak{U}, \mathscr{F}) \to \Gamma(\mathscr{F})$ is the projection onto the factor $\mathscr{F}(U_{i_0}) = \Gamma(\mathscr{F})$.
- For every $n \geq 0$, the map $h^{n+1} : C^{n+1}(\mathfrak{U}, \mathscr{F}) \to C^n(\mathfrak{U}, \mathscr{F})$ is the projection that sends to zero every factor $\mathscr{F}(U_{t_0,\dots,t_n})$ with $t_n < i_0$, and whose restriction to every factor $\mathscr{F}(U_{t_0,\dots,t_{n-1},i_0})$ is the identity map $\mathscr{F}(U_{t_0,\dots,t_{n-1},i_0}) \xrightarrow{\sim} \mathscr{F}(U_{t_0,\dots,t_{n-1}})$.

Remark 10.2.14. (i) In the situation of (10.2.4), it is clear that the rule $\mathscr{F} \mapsto R^{\mathrm{alt}}_\bullet(\mathfrak{U}, \mathscr{F})$ defines a functor from $\mathbb{Z}_T$-modules to chain complexes of $\mathbb{Z}_T$-modules. The latter then extends naturally to a functor from the category of chain complexes of $\mathbb{Z}_T$-modules to the category of double complexes of $\mathbb{Z}_T$-modules :

$$\mathsf{C}(\mathbb{Z}_T\text{-}\mathbf{Mod}) \to \mathsf{C}_2(\mathbb{Z}_T\text{-}\mathbf{Mod}) \qquad \mathscr{F}_\bullet \mapsto R^{\mathrm{alt}}_\bullet(\mathfrak{U}, \mathscr{F}_\bullet).$$

Likewise, $\perp^{\mathfrak{U}}_\bullet$ extends to a functor from augmented simplicial $\mathbb{Z}_T$-modules to augmented bisimplicial $\mathbb{Z}_T$-modules :

$$\widehat{s}.\mathbb{Z}_T\text{-}\mathbf{Mod} \to \widehat{s}.(\widehat{s}.\mathbb{Z}_T\text{-}\mathbf{Mod}) \qquad \mathscr{F}_\bullet \mapsto \perp^{\mathfrak{U}}_\bullet \mathscr{F}_\bullet.$$

(ii) Let now $\mathfrak{U}' := (U'_{i'} \mid i' \in I')$ be another family of objects of T. Then we may consider the augmented bisimplicial $\mathbb{Z}_T$-module

$$\perp^{\mathfrak{U},\mathfrak{U}'}_{\bullet\bullet} := \perp^{\mathfrak{U}'}_\bullet (\perp^{\mathfrak{U}}_\bullet \mathbb{Z}_T)$$

and we notice that

$$(\perp_{\bullet\bullet}^{\mathfrak{U},\mathfrak{U}'})^{\Delta} = \perp_{\bullet}^{\mathfrak{U}\times\mathfrak{U}'} \qquad \text{where } \mathfrak{U}\times\mathfrak{U}' := (U_i \times U'_{i'} \mid (i,i') \in I \times I').$$

In case both U_i and $U'_{i'}$ are subobjects of 1_T for every $i \in I$ and $i' \in I'$, we may also define the chain double complex

$$R_{\bullet\bullet}^{\mathrm{alt}}(\mathfrak{U},\mathfrak{U}') := R_{\bullet}^{\mathrm{alt}}(\mathfrak{U}',(R_{\bullet}^{\mathrm{alt}}(\mathfrak{U}))$$

and we notice that (notation of example 7.1.16(i))

$$R_{\bullet\bullet}^{\mathrm{alt}}(\mathfrak{U},\mathfrak{U}') = R_{\bullet}^{\mathrm{alt}}(\mathfrak{U}) \boxtimes_A R_{\bullet}^{\mathrm{alt}}(\mathfrak{U}').$$

10.2.15. In the situation of (10.2.1), let $\mathscr{A}$ be any T-ring; we consider the functor

$$\mathscr{A}\text{-}\mathbf{Mod} \to \mathsf{C}(\Gamma(\mathscr{A})\text{-}\mathbf{Mod}) \qquad \mathscr{F} \mapsto \overline{C}^{\bullet}(\mathfrak{U},\mathscr{F}) := \mathrm{Hom}_{\mathbb{Z}}(\overline{R}_{\bullet}(\mathfrak{U}),\mathscr{F}[0])$$

that assigns to every $\mathscr{A}$-module $\mathscr{F}$ its *Čech complex*, and we define as well the *Čech cohomology functor of $\mathscr{F}$* relative to the covering $\mathfrak{U}$, by setting :

$$H^i(\mathfrak{U},\mathscr{F}) := H^i\overline{C}^{\bullet}(\mathfrak{U},\mathscr{F}) \qquad \text{for every } i \in \mathbb{N}.$$

Suppose now that $\mathfrak{U}$ is a covering of T; since $\mathscr{F}$ represents a sheaf for the canonical topology on T, we easily see that the system of restriction maps $(\Gamma(\mathscr{F}) \to \mathscr{F}(U_i) \mid i \in I)$ induces a natural isomorphism

$$\Gamma(\mathscr{F}) \xrightarrow{\sim} H^0(\mathfrak{U},\mathscr{F}). \tag{10.2.16}$$

On the other hand, let $K^\bullet$ be any bounded below complex of $\mathscr{A}$-modules; lemma 10.2.3(iii) yields natural isomorphisms in $\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$ and in $\mathsf{D}^+(\Gamma(\mathscr{A})\text{-}\mathbf{Mod})$

$$R\mathscr{H}\!om^{\bullet}_{\mathbb{Z}}(\overline{R}_{\bullet}(\mathfrak{U}),K^\bullet) \xrightarrow{\sim} R\underline{\Gamma}K^\bullet \qquad R\mathrm{Hom}^{\bullet}_{\mathbb{Z}}(\overline{R}_{\bullet}(\mathfrak{U}),K^\bullet) \xrightarrow{\sim} R\Gamma K^\bullet.$$

Hence, after fixing an injective resolution $K^\bullet \xrightarrow{\sim} \mathscr{I}^\bullet$ we get a natural isomorphism

$$R\Gamma K^\bullet \xrightarrow{\sim} \mathrm{Tot}\,\overline{C}^{\bullet}(\mathfrak{U},\mathscr{I}^\bullet) \qquad \text{in } \mathsf{D}^+(\Gamma(\mathscr{A})\text{-}\mathbf{Mod}).$$

Thus, for every $p \in \mathbb{Z}$ let also define a presheaf $\mathscr{H}^p(K^\bullet)$ on T by the rule

$$\mathscr{H}^p(K^\bullet)(U) := R^p\Gamma(U,K^\bullet) \qquad \text{for every object } U \text{ of } T.$$

We may regard $\mathscr{H}^p(K^\bullet)$ as an object of the V-topos $T^{\wedge}_{\mathsf{V}}$, for some universe V such that T is V-small, and the family $\mathfrak{U}$ can be regarded as a system of objects of $T^{\wedge}_{\mathsf{V}}$, via the Yoneda imbedding $T \to T^{\wedge}_{\mathsf{V}}$. Then, the Čech cohomology functors of $\mathscr{H}^p(K^\bullet)$ relative to the covering $\mathfrak{U}$ are also well defined, and we deduce a 2-spectral sequence

$$E(\mathfrak{U})_2^{p,q} := H^p(\mathfrak{U},\mathscr{H}^q(K^\bullet)) \Rightarrow R^{p+q}\Gamma K^\bullet. \tag{10.2.17}$$

Notice also that

$$\mathscr{H}^0(\mathscr{F}[0]) = \mathscr{F} \qquad \text{for every } \mathbb{Z}_T\text{-module } \mathscr{F}$$

whence, natural maps

$$\Psi^p(\mathfrak{U},\mathscr{F}) : H^p(\mathfrak{U},\mathscr{F}) \to R^p\Gamma\mathscr{F} \qquad \text{for every } p \in \mathbb{N}$$

such that $\Psi^0(\mathfrak{U},\mathscr{F})$ is always an isomorphism (in fact, it is the inverse of the isomorphism (10.2.16)), and $\Psi^1(\mathfrak{U},\mathscr{F})$ is always an injective map.

10.2.18. In case U_i is a subobject of 1_T for every $i \in I$, we may repeat the considerations of (10.2.15) with the *alternating Čech complex*

$$\overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}) := \mathrm{Hom}_{\mathbb{Z}}(\overline{R}^{\mathrm{alt}}_\bullet(\mathfrak{U}), \mathscr{F}[0]).$$

Namely, let us set

$$H^i_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}) := H^i\overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}) \qquad \text{for every } i \in \mathbb{N}.$$

Then, proposition 10.2.6(ii) (together with example 7.1.25(ii)) yields a natural isomorphism

$$H^i_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}) \xrightarrow{\sim} H^i(\mathfrak{U}, \mathscr{F}) \qquad \text{for every } i \in \mathbb{N}$$

and if $\mathfrak{U}$ is a covering of T, obviously we get therefore a natural isomorphism

$$(10.2.19) \qquad R\Gamma K^\bullet \xrightarrow{\sim} \mathrm{Tot}\, \overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{I}^\bullet) \qquad \text{in } \mathsf{D}^+(\Gamma(\mathscr{A})\text{-}\mathbf{Mod}).$$

for any injective resolution $K^\bullet \xrightarrow{\sim} \mathscr{I}^\bullet$, and a 2-spectral sequence

$$(10.2.20) \qquad F(\mathfrak{U})^{p,q}_2 := H^p_{\mathrm{alt}}(\mathfrak{U}, \mathscr{H}^q(K^\bullet)) \Rightarrow R^{p+q}\Gamma K^\bullet.$$

Taking $K^\bullet := \mathscr{F}[0]$, there follows a natural map

$$\Psi^p_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}) : H^p_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}) \to R^p\Gamma\mathscr{F} \qquad \text{for every } p \in \mathbb{N}$$

and again, $\Psi^0_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F})$ is an isomorphism, whereas $\Psi^1_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F})$ is always an injective map. The following immediate corollary is often useful :

Corollary 10.2.21. *In the situation of* (10.2.15)*, suppose furthermore that*

$$\mathscr{H}^q(\mathscr{F}[0])(U_{\underline{t}}) = 0 \qquad \textit{for every integer } q > 0 \textit{ and every } \underline{t} \in I^q.$$

Then we have :

(i) *The map $\Psi^p(\mathfrak{U}, \mathscr{F})$ is an isomorphism for every $p \in \mathbb{N}$.*
(ii) *If U_i is a subobject of 1_T for every $i \in \mathbb{N}$, then the map $\Psi^p_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F})$ is an isomorphism for every $p \in \mathbb{N}$.*

Proof. The assumption of (i) (resp. (ii)) implies that $E(\mathfrak{U})^{p,q}_2 = 0$ (resp. $F(\mathfrak{U})^{p,q}_2 = 0$) for every $q > 0$, whence both contentions. ☐

10.2.22. Let now $C := (\mathscr{C}, J)$ be a small site whose finite non-empty products and fibre products are representable. Then, the finite products of $\mathscr{C}/X$ are representable, for every $X \in \mathrm{Ob}(\mathscr{C})$; for every such X, we denote by J_X the topology on $\mathscr{C}/X$ induced by J (see (4.7.2)).

Now, let S be either C or $(\mathscr{C}/X, J_X)$ for some $X \in \mathrm{Ob}(\mathscr{C})$, and denote by $\mathscr{J}(S)$ the set of all families of objects of S that generate a sieve covering the final object of $T := S^\sim$, for the canonical topology on T. Then $\mathscr{J}(S)$ is endowed with a partial ordering, by declaring that $\mathfrak{U} \leq \mathfrak{U}'$ if and only if the sieve generated by $\mathfrak{U}$ contains the sieve generated by $\mathfrak{U}'$, for every $\mathfrak{U}, \mathfrak{U}' \in \mathscr{J}(S)$. Notice that this is equivalent to saying that the family $\mathfrak{U}'$ is a refinement of $\mathfrak{U}$, when we regard $\mathfrak{U}$ and $\mathfrak{U}'$ as families of objects of the topos T. Especially, when $\mathfrak{U} \leq \mathfrak{U}'$, the discussion of (10.2.10) yields a map of complexes $\varphi_{\mathfrak{U},\mathfrak{U}'} : R_\bullet(\mathfrak{U}') \to R_\bullet(\mathfrak{U})$, and lemma 10.2.12 says that the homotopy class of $\varphi_{\mathfrak{U},\mathfrak{U}'}$ depends only on $\mathfrak{U}$ and $\mathfrak{U}'$, so we get a well defined functor

$$R_\bullet : \mathscr{J}(S)^o \to \mathsf{Hot}(\mathbb{Z}_T\text{-}\mathbf{Mod}) \qquad \mathfrak{U} \mapsto R_\bullet(\mathfrak{U}).$$

Now, let $\mathscr{F}$ be any abelian sheaf on S. We then get, for every $i \in \mathbb{N}$, an induced functor

$$H^i(-, \mathscr{F}) : \mathscr{J}(S) \to \mathbb{Z}\text{-}\mathbf{Mod} \qquad \mathfrak{U} \mapsto H^i(\mathfrak{U}, \mathscr{F}).$$

Notice now that $\mathscr{J}(S)$ is a small and filtered category; we may then define

$$\check{H}^i(S, \mathscr{F}) := \operatorname*{colim}_{\mathfrak{U} \in \mathscr{J}(S)} H^i(\mathfrak{U}, \mathscr{F})$$

and clearly the rule $\mathscr{F} \mapsto \check{H}^i(S, \mathscr{F})$ yields a well defined functor

$$\check{H}^i(S, -) : \mathbb{Z}_T\text{-}\mathbf{Mod} \to \mathbb{Z}\text{-}\mathbf{Mod} \qquad \text{for every } i \in \mathbb{N}.$$

In case $S = (\mathscr{C}/X, J_X)$, we shall denote this functor by $\check{H}(X, -)$. By the same token, it is also clear that we get as well a natural morphism of 2-spectral sequences

$$E(\mathfrak{U})_2^{\bullet\bullet} \to E(\mathfrak{U}')_2^{\bullet\bullet} \qquad \text{whenever } \mathfrak{U} \leq \mathfrak{U}'$$

for every bounded below complex $K^\bullet$ of $\mathbb{Z}_T$-modules whence, after taking colimits, a 2-spectral sequence

$$E_2^{p,q} := \check{H}^p(S, \mathscr{H}^q(K^\bullet)) \Rightarrow R^{p+q}\Gamma K^\bullet$$

that, in turn, gives us again natural maps, for every $\mathbb{Z}_T$-module $\mathscr{F}$

$$\check{\Psi}^p(S, \mathscr{F}) : \check{H}^p(S, \mathscr{F}) \to R^p\Gamma\mathscr{F} \qquad \text{for every } p \in \mathbb{N}$$

which, in case $S = (\mathscr{C}/X, J_X)$, shall be denoted simply $\check{\Psi}^p(X, \mathscr{F})$.

Lemma 10.2.23. *In the situation of* (10.2.22)*, let $\mathscr{F}$ be any $\mathbb{Z}_T$-module, and take $K^\bullet := \mathscr{F}[0]$. Then we have :*

(i) $E_2^{0,q} = 0$ *for every $q > 0$.*
(ii) *Both $\check{\Psi}^0(S, \mathscr{F})$ and $\check{\Psi}^1(S, \mathscr{F})$ are isomorphisms, and $\check{\Psi}^2(S, \mathscr{F})$ is injective.*

Proof. (i): Fix any injective resolution $\mathscr{F} \to \mathscr{I}^\bullet$, and let $\overline{s} \in E_2^{0,q}$ be any element; by definition, there exists a family $(U_i \mid i \in I)$ of objects of S that generates a sieve covering the final object of $S^\sim$, such that $\overline{s}$ is represented by an element

$$\overline{s}_\bullet \in \mathrm{Ker}\Big(\prod_{i\in I} H^q(\mathscr{I}^\bullet(U_i)) \xrightarrow{d_v^{0,q}} \prod_{(i,j)\in I^2} H^q(\mathscr{I}^\bullet(U_{(i,j)}))\Big)$$

where $d_v^{0,q}$ is the differential of the Čech complex in degree 0, as in remark 10.2.7(i). In turn, the class $\overline{s}_i \in H^q(\mathscr{I}^\bullet(U_i))$ is represented by a section $s_i \in \mathscr{I}^q(U_i)$ for every $i \in I$, such that $d_h^{0,q}(s_i) = 0$, where $d_h^{0,q} : \mathscr{I}^q(U_i) \to \mathscr{I}^{q+1}(U_i)$ denotes the differential in degree q of the complex $\mathscr{I}^\bullet$. Since the latter is exact in every degree $q > 0$, it follows that for every $i \in I$ there exist a family $(U_{i,\lambda} \to U_i \mid \lambda \in \Lambda_i)$ of objects of $\mathscr{C}/U_i$ that generates a sieve covering the final object of $(\mathscr{C}/U_i, J_{U_i})$, and for every $\lambda \in \Lambda_i$ a section $s_{i,\lambda} \in \mathscr{I}^{q-1}(U_{i,\lambda})$ such that $d_h^{0,q-1}(s_{i,\lambda}) = s_{i|U_{i,\lambda}}$. Set $\mathfrak{U} := \bigcup_{i\in I}\{U_{i,\lambda} \mid \lambda \in \Lambda_i\}$; then $\mathfrak{U}$ lies in $\mathscr{J}(S)$, and it is easily seen that the image of $\overline{s}$ vanishes in $H^0(\mathfrak{U}, \mathscr{H}^q(\mathscr{F}))$, whence the contention.

(ii) is an immediate consequence of (i). □

Theorem 10.2.24 (Cartan)**.** *In the situation of* (10.2.22)*, let $\mathscr{F}$ be any $\mathbb{Z}_T$-module such that*

$$\check{H}^i(X, \mathscr{F}) = 0 \qquad \textit{for every } X \in \mathrm{Ob}(\mathscr{C}) \textit{ and every } i > 0.$$

Then we have :

(i) *The map $\check{\Psi}^q(C, \mathscr{F})$ is an isomorphism for every $q \in \mathbb{N}$.*
(ii) *More precisely, the map $\Psi^q(\mathfrak{U}, \mathscr{F})$ is an isomorphism for every $q \in \mathbb{N}$ and every family $\mathfrak{U}$ of objects of $\mathscr{C}$ that covers the final object of T.*

Proof. (i): We argue by induction on $q \in \mathbb{N}$, and notice that the assertion for $q \leq 1$ is already known without any assumption on $\mathscr{F}$, by lemma 10.2.23(ii). Thus, let $i \geq 2$ and suppose that the assertion of the theorem is already known for every $q < i$, every site C and every abelian sheaf $\mathscr{F}$ on C. Notice that if $X \in \mathrm{Ob}(\mathscr{C})$ and $\varphi : Y \to X$ is any object of $\mathscr{C}/X$, we have a natural isomorphism of categories

$$(\mathscr{C}/X)/\varphi \xrightarrow{\sim} \mathscr{C}/Y$$

and the topology J_φ induced on $(\mathscr{C}/X)/\varphi$ by J_X agrees, under this identification, with the topology J_Y. Therefore, the site $\mathscr{C}/X$ fulfills the assumptions of the theorem, and by inductive assumption we deduce that $\check{\Psi}^q(X,\mathscr{F})$ is an isomorphism for every $q < i$, and therefore $R^q\Gamma(X,\mathscr{F}) = 0$ for every $X \in \mathrm{Ob}(\mathscr{C})$ and every $q = 1,\dots,i-1$. Summing up, we get $\mathscr{H}^q(\mathscr{F}) = 0$ whenever $1 \leq q < i$, whence $E_2^{pq} = 0$ for every $q = 1,\dots,i-1$ (notation of (10.2.22)). We also know that $E_2^{0q} = 0$ for every $q > 0$, by lemma 10.2.23(i); in this situation, it is easily seen that $E_2^{i,0} = E_\infty^{i0}$ and $E_\infty^{i-p,p} = 0$ for every $p > 0$, and then $\check{\Psi}^i(X,\mathscr{F})$ is indeed an isomorphism.

(ii) is an immediate consequence of (i) and corollary 10.2.21(i). □

10.2.25. We wish now to apply the foregoing results to the cohomology of quasi-coherent modules on a scheme. To begin with, let A be a ring, M an A-module; set $X := \mathrm{Spec}\, A$ and denote by $\mathscr{M}$ the quasi-coherent $\mathscr{O}_X$-module arising from M. Let also $\mathbf{f} := (f_1,\dots,f_r)$ be a sequence of elements of A, and for every integer $n \geq -1$ and every injective order-preserving map

$$\underline{t} : [n] \to \Sigma := \{1,\dots,r\} \qquad k \mapsto t_k$$

let $A_{\underline{t}} := A[f_{t_0}^{-1}\cdots f_{t_n}^{-1}]$ and $U_{\underline{t}} := \mathrm{Spec}\, A_{\underline{t}}$; we can describe as follows the $A_{\underline{t}}$-module $\mathscr{M}(U_{\underline{t}})$. For every such $\underline{t}$, consider the system of A-modules $((M_{\underline{t}}^{(k)},\varphi_k) \mid k \in \mathbb{N})$ such that $M_{\underline{t}}^{(k)} := M$ for every $k \in \mathbb{N}$, and the map $\varphi_k : M_{\underline{t}}^{(k)} \to M_{\underline{t}}^{(k+1)}$ is the scalar multiplication by $f_{t_0}\cdots f_{t_n}$ if $n \geq 0$, and it is $\mathbf{1}_M$ when $n = -1$. Then we have a natural identification

$$\mathscr{M}(U_{\underline{t}}) \xrightarrow{\sim} \operatorname*{colim}_{k\in\mathbb{N}} M_{\underline{t}}^{(k)} \qquad \text{for every } n \geq -1 \text{ and every } \underline{t} : [n] \to \Sigma. \tag{10.2.26}$$

Moreover, for every face map $\varepsilon_i : [n-1] \to [n]$ in Δ, we can describe as follows the restriction map $\rho_{i,\underline{t}} : \mathscr{M}(U_{\underline{t}\circ\varepsilon_i}) \to \mathscr{M}(U_{\underline{t}})$. We consider the morphism of directed systems

$$\rho_i^{(\bullet)} : M_{\varepsilon_i^*(\underline{t})}^{(\bullet)} \to M_{\underline{t}}^{(\bullet)} \qquad \text{such that} \qquad \rho_i^{(k)} := f_{t_i}^k \cdot \mathbf{1}_M \quad \text{for every } k \in \mathbb{N}.$$

Then, under the identifications (10.2.26), the map $\rho_{i,\underline{t}}$ corresponds to the map

$$\operatorname*{colim}_{k\in\mathbb{N}} \rho_i^{(k)} : \operatorname*{colim}_{k\in\mathbb{N}} M_{\underline{t}\circ\varepsilon_i)}^{(k)} \to \operatorname*{colim}_{k\in\mathbb{N}} M_{\underline{t}}^{(k)}.$$

For every $n \geq -1$ let $\Sigma_{\mathrm{alt}}^{n+1}$ be the set of all injective order-preserving maps $[n] \to \Sigma$, and set

$$D_{(k)}^n := \mathrm{Hom}_{\mathbf{Set}}(\Sigma_{\mathrm{alt}}^{n+1}, M) \qquad \text{for every } k \in \mathbb{N}$$

which we endow with the A-module structure inherited from M; consider also the map

$$d_{(k)}^n : D_{(k)}^n \to D_{(k)}^{n+1} \qquad (\mu : \Sigma_{\mathrm{alt}}^{n+1} \to M) \mapsto \Big(\underline{t} \mapsto \sum_{i=0}^{n+1} (-1)^i \cdot f_{t_i}^k \cdot \mu(\underline{t}\circ\varepsilon_i)\Big)$$

for every $k \in \mathbb{N}$. Then the system $(D_{(k)}^\bullet, d_{(k)}^\bullet)$ is a well defined complex of A-modules, for every $k \in \mathbb{N}$. Lastly, for every $k \in \mathbb{N}$ we consider the morphism of complexes

$$D_{(k)}^\bullet \to D_{(k+1)}^\bullet \qquad (\mu : \Sigma_{\mathrm{alt}}^{n+1} \to M) \mapsto (\underline{t} \mapsto f_{t_0}\cdots f_{t_n} \cdot \mu(\underline{t})).$$

Summing up, and comparing with remark 10.2.7(i) we obtain a natural identification

$$C_{\mathrm{alt}}^\bullet(\mathfrak{U},\mathscr{M}) \xrightarrow{\sim} \operatorname*{colim}_{k\in\mathbb{N}} D_{(k)}^\bullet \qquad \text{where } \mathfrak{U} := (U_1,\dots,U_r).$$

On the other hand, notice that, for every $n \geq -1$, the free A-module $\Lambda_A^{n+1} A^{\oplus r}$ admits the standard basis $(e_{t_0} \wedge \cdots \wedge e_{t_n} \mid \underline{t} \in \Sigma_{\mathrm{alt}}^{n+1})$, so we have as well a natural identification

$$\mathrm{Hom}_A(\Lambda_A^{n+1} A^{\oplus r}, M) \xrightarrow{\sim} D_{(k)}^n \qquad \text{for every } n \geq -1$$

and a direct inspection reveals that, under this latter identification, the differential $d_{(k)}^n$ of $D_{(k)}^\bullet$ corresponds to the differential $\mathrm{Hom}_A(d_{\mathbf{f}^k,n}, M)$, where $\mathbf{f}^k := (f_1^k,\dots,f_r^k)$, and $d_{\mathbf{f}^k,n}$ is the differential in degree n of the Koszul complex of the sequence $\mathbf{f}^k$ (see remark 7.8.1(ii)). Thus, we get finally a natural isomorphism of complexes of A-modules

$$C^\bullet_{\mathrm{alt}}(\mathfrak{U},\mathscr{M}) \xrightarrow{\sim} \operatorname*{colim}_{k\in\mathbb{N}} \mathbf{K}^\bullet(\mathbf{f}^k, M)[1] \tag{10.2.27}$$

where the transition maps $\mathbf{K}^\bullet(\mathbf{f}^k, M) \to \mathbf{K}^\bullet(\mathbf{f}^{k+1}, M)$ are the morphisms $\varphi_{\mathbf{f}}$ of (7.8.20). As a corollary, we get the following classical result of Grothendieck :

Theorem 10.2.28. *In the situation of* (10.2.25)*, the following holds :*

(i) *The natural map $M[0] \to R\Gamma\,\mathscr{M}$ is an isomorphism in $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})$.*

(ii) *Let Y be any separated scheme, $\mathscr{F}^\bullet$ a bounded below complex of quasi-coherent $\mathscr{O}_Y$-modules, and $\mathfrak{U}$ any affine open covering of Y. Then the natural map*

$$\operatorname{Tot}\overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U},\mathscr{F}^\bullet) \to R\Gamma\mathscr{F}^\bullet$$

is an isomorphism in $\mathsf{D}^+(\mathscr{O}_Y(Y)\text{-}\mathbf{Mod})$.

(iii) *Especially, if Y is a separated scheme that can be covered by r affine open subsets, then $H^i(Y,\mathscr{F}) = 0$ for every $i \geq r$, and every quasi-coherent $\mathscr{O}_Y$-module $\mathscr{F}$.*

Proof. (i): Since the affine open subsets of X of the form $\operatorname{Spec} A[f^{-1}]$ for $f \in A$ are a basis of the topology of X that is closed under finite intersections, theorem 10.2.24 reduces to showing that

$$H^0(\mathfrak{U},\mathscr{M}) = M \qquad \text{and} \qquad H^i(\mathfrak{U},\mathscr{M}) = 0 \qquad \text{for every } i > 0$$

where $\mathfrak{U} := (U_i,\dots,U_r)$ is the finite affine open covering of X associated with a sequence $\mathbf{f} := (f_1,\dots,f_r)$ as in (10.2.25). However, the condition $X = \bigcup_{i=1}^r U_i$ is equivalent to saying that the ideal generated by the system $\mathbf{f}$ is A, in which case the same holds for the ideal generated by $\mathbf{f}^k$, for every $k \in \mathbb{N}$, and then lemma 7.8.2(iii) says that the complex $H^\bullet(\mathbf{f}^k, M)$ is homotopically trivial for every $k \in \mathbb{N}$. Taking into account (10.2.27), the contention follows.

(ii): Pick any resolution $\mathscr{F}^\bullet \xrightarrow{\sim} \mathscr{I}^\bullet$ by a bounded below complex of injective $\mathscr{O}_Y$-modules; in view of (10.2.19), it suffices to show that the natural map of double complexes

$$\overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U},\mathscr{F}^\bullet) \to \overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U},\mathscr{I}^\bullet)$$

induces a quasi-isomorphism on total complexes. However, notice that the open subset $U_{\underline{t}} \subset Y$ is affine, for every $n \in \mathbb{N}$ and every $\underline{t} \in I^{n+1}_{\mathrm{alt}}$ (notation of (10.2.4)); hence, it suffices to check that the induced map $\mathscr{F}^\bullet(V) \to \mathscr{I}^\bullet(V)$ is a quasi-isomorphism, for every affine open subset $V \subset Y$. To this aim, consider the spectral sequence

$$E_1^{p,q} := H^p(V,\mathscr{F}^q) \Rightarrow H^{p+q}\mathscr{I}^\bullet(V).$$

Since V is affine, we have $E_1^{p,q} = 0$ for every $p > 0$, due to (i); on the other hand, the differential $d_1^{0,q} : E_1^{0,q} \to E_1^{0,q+1}$ is nothing else than the differential $d^q(V) : \mathscr{F}^q(V) \to \mathscr{F}^{q+1}(V)$, for every $q \in \mathbb{Z}$, whence the claim.

(iii): Indeed, if $\mathfrak{U}$ is such a covering, then the complex $\overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U},\mathscr{F})$ is an object of the category $\mathsf{C}^{[0,r-1]}(\mathscr{O}_Y(Y)\text{-}\mathbf{Mod})$, so the assertion follows from (ii). ☐

We conclude this section with an application of Čech cohomology to the computation of sheaf cohomology after change of base scheme; much more can be found in [62, Ch.III, §6].

10.2.29. Namely, consider a diagram of schemes

$$\begin{array}{ccccc} X_2 & \longrightarrow & X_1 & \longrightarrow & X_0 \\ {\scriptstyle\pi_2}\downarrow & & {\scriptstyle\pi_1}\downarrow & & \downarrow{\scriptstyle\pi_0} \\ S_2 & \longrightarrow & S_1 & \xrightarrow{\varphi} & S_0 \end{array}$$

whose two square subdiagram are cartesian, and bounded above complexes of quasi-coherent $\mathscr{O}_{X_0}$-modules $\mathscr{F}_0^\bullet$ and quasi-coherent $\mathscr{O}_{S_i}$-modules $\mathscr{G}_i^\bullet$ for $i = 1, 2$. Then, for every $q \in \mathbb{N}$ there exists a quasi-coherent $\mathscr{O}_{X_1}$-module

$$\mathscr{T}or_q^{S_0}(\mathscr{G}_1^\bullet, \mathscr{F}_0^\bullet)$$

characterized, up to unique isomorphism, by the following properties ([62, Ch.III, §6.5]) :

(a) For every affine open subsets $V_0 \subset S_0$, $V \subset S_1 \times_{S_0} V_0$ and $U \subset X_0 \times_{S_0} V_0$, there exists an isomorphism of $\mathscr{O}_{X_1}(V \times_{S_0} U)$-modules

$$\omega_{V,U} : \Gamma(V \times_{S_0} U, \mathscr{T}or_q^{S_0}(\mathscr{G}_1^\bullet, \mathscr{F}_0^\bullet)) \xrightarrow{\sim} H_q(\mathscr{G}_1^\bullet(V) \overset{\mathbf{L}}{\otimes}_{\mathscr{O}_{S_0}(V_0)} \mathscr{F}_0^\bullet(U)).$$

(b) For every V_0, V, U as in (a) and every inclusion of affine open subsets $V'_0 \subset V_0$, $V' \subset V \cap (S_1 \times_{S_0} V'_0)$ and $U' \subset U \cap (X_0 \times_{S_0} V'_0)$, the resulting diagram commutes :

$$\begin{array}{ccc}
\Gamma(V \times_{S_0} U, \mathscr{T}or_q^{S_0}(\mathscr{G}_1^\bullet, \mathscr{F}_0^\bullet)) & \xrightarrow{\omega_{V,U}} & H_q(\mathscr{G}_1^\bullet(V) \overset{\mathbf{L}}{\otimes}_{\mathscr{O}_{S_0}(V_0)} \mathscr{F}_0^\bullet(U)) \\
\downarrow & & \downarrow \\
\Gamma(V' \times_{S_0} U', \mathscr{T}or_q^{S_0}(\mathscr{G}_1^\bullet, \mathscr{F}_0^\bullet)) & \xrightarrow{\omega_{V',U'}} & H_q(\mathscr{G}_1^\bullet(V') \overset{\mathbf{L}}{\otimes}_{\mathscr{O}_{S_0}(V'_0)} \mathscr{F}_0^\bullet(U'))
\end{array}$$

whose left vertical arrow is the restriction map of the sheaf $\mathscr{T}or_q^{S_0}(\mathscr{G}_1^\bullet, \mathscr{F}_0^\bullet)$, and whose right vertical arrow is the map $H_q(\rho' \overset{\mathbf{L}}{\otimes}_\rho \rho'')$ associated with the restriction maps $\rho : \mathscr{O}_{S_0}(V_0) \to \mathscr{O}_{S_0}(V'_0)$, $\rho' : \mathscr{G}^\bullet(V) \to \mathscr{G}^\bullet(V')$ and $\rho'' : \mathscr{F}_0^\bullet(U) \to \mathscr{F}_0^\bullet(U')$.

Proposition 10.2.30. *In the situation of* (10.2.29)*, the following holds :*

(i) *There exists a natural (homological)* 2*-spectral sequence*

$$\mathscr{T}or_p^{S_1}(\mathscr{G}_2^\bullet, \mathscr{T}or_q^{S_0}(\mathscr{O}_{S_1}[0], \mathscr{F}_0^\bullet)) \Rightarrow \mathscr{T}or_{p+q}^{S_0}(\mathscr{G}_2^\bullet, \mathscr{F}_0^\bullet).$$

(ii) *Suppose that π_0 is quasi-compact and separated, $\mathscr{F}_0$ is a bounded complex, and both S_1 and S_0 are affine. Set $A_i := \mathscr{O}_{S_i}(S_i)$ for $i = 0, 1$. Then there exist two natural spectral sequences :*

$$E_2^{pq} := H^{-p}(X_1, \mathscr{T}or_q^{S_0}(\mathscr{G}^\bullet, \mathscr{F}_0^\bullet)) \Rightarrow H_{p+q}(R\Gamma\mathscr{G}^\bullet \overset{\mathbf{L}}{\otimes}_{A_0} R\Gamma\mathscr{F}_0^\bullet)$$
$$F_2^{pq} := H_p(R\Gamma\mathscr{G}^\bullet \overset{\mathbf{L}}{\otimes}_{A_0} H^{-q}(X_0, \mathscr{F}_0^\bullet)[0]) \Rightarrow H_{p+q}(R\Gamma\mathscr{G}^\bullet \overset{\mathbf{L}}{\otimes}_{A_0} R\Gamma\mathscr{F}_0^\bullet).$$

Proof. (i): This is obtained from the standard change of base ring spectral sequence, which is natural in all arguments, and therefore globalizes immediately to the sheaf-theoretic situation considered here : the details shall be left to the reader.

(ii): Under our assumptions, X_0 is quasi-compact and separated, hence we may find a finite affine covering $\mathfrak{U}$ of X_0, and by theorem 10.2.28(ii), the alternating Čech complex for $\mathfrak{U}$ computes the cohomology of $\mathscr{F}_\bullet^\bullet$; especially the complex $R\Gamma\mathscr{F}_0^\bullet$ is bounded. Moreover, we may find a bounded above Cartan-Eilenberg resolution $\mathscr{L}^\bullet \xrightarrow{\sim} \varphi_*\mathscr{G}^\bullet$ consisting of quasi-coherent flat $\mathscr{O}_{S_0}$-modules, and $H_i(R\Gamma\mathscr{G}^\bullet \overset{\mathbf{L}}{\otimes}_{A_0} R\Gamma\mathscr{F}_0^\bullet)$ is naturally isomorphic to the quasi-coherent $\mathscr{O}_{S_1}$-module associated with the A_1-module

$$H_i((\mathrm{Tot}\,\overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}_0^\bullet)) \otimes_{A_0} \mathscr{L}^\bullet(S_0))$$

for every $i \in \mathbb{Z}$. Then the first spectral sequence is the standard spectral sequence attached to the double complex $(\mathrm{Tot}\,\overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}_0^\bullet)) \boxtimes_{A_0} \mathscr{L}^\bullet(S_0)$; similarly one obtains the second spectral sequence : details left to the reader. □

10.3. **Quasi-coherent modules.** For any scheme X, we denote by

$$\mathscr{O}_X\text{-}\mathbf{Mod} \qquad \mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \qquad \mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{coh}} \qquad \mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{lfft}}$$

the category of all (resp. of quasi-coherent, resp. of coherent, resp. of locally free of finite type) $\mathscr{O}_X$-modules. Recall that there is a natural functor

$$\mathscr{O}_X(X)\text{-}\mathbf{Mod} \to \mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \qquad M \mapsto M^\sim \tag{10.3.1}$$

that assigns to every $\mathscr{O}_X(X)$-module the quasi-coherent module $M^\sim$ such that

$$M^\sim(U) := M \otimes_{\mathscr{O}_X(X)} \mathscr{O}_X(U) \qquad \text{for every affine open subset } U \subset X.$$

This functor is an equivalence, if X is affine. We notice :

Corollary 10.3.2. *Let A be a ring, $M^\bullet$ (resp. $N_\bullet$) a bounded below (resp. above) complex of A-modules. Set $X := \operatorname{Spec} A$ and denote by $M^{\bullet\sim}$ (resp. $N_\bullet^\sim$) the associated complex of quasi-coherent $\mathscr{O}_X$-modules. We have :*

(i) *The natural map*

$$R\mathrm{Hom}^\bullet_A(N_\bullet, M^\bullet) \to R\mathrm{Hom}^\bullet_{\mathscr{O}_X}(N_\bullet^\sim, M^{\bullet\sim})$$

is an isomorphism in $\mathsf{D}^+(A\text{-}\mathbf{Mod})$.

(ii) *If A is coherent and $N_\bullet$ is a complex of finitely presented A-modules, then the natural morphism*

$$R\mathrm{Hom}^\bullet_A(N_\bullet, M^\bullet)^\sim \to R\mathscr{H}om^\bullet_{\mathscr{O}_X}(N_\bullet^\sim, M^{\bullet\sim})$$

is an isomorphism in $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})$.

Proof. (i): We apply the trivial duality theorem 10.1.18 to the unique morphism

$$f : (X, \mathscr{O}_X) \to (\{\mathrm{pt}\}, A)$$

of ringed spaces, where $\{\mathrm{pt}\}$ denotes the one-point space. Since f is flat and all quasi-coherent $\mathscr{O}_X$-modules are f_*-acyclic, the assertion follows easily.

(ii): Due to (i), it suffices to show the following assertion. For every $f \in A$, the natural map

$$R\mathrm{Hom}^\bullet_A(N_\bullet, M^\bullet) \otimes_A A_f \to R\mathrm{Hom}^\bullet_{A_f}(N_{\bullet,f}, M^\bullet_f)$$

is an isomorphism in $\mathsf{D}(A_f\text{-}\mathbf{Mod})$. To this aim, notice that, since A is coherent, we may find a resolution $P_\bullet$ of $N_\bullet$ consisting of free A-modules of finite type (details left to the reader); then we come down to checking that the natural map $\mathrm{Hom}_A(P_i, M^j) \otimes_A A_f \to \mathrm{Hom}_{A_f}(P_{i,f}, M^j_f)$ is an isomorphism, which is obvious. □

We denote by

$$\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}} \qquad \mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$$

the full triangulated subcategory of $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})$ consisting of the complexes $K^\bullet$ such that $H^i K^\bullet$ is a quasi-coherent (resp. coherent) $\mathscr{O}_X$-module for every $i \in \mathbb{Z}$. As usual, we shall use also the variants $\mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$ (resp. $\mathsf{D}^-(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$, resp. $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$, resp. $\mathsf{D}^{[a,b]}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$) consisting of all objects of $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$ whose cohomology vanishes in sufficiently large negative degree (resp. sufficiently large positive degree, resp. outside a bounded interval, resp. outside the interval $[a, b]$), and likewise for the corresponding subcategories of $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$. Obviously, (10.3.1) induces a natural functor

$$\mathsf{D}(\mathscr{O}_X(X)\text{-}\mathbf{Mod}) \to \mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}} \qquad M^\bullet \mapsto M^{\bullet\sim}.$$

Proposition 10.3.3. *Let $f : Y \to X$ be a flat morphism of schemes, with X locally coherent (see definition* 8.1.58(i)*), and $K_\bullet \in \mathrm{Ob}(\mathsf{D}^-(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}})$ any complex. We have :*

(i) $R\mathscr{H}om^\bullet_{\mathscr{O}_X}(K_\bullet, L^\bullet) \in \mathrm{Ob}(\mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}})$ *for every* $L^\bullet \in \mathrm{Ob}(\mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}})$.

(ii) *For every* $L^\bullet \in \mathrm{Ob}(\mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod}))$ *the natural morphism*

$$f^*R\mathscr{H}om^\bullet_{\mathscr{O}_X}(K_\bullet, L^\bullet) \to R\mathscr{H}om^\bullet_{\mathscr{O}_Y}(f^*K_\bullet, f^*L^\bullet) \qquad (10.3.4)$$

is an isomorphism in $\mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})$).

Proof. (i): The assertion is local on X, so we may assume that $X = \mathrm{Spec}\, A$, for some coherent ring A. In this case, we may find a bounded below (resp. above) complex $M^\bullet$ (resp. $N_\bullet$) of finitely presented A-modules, with isomorphisms $K^\bullet \xrightarrow{\sim} M^{\bullet\sim}$, $L_\bullet \xrightarrow{\sim} N^\sim_\bullet$ in $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})$. By virtue of corollary 10.3.2(ii), we are then reduced to checking that $R\mathrm{Hom}^\bullet_A(N_\bullet, M^\bullet)$ lies in $\mathsf{D}(A\text{-}\mathbf{Mod}_{\mathrm{coh}})$. But this is easily seen, since we may find a resolution of $N_\bullet$ by a bounded above complex of free A-modules of finite type (details left to the reader).

(ii): Again, the question is local on X, so we may assume that $K_\bullet$ admits a resolution by a bounded above complex $P_\bullet$ of free $\mathscr{O}_X$-modules of finite type. Since f is flat, we have natural convergent spectral sequences

$$E_1^{pq} := f^*R^p\mathscr{H}om^\bullet_{\mathscr{O}_X}(P_q, L^\bullet) \Rightarrow f^*R^{p+q}\mathscr{H}om^\bullet_{\mathscr{O}_X}(K_\bullet, L^\bullet)$$
$$F_1^{pq} := R^p\mathscr{H}om^\bullet_{\mathscr{O}_Y}(f^*P_q, f^*L^\bullet) \Rightarrow R^{p+q}\mathscr{H}om^\bullet_{\mathscr{O}_Y}(f^*K_\bullet, f^*L^\bullet)$$

as well as a morphism of spectral sequences $E_\bullet^{\bullet\bullet} \to F_\bullet^{\bullet\bullet}$, such that $H^\bullet$(10.3.4) is a morphism of filtered $\mathscr{O}_Y$-modules, for the two finite filtrations induced by these spectral sequences on their abutments. It then suffices to check that the induced morphism $E_\infty^{pq} \to F_\infty^{pq}$ is an isomorphism for every $p, q \in \mathbb{Z}$, and this in turn will follow, if we show that the morphism $E_1^{pq} \to F_1^{pq}$ is an isomorphism; but the latter assertion is obvious. ☐

Corollary 10.3.5. *Let* $f : Y \to X$ *be a quasi-compact and quasi-separated morphism of schemes,* $\mathscr{F}$ *a flat quasi-coherent* $\mathscr{O}_X$*-module, and* $\mathscr{G}$ *any* $\mathscr{O}_Y$*-module. Then the natural map*

$$\mathscr{F} \otimes_{\mathscr{O}_X} Rf_*\mathscr{G} \to Rf_*(f^*\mathscr{F} \otimes_{\mathscr{O}_Y} \mathscr{G}) \qquad (10.3.6)$$

is an isomorphism in $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})$.

Proof. The assertion is local on X, hence we may assume that $X = \mathrm{Spec}\, A$ for some ring A, and $\mathscr{F} = M^\sim$ for some flat A-module M. By [120, Ch.I, Th.1.2], M is the colimit of a filtered family of free A-modules of finite rank; in view of proposition 10.1.10(ii), we may then assume that $M = A^{\oplus n}$ for some $n \geq 0$, in which case the assertion is obvious. ☐

Remark 10.3.7. Notice that, for an affine morphism $f : Y \to X$, the map (10.3.6) is an isomorphism for any quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ and any quasi-coherent $\mathscr{O}_Y$-module $\mathscr{G}$. The details shall be left to the reader.

Corollary 10.3.8. *Consider a cartesian diagram of schemes*

$$\begin{array}{ccc} Y' & \xrightarrow{g'} & Y \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f} \\ X' & \xrightarrow{g} & X \end{array}$$

such that f *is quasi-compact and quasi-separated, and* g *is flat. Then the natural map*

$$g^*Rf_*\mathscr{G} \to Rf'_*g'^*\mathscr{G} \qquad (10.3.9)$$

is an isomorphism in $\mathsf{D}(\mathscr{O}_{X'}\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$*, for every quasi-coherent* $\mathscr{O}_Y$*-module* $\mathscr{G}$.

Proof. We easily reduce to the case where both X and X' are affine, hence g is an affine morphism. In this case, it suffices to show that g_*(10.3.9) is an isomorphism, since $Rf_*\mathscr{G}$ lies in

$\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$ and $Rf'_*g'^*\mathscr{G}$ lies in $\mathsf{D}(\mathscr{O}_{X'}\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$ ([2, Th.5.6]). However, we have a commutative diagram

$$\begin{array}{ccccc} g_*(g^*Rf_*\mathscr{G}) & & \xrightarrow{\quad\alpha\quad} & & Rf_*\mathscr{G}\otimes_{\mathscr{O}_X} g_*\mathscr{O}_{X'} \\ \downarrow & & & & \downarrow \\ g_*(Rf'_*g'^*\mathscr{G}) & \xrightarrow{\sim} & Rf_*g'_*(g'^*\mathscr{G}) & \xrightarrow{\beta} & Rf_*(\mathscr{G}\otimes_{\mathscr{O}_Y} g'_*\mathscr{O}_{Y'}) \end{array}$$

whose left vertical arrow is g_*(10.3.9) and whose right vertical arrow is the natural isomorphism provided by corollary 10.3.5 (applied to the flat $\mathscr{O}_Y$-module $\mathscr{F} := g'_*\mathscr{O}_{Y'}$). Also, α and β are the natural maps obtained as in [59, Ch.0, (5.4.10)]; it is easily seen that these are isomorphisms, for all affine morphisms g and g'. The assertion follows. □

Remark 10.3.10. Corollary 10.3.8 is also proved in [2, Th.6.7]. Notice that the corollary fails if $\mathscr{G}$ is not quasi-coherent. For a counterexample, let $R := k[x,y]_\mathfrak{m}$, where k is a field and $\mathfrak{m} \subset k[x,y]$ is the maximal ideal generated by x and y; *i.e.* R is the local ring at the origin of the affine plane over k. Let $R^\wedge$ be the completion of R, $X := \mathrm{Spec}\, R$, $X' := \mathrm{Spec}\, R^\wedge$, and set $Y := X\setminus\{\mathfrak{m}R\}$ and $Y' := Y\times_X X'$. Let moreover $\mathfrak{p}\in Y$ be the prime ideal generated by x, and $\mathfrak{p}'$ its inverse image in Y'; take for $\mathscr{G}$ the $\mathscr{O}_Y$-module obtained by extension by zero of the restriction to $\{\mathfrak{p}\}$ of the structure sheaf of $\mathscr{O}_Y$. With this notation, suppose that the map (10.3.9) induces an isomorphism on the stalks at the closed points; in cohomological degree zero, this comes down to saying that the natural map $f : (R^\wedge)_\mathfrak{p} \to (R^\wedge)_{\mathfrak{p}'}$ is an isomorphism. However, notice that the restriction $R_\mathfrak{p} \to (R^\wedge)_{\mathfrak{p}'}$ of f induces a homeomorphism $\mathrm{Spec}\,(R^\wedge)_{\mathfrak{p}'} \xrightarrow{\sim} \mathrm{Spec}\, R_\mathfrak{p}$. On the other hand, we can exhibit a height one prime ideal $\mathfrak{q}\in\mathrm{Spec}\,(R^\wedge)_\mathfrak{p}$ whose image in $\mathrm{Spec}\, R_\mathfrak{p}$ is the generic point. Indeed, let $a(X)\in x\cdot k[[x]]$ be a power series that is transcendental over $k(x)$; the kernel of the surjective continuous map of $k[[x]]$-algebras $g : R^\wedge = k[[x,y]] \to k[[x]]$ such that $g(y) := a(x)$ is the ideal I generated by $y - a(x)$, hence the latter is a prime ideal of $R^\wedge$, and we take $\mathfrak{q} := I_\mathfrak{p}$. To see that the preimage of $\mathfrak{q}$ in $\mathrm{Spec}\, R_\mathfrak{p}$ is the generic point, it suffices to notice that the restriction $R_\mathfrak{p} \to k[[x]]$ of g is injective, as $a(x)$ is transcendental over $k(x)$.

10.3.11. There are obvious forgetful functors:

$$\iota_X : \mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \to \mathscr{O}_X\text{-}\mathbf{Mod} \qquad R\iota_X : \mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}}) \to \mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$$

and we wish to exhibit right adjoints to these functors. To this aim, suppose first that X is affine; then we may consider the functor:

$$\mathsf{qcoh}_X : \mathscr{O}_X\text{-}\mathbf{Mod} \to \mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \qquad \mathscr{F} \mapsto \mathscr{F}(X)^\sim$$

If $\mathscr{G}$ is a quasi-coherent $\mathscr{O}_X$-module, then clearly $\mathsf{qcoh}_X\mathscr{G} \simeq \mathscr{G}$; moreover, for any other $\mathscr{O}_X$-module $\mathscr{F}$, there is a natural bijection:

$$\mathrm{Hom}_{\mathscr{O}_X}(\mathscr{G},\mathscr{F}) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{O}_X(X)}(\mathscr{G}(X),\mathscr{F}(X)).$$

It follows easily that qcoh_X is the sought right adjoint.

10.3.12. Slightly more generally, let U be *quasi-affine*, *i.e.* a quasi-compact open subset of an affine scheme, and choose a quasi-compact open immersion $j : U \to X$ into an affine scheme X. In this case, we may define

$$\mathsf{qcoh}_U : \mathscr{O}_U\text{-}\mathbf{Mod} \to \mathscr{O}_X\text{-}\mathbf{Mod} \qquad \mathscr{F} \mapsto (\mathsf{qcoh}_X j_*\mathscr{F})_{|U}.$$

Since $j_* : \mathscr{O}_U\text{-}\mathbf{Mod} \to \mathscr{O}_X\text{-}\mathbf{Mod}$ is right adjoint to $j^* : \mathscr{O}_X\text{-}\mathbf{Mod} \to \mathscr{O}_U\text{-}\mathbf{Mod}$, we have a natural isomorphism: $\mathrm{Hom}_{\mathscr{O}_U}(\mathscr{G},\mathscr{F}) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{O}_X}(j_*\mathscr{G}, j_*\mathscr{F})$ for every $\mathscr{O}_U$-modules $\mathscr{G}$ and $\mathscr{F}$. Moreover, if $\mathscr{G}$ is quasi-coherent, the same holds for $j_*\mathscr{G}$ ([59, Ch.I, Cor.9.2.2]), whence a natural isomorphism $\mathscr{G} \simeq \mathsf{qcoh}_U\mathscr{G}$, by the foregoing discussion for the affine case. Summing up, this shows that qcoh_U is a right adjoint to ι_U, and especially it is independent, up to unique isomorphism, of the choice of j.

10.3.13. Next, suppose that X is quasi-compact and quasi-separated. We choose a finite covering $\mathfrak{U} := (U_i \mid i \in I)$ of X, consisting of affine open subsets, and set $U := \coprod_{i\in I} U_i$, the X-scheme which is the disjoint union (*i.e.* categorical coproduct) of the schemes U_i. We denote by $\mathfrak{U}_\bullet$ the simplicial covering such that $\mathfrak{U}_n := U \times_X \cdots \times_X U$, the $(n+1)$-th power of U, with the face maps given by the natural projections, and degeneracies induced by the diagonal map $U \to U \times_X U$; let also $\pi_n : \mathfrak{U}_n \to X$ be the natural morphism, for every $n \in \mathbb{N}$. Clearly we have $\pi_{n-1} \circ \partial_i = \pi_n$ for every face morphism $\partial_i : \mathfrak{U}_n \to \mathfrak{U}_{n-1}$. The simplicial scheme $\mathfrak{U}_\bullet$ (with the Zariski topology on each scheme $\mathfrak{U}_n$) can also be regarded as a fibred topos over the category Δ^o (notation of [75, §2.2]); then the datum $\mathscr{O}_{\mathfrak{U}_\bullet} := (\mathscr{O}_{\mathfrak{U}_n} \mid n \in \mathbb{N})$ consisting of the structure sheaves on each $\mathfrak{U}_n$ and the natural maps $\partial_i^* \mathscr{O}_{\mathfrak{U}_{n-1}} \to \mathscr{O}_{\mathfrak{U}_n}$ for every $n > 0$ and every $i = 0, \dots, n$ (and similarly for the degeneracy maps), defines a ring in the associated topos $\mathrm{Top}(\mathfrak{U}_\bullet)$ (see [75, §3.3.15]). We denote by $\mathscr{O}_{\mathfrak{U}_\bullet}\text{-}\mathbf{Mod}$ the category of $\mathscr{O}_{\mathfrak{U}_\bullet}$-modules in the topos $\mathrm{Top}(\mathfrak{U}_\bullet)$. The family $(\pi_n \mid n \in \mathbb{N})$ induces a morphism of topoi

$$\pi_\bullet : \mathrm{Top}(\mathfrak{U}_\bullet) \to s.X$$

where $s.X$ is the topos $\mathrm{Top}(X_\bullet)$ associated with the constant simplicial scheme $X_\bullet$ (with its Zariski topology) such that $X_n := X$ for every $n \in \mathbb{N}$ and such that all the face and degeneracy maps are $\mathbf{1}_X$. Clearly the objects of $s.X$ are nothing else than the cosimplicial Zariski sheaves on X. Especially, if we view a $\mathscr{O}_X$-module $\mathscr{F}$ as a constant cosimplicial $\mathscr{O}_X$-module, we may define the *augmented cosimplicial Čech $\mathscr{O}_X$-module*

$$\mathscr{F} \to \mathscr{C}^\bullet(\mathfrak{U}, \mathscr{F}) := \pi_{\bullet *} \circ \pi_\bullet^* \mathscr{F} \qquad (10.3.14)$$

associated with $\mathscr{F}$ and the covering $\mathfrak{U}$; in every degree $n \in \mathbb{N}$ this is defined by the rule :

$$\mathscr{C}^n(\mathfrak{U}, \mathscr{F}) := \pi_{n*}\pi_n^* \mathscr{F}$$

and the coface operators ∂^i are induced by the face morphisms ∂_i in the obvious way.

Lemma 10.3.15. (i) *The augmented complex* (10.3.14) *is aspherical for every $\mathscr{O}_X$-module $\mathscr{F}$.*

(ii) *If $\mathscr{F}$ is an injective $\mathscr{O}_X$-module, then* (10.3.14) *is homotopically trivial.*

Proof. (See also *e.g.* [79, Th.5.2.1].) The proof relies on the following alternative description of the cosimplicial Čech $\mathscr{O}_X$-module. Consider the adjoint pair :

$$(\pi^*, \pi_*) : \mathscr{O}_{\mathfrak{U}}\text{-}\mathbf{Mod} \rightleftarrows \mathscr{O}_X\text{-}\mathbf{Mod}$$

arising from our covering $\pi : \mathfrak{U} \to X$. Let $(\top := \pi_* \circ \pi^*, \eta, \mu)$ be the associated triple (see (7.10.3)), $\mathscr{F}$ any $\mathscr{O}_X$-module; we leave to the reader the verification that the resulting augmented cosimplicial complex $\mathscr{F} \to \top^\bullet\mathscr{F}$ – as defined in (7.10.2) – is none else than the augmented Čech complex (10.3.14). Thus, for every $\mathscr{O}_X$-module $\mathscr{F}$, the augmented complex $\pi^*\mathscr{F} \to \pi^*\mathscr{C}^\bullet(\mathfrak{U}, \mathscr{F})$ is homotopically trivial (proposition 7.10.5); since π is a covering morphism, (i) follows. Furthermore, by the same token, the augmented complex $\pi_*\mathscr{G} \to \mathscr{C}^\bullet(\mathfrak{U}, \pi_*\mathscr{G})$ is homotopically trivial for every $\mathscr{O}_{\mathfrak{U}}$-module $\mathscr{G}$; especially we may take $\mathscr{G} := \pi^*\mathscr{I}$, where $\mathscr{I}$ is an injective $\mathscr{O}_X$-module. On the other hand, when $\mathscr{I}$ is injective, the unit of adjunction $\mathscr{I} \to \top\mathscr{I}$ is split injective; hence the augmented complex $\mathscr{I} \to \mathscr{C}^\bullet(\mathfrak{U}, \mathscr{I})$ is a direct summand of the homotopically trivial complex $\top\mathscr{I} \to \mathscr{C}^\bullet(\mathfrak{U}, \top\mathscr{I})$, and (ii) follows. □

Notice now that the schemes $\mathfrak{U}_n$ are quasi-affine for every $n \in \mathbb{N}$, hence the functors $\mathsf{qcoh}_{\mathfrak{U}_n}$ are well defined as in (10.3.12), and indeed, the rule : $(\mathscr{F}_n \mid n \in \mathbb{N}) \mapsto (\mathsf{qcoh}_{\mathfrak{U}_n}\mathscr{F}_n \mid n \in \mathbb{N})$ yields a functor :

$$\mathsf{qcoh}_{\mathfrak{U}_\bullet} : \mathscr{O}_{\mathfrak{U}_\bullet}\text{-}\mathbf{Mod} \to \mathscr{O}_{\mathfrak{U}_\bullet}\text{-}\mathbf{Mod}.$$

This suggests to introduce a *quasi-coherent cosimplicial Čech $\mathscr{O}_X$-module* :

$$\mathsf{q}\mathscr{C}^\bullet(\mathfrak{U},\mathscr{F}) := \pi_{\bullet *}\circ \mathsf{qcoh}_{\mathfrak{U}_\bullet}\circ \pi_\bullet^*\mathscr{F}$$

for every $\mathscr{O}_X$-module $\mathscr{F}$ (regarded as a constant cosimplicial module in the usual way). More plainly, this is the cosimplicial $\mathscr{O}_X$-module such that :

$$\mathsf{q}\mathscr{C}^n(\mathfrak{U},\mathscr{F}) := \pi_{n*}\circ \mathsf{qcoh}_{\mathfrak{U}_n}\circ \pi_n^*\mathscr{F} \qquad \text{for every } n\in\mathbb{N}.$$

According to [59, Ch.I, Cor.9.2.2], the $\mathscr{O}_X$-modules $\mathsf{q}\mathscr{C}^n(\mathfrak{U},\mathscr{F})$ are quasi-coherent for all $n\in\mathbb{N}$. Finally, we define the functor :

$$\mathsf{qcoh}_X : \mathscr{O}_X\text{-}\mathbf{Mod}\to\mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \qquad \mathscr{F}\mapsto \mathrm{Equal}(\mathsf{q}\mathscr{C}^0(\mathfrak{U},\mathscr{F}) \overset{\partial^0}{\underset{\partial^1}{\rightrightarrows}} \mathsf{q}\mathscr{C}^1(\mathfrak{U},\mathscr{F}))$$

Proposition 10.3.16. (i) *In the situation of* (10.3.13)*, the functor* qcoh_X *is right adjoint to* ι_X.

(ii) *Let Y be any other quasi-compact and quasi-separated scheme, $f : X\to Y$ any morphism. Then the induced diagram of functors:*

$$\begin{array}{ccc} \mathscr{O}_X\text{-}\mathbf{Mod} & \xrightarrow{f_*} & \mathscr{O}_Y\text{-}\mathbf{Mod} \\ {\scriptstyle \mathsf{qcoh}_X}\downarrow & & \downarrow{\scriptstyle \mathsf{qcoh}_Y} \\ \mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}} & \xrightarrow{f_*} & \mathscr{O}_Y\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \end{array}$$

commutes up to a natural isomorphism of functors.

Proof. For every $n\in\mathbb{N}$ and every $\mathscr{O}_{\mathfrak{U}_n}$-module $\mathscr{H}$, the counit of the adjunction yields a natural map of $\mathscr{O}_{\mathfrak{U}_n}$-modules: $\mathsf{qcoh}_{\mathfrak{U}_n}\mathscr{H}\to\mathscr{H}$. Taking $\mathscr{H}$ to be $\pi_n^*\mathscr{F}$ on $\mathfrak{U}_n$ (for a given $\mathscr{O}_X$-module $\mathscr{F}$), these maps assemble to a morphism of cosimplicial $\mathscr{O}_X$-modules :

$$\mathsf{q}\mathscr{C}^\bullet(\mathfrak{U},\mathscr{F})\to\mathscr{C}^\bullet(\mathfrak{U},\mathscr{F}) \tag{10.3.17}$$

and it is clear that (10.3.17) is an isomorphism whenever $\mathscr{F}$ is quasi-coherent. Let now $\varphi : \mathscr{G}\to\mathscr{F}$ be a map of $\mathscr{O}_X$-modules, with $\mathscr{G}$ quasi-coherent; after applying the natural transformation (10.3.17) and forming equalizers, we obtain a commutative diagram :

$$\begin{array}{ccc} \mathsf{qcoh}_X\mathscr{G} & \xrightarrow{\sim} & \mathscr{G} \\ {\scriptstyle \mathsf{qcoh}_X\varphi}\downarrow & & \downarrow{\scriptstyle\varphi} \\ \mathsf{qcoh}_X\mathscr{F} & \longrightarrow & \mathscr{F} \end{array}$$

from which we see that the rule: $\varphi\mapsto\mathsf{qcoh}_X\varphi$ establishes a natural injection:

$$\mathrm{Hom}_{\mathscr{O}_X}(\mathscr{G},\mathscr{F})\to\mathrm{Hom}_{\mathscr{O}_X}(\mathscr{G},\mathsf{qcoh}_X\mathscr{F}) \tag{10.3.18}$$

and since $\mathrm{Hom}_{\mathscr{O}_X}(\mathscr{G},(10.3.17))$ is an isomorphism of cosimplicial $\mathscr{O}_X$-modules, (10.3.18) is actually a bijection, whence (i).

(ii) is obvious, since both $\mathsf{qcoh}_Y\circ f_*$ and $f_*\circ\mathsf{qcoh}_X$ are right adjoint to $f^*\circ\iota_Y=\iota_X\circ f^*$. □

Remark 10.3.19. The right adjoint functor qcoh_X was first constructed in [20, Exp.II, Lemma 3.2], for X quasi-compact and quasi-separated; a construction valid for all schemes X is found in [107, Tag 0781].

10.3.20. In the situation of (10.3.13), the functor qcoh_X is left exact, since it is a right adjoint, hence it gives rise to a left derived functor :

$$R\mathsf{qcoh}_X : \mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod}) \to \mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}}).$$

Proposition 10.3.21. *Let X be a quasi-compact and quasi-separated scheme. Then :*

(i) *$R\mathsf{qcoh}_X$ is right adjoint to $R\iota_X$.*
(ii) *Suppose moreover, that X is* semi-separated, i.e. *such that the diagonal morphism $X \to X \times_{\mathbb{Z}} X$ is affine. Then the unit of the adjunction $(R\iota_X, R\mathsf{qcoh}_X)$ is an isomorphism of functors.*

Proof. (i): The exactness of the functor ι_X implies that qcoh_X preserves injectives; the assertion is a formal consequence : the details shall be left to the reader.

(ii): Let $\mathscr{F}^\bullet$ be any complex of quasi-coherent $\mathscr{O}_X$-modules; we have to show that the natural map $\mathscr{F}^\bullet \to R\mathsf{qcoh}_X\mathscr{F}^\bullet$ is an isomorphism. Using a Cartan-Eilenberg resolution $\mathscr{F}^\bullet \xrightarrow{\sim} \mathscr{I}^{\bullet\bullet}$ we deduce a spectral sequence ([163, §5.7])

$$E_1^{pq} := R^p\mathsf{qcoh}_X H^q\mathscr{F}^\bullet \Rightarrow R^{p+q}\mathsf{qcoh}_X\mathscr{F}^\bullet$$

which easily reduces to checking the assertion for the cohomology of $\mathscr{F}^\bullet$, so we may assume from start that $\mathscr{F}^\bullet$ is a single $\mathscr{O}_X$-module placed in degree zero. Let us then choose an injective resolution $\mathscr{F} \xrightarrow{\sim} \mathscr{I}^\bullet$ (that is, in the category of all $\mathscr{O}_X$-modules); we have to show that $H^p\mathsf{qcoh}_X\mathscr{I}^\bullet = 0$ for $p > 0$. We deal first with the following special case :

Claim 10.3.22. Assertion (i) holds if X is affine.

Proof of the claim. Indeed, in this case, the chosen injective resolution of $\mathscr{F}$ yields a long exact sequence $0 \to \mathscr{F}(X) \to \mathscr{I}^\bullet(X)$, and therefore a resolution $\mathsf{qcoh}_X\mathscr{F} := \mathscr{F}(X)^\sim \to \mathsf{qcoh}_X\mathscr{I}^\bullet := \mathscr{I}^\bullet(X)^\sim$. ◊

For the general case, we choose any affine covering $\mathfrak{U}$ of X and we consider the cochain complex of cosimplicial complexes $\mathsf{q}\mathscr{C}^\bullet(\mathfrak{U}, \mathscr{I}^\bullet)$.

Claim 10.3.23. For any injective $\mathscr{O}_X$-module $\mathscr{I}$, the augmented complex:

$$\mathsf{qcoh}_X\mathscr{I} \to \mathsf{q}\mathscr{C}^\bullet(\mathfrak{U}, \mathscr{I})$$

is homotopically trivial.

Proof of the claim. It follows easily from proposition 10.3.16(ii) that

$$\mathsf{q}\mathscr{C}^\bullet(\mathfrak{U}, \mathscr{F}) \simeq \mathsf{qcoh}_X(\mathscr{C}^\bullet(\mathfrak{U}, \mathscr{F}))$$

for any $\mathscr{O}_X$-module $\mathscr{F}$. Then the claim follows from lemma 10.3.15(ii). ◊

We have a spectral sequence :

$$E_1^{pq} := H^p\mathsf{q}\mathscr{C}^\bullet(\mathfrak{U}, \mathscr{I}^q) \Rightarrow \mathrm{Tot}^{p+q}(\mathsf{q}\mathscr{C}^\bullet(\mathfrak{U}, \mathscr{I}^\bullet))$$

and it follows from claim 10.3.23 that $E_1^{pq} = 0$ whenever $p > 0$, and $E^{0q} = \mathsf{qcoh}_X\mathscr{I}^q$ for every $q \in \mathbb{N}$, so the spectral sequence $E^{\bullet\bullet}$ degenerates, and we deduce a quasi-isomorphism

$$\mathsf{qcoh}_X\mathscr{I}^\bullet \xrightarrow{\sim} \mathrm{Tot}^\bullet(\mathsf{q}\mathscr{C}^\bullet(\mathfrak{U}, \mathscr{I}^\bullet)). \tag{10.3.24}$$

On the other hand, for fixed $q \in \mathbb{N}$, we have $\mathsf{q}\mathscr{C}^q(\mathfrak{U}, \mathscr{I}^\bullet) = \pi_{n*}\mathsf{qcoh}_{\mathfrak{U}_n}\pi_n^*\mathscr{I}^\bullet$; since X is semi-separated, $\mathfrak{U}_n$ is affine, so the complex $\mathsf{qcoh}_{\mathfrak{U}_n}\pi_n^*\mathscr{I}^\bullet$ is a resolution of $\mathsf{qcoh}_{\mathfrak{U}_n}\pi_n^*\mathscr{F} = \pi_n^*\mathscr{F}$, by claim 10.3.22. Furthermore, $\pi_n : \mathfrak{U}_n \to X$ is an affine morphism, so $\mathsf{q}\mathscr{C}^q(\mathfrak{U}, \mathscr{I}^\bullet)$ is a resolution of $\pi_{n*}\pi_n^*\mathscr{F}$. Summing up, we see that $\mathrm{Tot}^\bullet(\mathsf{q}\mathscr{C}^\bullet(\mathfrak{U}, \mathscr{I}^\bullet))$ is quasi-isomorphic to $\mathscr{C}^\bullet(\mathfrak{U}, \mathscr{F})$, which is a resolution of $\mathscr{F}$, by lemma 10.3.15(i). Combining with (10.3.24), we deduce (ii). □

Theorem 10.3.25. *Let X be a quasi-compact semi-separated scheme. The forgetful functor*

$$R\iota_X : \mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}}) \to \mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$$

is an equivalence of categories, whose quasi-inverse is the restriction of $R\mathsf{qcoh}_X$.

Proof. By proposition 10.3.21(ii) we know already that the composition $R\mathsf{qcoh}_X \circ R\iota_X$ is a self-equivalence of $\mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}})$. For every complex $\mathscr{F}^\bullet$ in $\mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})$, the counit of adjunction $\varepsilon_{\mathscr{F}^\bullet} : R\iota_X \circ R\mathsf{qcoh}_X\mathscr{F}^\bullet \to \mathscr{F}^\bullet$ can be described as follows. Pick an injective resolution $\alpha : \mathscr{F}^\bullet \to \mathscr{I}^\bullet$; then $\varepsilon_{\mathscr{F}^\bullet}$ is defined by the diagram :

$$\mathsf{qcoh}_X\mathscr{I}^\bullet \xrightarrow{\varepsilon^\bullet} \mathscr{I}^\bullet \xleftarrow{\alpha} \mathscr{F}^\bullet$$

where, for each $n \in \mathbb{N}$, the map $\varepsilon^n : \mathsf{qcoh}_X\mathscr{I}^n \to \mathscr{I}^n$ is the counit of the adjoint pair $(\iota_X, \mathsf{qcoh}_X)$. It suffices then to show that $\varepsilon^\bullet$ is a quasi-isomorphism, when $\mathscr{I}^\bullet$ is an object of $\mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$. To this aim, we may further choose $\mathscr{I}^\bullet$ of the form $\mathrm{Tot}^\bullet(\mathscr{I}^{\bullet\bullet})$, where $\mathscr{I}^{\bullet\bullet}$ is a Cartan-Eilenberg resolution of $\mathscr{F}^\bullet$ (see [163, §5.7]). We then deduce a spectral sequence :

$$E_2^{pq} := R^p\mathsf{qcoh}_X H^q\mathscr{F}^\bullet \Rightarrow R^{p+q}\mathsf{qcoh}_X\mathscr{F}^\bullet.$$

The double complex $\mathscr{I}^{\bullet\bullet}$ also gives rise to a similar spectral sequence F_2^{pq}, and clearly $F_2^{pq} = 0$ whenever $p > 0$, and $F^{0q} = H^q\mathscr{F}^\bullet$. Furthermore, the counit of adjunction $\varepsilon^{\bullet\bullet} : \mathsf{qcoh}_X\mathscr{I}^{\bullet\bullet} \to \mathscr{I}^{\bullet\bullet}$ induces a morphism of spectral sequences $\omega^{pq} : E_2^{pq} \to F_2^{pq}$. Consequently, in order to prove that the $\varepsilon_{\mathscr{F}^\bullet}$ is a quasi-isomorphism, it suffices to show that ω^{pq} is an isomorphism for every $p, q \in \mathbb{N}$. This comes down to the assertion that $R^p\mathsf{qcoh}_X\mathscr{G} = 0$ for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{G}$, and every $p > 0$. However, we have $\mathscr{G} = R\iota_X\mathscr{G}$, so that $R\mathsf{qcoh}_X\mathscr{G} = R\mathsf{qcoh}_X \circ R\iota_X\mathscr{G}$, and then the contention follows from proposition 10.3.21(ii). ☐

Remark 10.3.26. Theorem 10.3.25 appeared in [158, Prop.B.16] and [20, Exp.II, Prop.3.5] (the latter is stated for separated schemes, but the proof works in the semi-separated case as well). The theorem holds also for any locally noetherian scheme X, by virtue of [87, Ch.II, Cor.7.19] (whose proof uses the structure of injective $\mathscr{O}_X$-modules, rather than the functor qcoh_X).

Lemma 10.3.27. *Let X be a quasi-compact and quasi-separated scheme, U a quasi-compact open subset of X, $\mathscr{H}$ a quasi-coherent $\mathscr{O}_X$-module, $\mathscr{G}$ a finitely presented quasi-coherent $\mathscr{O}_U$-module, and $\varphi : \mathscr{G} \to \mathscr{H}_{|U}$ an $\mathscr{O}_U$-linear map. Then:*

- (i) *There exist a finitely presented quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ on X, and a $\mathscr{O}_X$-linear map $\psi : \mathscr{F} \to \mathscr{H}$, such that $\mathscr{F}_{|U} = \mathscr{G}$ and $\psi_{|U} = \varphi$.*
- (ii) *Especially, every finitely presented quasi-coherent $\mathscr{O}_U$-module extends to a finitely presented quasi-coherent $\mathscr{O}_X$-module.*

Proof. (i): Let $(V_i \mid i = 1, \dots, n)$ be a finite affine open covering of X. For every $i = 0, \dots, n$, let us set $U_i := U \cup V_1 \cup \cdots \cup V_i$; we construct, by induction on i, a family of finitely presented quasi-coherent $\mathscr{O}_{U_i}$-modules $\mathscr{F}_i$, and morphisms $\psi_i : \mathscr{F}_i \to \mathscr{H}_{|U_i}$ such that $\mathscr{F}_{i+1|U_i} = \mathscr{F}_i$ and $\psi_{i+1|U_{i+1}} = \psi_i$ for every $i < n$. For $i = 0$ we have $U_0 = U$, and we set $\mathscr{F}_0 := \mathscr{G}$, $\psi_0 := \varphi$. Suppose that $i < n$ and that $\mathscr{F}_i$ and ψ_i have already been given. Since X is quasi-separated, the same holds for U_{i+1}, and the immersion $j : U_i \to U_{i+1}$ is quasi-compact; it follows that $j_*\mathscr{F}_i$ and $j_*\mathscr{H}_{|U_i}$ are quasi-coherent $\mathscr{O}_{U_i}$-modules ([59, Ch.I, Prop.9.4.2(i)]). We let

$$\mathscr{M} := j_*\mathscr{F}_i \times_{j_*\mathscr{H}_{|U_i}} \mathscr{H}_{|U_{i+1}}.$$

Then $\mathscr{M}$ is a quasi-coherent $\mathscr{O}_{U_{i+1}}$-module admitting a map $\mathscr{M} \to \mathscr{H}_{|U_{i+1}}$, and such that $\mathscr{M}_{|U_i} = \mathscr{F}_i$. We can then find a filtered family of quasi-coherent $\mathscr{O}_{V_{i+1}}$-modules of finite presentation $(\mathscr{M}_\lambda \mid \lambda \in \Lambda)$, whose colimit is $\mathscr{M}_{|V_{i+1}}$. Since $\mathscr{F}_i$ is finitely presented and $U_i \cap V_{i+1}$ is quasi-compact, there exists $\lambda \in \Lambda$ such that the induced morphism $\beta : \mathscr{M}_{\lambda|U_i \cap V_{i+1}} \to \mathscr{F}_{i|U_i \cap V_{i+1}}$ is an epimorphism. Notice moreover that the restriction of $\mathscr{K} := \mathrm{Ker}(\mathscr{M}_\lambda \to \mathscr{M}_{|V_{i+1}})$ to $U_i \cap V_{i+1}$

coincides with $\mathrm{Ker}(\beta)$; since $\mathrm{Ker}(\beta)$ is of finite type, and since $U_i \cap V_{i+1}$ is quasi-compact, there exists an $\mathscr{O}_{V_{i+1}}$-submodule of finite type $\mathscr{N}$ of $\mathscr{K}$ such that $\mathscr{N}_{|U_i\cap V_{i+1}} = \mathrm{Ker}(\beta)$. Set $\overline{\mathscr{M}}_\lambda := \mathscr{M}_\lambda/\mathscr{N}$; then β descends to an isomorphism $\overline{\beta} : \overline{\mathscr{M}}_\lambda \xrightarrow{\sim} \mathscr{F}_{i|U_i\cap V_{i+1}}$, and the map $\mathscr{M}_\lambda \to \mathscr{M}_{|V_{i+1}}$ factors through $\overline{\mathscr{M}}_\lambda$. We can thus define $\mathscr{F}_{i+1}$ by gluing $\mathscr{F}_i$ and $\overline{\mathscr{M}}_\lambda$ along $\overline{\beta}$; likewise, ψ_i and the induced map $\overline{\mathscr{M}}_\lambda \to \mathscr{M}_{|V_{i+1}} \to \mathscr{H}_{|V_{i+1}}$ glue to a map ψ_{i+1} as required. Clearly the pair $(\mathscr{F} := \mathscr{F}_n, \psi := \psi_n)$ is the sought extension of $(\mathscr{G}, \varphi)$.

(ii): Let 0_X be the final object in the category of $\mathscr{O}_X$-modules; to extend a finitely presented quasi-coherent $\mathscr{O}_U$-module $\mathscr{G}$, it suffices to apply (i) to the unique map $\mathscr{G} \to 0_{X|U}$. □

For ease of reference, we point out the following simple consequence of lemma 10.3.27.

Corollary 10.3.28. *Let U be a quasi-affine scheme, $\mathscr{E}$ a locally free $\mathscr{O}_U$-module of finite type. Then we may find integers $n, m \in \mathbb{N}$ and a left exact sequence of $\mathscr{O}_U$-modules :*

$$0 \to \mathscr{E} \to \mathscr{O}_U^{\oplus m} \to \mathscr{O}_U^{\oplus n}.$$

Proof. Set $\mathscr{E}^\vee := \mathscr{H}om_{\mathscr{O}_U}(\mathscr{E}, \mathscr{O}_U)$, and notice that $\mathscr{E}^\vee$ is a locally free $\mathscr{O}_U$-module of finite type, especially it is quasi-coherent and of finite presentation. By assumption, U is a quasi-compact open subset of an affine scheme X, hence $\mathscr{E}^\vee$ extends to a quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ of finite presentation (lemma 10.3.27(ii)); we have $\mathscr{F} = F^\sim$, for some finitely presented A-module F; we choose a presentation of F as the cokernel of an A-linear map $A^{\oplus n} \to A^{\oplus m}$, for some $m, n \in \mathbb{N}$, whence a presentation of $\mathscr{E}^\vee$ as the cokernel of a morphism $\mathscr{O}_U^{\oplus n} \to \mathscr{O}_U^{\oplus m}$, and after dualizing again, we get the sought left exact sequence. □

10.3.29. Let X be a scheme; for any quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, we consider the full subcategory $C/\mathscr{F}$ of the category $\mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}}/\mathscr{F}$ whose objects are all the maps $\varphi : \mathscr{G} \to \mathscr{F}$ such that $\mathscr{G}$ is a finitely presented $\mathscr{O}_X$-module (notation of (1.1.24)). We denote by

$$\iota_{\mathscr{F}} : C/\mathscr{F} \to \mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \qquad (\mathscr{G} \to \mathscr{F}) \mapsto \mathscr{G}$$

the restriction of the source functor. The first observation is:

Lemma 10.3.30. *$C/\mathscr{F}$ is a filtered category.*

Proof. Since $C/\mathscr{F}$ always admits the initial object $0 \to \mathscr{F}$, its set of objects is non-empty. Thus, according to remark 1.2.21(i), it suffices to check that $C/\mathscr{F}$ is directed and satisfies the coequalizing condition. However, say that $\varphi_i : \mathscr{G}_i \to \mathscr{F}$ $(i = 1, 2)$ are any two objects of $C/\mathscr{F}$; then obviously there is a unique morphism $\mathscr{G}_1 \oplus \mathscr{G}_2 \to \mathscr{F}$ whose restriction to $\mathscr{G}_i$ agrees with φ_i for $i = 1, 2$.

Next, suppose that $\beta_1, \beta_2 : \mathscr{G} \to \mathscr{G}'$ are two morphisms of finitely presented $\mathscr{O}_X$-modules and $\psi : \mathscr{G}' \to \mathscr{F}$ an object of $C/\mathscr{F}$ such that $\psi \circ \beta_1 = \psi \circ \beta_2$. Set $\mathscr{G}'' := \mathrm{Coker}\,(\beta_1 - \beta_2)$; it is easily seen that $\mathscr{G}''$ is a finitely presented $\mathscr{O}_X$-module and ψ factors through a unique morphism $\mathscr{G}'' \to \mathscr{F}$, whence the lemma. □

Proposition 10.3.31. *With the notation of* (10.3.29)*, suppose that X is quasi-compact and quasi-separated. Then, for any quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, the induced map*

$$\operatorname*{colim}_{C/\mathscr{F}} \iota_{\mathscr{F}} \to \mathscr{F}$$

is an isomorphism.

Proof. Let $\mathscr{F}'$ be such colimit; clearly there is a natural map $\mathscr{F}' \to \mathscr{F}$, and we have to show that it is an isomorphism. To this aim, we can check on the stalk over the points $x \in X$, hence we come down to showing :

Claim 10.3.32. Let $\mathscr{F}$ be any quasi-coherent $\mathscr{O}_X$-module. Then :

(i) For every $s \in \mathscr{F}_x$ there exist a finitely presented quasi-coherent $\mathscr{O}_X$-module $\mathscr{G}$, a morphism $\varphi : \mathscr{G} \to \mathscr{F}$ and $t \in \mathscr{G}_x$ such that $\varphi_x(t) = s$.

(ii) For every map $\varphi : \mathscr{G} \to \mathscr{F}$ with $\mathscr{G}$ finitely presented and quasi-coherent, and every $s \in \operatorname{Ker} \varphi_x$, there exists a commutative diagram of quasi-coherent $\mathscr{O}_X$-modules :

$$\begin{array}{ccc} \mathscr{G} & & \\ {\scriptstyle\psi}\downarrow & \searrow{\scriptstyle\varphi} & \\ \mathscr{H} & \longrightarrow & \mathscr{F} \end{array}$$

with $\mathscr{H}$ finitely presented and $\psi_x(s) = 0$.

Proof of the claim. (i): Let $U \subset X$ be an open subset such that s extends to a section $s_U \in \mathscr{F}(U)$; we deduce a map $\varphi_U : \mathscr{O}_U \to \mathscr{F}_{|U}$ by the rule $a \mapsto a \cdot s_U$ for every $a \in \mathscr{O}_U(U)$. In view of lemma 10.3.27(i), the pair $(\varphi_U, \mathscr{O}_U)$ extends to a pair $(\varphi, \mathscr{G})$ with the sought properties.

(ii): We apply (i) to the quasi-coherent $\mathscr{O}_X$-module $\operatorname{Ker} \varphi$, to find a finitely presented quasi-coherent $\mathscr{O}_X$-module $\mathscr{G}'$, a morphism $\beta : \mathscr{G}' \to \operatorname{Ker} \varphi$ and $t \in \mathscr{H}_x$ such that $\beta_x(t) = s$. Then we let $\psi : \mathscr{G} \to \mathscr{H} := \operatorname{Coker}(\mathscr{G}' \xrightarrow{\beta} \operatorname{Ker} \varphi \to \mathscr{G})$ be the natural map. By construction, $\mathscr{H}$ is finitely presented, $\psi_x(s) = 0$ and clearly φ factors through ψ. □

10.3.33. Let X be a coherent scheme, $U \subset X$ a quasi-compact open subset, $a, b \in \mathbb{Z}$ any two integers with $a \leq b$, and $\mathscr{H}^\bullet$ any object of $\mathsf{D}^{[a,b]}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$ such that $\mathscr{H}^\bullet_{|U}$ lies in $\mathsf{D}^{[a,b]}(\mathscr{O}_U\text{-}\mathbf{Mod})_{\mathrm{coh}}$. Let also $\mathscr{F}_i \subset H^i\mathscr{H}^\bullet$ be a quasi-coherent $\mathscr{O}_X$-submodule of finite type, for every $i = a, \dots, b$.

Proposition 10.3.34. *In the situation of* (10.3.33)*, the following holds :*

(i) *There exists an object $\mathscr{G}^\bullet$ of $\mathsf{D}^{[a,b]}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$, with a morphism $\varphi^\bullet : \mathscr{G}^\bullet \to \mathscr{H}^\bullet$ in $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$ such that :*
  (a) *$\varphi^\bullet_{|U}$ is an isomorphism.*
  (b) *$\mathscr{F}_i \subset \operatorname{Im} H^i\varphi^\bullet$ for every $i = a, \dots, b$.*

(ii) *If X is noetherian, we can find $\varphi^\bullet$ as in* (i) *such that $H^i\varphi^\bullet$ is a monomorphism, for every $i = a, \dots, b$.*

Proof. To start out, for any quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ such that $\mathscr{F}_{|U}$ is a coherent $\mathscr{O}_U$-module, define the category $C/\mathscr{F}$ as in (10.3.29), and consider the full subcategory $C'/\mathscr{F}$ (resp. $C''/\mathscr{F}$) of $C/\mathscr{F}$ whose objects are all the maps $\varphi : \mathscr{G} \to \mathscr{F}$ such that $\varphi_{|U}$ is an isomorphism (resp. an epimorphism).

Claim 10.3.35. $C'/\mathscr{F}$ and $C''/\mathscr{F}$ are filtered categories.

Proof of the claim. The proof of lemma 10.3.30 applies *verbatim* to show that both $C'/\mathscr{F}$ and $C''/\mathscr{F}$ satisfy the coequalizing condition of definition 1.2.19(v), and it also proves that $C''/\mathscr{F}$ is directed. Moreover, lemma 10.3.27(i) says that the sets of objects of these two categories are non-empty, which already implies that $C''/\mathscr{F}$ is filtered, by remark 1.2.21(i). By the same token, it remains only to check that $C'/\mathscr{F}$ satisfies the coequalizing condition. Hence, let $\varphi_i : \mathscr{G}_i \to \mathscr{F}$ $(i = 1, 2)$ be any two objects of $C'/\mathscr{F}$, and set $\mathscr{G}' := \mathscr{G}_1 \times_{\mathscr{F}} \mathscr{G}_2$; then $\mathscr{G}'$ is a quasi-coherent $\mathscr{O}_X$-module, and $\mathscr{G}'_{|U}$ is isomorphic to $\mathscr{F}_{|U}$, especially it is coherent. Then pick any object $\psi : \mathscr{G}'' \to \mathscr{G}'$ of the category $C''/\mathscr{G}'$, and denote by $\psi_i : \mathscr{G}'' \to \mathscr{G}_i$ $(i = 1, 2)$ the two morphisms induced by ψ; by construction we have $\varphi_1 \circ \psi_1 = \varphi_2 \circ \psi_2$. Hence, set $\mathscr{G} := \mathscr{G}_1 \amalg_{\mathscr{G}''} \mathscr{G}_2$; we get a unique morphism $\varphi : \mathscr{G} \to \mathscr{F}$ such that both φ_1 and φ_2 factor through φ and $\varphi_{|U}$ is an isomorphism. Since $\mathscr{G}$ is a finitely presented $\mathscr{O}_X$-module, we are done. ◇

Claim 10.3.36. With the foregoing notation, the following holds :

(i) $C'/\mathscr{F}$ is a cofinal subcategory of $C/\mathscr{F}$.
(ii) For every object $K^\bullet$ of $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$ and every $c \in \mathbb{Z}$, the natural map

$$\operatorname*{colim}_{C/\mathscr{F}} \mathrm{Hom}_{\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})}(K^\bullet, \iota_{\mathscr{F}}[c]) \to \mathrm{Hom}_{\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})}(K^\bullet, \mathscr{F}[c]) \tag{10.3.37}$$

is an isomorphism (notation of (10.3.29)).

Proof of the claim. (i): Since U is quasi-compact, it is easily seen that $C''/\mathscr{F}$ is cofinal in $C/\mathscr{F}$, so we are reduced to checking that $C'/\mathscr{F}$ is cofinal in $C''/\mathscr{F}$. Hence, let $\psi : \mathscr{G}' \to \mathscr{F}$ be any object of $C''/\mathscr{F}$; since $\mathscr{O}_X$ is coherent, $\mathscr{K} := \mathrm{Ker}\,\psi_{|U}$ is a coherent $\mathscr{O}_U$-module, therefore we may extend $\mathscr{K}$ to a coherent $\mathscr{O}_X$-module $\mathscr{K}'$ and the identity map of $\mathscr{K}$ to a morphism $\psi' : \mathscr{K}' \to \mathrm{Ker}\,\psi$ of $\mathscr{O}_X$-modules (lemma 10.3.27(i)). Set $\mathscr{G} := \mathscr{G}'/\psi'(\mathscr{K}')$; the induced map $\mathscr{G} \to \mathscr{F}$ is an object of $C'/\mathscr{F}$, whence the contention.

(ii): We have two spectral sequences

$$E_2^{pq} := \operatorname*{colim}_{C/\mathscr{F}} R^p\Gamma \circ R^q\mathscr{H}om^\bullet_{\mathscr{O}_X}(K^\bullet, \iota_{\mathscr{F}}[c]) \Rightarrow \operatorname*{colim}_{C/\mathscr{F}} \mathrm{Hom}_{\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})}(K^\bullet, \iota_{\mathscr{F}}[c+p+q])$$
$$F_2^{pq} := R^p\Gamma \circ R^q\mathscr{H}om^\bullet_{\mathscr{O}_X}(K^\bullet, \mathscr{F}[c]) \Rightarrow \mathrm{Hom}_{\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})}(K^\bullet, \mathscr{F}[c+p+q])$$

and a morphism of spectral sequences $E_\bullet^{\bullet\bullet} \to F_\bullet^{\bullet\bullet}$, such that (10.3.37) is a morphism of filtered abelian groups, for the two finite filtrations induced by these spectral sequences on their abutments. Since the functors $R^p\Gamma$ commute with filtered colimits, we deduce that it suffices to show that the natural morphism

$$\operatorname*{colim}_{C/\mathscr{F}} R^q\mathscr{H}om^\bullet_{\mathscr{O}_X}(K^\bullet, \iota_{\mathscr{F}}[c])) \to R^q\mathscr{H}om^\bullet_{\mathscr{O}_X}(K^\bullet, \mathscr{F}[c])$$

is an isomorphism for every $q \in \mathbb{Z}$. Then, a standard *dévissage* argument further reduces to the case where $K^\bullet$ is concentrated in a single degree, so we come down to checking that the functor $\mathscr{F} \mapsto R^q\mathscr{H}om^\bullet_{\mathscr{O}_X}(\mathscr{G}, \mathscr{F})$ commutes with filtered colimits of quasi-coherent $\mathscr{O}_X$-modules, for every coherent $\mathscr{O}_X$-module $\mathscr{G}$ and every $q \in \mathbb{Z}$. To this aim we may assume that X is affine, in which case – since $\mathscr{O}_X$ is coherent – $\mathscr{G}$ admits a resolution $\mathscr{L}^\bullet$ consisting of free $\mathscr{O}_X$-modules of finite rank; the latter are acyclic for the functor $\mathscr{H}om_{\mathscr{O}_X}$, so we are left with the assertion that the functor $\mathscr{F} \mapsto H^q\mathscr{H}om_{\mathscr{O}_X}(\mathscr{L}^\bullet, \mathscr{F})$ commutes with filtered colimits, which is clear. ◊

Claim 10.3.38. The proposition holds if $a = b$.

Proof of the claim. From proposition 10.3.31 and claim 10.3.36(i) we deduce that, for every $x \in X$ we may find an object $\varphi : \mathscr{G} \to H^a\mathscr{H}$ such that $\mathscr{F}_{a,x} \subset \mathrm{Im}\,\varphi_x$, and therefore $\mathscr{F}_{a|U_x} \subset \mathrm{Im}\,\varphi_{|U_x}$ for some open neighborhood U_x of x in X. Since X is quasi-compact and $C/\mathscr{F}$ is filtered, assertion (i) follows easily. Next, suppose that a morphism $\varphi : \mathscr{G} \to H^a\mathscr{H}$ has already been exhibited that fulfills conditions (i.a) and (i.b), and set $\mathscr{G}' := \mathrm{Im}\,\varphi$; to show assertion (ii), it suffices to remark that if X is noetherian, $\mathscr{G}'$ is still a coherent $\mathscr{O}_X$-module. ◊

We proceed now by induction on $b - a$, the case where $a = b$ having been covered by claim 10.3.38. Thus, suppose that $a < b$, and that the proposition is already known for every object of $\mathsf{D}^{[a+1,b]}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$ fulfilling the stated condition. We have a distinguished triangle

$$\mathscr{F}[-a] \to \mathscr{H}^\bullet \to \tau^{\geq a+1}\mathscr{H}^\bullet \xrightarrow{\alpha^\bullet} \mathscr{F}[1-a] \qquad \text{with } \mathscr{F} := H^a\mathscr{H}^\bullet$$

in $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$ (where $\tau^{\geq a+1}$ denotes the truncation functor : see remark 7.3.14(iv)). By inductive assumption, we may find an object $\mathscr{G}'^\bullet$ of $\mathsf{D}^{[a+1,b]}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$ and a morphism $\varphi'^\bullet : \mathscr{G}'^\bullet \to \tau^{\geq a+1}\mathscr{H}^\bullet$ in $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$ which restricts to an isomorphism on U and such that $\mathscr{F}_i \subset \mathrm{Im}\,H^i\varphi'^\bullet$ for every $i = a+1, \dots, b$. There follows a morphism of distinguished triangles :

$$\begin{array}{ccccccc} \mathscr{F}[-a] & \longrightarrow & \mathscr{H}'^\bullet & \longrightarrow & \mathscr{G}'^\bullet & \longrightarrow & \mathscr{F}[1-a] \\ \| & & \downarrow{\scriptstyle\beta^\bullet} & & \downarrow{\scriptstyle\varphi'^\bullet} & & \| \\ \mathscr{F}[-a] & \longrightarrow & \mathscr{H}^\bullet & \longrightarrow & \tau^{\geq a+1}\mathscr{H}^\bullet & \xrightarrow{\alpha^\bullet} & \mathscr{F}[1-a] \end{array}$$

for some object $\mathscr{H}'^\bullet$ of $\mathsf{D}^{[a,b]}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$, and clearly $\beta^\bullet$ restricts to an isomorphism on U and $H^a\beta^\bullet$ is an isomorphism. We may then replace $\mathscr{H}^\bullet$ by $\mathscr{H}'^\bullet$, and assume that $\tau^{\geq a+1}\mathscr{H}^\bullet$ lies in $\mathsf{D}^{[a+1,b]}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$.

By claim 10.3.36, we may find an object $\psi : \mathscr{G} \to \mathscr{F}$ of $C'/\mathscr{F}$ such that $\alpha^\bullet$ factors through $\psi[1-a]$ and a morphism $\omega^\bullet : \tau^{\geq a+1}\mathscr{H}^\bullet \to \mathscr{G}[1-a]$ in $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$. Moreover, by claim 10.3.38 we may assume that $\mathscr{F}_a \subset \mathrm{Im}\,\psi$, and also that ψ is a monomorphism, if X is noetherian. Then $\mathrm{Cone}\,\omega^\bullet[-1]$ lies in $\mathsf{D}^{[a,b]}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$, and the induced morphism $\mathrm{Cone}\,\omega^\bullet[-1] \to \mathscr{H}^\bullet$ will do. □

Corollary 10.3.39. *Let X be a coherent scheme, $U \subset X$ a quasi-compact open subset. Then the induced functor*

$$\mathsf{D}^{[a,b]}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}} \to \mathsf{D}^{[a,b]}(\mathscr{O}_U\text{-}\mathbf{Mod})_{\mathrm{coh}}$$

is essentially surjective, for every $a, b \in \mathbb{Z}$ with $a \leq b$.

Proof. Let $j : U \to X$ be the open immersion, $\mathscr{F}^\bullet$ an object of $\mathsf{D}^{[a,b]}(\mathscr{O}_U\text{-}\mathbf{Mod})_{\mathrm{coh}}$. By [61, Ch.III, Prop.1.4.10, Cor.1.4.12] and a standard spectral sequence argument, it is easily seen that

$$\mathscr{H}^\bullet := \tau^{\geq a} \circ \tau^{\leq b} Rj_*\mathscr{F}^\bullet$$

lies in $\mathsf{D}^{[a,b]}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$ and $\mathscr{H}^\bullet_{|U} = \mathscr{F}^\bullet$. Then the assertion follows immediately from proposition 10.3.34(i). □

10.4. **Depth and cohomology with supports.** This section introduces and studies local cohomology and the closely related notion of depth, in the context of arbitrary schemes (whereas the usual references restrict to the case of locally noetherian schemes).

10.4.1. To begin with, let $(X, \mathscr{A})$ be any ringed topological space, $i : Z \to X$ a closed immersion, set $U := X \setminus Z$ and denote by $j : U \to X$ the resulting open immersion. One defines the functor

$$\underline{\Gamma}_Z : \mathscr{A}\text{-}\mathbf{Mod} \to \mathscr{A}\text{-}\mathbf{Mod} \qquad \mathscr{F} \mapsto \mathrm{Ker}\,(\mathscr{F} \to j_*j^*\mathscr{F})$$

as well as its composition with the global section functor

$$\Gamma_Z : \mathscr{A}\text{-}\mathbf{Mod} \to \mathscr{A}(X)\text{-}\mathbf{Mod} \qquad \mathscr{F} \mapsto \Gamma(X, \underline{\Gamma}_Z\mathscr{F}).$$

It is clear that $\underline{\Gamma}_Z$ and Γ_Z are left exact functors, hence they give rise to right derived functors

$$R\underline{\Gamma}_Z : \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}) \to \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}) \qquad R\Gamma_Z : \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}) \to \mathsf{D}^+(\mathscr{A}(X)\text{-}\mathbf{Mod})$$

such that the natural morphism $\underline{\Gamma}_Z\mathscr{F} \to R^0\underline{\Gamma}_Z\mathscr{F}$ is an isomorphism, for every $\mathscr{A}$-module $\mathscr{F}$ (and likewise for $R^0\Gamma_Z$). Moreover, suppose that $\mathscr{F} \to \mathscr{I}^\bullet$ is a resolution of $\mathscr{F}$ by a complex of injective $\mathscr{A}$-modules; since injective sheaves are flabby (lemma 10.1.5(v)), we obtain a short exact sequence of complexes

$$0 \to \underline{\Gamma}_Z\mathscr{I}^\bullet \to \mathscr{I}^\bullet \to j_*j^*\mathscr{I}^\bullet \to 0$$

whence a natural exact sequence of $\mathscr{A}$-modules :

(10.4.2) $$0 \to \underline{\Gamma}_Z\mathscr{F} \to \mathscr{F} \to j_*j^*\mathscr{F} \to R^1\underline{\Gamma}_Z\mathscr{F} \to 0 \qquad \text{for every } \mathscr{A}\text{-module } \mathscr{F}$$

and natural isomorphisms :

(10.4.3) $$R^{q-1}j_*j^*\mathscr{F} \xrightarrow{\sim} R^q\underline{\Gamma}_Z\mathscr{F} \qquad \text{for all } q > 1.$$

Lemma 10.4.4. *In the situation of* (10.4.1)*, let* $\mathscr{B} \to \mathscr{A}$ *be any morphism of sheaves of rings on* X*. The following holds :*

(i) *Every flabby* $\mathscr{A}$*-module is* $\underline{\Gamma}_Z$*-acyclic.*

(ii) *The functor* $R\underline{\Gamma}_Z$ *commutes with the forgetful functor* $\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}) \to \mathsf{D}^+(\mathscr{B}\text{-}\mathbf{Mod})$.

(iii) *Suppose that* X *is locally coherent and quasi-separated, and that* Z *is a constructible closed subset of* X*. Then :*

(a) *Every qc-flabby* $\mathscr{A}$*-module is* $\underline{\Gamma}_Z$*-acyclic.*

(b) *For every* $i \in \mathbb{N}$ *the functor* $R^i\underline{\Gamma}_Z$ *commutes with filtered colimits of* $\mathscr{A}$*-modules.*

Proof. (i): First of all, if $\mathscr{F}$ is flabby on X, the natural morphism $\mathscr{F} \to j_*j^*\mathscr{F}$ is obviously an epimorphism; together with (10.4.2), this implies that $R^1\underline{\Gamma}_Z\mathscr{F} = 0$ when $\mathscr{F}$ is flabby. Next, (10.4.3), together with the fact that flabby $\mathscr{A}$-modules are acyclic for direct image functors such as j_* (lemma 10.1.5(ii)), implies that $R^i\underline{\Gamma}_Z\mathscr{F} = 0$ also for $i > 1$, whence the contention.

Assertion (iii.a) is checked in the same way : first one notices that, under the stated assumptions, the morphism $\mathscr{F} \to j_*j^*\mathscr{F}$ is an epimorphism also for all qc-flabby sheaves on X, which again gives the vanishing of $R^1\underline{\Gamma}_Z\mathscr{F}$; for the higher derived functors one then appeals to (10.4.3) and lemma 10.1.5(iv).

(iii.b): Suppose first that $i > 1$; in this case, the assertion follows from (10.4.3) and the following more general :

Claim 10.4.5. In the situation of (iii), the functor R^ij_* commutes with filtered colimits, for every $i \in \mathbb{N}$.

Proof of the claim. The claim can be checked at the stalks at the points $x \in X$, hence we may assume that X is quasi-compact, in which case the same holds for U. Now, on the one hand, $R^qj_*j^*\mathscr{F}$ is the sheaf associated with the presheaf given by the rule : $U' \mapsto H^q(U \cap U', \mathscr{F})$ for every open subset $U' \subset X$, so $(R^qj_*j^*\mathscr{F})_x$ is also the stalk at x of this presheaf. On the other hand, x admits a fundamental system of open neighborhoods consisting of quasi-compact open subsets, and if U' is such a neighborhood of x, the subset $U' \cap U$ is also quasi-compact, and the functor $\mathscr{F} \mapsto H^q(U \cap U', \mathscr{F})$ commutes with filtered colimits, by proposition 10.1.10(ii). The claim follows by combining these two observations. ◊

In case $i \leq 1$, we argue similarly with (10.4.2), which reduces to checking that both functors $\mathscr{F} \mapsto \mathscr{F}_x$ and $\mathscr{F} \mapsto (j_*j^*\mathscr{F})_x$ commute with filtered colimits; this is trivial for the former functor, and for the latter it is a special case of claim 10.4.5.

Lastly, (ii) is an immediate consequence of (i) and remark 7.3.31(vi), since any injective $\mathscr{A}$-module is a flabby $\mathscr{B}$-module (lemma 10.1.5(v)). □

10.4.6. In the situation of (10.4.1), let X' be the amalgamated sum in the following cocartesian diagram of topological spaces :

$$\begin{array}{ccc} U & \xrightarrow{\ j\ } & X \\ {\scriptstyle j}\downarrow & & \downarrow{\scriptstyle j'_1} \\ X & \xrightarrow{\ j'_2\ } & X' \end{array}$$

and let $\pi : X' \to X$ be the unique continuous map with $\pi \circ j'_i = \mathbf{1}_X$ for $i = 1, 2$. We notice :

Proposition 10.4.7. *In the situation of* (10.4.6)*, let also* $\mathscr{F}$ *be any sheaf on* X*. Then we have :*

(i) *If* $\mathscr{F}$ *is flabby, the same holds for* $\pi^*\mathscr{F}$*.*

(ii) *If moreover* $\mathscr{F}$ *is an* $\mathscr{A}$*-module, the following holds :*

(a) *We have a natural isomorphism in* $\mathsf{D}^+(\mathscr{A}(X)\text{-}\mathbf{Mod})$ *:*

$$R\Gamma\mathscr{F} \oplus R\Gamma_Z\mathscr{F} \xrightarrow{\sim} R\Gamma(\pi^*\mathscr{F}).$$

(b) *If* X *is coherent and* Z *is constructible in* X*, then* $R^i\Gamma_Z\mathscr{F} = 0$ *for every* $i > \dim X$*.*

(c) *If X is spectral and Z is constructible in X, define $d_{\mathscr{F}}$ as in theorem* 10.1.35(ii). *Then*

$$R^i\Gamma_Z\mathscr{F} = 0 \qquad \textit{for every } i > d_{\mathscr{F}}.$$

Proof. (i): Set $V_i := j'_i(X)$ for $i = 1, 2$; then X' admits the open covering $X' = V_1 \cup V_2$, and the restriction of $\pi^*\mathscr{F}$ is flabby on V_1 and V_2. Then the assertion follows from lemma 10.1.2.

(ii.a): For $i = 1, 2$ and every $\mathscr{A}$-module $\mathscr{G}$, we have a natural isomorphism of $\mathscr{A}(X)$-modules

$$\psi_{\mathscr{G},i} : \Gamma(X, \mathscr{F}) \xrightarrow{\sim} \Gamma(V_i, \mathscr{G}).$$

Moreover, for every $(\sigma, \tau) \in \Gamma\mathscr{G} \oplus \Gamma_Z\mathscr{G}$ there exists a unique section $\varphi_{\mathscr{G}}(\sigma, \tau) \in \Gamma(\pi^*\mathscr{G})$ whose restriction to V_1 agrees with $\psi_{\mathscr{G},1}(\sigma)$ and whose restriction to V_2 agrees with $\psi_{\mathscr{G}_2}(\sigma + \tau)$ (details left to the reader). The rule $(\sigma, \tau) \mapsto \varphi_{\mathscr{G}}(\sigma, \tau)$ yields a natural isomorphism

$$\varphi_{\mathscr{G}} : \Gamma\mathscr{G} \oplus \Gamma_Z\mathscr{G} \xrightarrow{\sim} \Gamma(\pi^*\mathscr{G}).$$

Now, let $\mathscr{F} \to \mathscr{G}^\bullet$ be a resolution of $\mathscr{F}$ by a complex of injective $\mathscr{A}$-modules; by lemma 10.1.5(v), the complex $\pi^*\mathscr{G}^\bullet$ is a resolution of $\pi^*\mathscr{F}$ by flabby $\pi^*\mathscr{A}$-modules. Combining with lemma 10.4.4(i) and remark 7.3.31(vi), we deduce that $\varphi_{\mathscr{G}^\bullet} : \Gamma\mathscr{G}^\bullet \oplus \Gamma_Z\mathscr{G}^\bullet \xrightarrow{\sim} \Gamma(\pi^*\mathscr{G}^\bullet)$ is the sought natural isomorphism.

Lastly, if X is coherent (resp. spectral) and Z is constructible, the open subsets V_1 and V_2 are coherent (resp. spectral) and retro-compact in X'; by lemma 8.1.15(iv), in this case X' is coherent (resp. X' is spectral, and it is easily seen that $d_{\pi^*\mathscr{F}} = d_{\mathscr{F}}$). Then (ii.b) and (ii.c) follow directly from (ii.a) and theorem 10.1.35. □

10.4.8. In the situation of (10.1.8), suppose that the maps g and g_λ, for every $\lambda \in \mathrm{Ob}(\Lambda)$ are open immersions, and set

$$Z := X \backslash Y \qquad Z_\lambda := X_\lambda \backslash Y_\lambda \qquad \text{for every } \lambda \in \mathrm{Ob}(\Lambda).$$

Consider also a compatible system $(\mathscr{G}_\lambda \mid \lambda \in \mathrm{Ob}(\Lambda))$ of sheaves on $X_\bullet$, where $\mathscr{G}_\lambda$ is a $\mathbb{Z}_{X_\lambda}$-module for every $\lambda \in \Lambda$, with transition maps

$$\varphi_u^{-1}\mathscr{G}_\lambda \to \mathscr{G}_\mu \qquad \text{for every morphism } u : \mu \to \lambda \text{ in } \Lambda$$

and set

$$\mathscr{G} := \operatorname*{colim}_{\lambda \in \mathrm{Ob}(\Lambda)} \varphi_\lambda^*\mathscr{G}_\lambda.$$

Notice that for every $\lambda \in \mathrm{Ob}(\Lambda)$ and every morphism $u : \mu \to \lambda$ in Λ we have

$$\varphi_u^{-1}Z_\lambda \subset Z_\mu \qquad \text{and} \qquad \varphi_\lambda^{-1}Z_\lambda \subset Z.$$

There follows a system of natural morphisms

$$\tau_u : \varphi_u^*\underline{\Gamma}_{Z_\lambda}\mathscr{G}_\lambda \to \underline{\Gamma}_{Z_\mu}\mathscr{G}_\mu \qquad \text{and} \qquad \tau_\lambda : \varphi_\lambda^*\underline{\Gamma}_{Z_\lambda}\mathscr{G}_\lambda \to \underline{\Gamma}_Z\mathscr{G}$$

amounting to a co-cone $\tau_\bullet$ with vertex $\underline{\Gamma}_Z\mathscr{G}$.

Proposition 10.4.9. *In the situation of* (10.4.8)*, the co-cone $\tau_\bullet$ induces a natural isomorphism*

$$\operatorname*{colim}_{\lambda \in \mathrm{Ob}(\Lambda)} \varphi_\lambda^* \, R^i\underline{\Gamma}_{Z_\lambda}\mathscr{G}_\lambda \xrightarrow{\sim} R^i\underline{\Gamma}_Z\mathscr{G} \qquad \textit{for every } i \in \mathbb{N}.$$

Proof. From proposition 10.1.10(ii) we deduce a natural isomorphism

$$\begin{aligned}\operatorname*{colim}_{\lambda \in \mathrm{Ob}(\Lambda)} \varphi_\lambda^* \, \underline{\Gamma}_{Z_\lambda}\mathscr{G}_\lambda &= \operatorname*{colim}_{\lambda \in \mathrm{Ob}(\Lambda)} \varphi_\lambda^* \, \mathrm{Ker}\,(\mathscr{G}_\lambda \to g_{\lambda*}g_\lambda^*\mathscr{G}_\lambda) \\ &\xrightarrow{\sim} \mathrm{Ker}\,(\mathscr{G} \to g_*g^*\mathscr{G}) = \underline{\Gamma}_Z\mathscr{G}.\end{aligned}$$

Now, let us choose a compatible system of injective resolutions $\mathscr{G}_\lambda \to \mathscr{I}_\lambda^\bullet$, so that the transition maps for the system $(\mathscr{G}_\lambda \mid \lambda \in \mathrm{Ob}(\Lambda))$ extend to a system of transition morphisms of complexes $(\mathscr{I}_\lambda^\bullet \mid \lambda \in \mathrm{Ob}(\Lambda))$. On the one hand, claim 10.1.11 says that

$$\mathscr{I}^\bullet := \operatorname*{colim}_{\lambda\in\mathrm{Ob}(\Lambda)} \varphi_\lambda^* \mathscr{I}_\lambda^\bullet$$

is a qc-flabby resolution of $\mathscr{G}$. On the other hand, the foregoing yields a natural isomorphism

$$\operatorname*{colim}_{\lambda\in\mathrm{Ob}(\Lambda)} \varphi_\lambda^* R^i\underline{\Gamma}_{Z_\lambda}\mathscr{G}_\lambda \xrightarrow{\sim} H^i\underline{\Gamma}_Z\mathscr{I}^\bullet.$$

Then the assertion follows from lemma 10.4.4(iii.a). □

Corollary 10.4.10. *Let $(X,\mathscr{A})$ be a ringed topological space with X locally spectral, $Z \subset X$ a constructible closed subset, $x \in Z$ any point, and denote by $j_x : X(x) \to X$ the inclusion map (notation of definition* 8.1.44(iii)*). We have a natural isomorphism of functors*

$$j_x^* R\underline{\Gamma}_Z \xrightarrow{\sim} R\underline{\Gamma}_{Z(x)} \qquad \textit{in } \mathsf{D}^+(j_x^*\mathscr{A}\text{-}\mathbf{Mod}).$$

Proof. We may assume that X is spectral, in which case $X(x)$ is the limit of the cofiltered system of all quasi-compact open neighborhoods of x in X, and if U is any such neighborhood, the inclusion map $U \to X$ is quasi-compact and quasi-separated. The sought morphism $\varphi^\bullet$ is then deduced from a co-cone constructed as in (10.4.8), and it suffices to check that $H^i\varphi^\bullet$ is an isomorphism on the underlying $\mathbb{Z}_{X(x)}$-modules for every $i \in \mathbb{Z}$, so the assertion is reduced to proposition 10.4.9. □

10.4.11. In the situation of (10.4.1), notice the natural isomorphism of $\mathscr{A}$-modules :

$$\mathscr{H}om_{\mathbb{Z}}(i_*\mathbb{Z}_Z, \mathscr{F}) \xrightarrow{\sim} \underline{\Gamma}_Z\mathscr{F} \qquad \text{for every } \mathscr{A}\text{-module } \mathscr{F}$$

whence a natural isomorphism of $\mathscr{A}(X)$-modules :

$$\mathrm{Hom}_{\mathbb{Z}}(i_*\mathbb{Z}_Z, \mathscr{F}) \xrightarrow{\sim} \Gamma_Z\mathscr{F} \qquad \text{for every } \mathscr{A}\text{-module } \mathscr{F}.$$

Now, let $\mathfrak{U} := (U_i \mid i \in I)$ be any open covering of U, indexed by a set I, and fix any total ordering on I. By proposition 10.2.6(iv), we get natural isomorphisms in $\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$ and $\mathsf{D}^+(\mathscr{A}(X)\text{-}\mathbf{Mod})$

$$R\mathscr{H}om^\bullet_{\mathbb{Z}}(R^{\mathrm{alt}}_\bullet(\mathfrak{U})[1], K^\bullet) \xrightarrow{\sim} R\underline{\Gamma}_Z K^\bullet \qquad R\mathrm{Hom}^\bullet_{\mathbb{Z}}(R^{\mathrm{alt}}_\bullet(\mathfrak{U})[1], K^\bullet) \xrightarrow{\sim} R\Gamma_Z K^\bullet$$

for every bounded below complex $K^\bullet$ of $\mathscr{A}$-modules. These isomorphisms allow us to compute $R\Gamma_Z K^\bullet$ as a *Čech cohomology functor*, as follows. Clearly, the rule : $\mathscr{F} \mapsto C^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F})$ defines a functor $\mathscr{A}\text{-}\mathbf{Mod} \to \mathsf{C}(\mathscr{A}(X)\text{-}\mathbf{Mod})$ (notation of definition 10.2.2(ii)). Now, pick any resolution $K^\bullet \xrightarrow{\sim} \mathscr{I}^\bullet$ by a bounded below complex of injective $\mathscr{A}$-modules; the foregoing yields a natural isomorphism :

$$R\Gamma_Z K^\bullet \xrightarrow{\sim} \mathrm{Tot}\, C^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{I}^\bullet)[-1] \qquad \text{in } \mathsf{D}^+(\mathscr{A}(X)\text{-}\mathbf{Mod}).$$

10.4.12. We define a bifunctor

$$\mathscr{H}om^\bullet_Z := \underline{\Gamma}_Z \circ \mathscr{H}om^\bullet_{\mathscr{A}} : \mathsf{C}(\mathscr{A}\text{-}\mathbf{Mod}) \times \mathsf{C}(\mathscr{A}\text{-}\mathbf{Mod})^o \to \mathsf{C}(\mathscr{A}\text{-}\mathbf{Mod}).$$

The bifunctor $\mathscr{H}om^\bullet_Z$ admits a right derived functor :

$$R\mathscr{H}om^\bullet_Z : \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}) \times \mathsf{D}(\mathscr{A}\text{-}\mathbf{Mod})^o \to \mathsf{D}(\mathscr{A}\text{-}\mathbf{Mod}).$$

The construction can be outlined as follows. First, for a fixed complex $K_\bullet$ of $\mathscr{A}$-modules, one can consider the right derived functor of the functor $\mathscr{G} \mapsto \mathscr{H}om^\bullet_Z(K_\bullet, \mathscr{G})$, which is denoted $R\mathscr{H}om^\bullet_Z(K_\bullet, -) : \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}) \to \mathsf{D}(\mathscr{A}\text{-}\mathbf{Mod})$. Next, one verifies that every quasi-isomorphism $K_\bullet \to K'_\bullet$ induces an isomorphism of functors : $R\mathscr{H}om^\bullet_Z(K'_\bullet, -) \xrightarrow{\sim} R\mathscr{H}om^\bullet_Z(K_\bullet, -)$, hence the natural transformation $K_\bullet \mapsto R\mathscr{H}om^\bullet_Z(K_\bullet, -)$ factors through

$\mathsf{D}(\mathscr{A}\text{-}\mathbf{Mod})$, and this is the sought bifunctor $R\mathscr{H}om^\bullet_Z$. In case $Z = X$, one recovers the functor $R\mathscr{H}om^\bullet_\mathscr{A}$ of (10.1.13).

Lemma 10.4.13. *In the situation of* (10.4.1)*, the following holds :*

(i) *The functor $\underline{\Gamma}_Z$ is right adjoint to i_*i^*. More precisely, for any two $\mathscr{A}$-modules $\mathscr{F}$ and $\mathscr{G}$ we have natural isomorphisms :*
 (a) $\mathscr{H}om_\mathscr{A}(\mathscr{F}, \underline{\Gamma}_Z\mathscr{G}) \xrightarrow{\sim} \mathscr{H}om_\mathscr{A}(i_*i^*\mathscr{F}, \mathscr{G})$.
 (b) $R\mathscr{H}om^\bullet_\mathscr{A}(\mathscr{F}, R\underline{\Gamma}_Z\mathscr{G}) \xrightarrow{\sim} R\mathscr{H}om^\bullet_\mathscr{A}(i_*i^*\mathscr{F}, \mathscr{G})$.

(ii) *If $\mathscr{F}$ is an injective (resp. flabby) $\mathscr{A}$-module on X, then the same holds for $\underline{\Gamma}_Z\mathscr{F}$.*

(iii) *There are natural isomorphisms of bifunctors :*

$$R\mathscr{H}om^\bullet_Z \xrightarrow{\sim} R\underline{\Gamma}_Z \circ R\mathscr{H}om^\bullet_\mathscr{A} \xrightarrow{\sim} R\mathscr{H}om^\bullet_\mathscr{A}(-, R\underline{\Gamma}_Z-)$$

(iv) *If $W \subset X$ is any other closed subset, there is a natural isomorphism of functors :*

$$R\underline{\Gamma}_{W\cap Z} \xrightarrow{\sim} R\underline{\Gamma}_W \circ R\underline{\Gamma}_Z.$$

(v) *If $f : (Y, \mathscr{B}) \to (X, \mathscr{A})$ is any morphism of ringed spaces, there is a natural isomorphism of functors :*

$$Rf_* \circ R\underline{\Gamma}_{f^{-1}Z} \xrightarrow{\sim} R\underline{\Gamma}_Z \circ Rf_* : \mathsf{D}^+(\mathscr{B}\text{-}\mathbf{Mod}) \to \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}).$$

(vi) *There is a natural isomorphism of bifunctors on $\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})^o \times \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$:*

$$R\mathscr{H}om^\bullet_Z(R\underline{\Gamma}_Z-, -) \xrightarrow{\sim} R\mathscr{H}om^\bullet_\mathscr{A}(R\underline{\Gamma}_Z-, -).$$

Proof. (i): To establish the isomorphism (a), one uses the short exact sequence

$$0 \to j_!j^*\mathscr{F} \to \mathscr{F} \to i_*i^*\mathscr{F} \to 0$$

to show that any map $\mathscr{F} \to \underline{\Gamma}_Z\mathscr{G}$ factors through $\mathscr{H} := i_*i^*\mathscr{F}$. Conversely, since $j_*j^*\mathscr{H} = 0$, it is clear that every map $\mathscr{H} \to \mathscr{G}$ must factor through $\underline{\Gamma}_Z\mathscr{G}$. The isomorphism (b) is derived easily from (a) and (ii).

(iii): According to [163, Th.10.8.2], the first isomorphism in (iii) is deduced from lemmata 10.4.4(i) and 10.1.16(ii). The second isomorphism in (iii) follows from [163, Th.10.8.2], and assertion (ii) concerning injective sheaves.

(ii): Suppose first that $\mathscr{F}$ is injective; let $\mathscr{G}_1 \to \mathscr{G}_2$ a monomorphism of $\mathscr{A}$-modules and $\varphi : \mathscr{G}_1 \to \underline{\Gamma}_Z\mathscr{F}$ any $\mathscr{A}$-linear map. By (i) we deduce a map $i_*i^*\mathscr{G}_1 \to \mathscr{F}$, which extends to a map $i_*i^*\mathscr{G}_2 \to \mathscr{F}$, by injectivity of $\mathscr{F}$. Finally, (i) again yields a map $\mathscr{G}_2 \to \underline{\Gamma}_Z\mathscr{F}$ extending φ.

Next, if $\mathscr{F}$ is flabby, let $V \subset X$ be any open subset, and $s \in \underline{\Gamma}_Z\mathscr{F}(V)$; since $s_{|V\setminus Z} = 0$, we can extend s to a section $s' \in \underline{\Gamma}_Z\mathscr{F}(V \cup (X \setminus Z))$. Since $\mathscr{F}$ is flabby, s' extends to a section $s'' \in \mathscr{F}(X)$; however, by construction s'' vanishes on the complement of Z.

(iv): Clearly $\underline{\Gamma}_{W\cap Z} = \underline{\Gamma}_W \circ \underline{\Gamma}_Z$, so the claim follows easily from (ii) and [163, Th.10.8.2].

(v): Since flabby $\mathscr{B}$-modules are acyclic for f_* and $\underline{\Gamma}_{f^{-1}Z}$ (lemmata 10.1.5(ii) and 10.4.4(i)), one can apply (ii) and [163, Th.10.8.2] to identify both functors with $R(\underline{\Gamma}_Z \circ f_*)$.

(vi): Let $I^\bullet$ and $J^\bullet$ be two bounded below complexes of injective $\mathscr{A}$-modules. Clearly any morphism $\underline{\Gamma}_Z I^\bullet \to J^\bullet$ vanishes on U, whence the assertion. □

Definition 10.4.14. Let X be a topological space, and $K^\bullet \in \mathsf{D}^+(\mathbb{Z}_X\text{-}\mathbf{Mod})$.

(i) The *depth of $K^\bullet$ along Z* is

$$\mathrm{depth}_Z K^\bullet := \sup\{n \in \mathbb{Z} \mid R^i\underline{\Gamma}_Z K^\bullet = 0 \text{ for all } i < n\} \in \mathbb{Z} \cup \{+\infty\}.$$

From lemma 10.4.13(ii,iv) and the Grothendieck spectral sequence ([126, Th.5.8.3]), we see that

$$\mathrm{depth}_W K^\bullet \geq \mathrm{depth}_Z K^\bullet \qquad \text{whenever } W \subset Z. \tag{10.4.15}$$

(ii) Let $\Phi := (Z_\lambda \mid \lambda \in \Lambda)$ be a family of closed subsets of X, and suppose that Φ is cofiltered by inclusion. Due to (10.4.15) it is reasonable to define the *depth of $K^\bullet$ along* Φ as

$$\mathrm{depth}_\Phi K^\bullet := \sup\{\mathrm{depth}_{Z_\lambda} K^\bullet \mid \lambda \in \Lambda\} \in \mathbb{Z} \cup \{+\infty\}.$$

10.4.16. Let now X be a scheme and $i : Z \to X$ a closed immersion of schemes, such that Z is constructible in X. Then the open immersion $j : X\backslash Z \to X$ is quasi-compact and separated, hence the functors $R^q j_*$ preserve the subcategories of quasi-coherent modules, for every $q \in \mathbb{N}$ ([61, Ch.III, Prop.1.4.10]). In light of (10.4.3) we deduce that $R^q\underline{\Gamma}_Z$ restricts to a functor :

$$R^q\underline{\Gamma}_Z : \mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \to \mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \qquad \text{for every } q \in \mathbb{N}.$$

Lemma 10.4.17. *In the situation of* (10.4.16)*, the following holds :*

(i) *The functor $R\underline{\Gamma}_Z$ restricts to a triangulated functor :*

$$R\underline{\Gamma}_Z : \mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}} \to \mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$$

(notation of (10.3.11)*).*

(ii) *Let $f : Y \to X$ be an affine morphism of schemes, $K^\bullet$ any object of $\mathsf{D}^+(\mathscr{O}_Y\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$. Then we have the identity :*

$$\mathrm{depth}_{f^{-1}Z} K^\bullet = \mathrm{depth}_Z Rf_* K^\bullet.$$

(iii) *Let $f : Y \to X$ be a flat morphism of schemes, $K^\bullet$ any object of $\mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$. Then the natural map*

$$f^* R\underline{\Gamma}_Z K^\bullet \to R\underline{\Gamma}_{f^{-1}Z} f^* K^\bullet$$

is an isomorphism in $\mathsf{D}^+(\mathscr{O}_Y\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$. Especially, we have

$$\mathrm{depth}_{f^{-1}Z} f^* K^\bullet \geq \mathrm{depth}_Z K^\bullet$$

and if f is faithfully flat, the inequality is actually an equality.

(iv) *Let $K^\bullet$ be any object of $\mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})$, and $\mathscr{F}$ a flat quasi-coherent $\mathscr{O}_X$-module. Then the natural map*

$$\mathscr{F} \otimes_{\mathscr{O}_X} R\underline{\Gamma}_Z K^\bullet \to R\underline{\Gamma}_Z(\mathscr{F} \otimes_{\mathscr{O}_X} K^\bullet)$$

is an isomorphism in $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})$.

Proof. (i): Indeed, if $K^\bullet$ is an object of $\mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$, we have a spectral sequence :

$$E_2^{pq} := R^p\underline{\Gamma}_Z H^q K^\bullet \Rightarrow R^{p+q}\underline{\Gamma}_Z K^\bullet.$$

(This spectral sequence is obtained from a Cartan-Eilenberg resolution of $K^\bullet$: see *e.g.* [163, §5.7].) Hence $R^\bullet\underline{\Gamma}_Z K^\bullet$ admits a finite filtration whose subquotients are quasi-coherent; then the lemma follows from [61, Ch.III, Prop.1.4.17].

(ii): To start with, a spectral sequence argument as in the foregoing shows that Rf_* restricts to a functor $\mathsf{D}^+(\mathscr{O}_Y\text{-}\mathbf{Mod})_{\mathrm{qcoh}} \to \mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$, and moreover we have natural identifications : $R^i f_* K^\bullet \xrightarrow{\sim} f_* H^i K^\bullet$ for every $i \in \mathbb{Z}$ and every object $K^\bullet$ of $\mathsf{D}^+(\mathscr{O}_Y\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$. In view of lemma 10.4.13(v), we derive natural isomorphisms : $R^i\underline{\Gamma}_Z Rf_* K^\bullet \xrightarrow{\sim} Rf_* R^i\underline{\Gamma}_{f^{-1}Z} K^\bullet$ for every object $K^\bullet$ of $\mathsf{D}^+(\mathscr{O}_Y\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$. The assertion follows easily.

(iii): A spectral sequence argument as in the proof of (i) allows us to assume that $K^\bullet = \mathscr{F}[0]$ for some quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$. In this case, let $j_X : X\backslash Z \to X$ and $j_Y : Y\backslash f^{-1}Z \to Y$ be the open immersions; considering the exact sequences f^*(10.4.2) and f^*(10.4.3), we reduce to showing that the natural map $f^* Rj_{X*} j_X^* \mathscr{F} \to Rj_{Y*} j_Y^* f^* \mathscr{F}$ is an isomorphism in $\mathsf{D}^+(\mathscr{O}_Y\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$. The latter assertion follows from corollary 10.3.8.

(iv): The map in question is obtained as follows. We may assume that $K^\bullet$ is a complex of injective $\mathscr{O}_X$-modules, and let $i : \underline{\Gamma}_Z K^\bullet \to K^\bullet$ be the inclusion map; clearly $\mathscr{F} \otimes_{\mathscr{O}_X} i$ factors through the inclusion map $\underline{\Gamma}_Z(\mathscr{F} \otimes_{\mathscr{O}_X} K^\bullet) \to \mathscr{F} \otimes_{\mathscr{O}_X} K^\bullet$, whence the sought map

$\omega_{\mathscr{F}} : \mathscr{F} \otimes_{\mathscr{O}_X} \underline{\Gamma}_Z K^\bullet \to \underline{\Gamma}_Z(\mathscr{F} \otimes_{\mathscr{O}_X} K^\bullet)$. Now, the assertion is local on X, hence we may assume that $X = \mathrm{Spec}\, A$ for some ring A, and $\mathscr{F} = F^\sim$ for some flat A-module F. Then F is the colimit of a filtered system $(L_\lambda \mid \lambda \in \Lambda)$ of free A-modules of finite rank ([120, Ch.I, Th.1.2]), and by virtue of lemma 10.4.4(iii.b), the map $\omega_{\mathscr{F}}$ is the colimit of the system of induced maps $(\omega_{L_\lambda^\sim} \mid \lambda \in \Lambda)$. Thus, we are reduced to the case where F is a free A-module of finite rank, in which case the assertion is clear. □

Proposition 10.4.18. *Let X be an affine scheme, $Z \subset X$ any closed subset, $\mathscr{F}^\bullet$ a bounded below complex of quasi-coherent $\mathscr{O}_X$-modules, and $\mathfrak{U} := (U_t \mid t \in I)$ a family of affine open subsets of X such that $\bigcup_{t\in I} U_t = X \setminus Z$. There exists a natural isomorphism*

$$R\Gamma_Z \mathscr{F}^\bullet \xrightarrow{\sim} \mathrm{Tot}\, C^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}^\bullet)[-1] \qquad \textit{in } \mathsf{D}^+(\mathscr{O}_X(X)\text{-}\mathbf{Mod})$$

(where $C^\bullet_{\mathrm{alt}}$ denotes the augmented alternating Čech complex).

Proof. Pick any resolution $\mathscr{F}^\bullet \xrightarrow{\sim} \mathscr{I}^\bullet$ by a bounded below complex of injective $\mathscr{O}_X$-modules; by virtue of (10.4.11) it suffices to show that the natural map of double complexes

$$C^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}^\bullet) \to C^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{I}^\bullet)$$

induces a quasi-isomorphism on total complexes. To this aim, we can argue as in the proof of theorem 10.2.28(ii) : the details shall be left to the reader (the condition that X is affine, is needed here, since we are dealing with the augmented Čech complex, whereas in the proof of theorem 10.2.28(ii) only the ordinary version intervenes, so for the proof of the latter it is only required that the intersection of any finite system of members of $\mathfrak{U}$ is affine). □

10.4.19. Let X be a scheme; for every $x \in X$, we consider the cofiltered family $\Phi(x)$ of all non-empty constructible closed subsets of $X(x) := \mathrm{Spec}\, \mathscr{O}_{X,x}$; clearly $\bigcap_{Z\in\Phi(x)} Z = \{x\}$. Let $K^\bullet$ be any object of $\mathsf{D}^+(\mathbb{Z}_X\text{-}\mathbf{Mod})$; we are interested in the quantities :

$$\delta(x, K^\bullet) := \mathrm{depth}_{\{x\}} K^\bullet(x) \qquad \text{and} \qquad \delta'(x, K^\bullet) := \mathrm{depth}_{\Phi(x)} K^\bullet(x)$$

(notation of definition 4.9.17(iii)). Especially, we wish to compute the depth of a complex $K^\bullet$ along a closed subset $Z \subset X$, in terms of the local invariants $\delta(x, K^\bullet)$ or $\delta'(x, K^\bullet)$, evaluated at the points $x \in Z$. This shall be achieved by theorem 10.4.21. To begin with, we remark :

Lemma 10.4.20. *With the notation of* (10.4.19)*, we have :*

(i) $\delta(x, K^\bullet) \geq \delta'(x, K^\bullet)$ *for every $x \in X$ and every $K^\bullet \in \mathrm{Ob}(\mathsf{D}^+(\mathbb{Z}_X\text{-}\mathbf{Mod}))$.*
(ii) *If the topological space $|X|$ underlying X is locally noetherian, the inequality of* (i) *is actually an equality.*
(iii) *If $\mathscr{F}$ is a flat quasi-coherent $\mathscr{O}_X$-module, then $\delta'(x, \mathscr{F}) \geq \delta'(x, \mathscr{O}_X)$.*

Proof. (i) follows easily from (10.4.15). Likewise, (ii) follows likewise from (10.4.15) and the fact that if $|X|$ is locally noetherian, $\{x\}$ is the smallest element of the family $\Phi(x)$.

(iii): According to [120, Ch.I, Th.1.2], the $\mathscr{O}_{X(x)}$-module $\mathscr{F}(x)$ is the colimit of a filtered system $(\mathscr{L}_\lambda \mid \lambda \in \Lambda)$ of free $\mathscr{O}_{X(x)}$-modules of finite rank. In view of lemma 10.4.4(iii.b), it is easily seen that

$$\mathrm{depth}_Z \mathscr{F} \geq \inf_{\lambda\in\Lambda} \mathrm{depth}_Z \mathscr{L}_\lambda = \mathrm{depth}_Z \mathscr{O}_X$$

for every closed constructible subset $Z \subset X$. The assertion follows. □

Theorem 10.4.21. *With the notation of* (10.4.19)*, let $Z \subset X$ be any closed constructible subset, $K^\bullet$ any object of* $\mathsf{D}^+(\mathbb{Z}_X\text{-}\mathbf{Mod})$*. Then*

$$\mathrm{depth}_Z K^\bullet = \inf \{\delta(x, K^\bullet) \mid x \in Z\} = \inf \{\delta'(x, K^\bullet) \mid x \in Z\}.$$

Proof. Let $d := \mathrm{depth}_Z K^\bullet$; in light of corollary 10.4.10, it is clear that $\delta(x, K^\bullet) \geq d$ for all $x \in Z$, hence, in order to prove the first identity it suffices to show :

Claim 10.4.22. Suppose $d < +\infty$. Then there exists $x \in Z$ such that $R^d\Gamma_{\{x\}}K^\bullet(x) \neq 0$.

Proof of the claim. By definition of d, we can find an open subset $V \subset X$ and a non-zero section $s \in \Gamma(V, R^d\underline{\Gamma}_Z K^\bullet)$. The support of s is a closed subset $S \subset Z$. Let x be a maximal point of S. From lemma 10.4.13(iv) we deduce a spectral sequence

$$E_2^{pq} := R^p\underline{\Gamma}_{\{x\}}R^q\underline{\Gamma}_{Z\cap X(x)}K^\bullet(x) \Rightarrow R^{p+q}\underline{\Gamma}_{\{x\}}K^\bullet(x)$$

and corollary 10.4.10 implies that $E_2^{pq} = 0$ whenever $q < d$, therefore :

$$R^d\underline{\Gamma}_{\{x\}}K^\bullet(x) \simeq R^0\underline{\Gamma}_{\{x\}}R^d\underline{\Gamma}_{Z\cap X(x)}K^\bullet(x).$$

However, the image of s in $R^d\underline{\Gamma}_{Z\cap X(x)}K^\bullet(x)$ is supported precisely at x, as required. ◇

Finally, since Z is constructible, $Z \cap X(x) \in \Phi(x)$ for every $x \in X$, hence $\delta'(x, K^\bullet) \geq d$. Then the second identity follows from the first and lemma 10.4.20(i). □

Corollary 10.4.23. *Let $Z \subset X$ be a closed and constructible subset, $\mathscr{F}$ a $\mathbb{Z}_X$-module, and $j : X\setminus Z \to X$ the induced open immersion. Then the natural map $\mathscr{F} \to j_*j^*\mathscr{F}$ is an isomorphism if and only if $\delta(x, \mathscr{F}) \geq 2$, if and only if $\delta'(x, \mathscr{F}) \geq 2$ for every $x \in Z$.* □

10.4.24. Let now X be an affine scheme, say $X := \mathrm{Spec}\, A$ for some ring A, and $Z \subset X$ a constructible closed subset. In this case, we wish to show that the depth of a complex of quasi-coherent $\mathscr{O}_X$-modules along Z can be computed in terms of Ext functors on the category of A-modules. This is the content of the following :

Proposition 10.4.25. *In the situation of* (10.4.24)*, let N be any finitely presented A-module such that* $\mathrm{Supp}\, N = Z$*, and $M^\bullet$ any bounded below complex of A-modules. Then :*

$$\mathrm{depth}_Z M^{\bullet\sim} = \sup\{n \in \mathbb{Z} \mid \mathrm{Ext}^j_A(N, M^\bullet) = 0 \textit{ for all } j < n\}.$$

Proof. ($M^{\bullet\sim}$ is the complex of quasi-coherent $\mathscr{O}_X$-modules determined by $M^\bullet$, as in (10.3)).

Claim 10.4.26. There is a natural isomorphism in $\mathsf{D}^+(A\text{-}\mathbf{Mod})$:

$$R\mathrm{Hom}^\bullet_A(N, M^\bullet) \xrightarrow{\sim} R\mathrm{Hom}^\bullet_{\mathscr{O}_X}(N^\sim, R\underline{\Gamma}_Z M^{\bullet\sim}).$$

Proof of the claim. Let $i : Z \to X$ be the closed immersion. The assumption on N implies that $N^\sim = i_*i^*N^\sim$; hence lemma 10.4.13(i.b) yields a natural isomorphism

$$(10.4.27) \qquad R\mathrm{Hom}^\bullet_{\mathscr{O}_X}(N^\sim, M^{\bullet\sim}) \xrightarrow{\sim} R\mathrm{Hom}^\bullet_{\mathscr{O}_X}(N^\sim, R\underline{\Gamma}_Z M^{\bullet\sim}).$$

The claim follows by combining corollary 10.3.2(i) and (10.4.27). ◇

From claim 10.4.26 we see already that $\mathrm{Ext}^j_A(N, M^\bullet) = 0$ whenever $j < \mathrm{depth}_Z M^{\bullet\sim}$. Suppose that $\mathrm{depth}_Z M^{\bullet\sim} = p < +\infty$; in this case, claim 10.4.26 gives an isomorphism :

$$\mathrm{Ext}^p_A(N, M^\bullet) \simeq \mathrm{Hom}_{\mathscr{O}_X}(N^\sim, R^p\underline{\Gamma}_Z M^{\bullet\sim}) \simeq \mathrm{Hom}_A(N, R^p\Gamma_Z M^{\bullet\sim})$$

where the last isomorphism holds by lemma 10.4.17. To conclude the proof, we have to exhibit a non-zero map from N to $Q := R^p\Gamma_Z M^{\bullet\sim}$. Let $F_0(N) \subset A$ denote the Fitting ideal of N; this is a finitely generated ideal, whose zero locus coincides with the support of N. More precisely, $\mathrm{Ann}_A(N)^r \subset F_0(N) \subset \mathrm{Ann}_A(N)$ for all sufficiently large integers $r > 0$. Let now $x \in Q$ be any non-zero element, and $f_1, \dots, f_k$ a finite system of generators for $F_0(N)$; since x vanishes on $X\setminus Z$, the image of x in Q_{f_i} is zero for every $i \leq k$, *i.e.* there exists $n_i \geq 0$ such that $f_i^{n_i}x = 0$ in Q. It follows easily that $F_0(N)^n \subset \mathrm{Ann}_A(x)$ for a sufficiently large integer n, and therefore x defines a map $\varphi : A/F_0(N)^n \to Q$ by the rule : $a \mapsto ax$. According to [75, Lemma 3.2.21], we can find a finite filtration $0 = J_m \subset \cdots \subset J_1 \subset J_0 := A/F_0(N)^n$ such that each J_i/J_{i+1} is quotient of a direct sum of copies of N. Let $s \leq m$ be the smallest integer such that $J_s \subset \mathrm{Ker}\,\varphi$. By restriction, φ induces a non-zero map $J_{s-1}/J_s \to Q$, whence a non-zero map $N^{(S)} \to Q$, for some set S, and finally a non-zero map $N \to Q$, as required. □

Remark 10.4.28. Notice that the existence of a finitely presented A-module N with $\mathrm{Supp}\, N = Z$ is equivalent to the constructibility of Z.

10.4.29. In the situation of (10.4.24), let $I \subset A$ be a finitely generated ideal such that $V(I) = Z$, and $M^\bullet$ a bounded below complex of A-modules. Then it is customary to set :

$$\mathrm{depth}_I M^\bullet := \mathrm{depth}_Z M^{\bullet\sim}$$

and the depth along Z of $M^{\bullet\sim}$ is also called the *I-depth* of $M^\bullet$. Moreover, if A is a local ring with maximal ideal $\mathfrak{m}_A$, we shall often use the standard notation :

$$\mathrm{depth}_A M^\bullet := \mathrm{depth}_{\{\mathfrak{m}_A\}} M^{\bullet\sim}$$

and this invariant is often called briefly the *depth* of $M^\bullet$. With this notation, theorem 10.4.21 can be rephrased as the identity :

$$\mathrm{depth}_I M^\bullet = \inf_{\mathfrak{p}\in V(I)} \mathrm{depth}_{A_\mathfrak{p}} M^\bullet_\mathfrak{p}. \qquad (10.4.30)$$

10.4.31. *Depth sensitivity of the Koszul complex.* Let now $\mathbf{f} := (f_1, \dots, f_r)$ be a finite system of generators of the ideal $I \subset A$, and $Z := \mathrm{Spec}\, A/I$. In this generality, the Koszul complex $\mathbf{K}^\bullet(\mathbf{f})$ of remark 7.8.1(ii) is not a resolution of the A-module A/I, and thus $H^\bullet(\mathbf{f}, M)$ (for an A-module M) does not necessarily agree with $\mathrm{Ext}^\bullet_A(A/I, M)$. Nevertheless, we have :

Proposition 10.4.32. (i) *In the situation of* (10.4.31), *let* $M^\bullet \in \mathrm{Ob}(\mathsf{D}^+(A\text{-}\mathbf{Mod}))$*; then :*

$$\mathrm{depth}_I M^\bullet = d := \sup\{i \in \mathbb{Z} \mid H^j(\mathbf{f}, M^\bullet) = 0 \textit{ for all } j < i\}.$$

(ii) *If* $d < +\infty$*, there are natural A-linear isomorphisms :*

$$H^d(\mathbf{f}, M^\bullet) \xrightarrow{\sim} \mathrm{Hom}_A(A/I, R^d\Gamma_Z M^{\bullet\sim}) \xrightarrow{\sim} \mathrm{Ext}^d_A(A/I, M^\bullet).$$

(iii) *Moreover we have a natural isomorphism in* $\mathsf{D}(A\text{-}\mathbf{Mod})$ *:*

$$\operatorname*{colim}_{m\in\mathbb{N}} \mathbf{K}^\bullet(\mathbf{f}^m, M^\bullet) \xrightarrow{\sim} R\Gamma_Z M^{\bullet\sim}$$

where the transition maps in the colimit are the maps $\boldsymbol{\varphi}^\bullet_{\mathbf{f}^n}$ *of* (7.8.20).

Proof. (i): Let $B := \mathbb{Z}[t_1, \dots, t_r] \to A$ be the ring homomorphism defined by the rule : $t_i \mapsto f_i$ for $i = 1, \dots, r$; we denote $\psi : X \to Y := \mathrm{Spec}\, B$ the induced morphism, $J \subset B$ the ideal generated by the system $\mathbf{t} := (t_i \mid i = 1, \dots, r)$, and set $W := V(J) \subset Y$. From lemma 10.4.13(v) we deduce a natural isomorphism in $\mathsf{D}(\mathscr{O}_Y\text{-}\mathbf{Mod})$:

$$\psi_* R\underline{\Gamma}_Z M^{\bullet\sim} \xrightarrow{\sim} R\underline{\Gamma}_W \psi_* M^{\bullet\sim}. \qquad (10.4.33)$$

Hence we are reduced to showing :

Claim 10.4.34. $d = \mathrm{depth}_J \psi_* M^\bullet$.

Proof of the claim. Notice that $\mathbf{t}$ is a regular sequence in B, hence $\mathrm{Ext}^\bullet_B(B/J, \psi_* M^\bullet) \simeq H^\bullet(\mathbf{t}, \psi_* M^\bullet)$; by proposition 10.4.25, there follows the identity :

$$\mathrm{depth}_J \psi_* M^\bullet = \sup\{n \in \mathbb{N} \mid H^i(\mathbf{t}, \psi_* M^\bullet) = 0 \text{ for all } i < n\}.$$

Then the assertion follows from lemma 7.8.2(iv). ◊

(ii): From lemma 10.4.13(i.b) and corollary 10.3.2(i) we derive a natural isomorphism :

$$R\mathrm{Hom}^\bullet_B(B/J, \psi_* M^\bullet) \xrightarrow{\sim} R\mathrm{Hom}^\bullet_{\mathscr{O}_Y}((B/J)^\sim, R\underline{\Gamma}_W \psi_* M^{\bullet\sim}).$$

However, due to (10.4.33) and claim 10.4.34 we may compute :

$$R^d\mathrm{Hom}^\bullet_{\mathscr{O}_Y}((B/J)^\sim, R\underline{\Gamma}_W \psi_* M^{\bullet\sim}) \xrightarrow{\sim} \mathrm{Hom}_B(B/J, R^d\Gamma_W \psi_* M^{\bullet\sim}) \xrightarrow{\sim} \mathrm{Hom}_A(A/I, R^d\Gamma_Z M^{\bullet\sim}).$$

The first claimed isomorphism easily follows. Similarly, one applies lemma 10.4.13(i.b) and corollary 10.3.2(i) to compute $\mathrm{Ext}^\bullet_A(A/I, M^\bullet)$, and deduces the second isomorphism of (ii) using (i). Assertion (iii) follows immediately from (10.2.27) and proposition 10.4.18. □

Corollary 10.4.35. *Let A be a noetherian ring, $I \subset A$ an ideal, $M^\bullet$ an object of $\mathsf{D}^+(A\text{-}\mathbf{Mod})$, and set $Z := \mathrm{Spec}\, A/I$. We have a natural isomorphism*

$$\operatorname*{colim}_{n\in\mathbb{N}} R^i\mathrm{Hom}^\bullet_A(A/I^n, M^\bullet) \xrightarrow{\sim} R^i\Gamma_Z M^{\bullet\sim} \qquad \textit{for every } i \in \mathbb{Z}.$$

Proof. This is obtained by combining proposition 10.4.32(iii) and remark 7.8.45. □

Corollary 10.4.36. *Let A be a noetherian ring, M an A-module, and $\mathbf{f} := (f_1, \dots, f_r)$ a finite sequence of elements of A that generates an ideal $I \subset A$. Suppose that :*

(a) $\mathrm{depth}_{A_\mathfrak{p}}(M_\mathfrak{p}) \geq r$ *for every* $\mathfrak{p} \in Z := \mathrm{Spec}\, A/I$.
(b) *Z has pure codimension r in* $\mathrm{Spec}\, A$.

Then $H^i(\mathbf{f}, M) = 0$ for every $i < r$, and for every $\mathfrak{p} \in Z$ we have :

$$\mathrm{depth}_{A_\mathfrak{p}}(M_\mathfrak{p}/IM_\mathfrak{p}) = \mathrm{depth}_{A_\mathfrak{p}}(M_\mathfrak{p}) - r \qquad \textit{and} \qquad \dim A_\mathfrak{p}/I_\mathfrak{p} = \dim(A_\mathfrak{p}) - r.$$

Proof. The stated vanishing for $H^i(\mathbf{f}, M)$ follows immediately from (10.4.30) and proposition 10.4.32(i). Next, we have $\dim A_\mathfrak{p}/I_\mathfrak{p} \geq \dim(A_\mathfrak{p}) - r$ for every $\mathfrak{p} \in Z$, by [126, Th.13.6(ii)], and the opposite inequality follows easily from (b).

For a given $\mathfrak{p} \in Z$, set $\delta_\mathfrak{p} := \mathrm{depth}_{A_\mathfrak{p}} M_\mathfrak{p}$; pick a sequence $\mathbf{f}' := (f_{r+1}, \dots, f_{r+n})$ in A whose image in $A_\mathfrak{p}$ generates $\mathfrak{p}A_\mathfrak{p}$, and set $\mathbf{f}'' := (f_1, \dots, f_{r+n})$ and $\overline{M} := M/IM$. By proposition 10.4.32(i) and lemma 7.8.2(vi), if $\delta_\mathfrak{p} = +\infty$, we have $H_i(\mathbf{f}'', M_\mathfrak{p}) = 0$ for every $i \in \mathbb{N}$, and otherwise $r \leq \delta_\mathfrak{p} \leq n$, and we have

$$H_{n+r-\delta_\mathfrak{p}}(\mathbf{f}'', M_\mathfrak{p}) \neq 0 \qquad \text{and} \qquad H_i(\mathbf{f}'', M_\mathfrak{p}) = 0 \qquad \text{for every } i > n + r - \delta_\mathfrak{p}.$$

By the same token, $H_i(\mathbf{f}, M_\mathfrak{p}) = 0$ for every $i > 0$, *i.e.* the natural map $\mathbf{K}_\bullet(\mathbf{f}, M_\mathfrak{p}) \to \overline{M}_\mathfrak{p}[0]$ is an isomorphism in $\mathsf{D}(A_\mathfrak{p}\text{-}\mathbf{Mod})$, so we get isomorphisms :

$$\mathbf{K}_\bullet(\mathbf{f}'', M_\mathfrak{p}) \xrightarrow{\sim} \mathbf{K}_\bullet(\mathbf{f}')\otimes_{A_\mathfrak{p}}\mathbf{K}_\bullet(\mathbf{f}, M_\mathfrak{p}) \xrightarrow{\sim} \mathbf{K}_\bullet(\mathbf{f}')\otimes_{A_\mathfrak{p}}\overline{M}_\mathfrak{p}[0] = \mathbf{K}_\bullet(\mathbf{f}', \overline{M}_\mathfrak{p}) \qquad \text{in } \mathsf{D}(A_\mathfrak{p}\text{-}\mathbf{Mod}).$$

Summing up, we see that, if $\delta_\mathfrak{p} = +\infty$, then $H_i(\mathbf{f}', \overline{M}_\mathfrak{p}) = 0$ for every $i \in \mathbb{N}$, and otherwise :

$$H^j(\mathbf{f}', \overline{M}_\mathfrak{p}) = H_{n-j}(\mathbf{f}', \overline{M}_\mathfrak{p}) = H_{n-j}(\mathbf{f}'', M_\mathfrak{p}) = 0 \qquad \text{whenever } n - j > n + r - \delta_\mathfrak{p}$$

and $H^{\delta_\mathfrak{p}-r}(\mathbf{f}', \overline{M}_\mathfrak{p}) = H_{n+r-\delta_\mathfrak{p}}(\mathbf{f}', \overline{M}_\mathfrak{p}) \neq 0$, which implies that $\mathrm{depth}_{A_\mathfrak{p}}(\overline{M}_\mathfrak{p}) = \delta_\mathfrak{p} - r$, again by proposition 10.4.32(i). □

Corollary 10.4.37. *In the situation of* (10.4.29)*, let B be a faithfully flat A-algebra. Then :*

$$\mathrm{depth}_{IB} B \otimes_A M^\bullet = \mathrm{depth}_I M^\bullet.$$

Proof. It is a special case of lemma 10.4.17(iii). Alternatively, one remarks that

$$\mathbf{K}^\bullet(\mathbf{g}, M^\bullet \otimes_A B) \simeq \mathbf{K}^\bullet(\mathbf{g}, M^\bullet) \otimes_A B \qquad \text{for every finite sequence of elements } \mathbf{g} \text{ in } A$$

which allows us to apply proposition 10.4.32(iii). □

Theorem 10.4.38. *Let $A \to B$ be a local homomorphism of local rings, and suppose that the maximal ideals $\mathfrak{m}_A$ and $\mathfrak{m}_B$ of A and B are finitely generated. Let also M be an A-module and N a B-module which is flat over A. Then we have :*

$$\mathrm{depth}_B(M \otimes_A N) = \mathrm{depth}_A M + \mathrm{depth}_{B/\mathfrak{m}_A B}(N/\mathfrak{m}_A N).$$

Proof. Let $\mathbf{f} := (f_1, \dots, f_r)$ and $\overline{\mathbf{g}} := (\overline{g}_1, \dots, \overline{g}_s)$ be finite systems of generators for $\mathfrak{m}_A$ and respectively $\overline{\mathfrak{m}}_B$, the maximal ideal of $B/\mathfrak{m}_A B$. We choose an arbitrary lifting of $\overline{\mathbf{g}}$ to a finite system $\mathbf{g}$ of elements of $\mathfrak{m}_B$; then $(\mathbf{f}, \mathbf{g})$ is a system of generators for $\mathfrak{m}_B$. We have a natural identification of complexes of B-modules :

$$\mathbf{K}_\bullet(\mathbf{f}, \mathbf{g}) \xrightarrow{\sim} \mathrm{Tot}_\bullet(\mathbf{K}_\bullet(\mathbf{f}) \otimes_A \mathbf{K}_\bullet(\mathbf{g}))$$

whence natural isomorphisms :

$$\mathbf{K}^\bullet((\mathbf{f}, \mathbf{g}), M \otimes_A N) \xrightarrow{\sim} \mathrm{Tot}^\bullet(\mathbf{K}^\bullet(\mathbf{f}, M) \otimes_A \mathbf{K}^\bullet(\mathbf{g}, N)).$$

A standard spectral sequence, associated with the filtration by rows, converges to the cohomology of this total complex, and since N is a flat A-module, $\mathbf{K}^\bullet(\mathbf{g}, N)$ is a complex of flat A-modules, so that the E_1 term of this spectral sequence is found to be :

$$E_1^{pq} \simeq H^q(\mathbf{f}, M) \otimes_A \mathbf{K}^p(\mathbf{g}, N)$$

and the differentials $d_1^{pq} : E_1^{pq} \to E_1^{p+1,q}$ are induced by the differentials of the complex $\mathbf{K}^\bullet(\mathbf{g}, N)$. Set $\kappa_A := A/\mathfrak{m}_A$; notice that $H^q(\mathbf{f}, M)$ is a κ_A-vector space, hence

$$H^q(\mathbf{f}, M) \otimes_A H^\bullet(\mathbf{g}, N) \simeq H^\bullet(H^q(\mathbf{f}, M) \otimes_{\kappa_A} \mathbf{K}^\bullet(\overline{\mathbf{g}}, N/\mathfrak{m}_A N))$$

and consequently :

$$E_2^{pq} \simeq H^q(\mathbf{f}, M) \otimes_{\kappa_A} H^p(\overline{\mathbf{g}}, N/\mathfrak{m}_A N).$$

Especially :

(10.4.39) $\qquad E_2^{pq} = 0$ if either $p < d := \mathrm{depth}_A M$ or $q < d' := \mathrm{depth}_{B/\mathfrak{m}_A B}(N/\mathfrak{m}_A N)$.

Hence $H^i((\mathbf{f}, \mathbf{g}), M \otimes_A N) = 0$ for all $i < d + d'$ and moreover, if d and d' are finite, $H^{d+d'}((\mathbf{f}, \mathbf{g}), M \otimes_A N) \simeq E_2^{dd'} \neq 0$. Now the sought identity follows readily from proposition 10.4.32(i). $\square$

Remark 10.4.40. Let d and d' be as in (10.4.39), and suppose that d and d' are finite. By inspection of the proof, we see that – under the assumptions of theorem 10.4.38 – a natural isomorphism has been exhibited :

$$\mathrm{Ext}_A^{d+d'}(B/\mathfrak{m}_B, M \otimes_A N) \simeq \mathrm{Ext}_A^d(A/\mathfrak{m}_A, M) \otimes_A \mathrm{Ext}_{B/\mathfrak{m}_A B}^{d'}(B/\mathfrak{m}_B, N/\mathfrak{m}_A N).$$

Definition 10.4.41. Let $(A, \mathfrak{m})$ be a local ring, and $M_\bullet \in \mathrm{Ob}(\mathsf{D}^b(A\text{-}\mathbf{Mod}))$. The *residual Tor dimension* of $M_\bullet$ is $\mathrm{rTor.dim}_A(M_\bullet) := \sup\{i \in \mathbb{Z} \mid H_i(M_\bullet \overset{\mathbf{L}}{\otimes}_A A/\mathfrak{m}) \neq 0\} \in \mathbb{Z} \cup \{\pm\infty\}$.

Remark 10.4.42. (i) If A is a noetherian local ring, and M is any A-module of finite type, then $\mathrm{rTor.dim}_A(M)$ equals the projective dimension of M : see [126, §19, Lemma 1].

(ii) Our next result generalizes [15, Th.4.1].

Theorem 10.4.43. *Let A be a local noetherian ring, and $M_\bullet \in \mathrm{Ob}(\mathsf{D}^b(A\text{-}\mathbf{Mod}))$. Then :*

(i) $\mathrm{depth}_A(M_\bullet) = +\infty$ *if and only if* $\mathrm{rTor.dim}_A(M_\bullet) = -\infty$.

(ii) *If* $\mathrm{rTor.dim}_A(M_\bullet) \in \mathbb{Z}$, *we have the* Auslander-Buchsbaum identity *:*

$$\mathrm{depth}_A(M_\bullet) + \mathrm{rTor.dim}_A(M_\bullet) = \mathrm{depth}_A A.$$

Proof. (ii): Let $d := \dim A$, and pick a *system of parameters* $\mathbf{f}$ of A, *i.e.* a sequence $(f_1, \dots, f_d)$ of d elements of A that generates a primary ideal. Using a Cartan-Eilenberg resolution of the Koszul complex $\mathbf{K}_\bullet(\mathbf{f})$ (see remark 7.8.1(ii)), we get a spectral sequence (see [163, §5.7])

$$E^2_{pq} := H_p(M_\bullet \overset{\mathbf{L}}{\otimes}_A H_q(\mathbf{f}, A)) \Rightarrow H_{p+q}(\mathbf{f}, M_\bullet).$$

Now, by proposition 10.4.32(i) and lemma 7.8.2(v), we have :

$$\mathrm{depth}_A A = d - e_A \quad \text{where } e_A := \inf\{i \in \mathbb{Z} \mid H_j(\mathbf{f}, A) = 0 \text{ for all } i > j\}$$

$$\mathrm{depth}_A M_\bullet = d - e_{M_\bullet} \quad \text{where } e_{M_\bullet} := \inf\{i \in \mathbb{Z} \mid H_j(\mathbf{f}, M_\bullet) = 0 \text{ for all } i > j\}.$$

Thus, we have to show that if $t_{M_\bullet} := \mathrm{rTor.dim}_A(M_\bullet) \in \mathbb{Z}$, then

$$e_{M_\bullet} = e_A + t_{M_\bullet}. \tag{10.4.44}$$

Claim 10.4.45. For every A-module $N \neq 0$ of finite length, we have :

$$H_{t_{M_\bullet}}(M_\bullet \overset{\mathbf{L}}{\otimes} N) \neq 0 \qquad \text{and} \qquad H_i(M_\bullet \overset{\mathbf{L}}{\otimes} N) = 0 \qquad \text{for every } i > t_{M_\bullet}.$$

Proof of the claim. There exists a finite filtration $0 := N_0 \subset N_1 \subset \cdots \subset N_{n-1} \subset N_n := N$ such that N_{i+1}/N_i is isomorphic to $A/\mathfrak{m}$ for $i = 0, \dots, n-1$. Hence, by a simple induction on the length n of the filtration, we are reduced to checking the following assertion : let $\Sigma_\bullet := (0 \to N' \to N \to A/\mathfrak{m} \to 0)$ be a short exact sequence of A-modules of finite length. The induced map $H_i(M_\bullet \overset{\mathbf{L}}{\otimes}_A N') \to H_i(M_\bullet \overset{\mathbf{L}}{\otimes}_A N)$ is an isomorphism for every $i \geq t_{M_\bullet}$. The latter follows easily, y considering the long exact homology sequence induced by the short exact sequence of complexes $M_\bullet \overset{\mathbf{L}}{\otimes}_A \Sigma_\bullet$. ◊

Now, since A is noetherian and $\mathbf{f}$ generates a primary ideal, $H_q(\mathbf{f}, A)$ is a module of finite length for every $q \in \mathbb{N}$ (lemma 7.8.2(i)). Claim 10.4.45 implies that $0 \neq E^2_{t_{M_\bullet}, e_A}$, and $E^2_{pq} = 0$ whenever either $p > t_{M_\bullet}$ or $q > e_A$, so that $E^2_{t_{M_\bullet}, e_A} = E^\infty_{t_{M_\bullet}, e_A}$, whence (10.4.44).

(i): If $t_{M_\bullet} \in \mathbb{Z}$, then (10.4.44) implies that $e_{M_\bullet} \in \mathbb{Z}$, since $e_A \in \mathbb{N}$; then in this case $\mathrm{depth}_A M_\bullet \in \mathbb{Z}$. If $t_{M_\bullet} = -\infty$, claim 10.4.45 says that $E^2_{pq} = 0$ for every $p, q \in \mathbb{Z}$, whence $H_i(\mathbf{f}, M) = 0$ for every $i \in \mathbb{Z}$, *i.e.* $\mathrm{depth}_A(M_\bullet) = +\infty$. Lastly, by proposition 10.4.32(iii), this condition holds if and only if $\mathrm{colim}_{m\in\mathbb{N}}\, \mathbf{K}^\bullet(\mathbf{f}^m, M^\bullet) = 0$ in $\mathsf{D}^b(A\text{-}\mathbf{Mod})$. Set

$$K_\bullet := \operatorname*{colim}_{m\in\mathbb{N}} \mathbf{K}_\bullet(\mathbf{f}^m) \qquad T_{m,\bullet} := t^{\leq -1}\mathbf{K}_\bullet(\mathbf{f}^m) \quad \text{for every } m \in \mathbb{N} \qquad T_\bullet := \operatorname*{colim}_{m\in\mathbb{N}} T_{m,\bullet}.$$

Then, in turn the latter means that $M^\bullet \otimes_A K_\bullet = 0$ in $\mathsf{D}^b(A\text{-}\mathbf{Mod})$ (lemma 7.8.2(v)). Set $k := A/\mathfrak{m}$; the short exact of complexes $0 \to A[0] \to K_\bullet \to T_\bullet \to 0$ induces a distinguished triangle in $\mathsf{D}^-(A\text{-}\mathbf{Mod})$:

$$M_\bullet \overset{\mathbf{L}}{\otimes}_A k[0] \to M_\bullet \overset{\mathbf{L}}{\otimes}_A K_\bullet \overset{\mathbf{L}}{\otimes}_A k[0] \to M_\bullet \overset{\mathbf{L}}{\otimes}_A T_\bullet \overset{\mathbf{L}}{\otimes}_A k[0] \to M_\bullet \overset{\mathbf{L}}{\otimes}_A k[1].$$

Notice that the transition maps $T_{m,\bullet} \to T_{m+1,\bullet}$ induce the zero maps $T_{m,\bullet} \otimes_A k \to T_{m+1,\bullet} \otimes_A k$ for every $m \in \mathbb{N}$; hence $T_\bullet \overset{\mathbf{L}}{\otimes}_A k[0] = 0$ in $\mathsf{D}(A\text{-}\mathbf{Mod})$, and therefore $M_\bullet \overset{\mathbf{L}}{\otimes}_A T_\bullet \overset{\mathbf{L}}{\otimes}_A k[0] = 0$ as well. Summing up, we conclude that if $\mathrm{depth}_A M_\bullet = +\infty$, then $M_\bullet \overset{\mathbf{L}}{\otimes}_A k[0] = 0$ in $\mathsf{D}(A\text{-}\mathbf{Mod})$, *i.e.* $t_{M^\bullet} = -\infty$. □

10.4.46. Let $f : X \to S$ be any morphism of schemes. Recall that an $\mathscr{O}_X$-module $\mathscr{F}$ is said to be *f-flat at a point* $x \in X$ if $\mathscr{F}_x$ is a flat $\mathscr{O}_{S,f(x)}$-module. We say that $\mathscr{F}$ is *f-flat over a point* $s \in S$ if $\mathscr{F}$ is f-flat at all points of $f^{-1}(s)$. Finally, we say that $\mathscr{F}$ is *f-flat* if $\mathscr{F}$ is f-flat at all the points of X ([59, Ch.0, §6.7.1]).

Corollary 10.4.47. *Let $f : X \to S$ be a finitely presented morphism of schemes, $\mathscr{F}$ a f-flat quasi-coherent $\mathscr{O}_X$-module of finite presentation, $\mathscr{G}$ any quasi-coherent $\mathscr{O}_S$-module, $x \in X$ any point, $i : f^{-1}f(x) \to X$ the natural morphism. Then :*

$$\delta'(x, \mathscr{F} \otimes_{\mathscr{O}_X} f^*\mathscr{G}) = \delta'(x, i^*\mathscr{F}) + \delta'(f(x), \mathscr{G}).$$

Proof. Set $s := f(x)$, and denote by

$$j_s : S(s) := \mathrm{Spec}\, \mathscr{O}_{S,s} \to S \qquad \text{and} \qquad f_s : X(s) := X \times_S S(s) \to S(s)$$

the induced morphisms. By inspecting the definitions, one checks easily that

$$\delta'(x, \mathscr{F} \otimes_{\mathscr{O}_X} f^*\mathscr{G}) = \delta'(x, \mathscr{F}_{|X(s)} \otimes_{\mathscr{O}_{X(s)}} f_s^*\mathscr{G}(s)) \qquad \text{and} \qquad \delta'(s, \mathscr{G}) = \delta'(s, \mathscr{G}(s))$$

(notation of definition 4.9.17(iii)). Thus, we may replace S by $S(s)$ and X by $X(s)$, and assume from start that S is a local scheme and s its closed point. Clearly we may also assume that X is affine and finitely presented over S. Then we can write S as the limit of a cofiltered family $(S_\lambda \mid \lambda \in \Lambda)$ of local noetherian schemes, with local transition maps, and we may assume that $f : X \to S$ is a limit of a cofiltered family $(f_\lambda : X_\lambda \to S_\lambda \mid \lambda \in \Lambda)$ of morphisms of finite type, such that $X_\mu = X_\lambda \times_{S_\lambda} S_\mu$ whenever $\mu \geq \lambda$. Likewise, we may descend $\mathscr{F}$ to a family $(\mathscr{F}_\lambda \mid \lambda \in \Lambda)$ of finitely presented quasi-coherent $\mathscr{O}_{X_\lambda}$-modules, such that $\mathscr{F}_\mu = \varphi^*_{\mu\lambda}\mathscr{F}_\lambda$ for every $\mu \geq \lambda$ (where $\varphi_{\mu\lambda} : X_\mu \to X_\lambda$ is the natural morphism). Furthermore, up to replacing Λ by some coinitial subset, we may assume that $\mathscr{F}_\lambda$ is f_λ-flat for every $\lambda \in \Lambda$ ([65, Ch.IV, Cor.11.2.6.1(ii)]). For every $\lambda \in \Lambda$, denote by $\psi_\lambda : S \to S_\lambda$ the natural morphism, so that $s_\lambda := \psi_\lambda(s)$ is the closed point of S_λ; for every constructible closed subset $Z_\lambda \subset S_\lambda$, the set $Z := \psi_\lambda^{-1} Z_\lambda$ is constructible and closed in S, and according to lemma 10.4.17(ii) we have $\mathrm{depth}_Z \mathscr{G} = \mathrm{depth}_{Z_\lambda} \psi_{\lambda *}\mathscr{G}$. On the other hand, every closed constructible subset $Z \subset S$ is of the form $\psi_\lambda^{-1} Z_\lambda$ for some $\lambda \in \Lambda$ and some Z_λ closed constructible in S_λ ([65, Ch.IV, Cor.8.3.11]), so that :

$$\delta'(s, \mathscr{G}) = \sup\{\delta'(s_\lambda, \psi_{\lambda *}\mathscr{G}) \mid \lambda \in \Lambda\}. \tag{10.4.48}$$

Similarly, for every $\lambda \in \Lambda$ let x_λ be the image of x in X_λ and denote by $i_\lambda : f_\lambda^{-1}(s_\lambda) \to X_\lambda$ the natural morphism. Notice that $f_\lambda^{-1}(s_\lambda)$ is a scheme of finite type over $\mathrm{Spec}\,\kappa(s_\lambda)$, especially it is noetherian, hence $\delta'(x_\lambda, i_\lambda^* \mathscr{F}_\lambda) = \delta(x_\lambda, i_\lambda^* \mathscr{F}_\lambda)$, by lemma 10.4.20(ii); by the same token we have as well the identity : $\delta'(x, i^*\mathscr{F}) = \delta(x, i^*\mathscr{F})$. Denote by $g_\lambda : f^{-1}(s) \to f_\lambda^{-1}(s_\lambda)$ and $g_{\lambda,x} : \mathrm{Spec}\,\mathscr{O}_{f^{-1}(s),x} \to \mathrm{Spec}\,\mathscr{O}_{f_\lambda^{-1}(s_\lambda),x_\lambda}$ the induced morphisms.

Claim 10.4.49. There exists $\lambda \in \Lambda$ such that $g_{\mu,x}^{-1}(x_\mu) = \{x\}$ for every $\mu \geq \lambda$.

Proof of the claim. Let Z be the topological closure of $\{x\}$ in $f^{-1}(s)$; we may find $\lambda \in \Lambda$ and a closed subset $Z_\lambda \subset f_\lambda^{-1}(s_\lambda)$ such that $Z = g_\lambda^{-1} Z_\lambda$ ([65, Ch.IV, Cor.8.3.11]). Since Z is irreducible and g_λ is surjective, it is easily seen that Z_λ is irreducible. Moreover, the topological closure Z'_λ of $\{x_\lambda\}$ in $f_\lambda^{-1}(s_\lambda)$ lies in Z_λ, and $g_\lambda^{-1} Z'_\lambda$ contains x; thus, $Z_\lambda = Z'_\lambda$. It follows that $g_{\lambda,x}^{-1}(x_\lambda) = \{x\}$, whence the assertion. ◊

Since $g_{\lambda,x}$ is faithfully flat, from claim 10.4.49 and corollary 10.4.37 we see that, after replacing Λ by a coinitial subset, we may assume :

$$\delta'(x_\lambda, i_\lambda^* \mathscr{F}_\lambda) = \delta'(x, i^*\mathscr{F}) \qquad \text{for every } \lambda \in \Lambda. \tag{10.4.50}$$

Claim 10.4.51. Let K be a field, X and Y two K-schemes, and set $Z := X \times_{\mathrm{Spec}\,K} Y$. Let also $p : Z \to X$ and $q : Z \to Y$ be the projections, $\mathscr{M}$ any $\mathscr{O}_X$-module, and $\mathscr{N}$ any $\mathscr{O}_Y$-module. Then we have :

$$\mathrm{Supp}\,(p^*\mathscr{M} \otimes_{\mathscr{O}_Z} q^*\mathscr{N}) = p^{-1}(\mathrm{Supp}\,\mathscr{M}) \cap q^{-1}(\mathrm{Supp}\,\mathscr{N}).$$

Proof of the claim. To ease notation, set $\mathscr{P} := p^*\mathscr{M} \otimes_{\mathscr{O}_Z} q^*\mathscr{N}$. Let $z \in Z$ be any point with $x := p(z) \in \mathrm{Supp}\,\mathscr{M}$ and $y := q(z) \in \mathrm{Supp}\,\mathscr{N}$; it suffices to show that $\mathscr{P}_z \neq 0$. Now, $\mathscr{O}_{Z,z}$ is a localization of $\mathscr{O}_{X,x} \otimes_K \mathscr{O}_{Y,y}$, at a prime ideal $\mathfrak{p}$, and $\mathscr{P}_z = (\mathscr{M}_x \otimes_K \mathscr{N}_y)_\mathfrak{p}$. We come down therefore to the following situation. Let A and B be two local K-algebras, $\mathfrak{m}_A \subset A$, $\mathfrak{m}_B \subset B$ the respective maximal ideals, $M \neq 0$ an A-module, $N \neq 0$ a B-modules, and $\mathfrak{p} \subset A \otimes_K B$ a prime ideal such that

$$\mathfrak{m}_A \otimes_K B + A \otimes_K \mathfrak{m}_B \subset \mathfrak{p}. \tag{10.4.52}$$

We have to check that $(M \otimes_K N)_\mathfrak{p} \neq 0$. To this aim, we may reduce easily to the case where M and N are cyclic modules, in which case there exist a surjective A-linear map $M \to \kappa(A) := A/\mathfrak{m}_A$ and a surjective B-linear map $N \to \kappa(B) := B/\mathfrak{m}_B$; we are then further reduced to showing that $(\kappa(A) \otimes_K \kappa(B))_\mathfrak{p} \neq 0$, which is ensured by (10.4.52). ◊

Next, notice that the local scheme $X(x)$ is the limit of the cofiltered system of local schemes $(X_\lambda(x_\lambda) \mid \lambda \in \Lambda)$. Let $Z_\lambda \subset X_\lambda(x_\lambda)$ be a closed constructible subset and set $Z := \varphi_\lambda^{-1} Z_\lambda$, where $\varphi_\lambda : X(x) \to X_\lambda(x_\lambda)$ is the natural morphism. Let Y_λ be the fibre product in the cartesian diagram of schemes :

$$\begin{array}{ccc} Y_\lambda & \xrightarrow{q_\lambda} & X_\lambda(x_\lambda) \\ {\scriptstyle p_\lambda}\downarrow & & \downarrow \\ S & \xrightarrow{\psi_\lambda} & S_\lambda. \end{array}$$

The morphism φ_λ factors through a unique morphism of S-schemes $\overline{\varphi}_\lambda : X(x) \to Y_\lambda$, and if $y_\lambda \in Y_\lambda$ is the image of the closed point x of $X(x)$, then $\overline{\varphi}_\lambda$ induces a natural identification $X(x) \stackrel{\sim}{\to} Y_\lambda(y_\lambda)$. To ease notation, let us set :

$$\mathscr{H} := \mathscr{F} \otimes_{\mathscr{O}_X} f^*\mathscr{G} \qquad \text{and} \qquad \mathscr{H}_\lambda := \mathscr{F}_\lambda \otimes_{\mathscr{O}_{X_\lambda}} f_\lambda^* \psi_{\lambda *}\mathscr{G}.$$

In view of corollary 10.4.10, there follows a natural isomorphism :

$$R\underline{\Gamma}_Z \mathscr{H}(x) \stackrel{\sim}{\to} \overline{\varphi}{}_\lambda^* R\underline{\Gamma}_{q_\lambda^{-1}(Z_\lambda)}(q_\lambda^* \mathscr{F}_\lambda(x_\lambda) \otimes_{\mathscr{O}_{Y_\lambda}} p_\lambda^* \mathscr{G}). \tag{10.4.53}$$

On the other hand, applying the projection formula (see remark 10.3.7) we get :

$$q_{\lambda *}(q_\lambda^* \mathscr{F}_\lambda(x_\lambda) \otimes_{\mathscr{O}_{Y_\lambda}} p_\lambda^* \mathscr{G}) \simeq \mathscr{H}_\lambda(x_\lambda). \tag{10.4.54}$$

Combining (10.4.53), (10.4.54) and lemma 10.4.13(v) we deduce :

$$R\underline{\Gamma}_Z \mathscr{H}(x) \simeq \varphi_\lambda^* R\underline{\Gamma}_{Z_\lambda} \mathscr{H}_\lambda(x_\lambda).$$

Notice that the foregoing argument applies also in case S is replaced by some S_μ for some $\mu \geq \lambda$ (and consequently X is replaced by X_μ); we arrive therefore at the inequality :

$$\delta'(x_\lambda, \mathscr{H}_\lambda) \leq \delta'(x_\mu, \mathscr{H}_\mu) \leq \delta'(x, \mathscr{H}) \qquad \text{whenever } \mu \geq \lambda. \tag{10.4.55}$$

Claim 10.4.56. $\delta'(x, \mathscr{H}) = \sup \{\delta'(x_\lambda, \mathscr{H}_\lambda) \mid \lambda \in \Lambda\}$.

Proof of the claim. Due to (10.4.55) we may assume – again after replacing Λ by a cofinal subset – that $\delta'(x_\lambda, \mathscr{H}_\lambda)$ is a constant $d \in \mathbb{N}$ independent of λ. Especially, $R^d\underline{\Gamma}_{Z_\lambda} \mathscr{H}_\lambda(x_\lambda) \neq 0$ for every $\lambda \in \Lambda$ and every closed constructible subset $Z_\lambda \subset X_\lambda(x_\lambda)$. We have to show that $R^d\underline{\Gamma}_Z \mathscr{H}(x) \neq 0$ for arbitrarily small constructible closed subsets $Z \subset X(x)$. However, given such Z, there exist $\lambda \in \Lambda$ and Z_λ closed constructible in $X_\lambda(x_\lambda)$ such that $Z = \varphi^{-1}(Z_\lambda)$ ([65, Ch.IV, Cor.8.3.11]). Say that:

$$S = \operatorname{Spec} A \qquad S_\lambda = \operatorname{Spec} A_\lambda \qquad X_\lambda(x_\lambda) = \operatorname{Spec} B_\lambda.$$

Hence $Y_\lambda \simeq \operatorname{Spec} A \otimes_{A_\lambda} B_\lambda$. Let also F_λ (resp. G) be a B_λ-module (resp. A-module) such that $F_\lambda^\sim \simeq \mathscr{F}_\lambda$ (resp. $G^\sim \simeq \mathscr{G}$). Then $\mathscr{H}_{|Y_\lambda} \simeq (F_\lambda \otimes_{A_\lambda} G)^\sim$. Let $\mathfrak{m}_\lambda \subset B_\lambda$ and $\mathfrak{n}_\lambda \subset A_\lambda$ be the maximal ideals. Up to replacing Z by a smaller subset, we may assume that $Z_\lambda = V(\mathfrak{m}_\lambda)$. To ease notation, set :

$$E_1 := \operatorname{Ext}^a_{A_\lambda}(\kappa(s_\lambda), G) \qquad E_2 := \operatorname{Ext}^b_{B_\lambda/\mathfrak{n}_\lambda B_\lambda}(\kappa(x_\lambda), F_\lambda/\mathfrak{n}_\lambda F_\lambda)$$

with $a = \delta'(s_\lambda, \psi_{\lambda *}\mathscr{G})$ and $b = d - a$. Proposition 10.4.32(i),(ii) and remark 10.4.40 say that

$$0 \neq E_3 := \operatorname{Ext}^d_{B_\lambda}(\kappa(x_\lambda), F_\lambda \otimes_{A_\lambda} G) \simeq E_1 \otimes_{\kappa(s_\lambda)} E_2.$$

To conclude, it suffices to show that $y_\lambda \in \operatorname{Supp} E_3$. However, claim 10.4.51 says that

$$\operatorname{Supp} E_3 = p_\lambda^{-1}(\operatorname{Supp} E_1) \cap q_\lambda^{-1}(\operatorname{Supp} E_2).$$

Now, $p_\lambda(y_\lambda) = s$, and clearly $s \in \operatorname{Supp} E_1$, since G is an A-module and s is the closed point of S; likewise, $q_\lambda(y_\lambda) = x_\lambda$ is the closed point of $X_\lambda(x_\lambda)$, therefore it is in the support of E_2. $\diamondsuit$

We can now conclude the proof : indeed, from theorem 10.4.38 we derive :

$$\delta'(x_\lambda, \mathscr{H}_\lambda) = \delta'(x, i_\lambda^* \mathscr{F}_\lambda) + \delta'(f(x), \psi_{\lambda *}\mathscr{G}) \qquad \text{for every } \lambda \in \Lambda$$

and then the corollary follows from (10.4.48), (10.4.50) and claim 10.4.56. □

10.4.57. Consider now a finitely presented morphism of schemes $f : X \to Y$, and a sheaf of ideals $\mathscr{I} \subset \mathscr{O}_X$ of finite type. Let $x \in X$ be any point, and set $y := f(x)$; notice that $f^{-1}(y)$ is an algebraic $\kappa(y)$-scheme, so that the local ring $\mathscr{O}_{f^{-1}(y),x}$ is noetherian. We let $\mathscr{I}(y) := i_y^{-1}\mathscr{I} \cdot \mathscr{O}_{f^{-1}(y)}$, which is a coherent sheaf of ideals of the fibre $f^{-1}(y)$. The *fibrewise $\mathscr{I}$-depth of X over Y at the point x* is the integer:

$$\mathrm{depth}_{\mathscr{I},f}(x) := \mathrm{depth}_{\mathscr{I}(y)_x}\mathscr{O}_{f^{-1}(y),x}.$$

In case $\mathscr{I} = \mathscr{O}_X$, the fibrewise $\mathscr{I}$-depth shall be called the *fibrewise depth* at the point x, and shall be denoted by $\mathrm{depth}_f(x)$. In view of (10.4.30) we have the identity:

$$\mathrm{depth}_{\mathscr{I},f}(x) = \inf\{\mathrm{depth}_f(z) \mid z \in V(\mathscr{I}(y)) \text{ and } x \in \overline{\{z\}}\}. \tag{10.4.58}$$

10.4.59. The fibrewise $\mathscr{I}$-depth can be computed locally as follows. For a given $x \in X$, set $y := f(x)$ and let $U \subset X$ be any affine open neighborhood of x such that $\mathscr{I}_{|U}$ is generated by a finite family $\mathbf{f} := (f_i)_{1\leq i\leq r}$, where $f_i \in \mathscr{I}(U)$ for every $i \leq r$. Then proposition 10.4.32(i) implies that :

$$\mathrm{depth}_{\mathscr{I},f}(x) = \sup\{n \in \mathbb{N} \mid H^i(\mathbf{K}^\bullet(\mathbf{f}, \mathscr{O}_X(U))_x \otimes_{\mathscr{O}_{Y,y}} \kappa(y)) = 0 \text{ for all } i < n\}. \tag{10.4.60}$$

Proposition 10.4.61. *In the situation of* (10.4.57)*, for every integer $d \in \mathbb{N}$ we define the subset:*

$$L_{\mathscr{I}}(d) := \{x \in X \mid \mathrm{depth}_{\mathscr{I},f}(x) \geq d\}.$$

Then the following holds:

(i) *$L_{\mathscr{I}}(d)$ is a constructible subset of X (see definition* 8.1.13(v)*).*

(ii) *Let $Y' \to Y$ be any morphism of schemes, set $X' := X \times_Y Y'$, and let $g : X' \to X$, $f' : X' \to Y'$ be the induced morphisms. Then:*

$$L_{g^*\mathscr{I}}(d) = g^{-1}L_{\mathscr{I}}(d) \qquad \textit{for every } d \in \mathbb{N}.$$

Proof. (ii): The identity can be checked on the fibres, hence we may assume that $Y = \operatorname{Spec} k$ and $Y' = \operatorname{Spec} k'$ for some fields $k \subset k'$. Let $x' \in X'$ be any point and $x \in X$ its image; since the map $\mathscr{O}_{X,x} \to \mathscr{O}_{X',x'}$ is faithfully flat, corollary 10.4.37 implies:

$$\mathrm{depth}_{g^*\mathscr{I},f'}(x') = \mathrm{depth}_{\mathscr{I},f}(x)$$

whence (ii).

(i): We may assume that $Y = \operatorname{Spec} A$, $X = \operatorname{Spec} B$, $\mathscr{I} = I^\sim$, where A is a ring, B is a finitely presented A-algebra, and $I \subset B$ is a finitely generated ideal, for which we choose a finite system of generators $\mathbf{f} := (f_i)_{1\leq i\leq r}$. We may also assume that A is reduced. Suppose first that A is noetherian; then, for every $i \in \mathbb{N}$ and $y \in Y$ let us set:

$$N_{\mathscr{I}}(i) = \bigcup_{y\in Y} \operatorname{Supp} H^i(\mathbf{K}^\bullet(\mathbf{f}, B) \otimes_A \kappa(y)).$$

Taking into account (10.4.30) and (10.4.60), we deduce:

$$L_{\mathscr{I}}(d) = \bigcap_{i=0}^{d-1}(X \setminus N_{\mathscr{I}}(i)).$$

It suffices therefore to show that each subset $N_{\mathscr{I}}(i)$ is constructible. For every $j \in \mathbb{N}$ we set:

$$\mathbf{Z}^j := \mathrm{Ker}(d^j : \mathbf{K}^j(\mathbf{f}, B) \to \mathbf{K}^{j+1}(\mathbf{f}, B)) \qquad \mathbf{B}^j := \mathrm{Im}(d^{j-1} : \mathbf{K}^{j-1}(\mathbf{f}, B) \to \mathbf{K}^j(\mathbf{f}, B)).$$

Using [65, Ch.IV, Cor. 8.9.5], one deduces easily that there exists an affine open subscheme $U \subset Y$, say $U = \operatorname{Spec} A'$ for some flat A-algebra A', such that $A' \otimes_A \mathbf{Z}^\bullet$, $A' \otimes_A \mathbf{B}^\bullet$ and $A' \otimes_A H^\bullet(\mathbf{K}^\bullet(\mathbf{f}, B))$ are flat A'-modules. By noetherian induction, we can then replace Y by U and X by $X \times_Y U$, and assume from start that $\mathbf{Z}^\bullet$, $\mathbf{B}^\bullet$ and $H^\bullet(\mathbf{K}^\bullet(\mathbf{f}, B))$ are flat A-modules. In such case, taking homology of the complex $\mathbf{K}^\bullet(\mathbf{f}, B)$ commutes with any base change; therefore:

$$N_{\mathscr{I}}(i) = \bigcup_{y \in Y} \operatorname{Supp} H^i(\mathbf{f}, B) \otimes_A \kappa(y) = \operatorname{Supp} H^i(\mathbf{f}, B)$$

whence the claim, since the support of a B-module of finite type is closed in X.

Finally, for a general ring A, we can find a noetherian subalgebra $A' \subset A$, an A'-algebra B' of finite type and a finitely generated ideal $I' \subset B'$ such that $B = A \otimes_{A'} B$ and $I = I'B$. Let $\mathscr{I}'$ be the sheaf of ideals on $X' := \operatorname{Spec} B'$ determined by I'; by the foregoing, $L_{\mathscr{I}'}(d)$ is a constructible subset of X'. Thus, the assertion follows from (ii), and the fact that a morphism of schemes is continuous for the constructible topology ([63, Ch.IV, Prop.1.8.2]). □

10.5. **Depth and associated primes.**

Definition 10.5.1. Let X be a scheme, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module.

(i) Let $x \in X$ be any point; we say that x is *associated with* $\mathscr{F}$ if there exists $f \in \mathscr{F}_x$ such that the radical of the annihilator of f in $\mathscr{O}_{X,x}$ is the maximal ideal of $\mathscr{O}_{X,x}$. If x is a point associated with $\mathscr{F}$ and x is not a maximal point of $\operatorname{Supp} \mathscr{F}$, we say that x is an *imbedded point* for $\mathscr{F}$. We shall denote :

$$\operatorname{Ass} \mathscr{F} := \{x \in X \mid x \text{ is associated with } \mathscr{F}\}.$$

(ii) We say that the $\mathscr{O}_X$-module $\mathscr{F}$ *satisfies condition* S_1 if every associated point of $\mathscr{F}$ is a maximal point of X.

(iii) Likewise, if X is affine, say $X = \operatorname{Spec} A$, and M is any A-module, we denote by $\operatorname{Ass}_A M \subset X$ (or just $\operatorname{Ass} M$, if the notation is not ambiguous) the set of prime ideals associated with the $\mathscr{O}_X$-module $M^\sim$ arising from M. An associated (resp. imbedded) point of $M^\sim$ is also called an *associated* (resp. *imbedded*) *prime ideal* of M.
We say that M *satisfies condition* S_1 if the same holds for the $\mathscr{O}_X$-module $M^\sim$.

(iv) Let $x \in X$ be a point, $\mathscr{G}$ a quasi-coherent $\mathscr{O}_X$-submodule of $\mathscr{F}$. We say that $\mathscr{G}$ is a *x-primary submodule* of $\mathscr{F}$ if $\operatorname{Ass} \mathscr{F}/\mathscr{G} = \{x\}$. We say that $\mathscr{G}$ is a *primary submodule* of $\mathscr{F}$ if there exists a point $x \in X$ such that $\mathscr{G}$ is x-primary.

(v) We say that a submodule $\mathscr{G}$ of the $\mathscr{O}_X$-module $\mathscr{F}$ admits a *primary decomposition* if there exist primary submodules $\mathscr{G}_1, \dots, \mathscr{G}_n \subset \mathscr{F}$ such that $\mathscr{G} = \mathscr{G}_1 \cap \cdots \cap \mathscr{G}_n$.

Remark 10.5.2. (i) Our definition of associated point is borrowed from [86, Partie I, Déf.3.2.1], and it corresponds to Bourbaki's notion of *weakly associated prime* ([34, Ch.IV, §1, Exerc.17]), also called *weak Bourbaki prime* in other works. Bourbaki's definition of associated prime, in [34, Ch.IV, §1, no.1] (which is the same as in [85, Exp.III, Déf.1.1]), agrees with ours for modules over noetherian rings (see lemma 10.5.3(ii)), but in general the two notions diverge.

(ii) For a noetherian ring A and a finitely generated A-module M, our condition S_1 is the same as in [89]. It also agrees with that of [64, Ch.IV, Déf.5.7.2], in case $\operatorname{Supp} M = \operatorname{Spec} A$.

Lemma 10.5.3. *Let A be a ring, and M any A-module. The following holds :*

(i) $\operatorname{Ass} M$ *is the set of all* $\mathfrak{p} \in \operatorname{Spec} A$ *with the following property. There exists* $m \in M$*, such that* $\mathfrak{p}$ *is a maximal point of the closed subset* $\operatorname{Supp}(m)$ *(*i.e. $\mathfrak{p}$ *is the preimage of a minimal prime ideal of the ring* $A/\operatorname{Ann}_A(m)$*).*

(ii) *If* $\mathfrak{p} \in \operatorname{Ass} M$*, and* $\mathfrak{p}$ *is finitely generated, there exists* $m \in M$ *with* $\mathfrak{p} = \operatorname{Ann}_A(m)$.

(iii) *The natural map* $M \to \prod_{\mathfrak{p} \in \operatorname{Ass} M} M_{\mathfrak{p}}$ *is injective.*

Proof. (i): Indeed, suppose that $m \in M\setminus\{0\}$ is any element, and $\mathfrak{p}$ is a maximal point of $V(\mathrm{Ann}_A(m))$; denote by $m_\mathfrak{p} \in M_\mathfrak{p} := M \otimes_A A_\mathfrak{p}$ the image of m. Then :

$$\mathrm{Ann}_{A_\mathfrak{p}}(m_\mathfrak{p}) = \mathrm{Ann}_A(m) \otimes_A A_\mathfrak{p}. \tag{10.5.4}$$

Hence $A_\mathfrak{p}/\mathrm{Ann}_{A_\mathfrak{p}}(m_\mathfrak{p}) = (A/\mathrm{Ann}_A(m)) \otimes_A A_\mathfrak{p}$, and the latter is by assumption a local ring of Krull dimension zero; it follows easily that the radical of $\mathrm{Ann}_{A_\mathfrak{p}}(m_\mathfrak{p})$ is $\mathfrak{p}A_\mathfrak{p}$, *i.e.* $\mathfrak{p} \in \mathrm{Ass}_A M$.

Conversely, suppose that $\mathfrak{p} \in \mathrm{Ass}_A M$; then there exists $m_\mathfrak{p} \in M_\mathfrak{p}$ such that the radical of $\mathrm{Ann}_{A_\mathfrak{p}}(m_\mathfrak{p})$ equals $\mathfrak{p}A_\mathfrak{p}$. We may assume that $m_\mathfrak{p}$ is the image of some $m \in M$; then (10.5.4) implies that $V(\mathrm{Ann}_A(m)) \cap \mathrm{Spec}\, A_\mathfrak{p} = V(\mathrm{Ann}_{A_\mathfrak{p}}(m_\mathfrak{p})) = \{\mathfrak{p}\}$, so $\mathfrak{p}$ is a maximal point of $V(\mathrm{Ann}_A(m))$.

(ii): Suppose $\mathfrak{p} \in \mathrm{Ass}\, M$ is finitely generated; by definition, there exists $y \in M_\mathfrak{p}$ such that the radical of $I := \mathrm{Ann}_{A_\mathfrak{p}}(y)$ equals $\mathfrak{p}A_\mathfrak{p}$. Since $\mathfrak{p}$ is finitely generated, some power of $\mathfrak{p}A_\mathfrak{p}$ is contained in I. Let $t \in \mathbb{N}$ be the smallest integer such that $\mathfrak{p}^t A_\mathfrak{p} \subset I$, and pick any non-zero element x in $\mathfrak{p}^{t-1}A_\mathfrak{p}y$; then $\mathrm{Ann}_{A_\mathfrak{p}}(x) = \mathfrak{p}A_\mathfrak{p}$. After clearing some denominators, we may assume that $x \in M$. Let $a_1, \dots, a_r$ be a finite set of generators for $\mathfrak{p}$; we may then find $t_1, \dots, t_r \in A\setminus\mathfrak{p}$ such that $t_i a_i x = 0$ in M, for every $i \leq r$. Set $x' := t_1 \cdot \ldots \cdot t_r x$; then $\mathfrak{p} \subset \mathrm{Ann}_A(x')$; however $\mathrm{Ann}_{A_\mathfrak{p}}(x') = \mathfrak{p}A_\mathfrak{p}$, therefore $\mathfrak{p} = \mathrm{Ann}_A(x')$, whence the contention.

(iii): The assertion means that for every $m \in M \setminus \{0\}$ there exists $\mathfrak{p} \in \mathrm{Ass}\, M$ such that the image of m does not vanish in $M_\mathfrak{p}$. But according to (i), $\mathrm{Ass}\, M$ contains every maximal point $\mathfrak{p}$ of $\mathrm{Supp}(m)$. ☐

Lemma 10.5.5. *Let X be a scheme, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module. Then :*

(i) $\mathrm{Ass}\,\mathscr{F} \subset \mathrm{Supp}\,\mathscr{F}$.
(ii) $\mathrm{Ass}\,\mathscr{F}_{|U} = U \cap \mathrm{Ass}\,\mathscr{F}$ *for every open subset* $U \subset X$.
(iii) $\mathscr{F} = 0$ *if and only if* $\mathrm{Ass}\,\mathscr{F} = \varnothing$.

Proof. (i) and (ii) are obvious. To show (iii), we may assume that X is affine, according to (ii). Then the assertion follows immediately from lemma 10.5.5(iii). ☐

Proposition 10.5.6. *Let X be a scheme, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module. We have :*

(i) $\mathrm{Ass}\,\mathscr{F} = \{x \in X \mid \delta(x, \mathscr{F}) = 0\}$.
(ii) *If* $0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}''$ *is an exact sequence of quasi-coherent $\mathscr{O}_X$-modules, then :*

$$\mathrm{Ass}\,\mathscr{F}' \subset \mathrm{Ass}\,\mathscr{F} \subset \mathrm{Ass}\,\mathscr{F}' \cup \mathrm{Ass}\,\mathscr{F}''.$$

(iii) *If $x \in X$ is any point, and $\mathscr{G}_1, \dots, \mathscr{G}_n$ (for some $n > 0$) are x-primary submodules of $\mathscr{F}$, then $\mathscr{G}_1 \cap \dots \cap \mathscr{G}_n$ is also x-primary.*
(iv) *Let $f : X \to Y$ be a finite morphism of schemes. Then*
  (a) *The natural map :*

$$\bigoplus_{x \in f^{-1}(y)} \Gamma_{\{x\}}\mathscr{F}_{|X(x)} \to \Gamma_{\{y\}} f_*\mathscr{F}_{|Y(y)}$$

  is a bijection for all $y \in Y$.
  (b) $\mathrm{Ass}\, f_*\mathscr{F} = f(\mathrm{Ass}\,\mathscr{F})$.
(v) *Suppose that $\mathscr{F}$ is the union of a filtered family $(\mathscr{F}_\lambda \mid \lambda \in \Lambda)$ of quasi-coherent $\mathscr{O}_X$-submodules. Then :*

$$\bigcup_{\lambda \in \Lambda} \mathrm{Ass}\,\mathscr{F}_\lambda = \mathrm{Ass}\,\mathscr{F}.$$

(vi) *Let $f : Y \to X$ be a flat morphism of schemes, and suppose that the topological space $|X|$ underlying X is locally noetherian. Then* $\mathrm{Ass}\, f^*\mathscr{F} \subset f^{-1}\mathrm{Ass}\,\mathscr{F}$.

Proof. (i) and (v) follow directly from the definitions.

(ii): Consider, for every point $x \in X$ the induced exact sequence of $\mathscr{O}_{X(x)}$-modules :

$$0 \to \underline{\Gamma}_{\{x\}}\mathscr{F}'_x \to \underline{\Gamma}_{\{x\}}\mathscr{F}_x \to \underline{\Gamma}_{\{x\}}\mathscr{F}''_x.$$

Then :

$$\mathrm{Supp}\,\underline{\Gamma}_{\{x\}}\mathscr{F}'_x \subset \mathrm{Supp}\,\underline{\Gamma}_{\{x\}}\mathscr{F}_x \subset \mathrm{Supp}\,\underline{\Gamma}_{\{x\}}\mathscr{F}'_x \cup \mathrm{Supp}\,\underline{\Gamma}_{\{x\}}\mathscr{F}''_x$$

which, in light of (i), is equivalent to the contention.

(iii): One applies (ii) to the natural injection : $\mathscr{F}/(\mathscr{G}_1 \cap \cdots \cap \mathscr{G}_n) \to \oplus_{i=1}^n \mathscr{F}/\mathscr{G}_i$.

(iv): We may assume that Y is a local scheme with closed point $y \in Y$. Let $x_1, \dots, x_n \in X$ be the finitely many points lying over y; for every $i, j \leq n$, we let

$$\pi_j : X(x_j) \to Y \qquad \text{and} \qquad \pi_{ij} : X(x_i) \times_X X(x_j) \to Y$$

be the natural morphisms. To ease notation, denote also by $\mathscr{F}_i$ (resp. $\mathscr{F}_{ij}$) the pull back of of $\mathscr{F}$ to $X(x_j)$ (resp. to $X(x_i) \times_X X(x_j)$). The induced morphism $U := X(x_1) \amalg \cdots \amalg X(x_n) \to X$ is faithfully flat, so descent theory yields an exact sequence of $\mathscr{O}_Y$-modules :

$$(10.5.7) \qquad 0 \longrightarrow f_*\mathscr{F} \longrightarrow \textstyle\prod_{j=1}^n \pi_{j*}\mathscr{F}_j \underset{p_2^*}{\overset{p_1^*}{\rightrightarrows}} \prod_{i,j=1}^n \pi_{ij*}\mathscr{F}_{ij}.$$

where $p_1, p_2 : U \times_X U \to U$ are the natural morphisms.

Claim 10.5.8. The induced maps :

$$\Gamma_{\{y\}}p_1^*, \Gamma_{\{y\}}p_2^* : \prod_{j=1}^n \Gamma_{\{y\}}\pi_{j*}\mathscr{F}_j \to \prod_{i,j=1}^n \Gamma_{\{y\}}\pi_{ij*}\mathscr{F}_{ij}$$

coincide.

Proof of the claim. Indeed, it suffices to verify that they coincide after projecting onto each factor $\mathscr{G}_{ij} := \Gamma_{\{y\}}\pi_{ij*}\mathscr{F}_{ij}$. But this is clear from definitions if $i = j$. On the other hand, if $i \neq j$, the image of π_{ij} in Y does not contain y, so the corresponding factor $\mathscr{G}_{ij}$ vanishes. ◊

From (10.5.7) and claim 10.5.8 we deduce that the natural map

$$\Gamma_{\{y\}}f_*\mathscr{F} \to \prod_{j=1}^n \Gamma_{\{y\}}\pi_{j*}\mathscr{F}_j$$

is a bijection. Clearly $\Gamma_{\{y\}}\pi_{j*}\mathscr{F}_j = \Gamma_{\{x\}}\mathscr{F}_j$, so both assertions follow easily.

(vi): Let $x \in X$ be any point; since $|X|$ is locally noetherian, the subset $\{x\}$ is closed and constructible in $X(x)$, and then $f^{-1}(x)$ is closed and constructible in $Y \times_X X(x)$. Hence $\delta(y, f^*\mathscr{F}) \geq \delta(x, \mathscr{F})$ for every $y \in f^{-1}(x)$ (lemma 10.4.17(iii) and theorem 10.4.21). Then the assertion follows from (i). □

Corollary 10.5.9. *In the situation of corollary* 10.4.47*, suppose furthermore that $|S|$ is a locally noetherian topological space. Then we have :*

$$\mathrm{Ass}\,\mathscr{F} \otimes_{\mathscr{O}_X} f^*\mathscr{G} = \bigcup_{s \in \mathrm{Ass}\,\mathscr{G}} \mathrm{Ass}\,\mathscr{F} \otimes_{\mathscr{O}_{S,s}} \kappa(s).$$

Proof. Under the stated assumptions, it is easily seen that, for every $x \in X$ (resp. $s \in S$), the subset $\{x\}$ (resp. $\{s\}$) is constructible in $X(x)$ (resp. in $S(s)$). Then the assertion follows immediately from proposition 10.5.6(i) and theorem 10.4.21. □

Remark 10.5.10. (i) Actually, it can be shown that the extra assumption on $|S|$ in corollary 10.5.9 is superflous : see [86, Part I, Prop.3.4.3].

(ii) In the situation of proposition 10.5.6, one could also consider the set of points $x \in X$ such that $\delta'(x, \mathscr{F}) = 0$. This set contains $\mathrm{Ass}\,\mathscr{F}$, by proposition 10.5.6(i) and lemma 10.4.20(i).

Such points are called *attached primes* or *strong Krull primes* of $\mathscr{F}$ in some literature : see *e.g.* [68], [67] (though the terminology "attached prime" is used also for a different, unrelated notion: see the footnote on page 404 of [67]).

Corollary 10.5.11. *Let X be a quasi-compact and quasi-separated scheme, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module and $\mathscr{G} \subset \mathscr{F}$ a quasi-coherent submodule. Then :*

(i) *For every quasi-compact open subset $U \subset X$ and every quasi-coherent primary $\mathscr{O}_U$-submodule $\mathscr{N} \subset \mathscr{F}_{|U}$, with $\mathscr{G}_{|U} \subset \mathscr{N}$, there exists a quasi-coherent primary $\mathscr{O}_X$-submodule $\mathscr{M} \subset \mathscr{F}$ such that $\mathscr{M}_{|U} = \mathscr{N}$ and $\mathscr{G} \subset \mathscr{N}$.*

(ii) *$\mathscr{G}$ admits a primary decomposition if and only if there exists a finite open covering $X = U_1 \cup \cdots \cup U_n$ consisting of quasi-compact open subsets, such that the submodules $\mathscr{G}_{|U_i} \subset \mathscr{F}_{|U_i}$ admit primary decompositions for every $i = 1, \dots, n$.*

Proof. Say that $\mathscr{N}$ is x-primary for some point $x \in U$, and set $Z := X \setminus U$. According to [59, Ch.I, Prop.9.4.2], we can extend $\mathscr{N}$ to a quasi-coherent $\mathscr{O}_X$-submodule $\mathscr{M}_1 \subset \mathscr{F}$; up to replacing $\mathscr{M}_1$ by $\mathscr{M}_1 + \mathscr{G}$, we may assume that $\mathscr{G} \subset \mathscr{M}_1$. Since $(\mathscr{F}/\mathscr{M}_1)_{|U} = \mathscr{F}_{|U}/\mathscr{N}$, it follows from lemma 10.5.5(ii) that $\mathrm{Ass}\,\mathscr{F}/\mathscr{M}_1 \subset \{x\} \cup Z$. Let $\overline{\mathscr{M}} := \underline{\Gamma}_Z(\mathscr{F}/\mathscr{M}_1)$, and denote by $\mathscr{M}$ the preimage of $\overline{\mathscr{M}}$ in $\mathscr{F}$. There follows a short exact sequence :

$$0 \to \overline{\mathscr{M}} \to \mathscr{F}/\mathscr{M}_1 \to \mathscr{F}/\mathscr{M} \to 0.$$

Clearly $R^1\underline{\Gamma}_Z\overline{\mathscr{M}} = 0$, whence a short exact sequence

$$0 \to \underline{\Gamma}_Z\overline{\mathscr{M}} \to \underline{\Gamma}_Z(\mathscr{F}/\mathscr{M}_1) \to \underline{\Gamma}_Z(\mathscr{F}/\mathscr{M}) \to 0.$$

We deduce that $\mathrm{depth}_Z(\mathscr{F}/\mathscr{M}) > 0$; then theorem 10.4.21 and proposition 10.5.6(i) show that $Z \cap \mathrm{Ass}\,(\mathscr{F}/\mathscr{M}) = \varnothing$, so that $\mathscr{M}$ is x-primary, as required.

(ii): We may assume that a covering $X = U_1 \cup \cdots \cup U_n$ is given with the stated property. For every $i \leq n$, let $\mathscr{G}_{|U_i} = \mathscr{N}_{i1} \cap \cdots \cap \mathscr{N}_{ik_i}$ be a primary decomposition; by (i) we may extend every $\mathscr{N}_{ij}$ to a primary submodule $\mathscr{M}_{ij} \subset \mathscr{F}$ containing $\mathscr{G}$. Then $\mathscr{G} = \bigcap_{i=1}^n \bigcap_{j=1}^{k_i} \mathscr{M}_{ij}$ is a primary decomposition of $\mathscr{G}$. □

10.5.12. Let A, B be two local rings, with A a domain, $f : A \to B$ a local ring homomorphism, M an f-flat B-module of finite presentation. Denote by K (resp. κ) the field of fractions (resp. the residue field) of A, and set

$$B_0 := B \otimes_A \kappa \qquad B_K := B \otimes_A K \qquad M_0 := M \otimes_A \kappa \qquad M_K := M \otimes_A K.$$

Proposition 10.5.13. *In the situation of* (10.5.12)*, suppose that :*

(a) *either, A and B are both noetherian rings*

(b) *or else, f is essentially of finite presentation.*

Let $\mathfrak{p} \in \mathrm{Ass}_{B_K} M_K$ be any point, and denote by $V(\mathfrak{p})$ the topological closure of $\{\mathfrak{p}\}$ in $\mathrm{Spec}\,B$*. Then all the maximal points of $V(\mathfrak{p}) \cap \mathrm{Spec}\,B_0$ lie in $\mathrm{Ass}_{B_0} M_0$.*

Proof. We consider first case (a). Via the inclusion map $\mathrm{Spec}\,B_K \to \mathrm{Spec}\,B$ we may regard $\mathfrak{p}$ as a prime ideal of B, and $\mathrm{Ass}_{B_K} M_K$ as a subset of $\mathrm{Ass}_B M$; by lemma 10.5.3(ii), there exists a cyclic B-submodule N of M such that $\mathrm{Ann}_B N = \mathfrak{p}$. Denote by $\mathfrak{m}_A$ the maximal ideal of A, endow M with its $\mathfrak{m}_A$-adic filtration $\mathrm{Fil}^\bullet M$, and N with the filtration $\mathrm{Fil}^\bullet N$ induced by $\mathrm{Fil}^\bullet M$. Let also $\mathrm{gr}^\bullet M$ and $\mathrm{gr}^\bullet N$ be the graded B_0-modules associated with these filtrations on M and N. Since M is f-flat, we have a B_0-linear isomorphism

$$\mathrm{gr}^i M \xrightarrow{\sim} (\mathfrak{m}_A^i/\mathfrak{m}_A^{i+1}) \otimes_\kappa M_0 \qquad \text{for every } i \in \mathbb{N}$$

which implies that $\mathrm{Ass}_B(\mathrm{gr}^i M) = \mathrm{Ass}_B M_0$ for every $i \in \mathbb{N}$. From this, proposition 10.5.6(ii) and an easy induction on $i \in \mathbb{N}$, we deduce that

$$\mathrm{Ass}_B(N/\mathrm{Fil}^i N) \subset \mathrm{Ass}_B(M/\mathrm{Fil}^i M) \subset \mathrm{Ass}_B M_0 \qquad \text{for every } i \in \mathbb{N}.$$

On the other hand, by the Artin-Rees lemma ([126, Th.8.5]), there exist $i, j \in \mathbb{N}$ such that

$$\mathfrak{m}_A^j N \subset \mathrm{Fil}^i N \subset \mathfrak{m}_A N$$

so that $\mathrm{Supp}\, N/\mathfrak{m}_A N = \mathrm{Supp}\, N/\mathrm{Fil}^i N$. However, lemma 10.5.3(i) implies that all the maximal points of $\mathrm{Supp}\, N/\mathrm{Fil}^i N$ lie in $\mathrm{Ass}_B(N/\mathrm{Fil}^i N)$. To conclude, it suffices to remark that the support of $N/\mathfrak{m}_A N$ equals $V(\mathfrak{p}) \cap \mathrm{Spec}\, B_0$.

Next, suppose that (b) holds, and say that $B = C_\mathfrak{q}$ for some finitely presented A-algebra C and some prime ideal $\mathfrak{q} \subset C$ whose preimage in A is the maximal ideal. We write A as the colimit of a filtered system $(A_\lambda \mid \lambda \in \Lambda)$ of noetherian local subrings, such that the transition maps $A_\mu \to A_\lambda$ are local ring homomorphisms for every $\lambda, \mu \in \Lambda$ with $\lambda \geq \mu$; then there exist $\mu \in \Lambda$ and an A_μ-algebra C_μ of finite type with an isomorphism of $C_\mu \otimes_{A_\mu} A \to C$ of A-algebras. For every $\lambda \geq \mu$, let $C_\lambda := C_\mu \otimes_{A_\mu} A_\lambda$, denote by $\mathfrak{q}_\lambda \subset C_\lambda$ the preimage of $\mathfrak{q}$ under the induced map $C_\lambda \to C$, and set $B_\lambda := (C_\lambda)_{\mathfrak{q}_\lambda}$. Clearly B is the colimit of the resulting filtered system of rings $(B_\lambda \mid \lambda \in \Lambda,\, \lambda \geq \mu)$, and the induced maps $A_\lambda \to B_\lambda$ are local ring homomorphisms, for every $\lambda \geq \mu$; therefore we may assume that there exists a finitely generated B_μ-module M_μ with a B-linear isomorphism $M_\mu \otimes_{B_\mu} B \xrightarrow{\sim} M$, and we may likewise define $M_\lambda := M_\mu \otimes_{B_\mu} B_\lambda$ for every $\lambda \geq \mu$. In view of [65, Ch.IV, Cor.11.2.6.1(i)], we may further assume that M_λ is a flat A_λ-module, for every $\lambda \geq \mu$, and after replacing Λ by a cofinal subset, we may assume that μ is the initial element of the partially ordered set Λ. Then, to ease notation, denote by K_λ (resp. κ_λ) the field of fractions (resp. the residue field) of A_λ, and set

$$\begin{array}{lll} B_{K,\lambda} := B_\lambda \otimes_{A_\lambda} K_\lambda & M_{K,\lambda} := M_\lambda \otimes_{A_\lambda} K_\lambda & C_{K,\lambda} := C_\lambda \otimes_{A_\lambda} K_\lambda \\ B_{0,\lambda} := B_\lambda \otimes_{A_\lambda} \kappa_\lambda & M_{0,\lambda} := M_\lambda \otimes_{A_\lambda} \kappa_\lambda & \end{array} \qquad \text{for every } \lambda \in \Lambda.$$

Notice that the resulting map $f_\lambda : C_{K,\lambda} \to C_K := C \otimes_A K$ induces an isomorphism

$$C_{K,\lambda} \otimes_{K_\lambda} K \xrightarrow{\sim} C_K.$$

So, f_λ is a flat ring homomorphism, hence the natural morphism $\varphi_{K,\lambda} : \mathrm{Spec}\, B_K \to \mathrm{Spec}\, B_{K,\lambda}$ is also flat, and proposition 10.5.6(vi) yields

$$\mathrm{Ass}_{B_K} M_K \subset \varphi_{K,\lambda}^{-1} \mathrm{Ass}_{B_{K,\lambda}}(M_{K,\lambda}) \qquad \text{for every } \lambda \in \Lambda. \tag{10.5.14}$$

Now, say that $\mathfrak{p} \in \mathrm{Ass}_{B_K} M_K$, and let $\mathfrak{p}_\lambda \subset B_{K,\lambda}$ be the preimage of $\mathfrak{p}$, for every $\lambda \in \Lambda$; we have $\mathfrak{p}_\lambda \in \mathrm{Ass}_{B_{K,\lambda}}(M_{K,\lambda})$ by virtue of (10.5.14), so in this situation the case (a) of the proposition applies and shows that

$$Z_\lambda := \mathrm{Max}(\mathrm{Spec}\, B_{0,\lambda}/\mathfrak{p}_\lambda B_{0,\lambda}) \subset Z'_\lambda := \mathrm{Ass}_{B_\lambda}(M_{0,\lambda}) \qquad \text{for every } \lambda \in \Lambda$$

(where, for a scheme Z, we have denoted $\mathrm{Max}(Z)$ the set of maximal points of Z). Notice moreover, that the natural morphism $\varphi_{0,\lambda} : \mathrm{Spec}\, B_0 \to \mathrm{Spec}\, B_{0,\lambda}$ is also flat, so we have

$$\mathrm{Max}(\mathrm{Spec}\, B_0/\mathfrak{p}_\lambda B_0) = \bigcup_{z \in Z_\lambda} \mathrm{Max}(\varphi_{0,\lambda}^{-1}(z)) \qquad \text{for every } \lambda \in \Lambda$$

by the going down theorem ([126, Th.9.5]). On the other hand, from [64, Ch.IV, Prop.4.2.7] we have

$$\bigcup_{z \in Z'_\lambda} \mathrm{Max}(\varphi_{0,\lambda}^{-1}(z)) = (\mathrm{Spec}\, B_0) \cap \mathrm{Ass}_{B_{0,\lambda} \otimes_{k_\lambda} \kappa}(M_{0,\lambda} \otimes_{\kappa_\lambda} \kappa) = \mathrm{Ass}_{B_0}(M_0)$$

for every $\lambda \in \Lambda$. Summing up, we are reduced to checking that there exists $\lambda \in \Lambda$ such that the surjection $B_0/\mathfrak{p}_\lambda B_0 \to B_0/\mathfrak{p} B_0$ is an isomorphism, *i.e.* such that $\mathfrak{p}_\lambda B_0 = \mathfrak{p} B_0$. However, clearly $\mathfrak{p} B_0$ is the filtered union of the system of subideals $(\mathfrak{p}_\lambda B_0 \mid \lambda \in \Lambda)$; but B_0 is a noetherian ring, so the claim is obvious. □

Lemma 10.5.15. *Let X be a quasi-separated and quasi-compact scheme, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module of finite type. Then the submodule $0 \subset \mathscr{F}$ admits a primary decomposition if and only if the following conditions hold:*

(a) $\mathrm{Ass}\,\mathscr{F}$ *is a finite set.*

(b) *For every $x \in \mathrm{Ass}\,\mathscr{F}$ there is a x-primary ideal $I \subset \mathscr{O}_{X,x}$ such that the natural map*

$$\Gamma_{\{x\}}\mathscr{F}_x \to \mathscr{F}_x/I\mathscr{F}_x$$

is injective.

Proof. In view of corollary 10.5.11(i) we are reduced to the case where X is an affine scheme, say $X = \mathrm{Spec}\,A$, and $\mathscr{F} = M^\sim$ for an A-module M of finite type. Suppose first that 0 admits a primary decomposition :

$$0 = \bigcap_{i=1}^{k} N_i. \tag{10.5.16}$$

Then the natural map $M \to \oplus_{i=1}^k M/N_i$ is injective, hence

$$\mathrm{Ass}\,M \subset \mathrm{Ass}\bigoplus_{i=1}^{k} M/N_i \subset \bigcup_{i=1}^{k} \mathrm{Ass}\,M/N_i \tag{10.5.17}$$

by proposition 10.5.6(ii), and this shows that (a) holds. Next, if N_i and N_j are $\mathfrak{p}$-primary for the same prime ideal $\mathfrak{p} \subset A$, we may replace both of them by their intersection (proposition 10.5.6(iii)). Proceeding in this way, we achieve that the N_i appearing in (10.5.16) are primary submodules for pairwise distinct prime ideals $\mathfrak{p}_1, \dots, \mathfrak{p}_k \subset A$. By (10.5.17) we have $\mathrm{Ass}\,M \subset \{\mathfrak{p}_1, \dots, \mathfrak{p}_k\}$. Suppose that $\mathfrak{p}_1 \notin \mathrm{Ass}\,M$, and set $Q := \mathrm{Ker}\,(M \to \oplus_{i=2}^k M/N_i)$. For every $j > 1$ we have $\Gamma_{\{\mathfrak{p}_j\}}(M/N_1)^\sim = 0$, therefore :

$$\Gamma_{\{\mathfrak{p}_j\}}Q^\sim_{\mathfrak{p}_j} = \mathrm{Ker}\,(\Gamma_{\{\mathfrak{p}_j\}}M^\sim_{\mathfrak{p}_j} \to \oplus_{i=1}^k (M/N_i)^\sim_{\mathfrak{p}_j}) = 0.$$

Hence $\mathrm{Ass}\,Q = \varnothing$, by proposition 10.5.6(i), and then $Q = 0$ by lemma 10.5.5(iii). In other words, we can omit N_1 from (10.5.16), and still obtain a primary decomposition of 0; iterating this argument, we may achieve that $\mathrm{Ass}\,M = \{\mathfrak{p}_1, \dots, \mathfrak{p}_k\}$. After these reductions, we see that

$$\Gamma_{\{\mathfrak{p}_j\}}(M/N_i)^\sim_{\mathfrak{p}_j} = 0 \qquad \text{whenever } i \neq j$$

and consequently :

$$\mathrm{Ker}\,(\varphi_j : \Gamma_{\{\mathfrak{p}_j\}}M^\sim_{\mathfrak{p}_j} \to (M/N_j)_{\mathfrak{p}_j}) = 0 \qquad \text{for every } j = 1, \dots, k.$$

Now, for given $j \leq k$, let $\overline{f}_1, \dots, \overline{f}_n$ be a system of non-zero generators for M/N_j; by assumption $I_i := \mathrm{Ann}_A(\overline{f}_i)$ is a $\mathfrak{p}_j$-primary ideal for every $i \leq n$. Hence $\mathfrak{q}_j := \mathrm{Ann}_A(M/N_j) = \bigcap_{i=1}^n I_i$ is $\mathfrak{p}_j$-primary as well; since φ_j factors through $(M/\mathfrak{q}_jM)_{\mathfrak{p}_j}$, we see that (b) holds.

Conversely, suppose that (a) and (b) hold. Say that $\mathrm{Ass}\,M = \{\mathfrak{p}_1, \dots, \mathfrak{p}_k\}$; for every $j \leq k$ we choose a $\mathfrak{p}_j$-primary ideal $\mathfrak{q}_j$ such that the map $\Gamma_{\{\mathfrak{p}_j\}}M^\sim_{\mathfrak{p}_j} \to M_{\mathfrak{p}_j}/\mathfrak{q}_jM_{\mathfrak{p}_j}$ is injective. Clearly $N_j := \mathrm{Ker}\,(M \to M_{\mathfrak{p}_j}/\mathfrak{q}_jM_{\mathfrak{p}_j})$ is a $\mathfrak{p}_j$-primary submodule of M; moreover, the induced map $\varphi : M \to \oplus_{j=1}^k M/N_j$ is injective, since $\mathrm{Ass}\,\mathrm{Ker}\,\varphi = \varnothing$ (proposition 10.5.6(ii) and lemma 10.5.5(iii)). In other words, $0 = \bigcap_{j=1}^k N_j$ is a primary decomposition of 0. □

Proposition 10.5.18. *Let X be a quasi-compact and quasi-separated scheme, and $0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$ a short exact sequence of quasi-coherent $\mathscr{O}_X$-modules of finite type such that*

(a) $\mathrm{Ass}\,\mathscr{F}' \cap \mathrm{Supp}\,\mathscr{F}'' = \varnothing$.

(b) *The submodules $0 \subset \mathscr{F}'$ and $0 \subset \mathscr{F}''$ admit primary decompositions.*

Then the submodule $0 \subset \mathscr{F}$ admits a primary decomposition.

Proof. The assumptions imply that $\mathrm{Ass}\,\mathscr{F}'$ and $\mathrm{Ass}\,\mathscr{F}''$ are finite sets, (lemma 10.5.15), hence the same holds for $\mathrm{Ass}\,\mathscr{F}$ (proposition 10.5.6(ii)). Given any point $x \in X$ and any x-primary ideal $I \subset \mathscr{O}_{X,x}$, we may consider the commutative diagram with exact rows:

$$\begin{array}{ccccccc} 0 & \longrightarrow & \Gamma_{\{x\}}\mathscr{F}'_x & \longrightarrow & \Gamma_{\{x\}}\mathscr{F}_x & \longrightarrow & \Gamma_{\{x\}}\mathscr{F}''_x \\ & & \downarrow{\scriptstyle\alpha} & & \downarrow{\scriptstyle\beta} & & \downarrow{\scriptstyle\gamma} \\ \mathrm{Tor}_1^{\mathscr{O}_{X,x}}(I,\mathscr{F}''_x) & \longrightarrow & \mathscr{F}'_x/I\mathscr{F}'_x & \longrightarrow & \mathscr{F}_x/I\mathscr{F}_x & \longrightarrow & \mathscr{F}''_x/I\mathscr{F}''_x \end{array}$$

Now, if $x \in \mathrm{Ass}\,\mathscr{F}'$, assumption (a) implies that $\Gamma_{\{x\}}\mathscr{F}''_x = 0 = \mathrm{Tor}_1^{\mathscr{O}_{X,x}}(I_x, \mathscr{F}''_x)$, and by (b) and lemma 10.5.15 we can choose I such that α is injective; a little diagram chase then shows that β is injective as well. Similarly, if $x \in \mathrm{Ass}\,\mathscr{F}''$, we have $\Gamma_{\{x\}}\mathscr{F}'_x = 0$ and we may choose I such that γ is injective, which implies again that β is injective. To conclude the proof it suffices to apply again lemma 10.5.15. □

Proposition 10.5.19. *Let Y be a quasi-compact and quasi-separated scheme, $f : X \to Y$ a finite morphism and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module of finite type. Then the $\mathscr{O}_X$-submodule $0 \subset \mathscr{F}$ admits a primary decomposition if and only if the same holds for the $\mathscr{O}_Y$-submodule $0 \subset f_*\mathscr{F}$.*

Proof. Under the stated assumptions, we can apply the criterion of lemma 10.5.15. To start out, it is clear from proposition 10.5.6(iv.b) that $\mathrm{Ass}\,\mathscr{F}$ is finite if and only if $\mathrm{Ass}\,f_*\mathscr{F}$ is finite. Next, suppose that $0 \subset \mathscr{F}$ admits a primary decomposition, let $y \in \mathrm{Ass}\,f_*\mathscr{F}$ be any point and set $f^{-1}(y) := \{x_1, \dots, x_n\}$; for every $j \leq n$ we can find an x_j-primary ideal $I_j \subset \mathscr{O}_X$ such that the map $\Gamma_{\{x_j\}}\mathscr{F}_{x_j} \to \mathscr{F}_{x_j}/I_j\mathscr{F}_{x_j}$ is injective. Let I be the kernel of the natural map $\mathscr{O}_Y \to f_*(\mathscr{O}_X/(I_1 \cap \cdots \cap I_n))$. Then I is a quasi-coherent y-primary ideal of $\mathscr{O}_Y$ and we deduce a commutative diagram :

$$\begin{array}{ccc} \bigoplus_{j=1}^n \Gamma_{\{x_j\}}(\mathscr{F}_{x_j}) & \longrightarrow & \Gamma_{\{y\}}(f_*\mathscr{F}_y) \\ \downarrow{\scriptstyle\alpha} & & \downarrow{\scriptstyle\beta} \\ \bigoplus_{j=1}^n \mathscr{F}_{x_j}/I\mathscr{F}_{x_j} & \longrightarrow & f_*\mathscr{F}_y/If_*\mathscr{F}_y \end{array} \tag{10.5.20}$$

whose horizontal arrows are isomorphisms, in view of proposition 10.5.6(iv.a), and where α is injective by construction. It follows that β is injective, so condition (b) of lemma 10.5.15 holds for the stalk $f_*\mathscr{F}_y$, and since $y \in \mathrm{Ass}\,f_*\mathscr{F}$ is arbitrary, we see that $0 \subset f_*\mathscr{F}$ admits a primary decomposition. Conversely, suppose that $0 \subset f_*\mathscr{F}$ admits a primary decomposition; then for every $y \in Y$ we can find a quasi-coherent y-primary ideal $I \subset \mathscr{O}_Y$ such that the map β of (10.5.20) is injective; hence α is injective as well, and again we deduce easily that $0 \subset \mathscr{F}$ admits a primary decomposition. □

Proposition 10.5.21. *Let X and $\mathscr{F}$ be as in lemma* 10.5.15, *$i : Z \to X$ a closed constructible immersion, and $U := X \setminus Z$. Suppose that :*

(a) *The $\mathscr{O}_U$-submodule $0 \subset \mathscr{F}_{|U}$ and the $\mathscr{O}_Z$-submodule $0 \subset i^*\mathscr{F}$ admit primary decompositions.*
(b) *The natural map $\underline{\Gamma}_Z\mathscr{F} \to i_*i^*\mathscr{F}$ is injective.*

Then the $\mathscr{O}_X$-submodule $0 \subset \mathscr{F}$ admits a primary decomposition.

Proof. We shall verify that conditions (a) and (b) of lemma 10.5.15 hold for $\mathscr{F}$. To check condition (a), it suffices to remark that $U \cap \mathrm{Ass}\,\mathscr{F} = \mathrm{Ass}\,\mathscr{F}_{|U}$ (which is obvious) and that $Z \cap \mathrm{Ass}\,\mathscr{F} \subset \mathrm{Ass}\,i^*\mathscr{F}$, which follows easily from our current assumption (b).

Next we check that condition (b) of *loc.cit.* holds. This is no problem for the points $x \in U \cap \mathrm{Ass}\,\mathscr{F}$, so suppose that $x \in Z \cap \mathrm{Ass}\,\mathscr{F}$. Moreover, we may also assume that X is affine, say $X = \operatorname{Spec} A$, so that $Z = V(J)$ for some ideal $J \subset A$. Due to proposition 10.5.19 we know that $0 \subset \mathscr{G} := i_*i^*\mathscr{F}$ admits a primary decomposition, hence we can find an x-primary ideal $I \subset A$ such that the natural map $\Gamma_{\{x\}}\mathscr{G} \to \mathscr{G}_x/I\mathscr{G}_x \simeq \mathscr{F}_x/(I+J)\mathscr{F}_x$ is injective. Clearly $I + J$ is again a x-primary ideal; since Z is closed and constructible, corollary 10.4.10 and our assumption (b) imply that the natural map $\Gamma_{\{x\}}\mathscr{F} \to \Gamma_{\{x\}}\mathscr{G}$ is injective, hence the same holds for the map $\Gamma_{\{x\}}\mathscr{F} \to \mathscr{F}_x/(I+J)\mathscr{F}_x$, as required. □

10.5.22. Let now A be a ring, $\mathfrak{p} \subset A$ any prime ideal, and $n \geq 1$ any integer; if $A/\mathfrak{p}^n$ does not admit imbedded primes, then the ideal $\mathfrak{p}^n$ is $\mathfrak{p}$-primary. In the presence of imbedded primes, this fails. For instance, we have the following :

Example 10.5.23. Let k be a field, $k[x, y]$ the free polynomial algebra in indeterminates x and y; consider the ideal $I := (xy, y^2)$, and set $A := k[x, y]/I$. Let $\overline{x}$ and $\overline{y}$ be the images of x and y in A; then $\mathfrak{p} := (\overline{y}) \subset A$ is a prime ideal, and $\mathfrak{p}^2 = 0$. However, $\mathfrak{m} := \operatorname{Ann}_A(\overline{y})$ is the maximal ideal generated by $\overline{x}$ and $\overline{y}$, so the ideal $0 \subset A$ is not $\mathfrak{p}$-primary.

There is however a natural sequence of $\mathfrak{p}$-primary ideals naturally attached to $\mathfrak{p}$. To explain this, let us remark, more generally, the following :

Lemma 10.5.24. *Let A be a ring, $\mathfrak{p} \subset A$ a prime ideal. Denote by $\varphi_\mathfrak{p} : A \to A_\mathfrak{p}$ the localization map. The rule :*

$$I \mapsto \varphi_\mathfrak{p}^{-1} I$$

induces a bijection from the set of $\mathfrak{p}A_\mathfrak{p}$-primary ideals of $A_\mathfrak{p}$, to the set of $\mathfrak{p}$-primary ideals of A.

Proof. Suppose that $I \subset A_\mathfrak{p}$ is $\mathfrak{p}A_\mathfrak{p}$-primary; since the natural map $A/\varphi_\mathfrak{p}^{-1}I \to A_\mathfrak{p}/I$ is injective, it is clear that $\varphi_\mathfrak{p}^{-1}I$ is $\mathfrak{p}$-primary. Conversely, suppose that $J \subset A$ is $\mathfrak{p}$-primary; we claim that $J = \varphi_\mathfrak{p}^{-1}(J_\mathfrak{p})$. Indeed, by assumption (and by lemma 10.5.5(iii)) we have $(A/J)_\mathfrak{q} = 0$ whenever $\mathfrak{q} \neq \mathfrak{p}$; it follows easily that the localization map $A/J \to A_\mathfrak{p}/J_\mathfrak{p}$ is an isomorphism, whence the contention. □

Definition 10.5.25. Keep the notation of lemma 10.5.24; for every $n \geq 0$ one defines the *n-th symbolic power* of $\mathfrak{p}$, as the ideal :

$$\mathfrak{p}^{(n)} := \varphi_\mathfrak{p}^{-1}(\mathfrak{p}^n A_\mathfrak{p}).$$

By lemma 10.5.24, the ideal $\mathfrak{p}^{(n)}$ is $\mathfrak{p}$-primary for every $n \geq 1$. More generally, for every A-module M, let $\varphi_{M,\mathfrak{p}} : M \to M_\mathfrak{p}$ be the localization map; then one defines the *$\mathfrak{p}$-symbolic filtration* on M, by the rule :

$$\operatorname{Fil}^{(n)}_\mathfrak{p} M := \varphi^{-1}_{M,\mathfrak{p}}(\mathfrak{p}^n M_\mathfrak{p}) \qquad \text{for every } n \geq 0.$$

The filtration $\operatorname{Fil}^{(\bullet)}_\mathfrak{p} M$ induces a (linear) topology on M, called the *$\mathfrak{p}$-symbolic topology*.

More generally, if $\Sigma \subset \operatorname{Spec} A$ is any subset, we define the *Σ-symbolic topology* on M, as the coarsest linear topology $\mathscr{T}_\Sigma$ on M such that $\operatorname{Fil}^{(n)}_\mathfrak{p} M$ is an open subset of $\mathscr{T}_\Sigma$, for every $\mathfrak{p} \in \Sigma$ and every $n \geq 0$. If Σ is finite, it is induced by the *Σ-symbolic filtration*, defined by the submodules :

$$\operatorname{Fil}^{(n)}_\Sigma M := \bigcap_{\mathfrak{p} \in \Sigma} \operatorname{Fil}^{(n)}_\mathfrak{p} M \qquad \text{for every } n \geq 0.$$

10.5.26. Let A be a ring, M an A-module, $I \subset A$ an ideal. We shall show how to characterize the finite subsets $\Sigma \subset \operatorname{Spec} A$ such that the Σ-symbolic topology on M agrees with the I-preadic topology (see theorem 10.5.35). Hereafter, we begin with a few preliminary observations. First, suppose that A is noetherian; then it is easily seen that, for every prime ideal $\mathfrak{p} \subset A$, and every $\mathfrak{p}A_\mathfrak{p}$-primary ideal $I \subset A_\mathfrak{p}$, there exists $n \in \mathbb{N}$ such that $\mathfrak{p}^n A_\mathfrak{p} \subset I$. From lemma 10.5.24 we deduce that every $\mathfrak{p}$-primary ideal of A contains a symbolic power of $\mathfrak{p}$; *i.e.*, every

$\mathfrak{p}$-primary ideal is open in the $\mathfrak{p}$-symbolic topology of A. More generally, let $\Sigma \subset \mathrm{Spec}\, A$ be any subset, M a finitely generated A-module, and $N \subset M$ a submodule; from the existence of a primary decomposition for N ([126, Th.6.8]), we see that N is open in the Σ-symbolic topology of M, whenever $\mathrm{Ass}\, M/N \subset \Sigma$. Especially, if $\mathrm{Ass}\, M/I^nM \subset \Sigma$ for every $n \in \mathbb{N}$, then the Σ-symbolic topology is finer than the I-preadic topology on M. On the other hand, clearly $I^nM \subset \mathrm{Fil}^{(n)}_{\mathfrak{p}} M$ for every $\mathfrak{p} \in \mathrm{Supp}\, M/IM$ and every $n \in \mathbb{N}$, so the I-preadic topology on M is finer than the $\mathrm{Supp}\, M/IM$-symbolic topology. Summing up, if we have :

$$\Sigma_0(M) := \bigcup_{n\in\mathbb{N}} \mathrm{Ass}\, M/I^nM \subset \Sigma \subset \mathrm{Supp}\, M/IM$$

then the Σ-symbolic topology on M agrees with the I-preadic topology. Notice that the above expression for $\Sigma_0(M)$ is a union of finite subsets ([126, Th.6.5(i)]), hence $\Sigma_0(M)$ is – *a priori* – at most countable; in fact, we shall show that $\Sigma_0(M)$ is finite. Indeed, for every $n \in \mathbb{N}$, set :

$$\mathrm{gr}^n_I A := I^n/I^{n+1} \qquad \mathrm{gr}^n_I M := I^nM/I^{n+1}M.$$

Then $\mathrm{gr}^\bullet_I A := \oplus_{n\in\mathbb{N}} \mathrm{gr}^n_I A$ is naturally a graded A/I-algebra, and $\mathrm{gr}^\bullet_I M := \oplus_{n\in\mathbb{N}} \mathrm{gr}^n_I M$ is a graded $\mathrm{gr}^\bullet_I A$-module. Let $\psi : \mathrm{Spec}\, \mathrm{gr}^\bullet_I A \to \mathrm{Spec}\, A/I$ be the natural morphism, and set :

$$\Sigma(M) := \psi(\mathrm{Ass}_{\mathrm{gr}^\bullet_I A}(\mathrm{gr}^\bullet_I M)).$$

Lemma 10.5.27. *With the notation of* (10.5.26)*, we have :*

$$\mathrm{Ass}_{A/I}(\mathrm{gr}^n_I M) \subset \Sigma(M) \qquad \textit{for every } n \in \mathbb{N}.$$

Proof. To ease notation, set $A_0 := A/I$ and $B := \mathrm{gr}^\bullet_I A$. Suppose that $\mathfrak{p} \in \mathrm{Ass}_{A_0}(\mathrm{gr}^n_I M)$; by lemma 10.5.3(i), there exists $m \in \mathrm{gr}^n_I M$ such that $\mathfrak{p}$ is the preimage of a minimal prime ideal of $A_0/\mathrm{Ann}_{A_0}(m)$. However, if we regard m as a homogeneous element of the B-module $\mathrm{gr}^\bullet_I M$, we have the obvious identity :

$$\mathrm{Ann}_{A_0}(m) = A_0 \cap \mathrm{Ann}_B(m) \subset B$$

from which we see that the induced map

$$A_0/\mathrm{Ann}_{A_0}(m) \to B/\mathrm{Ann}_B(m)$$

is injective, hence ψ restricts to a dominant morphism $V(\mathrm{Ann}_B(m)) \to V(\mathrm{Ann}_{A_0}(m))$. Especially, there exists $\mathfrak{q} \in V(\mathrm{Ann}_B(m))$ with $\psi(\mathfrak{q}) = \mathfrak{p}$; up to replacing $\mathfrak{q}$ by a generization, we may assume that $\mathfrak{q}$ is a maximal point of $V(\mathrm{Ann}_B(m))$, hence $\mathfrak{q}$ is an associated prime for $\mathrm{gr}^\bullet_I M$, again by lemma 10.5.3(i). □

10.5.28. An easy induction, starting from lemma 10.5.27, shows that $\mathrm{Ass}_A M/I^nM \subset \Sigma(M)$, for every $n \in \mathbb{N}$, therefore $\Sigma_0(M) \subset \Sigma(M)$. However, if A is noetherian, the same holds for $\mathrm{gr}^\bullet_I A$ (since the latter is a quotient of an A/I-algebra of finite type), hence $\Sigma(M)$ is finite, provided M is finitely generated ([126, Th.6.5(i)]), and *a fortiori*, the same holds for $\Sigma_0(M)$.

Remark 10.5.29. Another proof of the finiteness of $\Sigma_0(M)$ can be found in [42].

10.5.30. Next, we wish to show that actually there exists a *smallest* subset $\Sigma_{\min}(M) \subset \mathrm{Spec}\, A$ such that the $\Sigma_{\min}(M)$-symbolic topology on M agrees with I-preadic topology; after some simple reductions, this boils down to the following assertion. Let $\Sigma \subset \mathrm{Spec}\, A$ be a finite subset, and $\mathfrak{p}, \mathfrak{p}' \in \Sigma$ two elements, such that the Σ-symbolic topology on M agrees with both the $\Sigma \setminus \{\mathfrak{p}\}$-symbolic topology and the $\Sigma\setminus\{\mathfrak{p}'\}$-symbolic topology; then these topologies agree as well with the $\Sigma \setminus \{\mathfrak{p}, \mathfrak{p}'\}$-symbolic topology. Indeed, given any subset $\Sigma' \subset \mathrm{Spec}\, A$ with $\mathfrak{p} \in \Sigma'$, for the Σ'-symbolic and the $\Sigma' \setminus \{\mathfrak{p}\}$-symbolic topologies to agree, it is necessary and sufficient that, for every $n \in \mathbb{N}$ there exists $m \in \mathbb{N}$ such that :

$$\mathrm{Fil}^{(m)}_{\Sigma'\setminus\{\mathfrak{p}\}} M \subset \mathrm{Fil}^{(n)}_{\mathfrak{p}} M \qquad \text{or, what is the same :} \qquad \mathrm{Fil}^{(m)}_{\Sigma'\setminus\{\mathfrak{p}\}} M_{\mathfrak{p}} \subset \mathfrak{p}^n M_{\mathfrak{p}}.$$

In the latter inclusion, we may then replace $\Sigma' \setminus \{\mathfrak{p}\}$ by the smaller subset $\Sigma' \cap \mathrm{Spec}\, A_{\mathfrak{p}} \setminus \{\mathfrak{p}\}$, without changing the two terms. Suppose now that $\mathfrak{p}' \notin \mathrm{Spec}\, A_{\mathfrak{p}}$; then if we apply the above, first with $\Sigma' := \Sigma$, and then with $\Sigma' := \Sigma \setminus \{\mathfrak{p}'\}$, we see that the Σ-symbolic topology agrees with the $\Sigma\setminus\{\mathfrak{p}\}$-symbolic topology, if and only if the $\Sigma\setminus\{\mathfrak{p}'\}$-symbolic topology agrees with the $\Sigma\setminus\{\mathfrak{p}, \mathfrak{p}'\}$-symbolic topology, whence the contention. In case $\mathfrak{p}' \in \mathrm{Spec}\, A_{\mathfrak{p}}$, we may assume that $\mathfrak{p} \neq \mathfrak{p}'$, otherwise there is nothing to prove; then we shall have $\mathfrak{p} \notin \mathrm{Spec}\, A_{\mathfrak{p}'}$, so the foregoing argument still goes through, after reversing the roles of $\mathfrak{p}$ and $\mathfrak{p}'$.

10.5.31. Finally, theorem 10.5.35 will characterize the subset $\Sigma_{\min}(M)$ as in (10.5.28). To this aim, for every prime ideal $\mathfrak{p} \subset A$, let $A^\wedge_{\mathfrak{p}}$ denote the $\mathfrak{p}$-adic completion of A; we set :

$$\mathrm{Ass}_A(I, M) := \{\mathfrak{p} \in \mathrm{Spec}\, A \mid \text{there exists } \mathfrak{q} \in \mathrm{Ass}_{A^\wedge_{\mathfrak{p}}} M \otimes_A A^\wedge_{\mathfrak{p}} \text{ such that } \sqrt{\mathfrak{q} + IA^\wedge_{\mathfrak{p}}} = \mathfrak{p}A^\wedge_{\mathfrak{p}}\}$$

(where, for any ideal $J \subset A^\wedge_{\mathfrak{p}}$ we denote by $\sqrt{J} \subset A^\wedge_{\mathfrak{p}}$ the radical of J, so the above condition selects the points $\mathfrak{q} \in \mathrm{Spec}\, A^\wedge_{\mathfrak{p}}$, such that $\overline{\{\mathfrak{q}\}} \cap V(IA^\wedge_{\mathfrak{p}}) = \{\mathfrak{p}A^\wedge_{\mathfrak{p}}\}$).

Lemma 10.5.32. *Let A be a noetherian ring, M an A-module. Then we have :*

(i) $\mathrm{depth}_{A_{\mathfrak{p}}} M \otimes_A A_{\mathfrak{p}} = \mathrm{depth}_{A^\wedge_{\mathfrak{p}}} M \otimes_A A^\wedge_{\mathfrak{p}}$ *for every* $\mathfrak{p} \in \mathrm{Spec}\, A$.
(ii) $\mathrm{Ass}_A(0, M) = \mathrm{Ass}_A M$.
(iii) $\mathrm{Ass}_A(I, M) \subset V(I) \cap \mathrm{Supp}\, M$.
(iv) *Suppose that M is the union of a filtered family $(M_\lambda \mid \lambda \in \Lambda)$ of A-submodules. Then :*

$$\mathrm{Ass}_A(I, M) = \bigcup_{\lambda \in \Lambda} \mathrm{Ass}_A(I, M_\lambda).$$

(v) $\mathrm{Ass}_A(I, M)$ *contains the maximal points of* $V(I) \cap \mathrm{Supp}\, M$.

Proof. (iii) is immediate, and in view of [126, Th.8.8], (i) is a special case of corollary 10.4.37.

(ii): By definition, $\mathrm{Ass}_A(0, M)$ consists of all the prime ideals $\mathfrak{p} \subset A$ such that $\mathfrak{p}A^\wedge_{\mathfrak{p}}$ is an associated prime ideal of $M \otimes_A A^\wedge_{\mathfrak{p}}$; in light of proposition 10.5.6(i), the latter condition holds if and only if $\mathrm{depth}_{A^\wedge_{\mathfrak{p}}} M \otimes_A A^\wedge_{\mathfrak{p}} = 0$, hence if and only if $\mathrm{depth}_{A_{\mathfrak{p}}} M \otimes_A A_{\mathfrak{p}} = 0$, by (i); to conclude, one appeals again to proposition 10.5.6(i).

(iv): In view of proposition 10.5.6(v), we have $\mathrm{Ass}_{A^\wedge_{\mathfrak{p}}} M \otimes_A A^\wedge_{\mathfrak{p}} = \bigcup_{\lambda \in \Lambda} \mathrm{Ass}_{A^\wedge_{\mathfrak{p}}} M_\lambda \otimes_A A^\wedge_{\mathfrak{p}}$; the contention is an immediate consequence.

(v): In view of (iv), we are easily reduced to the case where M is a finitely generated A-module, in which case $\mathrm{Supp}\, M = V(J)$ for some ideal $J \subset A$. Hence, suppose that $\mathfrak{p} \subset A$ is a maximal point of $\mathrm{Spec}\, A/(I + J)$, in other words, the preimage of a minimal prime ideal of $A/(I + J)$; notice that $\mathrm{Supp}\, M \otimes_A A^\wedge_{\mathfrak{p}} = V(JA^\wedge_{\mathfrak{p}})$. Hence we have $(J + I)A^\wedge_{\mathfrak{p}} \subset \mathfrak{q} + IA^\wedge_{\mathfrak{p}}$ for every $\mathfrak{q} \in \mathrm{Supp}\, M \otimes_A A^\wedge_{\mathfrak{p}}$, so the radical of $\mathfrak{q} + IA^\wedge_{\mathfrak{p}}$ equals $\mathfrak{p}A^\wedge_{\mathfrak{p}}$, as required. ☐

Lemma 10.5.33 (Chevalley's theorem)**.** *Let $(A, \mathfrak{m})$ be an $\mathfrak{m}$-adically complete local noetherian ring, M a finitely generated A-module, and $(\mathrm{Fil}^n M \mid n \in \mathbb{N})$ a descending filtration consisting of A-submodules of M. Then the following conditions are equivalent :*

(a) $\bigcap_{n \in \mathbb{N}} \mathrm{Fil}^n M = 0$.
(b) *For every $i \in \mathbb{N}$ there exists $n \in \mathbb{N}$ such that* $\mathrm{Fil}^n M \subset \mathfrak{m}^i M$.

Proof. Clearly (b)⇒(a), hence suppose that (a) holds. For every $i, n \in \mathbb{N}$, set

$$J_{i,n} := \mathrm{Im}(\mathrm{Fil}^n M \to M/\mathfrak{m}^i M).$$

For given $i \in \mathbb{N}$, the A-module $M/\mathfrak{m}^i M$ is artinian, hence there exists $n \in \mathbb{N}$ such that $J_i := J_{i,n} = J_{i,n'}$ for every $n' \geq n$. Assertion (b) then follows from the following :

Claim 10.5.34. If (a) holds, $J_i = 0$ for every $i \in \mathbb{N}$.

Proof of the claim. By inspecting the definition, it is easily seen that the natural $A/\mathfrak{m}^{i+1}$-linear map $J_{i+1} \to J_i$ is surjective for every $i \in \mathbb{N}$, hence we are reduced to showing that $J := \lim_{i\in\mathbb{N}} J_i$ vanishes. However, J is naturally a submodule of $\lim_{i\in\mathbb{N}} M/\mathfrak{m}^i M \simeq M$, and if $x \in M$ lies in J, then we have $x \in \mathrm{Fil}^n M + \mathfrak{m}^i M$ for every $i, n \in \mathbb{N}$. Since $\mathrm{Fil}^n M$ is a closed subset for the $\mathfrak{m}$-adic topology of M ([126, Th.8.10(i)]), we have $\bigcap_{i\in\mathbb{N}}(\mathrm{Fil}^n M + \mathfrak{m}^i M) = \mathrm{Fil}^n M$, for every $n \in \mathbb{N}$, hence $x \in \bigcap_{n\in\mathbb{N}} \mathrm{Fil}^n M$, which vanishes, if (a) holds. □

The following theorem generalizes [145, Ch.VIII, §5, Cor.5] and [88, Prop.7.1], and is closely related to [148, Th.3.2]; see also [51, Th.3.6].

Theorem 10.5.35. *Let A be a noetherian ring, $I \subset A$ an ideal, M a finitely generated A-module, and $\Sigma \subset \mathrm{Spec}\, A/I$ a finite subset. Then the Σ-symbolic topology on M agrees with the I-preadic topology if and only if* $\mathrm{Ass}_A(I, M) \subset \Sigma$.

Proof. Let $\mathfrak{p} \in \mathrm{Ass}_A(I, M)\setminus\Sigma$, and suppose, by way of contradiction, that the Σ-symbolic topology agrees with the I-adic topology, *i.e.* for every $n \in \mathbb{N}$ there exists $m \in \mathbb{N}$ such that :

$$\mathrm{Fil}^{(m)}_\Sigma M \subset I^n M.$$

Let $X := \mathrm{Spec}\, A_\mathfrak{p}$ and $U := X\setminus\{\mathfrak{p}\}$; after localizing at the prime $\mathfrak{p}$, we deduce the inclusion :

$$\mathrm{Fil}^{(m)}_{\Sigma\cap U} M_\mathfrak{p} \subset I^n M_\mathfrak{p} \tag{10.5.36}$$

(cp. the discussion in (10.5.28)). Let also $\mathscr{M} := M^\sim$, the quasi-coherent $\mathscr{O}_X$-module associated to M; clearly we have $I^m M \subset \mathrm{Fil}^{(m)}_\mathfrak{q} M$ for every $\mathfrak{q} \in \mathrm{Spec}\, A/I$, hence (10.5.36) implies the inclusion :

$$\{x \in M_\mathfrak{p} \mid x_{|U} \in I^m\mathscr{M}(U)\} \subset I^n M_\mathfrak{p}.$$

Let $A^\wedge_\mathfrak{p}$ (resp. $M^\wedge_\mathfrak{p}$) be the $\mathfrak{p}$-adic completion of A (resp. of M), $f : X^\wedge := \mathrm{Spec}\, A^\wedge_\mathfrak{p} \to X$ the natural morphism, and set $U^\wedge := f^{-1}U = X^\wedge \setminus \{\mathfrak{p}A^\wedge_\mathfrak{p}\}$. Since f is faithfully flat, and U is quasi-compact, we deduce that :

$$\{x \in M^\wedge_\mathfrak{p} \mid x_{|U^\wedge} \in I^m f^*\mathscr{M}(U^\wedge)\} \subset I^n M^\wedge_\mathfrak{p}. \tag{10.5.37}$$

On the other hand, by assumption there exists $\mathfrak{q} \in \mathrm{Ass}_{A^\wedge_\mathfrak{p}} M^\wedge_\mathfrak{p}$ such that $\overline{\{\mathfrak{q}\}}\cap V(IA^\wedge_\mathfrak{p}) = \{\mathfrak{p}A^\wedge_\mathfrak{p}\}$, hence we may find $x \in M^\wedge_\mathfrak{p}$ whose support is $\overline{\{\mathfrak{q}\}}$ (lemma 10.5.3(ii)). It follows easily that the image of x vanishes in $f^*\mathscr{M}/I^m f^*\mathscr{M}(U)$ for all $m \in \mathbb{N}$, *i.e.* $x_{|U} \in I^m f^*\mathscr{M}(U)$ for every $m \in \mathbb{N}$, hence $x \in I^n M^\wedge_\mathfrak{p}$ for every $n \in \mathbb{N}$, in view of (10.5.37). However, $M^\wedge_\mathfrak{p}$ is separated for the $\mathfrak{p}$-adic topology, *a fortiori* also for the I-preadic topology, so $x = 0$, a contradiction.

Next, let $\mathfrak{p} \in \Sigma\setminus\mathrm{Ass}_A(I, M)$, set $\Sigma' := \Sigma\setminus\{\mathfrak{p}\}$, and suppose that the Σ-symbolic topology agrees with the I-adic topology; we have to prove that the latter agrees as well with the Σ'-symbolic topology. This amounts to showing that, for every $n \in \mathbb{N}$ there exists $m \in \mathbb{N}$ such that :

$$\mathrm{Fil}^{(m)}_{\Sigma'} M \subset \mathrm{Fil}^{(n)}_\mathfrak{p} M \qquad \text{or, what is the same :} \qquad \mathrm{Fil}^{(m)}_{\Sigma'} M_\mathfrak{p} \subset \mathfrak{p}^n M_\mathfrak{p}.$$

We may write :

$$\mathrm{Fil}^{(m)}_{\Sigma'} M_\mathfrak{p} = \{x \in M_\mathfrak{p} \mid x_{|U} \in (\mathrm{Fil}^{(m)}_{\Sigma'} M_\mathfrak{p})^\sim(U)\} = \{x \in M_\mathfrak{p} \mid x_{|U} \in (\mathrm{Fil}^{(m)}_{\Sigma} M_\mathfrak{p})^\sim(U)\}$$

from which it is clear that the contention holds if and only if, for every $n \in \mathbb{N}$ there exists $m \in \mathbb{N}$ such that :

$$\{x \in M_\mathfrak{p} \mid x_{|U} \in I^m\mathscr{M}(U)\} \subset \mathfrak{p}^n M_\mathfrak{p}.$$

Arguing as in the foregoing, we see that the latter condition holds if and only if :

$$\mathrm{Fil}^m M^\wedge_\mathfrak{p} := \{x \in M^\wedge_\mathfrak{p} \mid x_{|U^\wedge} \in I^m f^*\mathscr{M}(U^\wedge)\} \subset \mathfrak{p}^n M^\wedge_\mathfrak{p}.$$

In view of lemma 10.5.33, we are then reduced to showing the following :

Claim 10.5.38. $\bigcap_{m\in\mathbb{N}} \mathrm{Fil}^m M^\wedge_\mathfrak{p} = 0.$

Proof of the claim. Let x be an element in this intersection; for any $\mathfrak{q} \in U^\wedge \cap V(IA_\mathfrak{p}^\wedge)$, we have $x_\mathfrak{q} \in \bigcap_{m\in\mathbb{N}} \mathfrak{q}^m(M_\mathfrak{p}^\wedge)_\mathfrak{q}$, hence $x_\mathfrak{q} = 0$, by [126, Th.8.10(i)]. In other words, $\mathrm{Supp}(x) \cap U \cap V(I) = \varnothing$. Suppose that $x \neq 0$, and let $\mathfrak{q}$ be any maximal point of $\mathrm{Supp}(x)$; by lemma 10.5.3(i), $\mathfrak{q}$ is an associated prime, and the foregoing implies that $\{\mathfrak{q}\} \cap V(IA_\mathfrak{p}^\wedge) = \{\mathfrak{p}A_\mathfrak{p}^\wedge\}$, which contradicts the assumption that $\mathfrak{p} \notin \mathrm{Ass}_A(I, M)$. □

Corollary 10.5.39. *In the situation of theorem* 10.5.35*,* $\mathrm{Ass}_A(I, M)$ *is a finite set.*

Proof. We have already found a finite subset $\Sigma \subset \mathrm{Spec}\, A/I$ such that the Σ-symbolic topology on M agrees with the I-preadic topology (see (10.5.28)). The contention then follows straightforwardly from theorem 10.5.35. □

Example 10.5.40. Let k be a field with $\mathrm{char}\, k \neq 2$, and let $C \subset \mathbb{A}_k^2 := \mathrm{Spec}\, k[X, Y]$ be the nodal curve cut by the equation $Y^2 = X^2 + X^3$, so that the only singularity of C is the node at the origin $p := (0, 0) \in C$. Let $R := k[X, Y, Z]$, $A := R/(Y^2 - X^2 - X^3)$; denote by $\pi : \mathbb{A}_k^3 := \mathrm{Spec}\, R \to \mathbb{A}_k^2$ the linear projection which is dual to the inclusion $k[X, Y] \to R$, so that $D := \pi^{-1}C = \mathrm{Spec}\, A$. We define a morphism $\varphi : \mathbb{A}_k^1 := \mathrm{Spec}\, k[T] \to D$ by the rule : $T \mapsto (T^2 - 1, T(T^2 - 1), T)$ (*i.e.* φ is dual to the homomorphism of k-algebras such that $X \mapsto T^2 - 1$, $Y \mapsto T(T^2 - 1)$ and $Z \mapsto T$). Let $C' \subset D$ be the image of φ, with its reduced subscheme structure. It is easy to check that the restriction of π maps C' birationally onto C, so there are precisely two points $p'_0, p'_1 \in C'$ lying over p. Let $\mathfrak{n} := I(C') \subset A$, the prime ideal which is the generic point of the (irreducible) curve C'. We claim that the $\mathfrak{n}$-preadic topology on A does not agree with the $\mathfrak{n}$-symbolic topology. To this aim – in view of theorem 10.5.35 – it suffices to show that $\{p'_0, p'_1\} \subset \mathrm{Ass}_A(\mathfrak{n}, A)$. However, for any closed point $\mathfrak{p} \in \pi^{-1}(p)$, the $\mathfrak{p}$-adic completion $A_\mathfrak{p}^\wedge$ admits two distinct minimal primes, corresponding to the two branches of the nodal conic C at the node p, and the corresponding irreducible components of $B := \mathrm{Spec}\, A_\mathfrak{p}^\wedge$ meet along the affine line $V(Z)$. To see this, we may suppose that $\mathfrak{p} = (X, Y, Z)$, hence $A_\mathfrak{p}^\wedge \simeq k[[X, Y, Z]]/(Y^2 - X^2(1 + X))$, and notice that the latter is isomorphic to $k[[S, Y, Z]]/(Y^2 - S^2)$, via the isomorphism that sends $Y \mapsto Y$, $Z \mapsto Z$ and $S \mapsto X(1 + X)^{1/2}$ (the assumption on the characteristic of k ensures that $1 + X$ admits a square root in $k[[X]]$). Now, say that $\mathfrak{p} = p'_0$; then $C'_\mathfrak{p} := C' \cap B$ is contained in only one of the two irreducible components of B. Let $\mathfrak{q} \in B$ be the minimal prime ideal whose closure does not contain $C'_\mathfrak{p}$; then $\mathfrak{q} \in \mathrm{Ass} A_\mathfrak{p}^\wedge$ and $\overline{\{\mathfrak{q}\}} \cap C'_\mathfrak{p} = \{\mathfrak{p}A_\mathfrak{p}^\wedge\}$, therefore $p'_0 \in \mathrm{Ass}_A(\mathfrak{n}, A)$, as stated.

Example 10.5.41. Let A be an excellent normal ring, $I \subset A$ any ideal, and set $Z := V(I)$. Then $\mathrm{Ass}_A(I, A)$ is the set $\mathrm{Max}(Z)$ of all maximal points of Z. Indeed, $\mathrm{Max}(Z) \subset \mathrm{Ass}_A(I, A)$ by lemma 10.5.32(v). Conversely, suppose $\mathfrak{p} \in \mathrm{Ass}_A(I, A)$; the completion $A_\mathfrak{p}^\wedge$ is still normal ([126, Th.32.2(i)]), and therefore its only associated prime is 0, so the assumption means that the radical of $IA_\mathfrak{p}^\wedge$ is $\mathfrak{p}A_\mathfrak{p}^\wedge$. Equivalently, $\dim A_\mathfrak{p}^\wedge/IA_\mathfrak{p}^\wedge = 0$, so $\dim A_\mathfrak{p}/IA_\mathfrak{p} = 0$, which is the contention.

Definition 10.5.42. Let X be a noetherian scheme, $Y \subset X$ a closed subset, $\mathfrak{X}$ the formal completion of X along Y ([59, Ch.I, §10.8]), and $f : \mathfrak{X} \to X$ the natural morphism of locally ringed spaces. We say that the pair (X, Y) *satisfies the Lefschetz condition*, if for every open subset $U \subset X$ with $Y \subset U$, and every locally free $\mathscr{O}_U$-module $\mathscr{E}$ of finite type, the natural map

$$\Gamma(U, \mathscr{E}) \to \Gamma(\mathfrak{X}, f^*\mathscr{E})$$

is an isomorphism. In this case, we also say that $\mathrm{Lef}(X, Y)$ holds. (Cp. [85, Exp.X, §2].)

Lemma 10.5.43. *In the situation of definition* 10.5.42*, suppose that* $\mathrm{Lef}(X, Y)$ *holds, and let* $U \subset X$ *be any open subset such that* $Y \subset U$*. Then :*

(i) *The functor :*

$$\mathscr{O}_U\text{-}\mathbf{Mod}_{\mathrm{lfft}} \to \mathscr{O}_\mathfrak{X}\text{-}\mathbf{Mod}_{\mathrm{lfft}} \quad : \quad \mathscr{E} \mapsto f^*\mathscr{E}$$

is fully faithful (notation of (10.3)*).*

(ii) *Denote by* $\mathscr{O}_U\text{-}\mathsf{Alg}_{\mathrm{lfft}}$ *the category of* $\mathscr{O}_U$*-algebras, whose underlying* $\mathscr{O}_U$*-module is locally free of finite type, and define likewise* $\mathscr{O}_{\mathfrak{X}}\text{-}\mathsf{Alg}_{\mathrm{lfft}}$*. Then the functor :*

$$\mathscr{O}_U\text{-}\mathsf{Alg}_{\mathrm{lfft}} \to \mathscr{O}_{\mathfrak{X}}\text{-}\mathsf{Alg}_{\mathrm{lfft}} \quad : \quad \mathscr{A} \mapsto f^*\mathscr{A}$$

is fully faithful.

Proof. (i): Let $\mathscr{E}$ and $\mathscr{F}$ be any two locally free $\mathscr{O}_U$-modules of finite type. We have :

$$\mathrm{Hom}_{\mathscr{O}_U}(\mathscr{E},\mathscr{F}) = \Gamma(U, \mathscr{H}om_{\mathscr{O}_U}(\mathscr{E},\mathscr{F}))$$

and likewise we may compute $\mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(f^*\mathscr{E}, f^*\mathscr{F})$. However, the natural map :

$$f^*\mathscr{H}om_{\mathscr{O}_U}(\mathscr{E},\mathscr{F}) \to \mathscr{H}om_{\mathscr{O}_{\mathfrak{X}}}(f^*\mathscr{E}, f^*\mathscr{F})$$

is an isomorphism of $\mathscr{O}_{\mathfrak{X}}$-modules. The assertion follows.

(ii): An object of $\mathscr{O}_U\text{-}\mathsf{Alg}_{\mathrm{lfft}}$ is a locally free $\mathscr{O}_U$-module $\mathscr{A}$ of finite type, together with morphisms $\mathscr{A} \otimes_{\mathscr{O}_U} \mathscr{A} \to \mathscr{A}$ and $1_{\mathscr{A}} : \mathscr{O}_U \to \mathscr{A}$ of $\mathscr{O}_U$-modules, fulfilling the usual unitarity, commutativity and associativity conditions. An analogous description holds for the objects of $\mathscr{O}_{\mathfrak{X}}\text{-}\mathsf{Alg}_{\mathrm{lfft}}$, and for the morphisms of either category. Since $\mathscr{A} \otimes_{\mathscr{O}_U} \mathscr{A}$ is again locally free of finite type, the assertion follows easily from (i) : the details are left to the reader. □

Lemma 10.5.44. *Let A be a noetherian ring, $I \subset A$ an ideal, $U \subset \mathrm{Spec}\, A$ an open subset, $\mathfrak{U}$ the formal completion of U along $U \cap V(I)$. Consider the following conditions :*

(a) $\mathrm{Lef}(U, U \cap V(I))$ *holds.*

(b) *The natural map* $\rho_U : \Gamma(U, \mathscr{O}_U) \to \Gamma(\mathfrak{U}, \mathscr{O}_{\mathfrak{U}})$ *is an isomorphism.*

(c) *The natural map* $\rho : A \to \Gamma(\mathfrak{U}, \mathscr{O}_{\mathfrak{U}})$ *is an isomorphism.*

Then (c)⇒(b)⇔(a)*, and* (c) *implies that A is I-adically complete.*

Proof. Clearly (a)⇒(b), hence we assume that (b) holds, and we show (a). Let $V \subset U$ be an open subset with $U \cap V(I) \subset V$ and $\mathscr{E}$ a coherent locally free $\mathscr{O}_V$-module. As A is noetherian, V is quasi-compact, so we may find a left exact sequence $P_\bullet := (0 \to \mathscr{E} \to \mathscr{O}_V^{\oplus m} \to \mathscr{O}_V^{\oplus n})$ of $\mathscr{O}_V$-modules (corollary 10.3.28). Since the natural map of locally ringed spaces $f : \mathfrak{U} \to U$ is flat, the sequence f^*P is still left exact. Since the global section functors are left exact, there follows a ladder of left exact sequences :

$$\Gamma(V, P_\bullet) \to \Gamma(\mathfrak{U}, f^*P_\bullet)$$

which reduces the assertion to the case where $\mathscr{E} = \mathscr{O}_V$; the latter is covered by the following :

Claim 10.5.45. The natural map $\rho_V : \Gamma(V, \mathscr{O}_V) \to \Gamma(\mathfrak{U}, \mathscr{O}_{\mathfrak{U}})$ is an isomorphism.

Proof of the claim. The isomorphism ρ_U factors through ρ_V, hence the latter is a surjection. Suppose that $s \in \mathrm{Ker}\, \rho_V$, and $s \neq 0$; then we may find $x \in V$ such that the image s_x of s in $\mathscr{O}_{V,x}$ does not vanish. Moreover, we may find $a \in A$ whose image $a(x)$ in $\kappa(x)$ does not vanish, and such that as is the restriction of an element of A; especially, $as \in \Gamma(U, \mathscr{O}_U)$, and clearly the image of as in $\Gamma(V, \mathscr{O}_V)$ lies in $\mathrm{Ker}\, \rho_V$. Therefore, $as = 0$ in $\Gamma(U, \mathscr{O}_U)$; however the image as_x of as in $\mathscr{O}_{U,x}$ is non-zero by construction, a contradiction. This shows that ρ_V is injective, whence the claim. ◊

Finally, suppose that (c) holds; arguing as in the proof of claim 10.5.45, one sees that ρ_U is an isomorphism. Moreover, since $\Gamma(\mathfrak{U}, \mathscr{O}_{\mathfrak{U}}) \simeq \lim_{n \in \mathbb{N}} \Gamma(\mathfrak{U}, \mathscr{O}_{\mathfrak{U}}/I^n\mathscr{O}_{\mathfrak{U}})$, the morphism ρ factors through the natural A-linear map $i : A \to A^\wedge$ to the I-adic completion of A. The composition with ρ^{-1} yields an A-linear left inverse $s : A^\wedge \to A$ to i. Set $N := \mathrm{Ker}\, s$; clearly s is surjective, hence $A^\wedge \simeq A \oplus N$. It follows easily that $N/I^nN = 0$ for every $n \in \mathbb{N}$, especially $N \subset \bigcap_{n \in \mathbb{N}} I^n A^\wedge$. Therefore $N = 0$, since $A^\wedge$ is separated for the I-adic topology. □

Proposition 10.5.46. *Let $\varphi : A \to B$ be a flat homomorphism of noetherian rings, $I \subset A$ an ideal, $U \subset \mathrm{Spec}\, B$ an open subset. Set $f := \mathrm{Spec}\, \varphi : \mathrm{Spec}\, B \to \mathrm{Spec}\, A$, and assume that :*

(a) *B is complete for the IB-adic topology.*
(b) *For every $x \in V(I)$, we have : $\{y \in f^{-1}(x) \mid \delta(y, \mathscr{O}_{f^{-1}(x)}) = 0\} \subset U$.*
(c) *For every $x \in \mathrm{Ass}_A(I, A)$, we have : $\{y \in f^{-1}(x) \mid \delta(y, \mathscr{O}_{f^{-1}(x)}) \leq 1\} \subset U$.*

Then $\mathrm{Lef}(U, U \cap V(IB))$ *holds.*

Proof. Set $\Sigma := \mathrm{Ass}_A(I, A)$, and let $\mathfrak{U}$ be the formal completion of U along $V(IB)$; by theorem 10.5.35, the I-preadic topology on A agrees with the Σ-symbolic topology. Let also $\mathscr{J}$ be the family consisting of all ideals $J \subset A$ such that $\mathrm{Ass}\, A/J \subset \Sigma$; it follows that the natural maps :

$$B \to \lim_{J \in \mathscr{J}} B/JB \qquad \Gamma(\mathfrak{U}, \mathscr{O}_{\mathfrak{U}}) \to \lim_{J \in \mathscr{J}} \Gamma(U, \mathscr{O}_U/J\mathscr{O}_U)$$

are isomorphisms (see the discussion in (10.5.26)). In view of lemma 10.5.44, we are then reduced to showing :

Claim 10.5.47. The natural map $B/JB \to \Gamma(U, \mathscr{O}_U/J\mathscr{O}_U)$ is an isomorphism for every $J \in \mathscr{J}$.

Proof of the claim. Let $f : Y := \mathrm{Spec}\, B/JB \to X := \mathrm{Spec}\, A/J$ be the induced morphism; in view of corollary 10.4.23, it suffices to prove that $\delta(y, \mathscr{O}_Y) \geq 2$ whenever $y \in Y \setminus U$. Thus, set $x := f(y)$; by corollary 10.4.47 we have :

$$\delta(y, \mathscr{O}_Y) = \delta(y, \mathscr{O}_{f^{-1}(x)}) + \delta(x, \mathscr{O}_X).$$

Now, if $\delta(x, \mathscr{O}_X) = 1$, notice that $f(Y) \subset V(J) \subset V(I)$, by lemmata 10.5.3(i) and 10.5.32(iii); hence (b) implies the contention in this case. Lastly, if $\delta(x, \mathscr{O}_X) = 0$, then $x \in \mathrm{Ass}\, A/J$ by proposition 10.5.6, hence we use assumption (c) to conclude. □

10.6. **Cohomology of projective schemes.** We begin by recalling a few generalities on graded algebras and their homogeneous prime spectra; next we define the blow up of a scheme along a quasi-coherent sheaf of ideals, and we prove some basic results on the higher direct images of quasi-coherent modules under blow up morphisms.

10.6.1. Let $A := \oplus_{n \in \mathbb{N}} A_n$ be a $\mathbb{N}$-graded ring, and set $A_+ := \oplus_{n > 0} A_n$, which is an ideal of A. Following [60, Ch.II, (2.3.1)], one denotes by $\mathrm{Proj}\, A$ the set consisting of all *graded prime ideals* of A that do not contain A_+, and one endows $\mathrm{Proj}\, A$ with the topology induced from the Zariski topology of $\mathrm{Spec}\, A$. For every homogeneous element $f \in A_+$, set :

$$D_+(f) := D(f) \cap \mathrm{Proj}\, A$$

where as usual, $D(f) := \mathrm{Spec}\, A_f \subset \mathrm{Spec}\, A$. Clearly :

(10.6.2) $$D_+(fg) = D_+(f) \cap D_+(g) \qquad \text{for every homogeneous } f, g \in A_+.$$

The system of open subsets $D_+(f)$, for f ranging over the homogeneous elements of A_+, is a basis of the topology of $\mathrm{Proj}\, A$ ([60, Ch.II, Prop.2.3.4]), and obviously any system of homogeneous generators $(f_\lambda \mid \lambda \in \Lambda)$ for the ideal A_+ yields an open covering

$$\mathrm{Proj}\, A = \bigcup_{\lambda \in \Lambda} D_+(f_\lambda).$$

For any homogeneous element $f \in A_+$, let also $A_{(f)} \subset A_f$ be the subring consisting of all elements of degree zero (for the natural $\mathbb{Z}$-grading of A_f); in other words :

$$A_{(f)} := \sum_{k \in \mathbb{N}} A_k \cdot f^{-k} \subset A_f.$$

The topological space $\mathrm{Proj}\, A$ carries a sheaf of rings $\mathscr{O}$, with isomorphisms of ringed spaces :

$$\omega_f : (D_+(f), \mathscr{O}_{|D_+(f)}) \xrightarrow{\sim} \mathrm{Spec}\, A_{(f)} \qquad \text{for every homogeneous } f \in A_+.$$

and the system of isomorphisms ω_f is compatible, in an obvious way, with the inclusions :

$$j_{f,g} : D_+(fg) \subset D_+(f)$$

as in (10.6.2), and with the natural homomorphisms $A_{(f)} \to A_{(fg)}$. Especially, the locally ringed space $(\mathrm{Proj}\, A, \mathscr{O})$ is a separated scheme.

Example 10.6.3. For any $d \in \mathbb{N}$, and any ring R, take $A := R[T_0, \dots, T_d]$, endowed with its standard $\mathbb{N}$-grading such that $\mathrm{gr}_n A$ is the R-module generated by the monomials of total degree n, for every $n \in \mathbb{N}$. The scheme $\mathrm{Proj}\, A$ is the *projective d-dimensional space* over $\mathrm{Spec}\, R$, denoted

$$\mathbb{P}^d_R.$$

According to (10.6.1), it admits the standard affine covering $\mathbb{P}^d_R = \bigcup_{i=0}^d D_+(T_i)$. Set as well

$$\tau_{ij} := T_j/T_i \qquad \text{for every } i, j = 0, \dots, n.$$

Then clearly $A_i := A_{(T_i)} = R[\tau_{ij} \mid j = 0, \dots, d]$ is a free polynomial R-algebra in d variables, so that $U_i := D_+(T_i)$ is isomorphic to the d-dimensional affine space $\mathbb{A}^d_R$ over $\mathrm{Spec}\, R$, for every $i = 0, \dots, d$. For $i \neq j$, the intersection $U_{ij} := D_+(T_i T_j) = U_i \cap U_j$ corresponds, under these identifications, to the open subsets

$$\mathrm{Spec}\, A_i[\tau_{ij}^{-1}] \subset U_i \qquad \text{and} \qquad \mathrm{Spec}\, A_j[\tau_{ji}^{-1}] \subset U_j$$

so we get a commutative diagram of isomorphisms of R-algebras

$$\begin{array}{ccc} & \mathscr{O}_{\mathbb{P}^d_R}(U_{ij}) & \\ \swarrow & & \searrow \\ A_i[\tau_{ij}^{-1}] & \longrightarrow & A_j[\tau_{ji}^{-1}] \end{array}$$

whose downward arrows are induced by the maps ω_{T_i} and ω_{T_j} of (10.6.1), and where the horizontal arrow is given by the rule :

$$\tau_{ik} \mapsto \tau_{jk} \cdot \tau_{ji}^{-1} \qquad \text{for every } k = 0, \dots, d. \tag{10.6.4}$$

10.6.5. Let $A' := \oplus_{n \in \mathbb{N}} A'_n$ be another $\mathbb{N}$-graded ring, and $\varphi : A \to A'$ a homomorphism of graded rings (*i.e.* $\varphi(A_n) \subset A'_n$ for every $n \in \mathbb{N}$). Following [60, Ch.II, (2.8.1)], we let :

$$G(\varphi) := \mathrm{Proj}\, A' \setminus V(\varphi(A_+)).$$

This open subset of $\mathrm{Proj}\, A'$ is also the same as the union of all the open subsets of the form $D_+(\varphi(f))$, where f ranges over the homogeneous elements of A_+. The restriction to $G(\varphi)$ of $\mathrm{Spec}\, \varphi : \mathrm{Spec}\, A' \to \mathrm{Spec}\, A$, is a continuous map ${}^a\varphi : G(\varphi) \to \mathrm{Proj}\, A$. Moreover, we have the identity :

$${}^a\varphi^{-1}(D_+(f)) = D_+(\varphi(f)) \qquad \text{for every homogeneous } f \in A_+.$$

Furthermore, the homomorphism φ induces a homomorphism $\varphi_{(f)} : A_{(f)} \to A'_{(\varphi(f))}$, whence a morphism of schemes :

$$\Phi_f : D_+(\varphi(f)) \to D_+(f).$$

Let $g \in A_+$ be another homogeneous element; it is easily seen that :

$$j_{f,g} \circ \Phi_{fg} = (\Phi_f)_{|D_+(\varphi(fg))}.$$

It follows that the locally defined morphisms Φ_f glue to a unique morphism of schemes :

$$\mathrm{Proj}\, \varphi : G(\varphi) \to \mathrm{Proj}\, A$$

such that the diagram of schemes :

(10.6.6)
$$\begin{array}{ccc} \mathrm{Spec}\, A'_{(\varphi(f))} & \xrightarrow{\mathrm{Spec}\,\varphi_{(f)}} & \mathrm{Spec}\, A_{(f)} \\ {\scriptstyle \omega_{\varphi(f)}}\downarrow & & \downarrow{\scriptstyle \omega_f} \\ D_+(\varphi(f)) & \xrightarrow{(\mathrm{Proj}\,\varphi)_{|D_+(\varphi(f))}} & D_+(f) \end{array}$$

commutes for every homogeneous $f \in A_+$ ([60, Ch.II, Prop.2.8.2]). Lastly, we remark that, for every homogeneous element $f' \in A'_+$, the open subset $D_+(f')$ lies in $G(\varphi)$ if and only if f' lies in the radical of the ideal of A' generated by $\varphi(A_+)$ ([60, Ch.II, Cor.2.3.15]). Especially, $G(\varphi) = \mathrm{Proj}\, A'$ whenever $\varphi(A_+)$ generates the ideal A'_+.

10.6.7. To ease notation, set $Y := \mathrm{Proj}\, A$. Let $M := \oplus_{n\in\mathbb{Z}} M_n$ be a $\mathbb{Z}$-graded A-module (*i.e.* $A_k \cdot M_n \subset M_{k+n}$ for every $k \in \mathbb{N}$ and $n \in \mathbb{Z}$); for every homogeneous $f \in A_+$, denote by $M_{(f)} \subset M_f$ the submodule consisting of all elements of degree zero (for the natural $\mathbb{Z}$-grading of M_f). Clearly $M_{(f)}$ is an $A_{(f)}$-module in a natural way, whence a quasi-coherent $\mathscr{O}_{D_+(f)}$-module $M^\sim_{(f)}$; these modules glue to a unique quasi-coherent $\mathscr{O}_Y$-module $M^\sim$ ([60, Ch.II, Prop.2.5.2]). Especially, for every $n \in \mathbb{Z}$, let $A(n)$ be the $\mathbb{Z}$-graded A-module such that $A(n)_k := A_{n+k}$ for every $k \in \mathbb{Z}$ (with the convention that $A_k = 0$ if $k < 0$). We set :

$$\mathscr{O}_Y(n) := A(n)^\sim.$$

Any element $f \in A_n$ induces a natural isomorphism of $D_+(f)$-modules :

$$\mathscr{O}_Y(n)_{|D_+(f)} \xrightarrow{\sim} \mathscr{O}_{D_+(f)}$$

([60, Ch.II, Prop.2.5.7]). Hence, on the open subset

$$U_n(A) := \bigcup_{f\in A_n} D_+(f)$$

the sheaf $\mathscr{O}_Y(n)$ restricts to an invertible $\mathscr{O}_{U_n(A)}$-module. Especially, if A_1 generates the ideal A_+, the $\mathscr{O}_Y$-modules $\mathscr{O}_Y(n)$ are invertible, for every $n \in \mathbb{Z}$.

Example 10.6.8. Resume the notation of example 10.6.3. A direct inspection of the definitions shows that $A(n)_{(T_i)}$ is the A_i-module generated by all fractions of the form $T_0^{r_0}T_1^{r_1}\cdots T_d^{r_d}T_i^{-k}$, for every $k \in \mathbb{N}$ and every $(r_0, \dots, r_d) \in \mathbb{N}^{\oplus d+1}$ such that $r_0 + r_1 + \cdots + r_d = n + k$. In other words, $A(n)_{(T_i)}$ is the A_i-submodule of $A(n)_{T_i}$ generated by T_i^n. We see then directly that this is a free A_i-module of rank one. Moreover, we get a commutative diagram of isomorphisms

$$\begin{array}{ccc} & \mathscr{O}_{\mathbb{P}^d_R}(n)(U_{ij}) & \\ \swarrow & & \searrow \\ T_i^n A_i[\tau_{ij}^{-1}] & \longrightarrow & T_j^n A_j[\tau_{ji}^{-1}] \end{array}$$

whose downward arrows are induced by the restriction maps of the sheaf $\mathscr{O}_{\mathbb{P}^d_R}(n)$, and where the horizontal map is the $A_i[\tau_{ij}^{-1}]$-linear map given by the rule

$$T_i^n \mapsto T_j^n \cdot \tau_{ji}^n$$

and where the $A_i[\tau_{ij}^{-1}]$-module structure of $T_j^n A_j[\tau_{ji}^{-1}]$ is defined by restriction of scalars along the isomorphism $A_i[\tau_{ij}^{-1}] \xrightarrow{\sim} A_j[\tau_{ji}^{-1}]$ as in (10.6.4).

10.6.9. In the situation of (10.6.5), let $M := \oplus_{n\in\mathbb{Z}} M_n$ be a $\mathbb{Z}$-graded A-module. Then $M' := M \otimes_A A'$ is a $\mathbb{Z}$-graded A'-module, with the grading defined by the rule :

$$M'_n := \sum_{j+k=n} \mathrm{Im}(M_j \otimes_{\mathbb{Z}} A'_k \to M') \qquad \text{for every } n \in \mathbb{Z}$$

([60, Ch.II, (2.1.2)]). Then [60, Ch.II, Prop.2.8.8] yields a natural morphism of $\mathscr{O}_{G(\varphi)}$-modules:

$$\nu_M : (\mathrm{Proj}\,\varphi)^* M^{\sim} \to (M')^{\sim}_{|G(\varphi)}.$$

Moreover, set :

$$G_1(\varphi) := \bigcup_{f\in A_1} D_+(\varphi(f))$$

and notice that $G_1(\varphi) \subset U_1(A') \cap G(\varphi)$; by inspecting the proof of *loc.cit.* we see that the restriction $\nu_{M|G_1(\varphi)}$ is an isomorphism. Especially, ν_M is an isomorphism whenever A_1 generates the ideal A_+. It is also easily seen that $G_1(\varphi) = U_1(A')$ if $\varphi(A_+)$ generates A'_+.

For any $f \in A_1$, the restriction $(\nu_M)_{|D_+(\varphi(f))}$ can be described explicitly : namely, we have natural identifications

$$\omega^*_f(M^{\sim}_{|D_+(f)}) \xrightarrow{\sim} M^{\sim}_{(f)} \qquad \omega^*_{\varphi(f)}(M')^{\sim}_{|D_+(\varphi(f))} \xrightarrow{\sim} (M')^{\sim}_{(\varphi(f))}$$

and in view of (10.6.6), the morphism $(\nu_M)_{|D_+(\varphi(f))}$ is induced by the $A'_{(\varphi(f))}$-linear map :

$$M_{(f)} \otimes_{A_{(f)}} A'_{(\varphi(f))} \to M'_{(\varphi(f))}$$

given by the rule :

$$(m_k \cdot f^{-k}) \otimes (a'_j \cdot \varphi(f)^{-j}) \mapsto (m_k \otimes a'_j) \cdot \varphi(f)^{-j-k} \qquad \text{for all } k, j \in \mathbb{Z},\, m_k \in M_k,\, a'_j \in A'_j.$$

10.6.10. The foregoing results can be improved somewhat, in the following special situation. Let $R \to R'$ be a ring homomorphism, A a $\mathbb{N}$-graded R-algebra (hence the structure morphism $R \to A$ is a ring homomorphism $R \to A_0$); the ring $A' := R' \otimes_R A$ is naturally a $\mathbb{N}$-graded R'-algebra, and the induced map $\varphi : A \to A'$ is a homomorphism of graded rings. In this case, obviously $\varphi(A_+)$ generates the ideal A'_+, hence $G(\varphi) = \mathrm{Proj}\,A'$, and indeed, $\mathrm{Proj}\,\varphi$ induces an isomorphism of $\mathrm{Spec}\,R'$-schemes :

$$Y' \xrightarrow{\sim} \mathrm{Spec}\,R' \times_{\mathrm{Spec}\,R} Y$$

where again $Y := \mathrm{Proj}\,A$ and $Y' := \mathrm{Proj}\,A'$. Moreover, for every $\mathbb{Z}$-graded A-module M, the corresponding morphism ν_M is an isomorphism, regardless of whether or not A_1 generates A_+ ([60, Ch.II, Prop.2.8.10]). Especially, $\nu_{A(n)}$ is a natural identification ([60, Ch.II, Cor.2.8.11]) :

$$(\mathrm{Proj}\,\varphi)^* \mathscr{O}_Y(n) \xrightarrow{\sim} \mathscr{O}_{Y'}(n) \qquad \text{for every } n \in \mathbb{Z}.$$

10.6.11. Keep the notation of (10.6.1), and for every integer $d > 0$, set

$$A^{(d)}_n := A_{nd} \qquad \text{for every } n \in \mathbb{N}, \text{ and} \qquad A^{(d)} := \bigoplus_{n\in\mathbb{N}} A^{(d)}_n.$$

Clearly $A^{(d)}$ is an $\mathbb{N}$-graded ring, and a subring of A, but the inclusion map $j : A^{(n)} \to A$ is not a homomorphism of $\mathbb{N}$-graded rings. However, for every homogeneous element $f \in A_+$, the map j induces a natural identification of A-algebras :

$$A^{(d)}_{(f^d)} \xrightarrow{\sim} A_{(f)} \qquad (10.6.12)$$

which in turn yields a natural isomorphism of A_0-schemes ([60, Ch.II, Prop.2.4.7(i)])

$$\Omega^{(d)} : \mathrm{Proj}\,A \xrightarrow{\sim} \mathrm{Proj}\,A^{(d)} \qquad \text{for every } d > 0.$$

To ease notation, we shall let $Y := \mathrm{Proj}\,A$ and $Y^{(d)} := \mathrm{Proj}\,A^{(d)}$ for every integer $d > 0$. Likewise, if M is any $\mathbb{Z}$-graded A-module, we may consider that $\mathbb{Z}$-graded $A^{(d)}$-module $M^{(d)}$

whose homogeneous direct summand of degree n equals M_{nd}, for every $n \in \mathbb{Z}$. Then the inclusion map $M^{(d)} \to M$ induces natural identifications

(10.6.13) $$M^{(d)}_{(f^d)} \to M_{(f)} \qquad \text{for every homogeneous element } f \text{ of } A.$$

Indeed, it is easily seen that this map is surjective, and it is injective, since it is the restriction of the injective map $M^{(d)}_{f^d} \to M_{f^d}$. Moreover, if we endow $M_{(f)}$ with the $A^{(d)}_{(f^d)}$-module structure induced by (10.6.12), it is easily seen that (10.6.13) is an isomorphism of $A^{(d)}_{(f^d)}$-modules. Thus, we obtain a natural isomorphism of quasi-coherent $\mathscr{O}_{Y^{(d)}}$-modules

$$M^{(d)\sim} \xrightarrow{\sim} \Omega^{(d)}_* M^\sim.$$

Next, for every $n \in \mathbb{Z}$, let $M(n)$ be the $\mathbb{Z}$-graded A-module such that $M(n)_k := M_{n+k}$ for every $k \in \mathbb{Z}$ (with A-module structure deduced from that of M, in the obvious way). Clearly

$$M(nd)^{(d)} = M^{(d)}(n) \qquad \text{for every } n \in \mathbb{Z} \text{ and every } d > 0$$

whence an induced isomorphism of quasi-coherent $\mathscr{O}_{Y^{(d)}}$-modules

$$M^{(d)}(n)^\sim \xrightarrow{\sim} \Omega^{(d)}_* M(nd)^\sim \qquad \text{for every } n \in \mathbb{Z} \text{ and every } d > 0.$$

Especially, we have a natural identification

(10.6.14) $$\mathscr{O}_{Y^{(d)}}(n) \xrightarrow{\sim} \Omega^{(d)}_* \mathscr{O}_Y(nd) \qquad \text{for every } n \in \mathbb{Z} \text{ and every } d > 0.$$

10.6.15. Let X be a scheme, $\mathscr{A} := \oplus_{n\in\mathbb{N}}\mathscr{A}_n$ a $\mathbb{N}$-graded quasi-coherent $\mathscr{O}_X$-algebra on the Zariski site of X; we let $\mathscr{A}_+ := \oplus_{n>0}\mathscr{A}_n$. According to [60, Ch.II, Prop.3.1.2], there exists an X-scheme $\pi : \mathrm{Proj}\,\mathscr{A} \to X$, with natural isomorphisms of U-schemes :

$$\psi_U : U \times_X \mathrm{Proj}\,\mathscr{A} \xrightarrow{\sim} \mathrm{Proj}\,\mathscr{A}(U)$$

for every affine open subset $U \subset X$, and the system of isomorphisms ψ_U is compatible, in an obvious way, with inclusions $U' \subset U$ of affine open subsets. Especially, π is a separated morphism. For any integer $d > 0$, every $f \in \Gamma(X, \mathscr{A}_d)$ defines an open subset $D_+(f) \subset \mathrm{Proj}\,\mathscr{A}$, such that :

$$D_+(f) \cap \pi^{-1}U = D_+(f_{|U}) \subset \mathrm{Proj}\,\mathscr{A}(U) \qquad \text{for every affine open subset } U \subset X.$$

10.6.16. To ease notation, set $Y := \mathrm{Proj}\,\mathscr{A}$, and let again $\pi : Y \to X$ be the natural morphism. Let $\mathscr{M} := \oplus_{n\in\mathbb{Z}}\mathscr{M}_n$ be a $\mathbb{Z}$-graded $\mathscr{A}$-module, quasi-coherent as a $\mathscr{O}_X$-module; for every affine open subset $U \subset X$, the graded $\mathscr{A}(U)$-module $\mathscr{M}(U)$ yields a quasi-coherent $\mathscr{O}_{\pi^{-1}U}$-module $\mathscr{M}_U^\sim$, and every inclusion of affine open subsets $U' \subset U$ induces a natural isomorphism of $\mathscr{O}_{\pi^{-1}U'}$-modules : $\mathscr{M}^\sim_{U|U'} \xrightarrow{\sim} \mathscr{M}^\sim_{U'}$. Therefore the locally defined modules $\mathscr{M}^\sim_U$ glue to a well defined quasi-coherent $\mathscr{O}_Y$-module $\mathscr{M}^\sim$.

Especially, for every $n \in \mathbb{Z}$, denote by $\mathscr{A}(n)$ the $\mathbb{Z}$-graded $\mathscr{A}$-module such that $\mathscr{A}(n)_k := \mathscr{A}_{n+k}$ for every $k \in \mathbb{Z}$, with the convention that $\mathscr{A}_n = 0$ whenever $n < 0$. We set:

$$\mathscr{O}_Y(n) := \mathscr{A}(n)^\sim \qquad \text{and} \qquad \mathscr{M}^\sim(n) := \mathscr{M}^\sim \otimes_{\mathscr{O}_Y} \mathscr{O}_Y(n).$$

Denote by $U_n(\mathscr{A}) \subset Y$ the union of the open subsets $U_n(\mathscr{A}(U))$, for U ranging over the affine open subsets of X; from the discussion in (10.6.7), it clear that the restriction $\mathscr{O}_Y(n)_{|U_n(\mathscr{A})}$ is an invertible $\mathscr{O}_{U_n(\mathscr{A})}$-module. This open subset can be described as follows. For every $x \in X$, let :

(10.6.17) $$\mathscr{A}_n(x) := \mathscr{A}_{n,x} \otimes_{\mathscr{O}_{X,x}} \kappa(x) \qquad \text{and set} \qquad \mathscr{A}(x) := \oplus_{n\in\mathbb{N}}\mathscr{A}_n(x)$$

which is a $\mathbb{N}$-graded $\kappa(x)$-algebra; then :

(10.6.18) $$U_n(\mathscr{A}) = \{y \in Y \mid \mathscr{A}_n(\pi(y)) \not\subset \mathfrak{p}(y)\}$$

where $\mathfrak{p}(y) \subset \mathscr{A}(\pi(y))$ denotes the prime ideal corresponding to the point y.

10.6.19. Moreover, for every $\mathbb{Z}$-graded $\mathscr{A}$-module $\mathscr{M}$, and every $n \in \mathbb{Z}$, there exists a natural morphism of $\mathscr{O}_Y$-modules :

$$\mathscr{M}^\sim(n) \to \mathscr{M}(n)^\sim \tag{10.6.20}$$

where $\mathscr{M}(n)$ is the $\mathbb{Z}$-graded $\mathscr{A}$-module given by the rule : $\mathscr{M}(n)_k := \mathscr{M}_{n+k}$ for every $k \in \mathbb{N}$ ([60, Prop.3.2.16]). The restriction of (10.6.20) to the open subset $U_1(\mathscr{A})$ is an isomorphism ([60, Ch.II, Cor.3.2.8]). Especially, we have natural morphisms of $\mathscr{O}_Y$-modules :

$$\mathscr{O}_Y(n) \otimes_{\mathscr{O}_Y} \mathscr{O}_Y(m) \to \mathscr{O}_Y(n+m) \qquad \text{for every } n, m \in \mathbb{Z} \tag{10.6.21}$$

([60, Ch.II, Prop.3.2.6]) whose restrictions to $U_1(\mathscr{A})$ are isomorphisms. Furthermore, we have a natural morphism $\mathscr{M}_0 \to \pi_*\mathscr{M}^\sim$ of $\mathscr{O}_X$-modules ([60, Ch.II, (3.3.2.1)]), whence, by adjunction, a morphism of $\mathscr{O}_Y$-modules :

$$\pi^*\mathscr{M}_0 \to \mathscr{M}^\sim. \tag{10.6.22}$$

Applying (10.6.22) to the modules $\mathscr{M}_n = \mathscr{M}(n)_0$, and taking into account the isomorphism (10.6.20), we deduce a natural morphism of $\mathscr{O}_{U_1(\mathscr{A})}$-modules :

$$(\pi^*\mathscr{M}_n)_{|U_1(\mathscr{A})} \to \mathscr{M}^\sim(n)_{|U_1(\mathscr{A})} \tag{10.6.23}$$

which can be described as follows. Let $U \subset X$ be any affine open subset; for every $f \in \mathscr{A}_1(U)$, the restriction of (10.6.23) to $D_+(f) \subset \pi^{-1}U$ is given by the morphisms

$$\mathscr{M}_n(U) \otimes_{\mathscr{O}_X(U)} \mathscr{A}(U)_{(f)} \to \mathscr{M}(n)(U)_{(f)} := \sum_{k \in \mathbb{Z}} \mathscr{M}_{k+n}(U) \cdot f^{-k} \subset \mathscr{M}(U)_f.$$

induced by the scalar multiplication $\mathscr{M}_n \otimes_{\mathscr{O}_X} \mathscr{A}_k \to \mathscr{M}_{n+k}$. Especially, we have natural morphisms of $\mathscr{O}_Y$-modules :

$$\pi^*\mathscr{A}_n \to \mathscr{O}_Y(n) \qquad \text{for every } n \in \mathbb{N} \tag{10.6.24}$$

whose restrictions to $U_1(\mathscr{A})$ are epimorphisms. An inspection of the definition also shows that the diagram of $\mathscr{O}_Y$-modules :

$$\begin{array}{ccc} \pi^*\mathscr{A}_n \otimes_{\mathscr{O}_Y} \pi^*\mathscr{A}_m & \longrightarrow & \pi^*\mathscr{A}_{n+m} \\ \downarrow & & \downarrow \\ \mathscr{O}_Y(n) \otimes_{\mathscr{O}_Y} \mathscr{O}_Y(m) & \longrightarrow & \mathscr{O}_Y(n+m) \end{array} \tag{10.6.25}$$

commutes for every $n, m \in \mathbb{N}$, where the top horizontal arrow is induced by the graded multiplication $\mathscr{A}_n \otimes_{\mathscr{O}_X} \mathscr{A}_m \to \mathscr{A}_{n+m}$, the vertical arrows are the maps (10.6.24), and the bottom horizontal arrow is the map (10.6.21).

10.6.26. Next, let $\mathscr{A}' := \oplus_{n \in \mathbb{N}} \mathscr{A}'_n$ be another $\mathbb{N}$-graded quasi-coherent $\mathscr{O}_X$-algebra on the Zariski site of X, and $\varphi : \mathscr{A} \to \mathscr{A}'$ a morphism of graded $\mathscr{O}_X$-algebras; for every affine open subset $U \subset X$, we deduce a morphism $\varphi_U : \mathscr{A}(U) \to \mathscr{A}'(U)$ of graded $\mathscr{O}_X(U)$-algebras, whence an open subset $G(\varphi_U) \subset \operatorname{Proj} \mathscr{A}'(U)$ as in (10.6.5). If $V \subset U$ is a smaller affine open subset, the natural isomorphism

$$V \times_U \operatorname{Proj} \mathscr{A}'(U) \xrightarrow{\sim} \operatorname{Proj} \mathscr{A}'(V)$$

induces an identification $V \times_U G(\varphi_U) \xrightarrow{\sim} G(\varphi_V)$, hence there exists a well defined open subset $G(\varphi) \subset \operatorname{Proj} \mathscr{A}'$ such that the morphisms $\operatorname{Proj} \varphi_U$ glue to a unique morphism of X-schemes :

$$\operatorname{Proj} \varphi : G(\varphi) \to \operatorname{Proj} \mathscr{A}.$$

If $\mathscr{A}'_+$ is generated – locally on X – by $\varphi(\mathscr{A}_+)$, we have $G(\varphi) = \operatorname{Proj} \mathscr{A}'$.

Moreover, if $\mathscr{M}$ is a $\mathbb{Z}$-graded quasi-coherent $\mathscr{A}$-module, the morphisms $\nu_{\mathscr{M}(U)}$ assemble into a well defined morphism of $\mathscr{O}_{G(\varphi)}$-modules :

$$\nu_{\mathscr{M}} : (\mathrm{Proj}\,\varphi)^*\mathscr{M}^\sim \to (\mathscr{M}')^\sim_{|G(\varphi)}$$

where the grading of $\mathscr{M}' := \mathscr{M} \otimes_{\mathscr{A}} \mathscr{A}'$ is defined as in (10.6.9). Likewise, the union of the subsets $G_1(\varphi_U)$, for U ranging over the affine open subsets of X, is an open subset :

(10.6.27) $$G_1(\varphi) \subset U_1(\mathscr{A}') \cap G(\varphi)$$

such that the restriction $\nu_{\mathscr{M}|G_1(\varphi)}$ is an isomorphism. Especially, set $Y' := \mathrm{Proj}\,\mathscr{A}'$; we have a natural morphism :

(10.6.28) $$\nu_{\mathscr{A}(n)} : (\mathrm{Proj}\,\varphi)^*\mathscr{O}_Y(n) \to \mathscr{O}_{Y'}(n)_{|G(\varphi)}$$

which is an isomorphism, if $\mathscr{A}_1$ generates $\mathscr{A}_+$ locally on X. Again, we have $G_1(\varphi) = U_1(\mathscr{A}')$ whenever $\varphi(\mathscr{A}_+)$ generates $\mathscr{A}'_+$, locally on X.

10.6.29. The discussion in (10.6.10) implies that any morphism of schemes $f : X' \to X$ induces a natural isomorphism of X'-schemes ([60, Ch.II, Prop.3.5.3]) :

(10.6.30) $$\mathrm{Proj}\, f^*\mathscr{A} \xrightarrow{\sim} X' \times_X \mathrm{Proj}\,\mathscr{A}$$

and the description (10.6.18) implies that (10.6.30) restricts to an isomorphism :

$$U_n(f^*\mathscr{A}) \xrightarrow{\sim} X' \times_X U_n(\mathscr{A}) \qquad \text{for every } n \in \mathbb{N}.$$

Furthermore, set $Y' := \mathrm{Proj}\, f^*\mathscr{A}$, and let $\pi_Y : Y' \to Y$ be the morphism deduced from (10.6.30); the discussion in (10.6.10) implies as well that, for any $\mathbb{Z}$-graded quasi-coherent $\mathscr{A}$-module $\mathscr{M}$, there is a natural isomorphism :

$$(f^*\mathscr{M})^\sim \xrightarrow{\sim} \pi_Y^*\mathscr{M}^\sim$$

([60, Ch.II, Prop.3.5.3]). Especially, f induces a natural identification ([60, Ch.II, Cor.3.5.4]) :

(10.6.31) $$\mathscr{O}_{Y'}(n) \xrightarrow{\sim} \pi_Y^*\mathscr{O}_Y(n) \qquad \text{for every } n \in \mathbb{Z}.$$

10.6.32. Keep the notation of (10.6.16), and let $\mathscr{C}_X$ be the category whose objects are all the pairs $(\psi : Z \to X, \mathscr{L})$, where ψ is a morphism of schemes and $\mathscr{L}$ is an invertible $\mathscr{O}_Z$-module on the Zariski site of Z; the morphisms $(\psi : Z \to X, \mathscr{L}) \to (\psi' : Z' \to X, \mathscr{L}')$ are the pairs (β, h), where $\beta : Z \to Z'$ is a morphism of X-schemes, and $h : \beta^*\mathscr{L}' \xrightarrow{\sim} \mathscr{L}$ is an isomorphism of $\mathscr{O}_Z$-modules (with composition of morphisms defined in the obvious way). Consider the functor:

$$F_{\mathscr{A}} : \mathscr{C}_X^o \to \mathbf{Set}$$

which assigns to any object $(\psi, \mathscr{L})$ of $\mathscr{C}_X$, the set consisting of all homomorphisms of graded $\mathscr{O}_Z$-algebras :

$$g : \psi^*\mathscr{A} \to \mathrm{Sym}^\bullet_{\mathscr{O}_Z}\mathscr{L}$$

which are epimorphisms on the underlying $\mathscr{O}_Z$-modules (here $\mathrm{Sym}^\bullet_{\mathscr{O}_Z}\mathscr{L}$ denotes the symmetric $\mathscr{O}_Z$-algebra on the $\mathscr{O}_Z$-module $\mathscr{L}$); on a morphism (β, h) as in the foregoing, and an element $g' \in F_{\mathscr{A}}(\psi', \mathscr{L}')$, the functor acts by the rule :

$$F_{\mathscr{A}}(\beta, h)(g') := (\mathrm{Sym}^\bullet_{\mathscr{O}_Z} h) \circ \beta^* g'.$$

Lemma 10.6.33. *The object* $(\pi : U_1(\mathscr{A}) \to X, \mathscr{O}_Y(1)_{|U_1(\mathscr{A})})$ *of* $\mathscr{C}_X$ *represents the functor* $F_{\mathscr{A}}$.

Proof. Given an object $(\psi : Z \to X, \mathscr{L})$ of $\mathscr{C}_X$, and $g \in F_{\mathscr{A}}(\psi, \mathscr{L})$, set :

$$\mathbb{P}(\mathscr{L}) := \mathrm{Proj}\,(\mathrm{Sym}^\bullet_{\mathscr{O}_Z}\mathscr{L}).$$

According to [60, Ch.II, Cor.3.1.7, Prop.3.1.8(iii)], the natural morphism $\pi_Z : \mathbb{P}(\mathscr{L}) \to Z$ is an isomorphism, and clearly in this situation the natural maps (10.6.24) are isomorphisms :

$$(10.6.34) \qquad \pi_Z^*\mathscr{L}^{\otimes n} \xrightarrow{\sim} \mathscr{O}_{\mathbb{P}(\mathscr{L})}(n) \qquad \text{for every } n \in \mathbb{N}.$$

On the other hand, since g is an epimorphism, we have $G(g) = \mathbb{P}(\mathscr{L})$; taking (10.6.30) into account, we deduce a morphism of Z-schemes :

$$\mathrm{Proj}\,g : \mathbb{P}(\mathscr{L}) \to Y' := Z \times_X \mathrm{Proj}\,\mathscr{A}$$

which is the same as a morphism of X-schemes :

$$\mathbb{P}(g) : Z \to \mathrm{Proj}\,\mathscr{A}.$$

We need to show that the image of $\mathbb{P}(g)$ lies in the open subset $U_1(\mathscr{A})$; to this aim, we may assume that both X and Z are affine, say $X = \mathrm{Spec}\,R$, $Z = \mathrm{Spec}\,S$, in which case $\mathscr{A}$ is the quasi-coherent algebra associated to a $\mathbb{N}$-graded R-algebra A, $\mathscr{L}$ is the invertible module associated to a projective rank one S-module L, and $g : S \otimes_R A \to \mathrm{Sym}^\bullet_S L$ is a surjective homomorphism of R-algebras. Then locally on Z, $\mathscr{L}$ is generated by elements of the form $g(1 \otimes t)$, for some local sections t of $\mathscr{A}_1$, and up to replacing Z by an affine open subset, we may assume that $t \in A_1$ is an element such that $t' := g(1 \otimes t)$ generates the free S-module L. In this situation, we have $\mathbb{P}(\mathscr{L}) = D_+(t')$, and $\mathbb{P}(g)$ is the same as the morphism $\Phi_t : D_+(t') \to D_+(t)$ (notation of (10.6.5)); especially the image of $\mathbb{P}(g)$ lies in $U_1(\mathscr{A})$, as required.

Moreover, the isomorphism $\pi_Z : \mathbb{P}(\mathscr{L}) \xrightarrow{\sim} Z$ is induced by the natural identification:

$$(10.6.35) \qquad S = S[t']_{(t')}.$$

From this description, we also can extract an explicit expression for Φ_t; namely, it is induced by the map of R-algebras :

$$A_{(t)} \to S \qquad \text{such that} \qquad a_k \cdot t^{-k} \mapsto g(1 \otimes a_k) \cdot t'^{-k}$$

for every $k \in \mathbb{N}$, and every $a_k \in A_k$. Next, letting $n := 1$ in (10.6.28) and (10.6.31), we obtain a natural isomorphism of $\mathscr{O}_{\mathbb{P}(\mathscr{L})}$-modules :

$$\mathscr{O}_{\mathbb{P}(\mathscr{L})}(1) \xrightarrow{\sim} (\mathrm{Proj}\,g)^*\mathscr{O}_{Y'}(1) \xrightarrow{\sim} (\mathrm{Proj}\,g)^* \circ \pi_Y^*\mathscr{O}_Y(1) \xrightarrow{\sim} \pi_Z^* \circ \mathbb{P}(g)^*\mathscr{O}_Y(1)$$

(notice that, since by assumption g is an epimorphism, we have $G_1(g) = U_1(\mathrm{Sym}^\bullet_{\mathscr{O}_Z}\mathscr{L}) = \mathbb{P}(\mathscr{L})$, hence $\nu_{\psi^*\mathscr{A}(1)}$ is an isomorphism). Composition with (10.6.34) yields an isomorphism :

$$h(g) : \mathbb{P}(g)^*\mathscr{O}_Y(1) \xrightarrow{\sim} \mathscr{L}$$

of $\mathscr{O}_Z$-modules, whence a morphism in $\mathscr{C}_X$

$$(\mathbb{P}(g), h(g)) : (\psi, \mathscr{L}) \to (\pi_{|U_1(\mathscr{A})}, \mathscr{O}_Y(1)_{|U_1(\mathscr{A})}).$$

In case X and Z are affine, and $\mathscr{L}$ is associated to a free module L, generated by an element of the form $t' := g(1 \otimes t)$ as in the foregoing, we can describe explicitly $h(g)$; namely, a direct inspection of the construction shows that in this case $h(g)$ is induced by the map of S-modules

$$S \otimes_{A_{(t)}} A(1)_{(t)} \to L \quad : \quad s \otimes a_k \cdot t^{1-k} \mapsto s \cdot g(1 \otimes a_k) \cdot (t')^{1-k} \qquad \text{for every } s \in S, a_k \in A_k.$$

Conversely, let $\beta : Z \to U_1(\mathscr{A})$ be a morphism of X-schemes, and $h : \beta^*\mathscr{O}_Y(1)_{|U_1(\mathscr{A})} \xrightarrow{\sim} \mathscr{L}$ an isomorphism of $\mathscr{O}_Z$-modules. In view of the natural isomorphisms (10.6.21), we deduce, for every $n \in \mathbb{N}$, an isomorphism :

$$h^{\otimes n} : \beta^*\mathscr{O}_Y(n)_{|U_1(\mathscr{A})} \xrightarrow{\sim} \mathscr{L}^{\otimes n}.$$

Combining with the epimorphisms (10.6.24) :

$$\omega_n : (\pi^*\mathscr{A}_n)_{|U_1(\mathscr{A})} \to \mathscr{O}_Y(n)_{|U_1(\mathscr{A})}$$

we may define the epimorphism of $\mathscr{O}_Z$-modules :

$$g(\beta, h) := \bigoplus_{n\in\mathbb{N}} h^{\otimes n} \circ \beta^*(\omega_n) : \psi^*\mathscr{A} \to \mathrm{Sym}^\bullet_{\mathscr{O}_Z}\mathscr{L} \qquad (10.6.36)$$

which, in view of (10.6.25), is a homomorphism of graded $\mathscr{O}_Z$-algebras, *i.e.* $g(\beta, h) \in F(\psi, \mathscr{L})$. This homomorphism can be described explicitly, locally on Z : namely, say again that $X = \mathrm{Spec}\, R$, $Z = \mathrm{Spec}\, S$, $\mathscr{L} = L^\sim$ for a free S-module of rank one, and $\mathscr{A} = A^\sim$ for some $\mathbb{N}$-graded R-algebra A; suppose moreover that the image of β lies in an open subset $D_+(t) \subset U_1(\mathscr{A})$, for some $t \in A_1$. Then β comes from a ring homomorphism $\beta^\natural : A_{(t)} \to S$, h is an S-linear isomorphism $S \otimes_{A_{(t)}} A(1)_{(t)} \xrightarrow{\sim} L$, and $t' := h(1 \otimes t)$ is a generator of L; moreover, ω_n is the epimorphism deduced from the map :

$$A_n \otimes_R A_{(t)} \to A(n)_{(t)} \quad : \quad a_n \otimes b_k \cdot t^{-k} \mapsto a_n b_k \cdot t^{-k} \qquad \text{for every } a_n \in A_n,\ b_k \in A_k$$

By inspecting the construction, we see therefore that g is the direct sum of the morphisms :

$$g_n : S \otimes_R A_n \to L^{\otimes n} \quad : \quad s \otimes a_n \mapsto s \cdot \beta^\natural(a_n \cdot t^{-n}) \cdot t'^{\otimes n} \qquad \text{for every } s \in S,\ a_n \in A_n.$$

Finally, it is easily seen that the natural transformations :

$$g \mapsto (\mathbb{P}(g), h(g)) \qquad \text{and} \qquad (\beta, h) \mapsto g(\beta, h) \qquad (10.6.37)$$

are inverse to each other : indeed, the verification can be made locally on Z, hence we may assume that X and Z are affine, and $\mathscr{L}$ is free, in which case one may use the explicit formulae provided above. □

Definition 10.6.38. Let X be a scheme, $\mathscr{I}$ a quasi-coherent sheaf of ideals of $\mathscr{O}_X$.

(i) The *positive Rees algebra* of $\mathscr{I}$ is the quasi-coherent $\mathbb{N}$-graded $\mathscr{O}_X$-algebra

$$\mathsf{R}^+(\mathscr{I})_\bullet := \bigoplus_{n\in\mathbb{N}} \mathscr{I}^n$$

with multiplication law deduced in the obvious way from that of $\mathscr{O}_X$ (cp. definition 7.9.1(iii)).

(ii) The *blowing up* of $\mathscr{I}$ is the X-scheme

$$\mathrm{Proj}\, \mathsf{R}^+(\mathscr{I})_\bullet \to X.$$

Remark 10.6.39. (i) With the notation of definition 10.6.38, let $\pi : Y \to X$ be the blowing up of $\mathscr{I}$. Notice that $\mathscr{I}$ is an invertible $\mathscr{O}_X$-module if and only if it is generated, locally on X, by a regular section of $\mathscr{O}_X$, and then the natural map

$$\mathrm{Sym}^n_{\mathscr{O}_X}\mathscr{I} \to \mathscr{I}^n$$

is an isomorphism, for every $n \in \mathbb{N}$. Taking into account [60, Ch.II, Cor.3.1.7, Prop.3.1.8(iii)], it follows that if $\mathscr{I}$ is an invertible ideal, then the blowing up of $\mathscr{I}$ is an isomorphism.

(ii) Let $X' \to X$ be any flat morphism of schemes; in light of (10.6.29), we get a natural isomorphism from $X' \times_X Y \to X'$ to the blowing up of the quasi-coherent ideal $\mathscr{I}\mathscr{O}_{X'}$ of $\mathscr{O}_{X'}$.

(iii) Especially, let $U \subset X$ be the complement in X of the closed subscheme $\mathrm{Spec}\, \mathscr{O}_X/\mathscr{I}$. From (i) and (ii) we deduce that the restriction $\pi^{-1}U \to U$ of π is an isomorphism.

(iv) Notice that $\mathsf{R}^+(\mathscr{I})_\bullet$ is generated, locally on X, by its degree one direct summand $\mathscr{I}$, hence $\mathscr{O}_Y(1)$ is an invertible $\mathscr{O}_Y$-module. On the other hand, a simple inspection shows that

$$\mathsf{R}^+(\mathscr{I})_\bullet(n) = \mathscr{I}^n \cdot \mathsf{R}^+(\mathscr{I})_\bullet \qquad \text{for every } n \in \mathbb{N}$$

whence a natural identification

$$\mathscr{O}_Y(n) \xrightarrow{\sim} \mathscr{I}^n \cdot \mathscr{O}_Y \qquad \text{for every } n \in \mathbb{N}.$$

Proposition 10.6.40. *With the notation of definition* 10.6.38*, the blowing up* $Y \to X$ *of* $\mathscr{I}$ *is characterized, up to unique isomorphism of* X*-schemes, by the following two conditions :*

(i) *The sheaf of ideals* $\mathscr{I} \cdot \mathscr{O}_Y$ *is an invertible* $\mathscr{O}_Y$*-module.*
(ii) *For every* X*-scheme* Z *such that* $\mathscr{I} \cdot \mathscr{O}_Z$ *is an invertible* $\mathscr{O}_Z$*-module, there exists a unique morphism* $Z \to Y$ *of* X*-schemes.*

Proof. The uniqueness up to unique isomorphism of an X-scheme $\pi : Y \to X$ fulfilling conditions (i) and (ii) is clear. It remains to check that these conditions hold for $Y := \mathrm{Proj}\,\mathsf{R}^+(\mathscr{I})_\bullet$.

However, condition (i) follows immediately from remark 10.6.39(iv). Next, let $f : Z \to X$ be as in (ii), and set $\mathscr{L} := \mathscr{I} \cdot \mathscr{O}_Z$; the induced map $f^*\mathscr{O}_X \to \mathscr{O}_Z$ induces an epimorphism of $\mathscr{O}_Z$-modules

$$\varphi_n : f^*\mathscr{I}^n \to \mathscr{I}^n\mathscr{O}_Z \xrightarrow{\sim} \mathrm{Sym}^n_{\mathscr{O}_Z}\mathscr{L} \qquad \text{for every } n \in \mathbb{N}$$

and it is clear that the system $(\varphi_n \mid n \in \mathbb{N})$ amounts to a morphism of $\mathbb{N}$-graded $\mathscr{O}_Z$-algebras

$$\varphi_\bullet : f^*\mathsf{R}^+(\mathscr{I})_\bullet \to \mathrm{Sym}^\bullet_{\mathscr{O}_Z}\mathscr{L}$$

which in turn corresponds to a morphism $g : Z \to Y$ of X-schemes, by virtue of lemma 10.6.33. Lastly, let $g' : Z \to Y$ be any other morphism of X-schemes, and denote by $U \subset X$ (resp. $U' \subset Z$) the complement in X (resp. in Z) of the closed subset $\mathrm{Spec}\,\mathscr{O}_X/\mathscr{I}$ (resp. $\mathrm{Spec}\,\mathscr{O}_Z/\mathscr{I}\mathscr{O}_Z$); clearly $f(U') \subset U$, hence g and g' both restrict to morphisms $U' \to \pi^{-1}U$ of X-schemes. Then remark 10.6.39(iii) implies that

$$g_{|U'} = g'_{|U'}.$$

Next, since $\mathscr{I}\mathscr{O}_Z$ is generated, locally on Z, by a regular section of $\mathscr{O}_Z$, the open subset U' is *schematically dense* in Z ([65, Ch.IV, Déf.11.10.2]), and on the other hand, we know that π is a separated morphism (see (10.6.15)); in view of [65, Ch.IV, Prop.11.10.1] we deduce that $g = g'$, which concludes the verification of (ii). $\square$

10.6.41. We may generalize as follows remark 10.6.39(ii). Let $X \to X_0$ be a morphism of schemes, $\mathscr{I}_0 \subset \mathscr{O}_{X_0}$ a quasi-coherent ideal, and set $\mathscr{I} := \mathscr{I}_0\mathscr{O}_X$; let also $\pi_0 : Y_0 \to X_0$ and $\pi : Y \to X$ be the blowing up morphisms of $\mathscr{I}_0$ and resepctively $\mathscr{I}$. By proposition 10.6.40 there exists a unique morphism of schemes $\psi : Y \to Y_0$ that makes commute the diagram

(10.6.42)
$$\begin{array}{ccc} Y & \xrightarrow{\psi} & Y_0 \\ {\scriptstyle\pi}\downarrow & & \downarrow{\scriptstyle\pi_0} \\ X & \longrightarrow & X_0. \end{array}$$

Then we have :

Lemma 10.6.43. *The morphism of* X*-schemes* $\overline{\psi} : Y \to Y' := Y_0 \times_{X_0} X$ *induced by* ψ *is a closed immersion, and identifies* Y *with* $\mathrm{Spec}\,\mathscr{O}_{Y'}/\mathscr{J}$*, where*

$$\mathscr{J} := \bigcup_{n\in\mathbb{N}} \mathrm{Ann}_{\mathscr{O}_{Y'}}(\mathscr{I}^n).$$

Proof. Let $Z \to X$ be any morphism of schemes such that $\mathscr{I}\mathscr{O}_Z$ is an invertible $\mathscr{O}_Z$-module; since $\mathscr{I} = \mathscr{I}_0\mathscr{O}_X$, proposition 10.6.40 yields a unique morphism of X_0-schemes $Z \to Y_0$, so there exists a unique morphism of X-schemes $g : Z \to Y'$ as well. Next, since $\mathscr{I}\mathscr{O}_Z$ is invertible, it is easily seen that the induced morphism $\mathscr{O}_{Y'} \to g_*\mathscr{O}_Z$ factors through $\mathscr{O}_{Y'}/\mathscr{J}$, whence a unique morphism of X-schemes $Z \to Y'' := \mathrm{Spec}\,\mathscr{O}_{Y'}/\mathscr{J}$. Lastly, by construction

$\mathscr{I}\mathscr{O}_{Y'}$ is a locally principal ideal of $\mathscr{O}_{Y'}$, and then it is clear that $\mathscr{I}\mathscr{O}_{Y''}$ is an invertible $\mathscr{O}_{Y''}$-module. Summing up, we see that the morphism $Y'' \to X$ enjoys the universal property that characterizes the blowing up of $\mathscr{I}$, whence the lemma. □

10.6.44. Let A be a ring, $r \geq 1$ an integer, $\mathbf{f} := (f_1, \dots, f_r)$ a sequence of elements of A, and $I \subset A$ the ideal generated by $\mathbf{f}$. We view A as an algebra over the ring $A_0 := \mathbb{Z}[T_1, \dots, T_r]$, via the ring homomorphism

$$g : A_0 \to A \qquad T_i \mapsto f_i \qquad i = 1, \dots, r$$

and denote by $I_0 \subset A_0$ the ideal generated by $(T_1, \dots, T_r)$. Set also $X := \operatorname{Spec} A$, $X_0 := \operatorname{Spec} A_0$, let $\mathscr{I} \subset \mathscr{O}_X$ (resp. $\mathscr{I}_0 \subset \mathscr{O}_{X_0}$) be the quasi-coherent sheaf of ideals arising from I (resp. from I_0), and $\pi : Y \to X$ (resp. $\pi_0 : Y_0 \to X_0$) the blowing up of $\mathscr{I}$ (resp. of $\mathscr{I}_0$). Clearly $\mathscr{I}_0\mathscr{O}_Y = \mathscr{I}$, whence a commutative diagram (10.6.42), with bottom horizontal arrow given by $\operatorname{Spec} g : X \to X_0$. Furthermore, notice that we have systems of monomorphisms of invertible $\mathscr{O}_Y$-modules :

$$\text{(10.6.45)} \qquad \mathscr{O}_{Y_0}(n+1) \to \mathscr{O}_{Y_0}(n) \qquad \mathscr{O}_Y(n+1) \to \mathscr{O}_Y(n) \qquad \text{for every } n \in \mathbb{N}$$

corresponding to the inclusion maps $\mathscr{I}^{n+1}\mathscr{O}_{Y_0} \to \mathscr{I}^n\mathscr{O}_{Y_0}$ and $\mathscr{I}^{n+1}\mathscr{O}_Y \to \mathscr{I}^n\mathscr{O}_Y$ under the natural identifications of remark 10.6.39(iv).

Proposition 10.6.46. *With the notation of* (10.6.44)*, suppose moreover that the sequence* $\mathbf{f}$ *is completely secant. Then, for every* $n \in \mathbb{N}$ *we have :*

(i) *The natural map* $I^n \to H^0(Y, \mathscr{O}_Y(n))$ *is an isomorphism.*
(ii) $H^p(Y, \mathscr{O}_Y(n)) = 0$ *for every* $p > 0$.

Proof. We consider first the ring A_0 and the sequence $\mathbf{f}_0 := (T_1, \dots, T_r)$; we endow A_0 with its standard $\mathbb{N}$-grading, such that $\operatorname{gr}_n A_0$ is the $\mathbb{Z}$-module generated by the monomials of total degree n, for every $n \in \mathbb{N}$. Let also $\mathsf{R}_0^+ \subset A_0[V]$ be the Rees algebra associated with the I_0-adic filtration of A_0, so that $Y_0 = \operatorname{Proj} \mathsf{R}_0^+$ (see definition 7.9.1(iii); but since here we have a descending filtration on A_0, we let $V := U^{-1}$, so $\operatorname{gr}_n \mathsf{R}_0^+ := V^n I_0^n$ for every $n \in \mathbb{N}$). We consider the morphism of $\mathbb{N}$-graded $\mathbb{Z}$-algebras

$$h : A_0 \to \mathsf{R}_0^+ \qquad T_i \mapsto VT_i \qquad i = 1, \dots, r.$$

Notice that $\varphi(A_{0+})$ generates the ideal R_{0+}^+ of R_0^+, hence $\varphi := \operatorname{Proj} h$ is well defined on the whole of Y_0 (see (10.6.5)), and we get a commutative diagram of morphisms of schemes

$$\begin{array}{ccc} Y_0 & \xrightarrow{\varphi} & \mathbb{P}^{r-1}_{\mathbb{Z}} \\ {\scriptstyle \pi_0}\downarrow & & \downarrow \\ X_0 & \longrightarrow & \operatorname{Spec} \mathbb{Z}. \end{array}$$

For every $i = 1, \dots, r$, set $U_i := D_+(T_i) \subset \mathbb{P}^{r-1}_{\mathbb{Z}}$, and $U'_i := \varphi^{-1}U_i$. Recall that there are natural isomorphisms $\omega_i : \mathscr{O}_{\mathbb{P}^{r-1}_{\mathbb{Z}}}(U_i) \xrightarrow{\sim} A_i := \mathbb{Z}[\tau_{ij} \mid j = 1, \dots, r]$ (notation of example 10.6.3); we wish to give a corresponding description of the A_i-algebra $B_i := \mathscr{O}_{Y_0}(U'_i)$. To this aim, notice that, by definition, every element of $B_i \subset \mathbb{Z}[T_1, \dots, T_r, V, (VT_i)^{-1}]$ is a finite sum of terms of the form

$$\text{(10.6.47)} \quad (VT_1)^{\alpha_1} \cdots (VT_r)^{\alpha_r} \cdot (VT_i)^{-k} \cdot P(T_1, \dots, T_r) = \tau_{i1}^{\alpha_1} \cdots \tau_{ir}^{\alpha_r} \cdot P(T_i\tau_{i1}, \dots, T_i\tau_{ir})$$

where $k \in \mathbb{N}$ is any integer, $P \in A$ any polynomial, and $\alpha_1 + \cdots + \alpha_r = k$; *i.e.*

$$B_i = A_i[T_i] \qquad \text{for every } i = 1, \dots, r.$$

Likewise, for every $n \in \mathbb{N}$, the elements of $\mathsf{R}_0^+(n)_{(T_i)}$ are the finite sums of terms (10.6.47) where $k \in \mathbb{N}$ is any integer, $P \in A$ any polynomial, and $\alpha_1 + \cdots + \alpha_r = n + k$; *i.e.*

$$\mathsf{R}_0^+(n)_{(T_i)} = (VT_i)^n B_i \qquad \text{for every } i = 1, \dots, r.$$

For every $i \neq j$, set also $U_{ij} := U_i \cap U_j$ and $U'_{ij} := \varphi^{-1} U_{ij}$, and recall that the isomorphisms ω_i induce isomorphisms $\omega_{ij} : \mathscr{O}_{\mathbb{P}^{r-1}_{\mathbb{Z}}}(U_{ij}) \xrightarrow{\sim} A_i[\tau_{ij}^{-1}]$, such that the composition

$$\psi_{ij} := \omega_{ji} \circ \omega_{ij}^{-1} : A_i[\tau_{ij}^{-1}] \xrightarrow{\sim} A_j[\tau_{ji}^{-1}]$$

is given by the rule (10.6.4). There follow natural identifications $\mathscr{O}_{Y_0}(U'_{ij}) \xrightarrow{\sim} B_i[\tau_{ij}^{-1}]$, whence a commutative diagram

$$\begin{array}{ccc} A_i[\tau_{ij}^{-1}] & \xrightarrow{\psi_{ij}} & A_j[\tau_{ji}^{-1}] \\ \downarrow & & \downarrow \\ B_i[\tau_{ij}^{-1}] & \xrightarrow{\psi'_{ij}} & B_j[\tau_{ji}^{-1}] \end{array}$$

whose vertical arrows are induced by the map $\mathscr{O}_{\mathbb{P}^{r-1}_{\mathbb{Z}}} \to \varphi_* \mathscr{O}_{Y_0}$ associated with φ, and where ψ'_{ij} is the isomorphism given by the rule :

$$T_i \mapsto T_j \cdot \tau_{ji}.$$

Likewise, we get a commutative diagram

$$\begin{array}{ccc} & \mathscr{O}_{Y_0}(n)(U'_{ij}) & \\ \swarrow & & \searrow \\ (VT_i)^n B_i[\tau_{ij}^{-1}] & \longrightarrow & (VT_j)^n B_j[\tau_{ji}^{-1}] \end{array}$$

whose downward arrows are induced by the restriction maps of the sheaf $\mathscr{O}_{Y_0}(n)$, and where the horizontal map is the $B_i[\tau_{ij}^{-1}]$-linear map given by the rule

$$(VT_i)^n \mapsto (VT_j)^n \cdot \tau_{ji}^n$$

and where the $B_i[\tau_{ij}^{-1}]$-module structure of $(VT_j)^n B_j[\tau_{ji}^{-1}]$ is defined by restriction of scalars along the isomorphism ψ'_{ij}. Comparing with example 10.6.8 we deduce a natural isomorphism of $\mathscr{O}_{\mathbb{P}^{r-1}_{\mathbb{Z}}}$-modules :

$$\varphi_* \mathscr{O}_{Y_0}(n) \xrightarrow{\sim} \bigoplus_{k \in \mathbb{N}} \mathscr{O}_{\mathbb{P}^{r-1}_{\mathbb{Z}}}(n+k) \qquad \text{for every } n \in \mathbb{N}.$$

On the other hand, from [61, Ch.III, Prop.2.1.12] we get isomorphisms of $\mathbb{N}$-graded $\mathbb{Z}$-modules:

$$H^p\Big(\mathbb{P}^{r-1}_{\mathbb{Z}}, \bigoplus_{k \in \mathbb{N}} \mathscr{O}_{\mathbb{P}^{r-1}_{\mathbb{Z}}}(k)\Big) = \begin{cases} 0 & \text{for every } p > 0 \\ A & \text{for } p = 0 \end{cases}$$

Now, since φ is affine, we have

$$H^p(Y_0, \mathscr{O}_{Y_0}(n)) = H^p(\mathbb{P}^{r-1}_{\mathbb{Z}}, \varphi_* \mathscr{O}_{Y_0}(n)) \qquad \text{for every } n \in \mathbb{N}$$

and assertion (ii) already follows. We also deduce an isomorphism of $\mathbb{N}$-graded $\mathbb{Z}$-modules

$$H^0(Y_0, \mathscr{O}_{Y_0}(n)) \xrightarrow{\sim} H^0\Big(\mathbb{P}^{r-1}_{\mathbb{Z}}, \bigoplus_{k \in \mathbb{N}} \mathscr{O}_{\mathbb{P}^{r-1}_{\mathbb{Z}}}(n+k)\Big) = I_0^n$$

where $\mathrm{gr}_k I_0^n := \mathrm{gr}_{n+k} A$, for every $k \in \mathbb{N}$. To conclude the proof in this case, it remains only to check that this identification is the inverse of the natural map of (i). To this aim, we consider the induced commutative diagram

$$\begin{array}{ccc} H^0(Y_0, \mathscr{O}_{Y_0}(n)) & \longrightarrow & H^0(\mathbb{P}^{r-1}_{\mathbb{Z}}, \varphi_* \mathscr{O}_{Y_0}(n)) \\ \downarrow & & \downarrow \\ H^0(U'_i, \mathscr{O}_{Y_0}(n)) & \longrightarrow & H^0(U_i, \varphi_* \mathscr{O}_{Y_0}(n)). \end{array}$$

Now, let $T^\alpha := T_1^{\alpha_1} \cdots T_r^{\alpha_r} \in \mathrm{gr}_k I^n$ be any monomial (for any $k \in \mathbb{N}$); by inspecting the foregoing notation, we see that the image of T^α in $H^0(U'_i, \mathscr{O}_{Y_0}(n))$ equals $(VT_i)^n T_i^k \tau_{i,1}^{\alpha_1} \cdots \tau_{i,r}^{\alpha_r}$, which maps to the section $T_i^{n+k} \tau_{i,1}^{\alpha_1} \cdots \tau_{i,r}^{\alpha_r}$ of $H^0(U_i, \varphi_* \mathscr{O}_{Y_0}(n))$. But the latter is also the image of T^α under the restriction map $H^0(\mathbb{P}^{r-1}_{\mathbb{Z}}, \mathscr{O}_{\mathbb{P}^{r-1}}(n+k)) \to H^0(U_i, \mathscr{O}_{\mathbb{P}^{r-1}}(n+k))$, whence the contention.

Next, let A, $\mathbf{f}$ and I as in (10.6.44), and we define likewise $\mathsf{R}^+ \subset A[V]$ as the positive Rees algebra associated with the I-adic filtration of A; we consider the homomorphism of $\mathbb{N}$-graded $\mathbb{Z}$-algebras

$$G : \mathsf{R}_0^+ \to \mathsf{R}^+ \qquad V^n x \mapsto V^n g(x) \qquad \text{for every } n \in \mathbb{N} \text{ and every } x \in I_0^n.$$

Notice that G is even a morphism of $\mathbb{N}$-graded A_0-algebras, for the A_0-algebra structure on A and R^+ induced by g. There follows a morphism of $\mathbb{N}$-graded A-algebras

$$h' : A \otimes_{A_0} \mathsf{R}_0^+ \to \mathsf{R}^+$$

whose restriction $\mathrm{gr}_n h'$ is induced by the natural map $A \otimes_{A_0} I_0^n \to I^n$, for every $n \in \mathbb{N}$. The latter is an isomorphism for every $n \in \mathbb{N}$, by virtue of lemma 7.8.23, and it is clear that the morphism ψ of (10.6.44) equals $\mathrm{Proj}\, h'$; in view of (10.6.10), we deduce that the diagram (10.6.42) is cartesian under the current assumptions, and moreover h' induces natural isomorphisms of $\mathscr{O}_Y$-modules

$$\psi^* \mathscr{O}_{Y_0}(n) \xrightarrow{\sim} \mathscr{O}_Y(n) \qquad \text{for every } n \in \mathbb{N}.$$

Denote by $\mathfrak{U}'$ the affine open covering $(U'_i \mid i = 1, \dots, r)$ of Y_0, and set $\psi^{-1}\mathfrak{U}' := (\psi^{-1} U'_i \mid i = 1, \dots, r)$. there follows a natural isomorphism of alternating Čech complexes

$$(10.6.48) \qquad \overline{C}{}^\bullet_{\mathrm{alt}}(\mathfrak{U}', \mathscr{O}_{Y_0}(n)) \otimes_{A_0} A \xrightarrow{\sim} \overline{C}{}^\bullet_{\mathrm{alt}}(\psi^{-1}\mathfrak{U}', \mathscr{O}_Y(n)) \qquad \text{for every } n \in \mathbb{N}.$$

Claim 10.6.49. The natural map $\overline{C}{}^\bullet_{\mathrm{alt}}(\mathfrak{U}', \mathscr{O}_{Y_0}(n)) \overset{\mathbf{L}}{\otimes}_{A_0} A \to \overline{C}{}^\bullet_{\mathrm{alt}}(\mathfrak{U}', \mathscr{O}_{Y_0}(n)) \otimes_{A_0} A$ is an isomorphism in $\mathsf{D}(A\text{-}\mathbf{Mod})$, for every $n \in \mathbb{N}$.

Proof of the claim. We consider the standard spectral sequence

$$E_1^{pq} := \mathrm{Tor}_{-q}^{A_0}(\overline{C}{}^p_{\mathrm{alt}}(\mathfrak{U}', \mathscr{O}_{Y_0}(n)), A) \Rightarrow H^{p+q}(\overline{C}{}^\bullet_{\mathrm{alt}}(\mathfrak{U}', \mathscr{O}_{Y_0}(n)) \overset{\mathbf{L}}{\otimes}_{A_0} A)$$

and notice that it suffices to check that $E_1^{pq} = 0$ for every $p \neq 0$, since in that case the abutment is naturally isomorphic to the cohomology of the complex $(E_1^{0,\bullet}, d_1^{0,\bullet})$, which is the same as $\overline{C}{}^\bullet_{\mathrm{alt}}(\mathfrak{U}', \mathscr{O}_{Y_0}(n)) \otimes_{A_0} A$. However, with the foregoing notation, we see that $\overline{C}{}^q_{\mathrm{alt}}(\mathfrak{U}', \mathscr{O}_{Y_0}(n))$ is a direct sum of finitely many A_0-modules, each of which is a localization of B_i, for some $i \leq r$, so we are reduced to checking that $\mathrm{Tor}_p^{A_0}(B_i, A) = 0$ for $i = 1, \dots, r$ and every $p > 0$. But in turn, B_i is the degree 0 summand of a $\mathbb{Z}$-graded A_0-module, which is a localization of R_0^+, so we are further reduced to checking that $\mathrm{Tor}_p^{A_0}(\mathsf{R}_0^+, A) = 0$ for every $p > 0$, or equivalently, that $\mathrm{Tor}_p^{A_0}(I_0^n, A) = 0$ for every $p > 0$ and every $n \in \mathbb{N}$. The latter follows from lemma 7.8.23. ◇

Combining (10.6.48), claim 10.6.49 and theorem 10.2.28(ii), we get a natural isomorphism :

$$\overline{C}{}^\bullet_{\mathrm{alt}}(\mathfrak{U}', \mathscr{O}_{Y_0}(n)) \overset{\mathbf{L}}{\otimes}_{A_0} A \xrightarrow{\sim} R\Gamma(Y, \mathscr{O}_Y(n)) \qquad \text{in } \mathsf{D}(A\text{-}\mathbf{Mod}), \text{ for every } n \in \mathbb{N}.$$

By the same token, we have a natural isomorphism $\overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U}', \mathscr{O}_{Y_0}(n)) \xrightarrow{\sim} R\Gamma(Y_0, \mathscr{O}_{Y_0}(n))$ in $\mathsf{D}(A_0\text{-}\mathbf{Mod})$, whence a standard spectral sequence for every $n \in \mathbb{N}$

$$E(n)_2^{pq} := \mathrm{Tor}^{A_0}_{-p}(H^q(Y_0, \mathscr{O}_{Y_0}(n)), A) \Rightarrow H^{p+q}(\overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U}', \mathscr{O}_{Y_0}(n)) \overset{\mathbf{L}}{\otimes}_{A_0} A)$$

and the previous case tells us that $E(n)_2^{pq} = 0$ for every $q > 0$ and every $n \in \mathbb{N}$, and moreover $E(n)_2^{p0} = \mathrm{Tor}^{A_0}_{-p}(I_0^n, A)$ for every $p \in \mathbb{Z}$ and every $n \in \mathbb{N}$. Lastly, by invoking again lemma 7.8.23 we see that $E(n)_2^{p0} = 0$ whenever $p \neq 0$, and $E(n)_2^{00} = I_0^n A = I^n$ for every $n \in \mathbb{N}$, which concludes the proof of the proposition. □

Theorem 10.6.50. *With the notation of* (10.6.44)*, the following conditions are equivalent :*

(a) *The ring A satisfies condition* $(\mathrm{a})^{\mathrm{un}}_{\mathbf{f}}$.
(b) *The inverse system* $(H^p(Y, \mathscr{O}_Y(n)) \mid n \in \mathbb{N})$ *deduced from the system of maps* (10.6.45) *is uniformly essentially zero for every $p > 0$, and the same holds for the kernel and cokernel of the natural morphism of inverse systems* $(I^n \to H^0(Y, \mathscr{O}_Y(n)) \mid n \in \mathbb{N})$.
(c) *There exists $n \in \mathbb{N}$ such that $I^n \cdot H^p(Y, \mathscr{O}_Y) = 0$ for every $p > 0$, and I^n annihilates the kernel and cokernel of the natural map $A \to H^0(Y, \mathscr{O}_Y)$.*

Proof. Define $I_0 \subset A$, the positive Rees algebras R_0^+, R^+, and the morphism $\pi_0 : Y_0 \to X_0 := \mathrm{Spec}\, A_0$ as in the proof of proposition 10.6.46. We set $Y' := Y_0 \times_{X_0} X$ and define $\mathscr{J} \subset \mathscr{O}_{Y'}$, $\psi : Y \to Y$ and $\overline{\psi} : Y \to Y'$ as in lemma 10.6.43, so that $\mathscr{J}$ is the kernel of the induced map $\overline{\psi}^\sharp : \mathscr{O}_{Y'} \to \overline{\psi}_* \mathscr{O}_Y$. We shall consider as well the condition :

(d) There exists $k \in \mathbb{N}$ such that $I^k \mathscr{J} = I^k \cdot \mathscr{T}or_i^{X_0}(\mathscr{O}_{Y_0}, \mathscr{O}_X) = 0$ for every $i > 0$.

Claim 10.6.51. If condition (a) holds, there exists $k \in \mathbb{N}$ such that

$$I^k \cdot \mathrm{Tor}_i^{A_0}(I_0^n, A) = I^k \cdot \mathrm{Ker}(I_0^n \otimes_{A_0} A \to I^n) = 0 \qquad \text{for every } n \in \mathbb{N} \text{ and every } i > 0.$$

Proof of the claim. For every integer $p > 0$, let $k(p)$ be the step of the uniformly essentially zero system $(\mathrm{Tor}_p^{A_0}(A_0/I_0^n, A) \mid n \in \mathbb{N})$. For $p > 1$ (resp. for $p = 1$), the integer $k(p)$ is also the step of the uniformly essentially zero system $(T^n_{p-1} := \mathrm{Tor}^{A_0}_{p-1}(I_0^n, A) \mid n \in \mathbb{N})$ (resp. the uniformly essentially zero system $(K^n := \mathrm{Ker}(I_0^n \otimes_{A_0} A \to I^n) \mid n \in \mathbb{N})$). Now, for every $a \in I_0^{k(p)}$, scalar multiplication by a on I_0^n factors through the inclusion map $I_0^{n+k(p)} \to I_0^n$, so it induces the zero map on T^n_{p-1} (resp. on K^n) for every $n \in \mathbb{N}$. Lastly, recall that the homological dimension of A_0 equals $r + 1$, so $T^n_p = 0$ for every $p > r + 1$. We may therefore choose $k := \max(k(1), \dots, k(r + 1))$. ◊

(a)⇒(d): Indeed, recall that we have a natural $\mathscr{O}_{Y'}(U \times_{X_0} X)$-linear isomorphism

$$\Gamma(U \times_{X_0} X, \mathscr{T}or_i^{X_0}(\mathscr{O}_{Y_0}, \mathscr{O}_X)) \xrightarrow{\sim} T_i(U) := \mathrm{Tor}_i^{A_0}(H^0(\mathscr{O}_{Y_0}(U), A)$$

for every affine open subsets $U \subset Y_0$. Since Y' is quasi-compact, and taking into account lemma 10.6.43, it will then suffice to find $k \in \mathbb{N}$ and a finite open covering $U_\bullet := (U_\lambda \mid \lambda \in \Lambda)$ of Y_0 such that

- $I^k \cdot T_i(U_\lambda) = 0$ for every $i > 0$ and every $\lambda \in \Lambda$
- $I^k \cdot \mathrm{Ker}(\overline{\psi}^\sharp_{U_\lambda} : \mathscr{O}_{Y_0}(U_\lambda) \otimes_{A_0} A \to \mathscr{O}_Y(\overline{\psi}^{-1} U_\lambda)) = 0$ for every $\lambda \in \Lambda$.

However, we may choose $U_\bullet$ such $\mathscr{O}_{Y_0}(U_\lambda)$ is a direct summand of a graded localization of R_0^+, for every $\lambda \in \Lambda$; then $T_i(U_\lambda)$ is a direct summand of a localization of $\mathrm{Tor}_i^{A_0}(\mathsf{R}_0^+, A)$, and $\overline{\psi}^\sharp_{U_\lambda}$ is a direct summand of a localization of the natural map $\mathsf{R}_0^+ \otimes_{A_0} A \to \mathsf{R}^+$. Thus, the assertion follows from claim 10.6.51.

(b)⇒(c): The natural identification $\mathscr{I}^n \mathscr{O}_Y \xrightarrow{\sim} \mathscr{O}_Y(n)$ of remark 10.6.39(iv) yields exact cohomology sequences

$$H^p(Y, \mathscr{O}_Y(n)) \xrightarrow{\alpha_n^p} H^p(Y, \mathscr{O}_Y) \to H^p(Y, \mathscr{O}_Y/\mathscr{I}^n \mathscr{O}_Y) \qquad \text{for every } p, n \in \mathbb{N}.$$

However, assumption (b) implies that for every $p > 0$ there exists $k \in \mathbb{N}$ such that α_n^p is the zero map, for every $n \geq k$; hence, for such k the term $H^p(Y, \mathscr{O}_Y)$ is a submodule of $H^p(Y, \mathscr{O}_Y/\mathscr{I}^k\mathscr{O}_Y)$, which is obviously annihilated by I^k. By the same token we get a commutative ladder with exact rows for every $n \in \mathbb{N}$:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & I^n & \longrightarrow & A & \longrightarrow & A/I^n & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \beta_n} & & \downarrow{\scriptstyle \gamma_n} & & \downarrow{\scriptstyle \delta_n} & & \\ 0 & \longrightarrow & H^0(Y, \mathscr{O}_Y(n)) & \longrightarrow & H^0(Y, \mathscr{O}_Y) & \longrightarrow & H^0(Y, \mathscr{O}_Y/\mathscr{I}^n\mathscr{O}_Y) & & \end{array}$$

whence an exact sequence

$$0 \to \mathrm{Ker}\,\beta_n \xrightarrow{\tau_n} \mathrm{Ker}\,\gamma_n \to \mathrm{Ker}\,\delta_n \to \mathrm{Coker}\,\beta_n \xrightarrow{\sigma_n} \mathrm{Coker}\,\gamma_n \to \mathrm{Coker}\,\delta_n.$$

However, assumption (b) implies that there exists $n \in \mathbb{N}$ such that τ_n and σ_n both vanish; since $\mathrm{Ker}\,\delta_n$ and $\mathrm{Coker}\,\delta_n$ are both annihilated by I^n, we conclude that (c) holds.

Next, we show that (d) implies both (a) and (b). To this aim, we remark :

Claim 10.6.52. Suppose that condition (d) holds; then we have :

(i) The inverse system $(\mathscr{T}_n^i := \mathscr{T}or_i^{X_0}(\mathscr{O}_{Y_0}(n), \mathscr{O}_X) \mid n \in \mathbb{N})$ induced by the system of morphisms (10.6.45) is uniformly essentially zero, for every $i > 0$.

(ii) Likewise, the inverse system $(\mathscr{J}(n) := \mathrm{Ker}(\mathscr{O}_{Y'}(n) \to \overline{\psi}_*\mathscr{O}_Y(n)) \mid n \in \mathbb{N})$ is uniformly essentially zero.

Proof of the claim. (i): There exists an affine open covering $(U_1, \dots, U_r)$ of Y_0 such that

$$(\mathscr{I}\mathscr{O}_{Y_0})_{|U_i} = f_i\mathscr{O}_{Y_0} \qquad \text{for every } i = 1, \dots, r$$

and f_i is a regular element of $\mathscr{O}_{Y_0}(U_i)$, whence an identification

$$(\mathscr{I}^n\mathscr{O}_{Y_0})_{|U_i} = f_i^n\mathscr{O}_{U_i} \xrightarrow{\sim} \mathscr{O}_{U_i} \qquad \text{for every } i = 1, \dots, r.$$

Under this identification, the restriction $\mathscr{O}_{Y_0}(n+1)_{|U_i} \to \mathscr{O}_{Y_0}(n)_{|U_i}$ of the morphism (10.6.45) corresponds to the scalar multiplication by f_i. Hence, the inverse system $((\mathscr{T}_n^i)_{|U_i} \mid n \in \mathbb{N})$ is naturally identified with the inverse system $(\mathscr{T}_n'^i \mid n \in \mathbb{N})$ with $\mathscr{T}_n'^i := \mathscr{T}or_i^{X_0}(\mathscr{O}_{U_i}, \mathscr{O}_X)$ for every $i, n \in \mathbb{N}$, with transition maps given by scalar multiplication by f_i, whence (i).

For the proof of (ii) one argues in the same way, using the fact that $I^k\mathscr{J} = 0$ for some $k \in \mathbb{N}$ whose existence is ensured by condition (d) : the details shall be left to the reader. ◊

We consider now the inverse systems of spectral sequences provided by proposition 10.2.30

$$E(n)_2^{pq} := H^p(Y_0 \times_{X_0} X, \mathscr{T}or_{-q}^{X_0}(\mathscr{O}_{Y_0}(n), \mathscr{O}_X)) \Rightarrow H^{p+q}(A \overset{\mathbf{L}}{\otimes}_{A_0} R\Gamma\mathscr{O}_{Y_0}(n)) \tag{10.6.53}$$

where, as usual, the transition maps $E(n+1)_2^{pq} \to E(n)_2^{pq}$ are induced by the morphisms (10.6.45). Clearly $E_2^{pq} = 0$ if either $p < 0$ or $q > 0$, and claim 10.6.52(i) implies that the inverse system $(E(n)_2^{pq} \mid n \in \mathbb{N})$ is uniformly essentially zero whenever $q < 0$. It follows already that the inverse system $(E(n)_\infty^{pq} \mid n \in \mathbb{N})$ is uniformly essentially zero whenever $p + q < 0$. On the other hand, proposition 10.6.46 shows that

$$H^{-i}(A \overset{\mathbf{L}}{\otimes}_{A_0} R\Gamma\mathscr{O}_{Y_0}(n)) = \mathrm{Tor}_i^{A_0}(A, I_0^n) \qquad \text{for every } i \in \mathbb{Z}.$$

Summing up, and taking into account lemma 7.8.19, a simple induction shows that the system $(\mathrm{Tor}_i^{A_0}(A, I_0^n) \mid n \in \mathbb{N})$ is uniformly essentially zero for every $i > 0$. Notice also that $E(n)_2^{p0} = H^p(Y', \mathscr{O}_{Y'}(n)$ for every $n, p \in \mathbb{N}$.

Claim 10.6.54. (i) The inverse system $(E(n)^{p0}_s) \mid n \in \mathbb{N})$ is uniformly essentially zero, for every $p > 0$ and every $s \geq 2$.

(ii) The kernel and cokernel of the natural morphism of inverse systems

$$h_\bullet : (A \otimes_{A_0} I_0^n \mid n \in \mathbb{N}) \to (E(n)^{00}_2 \mid n \in \mathbb{N})$$

are both uniformly essentially zero.

Proof of the claim. (i): We argue by descending induction on p : if $p \geq r$, we have $E(n)^{p0}_2 = 0$ for every $n \in \mathbb{N}$, by theorem 10.2.28(iii), hence the claim trivially holds in this case. Thus, suppose that $q < r$, and that the claim is already known for every $p > q$ and every $s \geq 2$. We show, by descending induction on $s \geq 2$, that $(E(n)^{q0}_s \mid n \in \mathbb{N})$ is uniformly essentially zero. Since $E(n)^{q-s,s-1}_2 = 0$ for every $s \geq 2$, we have $E(n)^{q-s,s-1}_s = E(n)^{q+s,1-s}_s = 0$ as well, whenever $q + s \geq r$, and therefore $E(n)^{q0}_s = E(n)^{q0}_\infty = 0$ for every $p > 0$ and every $s \geq r$. Thus, suppose that $2 \leq t < r$, and that the assertion is known for every $s > t$; we consider the exact sequence of inverse systems

$$0 \to (E(n)^{q0}_{t+1} \mid n \in \mathbb{N}) \to (E(n)^{q0}_t \mid n \in \mathbb{N}) \to (E(n)^{q+t,1-t}_t \mid n \in \mathbb{N}).$$

Since $1 - t < 0$, the third term is uniformly essentially zero, and the same holds for the first term, by inductive assumption; by lemma 7.8.19, we deduce that the same holds for the middle term, as required.

(ii): The map h_n is the composition of the projection $h'_n : A \otimes_{A_0} I_0^n \to E(n)^{00}_\infty$ with the injective map $h''_n : E(n)^{00}_\infty \to E(n)^{00}_2$ deduced from the spectral sequences (10.6.53). But since the inverse system $(E(n)^{p,-p}_2 \mid n \in \mathbb{N})$ is uniformly essentially zero for every $p > 0$, and vanishes for $p \geq r$, the same holds for the inverse systems $(E(n)^{p,-p}_\infty \mid n \in \mathbb{N})$, and consequently the kernel of $h'_\bullet$ is uniformly essentially zero. Likewise, it is easily seen that the cokernel of $h''_\bullet$ is uniformly essentially zero. ◊

Define $\mathscr{J}(n)$ as in claim 10.6.52(ii), and set $J(n)^p := H^p(Y', \mathscr{J}(n)$ for every $n, p \in \mathbb{N}$; we get an exact sequence of inverse systems

$$(J(n)^p \mid n \in \mathbb{N}) \to (E(n)^{p0}_2 \mid n \in \mathbb{N}) \xrightarrow{k^p_\bullet} (H^p(Y, \mathscr{O}_Y(n)) \mid n \in \mathbb{N}) \to (J(n)^{p+1} \mid n \in \mathbb{N})$$

for every $p \in \mathbb{N}$, and claims 10.6.52(ii) and 10.6.54(i) imply that the first and third terms are uniformly essentially zero, whenever $p > 0$. Therefore, the same holds for the middle term. Lastly, we consider the commutative diagram

$$\begin{array}{ccc} (A \otimes_{A_0} I_0^n \mid n \in \mathbb{N}) & \xrightarrow{m_\bullet} & (I^n \mid n \in \mathbb{N}) \\ {\scriptstyle h_\bullet}\downarrow & & \downarrow{\scriptstyle l_\bullet} \\ (E(n)^{00}_2 \mid n \in \mathbb{N}) & \xrightarrow{k^0_\bullet} & (H^0(Y, \mathscr{O}_Y(n)) \mid n \in \mathbb{N}) \end{array}$$

where $m_\bullet$ is given by the natural surjections, and $h_\bullet$ is defined as in claim 10.6.54. Since the inverse system $(J(n)^p \mid n \in \mathbb{N})$ is uniformly essentially zero for $p = 0, 1$, we see that the kernel and cokernel of $k^0_\bullet$ are both uniformly essentially zero. In view of claim 10.6.54(ii), it follows immediately that the kernel of $m_\bullet$ is uniformly essentially zero, and the same holds for the kernel and cokernel of $l_\bullet$, which concludes the verification of both (a) and (b).

Lastly, we check that (c) implies both (a) and (b). To this aim we consider, for every $n \in \mathbb{N}$, the spectral sequences provided by proposition 10.2.30(ii)

$$E(n)^{pq}_2 := \mathrm{Tor}^{A_0}_{-p}(I_0^n, H^q(Y, \mathscr{O}_Y)) \Rightarrow H^{p+q}(I_0^n \overset{\mathbf{L}}{\otimes}_{A_0} R\Gamma \mathscr{O}_Y)$$

$$F(n)^{pq}_2 := H^p(Y, \mathscr{T}\!or^{X_0}_{-q}(\mathscr{I}_0^n, \mathscr{O}_Y)) \Rightarrow H^{p+q}(I_0^n \overset{\mathbf{L}}{\otimes}_{A_0} R\Gamma \mathscr{O}_Y).$$

Moreover, for every $\in \mathbb{N}$ denote by

$$\varphi_n : \mathscr{T}\!or_0^{X_0}(\mathscr{O}_{Y_0}, \mathscr{I}_0^n) = \pi_0^* \mathscr{I}_0^n \to \mathscr{I}_0^n \mathscr{O}_{Y_0} = \mathscr{O}_{Y_0}(n)$$

the natural morphism, and notice that $\psi^* \pi_0^* \mathscr{I}_0^n = \mathscr{T}\!or_0^{X_0}(\mathscr{I}_0^n, \mathscr{O}_Y)$.

Claim 10.6.55. (i) The inverse system $(\operatorname{Ker}\varphi_n \mid n \in \mathbb{N})$ is uniformly essentially zero, and the same holds for the inverse system $(\mathscr{T}\!or_q^{X_0}(\mathscr{I}_0^n, \mathscr{O}_Y) \mid n \in \mathbb{N})$, for every $q > 0$.

(ii) The inverse system $(H^i(I_0^n \overset{\mathbf{L}}{\otimes}_{A_0} R\Gamma\mathscr{O}_Y) \mid n \in \mathbb{N})$ is uniformly essentially zero for $i \neq 0$.

(iii) The spectral sequences $E(n)_2^{\bullet\bullet}$ induce, for every $p \in \mathbb{Z}$, an epimorphism of inverse systems $(E(n)_2^{p0} \mid n \in \mathbb{N}) \to (E(n)_\infty^{p0} \mid n \in \mathbb{N})$ whose kernel is uniformly essentially zero.

(iv) The spectral sequences $F(n)_2^{\bullet\bullet}$ induce, for every $p \in \mathbb{Z}$, a monomorphism of inverse systems $(F(n)_\infty^{p0} \mid n \in \mathbb{N}) \to (F(n)_2^{p0} \mid n \in \mathbb{N})$ whose cokernel is uniformly essentially zero.

(v) The inverse systems $(E(n)_2^{p,-p} \mid n \in \mathbb{N})$ and $(F(n)_2^{-p,p} \mid n \in \mathbb{N})$ are uniformly essentially zero for $p < 0$, and vanish identically for $p > 0$.

Proof of the claim. (i): We look at the spectral sequence

$$G(n)_{pq}^2 := \mathscr{T}\!or_p^{Y_0}(\mathscr{O}_Y, \mathscr{T}\!or_q^{X_0}(\mathscr{O}_{Y_0}, \mathscr{I}_0^n)) \Rightarrow \mathscr{T}\!or_{p+q}^{X_0}(\mathscr{I}_0^n, \mathscr{O}_Y)$$

of proposition 10.2.30(i). Since Y_0 is a noetherian scheme, corollary 7.9.22(iii) implies that the inverse system $(\mathscr{T}\!or_q^{X_0}(\mathscr{O}_{Y_0}, \mathscr{I}_0^n) \mid n \in \mathbb{N})$ is uniformly essentially zero for every $q > 0$, so the same holds for the inverse system $(G(n)_2^{pq} \mid n \in \mathbb{N})$, for every $p \in \mathbb{N}$ and every $q > 0$. By the same token, the inverse system $(\operatorname{Ker}\varphi_n \mid n \in \mathbb{N})$ is uniformly essentially zero; since the functor

$$\mathscr{T}\!or_p^{Y_0}(\mathscr{O}_Y, -) : \mathsf{D}^-(\mathscr{O}_{Y_0}\text{-}\mathbf{Mod}_{\mathrm{qcoh}}) \to \mathsf{D}^-(\mathscr{O}_Y\text{-}\mathbf{Mod}_{\mathrm{qcoh}})$$

is triangulated for every $p \in \mathbb{Z}$, we get a short exact sequence

$$0 \to \mathscr{T}\!or_p^{Y_0}(\mathscr{O}_Y, \operatorname{Ker}\varphi_n) \to G(n)_{p0}^2 \to \mathscr{T}\!or_p^{Y_0}(\mathscr{O}_Y, \mathscr{O}_{Y_0}(n)) \to 0 \qquad \text{for every } p, n \in \mathbb{N}$$

which shows that the inverse system $(G(n)_{p0}^2 \mid n \in \mathbb{N})$ is uniformly essentially zero for every $p > 0$. The assertion now follows by a simple induction, using lemma 7.8.19.

(ii): Condition (c) implies that the inverse system $(E(n)_2^{pq} \mid n \in \mathbb{N})$ is uniformly essentially zero for $q > 0$, and clearly it vanishes identically when either $q < 0$ or $p > 0$. It also vanishes identically for $q \geq r$, due to theorem 10.2.28(iii). Summing up, we see that the filtration induced by the spectral sequence $E(n)_2^{\bullet\bullet}$ on its abutment $H^i := H^i(I_0^n \overset{\mathbf{L}}{\otimes}_{A_0} R\Gamma\mathscr{O}_Y)$ is finite for every $i \in \mathbb{Z}$, and the inverse systems of its graded subquotients $(E(n)_\infty^{pq} \mid n \in \mathbb{N})$ are uniformly essentially zero whenever $p+q > 0$, whence the assertion in case $i > 0$, after invoking as usual lemma 7.8.19. For $i < 0$, we argue likewise, using the spectral sequences $F(n)_2^{\bullet\bullet}$: indeed, we see again easily that the filtration induced on the abutment H^i is finite for every $i \in \mathbb{Z}$; moreover, if $p < 0$ the inverse system $(F(n)_2^{pq} \mid n \in \mathbb{N})$ is identically zero, and it is uniformly essentially zero if $q < 0$, by virtue of (i), whence the assertion.

(iii): For $p > 0$ we have $E(n)_2^{p0} = 0$ for every $n \in \mathbb{N}$, so the assertion is trivial in this case. For $p \leq 0$, notice that $E(n)_s^{p+s,1-s} = 0$ for every $s \geq 2$, hence $E(n)_s^{p0}$ is a quotient of $E(n)_2^{p0}$ for every $s \geq 2$, whence a surjection $E(n)_2^{p0} \to E(n)_\infty^{p0}$ as sought. Moreover, notice that the inverse system $(E(n)_2^{p-s,s-1} \mid n \in \mathbb{N})$ is uniformly essentially zero for every $s \geq 2$, due to condition (c) and lemma 7.8.24, and it vanishes identically for $s \geq r$. Then the same holds for the inverse system $(E(n)_s^{p-s,s-1} \mid n \in \mathbb{N})$, for every $s \geq 2$, and the assertion follows easily.

(iv): For $p < 0$ we have $F(n)_2^{p0} = 0$ for every $n \in \mathbb{N}$, so the assertion is trivial in this case. For $p \geq 0$, notice that $F(n)_s^{p-s,s-1} = 0$ for every $s \geq 2$, hence $F(n)_s^{p0}$ is a submodule of $F(n)_2^{p0}$ for every $s \geq 2$, whence a injection $F(n)_\infty^{p0} \to F(n)_2^{p0}$ as sought. Moreover, notice that the inverse system $(F(n)_2^{p+s,1-s} \mid n \in \mathbb{N})$ is uniformly essentially zero for every $s \geq 2$, due to (i), and it vanishes identically for $s \geq r$. Then the same holds for the inverse system $(F(n)_s^{p+s,1-s} \mid n \in \mathbb{N})$, for every $s \geq 2$, and the assertion follows easily.

(v): The assertion for $p > 0$ is obvious, and the case $p < 0$ for $(E(n)_2^{p,-p} \mid n \in \mathbb{N})$ follows from condition (c) and lemma 7.8.24, and for $(F(n)_2^{-p,p} \mid n \in \mathbb{N})$ follows from (i). ◊

Assumption (c) implies that the natural map $A \to H^0(Y, \mathscr{O}_Y)$ induces a morphism of inverse systems

$$(\mathrm{Tor}_{-p}^{A_0}(I_0^n, A) \mid n \in \mathbb{N}) \to (E(n)_2^{p0} \mid n \in \mathbb{N}) \qquad \text{for every } p \in \mathbb{Z}$$

whose kernel and cokernel are uniformly essentially zero. Combining with claim 10.6.55(ii,iii), it follows already that the inverse system $(\mathrm{Tor}_p^{A_0}(A/I_0^n, A) \mid n \in \mathbb{N})$ is uniformly essentially zero for every $p > 1$. Next, since $\mathscr{O}_{Y_0}(n)$ is a flat $\mathscr{O}_{Y_0}$-module for every $n \in \mathbb{N}$, we have an exact sequence of $\mathscr{O}_Y$-modules

$$0 \to \psi^* \mathrm{Ker}\, \varphi_n \to \mathscr{T}\!or_0^{X_0}(\mathscr{I}_0^n, \mathscr{O}_Y) \to \psi^* \mathscr{O}_{Y_0}(n) = \mathscr{O}_Y(n) \to 0$$

whence exact sequences

$$H^p(Y, \psi^* \mathrm{Ker}\, \varphi_n) \to F(n)_2^{p0} \to H^p(Y, \mathscr{O}_Y(n)) \to H^{p+1}(Y, \psi^* \mathrm{Ker}\, \varphi_n)$$

for every $p \in \mathbb{Z}$ and every $n \in \mathbb{N}$. Combining with claim 10.6.55(ii,iv), we deduce that the inverse system $(H^p(Y, \mathscr{O}_Y(n)) \mid n \in \mathbb{N})$ is uniformly essentially zero for every $p > 0$.

Lastly, claim 10.6.55(v) implies that $(E(n)_\infty^{p,-p} \mid n \in \mathbb{N})$ and $(F(n)_\infty^{-p,p} \mid n \in \mathbb{N})$ vanish identically for every $p > 0$, and are uniformly essentially zero inverse systems for $p < 0$. It follows that the spectral sequences $E(n)_2^{\bullet\bullet}$ and $F(n)_2^{\bullet\bullet}$ induce respectively a monomorphism and an epimorphism

$$(E(n)_\infty^{00} \mid n \in \mathbb{N}) \to (H^0(I_0^n \overset{\mathbf{L}}{\otimes}_{A_0} R\Gamma \mathscr{O}_Y) \mid n \in \mathbb{N}) \to (F(n)_\infty^{00} \mid n \in \mathbb{N})$$

and the kernel and cokernel of the composition of these morphisms are uniformly essentially zero inverse systems. Taking into account claim 10.6.55(iv) we get therefore a commutative diagram of inverse systems

$$\begin{array}{ccccc}
(E(n)_2^{00} \mid n \in \mathbb{N}) & \longrightarrow & (E(n)_\infty^{00} \mid n \in \mathbb{N}) & \longrightarrow & (F(n)_\infty^{00} \mid n \in \mathbb{N}) \\
\| & & & & \downarrow \\
(I_0^n \otimes_{A_0} H^0(Y, \mathscr{O}_Y) \mid n \in \mathbb{N}) & \xrightarrow{\beta_\bullet} & (H^0(Y, \mathscr{O}_Y(n) \mid n \in \mathbb{N}) & \longleftarrow & (F(n)_2^{00} \mid n \in \mathbb{N})
\end{array}$$

all whose arrows, except possibly $\beta_\bullet$, have uniformly essentially zero kernels and cokernels, but then also $\beta_\bullet$ does.

Claim 10.6.56. $\beta_\bullet$ is the map induced by the identification $\omega_n : \mathscr{I}^n \mathscr{O}_Y \xrightarrow{\sim} \mathscr{O}_Y(n)$ of remark 10.6.39(iv) and the natural map $\psi^* \pi_0^* \mathscr{I}_0^n \to \mathscr{I}^n \mathscr{O}_Y$.

Proof of the claim. Indeed, by construction, the map $F(n)_2^{00} \to H^0(Y, \mathscr{O}_Y(n))$ is obtained from the identification ω_n and the natural isomorphism $\mathscr{T}\!or_0^{X_0}(\mathscr{O}_{Y_0}, \mathscr{I}_0^n) \xrightarrow{\sim} \psi^* \pi_0^* \mathscr{I}_0^n$, so we are reduced to checking that the map

$$E(n)_2^{00} = I_0^n \otimes_{A_0} H^0(Y, \mathscr{O}_Y) \to F(n)_2^{00} = H^0(Y, \psi^* \pi_0^* \mathscr{I}_0^n)$$

deduced from the foregoing commutative diagram, agrees with the standard one that assigns to any element $x \otimes s$ its class in $H^0(Y, \psi^* \pi_0^* \mathscr{I}_0^n)$. To this aim, set $U_i := D_+(f_i) \subset Y$ for $i = 1, \dots, r$, and let $Y'' := \amalg_{i=1}^r U_i$, the affine X-scheme given by the disjoint union of the affine open subsets $U_1, \dots, U_r$. We have an obvious morphism $\nu : Y'' \to Y$ of schemes, that restricts to the inclusion map on each open subset U_i of Y'', and let also $\psi'' := \psi \circ \nu : Y'' \to Y_0$. We have as well two systems of spectral sequences $E''(n)_2^{\bullet\bullet}$ and $F''(n)_2^{\bullet\bullet}$, obtained as in the foregoing, after replacing Y by Y'' and $\mathscr{O}_Y$ by $\mathscr{O}_{Y''}$. By functoriality of the spectral sequences, there follows a commutative diagram

$$\begin{array}{ccc} E(n)_2^{00} = I_0^n \otimes_{A_0} H^0(Y, \mathscr{O}_Y) & \longrightarrow & F(n)_2^{00} = H^0(Y, \psi^* \pi_0^* \mathscr{I}_0^n) \\ \downarrow & & \downarrow \\ E''(n)_2^{00} = I_0^n \otimes_{A_0} H^0(Y'', \mathscr{O}_{Y''}) & \longrightarrow & F''(n)_2^{00} = H^0(Y'', \psi''^* \pi_0^* \mathscr{I}_0^n) \end{array}$$

and notice that the right vertical arrow is injective. Thus, it suffices to check that the bottom horizontal arrow is the expected map. However, we have $E''(n)_2^{00} = E''(n)_\infty^{00} = E''(n)_\infty^0 = F''(n)_\infty^0 = F''(n)_\infty^{00} = F''(n)_2^{00}$ for every $n \in \mathbb{N}$, and a direct inspection shows that the bottom horizontal map is the identity map, whence the claim. ◊

From claim 10.6.56 and condition (c), it follows already that the natural morphism of inverse systems $(I_0^n \otimes_{A_0} A \mid n \in \mathbb{N}) \to (H^0(Y, \mathscr{O}_Y(n)) \mid n \in \mathbb{N})$ has uniformly essentially zero kernel and cokernel. But the latter factors as the composition of the epimorphism of inverse systems $(I_0^n \otimes_{A_0} A \mid n \in \mathbb{N}) \to (I^n \mid n \in \mathbb{N})$ and the natural morphism $(I^n \mid n \in \mathbb{N}) \to (H^0(Y, \mathscr{O}_Y(n)) \mid n \in \mathbb{N})$. It follows that the kernels and cokernels of both of the latter morphisms are uniformly essentially zero, and the proof of the theorem is concluded. □

Remark 10.6.57. By direct inspection of the proof, we obtain the following refinement of theorem 10.6.50. For every $r \in \mathbb{N}$ there exists an integer $\nu(r)$ such that, if the ring A satisfies condition $(\mathrm{a})_{\mathbf{f}}^{\mathrm{un}}$ with step $\leq r$, then the inverse system $(H^p(Y, \mathscr{O}_Y(n)) \mid n \in \mathbb{N})$ is uniformly essentially zero with step $\leq \nu(r)$, and the same holds for the kernel and cokernel of the inverse system $(I^n \to H^0(Y, \mathscr{O}_Y(n)) \mid n \in \mathbb{N})$. The detailed verification shall be left to the reader.

11. Duality theory

11.1. **Duality for quasi-coherent modules.** Let $f : X \to Y$ be a morphism of schemes; theorem 10.1.18 falls short of proving that Lf^* is a left adjoint to Rf_*, since the former functor is defined on bounded above complexes, while the latter is defined on complexes that are bounded below. This deficency has been overcome by N.Spaltenstein's paper [154], where he shows how to extend the usual constructions of derived functors to unbounded complexes. On the other hand, in many cases one can also construct a *right adjoint* to Rf_*. This is the subject of Grothendieck's duality theory. We shall collect the statements that we need from that theory, and refer to the original source [87] for the rather elaborate proofs.

11.1.1. For any morphism of schemes $f : X \to Y$, let $\overline{f} : (X, \mathscr{O}_X) \to (Y, f_*\mathscr{O}_X)$ be the corresponding morphism of ringed spaces. The functor

$$\overline{f}_* : \mathscr{O}_X\text{-}\mathbf{Mod} \to f_*\mathscr{O}_X\text{-}\mathbf{Mod}$$

admits a left adjoint $\overline{f}^*$ defined as usual ([59, Ch.0, §4.3.1]). In case f is affine, $\overline{f}$ is flat and the unit and counit of the adjunction restrict to isomorphisms of functors :

$$\mathbf{1} \to \overline{f}_* \circ \overline{f}^* : f_*\mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \to f_*\mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}}$$
$$\overline{f}^* \circ \overline{f}_* \to \mathbf{1} : \mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \to \mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}}.$$

on the corresponding subcategories of quasi-coherent modules ([60, Ch.II, Prop.1.4.3]). It follows easily that, on these subcategories, $\overline{f}^*$ is also a right adjoint to $\overline{f}_*$.

Lemma 11.1.2. *Keep the notation of* (11.1.1)*, and suppose that f is affine. Then the functor :*

$$\overline{f}^* : \mathsf{D}^+(f_*\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}} \to \mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$$

is right adjoint to the functor $R\overline{f}_* : \mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}} \to \mathsf{D}^+(f_*\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$. Moreover, the unit and counit of the resulting adjunction are isomorphisms of functors.

Proof. By trivial duality (theorem 10.1.18), $\overline{f}^*$ is left adjoint to $R\overline{f}_*$ on $\mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})$; it suffices to show that the unit (resp. and counit) of this latter adjunction are isomorphisms for every object $K^\bullet$ of $\mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$ (resp. $L^\bullet$ of $\mathsf{D}^+(f_*\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$). Concerning the unit, we can use a Cartan-Eilenberg injective resolution of $\overline{f}^*K^\bullet$, and a standard spectral sequence, to reduce to the case where $K^\bullet = \mathscr{F}[0]$ for a quasi-coherent $f_*\mathscr{O}_X$-module $\mathscr{F}$; however, the natural map $\overline{f}_* \circ \overline{f}^*\mathscr{F} \to R\overline{f}_* \circ \overline{f}^*\mathscr{F}$ is an isomorphism, so the assertion follows from (11.1.1). $\square$

Remark 11.1.3. (i) Even when both X and Y are affine, neither the unit nor the counit of adjunction in (11.1.1) is an isomorphism on the categories of all modules. For a counterexample concerning the unit, consider the case of a finite injection of domains $A \to B$, where A is local and B is semi-local (but not local); let $f : X := \operatorname{Spec} B \to \operatorname{Spec} A$ be the corresponding morphism, and denote by $\mathscr{F}$ the $f_*\mathscr{O}_X$-module supported on the closed point, with stalk equal to B. Then one verifies easily that $\overline{f}_* \circ \overline{f}^*\mathscr{F}$ is a direct product of finitely many copies of $\mathscr{F}$, indexed by the closed points of X. Concerning the counit, keep the same morphism f, let $U := X\setminus\{x\}$, where x is a closed point and set $\mathscr{F} := j_!\mathscr{O}_U$; then it is clear that $\overline{f}^* \circ \overline{f}_*\mathscr{F}$ is supported on the complement of the closed fibre of f.

(ii) Similarly, one sees easily that $\overline{f}^*$ is not a right adjoint to $\overline{f}_*$ on the category of all $f_*\mathscr{O}_X$-modules.

(iii) Incidentally, the analogous functor $\overline{f}^*_{\text{ét}}$ defined on the étale (rather than Zariski) site is a right adjoint to $\overline{f}_{\text{ét}*} : \mathscr{O}_{X,\text{ét}}\text{-}\mathbf{Mod} \to f_*\mathscr{O}_{X,\text{ét}}\text{-}\mathbf{Mod}$, and on these sites the unit and counit of the adjunctions are isomorphisms for all modules.

11.1.4. For the construction of the right adjoint $f^!$ to Rf_*, one considers first the case where f factors as a composition of a finite morphism followed by a smooth one, in which case $f^!$ admits a corresponding decomposition. Namely :

- In case f is smooth, we shall consider the functor :
$$f^\sharp : \mathsf{D}(\mathscr{O}_Y\text{-}\mathbf{Mod}) \to \mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod}) \qquad K^\bullet \mapsto f^*K^\bullet \otimes_{\mathscr{O}_X} \Lambda^n_{\mathscr{O}_X}\Omega^1_{X/Y}[n]$$
where n is the locally constant relative dimension function of f.
- In case f is finite, we shall consider the functor :
$$f^\flat : \mathsf{D}^+(\mathscr{O}_Y\text{-}\mathbf{Mod}) \to \mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod}) \qquad K^\bullet \mapsto \overline{f}^*R\mathscr{H}om^\bullet_{\mathscr{O}_Y}(f_*\mathscr{O}_X, K^\bullet).$$

If f is any quasi-projective morphism, such factorization can always be found locally on X, and one is left with the problem of patching a family of locally defined functors $((f_{|U_i})^! \mid i \in I)$, corresponding to an open covering $X = \bigcup_{i\in I} U_i$. Since such patching must be carried out in the derived category, one has to take care of many cumbersome complications.

11.1.5. Recall that a finite morphism $f : X \to Y$ is said to be *pseudo-coherent* if $f_*\mathscr{O}_X$ is a pseudo-coherent $\mathscr{O}_Y$-module. This condition is equivalent to the pseudo-coherence of f in the sense of [20, Exp.III, Déf.1.2].

Lemma 11.1.6. *Let $f : X \to Y$ be a finite morphism of schemes. Then :*

(i) *If f is finitely presented, the functor*
$$\mathscr{F} \mapsto \overline{f}^*\mathscr{H}om_{\mathscr{O}_Y}(f_*\mathscr{O}_X, \mathscr{F})$$
is right adjoint to $f_* : \mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \to \mathscr{O}_Y\text{-}\mathbf{Mod}_{\mathrm{qcoh}}$.

(ii) *If f is pseudo-coherent, the functor*
$$K^\bullet \mapsto \overline{f}^*R\mathscr{H}om^\bullet_{\mathscr{O}_Y}(f_*\mathscr{O}_X, K^\bullet) \quad : \quad \mathsf{D}^+(\mathscr{O}_Y\text{-}\mathbf{Mod})_{\mathrm{qcoh}} \to \mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$$
is right adjoint to
$$Rf_* : \mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}} \to \mathsf{D}^+(\mathscr{O}_Y\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$$
(notation of (10.3)*).*

Proof. (i): Under the stated assumptions, $f_*\mathscr{O}_X$ is a finitely presented $\mathscr{O}_Y$-module (by claim 9.1.35), hence the functor

$$\mathscr{F} \mapsto \mathscr{H}om_{\mathscr{O}_Y}(f_*\mathscr{O}_X, \mathscr{F}) \quad : \quad \mathscr{O}_Y\text{-}\mathbf{Mod} \to f_*\mathscr{O}_X\text{-}\mathbf{Mod}$$

preserves the subcategories of quasi-coherent modules, hence it restricts to a right adjoint for the forgetful functor $f_*\mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \to \mathscr{O}_Y\text{-}\mathbf{Mod}_{\mathrm{qcoh}}$ (claim 10.1.17). Then the assertion follows from (11.1.1).

(ii) is analogous : since $f_*\mathscr{O}_X$ is pseudo-coherent, the functor

$$K^\bullet \mapsto R\mathscr{H}om^\bullet_{\mathscr{O}_Y}(f_*\mathscr{O}_X, K^\bullet) \quad : \quad \mathsf{D}^+(\mathscr{O}_Y\text{-}\mathbf{Mod}) \to \mathsf{D}^+(f_*\mathscr{O}_X\text{-}\mathbf{Mod})$$

preserves the subcategories of complexes with quasi-coherent homology, hence it restricts to a right adjoint for the forgetful functor $\mathsf{D}^+(f_*\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{qcoh}} \to \mathsf{D}^+(\mathscr{O}_Y\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$, by lemma 10.1.16(iii). To conclude, it then suffices to apply lemma 11.1.2. ☐

Proposition 11.1.7. *Suppose that* $X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} W$ *are morphisms of schemes. Then :*

(i) *If f and g are finite and f is pseudo-coherent, there is a natural isomorphism of functors on* $\mathsf{D}^+(\mathscr{O}_Z\text{-}\mathbf{Mod})$ *:*

$$\xi_{f,g} : (g \circ f)^\flat \xrightarrow{\sim} f^\flat \circ g^\flat.$$

(ii) *If f and $g \circ f$ are finite and pseudo-coherent, and g is smooth of bounded fibre dimension, there is a natural isomorphism of functors on* $\mathsf{D}^+(\mathscr{O}_Z\text{-}\mathbf{Mod})$ *:*

$$\zeta_{f,g} : (g \circ f)^\flat \xrightarrow{\sim} f^\flat \circ g^\sharp.$$

(iii) *If f, g and $h \circ g$ are finite and pseudo-coherent, and h is smooth of bounded fibre dimension, then the diagram of functors on* $\mathsf{D}^+(\mathscr{O}_W\text{-}\mathbf{Mod})$ *:*

$$\begin{array}{ccc} (h \circ g \circ f)^\flat & \xrightarrow{\zeta_{g\circ f,h}} & (g \circ f)^\flat \circ h^\sharp \\ {\scriptstyle \xi_{f,h\circ g}}\downarrow & & \downarrow{\scriptstyle \xi_{f,g}\circ h^\sharp} \\ f^\flat \circ (h \circ g)^\flat & \xrightarrow{f^\flat(\zeta_{g,h})} & f^\flat \circ g^\flat \circ h^\sharp \end{array}$$

commutes.

(iv) *If, moreover*

$$\begin{array}{ccc} Y & \xrightarrow{g} & Z \\ {\scriptstyle h'}\downarrow & & \downarrow{\scriptstyle h} \\ W' & \xrightarrow{j} & W \end{array}$$

is a cartesian diagram of schemes, such that h is smooth of bounded fibre dimension and j is finite and pseudo-coherent, then there is a natural isomorphism of functors :

$$\vartheta_{j,h} : g^\flat \circ h^\sharp \xrightarrow{\sim} h'^\sharp \circ j^\flat.$$

Proof. This is [87, Ch.III, Prop.6.2, 8.2, 8.6]. We check only (i). There is a natural commutative diagram of ringed spaces :

$$\begin{array}{ccccc} (X, \mathscr{O}_X) & \xrightarrow{f} & (Y, \mathscr{O}_Y) & \xrightarrow{g} & (Z, \mathscr{O}_Z) \\ & {\scriptstyle \overline{f}}\searrow & \uparrow{\scriptstyle \alpha} & {\scriptstyle \overline{g}}\searrow & \uparrow{\scriptstyle \gamma} \\ & & (Y, f_*\mathscr{O}_X) & & (Z, g_*\mathscr{O}_Y) \\ & & & {\scriptstyle \varphi}\searrow & \uparrow{\scriptstyle \beta} \\ & & & & (Z, (g \circ f)_*\mathscr{O}_X) \end{array}$$

where :

$$\varphi \circ \overline{f} = \overline{g \circ f}. \tag{11.1.8}$$

By claim 10.1.17, the (forgetful) functors α_*, β_* and γ_* admit right adjoints :

$$\begin{aligned}
\alpha^\flat &: \mathscr{O}_Y\text{-}\mathbf{Mod} \to f_*\mathscr{O}_X\text{-}\mathbf{Mod} && : \mathscr{F} \mapsto \mathscr{H}om_{\mathscr{O}_Y}(f_*\mathscr{O}_X, \mathscr{F}) \\
\beta^\flat &: g_*\mathscr{O}_Y\text{-}\mathbf{Mod} \to (g\circ f)_*\mathscr{O}_X\text{-}\mathbf{Mod} && : \mathscr{F} \mapsto \mathscr{H}om_{g_*\mathscr{O}_Y}((g\circ f)_*\mathscr{O}_X, \mathscr{F}) \\
\gamma^\flat &: \mathscr{O}_Z\text{-}\mathbf{Mod} \to g_*\mathscr{O}_Y\text{-}\mathbf{Mod} && : \mathscr{F} \mapsto \mathscr{H}om_{\mathscr{O}_Z}(g_*\mathscr{O}_Y, \mathscr{F}).
\end{aligned}$$

Likewise, $(\gamma\circ\beta)_*$ admits a right adjoint $(\gamma\circ\beta)^\flat$ and the natural identification

$$\gamma_* \circ \beta_* \xrightarrow{\sim} (\gamma\circ\beta)_*$$

induces a natural isomorphisms of functors :

$$(\gamma\circ\beta)^\flat := \mathscr{H}om_{\mathscr{O}_Z}((g\circ f)_*\mathscr{O}_X, -) \xrightarrow{\sim} \beta^\flat \circ \gamma^\flat. \tag{11.1.9}$$

(Notice that, in general, there might be several choices of such natural transformations (11.1.9), but for the proof of (iii) – as well as for the construction of $f^!$ for more general morphisms f – it is essential to make an explicit and canonical choice.)

Claim 11.1.10. (i) $\alpha_* \circ \varphi^* = \overline{g}^* \circ \beta_*$.

(ii) The natural commutative diagram of sheaves :

$$\begin{array}{ccc}
\overline{g}^{-1} g_*\mathscr{O}_Y & \longrightarrow & \mathscr{O}_Y \\
\downarrow & & \downarrow \\
\overline{g}^{-1}(g\circ f)_*\mathscr{O}_X & \longrightarrow & f_*\mathscr{O}_X
\end{array}$$

is cocartesian.

Proof of the claim. (i) is an easy consequence of (ii). Assertion (ii) can be checked on the stalks, hence we may assume that $Z = \operatorname{Spec} A$, $Y = \operatorname{Spec} B$ and $X = \operatorname{Spec} C$ are affine schemes. Let $\mathfrak{p} \in Y$ be any prime ideal, and set $\mathfrak{q} := g(\mathfrak{p}) \in Z$; then $(\overline{g}^{-1}g_*\mathscr{O}_Y)_\mathfrak{p} = B_\mathfrak{q}$ (the $A_\mathfrak{q}$-module obtained by localizing the A-module B at the prime $\mathfrak{q}$). Likewise, $(\overline{g}^{-1}(g\circ f)_*\mathscr{O}_X)_\mathfrak{p} = C_\mathfrak{q}$ and $(f_*\mathscr{O}_X)_\mathfrak{p} = C_\mathfrak{p}$. Hence the claim boils down to the standard isomorphism : $C_\mathfrak{q} \otimes_{B_\mathfrak{q}} B_\mathfrak{p} \simeq C_\mathfrak{p}$. ◊

Let $I^\bullet$ be a bounded below complex of injective $\mathscr{O}_Z$-modules; by lemma 10.1.16(i), $\gamma^\flat I^\bullet$ is a complex of injective $g_*\mathscr{O}_Y$-modules; taking into account (11.1.9) we deduce a natural isomorphism of functors on $\mathsf{D}^+(\mathscr{O}_Z\text{-}\mathbf{Mod})$:

$$R(\gamma\circ\beta)^\flat \xrightarrow{\sim} R(\beta^\flat \circ \gamma^\flat) = R\beta^\flat \circ R\gamma^\flat. \tag{11.1.11}$$

Furthermore, (11.1.8) implies that $\overline{g \circ f}^* = \overline{f}^* \circ \varphi^*$. Combining with (11.1.11), we see that the sought $\xi_{f,g}$ is a natural transformation :

$$\overline{f}^* \circ \varphi^* \circ R\beta^\flat \circ R\gamma^\flat \to \overline{f}^* \circ R\alpha^\flat \circ \overline{g}^* \circ R\gamma^\flat$$

of functors on $\mathsf{D}^+(\mathscr{O}_Z\text{-}\mathbf{Mod})$. Hence (i) will follow from :

Claim 11.1.12. (i) There exists a natural isomorphism of functors :

$$g_*\mathscr{O}_Y\text{-}\mathbf{Mod} \to f_*\mathscr{O}_X\text{-}\mathbf{Mod} \quad : \quad \varphi^* \circ \beta^\flat \xrightarrow{\sim} \alpha^\flat \circ \overline{g}^*.$$

(ii) The natural transformation :

$$R(\alpha^\flat \circ \overline{g}^*) \to R\alpha^\flat \circ \overline{g}^*$$

is an isomorphism of functors : $\mathsf{D}^+(g_*\mathscr{O}_Y\text{-}\mathbf{Mod}) \to \mathsf{D}^+(f_*\mathscr{O}_X\text{-}\mathbf{Mod})$.

Proof of the claim. First we show how to construct a natural transformation as in (i); this is the same as exhibiting a map of functors : $\alpha_* \circ \varphi^* \circ \beta^\flat \to \overline{g}^*$. In view of claim 11.1.10(i), the latter can be defined as the composition of $\overline{g}^*$ and the counit of adjunction $\beta_* \circ \beta^\flat \to \mathbf{1}_{g_*\mathscr{O}_Y\text{-}\mathbf{Mod}}$.

Next, recall the natural transformation :

$$(11.1.13)\quad \overline{g}^*\mathscr{H}om_{g_*\mathscr{O}_Y}(\mathscr{F},\mathscr{G}) \to \mathscr{H}om_{\mathscr{O}_Y}(\overline{g}^*\mathscr{F},\overline{g}^*\mathscr{G}) \quad \text{for every } g_*\mathscr{O}_Y\text{-modules } \mathscr{F} \text{ and } \mathscr{G}$$

(defined so as to induce the pull-back map on global Hom functors). Notice that the natural map $\overline{g}^*\overline{g}_*\mathscr{F} \to \mathscr{F}$ (counit of adjunction) is an isomorphism for every quasi-coherent $\mathscr{O}_Y$-module $\mathscr{F}$. Especially, if $\mathscr{F} = g_*\mathscr{A}$ for a quasi-coherent $\mathscr{O}_Y$-module $\mathscr{A}$, then (11.1.13) takes the form :

$$(11.1.14)\qquad \overline{g}^*\mathscr{H}om_{g_*\mathscr{O}_Y}(\overline{g}_*\mathscr{A},\mathscr{G}) \to \mathscr{H}om_{\mathscr{O}_Y}(\mathscr{A},\overline{g}^*\mathscr{G}).$$

Furthermore, by inspecting the definitions (and the proof of claim 10.1.17), one verifies easily that the map $\varphi^*\circ\beta^\flat(\mathscr{G}) \to \alpha^\flat\circ\overline{g}^*(\mathscr{G})$ constructed above is the same as the map (11.1.14), taken with $\mathscr{A} = f_*\mathscr{O}_X$. Notice that, since f is pseudo-coherent, $f_*\mathscr{O}_X$ is even a finitely presented $\mathscr{O}_Y$-module; thus, in order to conclude the proof of (i), it suffices to show that (11.1.14) is an isomorphism for every finitely presented $\mathscr{O}_Y$-module $\mathscr{A}$ and every $g_*\mathscr{O}_Y$-module $\mathscr{G}$. To this aim, we may assume that Z and Y are affine; then we may find a presentation $\underline{\mathscr{E}} := (\mathscr{O}_Y^{\oplus p} \to \mathscr{O}_Y^{\oplus q} \to \mathscr{A} \to 0)$. We apply the natural transformation (11.1.14) to $\underline{\mathscr{E}}$, thereby obtaining a commutative ladder with left exact rows; then the five-lemma reduces the assertion to the case where $\mathscr{A} = \mathscr{O}_Y$, which is obvious. To prove assertion (ii) we may again assume that Y and Z are affine, in which case we can find a resolution $L_\bullet \to f_*\mathscr{O}_X$ consisting of free $\mathscr{O}_Y$-modules of finite rank. For a given bounded below complex $I^\bullet$ of injective $g_*\mathscr{O}_Y$-modules, choose a resolution $\overline{g}^*I^\bullet \to J^\bullet$ consisting of injective $\mathscr{O}_Y$-modules. We deduce a commutative ladder :

$$\begin{array}{ccccc}
\overline{g}^*\mathscr{H}om^\bullet_{g_*\mathscr{O}_Y}(\overline{g}_*\circ f_*\mathscr{O}_X, I^\bullet) & \xrightarrow{\mu_1} & \mathscr{H}om^\bullet_{\mathscr{O}_Y}(f_*\mathscr{O}_X,\overline{g}^*I^\bullet) & \xrightarrow{\mu_3} & \mathscr{H}om^\bullet_{\mathscr{O}_Y}(f_*\mathscr{O}_X, J^\bullet) \\
{\scriptstyle\lambda_1}\downarrow & & \downarrow & & \downarrow{\scriptstyle\lambda_2} \\
\overline{g}^*\mathscr{H}om^\bullet_{g_*\mathscr{O}_Y}(\overline{g}_*L_\bullet, I^\bullet) & \xrightarrow{\mu_2} & \mathscr{H}om^\bullet_{\mathscr{O}_Y}(L_\bullet,\overline{g}^*I^\bullet) & \xrightarrow{\mu_4} & \mathscr{H}om^\bullet_{\mathscr{O}_Y}(L_\bullet, J^\bullet).
\end{array}$$

Since $\overline{g}$ is flat, λ_1 is a quasi-isomorphism, and the same holds for λ_2. The maps μ_1 and μ_2 are of the form (11.1.14), hence they are quasi-isomorphisms, by the foregoing proof of (i). Finally, it is clear that μ_4 is a quasi-isomorphism as well, hence the same holds for $\mu_3 \circ \mu_1$, and (ii) follows. □

11.1.15. Let now $f : X \to Y$ be an *embeddable* morphism, *i.e.* such that it can be factored as a composition $f = g \circ h$ where $h : X \to Z$ is a finite pseudo-coherent morphism, $g : Z \to Y$ is smooth and separated, and the fibres of g have bounded dimension. One defines :

$$f^! := h^\flat \circ g^\sharp.$$

Lemma 11.1.16. *Let $X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} W$ be three embeddable morphisms of schemes, such that the compositions $g \circ f$, $h \circ g$ and $h \circ g \circ f$ are also embeddable. Then we have :*

(i) *There exists a natural isomorphism of functors*

$$\psi_{g,f} : (g \circ f)^! \xrightarrow{\sim} f^! \circ g^!.$$

Especially, $f^!$ is independent – up to a natural isomorphism of functors – of the choice of factorization as a finite morphism followed by a smooth morphism.

(ii) *The diagram of functors :*

$$\begin{array}{ccc} (h\circ g\circ f)^! & \xrightarrow{\psi_{h,g\circ f}} & (g\circ f)^!\circ h^! \\ \downarrow{\scriptstyle \psi_{h\circ g,f}} & & \downarrow{\scriptstyle \psi_{g,f}\circ h^!} \\ f^!\circ(h\circ g)^! & \xrightarrow{f^!(\psi_{h,g})} & f^!\circ g^!\circ h^! \end{array}$$

commutes.

Proof. The proof is a complicated verification, starting from proposition 11.1.7. See [87, Ch.III, Th.8.7] for details. ☐

11.1.17. Let $X \xrightarrow{f} Y \xrightarrow{g} Z$ be two finite and pseudo-coherent morphisms of schemes. The map $f^\natural : \mathscr{O}_Y \to f_*\mathscr{O}_X$ induces a natural transformation :

$$\mathscr{H}om^\bullet_{\mathscr{O}_Z}(g_*(f^\natural), -) : \beta_* \circ (\gamma\circ\beta)^\flat \to \gamma^\flat \tag{11.1.18}$$

(notation of the proof of proposition 11.1.7(i)) and we wish to conclude this section by exhibiting another compatibility involving (11.1.18) and the isomorphism $\xi_{f,g}$. To this aim, we consider the composition of isomorphism of functors on $\mathsf{D}^+(\mathscr{O}_Z\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$:

$$Rf_* \circ \overline{g\circ f}^* \xrightarrow{①} \alpha_* \circ R\overline{f}_* \circ \overline{f}^* \circ \varphi^* \xrightarrow{②} \alpha_* \circ \varphi^* \xrightarrow{③} \overline{g}^* \circ \beta_* \tag{11.1.19}$$

where :

① is deduced from (11.1.8) and the decomposition $f = \alpha \circ \overline{f}$.
② is induced from the counit of adjunction $\overline{\varepsilon} : R\overline{f}_* \circ \overline{f}^* \to \mathbf{1}$ provided by lemma 11.1.2.
③ is the identification of claim 11.1.10.

We define a morphism of functors as a composition :

$$Rf_* \circ (g\circ f)^\flat = Rf_* \circ \overline{g\circ f}^* \circ R(\gamma\circ\beta)^\flat \xrightarrow{④} \overline{g}^* \circ \beta_* \circ R(\gamma\circ\beta)^\flat \xrightarrow{⑤} g^\flat \tag{11.1.20}$$

where :

④ is the isomorphism (11.1.19) $\circ\, R(\gamma\circ\beta)^\flat$.
⑤ is the composition of $\overline{g}^*$ and the morphism $\beta_* \circ R(\gamma\circ\beta)^\flat \to R\gamma^\flat$ deduced from (11.1.18).

We have a natural diagram of functors on $\mathsf{D}^+(\mathscr{O}_Z\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$:

$$\begin{array}{ccccc} R(g\circ f)_*\circ(g\circ f)^\flat & \xrightarrow{⑥} & Rg_*\circ Rf_*\circ(g\circ f)^\flat & \xrightarrow{⑨} & Rg_*\circ g^\flat \\ \downarrow{\scriptstyle R(g\circ f)_*(\xi_{f,g})} & & \downarrow{\scriptstyle Rg_*\circ Rf_*(\xi_{f,g})} & & \uparrow{\scriptstyle ⑧} \\ R(g\circ f)_*\circ(f^\flat\circ g^\flat) & \xrightarrow{⑦} & Rg_*\circ Rf_*\circ(f^\flat\circ g^\flat) & = & Rg_*\circ(Rf_*\circ f^\flat)\circ g^\flat \end{array} \tag{11.1.21}$$

where :

⑥ and ⑦ are induced by the natural isomorphism $R(g\circ f)_* \xrightarrow{\sim} Rg_* \circ Rf_*$.
⑧ is induced by the counit of the adjunction $\varepsilon : Rf_* \circ f^\flat \to \mathbf{1}$.
⑨ is $Rg_* \circ$ (11.1.20).

Lemma 11.1.22. *In the situation of* (11.1.17), *diagram* (11.1.21) *commutes.*

Proof. The diagram splits into left and right subdiagrams, and clearly the left subdiagram commutes, hence it remains to show that the right one does too; to this aim, it suffices to consider the simpler diagram :

$$\begin{array}{ccc} Rf_* \circ (g\circ f)^\flat & \longrightarrow & g^\flat \\ {\scriptstyle Rf_*(\xi_{f,g})}\downarrow & \nearrow & \\ Rf_* \circ f^\flat \circ g^\flat & & \end{array}$$

whose horizontal arrow is (11.1.20), and whose upward arrow is deduced from the counit ε. However, the counit ε, used in ⑧, can be expressed in terms of the counit $\overline{\varepsilon} : R\overline{f}_* \circ \overline{f}^* \to \mathbf{1}$, used in ②, therefore we are reduced to considering the diagram of functors on $\mathsf{D}^+(\mathscr{O}_Z\text{-}\mathbf{Mod})_{\mathrm{qcoh}}$:

$$\begin{array}{ccccc} \alpha_* \circ R\overline{f}_* \circ \overline{f}^* \circ \varphi^* \circ R(\gamma\circ\beta)^\flat & \xrightarrow{\ (a)\ } & \alpha_* \circ \varphi^* \circ R(\gamma\circ\beta)^\flat & \xrightarrow{\ (e)\ } & \overline{g}^* \circ \beta_* \circ R(\gamma\circ\beta)^\flat \\ & & \downarrow{\scriptstyle (c)} & & \\ \downarrow{\scriptstyle Rf_*(\xi_{f,g})} & & \alpha_* \circ \varphi^* \circ R\beta^\flat \circ R\gamma^\flat & & \downarrow{\scriptstyle (5)} \\ & & \downarrow{\scriptstyle (d)} & & \\ \alpha_* \circ R\overline{f}_* \circ \overline{f}^* \circ R\alpha^\flat \circ g^\flat & \xrightarrow{\ (b)\ } & \alpha_* \circ R\alpha^\flat \circ \overline{g}^* \circ R\gamma^\flat & \xrightarrow{\ (f)\ } & g^\flat = \overline{g}^* \circ R\gamma^\flat \end{array}$$

where :

- ⓐ and ⓑ are induced from $\overline{\varepsilon}$.
- ⓒ is induced by the isomorphism (11.1.11).
- ⓓ is induced by the isomorphism of claim 11.1.12(i).
- ⓔ is induced by the identity of claim 11.1.10.
- ⓕ is induced by the counit $\alpha_* \circ R\alpha^\flat \to \mathbf{1}$.

Now, by inspecting the construction of $\xi_{f,g}$ one checks that the left subdiagram of the latter diagram commutes; moreover, from claim 11.1.12(ii) (and from lemma 10.1.16(i)), one sees that the right subdiagram is obtained by evaluating on complexes of injective modules the analogous diagram of functors on $\mathscr{O}_Z$-$\mathbf{Mod}$:

$$\begin{array}{ccc} \alpha_* \circ \varphi^* \circ (\gamma\circ\beta)^\flat & \xrightarrow{\ \boxed{e}\ } & \overline{g}^* \circ \beta_* \circ (\gamma\circ\beta)^\flat \\ \downarrow{\scriptstyle \boxed{c}} & & \\ \alpha_* \circ \varphi^* \circ \beta^\flat \circ \gamma^\flat & & \downarrow{\scriptstyle \boxed{5}} \\ \downarrow{\scriptstyle \boxed{d}} & & \\ \alpha_* \circ \alpha^\flat \circ \overline{g}^* \circ \gamma^\flat & \xrightarrow{\ \boxed{f}\ } & \overline{g}^* \circ \gamma^\flat . \end{array}$$

Furthermore, by inspecting the proof of claim 11.1.12(i), one verifies that $\boxed{f} \circ \boxed{d}$ is the same as the composition

$$\alpha_* \circ \varphi^* \circ \beta^\flat \circ \gamma^\flat \xrightarrow{(i)} \overline{g}^* \circ \beta_* \circ \beta^\flat \circ \gamma^\flat \xrightarrow{(j)} \overline{g}^* \circ \gamma^\flat$$

where (j) is deduced from the counit $\beta_* \circ \beta^\flat \to \mathbf{1}$, and (i) is deduced from the identity of claim 11.1.10. Hence we come down to showing that the diagram :

$$\begin{array}{ccc} \beta_* \circ (\gamma \circ \beta)^\flat & \xrightarrow{(11.1.18)} & \gamma^\flat \\ {\scriptstyle \beta_*(11.1.9)} \downarrow & \nearrow {\scriptstyle (k)} & \\ \beta_* \circ \beta^\flat \circ \gamma^\flat & & \end{array}$$

commutes in $g_*\mathscr{O}_Y$-$\mathbf{Mod}$, where (k) is deduced from the counit $\beta_* \circ \beta^\flat \to \mathbf{1}$. This is an easy verification, that shall be left to the reader. $\square$

11.2. **Cousin complexes.** In this section we study a special type of complexes of abelian sheaves, called *Cousin complexes*, defined on a large class of topological spaces. These complexes play an important role in the further development of duality theory for locally coherent schemes : in many cases the techniques explained in this section will allow to exhibit canonical representatives for the dualizing complexes that shall be investigated at length in section 11.3.

11.2.1. We resume the notation of (10.1.30), so $(X, \mathscr{A})$ is a ringed topological space, $\varphi : V \to X$ a locally closed immersion, we denote by $\overline{V}$ the topological closure of V in X, and we set $\partial V := \overline{V} \setminus V$. In (10.4.1) we have introduced the functor $\Gamma_{\overline{V}}$ of sections with support in $\overline{V}$, and its sheaf-valued variant $\underline{\Gamma}_{\overline{V}}$. We now extend these definitions to the case of a general locally closed immersion, by setting

$$\underline{\Gamma}_V := \varphi_* \circ \varphi^* \circ \underline{\Gamma}_{\overline{V}} : \mathscr{A}\text{-}\mathbf{Mod} \to \mathscr{A}\text{-}\mathbf{Mod} \qquad \Gamma_V := \Gamma \circ \underline{\Gamma}_V : \mathscr{A}\text{-}\mathbf{Mod} \to \mathscr{A}(X)\text{-}\mathbf{Mod}.$$

The functor $\underline{\Gamma}_V$ admits a derived functor

$$R\underline{\Gamma}_V : \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}) \to \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$$

obtained as usual by evaluating on injective resolutions of given bounded below complexes.

Remark 11.2.2. (i) We have the following explicit description of $\underline{\Gamma}_V$. Let $k : V \to X \setminus \partial V$ and $l : X \setminus \partial V \to X$ be respectively the closed and open immersions. Since $\varphi = l \circ k$, there exist natural isomorphisms

$$\underline{\Gamma}_V \xrightarrow{\sim} \varphi_* \circ k^* \circ l^* \circ \underline{\Gamma}_{\overline{V}} \xrightarrow{\sim} l_* \circ k_* \circ k^* \circ \underline{\Gamma}_V \circ l^* \xrightarrow{\sim} l_* \circ \underline{\Gamma}_V \circ l^*$$

where the last map is induced by the natural identification $k_* \circ k^* \circ \underline{\Gamma}_V \xrightarrow{\sim} \underline{\Gamma}_V$ provided by lemma 10.1.32. There follows a natural isomorphism

$$\underline{\Gamma}_V \mathscr{F}(S) \xrightarrow{\sim} \underline{\Gamma}_{\overline{V}} \mathscr{F}(S \setminus \partial V) \qquad \text{for every open subset } S \text{ of } X.$$

(ii) Notice that $\partial V = \varnothing$ if φ is a closed immersion; in this case, (i) says that the functor defined in (11.2.1) is naturally isomorphic to its namesake introduced in (10.4.1), so the current notation is consistent with that of section 10.4.

(iii) For a general locally closed subset V and any $\mathscr{A}$-module $\mathscr{F}$, the natural monomorphism $\iota_{\mathscr{F}} : \underline{\Gamma}_{\overline{V}} \mathscr{F} \to \mathscr{F}$ induces a natural transformation

$$\underline{\Gamma}_V \mathscr{F} \to \varphi_* \varphi^* \mathscr{F} \qquad (11.2.3)$$

which is a monomorphism for every such $\mathscr{F}$, since the functor $\varphi_* \varphi^*$ is left exact. Notice that if V is open in X, the map $\varphi^* \iota_{\mathscr{F}}$ is an isomorphism, so the same holds for (11.2.3).

Proposition 11.2.4. *In the situation of* (11.2.1)*, the functor* $\underline{\Gamma}_V$ *is right adjoint to* t_V.

Proof. For φ a closed immersion, remark 11.2.2(ii) reduces the assertion to lemma 10.4.13(i), since in this case $\varphi_! = \varphi_*$. The assertion is also clear in case φ is an open immersion, since in this case $\underline{\Gamma}_V$ is naturally isomorphic to the functor $\varphi_* \circ \varphi^*$, by remark 11.2.2(iii). Notice that $V = \overline{V} \cap (X \setminus \partial V)$. By proposition 10.1.33(i) (and by remark 1.1.17(i)) we are reduced to exhibiting a natural isomorphism of functors

$$\underline{\Gamma}_V \xrightarrow{\sim} \underline{\Gamma}_{X\setminus\partial V} \circ \underline{\Gamma}_{\overline{V}}.$$

But the existence of such an isomorphism is asserted already in remark 11.2.2(i). □

11.2.5. For our discussion, it will be important to know that in fact there exists a canonical adjunction for the pair $(t_V, \underline{\Gamma}_V)$. In view of the proof of proposition 11.2.4 (and of remark 1.1.17(i)), it suffices to exhibit a canonical pair (η^V, ε^V) of units and counits for this adjunction, in case φ is either an open or a closed immersion.

- Suppose first that φ is a closed immersion. Then we want natural transformations

$$\eta^V_{\mathscr{F}} : \mathscr{F} \to \underline{\Gamma}_V \circ \varphi_* \circ \varphi^* \mathscr{F} \qquad \varepsilon^V_{\mathscr{F}} : \varphi_* \circ \varphi^* \circ \underline{\Gamma}_V \mathscr{F} \to \mathscr{F}$$

related by the triangular identities of (1.1.13). However, remark 11.2.2(ii) yields a natural isomorphism $\eta_1 : \underline{\Gamma}_V \varphi_* \varphi^* \mathscr{F} \xrightarrow{\sim} \varphi_* \varphi^* \mathscr{F}$, and on the other hand, we have a canonical unit $\eta_2 : \mathscr{F} \to \varphi_* \varphi^* \mathscr{F}$ for the adjunction (φ^*, φ_*), so we take $\eta^V_{\mathscr{F}} := \eta_1^{-1} \circ \eta_2$. Likewise, let $\varepsilon_1 : \underline{\Gamma}_V \mathscr{F} \to \mathscr{F}$ be the natural monomorphism; we take $\varepsilon^V_{\mathscr{F}} := \varepsilon_1 \circ f_{\mathscr{F}}$, where $f_{\mathscr{F}} : t_V \circ \underline{\Gamma}_V \mathscr{F} \xrightarrow{\sim} \underline{\Gamma}_V \mathscr{F}$ is the isomorphism provided by lemma 10.1.32. The triangular identities may then be checked on the stalks : we leave the details to the reader.

- Next, if φ is an open immersion, we need to find natural transformations

$$\eta^V_{\mathscr{F}} : \mathscr{F} \to \varphi_* \circ \varphi^* \circ \varphi_! \circ \varphi^* \mathscr{F} \qquad \varepsilon^V_{\mathscr{F}} : \varphi_! \circ \varphi^* \circ \varphi_* \circ \varphi^* \mathscr{F} \to \mathscr{F}$$

again related by the same triangular identities. We take for $\eta^V_{\mathscr{F}}$ (resp. $\varepsilon^V_{\mathscr{F}}$) the composition of the natural unit $\mathscr{F} \to \varphi_* \varphi^* \mathscr{F}$ of the adjunction (φ^*, φ^*) (resp. the counit $\varphi_! \circ \varphi^* \mathscr{F} \to \mathscr{F}$ of the adjunction $(\varphi_!, \varphi^*)$), with the isomorphism

$$\varphi_* \varphi^* \mathscr{F} \xrightarrow{\sim} \varphi_* \varphi^* \varphi_! \varphi^* \mathscr{F} \qquad (\text{ resp. } \varphi_! \varphi^* \varphi_* \varphi^* \mathscr{F} \xrightarrow{\sim} \varphi_! \varphi^* \mathscr{F} \text{ })$$

deduced from the natural identification of $\varphi^* \circ \varphi_!$ (resp. of $\varphi^* \circ \varphi_*$) with the identity functor of $\varphi^* \mathscr{A}$-$\mathbf{Mod}$. The triangular identities are as usual checked on the stalks.

11.2.6. Due to proposition 11.2.4, and the subsequent observations in (11.2.5), all the constructions of proposition 10.1.33 have natural counterparts for the functors $\underline{\Gamma}_V$. Namely :

- If V and V' are any two locally closed subsets of X, there is a natural isomorphism

$$\beta_{V,V'} : \underline{\Gamma}_V \circ \underline{\Gamma}_{V'} \xrightarrow{\sim} \underline{\Gamma}_{V \cap V'}$$

and if $V'' \subset X$ is any other locally closed subset, the diagram of functors

$$\begin{array}{ccc} \underline{\Gamma}_V \circ \underline{\Gamma}_{V'} \circ \underline{\Gamma}_{V''} & \xrightarrow{\underline{\Gamma}_V * \beta_{V',V''}} & \underline{\Gamma}_V \circ \underline{\Gamma}_{V' \cap V''} \\ {\scriptstyle \beta_{V,V'} * \underline{\Gamma}_{V''}} \downarrow & & \downarrow {\scriptstyle \beta_{V,V' \cap V''}} \\ \underline{\Gamma}_{V \cap V'} \circ \underline{\Gamma}_{V''} & \xrightarrow{\beta_{V \cap V',V''}} & \underline{\Gamma}_{V \cap V' \cap V''} \end{array} \tag{11.2.7}$$

commutes.

- Moreover, suppose that the pair (V, V') satisfies either of the conditions (a), (b) of proposition 10.1.33(iii); then there exists a natural morphism

$$\gamma_{V,V'} : \underline{\Gamma}_V \to \underline{\Gamma}_{V'}.$$

which corresponds to $c^{V,V'}$ under the natural adjunction described in (11.2.5), and if V'' is any third locally closed subset of X, we get a commutative diagram

$$\begin{array}{ccc} \underline{\Gamma}_{V''} \circ \underline{\Gamma}_V & \xrightarrow{\underline{\Gamma}_{V''} * \gamma_{V,V'}} & \underline{\Gamma}_{V''} \circ \underline{\Gamma}_{V'} \\ {\scriptstyle \beta_{V'',V}} \downarrow & & \downarrow {\scriptstyle \beta_{V'',V'}} \\ \underline{\Gamma}_{V''\cap V} & \xrightarrow{\gamma_{V''\cap V, V''\cap V'}} & \underline{\Gamma}_{V''\cap V'}. \end{array}$$

- Lastly, in the situation of proposition 10.1.33(v) we have the identity :

$$\gamma_{V',V''} \circ \gamma_{V,V'} = \gamma_{V,V''} : \underline{\Gamma}_V \to \underline{\Gamma}_{V''}.$$

Remark 11.2.8. Let X be a topological space, $j : U \to X$ an open immersion, $\varphi : V \to X$ and $\varphi' : V' \to X$ two locally closed immersions fulfilling either of conditions (a),(b) of proposition 10.1.33(iii). The transformations $\gamma_{V,V'}$ can also be described explicitly, thanks to the following considerations.

(i) First, notice that the functors $t_\bullet$ on $\mathscr{A}$-modules, the unit $\eta^\bullet$ and the counit $\varepsilon^\bullet$ are all compatible with restriction to U, *i.e.* we have identities of functors on $j^*\mathscr{A}$-modules and of morphisms between such functors :

$$j^* * t_V = t_{U\cap V} \quad j^* * \eta^V = \varepsilon^{V\cap U} \quad j^* * \varepsilon^V = \eta^{V\cap U} \qquad \text{for every locally closed subset } V \subset X.$$

This is obvious for the truncation functors, and for the units and counits it follows by a simple inspection of the definition. Then, the uniqueness properties of the transformations $\tau^{\bullet\bullet}$ and $c^{\bullet\bullet}$ imply that the same compatibility with restriction to U holds for the latter.

(ii) It follows formally from (i) that the isomorphisms $\beta_{\bullet\bullet}$ and the transformations $\gamma_{\bullet\bullet}$ are likewise compatible with restriction to U. On the other hand, notice that the restriction map

$$\mathrm{Hom}_{\mathscr{A}\text{-}\mathbf{Mod}}(t_{V'}\mathscr{F}, \mathscr{G}) \to \mathrm{Hom}_{j^*\mathscr{A}\text{-}\mathbf{Mod}}((t_{V'}\mathscr{F})_{|U}, \mathscr{G}_{|U})$$

is a bijection for every $\mathscr{F}, \mathscr{G} \in \mathrm{Ob}(\mathscr{A}\text{-}\mathbf{Mod})$, whenever $V' \subset U$. We conclude that the restriction map

$$\mathrm{Hom}_{\mathscr{A}\text{-}\mathbf{Mod}}(\mathscr{F}, \underline{\Gamma}_{V'}\mathscr{G}) \to \mathrm{Hom}_{j^*\mathscr{A}\text{-}\mathbf{Mod}}(\mathscr{F}_{|U}, \underline{\Gamma}_{V'\cap U}\mathscr{G}_{|U})$$

is also bijective when $V' \subset U$. Letting $\mathscr{F} := \underline{\Gamma}_V\mathscr{G}$, we deduce that $\gamma_{V,V'}$ is determined by its restriction to U, which is just $\gamma_{V\cap U, V'\cap U}$.

(iii) Now, suppose first that $\psi : V \to V'$ is a closed immersion, and denote by $\overline{V}$ and $\overline{V}'$ the topological closures in X of V and respectively V'; notice that the unit of the adjunction (ψ^*, ψ_*) induces an isomorphism

$$\varphi'^* \circ \Gamma_{\overline{V}} \xrightarrow{\sim} \psi_* \circ \psi^* \circ \varphi'^* \circ \Gamma_{\overline{V}} \qquad (11.2.9)$$

since $(\varphi'^* \circ \Gamma_{\overline{V}}\mathscr{F})_{|V'\setminus V} = 0$ for every $\mathscr{A}$-module $\mathscr{F}$ (lemma 10.1.32). We claim that $\gamma_{V,V'}$ is the composition

$$\varphi_* \circ \varphi^* \circ \underline{\Gamma}_{\overline{V}} \xrightarrow{\sim} \varphi'_* \circ \psi_* \circ \psi^* \circ \varphi'^* \circ \underline{\Gamma}_{\overline{V}} \xrightarrow{\sim} \varphi'_* \circ \varphi'^* \circ \underline{\Gamma}_{\overline{V}} \to \varphi'_* \circ \varphi'^* \circ \underline{\Gamma}_{\overline{V}'}.$$

where the second map is the inverse of (11.2.9) and the third is deduced from $\gamma_{\overline{V},\overline{V}'} : \underline{\Gamma}_{\overline{V}} \to \underline{\Gamma}_{\overline{V}'}$. Indeed, notice that the foregoing construction is compatible with restriction to U; taking into account (iii), we may then replace X by its open subset $X \setminus \partial V'$, and assume that both φ and φ' are closed immersions. In this case, the assertion follows by direct inspection of the definition of the unit and counit of the adjunction $(t_\bullet, \underline{\Gamma}_\bullet)$, and of the definition of $t_\bullet$, in the case of closed immersions.

(iv) Likewise, if V' is an open subset of V, pick a factorization of $\varphi : V \to X$ as the composition of a closed immersion $i : V \to U$ and an open immersion $j : U \to X$. There is a unique open subset $U' \subset U$ such that $V' = U' \cap V$; denote by $j' : U' \to X$ the open immersion, and for any given $\mathscr{A}$-module $\mathscr{F}$, let $\eta_{\mathscr{F}} : \mathscr{F} \to j'_* j'^* \mathscr{F}$ be the unit of adjunction; according to remark 11.2.2, we may regard $\eta_{\mathscr{F}}$ as a natural transformation

$$\eta_{\mathscr{F}} : \mathscr{F} \to \underline{\Gamma}_{U'}\mathscr{F}$$

and we claim that $\gamma_{V,V'}$ is the composition

$$\underline{\Gamma}_V \xrightarrow{\underline{\Gamma}_V * \eta} \underline{\Gamma}_V \circ \underline{\Gamma}_{U'} \xrightarrow{\beta_{V,U'}} \underline{\Gamma}_{V'}.$$

For the proof, we may argue as in (iii) to see that $\gamma_{V,V'}$ is determined by its restriction to U', and since the proposed construction is compatible with restriction to U', we are then reduced to the case where $U' = U = X$ and therefore $V = V'$. However, clearly $c^{V,V}$ is the identity endomorphism of t_V, so it remains only to prove that the proposed map is the identity of $\underline{\Gamma}_V$, if $V = V'$. The latter can be checked easily, whence the claim. We could have used the above construction as a definition for $\gamma_{V,V'}$ in the case of open immersions, but the method we followed has the advantage of dispensing us from verifying that the resulting transformation is independent of the chosen factorization of φ.

11.2.10. Let $V \subset V'$ be a closed immersion of locally closed subsets of a topological space X; from remark 11.2.8(iii), it is clear that $\gamma_{V,V'}$ is a monomorphism. Moreover, we have :

Lemma 11.2.11. *In the situation of* (11.2.10)*, the sequence*

$$\Sigma_{V,V'} \quad : \quad 0 \to \underline{\Gamma}_V\mathscr{F} \xrightarrow{\gamma_{V,V'}} \underline{\Gamma}_{V'}\mathscr{F} \xrightarrow{\gamma_{V',V'\setminus V}} \underline{\Gamma}_{V'\setminus V}\mathscr{F}$$

is left exact for every $\mathscr{A}$-module $\mathscr{F}$.

Proof. Indeed, say that $V' = U \cap Z$ for some closed subset Z and open subset U; then $V = \overline{V} \cap U$, with $\overline{V}$ the topological closure of V in X, and in light of (11.2.6) we see that there is a natural isomorphism $\Sigma_{V,V'} \xrightarrow{\sim} \underline{\Gamma}_U(\Sigma_{\overline{V},Z})$. However, $\underline{\Gamma}_U$ is a left exact functor (since it admits a left adjoint), so it suffices to check that $\Sigma_{\overline{V},Z}$ is left exact. Thus, we may assume from start that V and V' are closed in X. By the same token, we see that $\Sigma_{V,V'} \simeq \underline{\Gamma}_{V'}(\Sigma_{V,X})$, so we may further assume that $V' = X$, in which case the sequence reduces to the initial segment of (10.4.2). □

Proposition 11.2.12. *With the notation of* (11.2.1)*, the following holds :*

(i) *If $\mathscr{F}$ is a flabby $\mathscr{A}$-module, the same holds for $\underline{\Gamma}_V\mathscr{F}$.*
(ii) *Every flabby $\mathscr{A}$-module is $\underline{\Gamma}_V$-acyclic.*
(iii) *If $\mathscr{B} \to \mathscr{A}$ is any morphism of sheaves of rings on X, the functor $R\underline{\Gamma}_V$ commutes with the forgetful functor* $\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}) \to \mathsf{D}^+(\mathscr{B}\text{-}\mathbf{Mod})$.
(iv) *If $\varphi' : V' \to X$ is any other locally closed immersion, there exists a natural isomorphism of functors :*

$$R\underline{\Gamma}_{V\cap V'} \xrightarrow{\sim} R\underline{\Gamma}_V \circ R\underline{\Gamma}_{V'} \qquad \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}) \to \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}).$$

(v) *Suppose that X is locally spectral and quasi-separated, and V is a constructible locally closed subset of X, then we have :*
   (a) *Every qc-flabby $\mathscr{A}$-module is $\underline{\Gamma}_V$-acyclic.*
   (b) *For every $i \in \mathbb{N}$, the functor $R^i\underline{\Gamma}_V$ commutes with filtered colimits of $\mathscr{A}$-modules.*
   (c) *For every $x \in V$, denote by $j_x : X(x) \to X$ the inclusion map (notation of definition* 8.1.44(iii)*). Then there exists a natural isomorphism*

$$j_x^* R\underline{\Gamma}_V \xrightarrow{\sim} R\underline{\Gamma}_{V(x)} \qquad \textit{in } \mathsf{D}^+(j_x^*\mathscr{A}\text{-}\mathbf{Mod}).$$

Proof. (i): By lemmata 10.4.13(ii) and 10.4.4(i), we know already that both assertions (i) and (ii) hold in case φ is a closed immersion; for the general case, we may then assume that φ is an open immersion. However, in this case both φ_* and φ^* take flabby sheaves to flabby sheaves (lemmata 10.1.2 and 10.1.5(ii)), and flabby sheaves are acyclic for both of these functors (lemma 10.1.5(ii)), so the assertion follows from remark 11.2.2(iii).

(iii) is clear from (ii), as every injective $\mathscr{A}$-module is a flabby $\mathscr{B}$-module (lemma 10.1.5(v)).

(iv) follows formally from (i), (ii) and (11.2.6) : details left to the reader.

(v.a): Since the assertion is local on X, we may assume that X is spectral, in which case V is the intersection of a closed constructible subset and an open constructible subset. By (iv) and lemma 10.1.5(iii), it then suffices to consider separately the cases where V is either open or closed in X. By lemma 10.4.4(iii.b) we know already the assertions in case V is a closed constructible subset of X, and the case where V is open follows easily from lemma 10.1.5(i,iv).

(v.b): We reduce again to the case where V is the intersection of a closed constructible subset Z and an open constructible subset U. Since – by (ii) – the functor $\underline{\Gamma}_Z$ transforms injective $\mathscr{A}$-modules into $\underline{\Gamma}_U$-acyclic $\mathscr{A}$-modules, we have a convergent spectral sequence

$$R^i\underline{\Gamma}_U \circ R^j\underline{\Gamma}_Z\mathscr{F} \Rightarrow R^{i+j}\underline{\Gamma}_V\mathscr{F}.$$

It then suffices to consider separately the case where V is either open or closed. These cases follow respectively from lemma 10.4.4(iii.b) and claim 10.4.5.

(v.c): Arguing as in the proof of (v.b), we reduce to consider separately the cases where V is either open or closed. For V closed, the assertion is corollary 10.4.10. For V open, the assertion follows from proposition 10.1.10(ii) and remark 11.2.2(iii), by arguing as in the proof of corollary 10.4.10 : details left to the reader. ☐

Remark 11.2.13. (i) Using proposition 11.2.12, the various compatibilities that have been found so far beween the functors $\underline{\Gamma}_V$ extend straightforwardly to their derived extensions. Especially, diagram (11.2.7) still commutes, after replacing the functors $\underline{\Gamma}_\bullet$ by their derived extensions everywhere, and the natural transformations $\beta_{\bullet\bullet}$ by their derived versions, provided by proposition 11.2.12(iii).

(ii) Likewise, if $V \subset V'$ (resp. $V' \subset V$) is any closed (resp. open) immersion of locally closed subsets of X, by deriving the morphisms $\gamma_{V,V'}$ of (11.2.6) we get a natural transformation

$$R\underline{\Gamma}_V \to R\underline{\Gamma}_{V'} \qquad (\text{ resp. } R\underline{\Gamma}_{V'} \to R\underline{\Gamma}_V\ ) \qquad \text{in } \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$$

and the compatibilities between the functors $\gamma_{\bullet\bullet}$ and $\beta_{\bullet\bullet}$ explicited in (11.2.6) hold, *mutatis mutandis*, also for the functors $R\underline{\Gamma}_\bullet$.

Lemma 11.2.14. *In the situation of* (11.2.10)*, let $\mathscr{F}$ be any flabby $\mathscr{A}$-module. Then, for every open subset $U \subset X$, the sequence*

$$0 \to \underline{\Gamma}_V\mathscr{F}(U) \to \underline{\Gamma}_{V'}\mathscr{F}(U) \to \underline{\Gamma}_{V'\setminus V}\mathscr{F}(U) \to 0$$

induced by the sequence $\Sigma_{V,V'}$ of lemma 11.2.11*, is short exact.*

Proof. We may assume that $U = X$, and it suffices to show that the map $g : \Gamma_{V'}\mathscr{F} \to \Gamma_{V'\setminus V}\mathscr{F}$ deduced from $\gamma_{V',V'\setminus V}$ is surjective, whenever $\mathscr{F}$ is flabby. To this aim, write $V' \setminus V = U' \cap V'$ for some open subset $U' \subset X$; then g is naturally identified with the map

$$\Gamma_X \circ \underline{\Gamma}_{V'}\mathscr{F} \to \Gamma_{U'} \circ \underline{\Gamma}_{V'}\mathscr{F}$$

deduced from $\gamma_{X,U'}$. But $\underline{\Gamma}_{V'}\mathscr{F}$ is still flabby (proposition 11.2.12(i)) so we are reduced to the case where $V' = X$, in which case g is naturally identified with the restriction map $\mathscr{F}(X) \to \mathscr{F}(X\setminus V)$, whence the contention. ☐

11.2.15. Let $(X, \mathscr{A})$ be a ringed topological space. A *family of supports* on X is a set Φ consisting of closed subsets of X, such that :

- $\varnothing \in \Phi$.
- If $Z \in \Phi$ and $Z' \subset Z$ is any closed subset, then $Z' \in \Phi$ as well.
- If $Z_1, Z_2 \in \Phi$, then $Z_1 \cup Z_2 \in \Phi$ as well.

Now, let Φ and Φ' be any two families of supports on X; we let $\Phi|\Phi'$ be the set whose elements are all the pairs $\underline{Z} := (Z, Z')$, where Z and Z' are arbitrary elements of Φ and respectively Φ', such that $Z' \subset Z$. We endow $\Phi|\Phi'$ with a partial ordering, by declaring that, for given pairs $\underline{Z}_1 := (Z_1, Z'_1), \underline{Z}_2 := (Z_2, Z'_2)$ of $\Phi|\Phi'$, we have $\underline{Z}_1 \leq \underline{Z}_2$ if $Z_1 \subset Z_2$ and $Z'_1 \subset Z'_2$. It is easily seen that $\Phi|\Phi'$ is filtered. To every object $\underline{Z} \in \Phi|\Phi'$ we assign the functor $\underline{\Gamma}_{Z\setminus Z'}$, and to any pair $(\underline{Z}_1, \underline{Z}_2)$ of elements of $\Phi|\Phi'$ with $\underline{Z}_1 \leq \underline{Z}_2$, we attach the composition

$$\underline{\Gamma}_{Z_1\setminus Z'_1} \xrightarrow{\gamma_{Z_1\setminus Z'_1, Z_2\setminus Z'_1}} \underline{\Gamma}_{Z_2\setminus Z'_1} \xrightarrow{\gamma_{Z_2\setminus Z'_2, Z_2\setminus Z'_1}} \underline{\Gamma}_{Z_2\setminus Z'_2} \tag{11.2.16}$$

(notation of (11.2.6)). We then define the functor

$$\underline{\Gamma}_{\Phi|\Phi'} := \operatorname*{colim}_{(Z,Z')\in\Phi|\Phi'} \underline{\Gamma}_{Z\setminus Z'} : \mathscr{A}\text{-}\mathbf{Mod} \to \mathscr{A}\text{-}\mathbf{Mod}$$

where the transition maps in the colimit are the maps (11.2.16), whence a derived functor

$$R\underline{\Gamma}_{\Phi|\Phi'} : \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}) \to \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$$

and we have a natural isomorphism of functors on $\mathscr{A}$-$\mathbf{Mod}$:

$$R^i\underline{\Gamma}_{\Phi|\Phi'} \xrightarrow{\sim} \operatorname*{colim}_{(Z,Z')\in\Phi|\Phi'} R^i\underline{\Gamma}_{Z\setminus Z'} \qquad \text{for every } i \in \mathbb{N}.$$

11.2.17. Keep the notation of (11.2.15). As a special case, we may take $\Phi' := \{\varnothing\}$, and we let

$$\underline{\Gamma}_\Phi := \underline{\Gamma}_{\Phi|\{\varnothing\}} : \mathscr{A}\text{-}\mathbf{Mod} \to \mathscr{A}\text{-}\mathbf{Mod}.$$

If Φ and Φ' are arbitrary family of supports, we have maps of partially ordered sets

$$\Phi \leftarrow \Phi|\Phi' \to \Phi' \quad : \quad Z \leftarrow\!\shortmid (Z, Z') \mapsto Z'.$$

Suppose moreover that $\Phi' \subset \Phi$; then both of these maps are cofinal, by lemma 1.5.7(i), and with lemma 11.2.10 and proposition 11.2.12(ii), we deduce a short exact sequence of complexes

$$0 \to \underline{\Gamma}_{\Phi'}\mathscr{I} \to \underline{\Gamma}_\Phi\mathscr{I} \to \underline{\Gamma}_{\Phi|\Phi'}\mathscr{I} \to 0 \tag{11.2.18}$$

for every flabby $\mathscr{A}$-module $\mathscr{I}$, whence a distinguished triangle of functors on $\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$:

$$R\underline{\Gamma}_{\Phi'} \to R\underline{\Gamma}_\Phi \to R\underline{\Gamma}_{\Phi|\Phi'} \to R\underline{\Gamma}_{\Phi'}[1].$$

11.2.19. Keep the notation of (11.2.15). Suppose now that X is sober and locally noetherian, and moreover that we are given a *weak codimension function* on X, *i.e.* a map

$$c : X \to \mathbb{Z}$$

such that $c(x) > c(y)$ whenever $x \neq y$ and x is a specialization of y in X. To the weak codimension function c we attach a system $(\Phi^p \mid p \in \mathbb{N})$ of families of supports, by the rule :

$$\Phi^p := \{Z \subset X \mid Z \text{ is closed in } X, \text{and } c(z) \geq p \text{ for every } z \in Z\} \qquad \text{for every } p \in \mathbb{N}.$$

For every $x \in X$, let also $j_x : X(x) \to X$ and $i_x : \{x\} \to X$ be the inclusion maps (notation of definition 8.1.44(iii)). Moreover, let us set $\Phi^p(x) := \{Z \cap X(x) \mid Z \in \Phi^p\}$, for every $p \in \mathbb{Z}$.

Lemma 11.2.20. *In the situation of* (11.2.19)*, the following holds for every $x \in X$:*

(i) *The topological space $X(x)$ is spectral, noetherian and finite dimensional, and the function c is bounded on $X(x)$.*
(ii) *There exists a natural isomorphism of functors on $\mathsf{D}^+(j_x^*\mathscr{A}\text{-}\mathbf{Mod})$:*

$$j_x^* R\underline{\Gamma}_{\Phi^p} \xrightarrow{\sim} R\underline{\Gamma}_{\Phi^p(x)} \qquad \textit{for every } p \in \mathbb{Z}.$$

(iii) *$(\Phi^p(x) \mid p \in \mathbb{Z})$ is the system of families of supports on $X(x)$ attached to the weak codimension function $c_{|X(x)}$.*

Proof. (i): Since the topology of $X(x)$ is induced from that of X, it is clear that $X(x)$ is noetherian, and we have already seen that it is spectral (remark 8.1.45(i)). Especially, $X(x)$ admits finitely many maximal points (remark 8.1.45(iii)); if $\eta_1, \dots, \eta_k$ are these maximal points, set $C := \max(c(\eta_1), \dots, c(\eta_k))$. Then it is clear that the restriction to $X(x)$ of the function c takes its values in the range $C, C+1, \dots, c(x)$, and it follows easily that the length of any descending sequence of points in $(X(x), \leq)$ is bounded by $c(x) - C$.

(ii) follows easily from proposition 11.2.12(v.c), since every closed subset of a locally noetherian topological space is constructible.

(iii): If Z is any closed subset of $X(x)$, denote by $\overline{Z}$ the topological closure of Z in X; since $X(x)$ is a pro-constructible subset of X, the same holds for $Z = X(x) \cap \overline{Z}$. Then $\overline{Z}$ is the set of specializations in X of the points of Z (proposition 8.1.47(i)). Especially, if $c(z) \geq p$ for every $z \in Z$, then $c(z) \geq p$ for every $z \in \overline{Z}$, and then clearly $Z \in \Phi^p(x)$. The assertion follows immediately. □

Proposition 11.2.21. *In the situation of* (11.2.19)*, we have a natural isomorphism of functors*

$$R^i\underline{\Gamma}_{\Phi^p|\Phi^{p+1}} \stackrel{\sim}{\to} \bigoplus_{c(x)=p} j_{x*} \circ R^i\underline{\Gamma}_{\{x\}} \circ j_x^* \qquad \text{for every } p \in \mathbb{Z} \text{ and } i \in \mathbb{N}.$$

Proof. Since the assertion is local on X, we may assume that X is noetherian. We consider first the case where $i = 0$, and we fix $p \in \mathbb{Z}$. Let $Z \in \Phi^p$ be any element; recall that Z has a finite number of irreducible components $Z_1, \dots, Z_k$ (proposition 8.1.4). Let η_i be the generic point of Z_i, so that $c(\eta_i) \geq p$ for every $i = 1, \dots, k$. For every $i, j = 1, \dots, k$ with $i \neq j$, set $Z_{ij} := Z_i \cap Z_j$; then, for every such i, j, every irreducible component of T of Z_{ij} and every $t \in T$, we must have $c(t) \geq c(\eta_T) > c(\eta_i)$, if η_T denotes the generic point of T. We conclude that $Z_{ij} \in \Phi^{p+1}$ for every $i, j = 1, \dots k$ with $i \neq j$. Set also

$$Z^{>p} := \bigcup_{c(\eta_i)>p} Z_i \cup \bigcup_{i\neq j} Z_{ij} \qquad \text{and} \qquad \Psi^{p+1} := \{(Z, Z') \in \Phi^p|\Phi^{p+1} \mid Z^{>p} \subset Z' \subset Z\}.$$

Since the subset Ψ^p is clearly cofinal in $\Phi^p|\Phi^{p+1}$, we deduce a natural isomorphism

$$\underline{\Gamma}_{\Phi^p|\Phi^{p+1}} \stackrel{\sim}{\to} \operatorname*{colim}_{(Z,Z')\in\Psi^p} \underline{\Gamma}_{Z\setminus Z'}.$$

However, say that $(Z, Z') \in \Psi^p$; we notice that the closed subset $V := Z\setminus Z'$ of $X\setminus Z'$ is the disjoint union of its irreducible components $V_1, \dots, V_t$, hence the topology induced by X on V is the coproduct (*i.e.* disjoint union) of the topologies induced by X on $V_1, \dots, V_t$, and there follows a natural isomorphism

$$\underline{\Gamma}_V \stackrel{\sim}{\to} \bigoplus_{i=1}^t \underline{\Gamma}_{V_i}. \tag{11.2.22}$$

Moreover, say that $\underline{Z}_1, \underline{Z}_2 \in \Psi^p$ and $\underline{Z}_1 \leq \underline{Z}_2$, and denote by $V_1, \dots, V_s$ (resp. $W_1, \dots, W_t$) the irreducible components of $V := Z_1\setminus Z_1'$ (resp. of $W := Z_2\setminus Z_2'$). A simple inspection of the definitions reveals that $s \leq t$ and – after reordering of the W_i – the subset W_i is open in V_i for every $i = 1, \dots, s$. Moreover, under the isomorphism (11.2.22), the transition map $\underline{\Gamma}_V \to \underline{\Gamma}_W$ is identified with the composition

$$\bigoplus_{i=1}^s \underline{\Gamma}_{V_i} \xrightarrow{\bigoplus_{i=1}^s \gamma_{V_i,W_i}} \bigoplus_{i=1}^s \underline{\Gamma}_{W_i} \to \bigoplus_{i=1}^t \underline{\Gamma}_{W_i}$$

(where the second map is the natural monomorphism). Hence, let Δ^p be the set of all locally closed subsets V of X fulfilling the following condition. There exists $x \in X$ with $c(x) = p$, and V is a non-empty open subset of the topological closure $\overline{\{x\}}$ of $\{x\}$ in X. We endow Δ^p with a partial ordering, by declaring that, for any $V, V' \in \Delta^p$ we have $V \leq V'$ if $V' \subset V$ (notice that Δ^p is usually not a filtered partially ordered set); from the foregoing, we get a natural isomorphism

$$\underline{\Gamma}_{\Phi|\Phi} \xrightarrow{\sim} \operatorname*{colim}_{V \in \Delta^p} \underline{\Gamma}_V$$

where, for every $V, V' \in \Delta^p$ such that $V \leq V'$, the transition map $\underline{\Gamma}_V \to \underline{\Gamma}_{V'}$ is again given by the transformation $\gamma_{V,V'}$ corresponding to the open immersion $V' \to V$.

Next, for every $x \in X$ such that $c(x) = p$, set $\Delta_x := \{V \in \Delta^p \mid x \in V\}$, and notice that the partially ordered set Δ^p is the coproduct (*i.e.* the disjoint union) of its partially ordered subsets Δ_x. We deduce a natural isomorphism

$$\underline{\Gamma}_{\Phi|\Phi} \xrightarrow{\sim} \bigoplus_{c(x)=p} \operatorname*{colim}_{V \in \Delta_x} \underline{\Gamma}_V.$$

Thus, we come down to checking the following :

Claim 11.2.23. For every $p \in \mathbb{Z}$ and every $x \in X$ such that $c(x) = p$, there exists a natural isomorphism of functors

$$\operatorname*{colim}_{V \in \Delta^p_x} \underline{\Gamma}_V \xrightarrow{\sim} j_{x*} \circ \underline{\Gamma}_{\{x\}} \circ j^*_x.$$

Proof of the claim. Let Σ_x be the set of all quasi-compact open neighborhoods of x in X, and endow Σ_x with the partial ordering such that, for every $U, U' \in \Sigma_x$ we have $U \leq U'$ if $U' \subset U$; then Σ_x is filtered, and there follows a morphism of partially ordered sets

$$\Sigma_x \to \Delta_x \qquad U \mapsto U \cap \overline{\{x\}}$$

and using lemma 1.5.7(i), it is easily seen that this map is cofinal. Now, for every $U \in \Sigma_x$, let $j_U : U \to X$ be the open immersion; we have a natural identification

$$\underline{\Gamma}_{U \cap \overline{\{x\}}} \xrightarrow{\sim} j_{U*} \circ j^*_U \circ \underline{\Gamma}_{\overline{\{x\}}}$$

whence a natural isomorphism

$$\operatorname*{colim}_{V \in \Delta_x} \underline{\Gamma}_V = \operatorname*{colim}_{U \in \Sigma_x} j_{U*} \circ j^*_U \circ \underline{\Gamma}_{\overline{\{x\}}}.$$

However, $X(x)$ is the limit of the filtered system of spectral spaces Σ_x, so the claim follows easily from proposition 10.1.10(ii) (details left to the reader). ◊

Next, let $i \in \mathbb{N}$ be arbitrary, let $\mathscr{F}$ be any $\mathscr{A}$-module, and pick any resolution $\mathscr{F} \to \mathscr{I}^\bullet$ consisting of injective $\mathscr{A}$-modules; by the foregoing case, we get a natural isomorphism of $\mathscr{A}$-modules

$$R^i\underline{\Gamma}_{\Phi^p|\Phi^{p+1}}\mathscr{F} \xrightarrow{\sim} \bigoplus_{c(x)=p} H^i(j_{x*} \circ \underline{\Gamma}_{\{x\}} \circ j^*_x \mathscr{I}^\bullet).$$

However, on the one hand, $j^*\mathscr{I}^\bullet$ is a complex of qc-flabby $j^*\mathscr{A}$-modules (claim 10.1.11); on the other hand, qc-flabby abelian sheaves are acyclic for the functor $\underline{\Gamma}_{\{x\}}$ (lemmata 10.4.4(iii.b) and 8.1.15(vi)), so we get a natural isomorphism

$$H^i(j_{x*} \circ \underline{\Gamma}_{\{x\}} \circ j^*_x \mathscr{I}^\bullet) \xrightarrow{\sim} H^i(j_{x*} \circ R\underline{\Gamma}_{\{x\}} \circ j^*_x \mathscr{F}) \qquad \text{for every } i \in \mathbb{N} \text{ and every } x \in X.$$

Lastly, notice that $R\underline{\Gamma}_{\{x\}} \circ j^*_x \mathscr{F}$ is a complex of $j^*\mathscr{A}$-modules supported on $\{x\}$, and the functor j_{x*} is exact on the full subcategory of $j^*\mathscr{A}$-**Mod** consisting of such sheaves; thus, we have a natural isomorphism

$$H^i(j_{x*} \circ R\underline{\Gamma}_{\{x\}} \circ j^*_x \mathscr{F}) \xrightarrow{\sim} j_{x*} \circ R^i\underline{\Gamma}_{\{x\}} \circ j^*_x \mathscr{F} \qquad \text{for every } i \in \mathbb{N} \text{ and every } x \in X.$$

Summing up, we obtain the proposition. □

Definition 11.2.24. Let $(X, \mathscr{A})$ be a ringed topological space, with X sober and locally noetherian, and c a weak codimension function on X.

(i) We say that an object $K^\bullet$ of $\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$ is a *c-Cohen-Macaulay complex*, if we have

$$R^i\underline{\Gamma}_{\{x\}}K^\bullet_{|X(x)} = 0 \qquad \text{for every } x \in X \text{ and every integer } i \neq c(x).$$

We denote by

$$\mathscr{A}\text{-}\mathsf{CM}^c$$

the full subcategory of $\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$ whose objects are the c-Cohen-Macaulay complexes.

(ii) We say that an object $C^\bullet$ of $\mathsf{C}^+(\mathscr{A}\text{-}\mathbf{Mod})$ is a *Cousin complex*, if there exists a family $(M_x \mid x \in X)$ where M_x is an $i_x^*\mathscr{A}$-module for every $x \in X$ (notation of (11.2.19)), such that

$$C^p = \bigoplus_{c(x)=p} i_{x*}M_x \qquad \text{for every } p \in \mathbb{Z}.$$

The full subcategory of $\mathsf{C}^+(\mathscr{A}\text{-}\mathbf{Mod})$ whose objects are the Cousin complexes is denoted

$$\mathscr{A}\text{-}\mathbf{Cousin}.$$

Lemma 11.2.25. *In the situation of definition* 11.2.24*, we have :*

(i) $R\underline{\Gamma}_{\{x\}} \circ j_x^* \circ i_{y*} = 0$ *for every* $x, y \in X$ *such that* $x \neq y$.

(ii) *If* $C^\bullet$ *is a Cousin complex of* $\mathscr{A}$*-modules, then* C^p *is qc-flabby, for every* $p \in \mathbb{Z}$.

Proof. (i): Notice that any $i_y^*\mathscr{A}$-module M is trivially qc-flabby, so the same holds for $i_{y*}M$ (lemma 10.1.5(iv)), and therefore also for $j_x^*j_{y*}M$ (claim 10.1.11). Since qc-flabby $\mathscr{A}$-modules are acyclic for $\underline{\Gamma}_{\{x\}}$ (lemma 10.4.4(iii.a)), we conclude that $R\underline{\Gamma}_{\{x\}}j_x^*i_{y*}$ is the derived functor of $\underline{\Gamma}_{\{x\}}j_x^*i_{y*}$; but it is easily seen that the latter vanishes, whence the assertion.

(ii): We have just seen that i_*M is qc-flabby, for every $i_x^*\mathscr{A}$-module M; on the other hand, all direct sums of qc-flabby $\mathscr{A}$-modules are qc-flabby (claim 10.1.11), whence the contention. $\square$

11.2.26. As j_x^* and $R^i\underline{\Gamma}_{\{x\}}$ commute with all direct sums (proposition 11.2.12(v.b)), lemma 11.2.25(i) implies that the localization $\mathsf{C}^+(\mathscr{A}\text{-}\mathbf{Mod}) \to \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$ restricts to a functor

$$F : \mathscr{A}\text{-}\mathbf{Cousin} \to \mathscr{A}\text{-}\mathsf{CM}^c.$$

Theorem 11.2.27. *The functor F of* (11.2.26) *is an equivalence of categories.*

Proof. We construct a quasi-inverse to F, as follows. First, we endow every object $C^\bullet$ of $\mathsf{C}(\mathscr{A}\text{-}\mathbf{Mod})$, with a descending filtration $\mathrm{Fil}^\bullet_\Phi C^\bullet$, by the rule

$$\mathrm{Fil}^p_\Phi C^\bullet := \underline{\Gamma}_{\Phi^p} C^\bullet$$

where $(\Phi^p \mid p \in \mathbb{Z})$ is the system of families of supports associated with the weak codimension function c, as in (11.2.19). We also denote by $\mathrm{gr}^\bullet_\Phi C^\bullet$ the resulting associated graded object of $\mathsf{C}(\mathscr{A}\text{-}\mathbf{Mod})$. Next, for every object $K^\bullet$ of $\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$ we choose a quasi-isomorphism $\beta^\bullet_K : K^\bullet \xrightarrow{\sim} \mathscr{I}^\bullet_K$, with $\mathscr{I}^\bullet_K$ a bounded below complex of injective $\mathscr{A}$-modules. Following (7.2.14), we denote $E(\mathscr{I}_K)^{\bullet\bullet}_\bullet$ the spectral sequence arising from the filtered complex $(\mathscr{I}^\bullet_K, \mathrm{Fil}^\bullet_\Phi \mathscr{I}^\bullet_K)$. In light of (11.2.18) we have a natural identification

$$\mathrm{gr}^p_\Phi \mathscr{I}^\bullet_K \xrightarrow{\sim} \underline{\Gamma}_{\Phi^p|\Phi^{p+1}} \mathscr{I}^\bullet_K$$

and combining with remark 7.2.16(ii), we get a natural isomorphism

$$E(\mathscr{I}_K)^{pq}_1 \xrightarrow{\sim} R^{p+q}\underline{\Gamma}_{\Phi^p|\Phi^{p+1}} K^\bullet.$$

Taking into account proposition 11.2.21 we deduce that

$$G(K)^\bullet := (E(\mathscr{I}_K)^{\bullet 0}_1, d(\mathscr{I}_K)^{\bullet 0}_1)$$

is a Cousin complex, for every $q \in \mathbb{Z}$. Moreover, every morphism $\varphi^\bullet : K^\bullet \to L^\bullet$ in the category $\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$ can be represented by a unique morphism $\mathscr{I}^\bullet_\varphi : \mathscr{I}^\bullet_K \to \mathscr{I}^\bullet_L$ in $\mathsf{Hot}(\mathscr{A}\text{-}\mathbf{Mod})$

(notation of definition 7.1.4(ii)), and notice that $\mathscr{I}^\bullet_\varphi$ is a morphism of filtered complexes; in light of (7.2.23) we deduce a well defined morphism $G(\varphi)^\bullet : G(K)^\bullet \to G(L)^\bullet$. In this way, we obtain a functor

$$G : \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}) \to \mathscr{A}\text{-}\mathbf{Cousin}$$

and we claim that the restriction of G to the subcategory $\mathscr{A}\text{-}\mathsf{CM}^c$ is the sought quasi-inverse.

We check first that $G \circ F$ is naturally isomorphic to the identity endofunctor of $\mathscr{A}\text{-}\mathbf{Cousin}$. To this aim, let us remark :

Claim 11.2.28. Let $K^\bullet$ be any c-Cohen-Macaulay complex. We have :

(i) $E(\mathscr{I}_K)^{pq}_1 = 0$ for every $p, q \in \mathbb{Z}$ with $q \neq 0$.

(ii) If $K^\bullet = FC^\bullet$ for a Cousin complex $C^\bullet$, the map $\beta^\bullet_K$ induces a natural isomorphism

$$\mathrm{gr}^p_\Phi C^\bullet \xrightarrow{\sim} E(\mathscr{I}_K)^{p0}_1[-p] \xrightarrow{\sim} C^p[-p] \qquad \text{for every } p \in \mathbb{Z}.$$

Proof of the claim. (i): Indeed, from proposition 11.2.21 we get a natural isomorphism

$$H^{p+q}(\mathrm{gr}^p_\Phi \mathscr{I}^\bullet_C) \xrightarrow{\sim} \bigoplus_{c(x)=p} j_{x*} \circ R^{p+q}\underline{\Gamma}_{\{x\}} K^\bullet_{|X(x)} \tag{11.2.29}$$

which vanishes for $q \neq 0$, since $K^\bullet$ is c-Cohen-Macaulay.

(ii): Let $C^\bullet$ and $(M_x \mid x \in X)$ be as in definition 11.2.24(ii); from (11.2.18) and lemma 11.2.25(ii), it follows that the natural map

$$\mathrm{gr}^\bullet_\Phi C^\bullet \to \underline{\Gamma}_{\Phi^p|\Phi^{p+1}} C^\bullet$$

is an isomorphism in $\mathsf{C}^+(\mathscr{A}\text{-}\mathbf{Mod})$. Also, combining with claim 10.1.11, we see that $C^\bullet_{|X(x)}$ is a complex of qc-flabby $j^*_x\mathscr{A}$-modules. By lemma 10.4.4(iii.a) we deduce that the natural map $\underline{\Gamma}_{\{x\}} C^\bullet_{|X(x)} \to R\underline{\Gamma}_{\{x\}} C^\bullet_{|X(x)}$ is an isomorphism in $\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$, for every $x \in X$. Moreover, since the functor $\underline{\Gamma}_{\{x\}}$ commutes with arbitrary direct sums (lemma 10.4.4(iii.b)), lemma 11.2.25(i) says that

$$\underline{\Gamma}_{\{x\}} C^\bullet_{|X(x)} = j^*_x i_{x*} M_x[-c(x)] \qquad \text{for every } x \in X.$$

Taking into account (11.2.29) (and again, proposition 11.2.21), the assertion follows. ◊

Now, let $C^\bullet$ be a cousin complex, and set $D^\bullet := GF(C)^\bullet$. From claim 11.2.28 we obtain a natural isomorphism

$$\mathrm{gr}^p_\Phi \mathscr{I}^\bullet_C \xrightarrow{\sim} C^p[-p] \qquad \text{for every } p \in \mathbb{Z}.$$

We need to show that, under this identification, the differential d^p_D of $D^p := H^p(\mathrm{gr}^p \mathscr{I}^\bullet_C)$ corresponds to the differential d^p_C of $C^\bullet$. However, on the one hand we have a commutative ladder

$$\begin{array}{ccccccccc}
0 & \to & \mathrm{gr}^{p+1}_\Phi C^\bullet & \to & \mathrm{Fil}^p_\Phi C^\bullet/\mathrm{Fil}^{p+2}_\Phi C^\bullet & \to & \mathrm{gr}^p_\Phi C^\bullet & \to & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \to & \mathrm{gr}^{p+1}_\Phi \mathscr{I}^\bullet_C & \to & \mathrm{Fil}^p_\Phi \mathscr{I}^\bullet_C/\mathrm{Fil}^{p+2}_\Phi \mathscr{I}^\bullet_C & \to & \mathrm{gr}^p_\Phi \mathscr{I}^\bullet_C & \to & 0
\end{array}$$

and claim 11.2.28(ii) says that both the first and third vertical arrows are isomorphisms, so the top row of is isomorphic to the bottom row. Moreover, we see that the top row is the natural short exact sequence

$$0 \to C^{p+1}[-p-1] \to t^{\leq p+1} t^{\geq p} C^\bullet \to C^p[-p] \to 0$$

where $t^{\leq p+1}$ and $t^{\geq p}$ are the brutal truncation functors of (7.1.1). Then it is clear that the boundary map $H^p(C^p[-p]) \to H^{p+1}(C^{p+1}[-p-1])$ in degree p associated with this short exact sequence, is none else than the differential d^p_C. Now the contention follows from the naturality of the boundary map, together with remark 7.2.16(ii).

Next, let $K^\bullet$ be any c-Cohen-Macaulay complex, and set

$$(\mathscr{J}_K, \mathrm{Fil}^\bullet \mathscr{J}_K) := \mathrm{Déc}\,(\mathscr{I}_K, \mathrm{Fil}^\bullet_\Phi \mathscr{I}^\bullet_K)$$

(notation of (7.2.24)). By proposition 7.2.26(i,ii) and claim 11.2.28(i), we have a natural epimorphism

$$u^\bullet : E(\mathscr{J}_K)^\bullet_0 \to E(\mathscr{I}_K)^\bullet_1 \qquad \text{in } \mathsf{C}^+(\mathscr{A}\text{-}\mathbf{Mod})$$

which induces an isomorphism in $\mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$. Moreover, from claim 11.2.28(i) we see that the subcomplex $(E(\mathscr{J}_K)^{p,n-p}_0 \mid n \in \mathbb{Z})$ lies in $\mathrm{Ker}\, u^\bullet$, for every $p \neq 0$, so $u^\bullet$ restricts to an isomorphism

$$E(\mathscr{J}_K)^{0,\bullet}_0 = \mathrm{gr}^0 \mathscr{J}^\bullet_K \xrightarrow{\sim} G(K)^\bullet \qquad \text{in } \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}) \tag{11.2.30}$$

(see remark 7.2.16(i)). We point out :

Claim 11.2.31. $\mathrm{Fil}^1 \mathscr{J}^\bullet_K$ and $\mathscr{J}^\bullet_K/\mathrm{Fil}^0 \mathscr{J}^\bullet_K$ are acyclic.

Proof of the claim. The assertion can be checked on the stalks over the points of X; taking into account lemma 11.2.20(ii,iii), we may then replace X by $X(x)$, for any point $x \in X$, and assume from start that c is bounded on X (lemma 11.2.20(i)). In this case, it is clear that the filtration $\mathrm{Fil}^\bullet_\Phi \mathscr{I}^\bullet_K$ is finite, for every complex $K^\bullet$ of $\mathscr{A}$-modules, and then the same holds for the filtration $\mathrm{Fil}^\bullet \mathscr{J}^\bullet_K$ (see (7.2.24)). In this situation, a simple induction argument reduces to checking that the associated subquotients $\mathrm{gr}^p \mathscr{J}^\bullet_K$ are acyclic, for every $p \neq 0$. However, combining remarks 7.2.9(i) and 7.2.16(ii), proposition 7.2.26(ii) and claim 11.2.28(i) we may compute

$$H^q \mathrm{gr}^p \mathscr{J}^\bullet_K \xrightarrow{\sim} E(\mathscr{J}_K)^{p,q-p}_1 \xrightarrow{\sim} E(\mathscr{I}_K)^{p+q,-p}_2 = 0 \qquad \text{for every } p, q \in \mathbb{Z} \text{ with } p \neq 0$$

whence the claim. ◊

Claim 11.2.31 yields a natural isomorphism

$$\mathrm{gr}^0 \mathscr{J}^\bullet_K \xrightarrow{\sim} \mathscr{J}^\bullet_K = \mathscr{I}^\bullet_K \qquad \text{in } \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod})$$

and combining with (11.2.30), we finally get an isomorphism

$$K^\bullet \xrightarrow{\sim} FG(K)^\bullet \qquad \text{in } \mathsf{D}^+(\mathscr{A}\text{-}\mathbf{Mod}).$$

Now the theorem follows from proposition 1.1.20(i). □

11.3. **Duality over coherent schemes.** If X is a locally coherent scheme (definition 8.1.58(i)) and $\mathscr{F}$ is an $\mathscr{O}_X$-module, we define the *dual $\mathscr{O}_X$-module*

$$\mathscr{F}^\vee := \mathscr{H}om_{\mathscr{O}_X}(\mathscr{F}, \mathscr{O}_X).$$

Moreover, for every morphism of $\mathscr{O}_X$-modules $\varphi : \mathscr{F} \to \mathscr{G}$, we denote by $\varphi^\vee : \mathscr{G}^\vee \to \mathscr{F}^\vee$ the induced (transpose) morphism. As usual, there is a natural morphism of $\mathscr{O}_X$-modules:

$$\beta_\mathscr{F} : \mathscr{F} \to \mathscr{F}^{\vee\vee}.$$

Definition 11.3.1. Let X be a locally coherent scheme, and $\mathscr{F}$ an $\mathscr{O}_X$-module.

(i) We say that $\mathscr{F}$ is *reflexive at a point* $x \in X$ if there exists an open neighborhood $U \subset X$ of x such that $\mathscr{F}_{|U}$ is a coherent $\mathscr{O}_U$-module, and $\beta_{\mathscr{F}|U}$ is an isomorphism.
(ii) We say that $\mathscr{F}$ is *reflexive* if it is reflexive at all points of X.
(iii) We denote by $\mathscr{O}_X$-$\mathbf{Rflx}$ the full subcategory of the category $\mathscr{O}_X$-$\mathbf{Mod}$, consisting of all the reflexive $\mathscr{O}_X$-modules. It contains $\mathscr{O}_X$-$\mathbf{Mod}_{\mathrm{lfft}}$ as a full subcategory (see (10.3)).
(iv) Suppose that $X = \mathrm{Spec}\, R$ for a coherent ring R, and $\mathscr{F} = M^\sim$ for an R-module M. Then we say that M is a *reflexive* R-module if $\mathscr{F}$ is a reflexive $\mathscr{O}_X$-module.

Lemma 11.3.2. *Let X be a locally coherent scheme, $x \in X$ any point, and $\mathscr{F}$ a coherent $\mathscr{O}_X$-module. We have :*

(i) $\mathscr{F}^\vee$ *is a coherent* $\mathscr{O}_X$*-module.*
(ii) *The following conditions are equivalent:*
  (a) $\mathscr{F}$ *is reflexive at the point* x.
  (b) $\mathscr{F}_x$ *is a reflexive* $\mathscr{O}_{X,x}$*-module.*
  (c) *The map* $\beta_{\mathscr{F},x} : \mathscr{F}_x \to (\mathscr{F}^{\vee\vee})_x$ *is an isomorphism.*

Proof. (i): The assertion is local on X, hence we may assume that there exists a presentation $\mathscr{O}_X^{\oplus n} \to \mathscr{O}_X^{\oplus m} \to \mathscr{F} \to 0$, whence – after taking duals – a left exact sequence $0 \to \mathscr{F}^\vee \to \mathscr{O}_X^{\oplus m} \to \mathscr{O}_X^{\oplus n}$. Since $\mathscr{O}_X$ is coherent, the assertion follows.
(ii) shall be left to the reader. □

Lemma 11.3.3. *Let* X *be a reduced locally coherent scheme, and* $\mathscr{F}$ *a quasi-coherent* $\mathscr{O}_X$*-module of finite type. Endow the set* $\operatorname{Max} X$ *of maximal points of* X *with the topology induced by* X*, and consider the following conditions :*
(a) *There exists a quasi-compact open immersion* $j : U \to X$ *with dense image, such that* $j^*\mathscr{F}$ *is a locally free* $\mathscr{O}_U$*-module.*
(b) *There exists a quasi-compact open immersion* $j : U \to X$ *with dense image, such that* $j^*\mathscr{F}$ *is a coherent* $\mathscr{O}_U$*-module.*
(c) *The rank function of* $\mathscr{F}$ *:*
$$X \to \mathbb{N} \qquad x \mapsto \dim_{\kappa(x)} \kappa(x) \otimes_{\mathscr{O}_{X,x}} \mathscr{F}_x$$
restricts to a locally constant function on $\operatorname{Max} X$.
(d) $\mathscr{F}^\vee$ *is a reflexive* $\mathscr{O}_X$*-module and* $\beta^\vee_{\mathscr{F}} \circ \beta_{\mathscr{F}^\vee} = \mathbf{1}_{\mathscr{F}^\vee}$.

Then (a)⇒(b)⇒(c)⇒(d) *and if* X *is coherent we have* (c)⇒(a) *as well.*

Proof. Let us check first that (c)⇒(a) in case X is coherent. Indeed, notice that j is quasi-compact if and only if U is retro-compact in X, and the latter holds if and only if U is open and constructible in X (lemma 8.1.19(iv.b,v.c)). It follows that the existence of j with the sought properties can be checked locally on X, hence we may assume that X is affine. By proposition 10.3.34(i) we may find a coherent $\mathscr{O}_X$-module $\mathscr{G}$ and an $\mathscr{O}_X$-linear epimorphism $\varphi : \mathscr{G} \to \mathscr{F}$. Now, fix any $\eta \in \operatorname{Max} X$ and write $\mathscr{K} := \operatorname{Ker} \varphi$ as the filtered union of the system $(\mathscr{K}_i \mid i \in I)$ of its quasi-coherent $\mathscr{O}_X$-submodules of finite type; since $\mathscr{O}_{X,\eta}$ is a field, there exists $i \in I$ such that $\mathscr{K}_{i,\eta} = \mathscr{K}_\eta$. Thus, after replacing $\mathscr{G}$ by $\mathscr{G}/\mathscr{K}_i$, we may assume that φ_η is an isomorphism. Moreover, by [126, Th.4.10] we may find an affine open neighborhood U_η of η in X, an integer $r \in \mathbb{N}$ and an isomorphism $\mathscr{G}_{|U_\eta} \stackrel{\sim}{\to} \mathscr{O}_{U_\eta}^{\oplus r}$, and by assumption (c) we may also assume that the rank function of $\mathscr{F}$ is constant on $\operatorname{Max} U_\eta$. In this case, φ_τ is an isomorphism for every $\tau \in \operatorname{Max} U_\eta$, so $\mathscr{K}_\tau = 0$ for every such point τ. Since X is reduced and $\mathscr{G}_{|U_\eta}$ is a locally free $\mathscr{O}_{U_\eta}$-module, it follows that $\mathscr{K}_{|U_\eta} = 0$. By proposition 8.1.59, we may then find a finite subset $\Sigma \subset \operatorname{Max} X$ such that $\bigcup_{\eta\in\Sigma} \operatorname{Max} U_\eta = \operatorname{Max} X$, and it is easily seen that the open subset $U := \bigcup_{\eta\in\Sigma} U_\eta$ fulfills condition (a).

(a)⇒(b) is obvious.

(b)⇒(c): Notice first that any U as in (b) contains $\operatorname{Max} X$, by proposition 8.1.47(iii). Then, since X is reduced, [126, Th.4.10] implies that, for every $\eta \in \operatorname{Max} X$, we may find an affine open neighborhood U_η of η in X such that $\mathscr{F}_{|U_\eta}$ is a locally free $\mathscr{O}_{U_\eta}$-module, whence (c).

(c)⇒(d): Let us show first that $\mathscr{F}^\vee$ is coherent, under condition (c). The assertion is local on X, hence we may assume that X is affine, in which case, as we have already seen, (c) implies that there exists a quasi-compact open immersion $j : U \to X$ fulfilling condition (a), and we also know that any such U contains $\operatorname{Max} X$. By proposition 10.3.34(i), we may then find a coherent $\mathscr{O}_X$-module $\mathscr{G}$ and an $\mathscr{O}_X$-linear epimorphism $\varphi : \mathscr{G} \to \mathscr{F}$ such that $j^*\varphi$ is an isomorphism. There follows a left exact sequence $0 \to \mathscr{F}^\vee \to \mathscr{G}^\vee \to (\operatorname{Ker} \varphi)^\vee$, and $\mathscr{G}^\vee$ is coherent, by lemma 11.3.2(i). Since $\operatorname{Max} X \subset U$, we have $(\operatorname{Ker} \varphi)_\eta = 0$ for every $\eta \in \operatorname{Max} X$, and since $\mathscr{O}_X$ is reduced, it follows easily that $(\mathrm{Ker}\,\varphi)^\vee = 0$, and the claim follows. Now, since X is reduced, the only associated points of $\mathscr{O}_X$ are the maximal points of X (*i.e.* $\mathscr{O}_X$ has no imbedded points). It follows easily that, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{G}$, the dual $\mathscr{G}^\vee$ satisfies condition S_1 (see definition 10.5.1(ii)). Next, rather generally, let $\mathscr{M}$ be any $\mathscr{O}_X$-module; directly from the definitions one derives the identity:

$$\beta^\vee_{\mathscr{M}} \circ \beta_{\mathscr{M}^\vee} = \mathbf{1}_{\mathscr{M}^\vee}. \tag{11.3.4}$$

It remains therefore only to show that $\beta^\vee_{\mathscr{F}}$ is a right inverse for $\beta_{\mathscr{F}^\vee}$ when $\mathscr{F}^\vee$ is coherent. Since $\mathscr{F}^{\vee\vee\vee}$ satisfies condition S_1, it suffices to check that, for every maximal point ξ, the induced map on stalks

$$\beta^\vee_{\mathscr{F},\xi} : \mathscr{F}^{\vee\vee\vee}_\xi \to \mathscr{F}^\vee_\xi$$

is a right inverse for $\beta_{\mathscr{F}^\vee,\xi}$. However, since $\mathscr{O}_{X,\xi}$ is a field, $\beta^\vee_{\mathscr{F},\xi}$ is a linear map of $\mathscr{O}_{X,\xi}$-vector spaces of the same finite dimension, hence it is an isomorphism, in view of (11.3.4). □

Remark 11.3.5. The following observation is often useful. Suppose that X is a locally coherent scheme, $\mathscr{F}$ an $\mathscr{O}_X$-module, reflexive at a given point $x \in X$. We can then choose a presentation $\mathscr{O}^{\oplus n}_{X,x} \to \mathscr{O}^{\oplus m}_{X,x} \to \mathscr{F}^\vee_x \to 0$, and after dualizing we deduce a left exact sequence

$$0 \to \mathscr{F}_x \to \mathscr{O}^{\oplus m}_{X,x} \xrightarrow{u} \mathscr{O}^{\oplus n}_{X,x}. \tag{11.3.6}$$

Especially, if $\mathscr{O}_{X,x}$ satisfies condition S_1 (in the sense of definition 10.5.1(iii)), then the same holds for $\mathscr{F}_x$. For the converse, suppose additionally that X is reduced, and let $x \in X$ be a point for which there exists a left exact sequence such as (11.3.6); then lemma 11.3.3 says that $\mathscr{F}$ is reflexive at x : indeed, $\mathscr{F}_x \simeq (\mathrm{Coker}\,u^\vee)^\vee$.

Lemma 11.3.7. (i) *Let $f : X \to Y$ be a flat morphism of locally coherent schemes. The induced functor $\mathscr{O}_Y$-$\mathbf{Mod} \to \mathscr{O}_X$-$\mathbf{Mod}$ restricts to a functor*

$$f^* : \mathscr{O}_Y\text{-}\mathbf{Rflx} \to \mathscr{O}_X\text{-}\mathbf{Rflx}.$$

- (ii) *Let X_0 be a quasi-compact and quasi-separated scheme, $(X_\lambda \mid \lambda \in \Lambda)$ a cofiltered family of coherent X_0-schemes with flat transition morphisms $\psi_{\lambda\mu} : X_\lambda \to X_\mu$ such that the structure morphisms $X_\lambda \to X_0$ are affine, and set $X := \lim_{\lambda\in\Lambda} X_\lambda$. Then:*
  - (a) *X is coherent.*
  - (b) *the natural functor: $2\text{-}\mathop{\mathrm{colim}}_{\lambda\in\Lambda^o} \mathscr{O}_{X_\lambda}$-$\mathbf{Rflx} \to \mathscr{O}_X$-$\mathbf{Rflx}$ is an equivalence.*
- (iii) *Suppose that f is surjective, and let $\mathscr{F}$ be any coherent $\mathscr{O}_Y$-module. Then $\mathscr{F}$ is reflexive if and only if $f^*\mathscr{F}$ is a reflexive $\mathscr{O}_X$-module.*

Proof. (i) follows easily from [75, Lemma 2.4.29(i.a)].

(ii): For every $\lambda \in \Lambda$, denote by $\psi_\lambda : X \to X_\lambda$ the natural morphism. Let $U \subset X$ be a quasi-compact open subset, $u : \mathscr{O}^{\oplus n}_U \to \mathscr{O}_U$ any morphism of $\mathscr{O}_U$-modules; by corollary 8.1.40(ii.a) there exist $\lambda \in \Lambda$ and a quasi-compact open subset $U_\lambda \subset X_\lambda$ such that $U = \psi^{-1}(U_\lambda)$. By [65, Ch.IV, Th.8.5.2(i)] we may then suppose that u descends to a homomorphism $u_\lambda : \mathscr{O}^{\oplus n}_{U_\lambda} \to \mathscr{O}_{U_\lambda}$, whose kernel is of finite type, since X_λ is coherent. Since the transition morphisms are flat, we have $\mathrm{Ker}\,u = \psi^*_\lambda(\mathrm{Ker}\,u_\lambda)$, whence (ii.a). Next, using [65, Ch.IV, Th.8.5.2] one sees easily that the functor of (ii.b) is fully faithful and moreover, every reflexive $\mathscr{O}_X$-module $\mathscr{F}$ descends to a coherent $\mathscr{O}_{X_\lambda}$-module $\mathscr{F}_\lambda$ for some $\lambda \in \Lambda$. For every $\mu \geq \lambda$ let $\mathscr{F}_\mu := \psi^*_{\mu\lambda}\mathscr{F}_\lambda$; since $\beta_{\mathscr{F}}$ is an isomorphism, *loc.cit.* shows that $\beta_{\mathscr{F}_\mu}$ is already an isomorphism for some $\mu \geq \lambda$, whence (ii.b).

(iii): By virtue of (i), we may assume that $f^*\mathscr{F}$ is reflexive, and we need to show that the same holds for $\mathscr{F}$. However, the natural map $f^*(\mathscr{F}^{\vee\vee}) \to (f^*\mathscr{F})^{\vee\vee}$ is an isomorphism (proposition 10.3.3(ii)), hence $f^*\beta_{\mathscr{F}} = \beta_{f^*\mathscr{F}}$ is an isomorphism. Since f is faithfully flat, we deduce that $\beta_{\mathscr{F}}$ is an isomorphism, as stated. □

Proposition 11.3.8. *Let X be a coherent scheme, $U \subset X$ a quasi-compact open subset. Then:*

(i) *If X is reduced, the restriction functor*

$$\mathscr{O}_X\text{-}\mathbf{Rflx} \to \mathscr{O}_U\text{-}\mathbf{Rflx}$$

is essentially surjective.

(ii) *Let $\mathscr{F}$ be a reflexive $\mathscr{O}_X$-module. If $\delta'(x, \mathscr{O}_X) \geq 2$ for all $x \in X \setminus U$, the natural map*

$$\mathscr{F} \to j_* j^* \mathscr{F}$$

is an isomorphism. Especially, the restriction functor of (i) *is an equivalence.*

Proof. (i): Given a reflexive $\mathscr{O}_U$-module $\mathscr{F}$, lemma 10.3.27(ii) says that we can find a finitely presented quasi-coherent $\mathscr{O}_X$-module $\mathscr{G}$ extending $\mathscr{F}^\vee$; since X is coherent, $\mathscr{G}$ is a coherent $\mathscr{O}_X$-module, hence the same holds for $\mathscr{G}^\vee$, which extends $\mathscr{F}$ and is reflexive in light of lemma 11.3.3.

(ii): Notice that the first assertion easily implies that the restriction functor of (i) is fully faithful, so the second assertion follows from the first together with (i).

Next, since the first assertion is local on X, we can suppose that there exists a left exact sequence $0 \to \mathscr{F} \to \mathscr{O}_X^{\oplus m} \to \mathscr{O}_X^{\oplus n}$ (see remark 11.3.5). Since the functor j_* is left exact, it then suffices to prove the contention for the sheaves $\mathscr{O}_X^{\oplus m}$ and $\mathscr{O}_X^{\oplus n}$, and thus we may assume from start that $\mathscr{F} = \mathscr{O}_X$. Then, since $X \setminus U$ is constructible, corollary 10.4.23 applies and yields the assertion. □

Corollary 11.3.9. *Let X be a locally coherent scheme, $f : X \to S$ a flat, locally finitely presented morphism, $j : U \to X$ a quasi-compact open immersion, $\mathscr{F}$ a reflexive $\mathscr{O}_X$-module. Suppose that*

(a) $\mathrm{depth}_f(x) \geq 1$ *for every point $x \in X \setminus U$, and*
(b) $\mathrm{depth}_f(x) \geq 2$ *for every maximal point η of S and every $x \in (X \setminus U) \cap f^{-1}(\eta)$.*
(c) $\delta'(s, \mathscr{O}_S) > 0$ *for every non-maximal point $s \in S$.*

Then the natural morphism $\mathscr{F} \to j_* j^* \mathscr{F}$ is an isomorphism.

Proof. Since f is flat, corollary 10.4.47 and our assumptions imply that $\delta'(x, \mathscr{O}_X) \geq 2$ for every $x \in X \setminus U$, so the assertion follows from proposition 11.3.8(ii). □

11.3.10. Let X be any scheme. Recall that the *rank* of an $\mathscr{O}_X$-module $\mathscr{F}$ of finite type, is the upper semicontinuous function:

$$\mathrm{rk}\,\mathscr{F} : X \to \mathbb{N} \qquad x \mapsto \dim_{\kappa(x)} \mathscr{F}_x \otimes_{\mathscr{O}_{X,x}} \kappa(x).$$

Clearly, if $\mathscr{F}$ is a is locally free $\mathscr{O}_X$-module of finite type, $\mathrm{rk}\,\mathscr{F}$ is a continuous function on X. The converse holds, provided X is a reduced scheme. Moreover, if $\mathscr{F}$ is of finite presentation, $\mathrm{rk}\,\mathscr{F}$ is a constructible function and there exists a dense open subset $U \subset X$ such that $\mathrm{rk}\,\mathscr{F}$ restricts to a continuous function on U. We denote by $\mathbf{Pic}\,X$ the full subcategory of $\mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{lfft}}$ consisting of all the objects whose rank is constant equal to one (*i.e.* the *invertible* $\mathscr{O}_X$-modules). In case X is locally coherent, we shall also consider the category $\mathbf{Div}\,X$ of *generically invertible* $\mathscr{O}_X$-modules, defined as the full subcategory of $\mathscr{O}_X\text{-}\mathbf{Rflx}$ consisting of all objects which are locally free of rank one on a dense open subset of X. If X is locally coherent, $\mathbf{Pic}\,X$ is a full subcategory of $\mathbf{Div}X$.

Remark 11.3.11. (i) Let A be any integral domain, and set $X = \mathrm{Spec}\,A$. Classically, one has a notion of reflexive fractional ideal of A (see [126, p.80] or example 6.4.38). Suppose now that A is also coherent, in which case we have the notion of reflexive A-module of definition 11.3.1(iv). We claim that these two notions overlap on the subclass of reflexive fractional ideals of finite type: more precisely, let $\mathbf{Div}(A)$ be the full subcategory of $A\text{-}\mathbf{Mod}$ whose objects are the finitely generated reflexive fractional ideals of A. Then the essential image of the functor

(11.3.12) $$\mathbf{Div}(A) \to \mathscr{O}_X\text{-}\mathbf{Mod} \qquad M \mapsto M^\sim$$

is the category $\mathbf{Div}\, X$, and (11.3.12) yields an equivalence of $\mathbf{Div}(A)$ with the latter category. Indeed, let $\mathscr{F}$ be any generically invertible $\mathscr{O}_X$-module, and set $I := \mathscr{F}(X)$; if K denotes the field of fractions of A, then $\dim_K I \otimes_A K = 1$. Let us then fix a K-linear isomorphism $I \otimes_A K \xrightarrow{\sim} K$, and notice that the induced A-linear map $I \to K$ is injective, since $\mathscr{F}$ is S_1 (remark 11.3.5). We may then view I as a finitely generated A-submodule of K, and then it is clear that I is a fractional ideal of A. Moreover, on the one hand $\mathscr{F}^\vee$ is the coherent $\mathscr{O}_X$-module $\mathrm{Hom}_A(I, A)^\sim$; on the other hand, the natural map $\mathrm{Hom}_A(I, A) \to \mathrm{Hom}_K(I \otimes_A K, K) = K$ is injective, and its image is the fractional ideal I^{-1} (see (6.4.35)). We easily deduce that I is a reflexive fractional ideal, and conversely it is easily seen that every $\mathscr{O}_X$-module in the essential image of (11.3.12) is generically invertible; since this functor is also obviously fully faithful, the assertion follows.

(ii) Let A be a coherent integral domain, and denote by $\mathrm{coh.Div}(A)$ the set of all coherent reflexive fractional ideals of A. It is easily seen that $\mathrm{coh.Div}(A)$ is a submonoid of $\mathrm{Div}(A)$, for the natural monoid structure introduced in example 6.4.38. More generally, if X is a coherent integral scheme, we may define a sheaf of monoids $\mathscr{D}iv_X$ on X, as follows. First, to any affine open subset $U \subset X$, we assign the monoid $\mathscr{D}iv_X(U) := \mathrm{coh.Div}(\mathscr{O}_X(U))$. For each inclusion $j : U' \subset U$ of affine open subset, notice that the restriction map $\mathscr{O}_X(U) \to \mathscr{O}_X(U')$ is a flat ring homomorphism, hence it gives a flat morphism of monoids $\mathscr{O}_X(U) \setminus \{0\} \to \mathscr{O}_X(U') \setminus \{0\}$. We then have an induced map of monoids $\mathscr{D}iv_X(j) : \mathscr{D}iv_X(U) \to \mathscr{D}iv_X(U')$, by virtue of lemma 6.4.45(iv). It is easily seen that the resulting presheaf $\mathscr{D}iv_X$ is a sheaf on the site of all affine open subsets of X. By [59, Ch.0, §3.2.2], the latter extends uniquely to a sheaf of monoids on X, which we denote again $\mathscr{D}iv_X$. We set

$$\mathrm{Div}(X) := \mathscr{D}iv_X(X).$$

If X is normal and locally noetherian (or more generally, if X is a *Krull scheme*, *i.e.* $\mathscr{O}_X(U)$ is a Krull ring, for every affine open subset $U \subset X$) then $\mathscr{D}iv_X$ is an abelian sheaf, and $\mathrm{Div}(X)$ is an abelian group (proposition 6.4.42(i,iii)).

11.3.13. For future reference, it is useful to recall some preliminaries concerning the determinant functors defined in [119]. Let X be a scheme. We denote by $\mathbf{gr.Pic}\, X$ the category of graded invertible $\mathscr{O}_X$-modules. An object of $\mathbf{gr.Pic}\, X$ is a pair (L, α), where L is an invertible $\mathscr{O}_X$-module and $\alpha : X \to \mathbb{Z}$ is a continuous function. A homomorphism $h : (L, \alpha) \to (M, \beta)$ is a homomorphism of $\mathscr{O}_X$-modules $h : L \to M$ such that $h_x = 0$ for every $x \in X$ with $\alpha(x) \neq \beta(x)$. We denote by $\mathbf{gr.Pic}^* X$ the subcategory of $\mathbf{gr.Pic}\, X$ with the same objects, and whose morphisms are the isomorphisms in $\mathbf{gr.Pic}\, X$. Notice that $\mathbf{gr.Pic}\, X$ is a tensor category : the tensor product of two objects (L, α) and (M, β) is the pair $(L, \alpha) \otimes (M, \beta) := (L \otimes_{\mathscr{O}_X} M, \alpha + \beta)$. We denote by $\mathscr{O}_X\text{-}\mathbf{Mod}^*_{\mathrm{lfft}}$ the category whose objects are the locally free $\mathscr{O}_X$-modules of finite type, and whose morphisms are the $\mathscr{O}_X$-linear isomorphisms. The *determinant* is the functor:

$$\det : \mathscr{O}_X\text{-}\mathbf{Mod}^*_{\mathrm{lfft}} \to \mathbf{gr.Pic}^* X \qquad F \mapsto (\Lambda^{\mathrm{rk}\, F}_{\mathscr{O}_X} F, \mathrm{rk}\, F).$$

Let $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{perf}}$ be the category of perfect complexes of $\mathscr{O}_X$-modules; recall that, by definition, every perfect complex is locally isomorphic to a bounded complex of locally free $\mathscr{O}_X$-modules of finite type. The category $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})^*_{\mathrm{perf}}$ is the subcategory of $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{perf}}$ with the same objects, and whose morphisms are the isomorphisms (*i.e.* the quasi-isomorphisms of complexes). The main theorem of chapter 1 of [119] can be stated as follows.

Lemma 11.3.14. *(*[119, Th.1]*) With the notation of* (11.3.13) *there exists, for every scheme X, an extension of the determinant functor to a functor:*

$$\mathsf{det} : \mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})^*_{\mathrm{perf}} \to \mathbf{gr.Pic}\, X.$$

These determinant functors commute with every base change. □

Proposition 11.3.15. *Let X be a regular scheme. Then every reflexive generically invertible $\mathscr{O}_X$-module is invertible.*

Proof. The question is local on X, hence we may assume that X is affine. Let $\mathscr{F}$ be a generically invertible $\mathscr{O}_X$-module, and $U \subset X$ a dense open subset such that $\mathscr{F}_{|U}$ is invertible. Denote by $Z_1, \dots, Z_t$ the irreducible components of $Z := X \setminus U$ whose codimension in X equals one, and for every $i = 1, \dots, t$, let η_i be the maximal point of Z_i, and set $A_i := \mathscr{O}_{X,\eta_i}$. Since $\mathscr{F}$ is S_1 (remark 11.3.5), the stalk $\mathscr{F}_{\eta_i}$ is a torsion-free A_i-module of finite type for every $i \leq t$; however, A_i is a discrete valuation ring, hence $\mathscr{F}_{\eta_i}$ is a free A_i-module, necessarily of rank one, for $i = 1, \dots, t$. Since $\mathscr{F}$ is coherent, it follows that there exists an open neighborhood U_i of η_i in X, such that $\mathscr{F}_{|U_i}$ is a free $\mathscr{O}_{|U_i}$-module. Hence, we may replace U by $U \cup U_1 \cup \cdots \cup U_t$ and assume that every irreducible component of Z has codimension > 1, therefore $\delta'(x, \mathscr{O}_X) \geq 2$ for every $x \in Z$. Now, $\mathscr{F}[0]$ is a perfect complex by Serre's theorem ([163, Th.4.4.16]), so the invertible $\mathscr{O}_X$-module $\det \mathscr{F}$ is well defined (lemma 11.3.14). Let $j : U \to X$ be the open immersion; in view of proposition 11.3.8, we deduce natural isomorphisms

$$\mathscr{F} \xrightarrow{\sim} j_*j^*\mathscr{F} \xrightarrow{\sim} j_*\mathsf{det}(j^*\mathscr{F}[0]) \xrightarrow{\sim} j_*j^*\mathsf{det}\,\mathscr{F}[0] \xleftarrow{\sim} \mathsf{det}\,\mathscr{F}[0]$$

and the assertion follows. □

We wish now to introduce a notion of duality better suited to derived categories of $\mathscr{O}_X$-modules (over a scheme X). Hereafter we only carry out a preliminary investigation of such derived duality – the full development of which, will be the task of section 11.5.

Definition 11.3.16. Let X be a locally coherent scheme. A complex $\omega^\bullet$ in $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$ (notation of (10.3)) is called *dualizing* if it fulfills the following two conditions :

(a) The functor :

$$\mathscr{D} : \mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})^o \to \mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod}) \qquad C^\bullet \mapsto R\mathscr{H}om^\bullet_{\mathscr{O}_X}(C^\bullet, \omega^\bullet)$$

restricts to a *duality functor* : $\mathscr{D} : \mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})^o_{\mathrm{coh}} \to \mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$.

(b) The natural transformation : $\eta_{C^\bullet} : C^\bullet \to \mathscr{D} \circ \mathscr{D}(C^\bullet)$ restricts to a *biduality isomorphism* of functors on the category $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$.

Remark 11.3.17. Let X be a locally coherent scheme, $\omega^\bullet$ an object of $\mathsf{D}^b(\mathscr{O}\text{-}\mathbf{Mod})_{\mathrm{coh}}$, and define the functor $\mathscr{D}$ as in definition 11.3.16.

(i) A standard *dévissage* argument shows that $\omega^\bullet$ is dualizing on X if and only if $\mathscr{D}(\mathscr{F}[0])$ lies in $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$, and the biduality map $\mathscr{F}[0] \to \mathscr{D} \circ \mathscr{D}(\mathscr{F}[0])$ is an isomorphism for every coherent $\mathscr{O}_X$-module $\mathscr{F}$.

(ii) Suppose that the complex $\omega^\bullet$ is dualizing on X. From the natural identification $\omega^\bullet \xrightarrow{\sim} R\mathscr{H}om^\bullet_{\mathscr{O}_X}(\mathscr{O}_X[0], \omega^\bullet)$, we deduce a natural isomorphism

$$R\mathscr{H}om^\bullet_{\mathscr{O}_X}(\omega^\bullet, \omega^\bullet) \xrightarrow{\sim} \mathscr{O}_X[0] \qquad \text{in } \mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod}).$$

Example 11.3.18. Suppose that X is a noetherian regular scheme (*i.e.* all the stalks $\mathscr{O}_{X,x}$ are regular rings). In light of Serre's theorem [163, Th.4.4.16], every object of $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$ is a perfect complex. It follows easily that the complex $\mathscr{O}_X[0]$ is dualizing. For more general schemes, the structure sheaf does not necessarily work, and the existence of a dualizing complex is a delicate issue. On the other hand, one may ask to what extent a complex is determined by the properties (a) and (b) of definition 11.3.16. Clearly, if $\omega^\bullet$ is dualizing on X, then so is any other complex of the form $\omega^\bullet \otimes_{\mathscr{O}_X} \mathscr{L}$, where $\mathscr{L}$ is an invertible $\mathscr{O}_X$-module. Also, any shift of $\omega^\bullet$ is again dualizing. Conversely, the following proposition 11.3.25 says that any two dualizing complexes are related in such manner, up to quasi-isomorphism.

Lemma 11.3.19. *Let $(X, \mathscr{O}_X)$ be any locally ringed space, and $P^\bullet$ and $Q^\bullet$ two objects of* $\mathsf{D}^-(\mathscr{O}_X\text{-}\mathbf{Mod})$ *with a quasi-isomorphism :*

$$P^\bullet \overset{\mathbf{L}}{\otimes}_{\mathscr{O}_X} Q^\bullet \overset{\sim}{\to} \mathscr{O}_X[0].$$

Then there exist an invertible $\mathscr{O}_X$-module $\mathscr{L}$, a continuous function $\sigma : |X| \to \mathbb{Z}$ and quasi-isomorphisms:

$$P^\bullet \overset{\sim}{\to} \mathscr{L}[\sigma] \qquad \textit{and} \qquad Q^\bullet \overset{\sim}{\to} \mathscr{L}^{-1}[-\sigma].$$

Proof. It suffices to verify that, locally on X, the complexes $P^\bullet$ and $Q^\bullet$ are of the required form; indeed in this case X will be a disjoint union of open sets U_n on which $H^\bullet P^\bullet$ is concentrated in degree n and $H^\bullet Q^\bullet$ is concentrated in degree $-n$. Note that $\mathscr{O}_X$-$\mathbf{Mod}$ is equivalent to the product of the categories $\mathscr{O}_{U_n}$-$\mathbf{Mod}$ and that the derived category of a product of abelian categories is the product of the derived categories of the factors.

Claim 11.3.20. Let A be a (commutative) local ring, $K^\bullet$ and $L^\bullet$ two objects of $\mathsf{D}^-(A\text{-}\mathbf{Mod})$ with a quasi-isomorphism

$$K^\bullet \overset{\mathbf{L}}{\otimes}_A L^\bullet \overset{\sim}{\to} A[0]. \tag{11.3.21}$$

Then there exist $s \in \mathbb{Z}$ and quasi-isomorphisms :

$$K^\bullet \overset{\sim}{\to} A[s] \qquad L^\bullet \overset{\sim}{\to} A[-s].$$

Proof of the claim. Set :

$$i_0 := \max(i \in \mathbb{Z} \mid (H^i K^\bullet) \neq 0) \quad \text{and} \quad j_0 := \max(i \in \mathbb{Z} \mid (H^i L^\bullet) \neq 0).$$

We may assume that $K^i = 0$ for every $i > i_0$, and that $L^\bullet$ is a bounded above complex of free A-modules. Then we may find a filtered system $(K^\bullet_\lambda \mid \lambda \in \Lambda)$ of complexes of A-modules bounded from above, such that

- $H^{i_0}(K^\bullet_\lambda)$ is a finitely generated A-module, for every $\lambda \in \Lambda$;
- the colimit of the system $(K^\bullet_\lambda \mid \lambda \in \Lambda)$ (in the category of complexes of A-modules) is isomorphic to $K^\bullet$.

From (11.3.21) we get an isomorphism $H^0(K^\bullet \otimes_A L^\bullet) \overset{\sim}{\to} A$, and it follows easily that the natural map $H^0(K^\bullet_\lambda \otimes_A L^\bullet) \to H^0(K^\bullet \otimes_A L^\bullet)$ is surjective for some $\lambda \in \Lambda$. For such λ, we may then find a morphism in $\mathsf{D}^-(A\text{-}\mathbf{Mod})$:

$$A[0] \to K^\bullet_\lambda \overset{\mathbf{L}}{\otimes}_A L^\bullet \tag{11.3.22}$$

whose composition with the natural map $K^\bullet_\lambda \overset{\mathbf{L}}{\otimes}_A L^\bullet \to K^\bullet \overset{\mathbf{L}}{\otimes}_A L^\bullet$ is the inverse of (11.3.21). Hence

$$(11.3.22) \overset{\mathbf{L}}{\otimes}_A K^\bullet : K^\bullet \to (K^\bullet_\lambda \overset{\mathbf{L}}{\otimes}_A L^\bullet) \overset{\mathbf{L}}{\otimes}_A K^\bullet \overset{\sim}{\to} K^\bullet_\lambda \overset{\mathbf{L}}{\otimes}_A (L^\bullet \overset{\mathbf{L}}{\otimes}_A K^\bullet) \overset{\sim}{\to} K^\bullet_\lambda$$

is a right inverse of the natural morphism $K^\bullet_\lambda \to K^\bullet$ in $\mathsf{D}^-(A\text{-}\mathbf{Mod})$. Especially, the induced map $H^{i_0}K^\bullet_\lambda \to H^{i_0}K^\bullet$ is surjective, *i.e.* $H^{i_0}K^\bullet$ is a finitely generated A-module. Likewise, we see that $H^{j_0}L^\bullet$ is a finitely generated A-module. Now, notice that

$$H^k(K^\bullet \overset{\mathbf{L}}{\otimes}_A L^\bullet) \simeq \begin{cases} H^{i_0}K^\bullet \otimes_A H^{j_0}L^\bullet & \text{for } k = i_0 + j_0 \\ 0 & \text{for } k > i_0 + j_0. \end{cases}$$

From Nakayama's lemma it follows easily that $H^{i_0+j_0}(K^\bullet \overset{\mathbf{L}}{\otimes}_A L^\bullet) \neq 0$, and then our assumptions imply that $i_0 + j_0 = 0$ and $H^{i_0}K^\bullet \otimes_A H^{j_0}L^\bullet \simeq A$. One deduces easily that $H^{i_0}K^\bullet \simeq A \simeq H^{j_0}L^\bullet$ (see *e.g.* [75, Lemma 4.1.5]). Furthermore, we can find a complex $K^\bullet_1$ in $\mathsf{D}^{<i_0}(A\text{-}\mathbf{Mod})$ (resp. $L^\bullet_1$ in $\mathsf{D}^{<j_0}(A\text{-}\mathbf{Mod})$) such that :

$$K^\bullet \simeq A[-i_0] \oplus K^\bullet_1 \qquad (\text{resp. } L^\bullet \simeq A[-j_0] \oplus L^\bullet_1)$$

whence a quasi-isomorphism :

$$\varphi : A[0] \xrightarrow{\sim} K^\bullet \overset{\mathbf{L}}{\otimes}_A L^\bullet \xrightarrow{\sim} A[0] \oplus K_1^\bullet[-j_0] \oplus L_1^\bullet[-i_0] \oplus (K_1^\bullet \overset{\mathbf{L}}{\otimes}_A L_1^\bullet).$$

However, by construction φ^{-1} restricts to an isomorphism on the direct summand $A[0]$, therefore $K_1^\bullet \simeq 0 \simeq L_1^\bullet$ in $\mathsf{D}(A\text{-}\mathbf{Mod})$, and the claim follows. ◊

Now, for any point $x \in X$, let $i_x : \{x\} \to X$ be the inclusion map, and set $K_x^\bullet := i_x^* K^\bullet$ for every complex $K^\bullet$ of $\mathscr{O}_X$-modules. Notice that if $K^\bullet$ is a complex of flat $\mathscr{O}_X$-modules, then $K_x^\bullet$ is a complex of flat $\mathscr{O}_{X,x}$-modules ([9, Exp.V, Prop.1.6(1)]), therefore the rule $K^\bullet \mapsto K_x^\bullet$ yields a well-defined functor $\mathsf{D}^-(\mathscr{O}_X\text{-}\mathbf{Mod}) \to \mathsf{D}^-(\mathscr{O}_{X,x}\text{-}\mathbf{Mod})$, and moreover we have a natural isomorphism

$$K_x^\bullet \overset{\mathbf{L}}{\otimes}_{\mathscr{O}_{X,x}} L_x^\bullet \xrightarrow{\sim} (K^\bullet \overset{\mathbf{L}}{\otimes}_{\mathscr{O}_X} L^\bullet)_x \qquad (11.3.23)$$

for every objects $K^\bullet, L^\bullet$ of $\mathsf{D}^-(\mathscr{O}_X\text{-}\mathbf{Mod})$. Especially, under the current assumptions, and in view of claim 11.3.20, we may find $s \in \mathbb{Z}$, and an isomorphism of $\mathscr{O}_{X,x}$-modules

$$H^s P_x^\bullet \otimes_{\mathscr{O}_{X,x}} H^{-s} Q_x^\bullet \xrightarrow{\sim} H^0(P_x^\bullet \overset{\mathbf{L}}{\otimes}_{\mathscr{O}_{X,x}} Q_x^\bullet) \xrightarrow{\sim} \mathscr{O}_{X,x}. \qquad (11.3.24)$$

Since $\mathscr{O}_{X,x}$ is local, we may thus find $a_x \in H^s P_x^\bullet$ and $b_x \in H^{-s} Q_x^\bullet$ such that (11.3.24) maps $a_x \otimes b_x$ to 1. Then a_x and b_x extend to local sections

$$a \in \Gamma(U, \mathrm{Ker}(d : P^s \to P^{s-1})) \qquad b \in \Gamma(U, \mathrm{Ker}(d : Q^{-s} \to P^{-s-1}))$$

on some neighborhood $U \subset X$ of x, and after shrinking U, we may assume that $a \otimes b$ gets mapped to 1, under the induced morphism of $\mathscr{O}_U$-modules

$$H^s P_{|U}^\bullet \otimes_{\mathscr{O}_U} H^{-s} Q_{|U}^\bullet \to H^0(P^\bullet \overset{\mathbf{L}}{\otimes}_{\mathscr{O}_X} Q^\bullet)_{|U} \xrightarrow{\sim} \mathscr{O}_U.$$

Then we obtain a well defined morphism in $\mathsf{D}^-(\mathscr{O}_U\text{-}\mathbf{Mod})$

$$\varphi : \mathscr{O}_U[s] \to P_{|U}^\bullet \qquad (\text{resp.} \quad \psi : \mathscr{O}_U[-s] \to Q_{|U}^\bullet)$$

by the rule : $t \mapsto t \cdot a$ (resp. $t \mapsto t \cdot b$) for every local section t of $\mathscr{O}_U$. Again by claim 11.3.20 and (11.3.23) we deduce that $\varphi_y : \mathscr{O}_{U,y}[s] \to P_y^\bullet$ is a quasi-isomorphism for every $y \in U$ (and likewise for ψ_y); . *i.e.* φ and ψ are the sought isomorphisms in $\mathsf{D}^-(\mathscr{O}_U\text{-}\mathbf{Mod})$. □

Proposition 11.3.25. *Suppose that $\omega_1^\bullet$ and $\omega_2^\bullet$ are two dualizing complexes for the locally coherent scheme X. Then there exist an invertible $\mathscr{O}_X$-module $\mathscr{L}$ and a continuous function $\sigma : |X| \to \mathbb{Z}$ such that*

$$\omega_2^\bullet \simeq \omega_1^\bullet \otimes_{\mathscr{O}_X} \mathscr{L}[\sigma] \qquad \textit{in } \mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}.$$

Proof. Denote by $\mathscr{D}_1$ and $\mathscr{D}_2$ the duality functors associated with ω_1 and respectively ω_2. By assumption, we can find complexes $P^\bullet, Q^\bullet$ in $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$ such that $\omega_2 \simeq \mathscr{D}_1(P^\bullet)$ and $\omega_1 \simeq \mathscr{D}_2(Q^\bullet)$, and therefore

$$\mathscr{D}_2(\mathscr{F}^\bullet) \simeq R\mathscr{H}om^\bullet_{\mathscr{O}_X}(\mathscr{F}^\bullet, \mathscr{D}_1(P^\bullet)) \simeq \mathscr{D}_1(\mathscr{F}^\bullet \overset{\mathbf{L}}{\otimes}_{\mathscr{O}_X} P^\bullet)$$

for every object $\mathscr{F}^\bullet$ of $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$ ([163, Th.10.8.7]).

Claim 11.3.26. Let $C^\bullet$ be an object of $\mathsf{D}^-(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$, such that $\mathscr{D}_1(C^\bullet)$ is in $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})$. Then $C^\bullet$ is in $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$.

Proof of the claim. For given $m, n \in \mathbb{N}$, the natural maps: $\tau^{\leq -n} C^\bullet \xrightarrow{\alpha} C^\bullet \xrightarrow{\beta} \tau^{\geq -m} C^\bullet$ induce morphisms

$$\mathscr{D}_1(\tau^{\geq -m} C^\bullet) \xrightarrow{\mathscr{D}_1(\beta)} \mathscr{D}_1(C^\bullet) \xrightarrow{\mathscr{D}_1(\alpha)} \mathscr{D}_1(\tau^{\leq -n} C^\bullet)$$

Say that $\omega^\bullet \simeq \tau_{\geq a}\omega^\bullet$ for some integer $a \in \mathbb{N}$. Then $\mathscr{D}_1(\tau^{\leq -n}C^\bullet)$ lies in $\mathsf{D}^{\geq n+a}(\mathscr{O}_X\text{-}\mathbf{Mod})$. Since $\mathscr{D}_1(C^\bullet)$ is bounded, it follows that $\mathscr{D}_1(\beta) = 0$ for n large enough. Consider now the commutative diagram :

$$\begin{array}{ccc} \tau^{\geq -n}C^\bullet & \xrightarrow{\beta\circ\alpha} & \tau^{\geq -m}C^\bullet \\ \downarrow & & \downarrow \eta \\ \mathscr{D}_1 \circ \mathscr{D}_1(\tau^{\geq -n}C^\bullet) & \xrightarrow{\mathscr{D}_1\circ\mathscr{D}_1(\beta\circ\alpha)} & \mathscr{D}_1 \circ \mathscr{D}_1(\tau^{\geq -m}C^\bullet) \end{array}$$

Since $\tau^{\geq -m}C^\bullet$ is a bounded complex, η is an isomorphism in $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})$, so $\beta \circ \alpha = 0$ whenever n is large enough. Clearly this means that $C^\bullet$ is bounded, as claimed. $\diamondsuit$

Applying claim 11.3.26 to $C^\bullet := \mathscr{F}^\bullet \overset{\mathbf{L}}{\otimes}_{\mathscr{O}_X} P^\bullet$ (which is in $\mathsf{D}^-(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$, since X is coherent) we see that the latter is a bounded complex, and by reversing the roles of ω_1 and ω_2 it follows that the same holds for $\mathscr{F}^\bullet \overset{\mathbf{L}}{\otimes}_{\mathscr{O}_X} Q^\bullet$. We then deduce isomorphisms in $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$

$$\mathscr{D}_1 \circ \mathscr{D}_2(\mathscr{F}^\bullet) \simeq \mathscr{F}^\bullet \overset{\mathbf{L}}{\otimes}_{\mathscr{O}_X} P^\bullet \qquad \text{and} \qquad \mathscr{D}_2 \circ \mathscr{D}_1(\mathscr{F}^\bullet) \simeq \mathscr{F}^\bullet \overset{\mathbf{L}}{\otimes}_{\mathscr{O}_X} Q^\bullet.$$

Letting $\mathscr{F}^\bullet := \mathscr{O}_X[0]$ we derive :

$$\mathscr{O}_X[0] \simeq \mathscr{D}_2 \circ \mathscr{D}_1 \circ \mathscr{D}_1 \circ \mathscr{D}_2(\mathscr{O}_X[0]) \simeq \mathscr{D}_2 \circ \mathscr{D}_1(P^\bullet) \simeq P^\bullet \overset{\mathbf{L}}{\otimes}_{\mathscr{O}_X} Q^\bullet.$$

Then lemma 11.3.19 says that $P^\bullet \simeq \mathscr{E}[\tau]$ for an invertible $\mathscr{O}_X$-module $\mathscr{E}$ and a continuous function $\tau : |X| \to \mathbb{Z}$. Consequently : $\omega_2 \simeq \mathscr{E}^\vee[-\tau] \otimes_{\mathscr{O}_X} \omega_1$, so the proposition holds with $\mathscr{L} := \mathscr{E}^\vee$ and $\sigma := -\tau$. $\square$

Lemma 11.3.27. *Let $f : X \to Y$ be a morphism of locally coherent schemes, and $\omega^\bullet_Y$ a dualizing complex on Y. We have :*

(i) *If f is finite and finitely presented, then $f^!\omega^\bullet_Y$ is dualizing on X.*
(ii) *If Y is coherent and f is a quasi-compact open immersion, $f^*\omega^\bullet_Y$ is dualizing on X.*

Proof. (i): Denote by $\overline{f} : (X, \mathscr{O}_X) \to (Y, f_*\mathscr{O}_X)$ the morphism of ringed spaces deduced from f. For any object $C^\bullet$ of $\mathsf{D}^-(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$ we have natural isomorphisms :

$$\begin{aligned} \mathscr{D}(C^\bullet) := R\mathscr{H}om_{\mathscr{O}_X}(C^\bullet, f^!\omega^\bullet_Y) &\xrightarrow{\sim} R\mathscr{H}om_{\mathscr{O}_X}(C^\bullet, \overline{f}^* R\mathscr{H}om_{\mathscr{O}_Y}(f_*\mathscr{O}_X, \omega^\bullet_Y)) \\ &\xrightarrow{\sim} \overline{f}^* R\mathscr{H}om_{f_*\mathscr{O}_X}(f_*C^\bullet, R\mathscr{H}om_{\mathscr{O}_Y}(f_*\mathscr{O}_X, \omega^\bullet_Y)) \\ &\xrightarrow{\sim} \overline{f}^* R\mathscr{H}om_{\mathscr{O}_Y}(f_*C^\bullet, \omega^\bullet_Y). \end{aligned}$$

Hence, if $C^\bullet$ is in $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$, the same holds for $\mathscr{D}(C^\bullet)$; especially, this applies to $f^!\omega_Y \simeq \mathscr{D}(\mathscr{O}_X[0])$, and we can compute :

$$\begin{aligned} \mathscr{D} \circ \mathscr{D}(C^\bullet) &\xrightarrow{\sim} \overline{f}^* R\mathscr{H}om_{\mathscr{O}_Y}(R\mathscr{H}om_{\mathscr{O}_Y}(f_*C^\bullet, \omega^\bullet_Y), \omega^\bullet_Y) \\ &\xrightarrow{\sim} \overline{f}^* f_*C^\bullet \xrightarrow{\sim} C^\bullet \end{aligned}$$

and by inspecting the definitions, one verifies that the resulting natural transformation $C^\bullet \to \mathscr{D} \circ \mathscr{D}(C^\bullet)$ is the biduality isomorphism. The claim follows.

(ii): Since $\mathscr{O}_Y$ is coherent, the natural map

$$f^* R\mathscr{H}om_{\mathscr{O}_Y}(\mathscr{G}[0], \omega^\bullet_Y) \to R\mathscr{H}om_{\mathscr{O}_X}(f^*\mathscr{G}[0], f^*\omega^\bullet_Y)$$

is an isomorphism in $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$, for every $\mathscr{O}_Y$-module $\mathscr{G}$. Then the assertion follows easily from lemma 10.3.27(ii) and remark 11.3.17(i). $\square$

Proposition 11.3.28. *Let A be a noetherian local ring, κ its residue field, $M^\bullet$ a bounded below complex of A-modules of finite type, and set $X := \mathrm{Spec}\, A$. We have :*

(i) *The following conditions are equivalent*
  (a) *There exists* $c \in \mathbb{Z}$ *such that* $R\mathrm{Hom}^\bullet_A(\kappa[0], M^\bullet) \simeq \kappa[c]$.
  (b) *The complex of* $\mathscr{O}_X$*-modules* $M^{\bullet\sim}$ *arising from* $M^\bullet$ *is dualizing on* X.
(ii) *If the equivalent conditions of* (i) *hold, then* $M^\bullet$ *has finite injective dimension.*

Proof. (i): We show first that (a)⇒(b). To this aim, in view of remark 11.3.17(i) and corollary 10.3.2(ii), it suffices to check :

Claim 11.3.29. Assume (a). Then, for every finitely generated A-module N, we have :
(i) $D^\bullet(N) := R\mathrm{Hom}^\bullet_A(N[0], M^\bullet) \in \mathsf{D}^{\leq -c}(A\text{-}\mathbf{Mod})$ (notation of (7.1)).
(ii) The natural map

$$N[0] \to DD^\bullet(N) := R\mathrm{Hom}^\bullet_A(D^\bullet(N), M^\bullet)$$

is an isomorphism.

Proof of the claim. We first show the claim for $N = \kappa$, in which case (i) holds by assumption. To check (ii), let $M^\bullet \stackrel{\sim}{\to} I^\bullet$ be a resolution consisting of a bounded below complex of injective A-modules, so that

$$D^\bullet(\kappa[0], M^\bullet) \stackrel{\sim}{\to} \mathrm{Hom}^\bullet_A(\kappa[0], I^\bullet) \stackrel{\sim}{\to} I^\bullet[\mathfrak{m}]$$

where $\mathfrak{m} \subset A$ is the maximal ideal, and $I^k[\mathfrak{m}]$ denotes the submodule of $\mathfrak{m}$-torsion elements in I^k, for every $k \in \mathbb{Z}$. Under these isomorphisms, it is easily seen that the biduality map of (ii) is identified with the unique one

$$\kappa \to H := \mathrm{Hot}_{A\text{-}\mathbf{Mod}}(I^\bullet[\mathfrak{m}], I^\bullet)$$

that sends $1 \in \kappa$ to the inclusion map $j^\bullet : I^\bullet[\mathfrak{m}] \to I^\bullet$ (details left to the reader). Now, it is clear that any morphism $I^\bullet[\mathfrak{m}] \to I^\bullet$ in $\mathsf{Hot}(A\text{-}\mathbf{Mod})$ factors through $j^\bullet$, and on the other hand, our assumption implies that $H \simeq \kappa$. Hence, pick a morphism $f^\bullet : I^\bullet[\mathfrak{m}] \to I^\bullet$ representing a generator for the A-module H, and write $f^\bullet = j^\bullet \circ g^\bullet$ for some endomorphism $g^\bullet$ of $I^\bullet[\mathfrak{m}]$; in other words, $f^\bullet$ is the image of $j^\bullet$ under the A-linear map

$$\mathrm{Hot}_{A\text{-}\mathbf{Mod}}(g^\bullet, I^\bullet) : H \to H$$

so the class of $j^\bullet$ cannot vanish in H, and (ii) follows in this case.

Next, we shall argue by induction on $d := \dim \mathrm{Supp}\, N$. If $d = 0$, then N is an A-module of finite length, in which case we argue by induction on the length l of N. If $l = 1$, we have $N \simeq \kappa$, so the assertions are already known. Suppose $l > 1$, and that both (i) and (ii) are already known for all A-modules of length $< d$; we may find an A-submodule $N' \subset N$ such that both N' and $N'' := N/N'$ have length $< d$. From the inductive assumption for N' and N'', and the induced distiguished triangle

$$D^\bullet(N'') \to D^\bullet(N) \to D^\bullet(N') \to D^\bullet(N'')[1]$$

we deduce that (i) holds for N. Likewise, since (ii) is known for both N' and N'', using the 5-lemma we deduce easily that the same holds also for N.

Lastly, suppose that $d > 0$, and both (i) and (ii) are already known for all A-modules of finite type whose support has dimension $< d$. Let $N' := \Gamma_{\{\mathfrak{m}\}} N$; both (i) and (ii) are already known for N', so the same *dévissage* argument as in the foregoing reduces to showing the claim for N/N', *i.e.* we may assume that $\mathfrak{m} \notin \mathrm{Ass}\, N$. Thus, let $t \in \mathfrak{m}$ be any element such that the scalar multiplication map $t \cdot \mathbf{1}_N$ is injective, so we have a short exact sequence

$$0 \to N \xrightarrow{t^k} N \to N_k := N/t^k N \to 0 \qquad \text{for every } k > 0.$$

Notice that $\dim \mathrm{Supp}\, N_k < d$: indeed, if $\mathfrak{p}$ is a minimal element of $\mathrm{Supp}\, N$, then $\mathfrak{p} \in \mathrm{Ass}\, N$ ([126, Th.6.5(iii)]), hence $t \notin \mathfrak{p}$, and therefore $\mathfrak{p} \notin \mathrm{Supp}\, N_k$. By inductive assumption, both (i) and (ii) hold for N_k (for every $k > 0$), and by considering the induced distinguished triangle

$$D^\bullet(N_k) \to D^\bullet(N) \xrightarrow{t^k} D^\bullet(N) \to D^\bullet(N_k)[1]$$

we deduce that scalar multiplication by t is an epimorphism on $H^j D^\bullet(N)$ whenever $j \geq -c$; but the latter is an A-module of finite type, so it must vanish, by Nakayama' lemma, and we conclude that (i) holds for N. Furthermore, by the same token we get an exact sequence

$$H^i DD^\bullet(N) \xrightarrow{t^k} H^i DD^\bullet(N) \to 0 \qquad \text{for every } i \neq 0$$

whence $H^i DD(N) = 0$ for $i \neq 0$, again by Nakayama's lemma. Lastly, for every $k > 0$ consider the ladder with exact rows :

$$\begin{array}{ccccccccc}
0 & \longrightarrow & N & \xrightarrow{t^k} & N & \longrightarrow & N_k & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle\alpha} & & \downarrow{\scriptstyle\alpha} & & \downarrow & & \\
0 & \longrightarrow & H^0 DD^\bullet(N) & \xrightarrow{t^k} & H^0 DD^\bullet(N) & \longrightarrow & H^0 DD^\bullet(N_k) & \longrightarrow & 0
\end{array}$$

whose right-most vertical arrow is an isomorphism, by inductive assumption. A simple diagram chase then yields

$$H^0 DD^\bullet(N) = t^k \cdot H^0 DD^\bullet(N) + \alpha(N)$$

so α is surjective, by Nakayama's lemma. To show the injectivity of α, let $x \in N$ be any non-zero element, and choose $k > 0$ such that $x \notin t^k N$, so the image of x does not vanish in N_k, whence necessarily $\alpha(x) \neq 0$, and the claim follows. ◊

(b)⇒(a): Let $i : \mathrm{Spec}\, \kappa \to X$ be the closed immersion; from corollary 10.3.2(ii) we know that $i^! M^{\bullet\sim}$ is the complex arising from the complex of κ-modules $R\mathrm{Hom}_A(\kappa[0], M^\bullet)$. On the other hand, $i^! M^{\bullet\sim}$ is dualizing on $\mathrm{Spec}\, \kappa$, by virtue of lemma 11.3.27(i); obviously, $\kappa[0]^\sim$ is also dualizing on the same scheme, so the assertion follows from proposition 11.3.25.

(ii): We notice more precisely :

Claim 11.3.30. Suppose that the conditions of (i) hold for $M^\bullet$, and moreover that $H^0 M^\bullet \neq 0$ and $H^i M^\bullet = 0$ for every $i < 0$. Then $c \leq 0$, and the injective dimension of $M^\bullet$ equals $-c$.

Proof of the claim. Under the assumptions of the claim, it is clear that $c \leq 0$. Pick a quasi-isomorphism $M^\bullet \xrightarrow{\sim} I^\bullet$, where $I^\bullet$ is an object of $\mathsf{C}^{[0,-c]}(A\text{-}\mathbf{Mod})$ such that I^j is an injective A-module for every $j < -c$. Notice that $I^0 \neq 0$, since $H^0 M^\bullet$ does not vanish. Let N be any A-module; a standard argument shows that

$$\mathrm{Ext}^1_A(N, I^c) \simeq R^{1-c}\mathrm{Hom}^\bullet_A(N[0], M^\bullet)$$

and the latter vanishes if N is finitely generated, by virtue of claim 11.3.29(i). It follows that I^c is injective as well (see *e.g.* [126, Th.B3]), so the injective dimension of $M^\bullet$ is $\leq -c$. But it is also $\geq -c$, due to condition (i.a). ◊

After replacing $M^\bullet$ by $M^\bullet[a]$ for a suitable $a \in \mathbb{Z}$, the assumptions of claim 11.3.30 can obviously be fulfilled, whence (ii). □

Let us recall the following :

Definition 11.3.31. Let X be a noetherian scheme.

(i) We say that X is *Gorenstein*, if $\mathscr{O}_X[0]$ is dualizing on X.

(ii) If $X = \mathrm{Spec}\, A$ is affine and Gorenstein, we also say that A is a *Gorenstein ring*.

Remark 11.3.32. (i) In view of example 11.3.18, every regular noetherian ring is Gorenstein.

(ii) Let A be any local noetherian ring, and κ the residue field of A. In light of proposition 11.3.28(i) (and of corollary 10.3.2(ii)), we see that A is Gorenstein if and only if there exists $c \in \mathbb{N}$ such that $R\mathrm{Hom}^\bullet_A(\kappa[0], A[0]) \simeq \kappa[c]$.

11.3.33. Let $A \to B$ be a flat homomorphism of local noetherian rings, κ_A (resp. κ_B) the residue field of A (resp. of B), and $K^\bullet$ a bounded complex of A-modules of finite type. Set $X := \mathrm{Spec}\, A$, $Y := \mathrm{Spec}\, B$, denote by $f : Y \to X$ the resulting morphism of local schemes, and let $K^{\bullet\sim}$ be the complex of $\mathscr{O}_X$-modules arising from $K^\bullet$. We have :

Proposition 11.3.34. *In the situation of* (11.3.33)*, the following conditions are equivalent :*

(a) *$f^*K^{\bullet\sim}$ is dualizing on Y.*
(b) *$K^{\bullet\sim}$ is dualizing on X and $B \otimes_A \kappa_A$ is a Gorenstein ring.*

Proof. Set $C := B \otimes_A \kappa_A$, $F := \mathrm{Spec}\, C$ and $Z := \mathrm{Spec}\, \kappa_B$, denote $i_1 : Z \to F$ and $i_2 : F \to Y$ the closed immersions, and let $i := i_2 \circ i_1$. In light of proposition 11.3.28(i) (and of corollary 10.3.2(ii)) we see that (a) holds if and only if there exists $c \in \mathbb{Z}$ such that $i^!(f^*K^{\bullet\sim}) \simeq \mathscr{O}_Z[c]$. However, recall that $i^! \simeq i_1^! \circ i_2^!$ (proposition 11.1.7(i)); invoking again proposition 11.3.28(i) we deduce that (a) holds if and only if $i_2^!(f^*K^{\bullet\sim})$ is dualizing on F. The latter is the complex of $\mathscr{O}_F$-modules arising from

$$(11.3.35) \qquad R\mathrm{Hom}^\bullet_B(C[0], B \otimes_A K^\bullet) \simeq B \otimes_A L^\bullet \quad \text{where} \quad L^\bullet := R\mathrm{Hom}^\bullet_A(\kappa_A[0], K^\bullet)$$

(proposition 10.3.3(ii) and corollary 10.3.2(ii)). Hence, suppose that (b) holds; from proposition 11.3.28(i) we conclude that $i_2^!(f^*K^{\bullet\sim}) \simeq \mathscr{O}_F[c]$ for some $c \in \mathbb{Z}$; the latter is dualizing on Z by assumption, whence (a). Conversely, suppose that (a) holds; from (11.3.35) we see that $B \otimes_A L^\bullet$ is a bounded complex of C-modules whose cohomology is a free C-module in every degree. We recall the following :

Claim 11.3.36. Let R be any ring, $M^\bullet$ a bounded complex of R-modules, such that $H^iM^\bullet$ is a projective R-module, for every $i \in \mathbb{Z}$. Then we have an isomorphism

$$M^\bullet \xrightarrow{\sim} \bigoplus_{i\in\mathbb{Z}} (H^iM^\bullet)[-i] \qquad \text{in } \mathsf{D}(R\text{-}\mathbf{Mod}).$$

Proof of the claim. We argue by induction on the cardinality c_M of $S_M := \{i \in \mathbb{Z} \mid H^iM^\bullet \neq 0\}$. If $c_M = 0$, the assertion is obvious. Suppose that $c_M > 0$, and that the assertion is known for every complex $P^\bullet$ as in the claim, with $c_P < c_M$. Let $a \in \mathbb{Z}$ be the largest element of S_M; after replacing $M^\bullet$ by its truncation $\tau^{\leq a}M^\bullet$, we may assume that $M^i = 0$ for every $i > a$. Then $H^aM^\bullet \simeq \mathrm{Coker}\,(d^{a-1} : M^{a-1} \to M^a)$, and since $H^aM^\bullet$ is a projective R-module, we may find an R-linear isomorphism $M \xrightarrow{\sim} (H^aM^\bullet) \oplus \mathrm{Im}\, d^{a-1}$. Denote by $P^\bullet$ the complex such that $P^i := M^i$ for every integer $i < a$, and such that $P^a := \mathrm{Im}\, d^{a-1}$, with differentials induced by those of $M^\bullet$; then $M^\bullet \simeq (H^aM^\bullet)[-a] \oplus P^\bullet$ in $\mathsf{D}(R\text{-}\mathbf{Mod})$, and $c_P < c_M$, so the assertion is known for $P^\bullet$, and the claim follows. ◊

In light of claim 11.3.36 and remark 11.3.17(ii), we easily see that $B \otimes_A L^\bullet \simeq C[a]$ in $\mathsf{D}^b(C\text{-}\mathbf{Mod})$ for some $a \in \mathbb{Z}$ (details left to the reader), and then clearly $L^\bullet \simeq k_A[c]$ in $\mathsf{D}^b(A\text{-}\mathbf{Mod})$. Taking into account proposition 11.3.28(i), assertion (b) follows. □

Proposition 11.3.37. *Let X be a noetherian scheme, $\mathscr{K}^\bullet$ an object of $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$. The following conditions are equivalent :*

(a) *$\mathscr{K}^\bullet$ is dualizing on X.*
(b) *$\mathscr{K}^\bullet(x)$ is dualizing on $X(x)$, for every $x \in X$ (notation of definition* 4.9.17(iii)*).*

Proof. (b)⇒(a): We notice the following :

Claim 11.3.38. Let X be a noetherian scheme, $\mathscr{K}^\bullet$ an object of $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$, and $x \in X$ any point. Suppose that the complex of $\mathscr{O}_{X(x)}$-modules $\mathscr{K}^\bullet(x)$ has finite injective dimension. Then, for every $\mathscr{F}^\bullet \in \mathsf{D}^b(\mathscr{O}_{X,x}\text{-}\mathbf{Mod})_{\mathrm{coh}}$ there exists an open neighborhood U of x in X such that $R\mathscr{H}om^\bullet_{\mathscr{O}_X}(\mathscr{F}^\bullet, \mathscr{K}^\bullet)_{|U}$ lies in $\mathsf{D}^b(\mathscr{O}_U\text{-}\mathbf{Mod})_{\mathrm{coh}}$.

Proof of the claim. The question is local on X, so we may assume that X is affine, say $X = \mathrm{Spec}\, A$ for a noetherian ring A; also, by theorem 10.3.25 we may assume that $\mathscr{K}^\bullet$ arises from a bounded complex $K^\bullet$ of A-modules of finite type (details left to the reader). Then, remark 11.3.17(i) and corollary 10.3.2(ii) reduce to checking that for every A-module M there exists an open neighborhood U of x in X, such that the A-modules $T^i(M) := H^i R\mathrm{Hom}^\bullet_A(M[0], K^\bullet)$ have support in $X \setminus U$, for every sufficiently large $i \in \mathbb{Z}$.

We shall argue by induction on the dimension d of the support of M; if $d = 0$, there is nothing to show, hence suppose that $d > 0$, and that the assertion is already known for every A-module whose support has dimension strictly less than d. By [126, 6.4] we may further reduce to the case where $M = A/\mathfrak{p}$, where $\mathfrak{p} \subset A$ is a prime ideal. Then, pick a finite system of generators $t_1, \dots, t_n \in A$ for $\mathfrak{p}$, and set $L_\bullet := \mathbf{K}_\bullet(t_1, \dots, t_n)$ (notation of remark 7.8.1(ii)). Now, $H_0 L_\bullet \simeq A/\mathfrak{p}$, and $H_i L_\bullet = 0$ for every $i > n$; moreover, lemma 7.8.2(ii) says that $H_i L_\bullet$ is an $A/\mathfrak{p}$-module of finite type, for every $i = 0, \dots, n$, and vanishes for $i \in \mathbb{Z}$ outside this range; therefore, we may find $f \in A \setminus \mathfrak{p}$ such that $(H_i L_\bullet)_f$ is a free $(A/\mathfrak{p})_f$-module of some finite rank $b(i) \in \mathbb{N}$, for every $i \in \mathbb{Z}$ ([126, Th.4.10(ii)]), and there exists an integer $m \leq n$ such that $b(m) \neq 0$ and $b(i) = 0$ for every $i > m$. By choosing an injective resolution of $K^\bullet$, we get a spectral sequence

$$E_2^{pq} := R^p\mathrm{Hom}^\bullet_A((H_q L_\bullet)[0], K^\bullet) \Rightarrow R^{p+q}\mathrm{Hom}^\bullet_A(L_\bullet, K^\bullet)$$

with differentials $d_r^{pq} : E_r^{pq} \to E_r^{p-r+1,q+r}$ for every $p, q \in \mathbb{Z}$ and every $r \geq 2$. Taking into account corollary 10.3.2(ii), we see that

$$(E_2^{pq})_f \simeq (E_2^{p,0})_f^{\oplus b(q)} \qquad \text{for every } p \in \mathbb{Z}. \tag{11.3.39}$$

By the same token, we also get a natural isomorphism

$$E_2^{p0}(x) := E_2^{p0} \otimes_A \mathscr{O}_{X,x} \simeq R^p\mathrm{Hom}^\bullet_{\mathscr{O}_{X(x)}}((A/\mathfrak{p})^\sim[0](x), \mathscr{K}^\bullet(x)) \qquad \text{for every } p \in \mathbb{Z}.$$

Since $\mathscr{K}^\bullet(x)$ has finite injective dimension, it follows that there exists an integer r such that $E_2^{p,0}(x) = 0$ whenever $p > r$. Since E_2^{pq} is an A-module of finite type for every $p, q \in \mathbb{Z}$, we deduce that there exists an open neighborhood U' of x in X, such that, for every $p = r+1, \dots, r+n$, the support of $E_2^{p,0}$ is contained in $X \setminus U'$ ([126, Th.4.10(i)]). In this case, the support of $(E_2^{pq})_f$ is also contained in $X \setminus U'$, for every $(p, q) \in \mathbb{Z}^{\oplus 2}$ with $p = r+1, \dots, r+n$.

Now, let $\mathfrak{q} \in U' \cap \mathrm{Spec}\, A_f$ be any prime ideal, and suppose that $(E_2^{p,0})_\mathfrak{q} \neq 0$ for some integer $p > r + n$. From (11.3.39), we deduce that $(E_2^{p,m})_\mathfrak{q} \neq 0$ as well, and it is easily seen that $(E_\infty^{p,m})_\mathfrak{q} = (E_2^{p,m})_\mathfrak{q}$. Especially

$$R^{p+m}\mathrm{Hom}^\bullet_A(L_\bullet, K^\bullet) \neq 0. \tag{11.3.40}$$

However, $L_\bullet$ is also a complex of free A-modules, therefore

$$R\mathrm{Hom}^\bullet_A(L_\bullet, K^\bullet) \simeq \mathrm{Hom}^\bullet_A(L_\bullet, K^\bullet) \qquad \text{in } \mathsf{D}(A\text{-}\mathbf{Mod}).$$

Thus, if we represent $K^\bullet$ via an object of $\mathsf{C}^{[a,b]}(A\text{-}\mathbf{Mod})$ (for some $a, b \in \mathbb{Z}$ with $a \leq b$: notation of (7.1)), then $R\mathrm{Hom}^\bullet_A(L_\bullet, K^\bullet)$ is represented by an object of $\mathsf{C}^{[a,b+n]}(A\text{-}\mathbf{Mod})$, and consequently, $R^i\mathrm{Hom}^\bullet_A(L_\bullet, K^\bullet) = 0$ for $i > b + n$. Taking into account (11.3.40), we conclude that $p \leq p + m \leq b + n$, so that

$$T^i(M)_\mathfrak{q} = 0 \qquad \text{whenever } i > n + \max(b, r) \text{ and } \mathfrak{q} \in U' \cap \mathrm{Spec}\, A_f. \tag{11.3.41}$$

On the other hand, from the short exact of A-modules

$$0 \to M \xrightarrow{f} M \to M/fM \to 0$$

we see that $T^i(M)/fT^i(M) \subset T^{i+1}(M/fM)$ for every $i \in \mathbb{Z}$; since the support of M/fM has dimension $< d$, the inductive assumption tells us that there exist $N \in \mathbb{N}$ and an open neighborhood U'' of x in X such that the support of $T^{i+1}(M/fM)$ lies in $X \setminus U''$, for every $i > N$. From this, Nakayama's lemma implies that

$$T^i(M)_{\mathfrak{q}} = 0 \qquad \text{for every } \mathfrak{q} \in \operatorname{Spec} A/fA \text{ and every } i > N.$$

Combining with (11.3.41), we conclude that $U := U' \cap U''$ will do. ◊

Since X is quasi-compact, assumption (b), claim 11.3.38 and proposition 11.3.28(ii) imply that the rule : $\mathscr{F}^\bullet \mapsto \mathscr{D}(\mathscr{F}^\bullet) := R\mathscr{H}om^\bullet_{\mathscr{O}_X}(\mathscr{F}^\bullet, \mathscr{K}^\bullet)$ takes objects of $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$ to objects of the same category. Then, corollary 10.3.2(ii) and assumption (b) imply that the natural map $\mathscr{F}[0](x) \to \mathscr{D} \circ \mathscr{D}(\mathscr{F}[0])(x)$ is an isomorphism in $\mathsf{D}^b(\mathscr{O}_{X(x)}\text{-}\mathbf{Mod})$ for every $x \in X$ and every coherent $\mathscr{O}_X$-module $\mathscr{F}$, whence (a).

(a)⇒(b): Let $x \in X$ be any point, and $\mathscr{M}$ any coherent $\mathscr{O}_{X(x)}$-module; we may extend $\mathscr{M}$ to a coherent $\mathscr{O}_U$-module on some affine open neighborhood U of x in X, and then the latter can be further extended to a coherent $\mathscr{O}_X$-module $\mathscr{F}$ (lemma 10.3.27(ii)). According to corollary 10.3.2(ii), the natural map $\mathscr{D}(\mathscr{F}[0])(x) \to R\mathscr{H}om^\bullet_{\mathscr{O}_{X(x)}}(\mathscr{M}[0], \mathscr{K}^\bullet(x))$ is an isomorphism in $\mathsf{D}^b(\mathscr{O}_{X(x)}\text{-}\mathbf{Mod})$, whence (b). □

Corollary 11.3.42. *Let $f : Y \to X$ be a morphism of finite type between affine noetherian schemes, and $\omega^\bullet$ a dualizing complex on X. Then $f^!\omega^\bullet$ is a dualizing complex on Y.*

Proof. We may factor f as the composition of a closed immersion $g : Y \to Z$ followed by a smooth and affine morphism $h : Z \to X$. In light of lemmata 11.3.27(i) and 11.1.16(i), it then suffices to check that $h^!\omega^\bullet$ is dualizing on Z, so we may assume from start that f is smooth, in which case we are reduced to showing that $f^*\omega^\bullet$ is dualizing on Y. Let $y \in Y$ be any point, set $x := f(y)$, and denote by $f_y : Y(y) \to X(x)$ the morphism induced by f; taking into account proposition 11.3.37, we are further reduced to checking that $f_y^*(\omega^\bullet_{|X(x)})$ is dualizing on $Y(y)$. However, the latter assertion follows easily from proposition 11.3.34, remark 11.3.32(i) and [126, Th.28.7]. □

Corollary 11.3.43. *Let A be a noetherian ring, $x \in X := \operatorname{Spec} A$ any point, and $K^\bullet$ any object of $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$. Suppose that the following holds :*

(a) *Every irreducible reduced closed subscheme $Z \subset X$ containing x admits a dense open subset which is Gorenstein (see definition* 11.3.31(i)*).*
(b) *$K^\bullet(x)$ is dualizing on $X(x)$.*

Then there exists an open neighborhood U of x in X, such that $K^\bullet_{|U}$ is dualizing on U.

Proof. We begin with the following :

Claim 11.3.44. For every reduced and irreducible closed subscheme Z of X containing x, there exists a dense open subset U_Z of Z such that $K^\bullet(z)$ is dualizing on $X(z)$, for every $z \in U_Z$.

Proof of the claim. Let $i_Z : Z \to X$ be the closed immersion, and set $i_{Z(x)} := i_Z \times_X X(x) : Z(x) \to X(x)$; in view of proposition 10.3.3(ii), we easily see that there is a natural isomorphism

$$i^!_{Z(x)} K^\bullet(x) \xrightarrow{\sim} (i^!_Z K^\bullet)(x) \qquad \text{in } \mathsf{D}(\mathscr{O}_{Z(x)}\text{-}\mathbf{Mod}).$$

Hence, due to (b) and lemma 11.3.27, $(i^!_Z K^\bullet)(x)$ is dualizing on $Z(x)$. Denote by η_Z the generic point of Z; it follows that $(i^!_Z K^\bullet)(\eta_Z)$ is dualizing on $Z(\eta_Z)$ (proposition 11.3.37), and therefore it is isomorphic to $\mathscr{O}_{Z(\eta_Z)}[c]$ in $\mathsf{D}(\mathscr{O}_{Z(\eta_Z)}\text{-}\mathbf{Mod})$, due to (a). On the other hand, claim

11.3.38 implies that there exists an open neighborhood U'_Z of x in Z, such that $(i^!_Z K^\bullet)_{|U'_Z}$ lies in $\mathsf{D}^b(\mathscr{O}_{U'_Z}\text{-}\mathbf{Mod})_{\mathrm{coh}}$. It then follows easily that there exists a smaller open subset $U_Z \subset U'_Z$ of Z, such that $(i^!_Z K^\bullet)_{|U_Z} \simeq \mathscr{O}_{U_Z}[c]$ in $\mathsf{D}(\mathscr{O}_{U'_E}\text{-}\mathbf{Mod})$ (details left to the reader). In view of (a), we may then further shrink U_Z, and assume that $(i^!_Z K^\bullet)_{|U_Z}$ is dualizing on U_Z. Now, let $y \in U_Z$ be any point, denote by $i_1 : \operatorname{Spec} \kappa(y) \to Z(y)$ and $i_2 : Z(y) \to X(y)$ the closed immersions, and set $i_y := i_2 \circ i_1$. By proposition 11.3.37, the complex $i^!_2 K^\bullet(y) \simeq (i^!_Z K^\bullet)(y)$ is dualizing on $Z(y)$, so $i^!_y K^\bullet(y) \simeq i^!_1(i^!_2 K^\bullet(y))$ is dualizing on $\operatorname{Spec} \kappa(y)$ (lemma 11.3.27(i)), and consequently $K^\bullet(y)$ is dualizing on $X(y)$ (proposition 11.3.28(i)). The claim follows. $\Diamond$

Denote by $\mathscr{Z}$ the set of all reduced and irreducible closed subschemes of X containing x, and for every $Z \in \mathscr{Z}$, let U_Z be the largest open subset of Z such that $K^\bullet(y)$ is dualizing on $X(y)$ for every $y \in U_Z$. The subset $U := \bigcup_{Z \in \mathscr{Z}} U_Z$ is ind-constructible in X, and it is clearly generizing (proposition 11.3.37). Thus, U is open in X ([63, Ch.IV, Th.1.10.1]), and to conclude the proof, it suffices – again, by virtue of proposition 11.3.37 – to check that $x \in U$. Suppose that the latter fails, and let $Z \subset X$ be the closure of $\{x\}$ in X, endowed with its reduced subscheme structure; by assumption, $Z \cap U = \varnothing$; on the other hand, $Z \in \mathscr{Z}$, so that $U_Z \neq \varnothing$, by claim 11.3.44. The contradiction proves the assertion. $\square$

Remark 11.3.45. Let A be a noetherian ring, and set $X := \operatorname{Spec} A$.

(i) If X admits a dualizing complex, then every irreducible reduced closed subscheme $Z \subset X$ admits a dense open subset U which is Gorenstein. Indeed, let η_Z be the generic point of Z; we know that Z admits a dualizing complex $\omega^\bullet_Z$ (lemma 11.3.27(i)), hence $\omega^\bullet_Z(\eta_Z)$ is dualizing on $Z(\eta_Z)$ (proposition 11.3.37). But then there exists an isomorphism $\mathscr{O}_{Z(\eta_Z)}[c] \xrightarrow{\sim} \omega^\bullet(\eta_Z)$ in $\mathsf{D}^b(\mathscr{O}_{Z(\eta_Z)}\text{-}\mathbf{Mod})$ for some $c \in \mathbb{Z}$ (proposition 11.3.25), and any such isomorphism extends to an isomorphism $\mathscr{O}_U[c] \xrightarrow{\sim} (\omega^\bullet_Z)_{|U}$ on some open subset $U \subset Z$; since $(\omega^\bullet_Z)_{|U}$ is dualizing on U (lemma 11.3.27(ii)), the assertion follows.

(ii) The observation in (i) shows that the converse of corollary 11.3.43 holds as well : if $x \in X$ is any point, and U any open neighborhood of x in X such that U admits a dualizing complex, then conditions (a) and (b) of corollary 11.3.43 holds for x.

(iii) If A is local and X admits a dualizing complex, then the *formal fibres* of A are Gorenstein, *i.e.*, if we denote $A^\wedge$ the completion of A and set $X^\wedge := \operatorname{Spec} A^\wedge$, then $X^\wedge \times_X \operatorname{Spec} \kappa(x)$ is a Gorenstein scheme, for every $x \in X$. Indeed, notice that $A^\wedge \otimes_A A/\mathfrak{p}$ is the completion of $A/\mathfrak{p}$, for every $\mathfrak{p} \in \operatorname{Spec} A$, and $\operatorname{Spec} A/\mathfrak{p}$ admits a dualizing complex, if X does (lemma 11.3.27(i)); hence we may replace A by its image in $\kappa(x)$ and assume from start that A is a local noetherian domain, and x the generic point of X. Let $\omega^\bullet$ be a dualizing complex on X, and $f : X^\wedge \to X$ the natural morphism; by proposition 11.3.34, the complex $f^*\omega^\bullet$ is dualizing on $X^\wedge$. On the other hand, by (i) there exists a non-empty open subset $U \subset X$ which is Gorenstein, and therefore $\omega^\bullet_{|U} \simeq \mathscr{O}_U[c]$ for some $c \in \mathbb{Z}$. Due to lemma 11.3.27(ii), it follows that $f^{-1}U$ is Gorenstein as well, and then the same holds for $f^{-1}(x)$, by proposition 11.3.37.

(iv) If A is local and complete, then X admits a dualizing complex. Indeed, in this case A is a quotient of a regular local ring ([126, Th.29.4(ii)]), so the assertion follows from lemma 11.3.27(i) and example 11.3.18.

Corollary 11.3.46. *Let X be any noetherian scheme, $\omega^\bullet$ a dualizing complex on X. We have :*

(i) *For every $x \in X$ there exists a unique $c \in \mathbb{Z}$ such that*

$$J(x) := R^c\Gamma_{\{x\}}\omega^\bullet_{|X(x)} \neq 0.$$

(ii) *For every $x \in X$, the A-module $J(x)$ is the injective hull of the residue field $\kappa(x)$.*

Proof. In view of proposition 11.3.37, we may assume that X is local and x is its closed point; say that $X = \operatorname{Spec} A$ for some local noetherian ring A, in which case $\omega^\bullet$ is the $\mathscr{O}_X$-module arising from a bounded complex $M^\bullet$ of A-modules of finite type. We notice :

Claim 11.3.47. Let $\mathfrak{m} \subset A$ be the maximal ideal. There exists a unique $c \in \mathbb{Z}$ such that

(i) $T^i(N) := R^i\mathrm{Hom}^\bullet_A(N, M^\bullet) = 0$ for every A-module N of finite type supported at $\{x\}$ and every $i \neq c$.

(ii) The map $T^c(A/\mathfrak{m}^n) \to T^c(A/\mathfrak{m}^{n+1})$ induced by the projection $A/\mathfrak{m}^{n+1} \to A/\mathfrak{m}^n$ is injective, for every $n \in \mathbb{N}$.

Proof of the claim. (i): By proposition 11.3.28(i), we know already that there exists $c \in \mathbb{N}$ such that $T^i(A/\mathfrak{m}) = 0$ if and only if $i \neq c$. We must therefore check that the claim holds for this value of c. Now, let N be any A-module of finite type supported at $\{x\}$; we may find a finite filtration $N_0 := 0 \subset N_1 \subset \cdots \subset N_k$ consisting of A-submodules, such that $N_{j+1}/N_j \simeq A/\mathfrak{m}$ for every $i = 0, \dots, k-1$. We deduce short exact sequences

$$T^i(A/\mathfrak{m}) \to T^i(N_{j+1}) \to T^i(N_j) \qquad \text{for every } i \in \mathbb{N} \text{ and every } j = 0, \dots, k-1$$

whence the contention, by a simple induction on j.

(ii) is similar : arguing as in the foregoing, we get an exact sequence

$$T^{c-1}(\mathfrak{m}^{n+1}/\mathfrak{m}^n) \to T^c(A/\mathfrak{m}^n) \to T^c(A/\mathfrak{m}^{n+1})$$

whence the assertion. ◊

On the other hand, corollary 10.4.35 yields a natural identification :

$$J(x) \xrightarrow{\sim} \operatorname*{colim}_{n \in \mathbb{N}} T^c(A/\mathfrak{m}^n) \qquad (11.3.48)$$

and then assertion (i) follows proposition 11.3.28(i) and claim 11.3.47.

(ii): Claim 11.3.47 also implies that T^c is an exact functor on the full subcategory of A-**Mod** whose objects are the A-modules supported at $\{x\}$. By proposition 7.11.31, remark 7.11.32(i,ii) and (11.3.48) we deduce already that $J(x)$ is an injective A-module. Next, let $\kappa(x)^\sim$ be the quasi-coherent $\mathscr{O}_X$-module arising from $\kappa(x)$; we have natural identifications

$$\begin{aligned}
\mathrm{Hom}_A(\kappa(x), J(x))[c] &\xrightarrow{\sim} R\mathrm{Hom}^\bullet_{\mathscr{O}_X}(\kappa(x)^\sim[0], R\underline{\Gamma}_{\{x\}}\omega^\bullet) && \text{(by corollary 10.3.2(i))}\\
&\xrightarrow{\sim} R\Gamma_{\{x\}} \circ R\mathscr{H}om^\bullet_{\mathscr{O}_X}(\kappa(x)^\sim[0], \omega^\bullet) && \text{(by lemma 10.4.13(iii))}\\
&\xrightarrow{\sim} R\mathrm{Hom}^\bullet_{\mathscr{O}_X}(\kappa(x)^\sim[0], \omega^\bullet) && (\text{as } \mathrm{Supp}\,\kappa(x) = \{x\})\\
&\xrightarrow{\sim} R\mathrm{Hom}^\bullet_A(\kappa(x)[0], M^\bullet) && \text{(by corollary 10.3.2(i))}\\
&\xrightarrow{\sim} \kappa(x)[c] && \text{(by proposition 11.3.28(i)).}
\end{aligned}$$

Then the assertion follows immediately from theorem 7.11.22. □

11.3.49. Let X be a noetherian scheme that admits a dualizing complex $\omega^\bullet$. According to corollary 11.3.46, we get a well defined function

$$c_X : |X| \to \mathbb{Z}$$

by assigning to each $x \in X$ the unique $c_X(x) \in \mathbb{Z}$ such that $R^{c_X(x)}\Gamma_{\{x\}}\omega^\bullet_{|X(x)}$ does not vanish. With this notation, we may state :

Lemma 11.3.50. *In the situation of* (11.3.49)*, let $x, y \in X$ be any two points, such that x is an immediate specialization of y. Then*

$$c_X(x) = c_X(y) + 1.$$

Proof. By proposition 11.3.37 we may replace X by $X(x)$, and ω by $\omega_{|X(x)}$, and assume from start that X is local, and x is its closed point. Let $Z \subset X$ be the topological closure of $\{y\}$, endowed with its reduced closed subscheme structure. If we denote $i : Z \to X$ the corresponding closed immersion, then $i^!\omega$ is dualizing on Z (lemma 11.3.27(i)). Fix $z \in Z$, let

$i_z : Z(z) \to X(z)$ be the induced closed immersion, and set $c := c_X(z)$; we get natural isomorphisms :

$$
\begin{aligned}
R\Gamma_{\{z\}}(i^!\omega^\bullet)_{|Z(z)} &\xrightarrow{\sim} R\Gamma_{\{z\}} \circ R\mathscr{H}om^\bullet_{\mathscr{O}_{X(z)}}(i_{z,*}\mathscr{O}_{Z(y)}, \omega^\bullet_{|X(z)}) && \text{(by proposition 10.3.3(ii))} \\
&\xrightarrow{\sim} R\mathrm{Hom}^\bullet_{\mathscr{O}_{X(z)}}(i_{z,*}\mathscr{O}_{Z(y)}, R\underline{\Gamma}_{\{z\}}\omega^\bullet_{|X(z)}) && \text{(by lemma 10.4.13(iii))} \\
&\xrightarrow{\sim} \mathrm{Hom}^\bullet_{\mathscr{O}_{X(z)}}(i_{z,*}\mathscr{O}_{Z(y)}, R^c\underline{\Gamma}_{\{z\}}\omega^\bullet_{|X(z)})[-c] && \text{(by corollary 11.3.46)}
\end{aligned}
$$

which shows that

$$c_Z(z) = c_X(z)$$

provided c_Z is defined via $i^!\omega^\bullet$. Hence, we may replace X by Z, and assume additionally that $X = \mathrm{Spec}\, A$, where A is a one-dimensional local noetherian domain, and y is the generic point of X. In this case, $\omega^\bullet$ is the complex of $\mathscr{O}_X$-module arising from a bounded complex $M^\bullet$ of A-modules of finite type, and clearly

$$R^{c_X(y)}\Gamma_{\{y\}}\omega^\bullet_{|X(y)} \xrightarrow{\sim} H^{c_X(y)}(\omega^\bullet_y) \simeq H^{c_X(y)}(M^\bullet) \otimes_A K$$

where K is the field of fractions of A. To compute $c_X(x)$, we apply proposition 10.4.32(iii); to this aim, let f be any non-zero element of the maximal ideal of A; we get

$$R^i\Gamma_{\{x\}}\omega^\bullet \xrightarrow{\sim} \operatorname*{colim}_{n\in\mathbb{N}} H^i(f^n, M^\bullet) \qquad \text{for every } i \in \mathbb{Z}$$

(notation of remark 7.8.1(iii)). By inspecting the definitions, we find a ladder with exact rows

$$
\begin{array}{ccccc}
H^iM^\bullet & \xrightarrow{f^n} & H^iM^\bullet & \longrightarrow & H^{i+1}(f^n, M^\bullet) \\
\| & & \downarrow{\scriptstyle f} & & \downarrow \\
H^iM^\bullet & \xrightarrow{f^{n+1}} & H^iM^\bullet & \longrightarrow & H^{i+1}(f^{n+1}, M^\bullet)
\end{array}
\qquad \text{for every } i \in \mathbb{Z} \text{ and } n \in \mathbb{N}
$$

whence – after taking colimits – an exact sequence

$$H^iM^\bullet \xrightarrow{\alpha_i} (H^iM^\bullet) \otimes_A K \xrightarrow{\beta_i} R^{i+1}\Gamma_{\{x\}}M^\bullet \qquad \text{for every } i \in \mathbb{Z}$$

where α_i is induced by the inclusion map $A \to K$. However, if $(H^iM^\bullet) \otimes_A K \neq 0$, clearly α_i cannot be surjective, so $\mathrm{Im}\,\beta_i \neq 0$, and the lemma follows. □

Example 11.3.51. Let K be any field, and A a K-algebra of finite type. Set $S := \mathrm{Spec}\, K$, $X := \mathrm{Spec}\, A$, and denote by $f : X \to S$ the structure morphism. Since $\mathscr{O}_S[0]$ is dualizing on S, the complex $\omega^\bullet := f^!\mathscr{O}_S[0]$ is dualizing on X (corollary 11.3.42). In this case, the function c_X associated with ω_X as in (11.3.49) can be determined explicitly as follows. First, we may find a closed immersion $i : X \to Y := \mathbb{A}^n_S$ for some n, and if $p : Y \to S$ is the structure morphism, the proof of lemma 11.3.50 shows that $c_X = c_Y \circ i$, where c_Y is the function of the same type associated with $g^!\mathscr{O}_S[0]$. Hence, we may assume that $X = \mathbb{A}^n_S$, in which case $\omega^\bullet \simeq \mathscr{O}_X[n]$. Then X is regular ([126, Th.28.7]), so for every $x \in X$ we may compute :

$$c_X(x) = \mathrm{depth}_{\{x\}}\mathscr{O}_{X(x)} - n = n - \mathrm{tr.\,deg}(\kappa(x)/K) - n = -\mathrm{tr.\,deg}(\kappa(x)/K).$$

Theorem 11.3.52. *Let A be a noetherian ring, and suppose that $X := \mathrm{Spec}\, A$ admits a dualizing complex. Then A is universally catenary.*

Proof. In light of corollary 11.3.42, it suffices to show that A is catenary. But this follows easily from lemma 11.3.50 (details left to the reader). □

11.3.53. In the situation of (11.3.49), lemma 11.3.50 shows that c_X is a weak codimension function, with the terminology of (11.2.19). Then corollary 11.3.46(i) means precisely that $\omega^\bullet$ is a c_X-Cohen-Macaulay complex of $\mathscr{O}_X$-modules on X (see definition 11.2.24(i)). By theorem 11.2.27, we may then find a Cousin complex of $\mathscr{O}_X$-modules $\mathscr{R}^\bullet_\omega$, unique up to isomorphism of complexes, such that $\omega^\bullet$ is isomorphic to $\mathscr{R}^\bullet_\omega$ in $\mathsf{D}^+(\mathscr{O}_X\text{-}\mathbf{Mod})$. We call $\mathscr{R}^\bullet_\omega$ the *residual complex* arising from $\omega^\bullet$. By corollary 11.3.46(ii) we see that

$$\mathscr{R}^p_\omega = \bigoplus_{c_X(x)=p} E(x)^\sim \qquad \text{for every } p \in \mathbb{Z}$$

where $E(x)$ is an injective hull of the A-module $\kappa(x)$, for every $x \in X$ (notation of (10.3)).

11.3.54. For every coherent scheme X, consider the category

$$\mathsf{Dual}_X$$

whose objects are the pairs $(U, \omega^\bullet_U)$, where $U \subset X$ is an open subset, and $\omega^\bullet_U$ is a dualizing complex on X. The morphisms $(U, \omega^\bullet_U) \to (U', \omega^\bullet_{U'})$ are the pairs (j, β), where $j : U \to U'$ is an inclusion map of open subsets of X, and $\beta : j^*\omega^\bullet_{U'} \xrightarrow{\sim} \omega^\bullet_U$ is an isomorphism in $\mathsf{D}^b(\mathscr{O}_U\text{-}\mathbf{Mod})$. Let X_{Zar} denote the full subcategory of Sch/X whose objects are the (Zariski) open subsets of X; it follows easily from lemma 11.3.27(ii), that the forgetful functor

$$(11.3.55) \qquad \mathsf{Dual}_X \to X_{\mathrm{Zar}} \qquad (U, \omega^\bullet_U) \mapsto U$$

is a fibration (see definition 3.1.2(ii)) With this notation, we have :

Proposition 11.3.56. *Every descent datum for the fibration* (11.3.55) *is effective.*

Proof. Let $((U_i, \omega^\bullet_i); \beta_{ij} \mid i, j = 1, \dots, n)$ be a descent datum for the fibration (11.3.55); this means that each $(U_i, \omega^\bullet_i)$ is an object of Dual_X, and if let $U_{ij} := U_i \cap U_j$ for every $i, j \leq n$, then

$$\beta_{ij} : \omega^\bullet_{i|U_{ij}} \xrightarrow{\sim} \omega^\bullet_{j|U_{ij}}$$

are isomorphisms in $\mathsf{D}^b(\mathscr{O}_{U_{ij}}\text{-}\mathbf{Mod})$, fulfilling a suitable cocycle condition (see (3.5.22)).

We shall show, by induction on $k = 1, \dots, n$, that there exists a dualizing complex $\omega^\bullet_{X_k}$ on $X_k := U_1 \cup \cdots \cup U_k$, such that the descent datum $((U_i, \omega^\bullet_i); \beta_{ij} \mid i, j = 1, \dots, k)$ is isomorphic to the descent datum relative to the family $(U_i \mid i = 1, \dots, k)$ determined by $(X_k, \omega^\bullet_{X_k})$.

For $k = 1$, there is nothing to prove. Next, suppose that $k > 1$, and $\omega^\bullet_{X_{k-1}}$ with the sought properties has already been constructed. If $k - 1 = n$, we are done; otherwise, let $V_k := X_k \cap U_{k+1}$, set $\mathfrak{U}_k := (U_{i,k+1} \mid i = 1, \dots, k)$, and $C^\bullet := R\mathscr{H}om^\bullet_{\mathscr{O}_{V_k}}(\omega^\bullet_{X_k|V_k}, \omega^\bullet_{k+1|V_k})$. The system of morphisms $(\beta_{i,k+1} \mid i = 1, \dots, k)$ determines a class c_k in the Čech cohomology group $H^0(\mathfrak{U}_k, C^\bullet)$. However, we have a spectral sequence (see lemma 10.3.15) :

$$E^{pq}_2 := H^p(\mathfrak{U}_k, H^q C^\bullet) \Rightarrow H^{p+q} R\mathrm{Hom}^\bullet_{\mathscr{O}_{V_k}}(\omega^\bullet_{X_k|V_k}, \omega^\bullet_{k+1|V_k}).$$

Claim 11.3.57. $E^{pq}_2 = 0$ for every $q < 0$.

Proof of the claim. More precisely, we check that $H^q C^\bullet = 0$ for every $q < 0$. Indeed, by lemma 11.3.27(ii), that both $\omega^\bullet_{X_k|V_k}$ and $\omega^\bullet_{k+1|V_k}$ are dualizing on V_k. Moreover, on $U_{i,k+1}$ they restrict to isomorphic objects of $\mathsf{D}^b(\mathscr{O}_{U_{i,k+1}}\text{-}\mathbf{Mod})$, for every $i = 1, \dots, k$. It follows easily from proposition 11.3.25 that there exists an invertible $\mathscr{O}_{V_k}$-module $\mathscr{L}$ and an isomorphism

$$\omega^\bullet_{X_k|V_k} \xrightarrow{\sim} \omega^\bullet_{k+1|V_k} \otimes_{\mathscr{O}_{V_k}} \mathscr{L} \qquad \text{in } \mathsf{D}^b(\mathscr{O}_{V_k}\text{-}\mathbf{Mod}).$$

Therefore, the biduality map induces an isomorphism

$$R\mathscr{H}om^\bullet_{\mathscr{O}_{V_k}}(\omega^\bullet_{X_k|V_k}, \omega^\bullet_{k+1|V_k}) \xrightarrow{\sim} \mathscr{L}[0]$$

whence the claim. ◊

Claim 11.3.57 implies that c_k corresponds to an element of $H^0R\mathrm{Hom}^\bullet_{\mathscr{O}_{V_k}}(\omega^\bullet_{X_k|V_k}, \omega^\bullet_{k+1|V_k})$, and by construction, it is clear that this global section is an isomorphism $c_k : \omega^\bullet_{X_k|V_k} \xrightarrow{\sim} \omega^\bullet_{k+1|V_k}$ in $\mathsf{D}^b(\mathscr{O}_{V_k}\text{-}\mathbf{Mod})$. By definition, c_k is represented by a diagram of quasi-isomorphisms :

$$\omega^\bullet_{X_k|V_k} \leftarrow T^\bullet \rightarrow \omega^\bullet_{k+1|V_k} \qquad \text{in } \mathsf{C}(\mathscr{O}_{V_k}\text{-}\mathbf{Mod}) \tag{11.3.58}$$

for some complex $T^\bullet$. Let $T_!$ be the $\mathscr{O}_{X_{k+1}}$-module obtained as extension by zero of T, and define likewise $(\omega^\bullet_{X_k})_!$ and $(\omega^\bullet_{k+1})_!$. We let $\omega^\bullet_{X_{k+1}}$ be the cone of the map of complexes

$$T_! \rightarrow (\omega^\bullet_{X_k})_! \oplus (\omega^\bullet_{k+1})_!$$

deduced from (11.3.58). An easy inspection shows that this complex is dualizing on X_{k+1}, and it fulfills the stated condition. □

Remark 11.3.59. The proof of proposition 11.3.56 is a special case of a general technique for "glueing perverse sheaves" developed in [18].

In the study of duality for derived categories of modules, the role of reflexive modules is taken by the more general class of Cohen-Macaulay modules. There is a version of this theory for noetherian regular schemes, and a relative variant, for smooth morphisms. Let us begin by recalling the following :

Definition 11.3.60. Let $(A, \mathfrak{m}_A)$ be a local ring, M an A-module.

(i) Let $\mathscr{M}$ be the set of all finitely generated A-submodules M. The *dimension* of M is

$$\dim_A M := \sup(\dim \operatorname{Supp} M' \mid M' \in \mathscr{M}).$$

(ii) Suppose that the open subset $\operatorname{Spec} A \setminus \{\mathfrak{m}_A\}$ is quasi-compact, and $\operatorname{depth}_A M < +\infty$. If $\dim_A M = \operatorname{depth}_A M$, we say that M is a *Cohen-Macaulay* A-module. The category

$$A\text{-}\mathsf{CM}$$

is the full subcategory of A-$\mathbf{Mod}$ consisting of all finitely presented Cohen-Macaulay A-modules. For every $n \in \mathbb{N}$, we let A-CM_n be the full subcategory of A-CM whose objects are the Cohen-Macaulay A-modules of dimension n.

(iii) If A is a Cohen-Macaulay A-module, we say that A is a *Cohen-Macaulay* local ring.

(iv) Let X be a scheme, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module. We say that $\mathscr{F}$ is a *Cohen-Macaulay* $\mathscr{O}_X$-module, if $\mathscr{F}_x$ is a Cohen-Macaulay $\mathscr{O}_{X,x}$-module, for every $x \in X$. We say that X is a *Cohen-Macaulay* scheme, if $\mathscr{O}_X$ is a Cohen-Macaulay $\mathscr{O}_X$-module.

(v) Let B be another local ring, $\varphi : A \rightarrow B$ a local ring homomorphism. The category

$$\varphi\text{-}\mathsf{CM}$$

of *φ-Cohen-Macaulay modules* is the full subcategory of B-$\mathbf{Mod}$ whose objects are all the finitely presented B-modules N that are φ-flat, and such that $N/\mathfrak{m}_A N$ is a Cohen-Macaulay B-module. For every $n \in \mathbb{N}$, we let φ-CM_n be the full subcategory of φ-CM whose objects are the φ-Cohen-Macaulay modules N with $\dim_B N/\mathfrak{m}_A N = n$.

(vi) Let $f : X \rightarrow Y$ be a locally finitely presented morphism of schemes, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module, $x \in X$ any point, and set $y := f(x)$. We say that $\mathscr{F}$ is *f-Cohen-Macaulay* at the point x, if $\mathscr{F}_x$ is a $f^\natural_x$-Cohen-Macaulay module. We say that f is *Cohen-Macaulay* at the point x, if $\mathscr{O}_X$ is f-Cohen-Macaulay at the point x (cp. [64, Ch.IV, Déf.6.8.1]).

(vii) Let f and $\mathscr{F}$ be as in (vi). We say that $\mathscr{F}$ is f-Cohen-Macaulay (resp. that f is Cohen-Macaulay) if $\mathscr{F}$ (resp. $\mathscr{O}_X$) is f-Cohen-Macaulay at every point $x \in X$.

(viii) Let f and $\mathscr{F}$ be as in (vi). The *f-Cohen-Macaulay locus* of $\mathscr{F}$ is the subset

$$CM(f,\mathscr{F}) \subset X$$

consisting of all $x \in X$ such that f is Cohen-Macaulay at x. The subset $CM(f,\mathscr{O}_X)$ is also called the *Cohen-Macaulay locus of f* and is denoted briefly $CM(f)$.

Remark 11.3.61. Let $(A,\mathfrak{m}_A)$ be any local ring; set $X := \mathrm{Spec}\, A$, and for every A-module M, let $M^\sim$ be the quasi-coherent $\mathscr{O}_X$-module arising from M. Then, with the notation of theorem 10.1.35(i), we have

$$\dim_A M = d_{M^\sim} \qquad \text{for every } A\text{-module } M.$$

For the proof, let $\mathscr{M}$ be the set of all finitely generated A-submodules of M. Clearly $d_{M^\sim} = \sup(d_{M'^\sim} \mid M' \in \mathscr{M})$, so we are reduced to the case where M is finitely generated. Then $\mathrm{Supp}\, M$ is a closed subset of X, and $\dim_A M = \dim(\mathrm{Supp}\, M)$; moreover, clearly $\mathrm{Supp}\, M = \mathrm{Supp}\, M^\sim$, and the assertion folows easily.

Lemma 11.3.62. *Let $f : X \to Y$ be a locally finitely presented morphism of schemes, and $\mathscr{F}$ a finitely presented $\mathscr{O}_X$-module such that* $\mathrm{Supp}\,\mathscr{F} = X$. *We have :*

(i) *$CM(f,\mathscr{F})$ is an open subset of X,*
(ii) *The restriction $CM(f) \to Y$ of f is locally equidimensional.*
(iii) *Let $g : X' \to X$ be another morphism of schemes, $x' \in X'$ a point such that g is étale at x'. Then $g(x') \in CM(f,\mathscr{F})$ if and only if $x' \in CM(f \circ g, g^*\mathscr{F})$.*
(iv) *If $x \in CM(f)$, then $\delta'(x,\mathscr{O}_X) = \delta'(f(x),\mathscr{O}_Y) + \dim \mathscr{O}_{f^{-1}(fx),x}$ (notation of* (10.4.19)*).*

Proof. (i) and (ii) follow easily from [65, Ch.IV, Prop.15.4.3] and [64, Ch.IV, Prop.2.3.4].

(iii) follows from corollary 10.4.37. Lastly, (iv) is an immediate consequence of corollary 10.4.47. □

Remark 11.3.63. (i) The terminology "locally equidimensional" follows [66, $\mathrm{Err}_{\mathrm{IV}}35$], which modifies the terminology "equidimensional" of [65, Ch.IV, Déf.13.3.2]. Hence, a morphism of schemes $f : X \to Y$ locally of finite type is locally equidimensional, if it verifies the equivalent conditions of [65, Ch.IV, Prop.13.3.1] at every point $x \in X$. However, the *caveat* here is that the said conditions are *not* quite equivalent as stated : they become equivalent if one omits the words "contenant y" in line 2 of *loc.cit.* (with unchanged proof). So, the correct definition of "locally equidimensional" is in terms of the cited proposition thus amended.

(ii) A counterexample to [65, Ch.IV, Prop.13.3.1] is given by the identity morphism $X \to X$ of a scheme X with a point x such that the union of the irreducible components of X passing through x does not contain an open neighborhood of x in X (*e.g.* take X whose underlying topological space is zero-dimensional and not discrete); then $\mathbf{1}_X$ satisfies condition b) of [65, Ch.IV, Prop.13.3.1], but does not satisfy conditions a),a′) and a″).

Proposition 11.3.64. *Let A be a regular local ring of dimension d, and M a finitely generated Cohen-Macaulay A-module. Then :*

(i) $\mathrm{Ext}^i_A(M,A) = 0$ *for every $i \neq c := d - \dim M$.*
(ii) *The A-module $\mathscr{D}(M) := \mathrm{Ext}^c_A(M,A)$ is Cohen-Macaulay.*
(iii) *The natural map $M \to \mathrm{Ext}^c(\mathscr{D}(M),A)$ is an isomorphism, and* $\mathrm{Supp}\,\mathscr{D}(M) = \mathrm{Supp}\, M$.
(iv) *For every $n \in \mathbb{N}$, we have an equivalence of categories :*

$$\mathscr{D} : A\text{-}\mathsf{CM}_n \to A\text{-}\mathsf{CM}_n^o \qquad N \mapsto \mathrm{Ext}^{d-n}_A(N,A).$$

Proof. (i): According to [63, Ch.0, Prop.17.3.4], the projective dimension of M equals c, so we may find a minimal free resolution $0 \to L_c \to \cdots \to L_1 \to L_0 \to M$ for M of length c. Hence, we need only prove the sought vanishing for every $i < c$. Set $X := \mathrm{Spec}\, A$,

$Z := \mathrm{Supp}\, M \subset X$. By virtue of proposition 10.4.25, it suffices to show that $\mathrm{depth}_Z \mathscr{O}_X \geq c$. In light of (10.4.30), this comes down to showing that $\mathscr{O}_{X,z}$ is a local ring of depth $\geq c$, for every $z \in Z$. The latter holds, since $\mathscr{O}_{X,z}$ is a regular local ring of dimension $\geq c$ ([63, Ch.0, Cor.16.5.12]).

(ii): From (i) we deduce that $L^\vee_\bullet := (L^\vee_0 \to \cdots \to L^\vee_n)$, together with its natural augmentation $L^\vee_n \to \mathscr{D}(M)$, is a free resolution of $\mathscr{D}(M)$; especially, the projective dimension of $\mathscr{D}(M)$ is $\leq c$, and therefore

$$\mathrm{depth}_A \mathscr{D}(M) \geq \dim M$$

again by [63, Ch.0, Prop.17.3.4]. On the other hand, it follows easily from [163, Prop.3.3.10] that $\mathrm{Supp}\, \mathscr{D}(M) \subset \mathrm{Supp}\, M$, so $\mathscr{D}(M)$ is Cohen-Macaulay.

(iii): From the proof of (ii) we see that $R\mathrm{Hom}_A(\mathscr{D}(M), A)$ is computed by the complex $L^{\vee\vee}_\bullet = L_\bullet$, whence the first assertion. Invoking again [163, Prop.3.3.10], we deduce that $\mathrm{Supp}\, M \subset \mathrm{Supp}\, \mathscr{D}(M)$; since the converse inclusion is already known, these two supports coincide.

(iv) follows straightforwardly from (ii) and (iii). □

Corollary 11.3.65. *Let X be a regular noetherian scheme, and $j : Y \to X$ a closed immersion. We have :*

(i) *Y admits a dualizing complex $\omega^\bullet_Y$.*

(ii) *If Y is a Cohen-Macaulay scheme, then we may find a dualizing complex $\omega^\bullet_Y$ that is concentrated in degree 0. Moreover, $H^0(\omega^\bullet_Y)$ is a Cohen-Macaulay $\mathscr{O}_Y$-module.*

Proof. Indeed, lemma 11.3.27(i) shows that the complex $\omega^\bullet_Y := j^* R\mathscr{H}om_{\mathscr{O}_X}(j_*\mathscr{O}_Y, \mathscr{O}_X)$ will do. According to proposition 11.3.64(i,ii), this complex fulfills the condition of (ii), up to a suitable shift. □

11.3.66. Let $f : X \to S$ be a smooth quasi-compact morphism of schemes, $\mathscr{F}$ a finitely presented quasi-coherent $\mathscr{O}_X$-module, $x \in X$ any point, and $s := f(x)$. Set

$$A := \mathscr{O}_{S,s} \qquad B := \mathscr{O}_{X,x} \qquad F := \mathscr{F}_x \qquad B_0 := B \otimes_A \kappa(s) \qquad F_0 := F \otimes_A \kappa(s).$$

Theorem 11.3.67. *In the situation of* (11.3.66)*, suppose that F is a $f^\natural_x$-Cohen-Macaulay module. Then we may find an open neighborhood $U \subset X$ of x in X such that the following holds:*

(i) *There exists a finite resolution of the $\mathscr{O}_U$-module $\mathscr{F}_{|U}$, of length $n := \dim B_0 - \dim_B F_0$*

$$\Sigma_\bullet \quad : \quad 0 \to \mathscr{L}_n \to \mathscr{L}_{n-1} \to \cdots \to \mathscr{L}_0 \to \mathscr{F}_{|U} \to 0$$

consisting of free $\mathscr{O}_U$-modules of finite rank. Moreover, $\Sigma_\bullet$ is universally $\mathscr{O}_S$-exact, i.e. *for every coherent $\mathscr{O}_S$-module $\mathscr{G}$, the complex $\Sigma_\bullet \otimes_{\mathscr{O}_X} f^*\mathscr{G}$ is still exact.*

(ii) *The complex $K^\bullet := R\mathscr{H}om^\bullet_{\mathscr{O}_U}(\mathscr{F}_{|U}, \mathscr{O}_U)$ is concentrated in degree n.*

(iii) *The natural map $\mathscr{F}_{|U} \to R\mathscr{H}om_{\mathscr{O}_U}(K^\bullet, \mathscr{O}_U)$ is an isomorphism in* $\mathsf{D}(\mathscr{O}_U\text{-}\mathbf{Mod})$.

(iv) *The B-module $G := H^n K^\bullet_x$ is $f^\natural_x$-Cohen-Macaulay, and* $\mathrm{Supp}\, G = \mathrm{Supp}\, F$.

Proof. (i): According to proposition 7.3.53, the B-module F admits a minimal free resolution

$$\Sigma_{x,\bullet} \quad : \quad \cdots \to L_2 \xrightarrow{d_2} L_1 \xrightarrow{d_1} L_0 \xrightarrow{\varepsilon} F \to 0$$

that is universally A-exact; especially, $d_i(L_i)$ is a flat A-module, for every $i \in \mathbb{N}$. It also follows that $\Sigma_{x,\bullet} \otimes_A \kappa(s)$ is a minimal free resolution of the B_0-module F_0. Since the latter is Cohen-Macaulay, and B_0 is a regular local ring ([66, Ch.IV, Th.17.5.1]), the projective dimension of the B_0-module F_0 equals n ([63, Ch.0, Prop.17.3.4]), therefore $d_n(L_n) \otimes_A \kappa(s)$ is a free B_0-module, so $d_n(L_n)$ is a flat B-module (lemma 7.11.35); then we deduce that it is actually a free B-module, as it is finitely presented. Since $\Sigma_{x,\bullet}$ is minimal, we conclude that $L_i = 0$ for every $i > n$. We may now extend $\Sigma_{x,\bullet}$ to a finite resolution $\Sigma_\bullet$ of $\mathscr{F}_{|U}$ by free $\mathscr{O}_U$-modules on some open neighborhood U of x, and after replacing U by a smaller neighborhood of U, we may assume that $\mathscr{F}_{|U}$ is $f_{|U}$-flat ([65, Ch.IV, Th.11.3.1]), hence $\Sigma_\bullet$ is universally $\mathscr{O}_S$-exact, as stated.

(ii): Let $L_\bullet := (L_n \to \cdots \to L_0)$ be the complex obtained after omitting F from the resolution $\Sigma_{x,\bullet}$ (where L_0 is placed in degree 0). Then $K^\bullet$ is isomorphic to $L_\bullet^\vee := \mathrm{Hom}_B(L_\bullet, B)$. On the other hand, the universal exactness property of $\Sigma_{x,\bullet}$ implies that

$$\mathrm{Hom}_{B_0}(L_\bullet \otimes_A \kappa(s), B_0) = L_\bullet^\vee \otimes_A \kappa(s)$$

computes $R\mathrm{Hom}^\bullet_{B_0}(F_0, B_0)$. In view of proposition 11.3.64(i), we have $\mathrm{Ext}^i_{B_0}(F_0, B_0) = 0$ for every $i \neq n$. From this, a repeated application of [65, Ch.IV, Prop.11.3.7] shows that $L_\bullet^\vee$ is concentrated in degree n as well, and after shrinking U, we may assume that (ii) holds (details left to the reader).

(iii): Let $\mathscr{L}_\bullet := (\mathscr{L}_n \to \cdots \to \mathscr{L}_0)$ be the complex obtained by omitting $\mathscr{F}_{|U}$ form the resolution $\Sigma_\bullet$; the proof of (iii) shows that $R\mathscr{H}om_{\mathscr{O}_U}(K^\bullet, \mathscr{O}_U)$ is computed by $\mathscr{L}_\bullet^{\vee\vee} = \mathscr{L}_\bullet$, whence the contention.

(iv): By the same token, [65, Ch.IV, Prop.11.3.7] implies that $\mathrm{Coker}\, d_i^\vee$ is a flat A-module, for every $i = 1, \dots, n$. Especially, G is a flat A-module, and the complex $L_\bullet^\vee[-n]$, with its natural augmentation $L_n^\vee \to G$, is a universally A-exact and free resolution of the B-module G. Especially, the projective dimension of G is $\leq n$, therefore

$$\mathrm{depth}_B G \geq \dim_B F_0 \qquad (11.3.68)$$

by [63, Ch.0, Prop.17.3.4]. From (iii) we also see that the induced map

$$F_\mathfrak{p} \to \mathrm{Ext}^n_{B_\mathfrak{p}}(G_\mathfrak{p}, B_\mathfrak{p})$$

is an isomorphism, for every prime ideal $\mathfrak{p} \subset B$; therefore $\mathrm{Supp}\, F \subset \mathrm{Supp}\, G$. Symmetrically, the same argument yields $\mathrm{Supp}\, G \subset \mathrm{Supp}\, F$. Hence the supports of F and G agree. Lastly, combining with (11.3.68) we see that G is Cohen-Macaulay. □

11.3.69. Keep the notation of (11.3.66), and let $\varphi := f_x^\natural : A \to B$. Theorem 11.3.67(iii,iv) implies that, for every $n \in \mathbb{N}$, the functor

$$\mathscr{D}_\varphi : \varphi\text{-}\mathsf{CM}_n \to \varphi\text{-}\mathsf{CM}_n^o \qquad M \mapsto \mathrm{Ext}_B^{\dim B_0 - n}(M, B)$$

is an equivalence, and the natural map $M \to \mathscr{D}_\varphi \circ \mathscr{D}_\varphi(M)$ is an isomorphism, for every φ-Cohen-Macaulay module M. We shall see later also a relative variant of corollary 11.3.65, in a more special situation (see proposition 11.5.5).

11.4. **Schemes over a valuation ring.** Throughout this section, $(K, |\cdot|)$ is a valued field, whose valuation ring (resp. maximal ideal, resp. residue field, resp. value group) shall be denoted K^+ (resp. $\mathfrak{m}_K$, resp. κ, resp. Γ). Also, we let

$$S := \mathrm{Spec}\, K^+ \qquad \text{and} \qquad S_{/b} := \mathrm{Spec}\, K^+/bK^+ \qquad \text{for every } b \in \mathfrak{m}_K$$

(so $S_{/0} = S$) and we denote by $s := \mathrm{Spec}\, \kappa$ (resp. by $\eta := \mathrm{Spec}\, K$) the closed (resp. generic) point of S. More generally, for every S-scheme X we let as well

$$X_{/b} := X \times_S S_{/b} \qquad \text{for every } b \in \mathfrak{m}_K.$$

A basic fact, that follows immediately from corollary 9.1.28, is that every finitely presented S-scheme is coherent (this can also be deduced easily from [86, Part I, Th.3.4.6]).

Lemma 11.4.1. *Let X be an irreducible scheme, and $f : X \to S$ a flat morphism of schemes of finite type, $x \in X$, and $y := f(x)$. The following holds :*

(i) *The scheme $f^{-1}(y)$ is equidimensional of dimension* $\dim f^{-1}(\eta)$.
(ii) *The local ring $\mathscr{O}_{f^{-1}(y),x}$ is equidimensional.*

Proof. (i): After replacing K by the residue field $\kappa(y)$, and K^+ by its image in $\kappa(y)$ (which is a valuation ring of $\kappa(y)$: see [126, Th.10.1(iii)]), the assertion follows from [65, Ch.IV, Cor.13.1.6 and Lemme 14.3.10].

(ii) follows easily from (i) and [64, Ch.IV, Prop.5.2.1]. □

Proposition 11.4.2. *Let $f : X \to S$ be a flat and finitely presented morphism, $\mathscr{F}$ a coherent $\mathscr{O}_X$-module, $x \in X$ any point, $y := f(x)$, and suppose that $f^{-1}(y)$ is a regular scheme (this holds* e.g. *if f is a smooth morphism). Let also $n := \dim \mathscr{O}_{f^{-1}(y),x}$. Then:*

(i) $\mathrm{proj.dim}_{\mathscr{O}_{X,x}} \mathscr{F}_x \leq n+1$ *(here we set* $\mathrm{proj.dim}_{\mathscr{O}_{X,x}} 0 := 0$*).*

(ii) *If $\mathscr{F}$ is f-flat at the point x, then* $\mathrm{proj.dim}_{\mathscr{O}_{X,x}} \mathscr{F}_x \leq n$.

(iii) *If $\mathscr{F}$ is reflexive at the point x, then* $\mathrm{proj.dim}_{\mathscr{O}_{X,x}} \mathscr{F}_x \leq \max(0, n-1)$.

(iv) *If f has regular fibres, and $\mathscr{F}$ is reflexive and generically invertible (see* (11.3.10)*), then $\mathscr{F}$ is invertible.*

(v) *All the fibres of the induced morphism $f_x : X(x) \to S(y)$ are regular and irreducible.*

Proof. To start out, we may assume that X is affine, and then it follows easily from lemma 11.3.7(ii.a) that $\mathscr{O}_X$ is coherent.

(ii): Since $\mathscr{O}_X$ is coherent, we can find a possibly infinite resolution

$$\cdots \to E_2 \to E_1 \to E_0 \to \mathscr{F}_x \to 0$$

by free $\mathscr{O}_{X,x}$-modules E_i ($i \in \mathbb{N}$) of finite rank; set $E_{-1} := \mathscr{F}_x$ and $L := \mathrm{Im}(E_n \to E_{n-1})$. It suffices to show that the $\mathscr{O}_{X,x}$-module L is free. For every $\mathscr{O}_{X,x}$-module M we shall let $M(y) := M \otimes_{\mathscr{O}_{X,x}} \mathscr{O}_{f^{-1}(y),x}$. Since L and $\mathscr{F}_x$ are torsion-free, hence flat K^+-modules, the induced sequence of $\mathscr{O}_{f^{-1}(y),x}$-modules:

$$0 \to L(y) \to E_{n-1}(y) \to \cdots \to E_1(y) \to E_0(y) \to \mathscr{F}_x(y) \to 0$$

is exact; since $f^{-1}(y)$ is a regular scheme, $L(y)$ is a free $\mathscr{O}_{f^{-1}(y),x}$-module of finite rank. Since L is also flat as a K^+-module, [65, Ch.IV, Prop.11.3.7] and Nakayama's lemma show that any set of elements of L lifting a basis of $L(y)$, is a free basis of L.

(i): Locally on X we can find an epimorphism $\mathscr{O}_X^{\oplus n} \to \mathscr{F}$, whose kernel $\mathscr{G}$ is again a coherent $\mathscr{O}_X$-module, since $\mathscr{O}_X$ is coherent. Clearly it suffices to show that $\mathscr{G}$ admits, locally on X, a finite free resolution of length $\leq n$, which holds by (ii), since $\mathscr{G}$ is f-flat.

(iii): Suppose $\mathscr{F}$ is reflexive at x; by remark 11.3.5 we can find a left exact sequence

$$0 \to \mathscr{F}_x \to \mathscr{O}_{X,x}^{\oplus m} \xrightarrow{\alpha} \mathscr{O}_{X,x}^{\oplus n}.$$

It follows that $\mathrm{proj.dim}_{\mathscr{O}_{X,x}} \mathscr{F}_x = \max(0, \mathrm{proj.dim}_{\mathscr{O}_{X,x}}(\mathrm{Coker}\,\alpha) - 2) \leq \max(0, n-1)$, by (i).

(iv): Suppose that $\mathscr{F}$ is generically invertible, let $j : U \to X$ be the maximal open immersion such that $j^*\mathscr{F}$ is an invertible $\mathscr{O}_U$-module, and set $Z := X \setminus U$. Under the current assumptions, X is reduced; it follows easily that U is the set where $\mathrm{rk}\,\mathscr{F} = 1$, and that j is quasi-compact (since the rank function is constructible : see (11.3.10)). It follows from (iii) that $Z \cap f^{-1}(y)$ has codimension ≥ 2 in $f^{-1}(y)$, for every $y \in S$. Hence the conditions of corollary 11.3.9 are fulfilled, and furthermore $\mathscr{F}[0]$ is a perfect complex by (ii), so the invertible $\mathscr{O}_X$-module $\det \mathscr{F}$ is well defined (lemma 11.3.14). Then (iv) follows from the natural isomorphisms :

$$\mathscr{F} \xrightarrow{\sim} j_*j^*\mathscr{F} \xrightarrow{\sim} j_*\mathsf{det}(j^*\mathscr{F}[0]) \xrightarrow{\sim} j_*j^*\mathsf{det}\,\mathscr{F}[0] \xleftarrow{\sim} \mathsf{det}\,\mathscr{F}[0].$$

(v): Let $y' \in S(y)$ be any point; we need to check that $f_x^{-1}(y')$ is an irreducible regular scheme, and after replacing K^+ by a quotient, we may assume that y' is the generic point of S; after further replacing K^+ by a localization, we may also assume that y is the closed point of S. Set $A := \mathscr{O}_{X,x}$; by assumption, $f_x^{-1}(y)$ is a regular scheme, hence $\mathfrak{p} := \mathfrak{m}_K A$ is a prime ideal of A, so that $A_\mathfrak{p}$ is a valuation ring (proposition 9.1.34(ii)), and especially, it is a domain. Moreover, [65, Ch.IV, Prop.11.3.7] implies that for every $h \in A \setminus \mathfrak{p}$, scalar multiplication by h

is injective on A; thus, the localization map $A \to A_\mathfrak{p}$ is injective as well, so A is a domain. This already proves that $f_x^{-1}(y') = \operatorname{Spec} K \otimes_{K^+} A$ is irreducible. Next, let $\mathfrak{q} \subset A$ be any prime ideal with $\mathfrak{q} \cap K^+ = \{0\}$, and M any $A_\mathfrak{q}$-module of finite type; pick a finitely presented A-module N with an isomorphism $N_\mathfrak{q} \xrightarrow{\sim} M$. By (i), there exists a finite resolution $L_\bullet$ of N, consisting of free A-modules of finite rank; then $A_\mathfrak{q} \otimes_A L_\bullet$ is a finite resolution of M by free $A_\mathfrak{q}$-modules of finite rank. By Serre's theorem [126, Th.19.2], this shows that $A_\mathfrak{q}$ is regular, as required. □

Proposition 11.4.3. *Let X be a scheme, $\mathscr{E}$ a locally free $\mathscr{O}_X$-module of finite rank > 1 at every point of X, and denote by $\pi : \mathbb{P}(\mathscr{E}) \to X$ the structure morphism of the projective X-scheme associated with $\mathscr{E}$. Then the map*

$$H^0(X, \mathbb{Z}) \oplus \operatorname{Pic} X \to \operatorname{Pic} \mathbb{P}(\mathscr{E}) \qquad (r, \mathscr{L}) \mapsto \mathscr{O}_{\mathbb{P}(\mathscr{E})}(r) \otimes \pi^*\mathscr{L}$$

is an isomorphism of abelian groups.

Proof. To begin with, let us recall the following well known :

Claim 11.4.4. Let $f : Y \to T$ be a proper morphism of noetherian schemes, $\mathscr{F}$ a coherent f-flat $\mathscr{O}_Y$-module, $t \in T$ a point, $p \in \mathbb{N}$ an integer, and denote $i_t : f^{-1}(t) \to Y$ the natural immersion. Suppose that $H^{p+1}(f^{-1}(t), i_t^*\mathscr{F}) = 0$. Then the natural map

$$(R^p f_* \mathscr{F})_t \to H^p(f^{-1}(t), i_t^* \mathscr{F})$$

is surjective.

Proof of the claim. In light of [61, Ch.III, Prop.1.4.15], we easily reduce to the case where T is a local scheme, say $T = \operatorname{Spec} A$ for some noetherian local ring A, and t is the closed point of T. Set $k := \kappa(t)$, and for every $q \in \mathbb{N}$, consider the functor

$$F_{-q} : A\text{-}\mathbf{Mod} \to A\text{-}\mathbf{Mod} \qquad M \mapsto H^0(T, R^p f_*(f^* M^\sim \otimes_{\mathscr{O}_Y} \mathscr{F}))$$

(notation of (10.3)). Since $\mathscr{F}$ is f-flat, the system $(F_{-q} \mid q \in \mathbb{N})$ defines a homological functor. The assertion is that $F_{-p-1}(k) = 0$, in which case [62, Ch.III, Cor.7.5.3] (together with [61, Ch.III, Th.3.2.1 and Th.4.1.5]) says that $F_{-p-1}(M) = 0$ for every A-module M. Hence, F_{-p-1} is trivially an exact functor, and it follows that the natural map $F_{-p}(A) \to F_{-p}(k)$ is surjective ([62, Ch.III, Prop.7.5.4]), which is the claim. ◊

Now, the injectivity of the stated map is clear (details left to the reader). For the surjectivity, let $\mathscr{G}$ be an invertible $\mathscr{O}_{\mathbb{P}(\mathscr{E})}$-module, $x \in X$ any point, and $U \subset X$ an affine open neighborhood of x in X such that $\mathscr{E}_{|U}$ is a free $\mathscr{O}_X$-module of constant rank $n+1$ (for some $n \in \mathbb{N} \setminus \{0\}$), so that we have an isomorphism of U-schemes $\mathbb{P}^n_U \xrightarrow{\sim} \mathbb{P}(\mathscr{E}_{|U})$, where $\mathbb{P}^n_U$ denotes the projective scheme of relative dimension n over U. Write U as the limit of a filtered system $(U_\lambda \mid \lambda \in \Lambda)$ of affine noetherian schemes, and for every $\lambda \in \Lambda$, let $p_\lambda : \mathbb{P}^n_U \to \mathbb{P}^n_{U_\lambda}$ be the induced morphism, and $\pi_\lambda : \mathbb{P}^n_{U_\lambda} \to U_\lambda$ the projection; for some $\mu \in \Lambda$, we may find an invertible $\mathscr{O}_{\mathbb{P}^n_{U_\mu}}$-module $\mathscr{G}_\mu$ with an isomorphism $\mathscr{G}_{|\mathbb{P}^n_U} \xrightarrow{\sim} p_\mu^* \mathscr{G}_\mu$. Let $y \in U_\mu$ be the image of x, and $i_y : \mathbb{P}^n_{\kappa(y)} \to \mathbb{P}^n_{U_\mu}$ the natural immersion; we have $i_y^* \mathscr{G}_\mu \simeq \mathscr{O}_{\mathbb{P}^n_{\kappa(y)}}(r)$ for some $r \in \mathbb{Z}$. Set $\mathscr{F} := \mathscr{G}_\mu(-r)$, and notice that $H^1(\mathbb{P}^n_{\kappa(y)}, i_y^* \mathscr{F}) = 0$; moreover, $H := H^0(\mathbb{P}^n_{\kappa(y)}, i_y^* \mathscr{F})$ is a one-dimensional $\kappa(y)$-vector space. From claim 11.4.4, it follows that there exist an open neighborhood V_μ of y in U_μ, and a section $s \in H^0(\pi_\mu^{-1} V_\mu, \mathscr{F})$ mapping to a generator of H. The section s defines a map of $\mathscr{O}_{\mathbb{P}^n_{V_\mu}}$-modules $\varphi : \mathscr{O}_{\mathbb{P}^n_{V_\mu}}(r) \to \mathscr{G}_{\mu|\pi_\mu^{-1} V_\mu}$. Furthermore, since $i_y^* \mathscr{F} \simeq \mathscr{O}_{\mathbb{P}^n_{\kappa(y)}}$, it is easily seen that φ restricts to an isomorphism on some open subset of the form $\pi_\mu^{-1} W_\mu$, where $W_\mu \subset V_\mu$ is an affine open neighborhood of y in U_μ. Then $W := W_\mu \times_{U_\mu} U$ is an affine open neighborhood of x in X, and φ induces an isomorphism $\mathscr{O}_{\mathbb{P}^n_W}(r) \xrightarrow{\sim} \mathscr{G}_{|\pi^{-1} W}$ of $\mathscr{O}_{\mathbb{P}^n_W}$-modules.

Summing up, since $x \in X$ is arbitrary, we may find an affine open covering $X = \bigcup_{i \in I} U_i$, and for every $i \in I$ an integer r_i and an isomorphism $\varphi_i : \mathscr{O}_{\mathbb{P}(\mathscr{E}_i)}(r_i) \xrightarrow{\sim} \mathscr{G}_{|\mathbb{P}(\mathscr{E}_i)}$ of $\mathscr{O}_{\mathbb{P}(\mathscr{E}_i)}$-modules, with $\mathscr{E}_i := \mathscr{E}_{|U_i}$. Then, for every $i, j \in I$ such that $U_{ij} := U_i \cap U_j \neq \varnothing$, the composition of the restriction of φ_i followed by the restriction of φ_j^{-1}, is an isomorphism of $\mathscr{O}_{\mathbb{P}(\mathscr{E}_{ij})}$-modules

$$\varphi_{ij} : \mathscr{O}_{\mathbb{P}(\mathscr{E}_{ij})}(r_i) \xrightarrow{\sim} \mathscr{O}_{\mathbb{P}(\mathscr{E}_{ij})}(r_j) \qquad \text{where } \mathscr{E}_{ij} := \mathscr{E}_{|U_{ij}}.$$

This already implies that $r_i = r_j$ whenever $U_{ij} \neq \varnothing$, hence the rule : $x \mapsto r_i$ if $x \in U_i$ yields a well defined continuous map $r : X \to \mathbb{Z}$. We are therefore easily reduced to the case where r is constant on X, and after tensoring by $\mathscr{O}_{\mathbb{P}(\mathscr{E})}(-r)$, we may even assume that $r = 0$.

In this case, each φ_i is an isomorphism $\varphi_i : \pi_i^*\mathscr{L}_i \xrightarrow{\sim} \mathscr{G}_{|\mathbb{P}(\mathscr{E}_i)}$, where $\pi_i : \mathbb{P}(\mathscr{E}_i) \to U_i$ denotes the restriction of π, and $\mathscr{L}_i$ is an invertible $\mathscr{O}_{U_i}$-module. Then, for each $i, j \in I$ let also $\pi_{ij} : \mathbb{P}(\mathscr{E}_{ij}) \to U_{ij}$ be the restriction of π; we get unique isomorphisms of $\mathscr{O}_{\mathbb{P}(\mathscr{E}_{ij})}$-modules

$$\varphi_{ij} : \pi_{ij}^*\mathscr{L}_{i|U_{ij}} \xrightarrow{\sim} \pi_{ij}^*\mathscr{L}_{j|U_{ij}} \qquad \text{such that} \qquad \varphi_{j|U_{ij}} \circ \varphi_{ij} = \varphi_{i|U_{ij}} \qquad \text{for all } i, j \in I$$

whence a unique system of isomorphisms of $\mathscr{O}_{U_{ij}}$-modules :

$$\psi_{ij} : \mathscr{L}_{i|U_{ij}} \xrightarrow{\sim} \mathscr{L}_{j|U_{ij}} \qquad \text{such that} \qquad \varphi_{ij} = \pi_{ij}^*\psi_{ij} \qquad \text{for every } i, j \in I.$$

Now, for every $i, j, k \in I$ let $U_{ijk} := U_{ij} \cap U_k$ and $\mathscr{E}_{ijk} := \mathscr{E}_{|U_{ijk}}$; it is easily seen that

$$\varphi_{jk|\mathbb{P}(\mathscr{E}_{ijk})} \circ \varphi_{ij|\mathbb{P}(\mathscr{E}_{ijk})} = \varphi_{ik|\mathbb{P}(\mathscr{E}_{ijk})} \quad \text{whence} \quad \psi_{jk|U_{ijk}} \circ \psi_{ij|U_{ijk}} = \psi_{ik|U_{ijk}}.$$

Hence, there exists an invertible $\mathscr{O}_X$-module $\mathscr{L}$ with a system of isomorphisms :

$$(\lambda_i : \mathscr{L}_{|U_i} \xrightarrow{\sim} \mathscr{L}_i \mid i \in I) \qquad \text{such that} \qquad \psi_{ij} \circ \lambda_{i|U_{ij}} = \lambda_{j|U_{ij}} \qquad \text{for every } i, j \in I.$$

It follows that the system of induced isomorphisms :

$$\varphi_i \circ \pi_i^*(\lambda_i) : (\pi^*\mathscr{L})_{|\mathbb{P}(\mathscr{E}_i)} \xrightarrow{\sim} \mathscr{G}_{|\mathbb{P}(\mathscr{E}_i)}$$

glues to yield an isomorphism of $\mathscr{O}_{\mathbb{P}(\mathscr{E})}$-modules $\pi^*\mathscr{L} \xrightarrow{\sim} \mathscr{G}$, and that concludes the proof. □

Corollary 11.4.5. *Let $f : X \to S$ be a smooth morphism of finite presentation, set $\mathbb{G}_{m,X} := X \times_S \operatorname{Spec} K^+[T, T^{-1}]$, and denote by $\pi : \mathbb{G}_{m,X} \to X$ the natural morphism. Then the map*

$$\operatorname{Pic} X \to \operatorname{Pic} \mathbb{G}_{m,X} \qquad \mathscr{L} \mapsto \pi^*\mathscr{L}$$

is an isomorphism.

Proof. To start out, the map is injective, since π admits a section. Next, let $j : \mathbb{G}_{m,X} \to \mathbb{P}^1_X$ be the natural open immersion, and denote again by $\pi : \mathbb{P}^1_X \to X$ the natural projection. According to theorem 10.3.25 and proposition 11.4.2(i), every invertible $\mathscr{O}_{\mathbb{G}_{m,X}}$-module extends to an invertible $\mathscr{O}_{\mathbb{P}^1_X}$-module (namely the determinant of a coherent extension). Since $j^*\mathscr{O}_{\mathbb{P}^1_X}(n) \simeq \mathscr{O}_{\mathbb{G}_{m,X}}$, the claim follows from proposition 11.4.3. □

Remark 11.4.6. The proof of proposition 11.4.3 follows [131, p.20] and [132, Lecture 13, Prop.3]. Of course, statements related to corollary 11.4.5 abound in the literature, and more general results are available: see *e.g.* [16] and [156].

Proposition 11.4.7. *Let $f : X \to S$ be a smooth morphism of finite type, $j : U \to X$ an open immersion, and $Z := X \setminus U$; suppose that X and U are quasi-compact and quasi-separated. Then:*

- (i) *Every invertible $\mathscr{O}_U$-module extends to an invertible $\mathscr{O}_X$-module.*
- (ii) *Suppose furthermore, that:*
  - (a) *For every point $y \in S$, the codimension of $Z \cap f^{-1}(y)$ in $f^{-1}(y)$ is ≥ 1, and*
  - (b) *The codimension of $Z \cap f^{-1}(\eta)$ in $f^{-1}(\eta)$ is ≥ 2.*

  Then the restriction functors:

(11.4.8) $$\mathscr{O}_X\text{-}\mathbf{Rflx} \to \mathscr{O}_U\text{-}\mathbf{Rflx} \qquad \mathbf{Pic}\, X \to \mathbf{Pic}\, U$$

are equivalences.

Proof. (i): First let us notice :

Claim 11.4.9. X is a finite disjoint union of normal integral schemes.

Proof of the claim. Since X is quasi-compact, the assertion is easily reduced to the case where $X = \mathrm{Spec}\, A$, for a smooth K^+-algebra A. Then A is integrally closed in $A_K := K \otimes_{K^+} A$, by proposition 9.8.3, and A_K is smooth over K, so it is a product of finitely many normal domains. The idempotents corresponding to this decomposition are integral over A, hence they lie in A. Thus, A is itself a product of finitely many normal domains, which is the claim. ◊

In view of claim 11.4.9, we may assume from start that X is integral, and then U is either empty (in which case there is nothing to prove), or dense in X, in which case the assertion follows from propositions 11.3.8(i) and 11.4.2(iv).

(ii): We begin with the following:

Claim 11.4.10. Under the assumptions of (ii), the functors (11.4.8) are faithful.

Proof of the claim. Since f is smooth, all the stalks of $\mathscr{O}_X$ are reduced ([66, Ch.IV, Prop.17.5.7]). Since every point of Z is specialization of a point of U, the claim follows easily from remark 11.3.5. ◊

Under assumptions (a) and (b), the conditions of corollary 11.3.9 are fulfilled, and one deduces that (11.4.8) are full functors, hence fully faithful, in view of claim 11.4.10. The essential surjectivity of the restriction functor for reflexive $\mathscr{O}_X$-modules is already known, by proposition 11.3.8(i). □

Lemma 11.4.11. *Let $f : X \to S$ be a flat, finitely presented morphism, and denote by $U \subset X$ the maximal open subset such that the restriction $f_{|U} : U \to S$ is smooth. Suppose that the following two conditions hold:*

(a) *For every point $y \in S$, the fibre $f^{-1}(y)$ is geometrically reduced.*

(b) *The generic fibre $f^{-1}(\eta)$ is geometrically normal.*

Then the restriction functor induces an equivalence of categories (notation of (11.3.10)*) :*

$$\mathbf{Div}\, X \xrightarrow{\sim} \mathbf{Pic}\, U. \tag{11.4.12}$$

Proof. Let $\mathscr{F}$ be any generically invertible reflexive $\mathscr{O}_X$-module; it follows from proposition 11.4.2(iv) that $\mathscr{F}_{|U}$ is an invertible $\mathscr{O}_U$-module, so the functor (11.4.12) is well defined. Let $y \in S$ be any point; condition (a) says in particular that the fibre $f^{-1}(y)$ is generically smooth over $\kappa(y)$ ([126, Th.28.7]). Then it follows from [66, Ch.IV, Th.17.5.1] that $U \cap f^{-1}(y)$ is a dense open subset of $f^{-1}(y)$, and if $x \in f^{-1}(y)\backslash U$, then the depth of $\mathscr{O}_{f^{-1}(y),x}$ is ≥ 1, since the latter is a reduced local ring of dimension ≥ 1. Similarly, condition (b) and Serre's criterion [126, Ch.8, Th.23.8] say that for every $x \in f^{-1}(\eta)\backslash U$, the local ring $\mathscr{O}_{f^{-1}(\eta),x}$ has depth ≥ 2. Furthermore, [65, Ch.IV, Prop.9.9.4] implies that the open immersion $j : U \to X$ is quasi-compact; summing up, we see that all the conditions of corollary 11.3.9 are fulfilled, so that $\mathscr{F} = j_*j^*\mathscr{F}$ for every reflexive $\mathscr{O}_X$-module $\mathscr{F}$. This already means that (11.4.12) is fully faithful. To conclude, it suffices to invoke proposition 11.3.8(i). □

11.4.13. Let $K(\mathsf{T})$ be the fraction field of the free polynomial K-algebra $K[\mathsf{T}]$. For every $\gamma \in \Gamma$ one can define an extension of $|\cdot|$ to a *Gauss valuation* $|\cdot|_{0,\gamma} : K(\mathsf{T}) \to \Gamma$ ([75, Ex.6.1.4(iii)]). If $f(\mathsf{T}) := \sum_{i=0}^{d} a_i \mathsf{T}^i$ is any polynomial, then $|f(\mathsf{T})|_{0,\gamma} = \max\{|a_i| \cdot \gamma^i \mid i = 0, \dots, d\}$. We let $V(\gamma)$ be the valuation ring of $|\cdot|_{0,\gamma}$, and set

$$R(\gamma) := K[\mathsf{T}, \mathsf{T}^{-1}] \cap V(1) \cap V(\gamma).$$

Since $K[\mathsf{T}, \mathsf{T}^{-1}]$ is a Dedekind domain, $R(\gamma)$ is an intersection of valuation rings of the field $K(\mathsf{T})$, hence it is a normal domain. By inspecting the definition we see that $R(\gamma)$ consists of all the elements of the form $f(\mathsf{T}) := \sum_{i=-n}^{n} a_i \mathsf{T}^i$, such that $|a_i| \leq 1$ and $|a_i| \cdot \gamma^i \leq 1$ for every $i = -n, \dots, n$. Suppose now that $\gamma \leq 1$, and choose $c \in K^+$ with $|c| = \gamma$; then every such $f(\mathsf{T})$ can be written uniquely in the form $\sum_{i=0}^{n} a_i \mathsf{T}^i + \sum_{j=1}^{n} b_j (c\mathsf{T}^{-1})^j$, where $a_i, b_j \in K^+$ for every $i, j \leq n$. Conversely, every such expression yields an element of $R(\gamma)$. In other words, we obtain a surjection of K^+-algebras $K^+[\mathsf{X}, \mathsf{Y}] \to R(\gamma)$ by the rule: $\mathsf{X} \mapsto \mathsf{T}$, $\mathsf{Y} \mapsto c\mathsf{T}^{-1}$. Obviously the kernel of this map contains the ideal $(\mathsf{XY} - c)$, and we leave to the reader the verification that the induced map

$$K^+[\mathsf{X}, \mathsf{Y}]/(\mathsf{XY} - c) \to R(\gamma) \qquad (11.4.14)$$

is indeed an isomorphism.

11.4.15. Throughout the following discussion, we shall assume that $\gamma \leq 1$. Every $\delta \in \Gamma$ with $\gamma \leq \delta \leq 1$, determines a prime ideal $\mathfrak{p}(\delta) := \{f \in R(\gamma) \mid |f|_{0,\delta} < 1\} \subset R(\gamma)$, such that $\mathfrak{m}_K R(\gamma) \subset \mathfrak{p}(\delta)$. Then it is easy to see that $R(\gamma)_{\mathfrak{p}(\delta)} \subset V(\delta)$, and moreover :

$$R(\gamma)_{\mathfrak{p}(\gamma)} = V(\gamma) \qquad R(\gamma)_{\mathfrak{p}(1)} = V(1)$$

since $V(1)$ (resp. $V(\gamma)$) is already a localization of $K^+[\mathsf{T}]$ (resp. of $K^+[c\mathsf{T}^{-1}]$). In case $\gamma < 1$, (11.4.14) implies that $R(\gamma) \otimes_{K^+} \kappa \simeq \kappa[\mathsf{X}, \mathsf{Y}]/(\mathsf{XY})$, and it follows easily that $\mathfrak{p}(1)$ and $\mathfrak{p}(\gamma)$ correspond to the two minimal prime ideals of $\kappa[\mathsf{X}, \mathsf{Y}]/(\mathsf{XY})$. In case $\gamma = 1$, we have $R(1) \otimes_{K^+} \kappa \simeq \kappa[\mathsf{X}, \mathsf{X}^{-1}]$, and again $\mathfrak{p}(1)$ corresponds to the generic point of $\mathrm{Spec}\, \kappa[\mathsf{X}, \mathsf{X}^{-1}]$. Notice that the natural morphism

$$f_\gamma : \mathbb{T}_K(\gamma) := \mathrm{Spec}\, R(\gamma) \to S$$

restricts to a smooth morphism $f_\gamma^{-1}(\eta) \to \mathrm{Spec}\, K$; moreover the closed fibre $f_\gamma^{-1}(s)$ is geometrically reduced. Notice also that $\mathbb{T}_K(\gamma) \times_S \mathrm{Spec}\, E^+ \simeq \mathbb{T}_E(\gamma)$ for every extension of valued fields $K \subset E$. In the following, we will write just $\mathbb{T}(\gamma)$ in place of $\mathbb{T}_K(\gamma)$, unless we have to deal with more than one base ring.

Proposition 11.4.16. *Keep the notation of* (11.4.15)*, and let $g : X \to \mathbb{T}(\gamma)$ be an étale morphism, $\mathscr{F}$ a coherent $\mathscr{O}_X$-module. Set $h := f_\gamma \circ g : X \to S$ and denote by $i_s : h^{-1}(s) \to X$ the natural morphism. Then $\mathscr{F}$ is reflexive at the point $x \in h^{-1}(s)$ if and only if the following three conditions hold:*

(a) *$\mathscr{F}$ is h-flat at the point x.*
(b) *$\mathscr{F}_x \otimes_{K^+} K$ is a reflexive $\mathscr{O}_{X,x} \otimes_{K^+} K$-module.*
(c) *The $\mathscr{O}_{h^{-1}(s),x}$-module $i_s^* \mathscr{F}_x$ satisfies condition S_1 (see definition* 10.5.1(iii)*).*

Proof. Suppose that $\mathscr{F}$ is reflexive at the point x; then it is easy to check that (a) and (b) hold. We prove (c): by remark 11.3.5 we can find a left exact sequence

$$0 \to \mathscr{F}_x \xrightarrow{\alpha} \mathscr{O}_{X,x}^{\oplus m} \xrightarrow{\beta} \mathscr{O}_{X,x}^{\oplus n}.$$

Then $\mathrm{Im}\, \beta$ is a flat K^+-module, since it is a submodule of the flat K^+-module $\mathscr{O}_{X,x}^{\oplus n}$; hence $\alpha \otimes_{K^+} \mathbf{1}_\kappa : i_s^* \mathscr{F}_x \to \mathscr{O}_{h^{-1}(s),x}^{\oplus m}$ is still injective, so we are reduced to showing that $h^{-1}(s)$ is a reduced scheme, which follows from [66, Ch.IV, Prop.17.5.7] and the fact that $f_\gamma^{-1}(s)$ is reduced.

Conversely, suppose that conditions (a)–(c) hold.

Claim 11.4.17. Let ξ be the generic point of an irreducible component of $h^{-1}(s)$. Then:

(i) $\mathscr{F}_x$ is a torsion-free $\mathscr{O}_{X,x}$-module.
(ii) $\mathscr{O}_{X,\xi}$ is a valuation ring.
(iii) Suppose that the closure of ξ contains x. Then $\mathscr{F}_\xi$ is a free $\mathscr{O}_{X,\xi}$-module of finite rank.

Proof of the claim. (i): By (a), the natural map $\mathscr{F}_x \to \mathscr{F}_x \otimes_{K^+} K$ is injective; since (b) implies that $\mathscr{F}_x \otimes_{K^+} K$ is a torsion-free $\mathscr{O}_{X,x}$-module, the same must then hold for $\mathscr{F}_x$.

(ii) follows from proposition 9.1.34(ii).

(iii): Suppose that $x \in \overline{\{\xi\}}$. We derive easily from (i) that $\mathscr{F}_\xi$ is a torsion-free $\mathscr{O}_{X,\xi}$-module, so the assertion follows from (ii) and [34, Ch.VI, §3, n.6, Lemma 1]. ♢

By (b), the morphism $\beta_{\mathscr{F},x} \otimes_{K^+} \mathbf{1}_K : \mathscr{F}_x \otimes_{K^+} K \to \mathscr{F}_x^{\vee\vee} \otimes_{K^+} K$ is an isomorphism (notation of (11.3)); since $\mathscr{F}$ is h-flat at x, we deduce easily that $\beta_{\mathscr{F},x}$ is injective and $C := \operatorname{Coker} \beta_{\mathscr{F},x}$ is a torsion K^+-module. To conclude, it remains only to show:

Claim 11.4.18. C is a flat K^+-module.

Proof of the claim. In view of lemma 7.11.35, it suffices to show that $\operatorname{Tor}_1^{K^+}(C, \kappa(s)) = 0$. However, from the foregoing we derive a left exact sequence

$$0 \longrightarrow \operatorname{Tor}_1^{K^+}(C, \kappa(s)) \longrightarrow \mathscr{F}_x \otimes_{K^+} \kappa(s) \xrightarrow{\beta_{\mathscr{F},x} \otimes_{K^+} \kappa(s)} \mathscr{F}_x^{\vee\vee} \otimes_{K^+} \kappa(s).$$

We are thus reduced to showing that $\beta_{\mathscr{F},x} \otimes_{K^+} \kappa(s)$ is an injective map. In view of condition (c), it then suffices to prove that $\beta_{\mathscr{F},\xi}$ is an isomorphism, whenever ξ is the generic point of an irreducible component of $h^{-1}(s)$ containing x. The latter assertion holds by virtue of claim 11.4.17(iii). □

11.4.19. For a given $\rho \in \Gamma$, let us pick $a \in K \setminus \{0\}$ such that $|a| = \rho$; we define the fractional ideal $I(\rho) \subset K[\mathsf{T}, \mathsf{T}^{-1}]$ as the $R(\gamma)$-submodule generated by T and a. The module $I(\rho)$ determines a quasi-coherent $\mathscr{O}_{\mathbb{T}(\gamma)}$-module $\mathscr{I}(\rho)$.

Lemma 11.4.20. *With the notation of* (11.4.19)*:*

(i) *$\mathscr{I}(\rho)$ is a reflexive $\mathscr{O}_{\mathbb{T}(\gamma)}$-module for every $\rho \in \Gamma$.*

(ii) *There exists a short exact sequence of $R(\gamma)$-modules:*

$$0 \to I(\rho^{-1}\gamma) \to R(\gamma)^{\oplus 2} \to I(\rho) \to 0.$$

Proof. To start with, let $a \in K \setminus \{0\}$ with $|a| = \rho$.

Claim 11.4.21. If either $\rho \geq 1$ or $\rho \leq \gamma$, then $I(\rho)$ and $I(\rho^{-1}\gamma)$ are rank one, free $R(\gamma)$-modules.

Proof of the claim. If $\rho \geq 1$ (resp. $\rho \leq \gamma$) then $\rho^{-1}\gamma \leq \gamma$ (resp. $\rho^{-1}\gamma \geq 1$), hence it suffices to show that $I(\rho)$ is free of rank one, in both cases. Suppose first that $\rho \geq 1$; in this case, multiplication by a^{-1} yields an isomorphism of $R(\gamma)$-modules $I(\rho) \xrightarrow{\sim} R(\gamma)$. Next, suppose that $\rho \leq \gamma$. Then $I(\rho)$ is the ideal (T, a), where $a = c \cdot b$ for some $b \in K^+$ and $|c| = \gamma$. Therefore $I(\rho) = (\mathsf{T}, \mathsf{T} \cdot (c\mathsf{T}^{-1}) \cdot b) = \mathsf{T} \cdot (1, c\mathsf{T}^{-1}b) = \mathsf{T}R(\gamma)$, and again $I(\rho)$ is a free $R(\gamma)$-module of rank one. ♢

In view of claim 11.4.21, we may assume that $\gamma < \rho < 1$. Let (e_1, e_2) be the canonical basis of the free $R(\gamma)$-module $R(\gamma)^{\oplus 2}$; we consider the $R(\gamma)$-linear surjection $\pi : R(\gamma)^{\oplus 2} \to I(\rho)$ determined by the rule: $e_1 \mapsto \mathsf{T}$, $e_2 \mapsto a$. Clearly $\operatorname{Ker} \pi$ contains the submodule $M(\rho) \subset R(\gamma)^{\oplus 2}$ generated by:

$$f_1 := ae_1 - \mathsf{T}e_2 \quad \text{and} \quad f_2 := c\mathsf{T}^{-1}e_1 - ca^{-1}e_2.$$

Let $\mathscr{N}$ be the quasi-coherent $\mathscr{O}_{\mathbb{T}(\gamma)}$-module associated with $N := R(\gamma)^{\oplus 2}/M(\rho)$.

Claim 11.4.22. With the foregoing notation:

(i) N is a flat K^+-module.

(ii) $K^+[c^{-1}] \otimes_{K^+} N$ is a free $K^+[c^{-1}] \otimes_{K^+} R(\gamma)$-module of rank one.

(iii) $K \otimes_{K^+} M(\rho) = K \otimes_{K^+} \operatorname{Ker} \pi$.

Proof of the claim. (i): We let $\mathrm{gr}_\bullet R(\gamma)$ be the T-adic grading on $R(\gamma)$ (*i.e.* $\mathrm{gr}_i R(\gamma) = \mathsf{T}^i \cdot K \cap R(\gamma)$ for every $i \in \mathbb{Z}$), and we define a compatible grading on $R(\gamma)^{\oplus 2}$ by setting: $\mathrm{gr}_i R(\gamma)^{\oplus 2} := (\mathrm{gr}_{i-1} R(\gamma) \cdot e_1) \oplus (\mathrm{gr}_i R(\gamma) \cdot e_2)$ for every $i \in \mathbb{Z}$. Since f_1 and f_2 are homogeneous elements, we deduce by restriction a grading $\mathrm{gr}_\bullet M(\rho)$ on $M(\rho)$, and a quotient grading $\mathrm{gr}_\bullet N$ on N, whence a short exact sequence of graded K^+-modules:

$$0 \to \mathrm{gr}_\bullet M(\rho) \xrightarrow{\mathrm{gr}_\bullet j} \mathrm{gr}_\bullet R(\gamma)^{\oplus 2} \to \mathrm{gr}_\bullet N \to 0.$$

However, by inspecting the definitions, it is easy to see that $\mathrm{gr}_\bullet j$ is a split injective map of free K^+-modules, hence $\mathrm{gr}_\bullet N$ is a free K^+-module, and then the same holds for N.

(ii) is easy and shall be left to the reader.

(iii): Similarly, one checks easily that $K \otimes_{K^+} I(\rho)$ is a free $K \otimes_{K^+} R(\gamma)$-module of rank one; then, by (ii) the quotient map $K \otimes_{K^+} N \to K \otimes_{K^+} I(\rho)$ is necessarily an isomorphism, whence the assertion. ◊

Claim 11.4.23. $\mathscr{N}$ is a reflexive $\mathscr{O}_{\mathbb{T}(\gamma)}$-module.

Proof of the claim. Since $\mathscr{N}$ is coherent, it suffices to show that $\mathscr{N}_x$ is a reflexive $\mathscr{O}_{\mathbb{T}(\gamma),x}$-module, for every $x \in \mathbb{T}(\gamma)$ (lemma 11.3.2(ii)). Let $y := f_\gamma(x)$; we may then replace $\mathscr{N}$ by its restriction to $\mathbb{T}(\gamma) \times_S S(y)$, which allows to assume that $y = s$ is the closed point of S. In this case, we can apply the criterion of proposition 11.4.16 to the morphism $f_\gamma : \mathbb{T}(\gamma) \to S$. We already know from claim 11.4.22(i) that $\mathscr{N}$ is f_γ-flat. Moreover, by claim 11.4.22(ii) we see that the restriction of $\mathscr{N}$ to $f_\gamma^{-1}(\eta)$ is reflexive. As $\gamma < \rho < 1$, by inspecting the definition and using the presentation (11.4.14), we deduce an isomorphism :

$$\kappa \otimes_{K^+} N \simeq \overline{R}^{\oplus 2}/(\mathsf{X}e_2, \mathsf{Y}e_1) \simeq (\overline{R}/\mathsf{X}\overline{R}) \oplus (\overline{R}/\mathsf{Y}\overline{R})$$

where $\overline{R} := \kappa[\mathsf{X}, \mathsf{Y}]/(\mathsf{XY}) \simeq \kappa \otimes_{K^+} R(\gamma)$. Thus, the $\overline{R}$-module $\kappa \otimes_{K^+} N$ satisfies condition S_1, whence the claim. ◊

It follows from claim 11.4.22(i,iii) that the quotient map $N \to I(\rho)$ is an isomorphism, so $\mathscr{I}(\rho)$ is reflexive, by claim 11.4.23. Next, let us define an $R(\gamma)$-linear surjection $\pi' : R(\gamma)^{\oplus 2} \to M(\rho)$ by the rule: $e_i \mapsto f_i$ for $i = 1, 2$. One checks easily that $\mathrm{Ker}\, \pi'$ contains the submodule generated by the elements $ca^{-1}e_1 - Te_2$ and $ce_1 - aTe_2$, and the latter is none else than the module $M(\rho^{-1}\gamma)$, according to our notation (notice that $\gamma < \rho^{-1}\gamma < 1$). We deduce a surjection of torsion-free $R(\gamma)$-modules $I(\rho^{-1}\gamma) \xrightarrow{\sim} R(\gamma)^{\oplus 2}/M(\rho^{-1}\gamma) \to M(\rho)$, which induces an isomorphism after tensoring by K, therefore $I(\rho^{-1}\gamma) \xrightarrow{\sim} M(\rho)$, which establishes (ii). □

11.4.24. Let $\mathbb{T}(\gamma)_{\mathrm{sm}} \subset \mathbb{T}(\gamma)$ be the largest open subset which is smooth over S. Set $S_\gamma := \mathrm{Spec}\, K^+/cK^+$; it is easy to see that $f_\gamma^{-1}(S \setminus S_\gamma) \subset \mathbb{T}(\gamma)_{\mathrm{sm}}$, and for every $y \in S_\gamma$, the difference $f_\gamma^{-1}(y) \setminus \mathbb{T}(\gamma)_{\mathrm{sm}}$ consists of a single point.

Proposition 11.4.25. *Let $\Delta(\gamma) \subset \Gamma$ be the smallest convex subgroup containing γ. Then there is a natural isomorphism of groups:*

$$\mathrm{Pic}\, \mathbb{T}(\gamma)_{\mathrm{sm}} \xrightarrow{\sim} \Delta(\gamma)/\gamma^{\mathbb{Z}}.$$

Proof. We consider the affine covering of $\mathbb{T}(\gamma)_{\mathrm{sm}}$ consisting of the two open subsets

$$U := \mathrm{Spec}\, K^+[\mathsf{T}, \mathsf{T}^{-1}] \qquad \text{and} \qquad V := \mathrm{Spec}\, K^+[c\mathsf{T}^{-1}, c^{-1}\mathsf{T}]$$

with intersection $U \cap V = \mathrm{Spec}\, K^+[c^{-1}, \mathsf{T}, \mathsf{T}^{-1}]$. We notice that both U and V are S-isomorphic to $\mathbb{G}_{m,S}$, and therefore

$$\mathrm{Pic}\, U = \mathrm{Pic}\, V = 0 \tag{11.4.26}$$

by corollary 11.4.5. From (11.4.26), a standard computation yields a natural isomorphism:

$$\mathrm{Pic}\, \mathbb{T}(\gamma)_{\mathrm{sm}} \xrightarrow{\sim} \mathscr{O}_{\mathbb{T}(\gamma)}(U)^\times \backslash \mathscr{O}_{\mathbb{T}(\gamma)}(U \cap V)^\times / \mathscr{O}_{\mathbb{T}(\gamma)}(V)^\times.$$

(Here, for a ring A, the notation $A^\times$ means the invertible elements of A.) However, $\mathscr{O}_{\mathbb{T}(\gamma)}(U)^\times = (K^+)^\times \cdot (c\mathsf{T}^{-1})^{\mathbb{Z}}$, $\mathscr{O}_{\mathbb{T}(\gamma)}(U \cap V)^\times = (K^+[c^{-1}])^\times \cdot \mathsf{T}^{\mathbb{Z}}$ and $\mathscr{O}_{\mathbb{T}(\gamma)}(V) = (K^+)^\times \cdot \mathsf{T}^{\mathbb{Z}}$, whence the contention. □

11.4.27. Proposition 11.4.25 establishes a natural bijection between the set of isomorphism classes of invertible $\mathscr{O}_{\mathbb{T}(\gamma)_{\mathrm{sm}}}$-modules and the set :

$$]\gamma, 1] := \{\rho \in \Gamma \mid \gamma < \rho < 1\} \cup \{1\}.$$

On the other hand, lemma 11.4.11 yields a natural bijection between $\mathrm{Pic}\, \mathbb{T}(\gamma)_{\mathrm{sm}}$ and the set of isomorphism classes of generically invertible reflexive $\mathscr{O}_{\mathbb{T}(\gamma)}$-modules. Furthermore, lemma 11.4.20 provides already a collection of such reflexive modules, and by inspection of the proof, we see that the family of sheaves $\mathscr{I}(\rho)$ is really parametrized by the subset $]\gamma, 1]$ (since the other values of ρ correspond to free $\mathscr{O}_{\mathbb{T}(\gamma)}$-modules of rank one). The two parametrizations are essentially equivalent. Indeed, let $a \in K \setminus \{0\}$ be any element such that $\rho := |a| \in]\gamma, 1]$. With the notation of the proof of proposition 11.4.25, we can define isomorphisms

$$\varphi : \mathscr{O}_U \xrightarrow{\sim} \mathscr{I}(\rho)_{|U} \qquad \psi : \mathscr{O}_V \xrightarrow{\sim} \mathscr{I}(\rho)_{|V}$$

by letting: $\varphi(1) := \mathsf{T}$ and $\psi(1) := a$. To verify that φ is an isomorphism, it suffices to remark that T is a unit on U, so $\mathscr{I}(\rho)_{|U} = \mathsf{T}\mathscr{O}_U = \mathscr{O}_U$. Likewise, on V we can write $\mathsf{T} = a \cdot (a^{-1}c) \cdot (c^{-1}\mathsf{T})$, so $\mathscr{I}(\rho)_{|V} = a\mathscr{O}_V$, and ψ is an isomorphism. Hence $\mathscr{I}(\rho)$ is isomorphic to the (unique) $\mathscr{O}_{\mathbb{T}(\gamma)}$-module whose global sections consist of all the pairs $(s_U, s_V) \in \mathscr{O}_U(U) \times \mathscr{O}_V(V)$, such that $\mathsf{T}^{-1}s_{U|U\cap V} = a^{-1}s_{V|U\cap V}$. Clearly, under the bijection of proposition 11.4.25, the invertible sheaf $\mathscr{I}(\rho)_{|\mathbb{T}(\gamma)_{\mathrm{sm}}}$ corresponds to the class of ρ in $\Delta(\gamma)/\gamma^{\mathbb{Z}}$. In particular, this shows that the reflexive $\mathscr{O}_{\mathbb{T}(\gamma)}$-modules $\mathscr{I}(\rho)$ are pairwise non-isomorphic for $\rho \in]\gamma, 1]$, and that every reflexive generically invertible $\mathscr{O}_{\mathbb{T}(\gamma)}$-module is isomorphic to one such $\mathscr{I}(\rho)$.

11.4.28. When $\gamma < 1$ and $t \in \mathbb{T}(\gamma)$ is the singular point of the closed fibre, the discussion of (11.4.27) also applies to describe the set $\overline{\mathrm{coh.Div}}(\mathscr{O}_{\mathbb{T}(\gamma),t})$ of isomorphism classes of coherent reflexive fractional ideals of $\mathscr{O}_{\mathbb{T}(\gamma),t}$ (remark 11.3.11(ii)). Indeed, any such module M extends to a reflexive $\mathscr{O}_{\mathbb{T}(\gamma)}$-module (first one uses lemma 11.3.7(ii.b) to extend M to some quasi-compact open subset $U \subset \mathbb{T}(\gamma)$, and then one may extend to the whole of $\mathbb{T}(\gamma)$, via proposition 11.3.8)(i). Hence $M \simeq \mathscr{I}(\rho)_t$ for some $\rho \in]\gamma, 1]$. It follows already that $\mathrm{coh.Div}(\mathscr{O}_{\mathbb{T}(\gamma),t})$ is naturally an abelian group, with multiplication law given by the rule :

$$(M, N) \mapsto M \odot N := j_*j^*(M \otimes_{\mathscr{O}_{\mathbb{T}(\gamma),t}} N) \qquad \text{for any two classes } M, N \in \mathrm{Div}(\mathscr{O}_{\mathbb{T}(\gamma),t})$$

where $j : \mathbb{T}(\gamma)_{\mathrm{sm}} \cap \mathrm{Spec}\, \mathscr{O}_{\mathbb{T}(\gamma),t} \to \mathrm{Spec}\, \mathscr{O}_{\mathbb{T}(\gamma),t}$ is the natural open immersion. Indeed, $M \odot N$ is reflexive (by proposition 11.3.8(i) and corollary 11.3.9), and the composition law $\odot$ is clearly associative and commutative, with $\mathscr{O}_{\mathbb{T}(\gamma),t}$ as neutral element; moreover, for any $\rho \in \Delta(\gamma)$, the class of $\mathscr{I}(\rho)_t$ admits the inverse $j_*((j^*\mathscr{I}(\rho)_t)^\vee)$. Furthermore, the modules $\mathscr{I}(\rho)_t$ are pairwise non-isomorphic for $\rho \in]\gamma, 1]$. Indeed, using the group law $\odot$, the assertion follows once we know that $\mathscr{I}(\rho)_t$ is not trivial, whenever $\rho \in]\gamma, 1[$. However, from the presentation of lemma 11.4.20(ii) one sees that $\mathscr{I}(\rho)_t \otimes_{\mathscr{O}_{\mathbb{T}(\gamma),t}} \kappa(t)$ is a two-dimensional $\kappa(t)$-vector space, so everything is clear. Moreover, a simple inspection shows that the composition law $\odot$ thus defined, agrees with the composition law of the monoid $\mathrm{coh.Div}(\mathscr{O}_{T(\gamma),t})$ given in remark 11.3.11(ii). Summing, we get a natural group isomorphism :

$$\overline{\mathrm{coh.Div}}(\mathscr{O}_{\mathbb{T}(\gamma),t}) \xrightarrow{\sim} \Delta(\gamma)/\gamma^{\mathbb{Z}}.$$

The following theorem generalizes this classification to reflexive modules of arbitrary generic rank.

Theorem 11.4.29. *Let $g : X \to \mathbb{T}(\gamma)$ be a pro-étale morphism, $x \in X$ any point, M a reflexive $\mathscr{O}_{X,x}$-module. Then there exist $\rho_1, \dots, \rho_n \in]\gamma, 1]$ and an isomorphism of $\mathscr{O}_{X,x}$-modules:*

$$M \xrightarrow{\sim} \bigoplus_{i=1}^{n} g^*\mathscr{I}(\rho_i)_x.$$

Proof. Using lemma 11.3.7(ii.b), we are easily reduced to the case where g is étale. Set $t := g(x)$; first of all, if $t \in \mathbb{T}(\gamma)_{\mathrm{sm}}$, then X is smooth over S at the point t, and consequently M (resp. $\mathscr{I}(\rho)_t$) is a free $\mathscr{O}_{X,x}$-module (resp. $\mathscr{O}_{\mathbb{T}(\gamma),t}$-module) of finite rank (by proposition 11.4.2(iii)), so the assertion is obvious in this case. Hence we may assume that $\gamma < 1$ and t is the unique point in the closed fibre of $\mathbb{T}(\gamma) \setminus \mathbb{T}(\gamma)_{\mathrm{sm}}$. Next, let $K^{\mathrm{sh}+}$ be the strict henselization of K^+; denote by $h : \mathbb{T}_{K^{\mathrm{sh}}}(\gamma) \to \mathbb{T}_K(\gamma)$ the natural map, and set $X' := X \times_{\mathbb{T}_K(\gamma)} \mathbb{T}_{K^{\mathrm{sh}}}(\gamma)$. Choose also a point $x' \in X'$ lying over x, and let $t' \in \mathbb{T}_{K^{\mathrm{sh}}}(\gamma)$ be the image of x'; then t' is the unique point of $\mathbb{T}_{K^{\mathrm{sh}}}(\gamma)$ with $h(t') = t$. We have a commutative diagram of ring homomorphisms:

$$\begin{array}{ccc} \mathscr{O}_{\mathbb{T}(\gamma),t} & \xrightarrow{g_x^\natural} & \mathscr{O}_{X,x} \\ {\scriptstyle h_t^\natural}\downarrow & & \downarrow \\ \mathscr{O}_{\mathbb{T}_{K^{\mathrm{sh}}}(\gamma),t'} & \longrightarrow & \mathscr{O}_{X',x'} \end{array}$$

whence an essentially commutative diagram of functors:

$$\begin{array}{ccc} \mathscr{O}_{\mathbb{T}(\gamma),t}\text{-}\mathbf{Rflx} & \xrightarrow{g_x^*} & \mathscr{O}_{X,x}\text{-}\mathbf{Rflx} \\ {\scriptstyle h_t^*}\downarrow & & \downarrow{\scriptstyle \beta} \\ \mathscr{O}_{\mathbb{T}_{K^{\mathrm{sh}}}(\gamma),t'}\text{-}\mathbf{Rflx} & \xrightarrow{\alpha} & \mathscr{O}_{X',x'}\text{-}\mathbf{Rflx}. \end{array}$$

Since K and K^{sh} have the same value group, the discussion in (11.4.28) shows that h_t^* induces bijections on the isomorphism classes of generically invertible modules. On the other hand, proposition 7.11.12 implies that the functor β induces injections on isomorphism classes. Consequently, in order to prove the theorem, we may replace the pair (X, x) by (X', x'), and assume from start that $K = K^{\mathrm{sh}}$.

In terms of the presentation 11.4.14 we can write $\mathbb{T}(\gamma) \times_S \operatorname{Spec} \kappa(s) = Z_1 \cup Z_2$, where Z_1 (resp. Z_2) is the reduced irreducible component on which X (resp. Y) vanishes. By inspecting the definitions, it is easy to check that $Z_1 \simeq \mathbb{A}^1_\kappa \simeq Z_2$ as κ-schemes. Let ξ_i be the generic point of Z_i, for $i = 1, 2$; clearly $\{t\} = Z_1 \cap Z_2$, hence $W_i := X \times_{\mathbb{T}(\gamma)} Z_i$ is non-empty and étale over Z_i, so $\mathscr{O}_{W_i,x}$ is an integral domain, hence $g^{-1}(\xi_i)$ contains exactly one point ζ_i that specializes to x, for both $i = 1, 2$. To ease notation, let us set $A := \mathscr{O}_{X,x}$. Then $\operatorname{Spec} A \otimes_{K^+} \kappa$ consists of exactly three points, namely x, ζ_1 and ζ_2. Set $M(\zeta_i) := M \otimes_A \kappa(\zeta_i)$, and notice that $n := \dim_{\kappa(\zeta_1)} M(\zeta_1) = \dim_{\kappa(\zeta_2)} M(\zeta_2)$, since M restricts to a locally free module over $(\operatorname{Spec} A)_{\mathrm{sm}}$, the largest essentially smooth open S-subscheme of $\operatorname{Spec} A$, which is connected. We choose a basis $\overline{e}_1, \dots, \overline{e}_n$ (resp $\overline{e}'_1, \dots, \overline{e}'_n$) for $M(\zeta_1)^\vee$ (resp. $M(\zeta_2)^\vee$), which we can then lift to a system of sections $e_1, \dots, e_n \in M^\vee_{\zeta_1} := M^\vee \otimes_A \mathscr{O}_{X,\zeta_1}$ (and likewise we construct a system $e'_1, \dots, e'_n \in M^\vee_{\zeta_2}$). Let $\mathfrak{p}_i \subset A$ be the prime ideal corresponding to ζ_i ($i = 1, 2$); after multiplication by an element of $A \setminus \mathfrak{p}_i$, we may assume that $e_1, \dots, e_n \in M^\vee$ (and likewise for $e'_1, \dots, e'_n$). Finally, we set $e''_i := \mathsf{Y}e_i + \mathsf{X}e'_i$ for every $i = 1, \dots, n$; it is clear that the system $(e''_1, \dots, e''_n)$ induces bases of $M(\zeta_i)^\vee$ for both $i = 1, 2$. We wish to consider the map:

$$j : M \to A^{\oplus n} \qquad m \mapsto (e''_1(m), \dots, e''_n(m)).$$

Set $C := \operatorname{Coker} j$, $I := \operatorname{Ann}_A C$, and $B := A/I$.

Claim 11.4.30. (i) The maps $M_{\zeta_i} \to \mathscr{O}^{\oplus n}_{X,\zeta_i}$ induced by j are isomorphisms.
(ii) $\mathrm{Ker}\, j = \mathrm{Ker}\, j \otimes_A \mathbf{1}_\kappa = 0$.
(iii) B is a finitely presented K^+-module, and C is a free K^+-module of finite rank.

Proof of the claim. (i): Using Nakayama's lemma, one deduces easily that these maps are surjective; since M_{ζ_i} is a free $\mathscr{O}_{X,\zeta_i}$-module of rank n, they are also necessarily injective.

(ii): Since $\mathscr{O}_{X,x}$ is normal, $\{0\}$ is its only associated prime; then the injectivity of j (resp. of $j \otimes_A \mathbf{1}_\kappa$) follows from (i), and the fact that M (resp. $M \otimes_A \kappa$) satisfies condition S_1, by remark 11.3.5 (resp. by proposition 11.4.16).

(iii): First of all, since A is coherent, I is a finitely generated ideal of A. Let $f : \mathrm{Spec}\, B \to \mathrm{Spec}\, K^+$ be the natural morphism. Since C is a finitely presented A-module, its support Z is a closed subset of $\mathrm{Spec}\, A$. From (i) we see that $Z \cap \mathrm{Spec}\, A \otimes_{K^+} \kappa \subset \{x\}$; on the other hand, Z is also the support of the closed subscheme $\mathrm{Spec}\, B$ of $\mathrm{Spec}\, A$. Therefore

$$f^{-1}(s) \cap \mathrm{Spec}\, B \subset \{x\}. \tag{11.4.31}$$

Since K^+ is henselian, it follows easily from (11.4.31) and [66, Ch.IV, Th.18.5.11(c″)] that B is a finite K^+-algebra of finite presentation, hence also a finitely presented K^+-module (claim 9.1.35). Since C is a finitely presented B-module, we conclude that C is finitely presented as K^+-module, as well. From (ii) we deduce a short exact sequence: $0 \to M \to A^{\oplus n} \to C \to 0$, and then the long exact Tor sequence yields: $\mathrm{Tor}^A_1(C, \kappa) = 0$ (cp. the proof of claim 11.4.18). We conclude by [34, Ch.II, §3, n.2, Cor.2 of Prop.5]. ◊

Claim 11.4.32. The composed morphism: $\mathrm{Spec}\, B \to \mathrm{Spec}\, A \to \mathbb{T}(\gamma)$ is a closed immersion.

Proof of the claim. Let $\mathfrak{p} \subset R(\gamma)$ be the maximal ideal corresponding to t, so that $\mathscr{O}_{\mathbb{T}(\gamma),t} = R(\gamma)_\mathfrak{p}$. From claim 11.4.30(iii) we see that the natural morphism $\psi : R(\gamma)_\mathfrak{p} \to B$ is finite. Moreover, $A/\mathfrak{p}A \simeq R(\gamma)/\mathfrak{p}$, hence $\psi \otimes_{R(\gamma)} \mathbf{1}_{R(\gamma)/\mathfrak{p}}$ is a surjection. By Nakayama's lemma we deduce that ψ is already a surjection, *i.e.* the induced morphism $\mathrm{Spec}\, B \to \mathrm{Spec}\, R(\gamma)_\mathfrak{p}$ is a closed immersion. Let $J_\mathfrak{p} := \mathrm{Ker}\, \psi$, $J := R(\gamma) \cap J_\mathfrak{p}$ and $D := R(\gamma)/J$. We are reduced to showing that the induced map $D \to D_\mathfrak{p}$ is an isomorphism. However, let $e \in R(\gamma) \setminus \mathfrak{p}$; since $D_\mathfrak{p} \simeq B$ is finite over K^+, we can find a monic polynomial $P[T] \in K^+[T]$ such that $P(e^{-1}) = 0$, therefore an identity of the form $1 = e \cdot Q(e)$ holds in $D_\mathfrak{p}$ for some polynomial $Q(T) \in K^+[T]$. But then the same identity holds already in the subring D, *i.e.* the element e is invertible in D, and the claim follows. ◊

Now, C is a finitely generated B-module, hence also a finitely generated $R(\gamma)$-module, due to claim 11.4.32. We construct a presentation of C in the following way. First of all, we have a short exact sequence of $R(\gamma) \otimes_{K^+} R(\gamma)$-modules:

$$\underline{E} \;:\; 0 \to \Delta \to R(\gamma) \otimes_{K^+} R(\gamma) \xrightarrow{\mu} R(\gamma) \to 0$$

where μ is the multiplication map. The homomorphism $R(\gamma) \to R(\gamma) \otimes_{K^+} R(\gamma) : a \mapsto 1 \otimes a$ fixes an $R(\gamma)$-module structure on every $R(\gamma) \otimes_{K^+} R(\gamma)$-module (the *right* $R(\gamma)$-module structure), and clearly $\underline{E}$ is split exact, when regarded as a sequence of $R(\gamma)$-modules via this homomorphism. Moreover, in terms of the presentation (11.4.14), the $R(\gamma) \otimes_{K^+} R(\gamma)$-module Δ is generated by the elements $\mathsf{X} \otimes 1 - 1 \otimes \mathsf{X}$ and $\mathsf{Y} \otimes 1 - 1 \otimes \mathsf{Y}$. Let n be the rank of the free K^+-module C (claim 11.4.30(iii)); there follows an exact sequence

$$\underline{E} \otimes_{R(\gamma)} C \;:\; 0 \to \Delta \otimes_{R(\gamma)} C \to R(\gamma)^{\oplus n} \to C \to 0$$

which we may and do view as a short exact sequence of $R(\gamma)$-modules, via the *left* $R(\gamma)$-module structure induced by the restriction of scalars $R(\gamma) \to R(\gamma) \otimes_{K^+} R(\gamma) : a \mapsto a \otimes 1$. The elements $\mathsf{X}, \mathsf{Y} \in R(\gamma)$ act as K^+-linear endomorphisms on C; one can then find bases $(b_i \mid i = 1, \dots, n)$ and $(b'_i \mid i = 1, \dots, n)$ of C, and elements $a_1, \dots, a_n \in K^+ \setminus \{0\}$ such that

$\mathsf{X}b_i = a_i b'_i$ for every $i \leq n$. Since $\mathsf{XY} = c$ in $R(\gamma)$, it follows that $\mathsf{Y}b'_i = ca_i^{-1}b_i$ for every $i \leq n$. With this notation, it is clear that $\Delta \otimes_{R(\gamma)} C$, with its left $R(\gamma)$-module structure, is generated by the elements:

$$\mathsf{X} \otimes b_i - 1 \otimes a_i b'_i \quad \text{and} \quad \mathsf{Y} \otimes b'_i - 1 \otimes ca_i^{-1}b_i \quad (i = 1, \dots, n).$$

For every $i \leq n$, let F_i be the $R(\gamma)$-module generated freely by elements $(\varepsilon_i, \varepsilon'_i)$, and $\Delta_i \subset F_i$ the submodule generated by $\mathsf{X}\varepsilon_i - a_i\varepsilon'_i$ and $\mathsf{Y}\varepsilon'_i - ca_i^{-1}\varepsilon_i$. Moreover, let us write $b'_i = \sum_{j=1}^n u_{ij}b_j$ with unique $u_{ij} \in K^+$, let F be the free $R(\gamma)$-module with basis $(e_i \mid i = 1, \dots, n)$, and define $\varphi : F \to \oplus_{i=1}^n F_i$ by the rule: $e_i \mapsto \varepsilon'_i - \sum_{j=1}^n u_{ij}\varepsilon_j$ for every $i \leq n$. We deduce a right exact sequence of $R(\gamma)$-modules:

$$F \oplus \bigoplus_{i=1}^n \Delta_i \xrightarrow{\psi_1} \bigoplus_{i=1}^n F_i \xrightarrow{\psi_2} C \to 0$$

where:

$$\begin{aligned} &\psi_1(f, d_1, \dots, d_n) = \varphi(f) + (d_1, \dots, d_n) && \text{for every } f \in F \text{ and } d_i \in \Delta_i \\ &\psi_2(\varepsilon_i) = b_i \quad \text{and} \quad \psi_2(\varepsilon'_i) = b'_i && \text{for every } i = 1, \dots, n. \end{aligned}$$

Claim 11.4.33. ψ_1 is injective.

Proof of the claim. Let L be the field of fractions of $R(\gamma)$; since the domain of ψ_1 is a torsion-free K^+-module, it suffices to verify that $\psi \otimes_{R(\gamma)} \mathbf{1}_L$ is injective. However, on the one hand $C \otimes_{R(\gamma)} L = 0$, and on the other hand, each $\Delta_i \otimes_{R(\gamma)} L$ is an L-vector space of dimension one, so the claim follows by comparing dimensions. ◊

By inspecting the definitions and the proof of lemma 11.4.20, one sees easily that

$$\Delta_i \simeq I(|a_i^{-1}c|) \quad \text{for every } i \leq n. \tag{11.4.34}$$

Moreover, by remark (7.3.50)(iii), there exist $p \in \mathbb{N}$ and an $R(\gamma)$-linear isomorphism:

$$\operatorname{Ker} \psi_2 \xrightarrow{\sim} R(\gamma)^{\oplus p} \oplus \operatorname{Syz}^1_{R(\gamma)} C. \tag{11.4.35}$$

On the other hand, remark (7.3.50)(iii) and claim 11.4.30(ii) also shows that there exist $q \in \mathbb{N}$ and an A-linear isomorphism:

$$M \xrightarrow{\sim} A^{\oplus q} \oplus \operatorname{Syz}^1_A C. \tag{11.4.36}$$

Combining (11.4.35) and (11.4.36) and using lemma 7.3.51, we deduce an $R(\gamma)^{\mathrm{h}}$-linear isomorphism:

$$\begin{aligned} (R(\gamma)^{\mathrm{h}})^{\oplus q} \oplus (R(\gamma)^{\mathrm{h}} \otimes_{R(\gamma)} \operatorname{Ker} \psi_2) &\xrightarrow{\sim} (R(\gamma)^{\mathrm{h}})^{\oplus p+q} \oplus (R(\gamma)^{\mathrm{h}} \otimes_{R(\gamma)} \operatorname{Syz}^1_{R(\gamma)} C) \\ &\xrightarrow{\sim} (R(\gamma)^{\mathrm{h}})^{\oplus p+q} \oplus \operatorname{Syz}^1_{R(\gamma)^{\mathrm{h}}}(R(\gamma)^{\mathrm{h}} \otimes_{R(\gamma)} C) \\ &\xrightarrow{\sim} (R(\gamma)^{\mathrm{h}})^{\oplus p+q} \oplus (R(\gamma)^{\mathrm{h}} \otimes_A \operatorname{Syz}^1_A C) \\ &\xrightarrow{\sim} (R(\gamma)^{\mathrm{h}})^{\oplus p} \oplus (R(\gamma)^{\mathrm{h}} \otimes_A M). \end{aligned}$$

By claim 11.4.33 and (11.4.34) it follows that $(R(\gamma)^{\mathrm{h}})^{\oplus p} \oplus (R(\gamma)^{\mathrm{h}} \otimes_A M)$ is a direct sum of modules of the form $R(\gamma)^{\mathrm{h}} \otimes_{R(\gamma)} I(\rho_i)$, for various $\rho_i \in \Gamma$ (recall that $I(1) = R(\gamma)$). Notice that every $I(\rho_i)$ is generically of rank one, hence indecomposable. Then it follows from corollary 7.11.11 that $R(\gamma)^{\mathrm{h}} \otimes_A M$ is a direct sum of various indecomposable $R(\gamma)^{\mathrm{h}}$-modules of the form $R(\gamma)^{\mathrm{h}} \otimes_A g^*\mathscr{I}(\rho_i)_x$. Finally, we apply proposition 7.11.12 to conclude the proof of the theorem. □

The rest of this section shall be concerned with some results that hold in the special case where the valuation of K has rank one.

Theorem 11.4.37. *Suppose that K is a valued field of rank one. Let $f : X \to S$ be a finitely presented morphism, $\mathscr{F}$ a coherent $\mathscr{O}_X$-module. Then :*

(i) *Every coherent proper submodule $\mathscr{G} \subset \mathscr{F}$ admits a primary decomposition.*

(ii) $\mathrm{Ass}\,\mathscr{F}$ *is a finite set.*

Proof. By lemma 10.5.15, assertion (ii) follows from (i). Using corollary 10.5.11(ii) we reduce easily to the case where X is affine, say $X = \mathrm{Spec}\,A$ for a finitely presented K^+-algebra A, and $\mathscr{F} = M^\sim$, $\mathscr{G} = N^\sim$ for some finitely presented A-modules $N \subset M \neq 0$. By considering the quotient M/N, we further reduce the proof to the case where $N = 0$. Let us choose a closed imbedding $i : X \to \mathrm{Spec}\,B$, where $B := K^+[T_1, \dots, T_r]$ is a free polynomial K^+-algebra; by proposition 10.5.19, the submodule $0 \subset \mathscr{F}$ admits a primary decomposition if and only if the submodule $0 \subset i_*\mathscr{F}$ does. Thus, we may replace A by B, and assume that $A = K^+[T_1, \dots, T_r]$, in which case we shall argue by induction on r. Let ξ denote the maximal point of $f^{-1}(s)$; by claim 9.1.33, $V := \mathscr{O}_{X,\xi}$ is a valuation ring with value group Γ. Then [75, Lemma 6.1.14] says that

$$M_\xi \simeq V^{\oplus m} \oplus (V/b_1V) \oplus \cdots \oplus (V/b_kV)$$

for some $m \in \mathbb{N}$ and elements $b_1, \dots, b_k \in \mathfrak{m}_K \setminus \{0\}$. After clearing some denominators, we may then find a map $\varphi : M' := A^{\oplus m} \oplus (A/b_1A) \oplus \cdots \oplus (A/b_kA) \to M$ whose localization φ_ξ is an isomorphism.

Claim 11.4.38. $\mathrm{Ass}\,A/bA = \{\xi\}$ whenever $b \in \mathfrak{m}_K \setminus \{0\}$.

Proof of the claim. Clearly $\mathrm{Ass}\,A/bA \subset f^{-1}(s)$. Let $x \in f^{-1}(s)$ be a non-maximal point. Thus, the prime ideal $\mathfrak{p} \subset A$ corresponding to x is not contained in $\mathfrak{m}_K A$, *i.e.* there exists $a \in \mathfrak{p}$ such that $|a|_A = 1$. Suppose by way of contradiction, that $x \in \mathrm{Ass}\,A/bA$; then we may find $c \in A$ such that $c \notin bA$ but $a^n c \in bA$ for some $n \in \mathbb{N}$. The conditions translate respectively as the inequalities :

$$|c|_A > |b|_A \qquad \text{and} \qquad |a^n|_A \cdot |c|_A = |a^n c|_A \leq |b|_A$$

which are incompatible, since $|a^n|_A = 1$. ◊

Since $(\mathrm{Ker}\,\varphi)_\xi = 0$, claim 11.4.38 and proposition 10.5.6(ii) imply that $\mathrm{Ass}\,\mathrm{Ker}\,\varphi = \varnothing$; therefore $\mathrm{Ker}\,\varphi = 0$, by lemma 10.5.5(iii). Moreover, the submodule $N_1 := A^{\oplus m}$ (resp. $N_2 := (A/b_1A) \oplus \cdots \oplus (A/b_kA)$) of M' is either ξ-primary (resp. $\{0\}$-primary), or else equal to M'; in the first case, $0 \subset M'$ admits the primary decomposition $0 = N_1 \cap N_2$, and in the second case, either 0 is primary, or else $M' = 0$ has the empty primary decomposition. Now, if $r = 0$ then $M = M'$ and we are done. Suppose therefore that $r > 0$ and that the theorem is known for all integers $< r$. Set $M'' := \mathrm{Coker}\,\varphi$; clearly $\xi \notin \mathrm{Supp}\,M''$, so by proposition 10.5.18 we are reduced to showing that the submodule $0 \subset M''$ admits a primary decomposition. We may then replace M by M'' and assume from start that $\xi \notin \mathrm{Supp}\,\mathscr{F}$. Let $\mathscr{F}^t \subset \mathscr{F}$ be the K^+-torsion submodule; clearly $\mathscr{F}/\mathscr{F}^t$ is a flat K^+-module, hence it is a finitely presented $\mathscr{O}_X$-module (proposition 9.1.27), so $\mathscr{F}^t$ is a finitely generated $\mathscr{O}_X$-module, by [37, §1, n.4, Prop.6]. Hence we may find a non-zero $a \in \mathfrak{m}_K$ such that $a\mathscr{F}^t = 0$, *i.e.* the natural map $\mathscr{F}^t \to \mathscr{F}/a\mathscr{F}$ is injective. Denote by $i : Z := V(\mathrm{Ann}\,\mathscr{F}/a\mathscr{F}) \to X$ the closed immersion.

Claim 11.4.39. There exists a finite morphism $g : Z \to \mathbb{A}^{r-1}_S$.

Proof of the claim. Since $\xi \notin \mathrm{Supp}\,\mathscr{F}$, we have $I \not\subset \mathfrak{m}_K A$, *i.e.* we can find $b \in I$ such that $|b|_A = 1$. Set $W := V(a, b) \subset X$; it suffices to exhibit a finite morphism $W \to \mathbb{A}^{r-1}_S$. By [33, §5.2.4, Prop.2], we can find an automorphism $\sigma : A/aA \to A/aA$ such that $\sigma(b) = u \cdot b'$, where u is a unit, and $b' \in (K^+/aK^+)[T_1, \dots, T_r]$ is of the form $b' = T_r^k + \sum_{j=0}^{k-1} a_j T_r^j$, for some $a_0, \dots, a_{k-1} \in (K^+/aK^+)[T_1, \dots, T_{r-1}]$. Hence the ring $A/(aA + bA) = A/(aA + b'A)$ is finite over $K^+[T_1, \dots, T_{r-1}]$, and the claim follows. ◊

Claim 11.4.40. The $\mathscr{O}_X$-submodule $0 \subset \mathscr{F}/a\mathscr{F}$ admits a primary decomposition.

Proof of the claim. Let $\mathscr{G} := (\mathscr{F}/a\mathscr{F})_{|Z}$. By our inductive assumption the submodule $0 \subset g_*\mathscr{G}$ on $\mathbb{A}^{r-1}_S$ admits a primary decomposition; a first application of proposition 10.5.19 then shows that the submodule $0 \subset \mathscr{G}$ on Z admits a primary decomposition, and a second application proves the same for the submodule $0 \subset i_*\mathscr{G} = \mathscr{F}/a\mathscr{F}$. ◊

Finally, let $j : Y := V(a) \subset X$ be the closed immersion, and set $U := X \setminus Y$. By construction, the natural map $\underline{\Gamma}_Y\mathscr{F} \to j_*j^*\mathscr{F}$ is injective. Furthermore, U is an affine noetherian scheme, so [126, Th.6.8] ensures that the $\mathscr{O}_U$-submodule $0 \subset \mathscr{F}_{|U}$ admits a primary decomposition. The same holds for $j^*\mathscr{F}$, in view of claim 11.4.40. To conclude the proof, it remains only to invoke proposition 10.5.21. □

Corollary 11.4.41. *Let K be a valued field of rank one, $f : X \to S$ a finitely presented morphism, $\mathscr{F}$ a coherent $\mathscr{O}_X$-module, and $\underline{\mathscr{I}} := (\mathscr{I}_\lambda \mid \lambda \in \Lambda)$ a cofiltered family such that :*

(a) *$\mathscr{I}_\lambda \subset \mathscr{O}_X$ is a coherent ideal for every $\lambda \in \Lambda$.*
(b) *$\mathscr{I}_\lambda \cdot \mathscr{I}_\mu \in \underline{\mathscr{I}}$ whenever $\mathscr{I}_\lambda, \mathscr{I}_\mu \in \underline{\mathscr{I}}$.*

Then the following holds :

(i) *$\mathscr{F}_\lambda := \mathrm{Ann}_{\mathscr{F}}(\mathscr{I}_\lambda) \subset \mathscr{F}$ is a submodule of finite type for every $\lambda \in \Lambda$.*
(ii) *There exists $\lambda \in \Lambda$ such that $\mathscr{F}_\mu \subset \mathscr{F}_\lambda$ for every $\mu \in \Lambda$.*

Proof. We easily reduce to the case where X is affine, say $X = \mathrm{Spec}\, A$ with A finitely presented over K^+, and for each $\lambda \in \Lambda$ the ideal $I_\lambda := \Gamma(X, \mathscr{I}_\lambda) \subset A$ is finitely generated.

(i): For given $\lambda \in \Lambda$, let $f_1, \dots, f_k$ be a finite system of generators of I_λ; then $\mathscr{F}_\lambda$ is the kernel of the map $\varphi : \mathscr{F} \to \mathscr{F}^{\oplus k}$ defined by the rule : $m \mapsto (f_1 m, \dots, f_k m)$, which is finitely generated because A is coherent.

(ii): By theorem 11.4.37 we can find primary submodules $\mathscr{G}_1, \dots, \mathscr{G}_n \subset \mathscr{F}$ such that $\mathscr{G}_1 \cap \cdots \cap \mathscr{G}_n = 0$; for every $i \leq n$ and $\lambda \in \Lambda$ set $\mathscr{H}_i := \mathscr{F}/\mathscr{G}_i$ and $\mathscr{H}_{i,\lambda} := \mathrm{Ann}_{\mathscr{H}_i}(\mathscr{I}_\lambda)$. Since the natural map $\mathscr{F} \to \oplus_{i=1}^n \mathscr{H}_i$ is injective, we have :

$$\mathscr{F}_\lambda = \mathscr{F} \cap (\mathscr{H}_{1,\lambda} \oplus \cdots \oplus \mathscr{H}_{n,\lambda}) \qquad \text{for every } \lambda \in \Lambda.$$

It suffices therefore to prove that, for every $i \leq n$, there exists $\lambda \in \Lambda$ such that $\mathscr{H}_{i,\mu} = \mathscr{H}_{i,\lambda}$ for every $\mu \in \Lambda$. Say that $\mathscr{H}_i$ is $\mathfrak{p}$-primary, for some prime ideal $\mathfrak{p} \subset A$; suppose now that there exists λ such that $I_\lambda \subset \mathfrak{p}$; since I_λ is finitely generated, we deduce that $I^n_\lambda \mathscr{H}_i = 0$ for $n \in \mathbb{N}$ large enough; from (b) we see that $\mathscr{I}^n_\lambda \in \underline{\mathscr{I}}$, so (ii) holds in this case. In case $I_\lambda \not\subset \mathfrak{p}$ for every $\lambda \in \Lambda$, we have $\mathrm{Ann}_{\mathscr{H}_i}(\mathscr{I}_\lambda) = 0$ for every $\lambda \in \Lambda$, so (ii) holds in this case as well. □

Corollary 11.4.42. *Suppose A is a valuation ring with value group Γ_A, and $\varphi : K^+ \to A$ is an essentially finitely presented local homomorphism from a valuation ring K^+ of rank one. Then:*

(i) *If the valuation of K is not discrete, φ induces an isomorphism $\Gamma \xrightarrow{\sim} \Gamma_A$.*
(ii) *If $\Gamma \simeq \mathbb{Z}$ and φ is flat, φ induces an inclusion $\Gamma \subset \Gamma_A$, and $(\Gamma_A : \Gamma)$ is finite.*

Proof. Suppose first that $\Gamma \simeq \mathbb{Z}$; then A is noetherian, hence Γ_A is discrete of rank one as well, and the assertion follows easily. In case Γ is not discrete, we claim that A has rank ≤ 1. Indeed, suppose by way of contradiction, that the rank of A is higher than one, and let $\mathfrak{m}_A \subset A$ be the maximal ideal; then we can find $a, b \in \mathfrak{m}_A \setminus \{0\}$ such that $a^{-i}b \in A$ for every $i \in \mathbb{N}$. Let us consider the A-module $M := A/bA$; we notice that $\mathrm{Ann}_M(a^i) = a^{-i}bA$ form a strictly increasing sequence of ideals, contradicting corollary 11.4.41(ii). Next we claim that φ is flat. Indeed, suppose this is not the case; then A is a κ-algebra. Let $\mathfrak{p} \subset A$ be the maximal ideal; by lemma 9.1.32, we may assume that $A/\mathfrak{p}$ is a finite extension of κ. Now, choose any finitely presented quotient $\overline{A}$ of A supported at $\mathfrak{p}$; it follows easily that $\overline{A}$ is integral over K^+, hence it is a finitely presented K^+-module by proposition 9.1.34(i), and its annihilator contains $\mathfrak{m}_K$, which is absurd in view of [75, Lemma 6.1.14]. Next, since Γ is not discrete, one sees easily that $\mathfrak{m}_K A$ is a prime ideal, and in light of the foregoing, it must then be the maximal ideal. Now the assertion follows from proposition 9.1.34(ii). □

11.4.43. Let K be a valued field of rank one, B a finitely presented K^+-algebra, and consider a pair $\underline{A} := (A, \mathrm{Fil}_\bullet A)$ consisting of a B-algebra and a B-algebra filtration on A; let also M be a finitely generated A-module, and $\mathrm{Fil}_\bullet M$ a good $\underline{A}$-filtration on M (see definition 7.9.4). By definition, this means that the Rees module $\mathsf{R}(\underline{M})_\bullet$ of the filtered $\underline{A}$-module $\underline{M} := (M, \mathrm{Fil}_\bullet M)$ is finitely generated over the graded Rees B-algebra $\mathsf{R}(\underline{A})_\bullet$. We have :

Proposition 11.4.44. *In the situation of* (11.4.43)*, suppose that A is a finitely presented B-algebra, M is a finitely presented A-module, and* $\mathrm{Fil}_\bullet A$ *is a good filtration. Then :*

(i) $\mathsf{R}(\underline{A})_\bullet$ *is a finitely presented B-algebra, and* $\mathsf{R}(\underline{M})_\bullet$ *is a finitely presented* $\mathsf{R}(\underline{A})_\bullet$*-module.*

(ii) *If furthermore,* $\mathrm{Fil}_\bullet A$ *is a positive filtration (see definition* 7.9.4(ii)*), then* $\mathrm{Fil}_i M$ *is a finitely presented B-module, for every $i \in \mathbb{Z}$.*

Proof. By lemma 7.9.8, there exists a finite system of generators $\mathbf{m} := (m_1, \dots, m_n)$ of M, and a sequence of integers $\mathbf{k} := (k_1, \dots, k_n)$ such that $\mathrm{Fil}_\bullet M$ is of the form (7.9.7).

(i): Consider first the case where A is a free B-algebra of finite type, say $A = B[t_1, \dots, t_p]$, such that $\mathrm{Fil}_\bullet A$ is the good filtration associated with the system of generators $\mathbf{t} := (t_1, \dots, t_p)$ and the sequence of integers $\mathbf{r} := (r_1, \dots, r_p)$, and moreover M is a free A-module with basis $\mathbf{m}$. Then $\mathsf{R}(\underline{A})_\bullet$ is also a free B-algebra of finite type (see example 7.9.5). Moreover, for every $j \leq n$, let $M_j \subset M$ be the A-submodule generated by m_j, and denote by $\mathrm{Fil}_\bullet M_j$ the good $\underline{A}$-filtration associated with the pair $(\{m_j\}, \{k_j\})$; clearly $\mathrm{Fil}_\bullet M = \mathrm{Fil}_\bullet M_1 \oplus \cdots \oplus \mathrm{Fil}_\bullet M_n$, therefore $\mathsf{R}(\underline{M})_\bullet = \mathsf{R}(\underline{M}_1)_\bullet \oplus \cdots \oplus \mathsf{R}(\underline{M}_n)_\bullet$, where $\underline{M}_j := (M_j, \mathrm{Fil}_\bullet M_j)$ for every $j \leq n$. Obviously each $\mathsf{R}(\underline{A})_\bullet$-module $\mathsf{R}(\underline{M}_j)_\bullet$ is free of rank one, so the proposition follows in this case.

Next, suppose that A is a free B-algebra of finite type, and M is arbitrary. Let F be a free A-module of rank n, $\mathbf{e} := (e_1, \dots, e_n)$ a basis of F, and define an A-linear surjection $\varphi : F \to M$ by the rule $e_j \mapsto m_j$ for every $j \leq n$. Then φ is even a map of filtered $\underline{A}$-modules, provided we endow F with the good $\underline{A}$-filtration $\mathrm{Fil}_\bullet F$ associated with the pair $(\mathbf{e}, \mathbf{k})$. More precisely, let $N := \mathrm{Ker}\,\varphi$; then the filtration $\mathrm{Fil}_\bullet M$ is induced by $\mathrm{Fil}_\bullet F$, meaning that $\mathrm{Fil}_i M := (N + \mathrm{Fil}_i F)/N$ for every $i \in \mathbb{Z}$. Obviously the natural map $\mathsf{R}(\underline{F})_\bullet \to \mathsf{R}(\underline{M})_\bullet$ is surjective, and its kernel is the Rees module $\mathsf{R}(\underline{N})_\bullet$ corresponding to the filtered $\underline{A}$-module $\underline{N} := (N, \mathrm{Fil}_\bullet N)$ with $\mathrm{Fil}_i N := N \cap \mathrm{Fil}_i F$ for every $i \in \mathbb{Z}$. Let $\mathbf{x} := (x_1, \dots, x_s)$ be a finite system of generators of N, and choose a sequence of integers $\mathbf{j} := (j_1, \dots, j_s)$ such that $x_i \in \mathrm{Fil}_{j_i} N$ for every $i \leq s$; denote by $\underline{L}$ the filtered $\underline{A}$-module associated as in (7.9.6), with the A-module N and the pair $(\mathbf{x}, \mathbf{j})$. Thus, $\mathsf{R}(\underline{L})_\bullet$ is a finitely generated graded $\mathsf{R}(\underline{A})_\bullet$-submodule of $\mathsf{R}(\underline{N})_\bullet$. To ease notation, set $\overline{N} := \mathsf{R}(\underline{N})_\bullet/\mathsf{R}(\underline{L})_\bullet$ and $\overline{F} := \mathsf{R}(\underline{F})_\bullet/\mathsf{R}(\underline{L})_\bullet$. Recall (definition 7.9.1(iii)) that $\mathsf{R}(\underline{A})_\bullet$ is a graded B-subalgebra of $A[U, U^{-1}]$; then we have :

Claim 11.4.45. $\overline{N} = \bigcup_{n \in \mathbb{N}} \mathrm{Ann}_{\overline{F}}(U^n)$.

Proof of the claim. It suffices to consider a homogeneous element $y := U^i z \in \mathsf{R}(\underline{F})_i$, for some some $z \in \mathrm{Fil}_i F$. Suppose that $U^n y \in \mathsf{R}(\underline{L})_{i+n}$; especially, $U^{i+n} z \in \mathsf{R}(\underline{N})_{i+n}$, so $z \in N$, hence $y \in \mathsf{R}(\underline{N})_i$. Conversely, suppose that $y \in \mathsf{R}(\underline{N})_i$; write $z = x_1 a_1 + \cdots + x_s a_s$ for some $a_1, \dots, a_s \in A$. Say that $a_r \in \mathrm{Fil}_{b_r} A$ for every $r \leq s$, and set $l := \max(i, b_1 + j_1, \dots, b_s + j_s)$. Then $U^{l-i} y = U^l z \in \mathsf{R}(\underline{L})_l$. ◊

By the foregoing, $\mathsf{R}(\underline{F})_\bullet$ is finitely presented over $\mathsf{R}(\underline{A})_\bullet$. It follows that $\overline{N}$ is finitely generated (corollary 11.4.41), hence $\mathsf{R}(\underline{N})_\bullet$ is a finitely generated $\mathsf{R}(\underline{A})_\bullet$-module, so finally $\mathsf{R}(\underline{M})_\bullet$ is finitely presented over $\mathsf{R}(\underline{A})_\bullet$.

Lastly, consider the case of an arbitrary finitely presented B-algebra A, endowed with the good B-algebra filtration associated with a system of generators $\mathbf{x} := (x_1, \dots, x_p)$ and the sequence of integers $\mathbf{r}$. We map the free B-algebra $P := B[t_1, \dots, t_p]$ onto A, by the rule: $t_j \mapsto x_j$ for every $j \leq p$. This is even a map of filtered algebras, provided we endow P with the good filtration $\mathrm{Fil}_\bullet P$ associated with the pair $(\mathbf{t}, \mathbf{r})$; more precisely, $\mathrm{Fil}_\bullet P$ induces the filtration $\mathrm{Fil}_\bullet A$ on A, hence $\mathrm{Fil}_\bullet A$ is a good $\underline{P}$-filtration. By the foregoing case, we then deduce that $\mathsf{R}(\underline{A})_\bullet$ is a finitely presented $\mathsf{R}(\underline{P})_\bullet$-module (where $\underline{P} := (P, \mathrm{Fil}_\bullet P)$), hence also a finitely presented K^+-algebra. Moreover, M is a finitely presented P-module, and clearly $\mathrm{Fil}_\bullet M$ is good when regarded as a $\underline{P}$-filtration, hence $\mathsf{R}(\underline{M})_\bullet$ is a finitely presented $\mathsf{R}(\underline{P})_\bullet$-module, so also a finitely presented $\mathsf{R}(\underline{A})_\bullet$-module.

(ii): The positivity condition implies that $\mathsf{R}(\underline{A})_0 = B$; then, taking into account (i), the assertion is just a special case of proposition 7.6.11(iii). □

Theorem 11.4.46 (Artin-Rees lemma). *Let K be a valued field of rank one, A an essentially finitely presented K^+-algebra, $I \subset A$ an ideal of finite type, M a finitely presented A-module, $N \subset M$ a finitely generated submodule. Then there exists an integer $c \in \mathbb{N}$ such that :*

$$I^n M \cap N = I^{n-c}(I^c M \cap N) \qquad \text{for every } n \geq c.$$

Proof. We reduce easily to the case where A is a finitely presented K^+-algebra; then, with all the work done so far, we only have to repeat the argument familiar from the classical noetherian case. Indeed, let us define a filtered K^+-algebra $\underline{A} := (A, \mathrm{Fil}_\bullet A)$ by the rule : $\mathrm{Fil}_n A := I^{-n}$ if $n \leq 0$, and $\mathrm{Fil}_n A := A$ otherwise; also let $\underline{M} := (M, \mathrm{Fil}_\bullet M)$ be the filtered $\underline{A}$-module such that $\mathrm{Fil}_i M := M \cdot \mathrm{Fil}_i A$ for every $i \in \mathbb{Z}$. We endow $Q := M/N$ with the filtration $\mathrm{Fil}_\bullet Q$ induced from $\mathrm{Fil}_\bullet M$, so that the natural projection $M \to M/N$ yields a map of filtered $\underline{A}$-modules $\underline{M} \to \underline{Q} := (Q, \mathrm{Fil}_\bullet Q)$. By proposition 11.4.44, there follows a surjective map of finitely presented graded $\mathsf{R}(\underline{A})_\bullet$-modules : $\pi_\bullet : \mathsf{R}(\underline{M})_\bullet \to \mathsf{R}(\underline{Q})_\bullet$, whose kernel in degree $k \leq 0$ is the A-module $I^{-k} M \cap N$. Hence we can find a finite (non-empty) system $f_1, \dots, f_r$ of generators for the $\mathsf{R}(\underline{A})_\bullet$-module $\mathrm{Ker}\, \pi_\bullet$; clearly we may assume that each f_i is homogeneous, say of degree d_i; we may also suppose that $d_i \leq 0$ for every $i \leq r$, since $\mathrm{Ker}\, \pi_0$ generates $\mathrm{Ker}\, \pi_n$, for every $n \geq 0$. Let $d := \min(d_i \mid i = 1, \dots, r)$; by inspecting the definitions, one verifies easily that

$$\mathsf{R}(\underline{A})_i \cdot \mathrm{Ker}\, \pi_j \subset \mathsf{R}(\underline{A})_{i+j-d} \cdot \mathrm{Ker}\, \pi_d \qquad \text{whenever } i + j \leq d \text{ and } 0 \geq j \geq d.$$

Therefore $\mathrm{Ker}\, \pi_{d+k} = \mathsf{R}(\underline{A})_k \cdot \mathrm{Ker}\, \pi_d$ for every $k \leq 0$, so the assertion holds with $c := -d$. □

11.4.47. In the situation of theorem 11.4.46, let M be any finitely presented A-module; we denote by $M^\wedge$ the I-adic completion of M, which is an $A^\wedge$-module.

Corollary 11.4.48. *With the notation of* (11.4.47)*, the following holds :*

(i) *The functor $M \mapsto M^\wedge$ is exact on the category of finitely presented A-modules.*
(ii) *For every finitely presented A-module M, the natural map $M \otimes_A A^\wedge \to M^\wedge$ is an isomorphism.*
(iii) *$A^\wedge$ is flat over A. If additionally $I \subset \mathrm{rad}\, A$ (the Jacobson radical of A), then $A^\wedge$ is faithfully flat over A.*

Proof. (i): Let $N \subset M$ be any injection of finitely presented A-modules; by theorem 11.4.46, the I-adic topology on M induces the I-adic topology on N. Then the assertion follows from proposition 8.2.13(i,v).

(ii): Choose a presentation $A^{\oplus p} \to A^{\oplus q} \to M \to 0$. By (i) we deduce a commutative diagram with exact rows :

$$\begin{array}{ccccccc} A^{\oplus p} \otimes_A A^\wedge & \longrightarrow & A^{\oplus q} \otimes_A A^\wedge & \longrightarrow & M \otimes_A A^\wedge & \longrightarrow & 0 \\ \downarrow & & \downarrow & & \downarrow & & \\ (A^{\oplus p})^\wedge & \longrightarrow & (A^{\oplus q})^\wedge & \longrightarrow & M^\wedge & \longrightarrow & 0 \end{array}$$

and clearly the two left-most vertical arrows are isomorphisms. The claim follows.

(iii): The first assertion means that the functor $M \mapsto M \otimes_A A^\wedge$ is exact; this follows from (i) and (ii), via a standard reduction to the case where M is finitely presented. Suppose next that $I \subset \mathrm{rad}\, A$; to conclude, it suffices to show that the image of the natural map $\mathrm{Spec}\, A^\wedge \to \mathrm{Spec}\, A$ contains the maximal spectrum $\mathrm{Max}\, A$ ([126, Th.7.3]). Since the natural map $\mathrm{Max}\, A/I \to \mathrm{Max}\, A$ is a bijection, the latter assertion follows from the :

Claim 11.4.49. For every finitely presented A-module M, the natural map $i_M : M \to M^\wedge$ induces an isomorphism $M/IM \stackrel{\sim}{\to} M^\wedge/IM^\wedge$.

Proof of the claim. From (i) we get a natural identification : $M^\wedge/(IM)^\wedge \stackrel{\sim}{\to} (M/IM)^\wedge \stackrel{\sim}{\to} M/IM$, whose inverse is the map induced by i_M. However, by (ii) the image of $(IM)^\wedge$ in $M^\wedge$ is the same as the image of $IM \otimes_A A^\wedge$, which is the same as the image of $IM^\wedge$. □

Theorem 11.4.50. *Let K be a valued field of rank one, $B \to A$ a map of finitely presented K^+-algebras. Then :*

(i) *If M is an ω-coherent A-module, M is ω-coherent as a B-module.*

(ii) *If J is a coh-injective B-module, and $I \subset B$ is a finitely generated ideal, we have :*
  (a) *$\mathrm{Hom}_B(A, J)$ is a coh-injective A-module.*
  (b) *$\bigcup_{n \in \mathbb{N}} \mathrm{Ann}_J(I^n)$ is a coh-injective B-module.*

(iii) *If $(J_n, \varphi_n \mid n \in \mathbb{N})$ is a direct system consisting of coh-injective B/I^n-modules J_n and B-linear maps $\varphi_n : J_n \to J_{n+1}$ (for every $n \in \mathbb{N}$), then $\mathrm{colim}_{n \in \mathbb{N}} J_n$ is a coh-injective B-module.*

Proof. (See (7.11.25) for the generalities on coh-injective and ω-coherent modules.)

(i): We reduce easily to the case where M is finitely presented over A. Let $x_1, \dots, x_p$ be a system of generators for the B-algebra A, and $m_1, \dots, m_n$ a system of generators for the A-module M. We let $\underline{A} := (A, \mathrm{Fil}_\bullet A)$, where $\mathrm{Fil}_\bullet A$ is the good B-algebra filtration associated with the pair $\mathbf{x} := (x_1, \dots, x_p)$ and $\mathbf{r} := (1, \dots, 1)$; likewise, let $\underline{M}$ be the filtered $\underline{A}$-module defined by the good $\underline{A}$-filtration on M associated with $\mathbf{m} := (m_1, \dots, m_n)$ and $\mathbf{k} := (0, \dots, 0)$ (see definition 7.9.4). Then claim follows easily after applying proposition 11.4.44(ii) to the filtered B-algebra $\underline{A}$ and the filtered $\underline{A}$-module $\underline{M}$.

(ii.a): Let $N \subset M$ be two coherent A-modules, and $\varphi : N \to \mathrm{Hom}_B(A, J)$ an A-linear map. According to claim 10.1.17, φ corresponds by adjunction to a unique B-linear map $\overline{\varphi} : N \to J$; on the other hand by (i), M, and M/N are ω-coherent B-modules, hence $\overline{\varphi}$ extends to a B-linear map $\overline{\psi} : M \to J$ (lemma 7.11.27). Under the adjunction, $\overline{\psi}$ corresponds to an A-linear extension $\psi : M \to \mathrm{Hom}_B(A, J)$ of φ.

(iii): Let $M \subset N$ be two finitely presented B-modules, $f : M \to J := \mathrm{colim}_{n \in \mathbb{N}} J_n$ a B-linear map. Since M is finitely generated, f factors through a map $f_n : M \to J_n$ and the natural map $J_n \to J$, provided n is large enough ([75, Prop.2.3.16(ii)]). By theorem 11.4.46 there exists $c \in \mathbb{N}$ such that $I^{n+c}N \cap M \subset I^n M$. Hence

$$f_{n+c} := \varphi_{n+c-1} \circ \cdots \circ \varphi_n \circ f_n : M \to J_{n+c}$$

factors through a unique B/I^{n+c}-linear map $\overline{f}_{n+c} : \overline{M} := M/(I^{n+c}N \cap M) \to J_{n+c}$; since I^{n+c} is finitely generated, $\overline{M}$ is a coherent submodule of the coherent B-module $\overline{N} := N/I^{n+c}N$, therefore $\overline{f}_{n+c}$ extends to a map $\overline{g} : \overline{N} \to J_{n+c}$. The composition of $\overline{g} : \overline{N} \to J_{n+c}$ with the projection $N \to \overline{N}$ and the natural map $J_{n+c} \to J$, is the sought extension of f.

(ii.b): Letting $A := B/I^n$ in (ii.a), we deduce that $J_n := \mathrm{Ann}_J(I^n)$ is a coh-injective B/I^n-module, for every $n \in \mathbb{N}$. Then the assertion follows from (iii). □

11.5. **Local duality.** Throughout this section we let $(K, |\cdot|)$ be a valued field of rank one. We shall continue to use the general notation of (11.4).

11.5.1. Let A be finitely presented K^+-algebra, $I \subset A$ an ideal generated by a finite system $\mathbf{f} := (f_i \mid i = 1, \dots, r)$, and denote by $i : Z := V(I) \to X := \mathrm{Spec}\, A$ the natural closed immersion. Let also $\mathscr{I} \subset \mathscr{O}_X$ be the ideal arising from I. For every $n \geq 0$ there is a natural epimorphism

$$i_* i^{-1}\mathscr{O}_X \to \mathscr{O}_X/\mathscr{I}^n$$

whence natural morphisms in $\mathsf{D}(A\text{-}\mathbf{Mod})$:

$$R\mathrm{Hom}^\bullet_{\mathscr{O}_X}(\mathscr{O}_X/\mathscr{I}^n, \mathscr{F}^\bullet) \to R\mathrm{Hom}^\bullet_{\mathscr{O}_X}(i_* i^{-1}\mathscr{O}_X, \mathscr{F}^\bullet) \xrightarrow{\sim} R\Gamma_Z \mathscr{F}^\bullet \qquad (11.5.2)$$

for any bounded below complex $\mathscr{F}^\bullet$ of $\mathscr{O}_X$-modules.

Theorem 11.5.3. *In the situation of* (11.5.1)*, let $M^\bullet$ be any object of* $\mathsf{D}^+(A\text{-}\mathbf{Mod})$*. Then* (11.5.2) *induces natural isomorphisms :*

$$\operatorname*{colim}_{n\in\mathbb{N}} \mathrm{Ext}^i_A(A/I^n, M^\bullet) \xrightarrow{\sim} R^i\Gamma_Z M^{\bullet\sim} \qquad \textit{for every } i \in \mathbb{N}.$$

Proof. For $\mathscr{F}^\bullet := M^{\bullet\sim}$, trivial duality (theorem 10.1.18) identifies the source of (11.5.2) with $R\mathrm{Hom}^\bullet_A(A/I^n, M^\bullet)$; then one takes cohomology in degree i and forms the colimit over n to define the sought map. Next, by usual spectral sequence arguments, we may reduce to the case where $M^\bullet$ is a single A-module M sitting in degree zero (see *e.g.* the proof of proposition 10.3.21(i)). By inspecting the definitions, one verifies easily that the morphism thus defined is the composition of the isomorphism of proposition 10.4.32(iii) and the map (7.8.41) (see the proof of proposition 10.4.32(iii)); then it suffices to show that the inverse system $(H_i\mathbf{K}_\bullet(\mathbf{f}^n) \mid n \in \mathbb{N})$ is essentially zero when $i > 0$ (lemma 7.8.42). By lemma 7.8.44, this will in turn follow, provided the following holds. For every finitely presented quotient B of A, and every $b \in B$, there exists $p \in \mathbb{N}$ such that $\mathrm{Ann}_B(b^q) = \mathrm{Ann}_B(b^p)$ for every $q \geq p$. This latter assertion is a special case of corollary 11.4.41. □

Corollary 11.5.4. *In the situation of theorem* 11.5.3*, we have natural isomorphisms :*

$$\operatorname*{colim}_{n\in\mathbb{N}} \mathrm{Ext}^i_A(I^n, M^\bullet) \xrightarrow{\sim} H^i(X\setminus Z, M^{\bullet\sim}) \qquad \textit{for every } i \in \mathbb{N}.$$

Proof. Set $U := X \setminus Z$. We may assume that $M^\bullet$ is a complex of injective A-modules, in which case the sought map is obtained by taking colimits over the direct system of composed morphisms :

$$\mathrm{Hom}_A(I^n, M^\bullet) \xrightarrow{\beta_n} \Gamma(U, M^\bullet) \to R\Gamma(U, M^{\bullet\sim})$$

where β_n is induced by the identification $(I^n)^\sim_{|U} = \mathscr{O}_U$ and the natural isomorphism :

$$\mathrm{Hom}_{\mathscr{O}_U}(\mathscr{O}_U, M^{\bullet\sim}) \simeq \Gamma(U, M^{\bullet\sim}).$$

The complex $R\Gamma(U, M^{\bullet\sim})$ is computed by a Cartan-Eilenberg injective resolution $M^{\bullet\sim} \xrightarrow{\sim} \mathscr{M}^\bullet$ of $\mathscr{O}_X$-modules, and then the usual arguments allow to reduce to the case where $M^\bullet$ consists of a single injective A-module M placed in degree zero. Finally, from the short exact sequence $0 \to I^n \to A \to A/I^n \to 0$ we deduce a commutative ladder with exact rows :

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{Hom}_A(A/I^n, M) & \longrightarrow & M & \longrightarrow & \mathrm{Hom}_A(I^n, M) & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \alpha_n} & & \| & & \downarrow{\scriptstyle \beta_n} & & \downarrow \\ 0 & \longrightarrow & \Gamma_Z M^\sim & \longrightarrow & M & \longrightarrow & \Gamma(U, M^\sim) & \longrightarrow & R^1\Gamma_Z M^\sim \longrightarrow 0 \end{array}$$

where α_n is induced from (11.5.2). From theorem 11.5.3 it follows that $\mathrm{colim}_{n\in\mathbb{N}}\,\alpha_n$ is an isomorphism, and $R^i\Gamma_Z M^\sim$ vanishes for all $i > 0$; hence $\mathrm{colim}_{n\in\mathbb{N}}\,\beta_n$ is an isomorphism, and the contention follows. □

Proposition 11.5.5. *Let $X \xrightarrow{f} Y \xrightarrow{g} S$ be two finitely presented morphisms of schemes.*

(i) *If g is smooth, $\mathscr{O}_Y[0]$ is a dualizing complex on Y.*
(ii) *If g is smooth and f is a closed immersion, then X admits a dualizing complex $\omega^\bullet_X$.*
(iii) *If X and Y are affine and $\omega^\bullet_Y$ is a dualizing complex on Y, then $f^!\omega^\bullet_Y$ is dualizing on X (notation of* (11.1.15)*).*
(iv) *Every finitely presented quasi-separated S-scheme admits a dualizing complex.*

Proof. (i) is an immediate consequence of proposition 11.4.2(i).

(ii): As in the proof of corollary 11.3.65, this follows directly from (i) and lemma 11.3.27(i).

(iii): Let us choose a factorization $f = p_Y \circ i$ where $i : X \to \mathbb{A}^n_Y$ is a finitely presented closed immersion, and $p_Y : \mathbb{A}^n_Y \to Y$ the smooth projection onto Y. In view of lemma 11.3.27(i) and (11.1.15), it suffices to prove the assertion for the morphism p_Y. To this aim, we pick a closed finitely presented immersion $h : Y \to \mathbb{A}^m_S$ and consider the fibre diagram :

$$\begin{array}{ccc} \mathbb{A}^n_Y & \xrightarrow{h'} & \mathbb{A}^{n+m}_S \\ {\scriptstyle p_Y}\downarrow & & \downarrow{\scriptstyle p_S} \\ Y & \xrightarrow{h} & \mathbb{A}^m_S. \end{array}$$

By (i) we know that the scheme $\mathbb{A}^m_S$ admits a dualizing complex $\omega^\bullet$, and then lemma 11.3.27(i) says that $h^!\omega^\bullet$ is dualizing as well. By proposition 11.3.25 we deduce that $\omega^\bullet_Y \simeq \mathscr{L}[\sigma] \otimes_{\mathscr{O}_Y} h^!\omega^\bullet$ for some invertible $\mathscr{O}_Y$-module $\mathscr{L}$ and some continuous function $\sigma : |Y| \to \mathbb{Z}$. Since p_Y is smooth, we can compute: $p^!_Y\omega^\bullet_Y \simeq (p^!_Y \circ h^!\omega^\bullet) \otimes_{\mathscr{O}_{\mathbb{A}^n_Y}} p^*_Y\mathscr{L}[\sigma]$, hence $p^!_Y\omega^\bullet_Y$ is dualizing if and only if the same holds for $p^!_Y \circ h^!\omega^\bullet$. By proposition 11.1.7(iv), the latter complex is isomorphic to $h'^\flat \circ p^!_S\omega^\bullet$ and again using lemma 11.3.27(i) we reduce to checking that $p^!_S\omega^\bullet$ is dualizing, which is clear from (i).

(iv): Let $f : X \to S$ be a finitely presented morphism, with X quasi-separated. If X is affine, (iii) says that $f^!\mathscr{O}_S[0]$ is dualizing on X. In the general case, let $(U_i \mid i = 1, \dots, n)$ be a finite covering of X consisting of affine open subsets; for each $i, j, k = 1, \dots, n$, denote by $f_i : U_i \to S$ the restriction of f, set $U_{ij} := U_i \cap U_j$, $U_{ijk} := U_{ij} \cap U_k$, and let $g_{ij} : U_{ij} \to U_i$ be the inclusion map. We know that $f^!_i\mathscr{O}_S[0]$ is dualizing on U_i, for every $i = 1, \dots, n$; moreover, for every $i, j = 1, \dots, n$ there exists a natural isomorphism

$$\psi_{ij} : g^*_{ij}f^!_i\mathscr{O}_S[0] \xrightarrow{\sim} g^*_{ji}f^!_j\mathscr{O}_S[0]$$

fulfilling the cocycle condition

$$\psi_{jk|U_{ijk}} \circ \psi_{ij|U_{ijk}} = \psi_{ik|U_{ijk}} \qquad \text{for every } i, j, k = 1, \dots, n$$

(lemma 11.1.16). In other words, $((U_i, f^!_i\mathscr{O}_S[0]); \psi_{ij} \mid i, j = 1, \dots, n)$ is a descent datum for the fibration (11.3.55). Then the assertion follows from proposition 11.3.56. □

Example 11.5.6. (i) For given $b \in \mathfrak{m}_K$, let $i_b : S_{/b} \to S$ be the closed immersion. If $b \neq 0$, a simple computation yields a natural isomorphism in $\mathsf{D}(\mathscr{O}_{S_{/b}}\text{-}\mathbf{Mod})$:

$$i_b^! \mathscr{O}_S \xrightarrow{\sim} \mathscr{O}_{S_{/b}}[-1].$$

By proposition 11.5.5(i,iii), we deduce that $\mathscr{O}_{S_{/b}}[0]$ is a dualizing complex on $S_{/b}$, for every $b \in \mathfrak{m}_K$.

(ii) Next, let $f : X \to S_{/b}$ be an affine finitely presented Cohen-Macaulay morphism, of constant fibre dimension n. Then $\omega_X^\bullet := f^! \mathscr{O}_{S_{/b}}[0]$ is a dualizing complex on X, by (i) and proposition 11.5.5(iii). Moreover, $\omega_X^\bullet$ is concentrated in degree $-n$, and $H^{-n}\omega_X^\bullet$ is a finitely presented f-Cohen-Macaulay $\mathscr{O}_X$-module. Indeed, let $i : X \to Y := \mathbb{A}^m_{S_{/b}}$ be a closed immersion of $S_{/b}$-schemes, and denote by $g : Y \to S_{/b}$ the projection. Fix any $x \in X$, let $y := i(x)$ and set

$$d_x := \dim \mathscr{O}_{f^{-1}(fx),x} \qquad d_y := \dim \mathscr{O}_{g^{-1}(gy),y}.$$

We have a natural isomorphism in $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})$

$$\omega_X^\bullet \xrightarrow{\sim} i^! \mathscr{O}_Y[m] \xrightarrow{\sim} i^* R\mathscr{H}om^\bullet_{\mathscr{O}_Y}(i_*\mathscr{O}_X, \mathscr{O}_Y[m])$$

(lemma 11.1.16(i)), and by assumption $i_*\mathscr{O}_X$ is a g-Cohen-Macaulay $\mathscr{O}_Y$-module; by theorem 11.3.67(ii), it follows that $\omega^\bullet_{X,x}$ is concentrated in degree $d_y - d_x - m$, and its cohomology in that degree is f-Cohen-Macaulay, as asserted. Lastly, since the fibres of f and g are equidimensional ([64, Ch.IV, Prop.5.2.1] and lemma 11.3.62(ii)), it is easily seen that $d_y - d_x = m - n$ (details left to the reader), whence the claim.

11.5.7. For any finitely presented morphism $f : X \to S$ we consider the map :

$$d : |X| \to \mathbb{Z} \qquad x \mapsto \mathrm{tr.\,deg}(\kappa(x)/\kappa(f(x))) + \dim \overline{\{f(x)\}}.$$

Lemma 11.5.8. *With the notation of* (11.5.7)*, let $x, y \in X$, and suppose that x is a specialization of y. We have :*

(i) *x is an immediate specialization of y if and only if $d(y) = d(x) + 1$.*
(ii) *If X is irreducible, $d(x) - d(y) = \dim X(y) - \dim X(x)$.*
(iii) *X is catenary and of finite Krull dimension.*
(iv) *If f is flat, then $\dim \mathscr{O}_{X,x} = \dim \mathscr{O}_{f^{-1}(fx),x} + \dim \mathscr{O}_{S,f(x)}$.*
(v) *If f is Cohen-Macaulay at the point x, then $\mathscr{O}_{X,x}$ is equidimensional.*

Proof. (i): In case $f(x) = f(y)$, the assertion follows from [64, Ch.IV, Prop.5.2.1]. Hence, suppose that $f(x) = s$, $f(y) = \eta$; let Z be the topological closure of $\{y\}$ in X, and endow Z with its reduced subscheme structure; notice that Z is an S-scheme of finite type. By assumption, X is quasi-compact and quasi-separated, hence $\{y\}$ is a pro-constructible subset of X, and therefore Z is the set of all specializations of y in X ([63, Ch.IV, Th.1.10.1]). Especially, y is the unique maximal point of $Z_\eta := Z \cap f^{-1}(\eta)$; also, if x is an immediate specialization of y, then x is a maximal point of $Z_s := Z \cap f^{-1}(s)$, and by lemma 11.4.1(i) and [64, Ch.IV, Prop.5.2.1], the latter implies that $d(y) = d(x) + 1$.

Conversely, suppose that $d(y) = d(x) + 1$; from lemma 11.4.1(i) and [64, Ch.IV, Prop.5.2.1] we deduce that x is a maximal point of Z_s; then x is an immediate specialization of y in X, since otherwise x would be an immediate specialization in X of a proper specialization y' of y in Z_η, and in this case, by the foregoing we would get $d(y') = d(x) + 1$, *i.e.* $d(y) = d(y')$, contradicting [64, Ch.IV, Prop.5.2.1].

(iii) It is easily seen that X has finite Krull dimension. Now, consider any sequence $y_0, \dots, y_n$ of points of X, with $y_0 := y$, $y_n := x$, and such that y_{i+1} is an immediate specialization of y_i, for $i = 0, \dots, n-1$; from (i) we deduce that $n = d(y) - d(x)$, especially n is independent of the chosen chain of specializations, so X is catenary.

(ii): We reduce easily to the case where y is the maximal point of X, in which case we may argue as in the proof of (iii) (details left to the reader).

(iv): If $f(x) = \eta$, the identity is [64, Ch.IV, Cor.6.1.2], hence we may assume that $f(x) = s$, and we need to check that

$$\dim X(x) = \dim \mathscr{O}_{f^{-1}(s),x} + 1.$$

Now, notice that – by the flatness assumption – every irreducible component of X intersect $f^{-1}(\eta)$, and it is therefore itself a flat S-scheme (with its reduced subscheme structure). Since $f^{-1}(\eta)$ is a noetherian scheme, it also follows that the set of irreducible components of X is finite; thus, let $X_1, \dots, X_n$ be the reduced irreducible components of X containing x, and $f_i : X_i \to S$ ($i = 1, \dots, n$) the corresponding restrictions of f. Then

$$\dim \mathscr{O}_{X,x} = \max_{1 \leq i \leq n} \dim \mathscr{O}_{X_i,x} \qquad \text{and} \qquad \dim \mathscr{O}_{f^{-1}(s),x} = \max_{1 \leq i \leq n} \dim \mathscr{O}_{f_i^{-1}(s),x}$$

so that it suffices to show the stated identity for each of the morphisms $f_1, \dots, f_n$. Hence, we may assume that X is irreducible, and we let z be the maximal point of X, and y any maximal generization of x in $f^{-1}(s)$. By lemma 11.4.1(i), $f^{-1}(s)$ is equidimensional, and we have

$$\dim \mathscr{O}_{f^{-1}(s),x} = \dim f^{-1}(s) - d(x) \qquad \text{and} \qquad \dim f^{-1}(s) = d(y)$$

([64, Ch.IV, Cor.5.2.3]). Arguing as in the proof of (i), we see that z is an immediate generization of y, hence $d(z) = d(y) + 1$. So, we come down to showing that $\dim X(x) = d(z) - d(x)$; the latter follows from (ii), since $\dim X(z) = 0$.

(v): By lemma 11.3.62(ii), the morphism f is equidimensional at the point x. Especially, $f(u) = \eta$ for every maximal point u of $\operatorname{Spec} \mathscr{O}_{X,x}$, and there exist an open neighborhood U of x in X and an integer $e \in \mathbb{N}$, such that $f^{-1}f(y)$ is equidimensional of dimension e, for every $y \in U$. Since f is finitely presented, it follows that

$$\operatorname{tr.deg}(\kappa(y)/\kappa(f(y))) = e$$

for every $y \in U$ such that y is maximal in $f^{-1}f(y)$ ([126, Th.5.6]). Hence, $d(u) = e + 1$ for every maximal point u of $\operatorname{Spec} \mathscr{O}_{X,x}$, and especially, for every such u, the difference $d(x) - d(u)$ is independent of u; in light of (i), the assertion follows. □

Lemma 11.5.9. (i) *The K^+-module K/K^+ is coh-injective.*

(ii) *Let A be a finitely presented K^+-algebra, $I \subset A$ a finitely generated ideal, J a coh-injective K^+-module. Then the A-module*

$$J_A := \operatorname*{colim}_{n \in \mathbb{N}} \operatorname{Hom}_{K^+}(A/I^n, J)$$

is coh-injective.

Proof. (i): It suffices to show that $\operatorname{Ext}^1_{K^+}(M, K/K^+) = 0$ whenever M is a finitely presented K^+-module. This is clear when $M = K^+$, and then [75, Ch.6, Lemma 6.1.14] reduces to the case where $M = K^+/aK^+$ for some $a \in \mathfrak{m}_K \setminus \{0\}$; in that case we can compute using the free resolution $K^+ \xrightarrow{a} K^+ \to M$, and the claim follows easily.

(ii): According to theorem 11.4.50(ii.a), the A-module $J'_A := \operatorname{Hom}_{K^+}(A, J)$ is coh-injective. However, $J_A = \bigcup_{n \in \mathbb{N}} \operatorname{Ann}_{J'_A}(I^n)$, so the assertion follows from theorem 11.4.50(ii.b). □

Theorem 11.5.10. *Let $f : X \to S$ be a finitely presented affine morphism. Then for every point $x \in X$, the $\mathscr{O}_{X,x}$-module*

$$J(x) := R^{1-d(x)}\Gamma_{\{x\}}(f^! \mathscr{O}_S[0])_{|X(x)}$$

is coh-injective, and we have a natural isomorphism in $\mathsf{D}(\mathscr{O}_{X,x}\text{-}\mathbf{Mod})$:

$$R\Gamma_{\{x\}}(f^! \mathscr{O}_S[0])_{|X(x)} \simeq J(x)[d(x) - 1].$$

Proof. Fix $x \in X$ and set $d := d(x)$.

Claim 11.5.11. The theorem holds in case $f(x) = \eta$.

Proof of the claim. Indeed, let $f_\eta : f^{-1}(\eta) \to S(\eta) := \mathrm{Spec}\, K$ be the restriction of f; according to lemma 11.1.16(i), $f^!_\eta \mathscr{O}_{S(\eta)}[0]$ is the restriction of $f^!\mathscr{O}_S[0]$, so the claim follows immediately from example 11.3.51. ◊

Hence, suppose that $f(x) = s$, the closed point of S, and say that $X = \mathrm{Spec}\, A$.

Claim 11.5.12. We may assume that x is closed in X, hence that $\kappa(x)$ is finite over $\kappa(s)$.

Proof of the claim. Arguing as in the proof of lemma 9.1.32, we can find a factorization of the morphism f as a composition $X \xrightarrow{g} Y := \mathbb{A}^d_S \xrightarrow{h} S$, such that $\xi := g(x)$ is the generic point of $h^{-1}(s) \subset Y$, the morphism g is finitely presented, and the stalk $\mathscr{O}_{Y,\xi}$ is a valuation ring. Moreover, let $g_y := g \times_Y \mathbf{1}_{Y(y)} : X(y) := X \times_Y Y(y) \to Y(y)$; we have a natural isomorphism

$$(f^!\mathscr{O}_S[0])_{|X(y)} \simeq g^!_y \mathscr{O}_{Y(y)}[d].$$

Then we may replace f by g_y, and K^+ by $\mathscr{O}_{Y,\xi}$, whence the claim. ◊

Hence, suppose now that x is closed in X, let $\mathfrak{p} \subset A$ be the maximal ideal corresponding to x, and $\overline{\mathfrak{p}}$ the image of $\mathfrak{p}$ in $\overline{A} := A \otimes_{K^+} \kappa$; we choose a finite system of elements $b_1, \dots, b_r \in \mathscr{O}_X(X)$ whose images in $\overline{A}$ generate $\overline{\mathfrak{p}}$. Pick any non-zero $a \in \mathfrak{m}_K$, and let $I \subset A$ be the ideal generated by the system $(a, b_1, \dots, b_r)$, and $\mathscr{I} \subset \mathscr{O}_X$ the corresponding coherent ideal; clearly $V(I) = \{x\}$, hence theorem 11.5.3 yields a natural isomorphism :

$$\text{(11.5.13)} \qquad \operatorname*{colim}_{n\in\mathbb{N}} R^i\mathrm{Hom}^\bullet_{\mathscr{O}_X}(\mathscr{O}_X/\mathscr{I}^n, f^!\mathscr{O}_S[0]) \xrightarrow{\sim} R^i\Gamma_{\{x\}} f^!\mathscr{O}_S[0] \qquad \text{for every } i \in \mathbb{Z}$$

where the transition maps in the colimit are induced by the natural maps $\mathscr{O}_X/\mathscr{I}^n \to \mathscr{O}_X/\mathscr{I}^m$, for every $n \geq m$. However, from lemmata 11.1.6(ii), 11.1.16(i) and corollary 10.3.2(i) we deduce as well natural isomorphisms :

$$R\mathrm{Hom}^\bullet_{\mathscr{O}_X}(\mathscr{O}_X/\mathscr{I}^n, f^!\mathscr{O}_S[0]) \xrightarrow{\sim} R\mathrm{Hom}^\bullet_{\mathscr{O}_S}(f_*\mathscr{O}_X/\mathscr{I}^n, \mathscr{O}_S) \xrightarrow{\sim} R\mathrm{Hom}^\bullet_{K^+}(A/I^n, K^+).$$

We wish to compute these Ext groups by means of lemma 7.11.27(iii); to this aim, let us remark first that A/I^n is an integral K^+-algebra for every $n \in \mathbb{N}$, hence it is a finitely presented torsion K^+-module, according to proposition 9.1.34(i). We may then use the coh-injective resolution $K^+[0] \to (0 \to K \to K/K^+ \to 0)$ (lemmata 11.5.9(i), 7.11.27(iii)) to compute :

$$\mathrm{Ext}^i_{K^+}(A/I^n, K^+) = \begin{cases} J_n := \mathrm{Hom}_{K^+}(A/I^n, K/K^+) & \text{if } i = 1 \\ 0 & \text{otherwise.} \end{cases}$$

Now the theorem follows from lemma 11.5.9(i) and theorem 11.4.50(ii.a),(iii).

We could also appeal directly to lemma 11.5.9(ii), provided we already knew that the foregoing natural identifications transform the direct system whose colimit appears in (11.5.13), into the direct system $(J_n \mid n \in \mathbb{N})$ whose transition maps are induced by the natural maps $A/I^n \to A/I^m$, for every $n \geq m$. For the sake of completeness, we check this latter assertion.

For every $n \geq m$, let $j_n : X_n := \mathrm{Spec}\, A/I^n \to X$ and $j_{mn} : X_m \to X_n$ be the natural closed immersions. We have a diagram of functors :

$$\begin{array}{ccccc}
j_{m*} \circ j^!_{mn} \circ (f \circ j_n)^! & \xrightarrow{\zeta_1} & j_{n*} \circ (j_{mn*} \circ j^!_{mn}) \circ j^!_n \circ f^! & \xleftarrow{\xi_2} & j_{m*} \circ j^!_m \circ f^! \\
{\scriptstyle \xi_1} \uparrow & \searrow^{\varepsilon_1} & & \searrow^{\varepsilon_2} & \downarrow {\scriptstyle \alpha_{mn}} \\
j_{m*} \circ (f \circ j_m)^! & \xrightarrow{\beta_{mn}} & j_{n*} \circ (f \circ j_n)^! & \xrightarrow{\zeta_2} & j_{n*} \circ j^!_n \circ f^!
\end{array}$$

where :

- ζ_1 and ζ_2 are induced by the natural isomorphism $\psi_{f,j_n} : (f \circ j_n)^! \xrightarrow{\sim} j^!_n \circ f^!$ of lemma 11.1.16(i).
- ξ_1 (resp. ξ_2) is induced by the isomorphism $\psi_{f\circ j_n, j_{mn}}$ (resp. $\psi_{j_n, j_{mn}}$).

- ε_1 and ε_2 are induced by the counit of adjunction $j_{mn*} \circ j^!_{mn} \to \mathbf{1}_{\mathsf{D}^+(\mathscr{O}_{X_n}\text{-}\mathbf{Mod})}$.
- β_{mn} (resp. α_{mn}) is induced by the natural map $(f \circ j_n)_*\mathscr{O}_{X_n} \to (f \circ j_m)_*\mathscr{O}_{X_m}$ (resp. by the map $j_{n*}\mathscr{O}_{X_n} \to j_{m*}\mathscr{O}_{X_m}$).

It follows from lemma 11.1.22 that the two triangular subdiagrams commute, and it is also clear that the same holds for the inner quadrangular subdiagram. Moreover, lemma 11.1.16(ii) yields a commutative diagram

$$
\begin{array}{ccc}
(f \circ j_m)^! & \xrightarrow{\psi_{f,j_m}} & j^!_m \circ f^! \\
{\scriptstyle \psi_{f\circ j_n, j_{mn}}}\downarrow & & \downarrow{\scriptstyle \psi_{j_n,j_{mn}} \circ f^!} \\
j^!_{mn} \circ (f \circ j_n)^! & \xrightarrow{j^!_{mn}(\psi_{f,j_n})} & j^!_{mn} \circ j^!_n \circ f^!
\end{array}
\tag{11.5.14}
$$

such that j_{m*}(11.5.14) is the diagram :

$$
\begin{array}{ccc}
j_{m*} \circ (f \circ j_m)^! & \xrightarrow{j_{m*}(\psi_{f,j_m})} & j_{m*} \circ j^!_m \circ f^! \\
{\scriptstyle \xi_1}\downarrow & & \downarrow{\scriptstyle \xi_2} \\
j_{m*} \circ j^!_{mn} \circ (f \circ j_n)^! & \xrightarrow{\zeta_1} & j_{m*} \circ j^!_{mn} \circ j^!_n \circ f^!.
\end{array}
$$

We then arrive at the following commutative diagram :

$$
\begin{array}{ccc}
R\mathrm{Hom}^\bullet_{\mathscr{O}_S}(\mathscr{O}_X/\mathscr{I}^m, \mathscr{O}_S) & \xrightarrow{R\Gamma(\psi_{f,j_m})} & R\mathrm{Hom}^\bullet_{\mathscr{O}_X}(\mathscr{O}_X/\mathscr{I}^m, f^!\mathscr{O}_S[0]) \\
{\scriptstyle R\Gamma(\beta_{mn})}\downarrow & & \downarrow{\scriptstyle R\Gamma(\alpha_{mn})} \\
R\mathrm{Hom}^\bullet_{\mathscr{O}_S}(\mathscr{O}_X/\mathscr{I}^n, \mathscr{O}_S) & \xrightarrow{R\Gamma(\psi_{f,j_n})} & R\mathrm{Hom}^\bullet_{\mathscr{O}_X}(\mathscr{O}_X/\mathscr{I}^n, f^!\mathscr{O}_S[0]).
\end{array}
$$

Now, the maps $R\Gamma(\alpha_{mn})$ are the transition morphisms of the inductive system whose colimit appears in (11.5.13), hence we may replace the latter by the inductive system formed by the maps $R\Gamma(\beta_{mn})$. Combining with corollary 10.3.2(i), we finally deduce natural A-linear isomorphisms

$$\operatorname*{colim}_{n\in\mathbb{N}} \mathrm{Ext}^i_{K^+}(A/I^n, K^+) \xrightarrow{\sim} R^i\Gamma_{\{x\}}f^!\mathscr{O}_S[0]$$

where the transition maps in the colimit are induced by the natural maps $A/I^n \to A/I^m$, for every $n \geq m$. Our assertion is an immediate consequence. $\square$

11.5.15. Let A be a local ring, set $X := \operatorname{Spec} A$ let $x \in X$ be the closed point, and suppose that

(a) either, A is noetherian and X admits a dualizing complex
(b) or else, A is essentially of finite presentation over K^+.

Notice that X admits a dualizing complex in case (b) as well. Indeed, in that case one can find a finitely presented affine S-scheme Y and a point $y \in Y$ such that $X \simeq \operatorname{Spec} \mathscr{O}_{Y,y}$; by proposition 11.5.5(iv), Y admits a dualizing complex $\omega^\bullet_Y$, and since every coherent $\mathscr{O}_X$-module extends to a coherent $\mathscr{O}_Y$-module, one verifies easily that the restriction of $\omega^\bullet_Y$ is dualizing for X (cp. the proof of proposition 11.3.37). Hence, let $\omega^\bullet$ be a dualizing complex for X. In case (a) (resp. in case (b)), it follows easily from corollary 11.3.46 (resp. from theorem 11.5.10 and propositions 11.5.5(iii) and 11.3.25), that there exists a unique $c \in \mathbb{Z}$ such that

$$J(x) := R^c\Gamma_{\{x\}}\omega^\bullet \neq 0.$$

Moreover, $J(x)$ is a coh-injective A-module, hence by lemma 7.11.27(iii), we obtain a well defined functor

$$D : \mathsf{D}^b(A\text{-}\mathbf{Mod}) \to \mathsf{D}^b(A\text{-}\mathbf{Mod})^o \quad : \quad C^\bullet \mapsto \mathrm{Hom}^\bullet_A(C^\bullet, J(x)). \tag{11.5.16}$$

Furthermore, let $\mathsf{D}^b_{\{x\}}(A\text{-}\mathbf{Mod}_{\mathrm{coh}})$ be the full subcategory of $\mathsf{D}^b(A\text{-}\mathbf{Mod}_{\mathrm{coh}})$ consisting of all complexes $C^\bullet$ such that $\mathrm{Supp}\, H^\bullet C^\bullet \subset \{x\}$. We have the following :

Corollary 11.5.17 (Local duality)**.** *In the situation of* (11.5.15)*, the following holds :*

(i) *The functor* (11.5.16) *restricts to an equivalence of categories :*

$$D_x : \mathsf{D}^b_{\{x\}}(A\text{-}\mathbf{Mod}_{\mathrm{coh}}) \stackrel{\sim}{\to} \mathsf{D}^b_{\{x\}}(A\text{-}\mathbf{Mod}_{\mathrm{coh}})^o$$

and the natural transformation $C_\bullet \to D_x \circ D_x(C_\bullet)$ is an isomorphism of functors.

(ii) *For every $i \in \mathbb{Z}$ there exists a natural isomorphism of functors :*

$$R^i\Gamma_{\{x\}} \circ \mathscr{D} \stackrel{\sim}{\to} D \circ R^{c-i}\Gamma \quad : \quad \mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}} \to A\text{-}\mathbf{Mod}^o$$

where $\mathscr{D}$ is the duality functor corresponding to $\omega^\bullet$ (see definition 11.3.16*).*

(iii) *Let c and $\mathscr{D}$ be as in* (ii)*, $I \subset A$ a finitely generated ideal such that $V(I) = \{x\}$, and denote by $A^\wedge$ the I-adic completion of A. Then for every $i \in \mathbb{Z}$ there exists a natural isomorphism of functors :*

$$D \circ R^i\Gamma_{\{x\}} \circ \mathscr{D} \stackrel{\sim}{\to} A^\wedge \otimes_A R^{c-i}\Gamma \quad : \quad \mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}} \to A^\wedge\text{-}\mathbf{Mod}^o_{\mathrm{coh}}.$$

Proof. Let $C_\bullet$ be any object of $\mathsf{D}^b_{\{x\}}(A\text{-}\mathbf{Mod}_{\mathrm{coh}})$; we denote by $i : \{x\} \to X$ the natural closed immersion. Obviously $C^\sim_\bullet = i_* i^{-1} C^\sim_\bullet$ (notation of (10.3)), therefore :

$$\begin{aligned}
\mathrm{Hom}^\bullet_A(C_\bullet, J(x)) &\stackrel{\sim}{\to} R\mathrm{Hom}^\bullet_A(C_\bullet, J(x)) && \text{by lemma 7.11.27(iii)}\\
&\stackrel{\sim}{\to} R\mathrm{Hom}^\bullet_{\mathscr{O}_X}(C^\sim_\bullet, R\underline{\Gamma}_{\{x\}}\omega^\bullet[c]) && \text{by theorem 10.1.18}\\
&\stackrel{\sim}{\to} R\mathrm{Hom}^\bullet_{\mathscr{O}_X}(i_* i^{-1} C^\sim_\bullet, \omega^\bullet[c]) && \text{by lemma 10.4.13(i.b)}\\
&\stackrel{\sim}{\to} R\mathrm{Hom}^\bullet_{\mathscr{O}_X}(C^\sim_\bullet, \omega^\bullet[c])
\end{aligned}$$

which easily implies (i). Next, we compute, for any object $\mathscr{F}^\bullet$ of $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$:

$$\begin{aligned}
R^i\Gamma_{\{x\}}\mathscr{D}(\mathscr{F}^\bullet) &\stackrel{\sim}{\to} R^i\mathrm{Hom}^\bullet_{\mathscr{O}_X}(\mathscr{F}^\bullet, R\Gamma_{\{x\}}\omega^\bullet) && \text{by lemma 10.4.13(iii)}\\
&\stackrel{\sim}{\to} R^i\mathrm{Hom}^\bullet_{\mathscr{O}_X}(\mathscr{F}^\bullet, J(x)[-c])\\
&\stackrel{\sim}{\to} R^i\mathrm{Hom}^\bullet_A(R\Gamma\mathscr{F}^\bullet, J(x)[-c]) && \text{by theorem 10.1.18}\\
&\stackrel{\sim}{\to} \mathrm{Hom}_A(R^{c-i}\Gamma\mathscr{F}^\bullet, J(x)) && \text{by lemma 7.11.27(iii)}
\end{aligned}$$

whence (ii). Finally, let $\mathscr{F}^\bullet$ be any object of $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$; if A is as in case (b) of (11.5.15), we compute :

$$\begin{aligned}
A^\wedge \otimes_A R^{c-i}\Gamma\mathscr{F}^\bullet &\stackrel{\sim}{\to} \lim_{n\in\mathbb{N}} (A/I^n) \otimes_A R^{c-i}\Gamma\mathscr{F}^\bullet && \text{by corollary 11.4.48(ii)}\\
&\stackrel{\sim}{\to} \lim_{n\in\mathbb{N}} D \circ D((A/I^n) \otimes_A R^{c-i}\Gamma\mathscr{F}^\bullet) && \text{by (i)}\\
&\stackrel{\sim}{\to} \lim_{n\in\mathbb{N}} D(\mathrm{Hom}_A(A/I^n, R^i\Gamma_{\{x\}}\mathscr{D}(\mathscr{F}^\bullet))) && \text{by (ii)}\\
&\stackrel{\sim}{\to} D(\operatorname*{colim}_{n\in\mathbb{N}} \mathrm{Hom}_A(A/I^n, R^i\Gamma_{\{x\}}\mathscr{D}(\mathscr{F}^\bullet)))\\
&\stackrel{\sim}{\to} D(R^i\Gamma_{\{x\}}\mathscr{D}(\mathscr{F}^\bullet))
\end{aligned}$$

so (iii) holds as well. If A is as in case (a) of (11.5.15), the same proof works : instead of corollary 11.4.48(ii), one has just to appeal to [126, Th.8.7 and Th.8.8]. ☐

Corollary 11.5.18. *Let $(A, \mathfrak{m})$ be a local noetherian ring, complete and separated for its $\mathfrak{m}$-adic topology, $\omega^\bullet$ a dualizing complex for $X := \mathrm{Spec}\, A$, and $c \in \mathbb{Z}$ the unique integer such that $J := R^c\Gamma_{\{\mathfrak{m}\}}\omega^\bullet \neq 0$. Let also $M^\bullet$ be a bounded complex of A-modules, and $M^{\bullet\sim}$ the induced complex of quasi-coherent $\mathscr{O}_X$-modules. Then we have a natural isomorphism*

$$\mathrm{Ext}^{c-i}_A(M^\bullet, \omega^\bullet) \stackrel{\sim}{\to} \mathrm{Hom}_A(R^i\Gamma_{\{\mathfrak{m}\}}M^{\bullet\sim}, J) \qquad \textit{for every } i \in \mathbb{Z}.$$

Proof. We may find a filtered system $(M^\bullet_\lambda \mid \lambda \in \Lambda)$ of bounded complexes of A-modules, such that M^n_λ is a submodule of finite type of M^n, for every $n \in \mathbb{Z}$, and such that $M^\bullet = \mathrm{colim}_{\lambda\in\Lambda} M^\bullet_\lambda$ in $\mathsf{C}^b(A\text{-}\mathbf{Mod})$ (details left to the reader). There follows a natural isomorphism of A-modules :

$$\mathrm{Hom}_A(R^i\Gamma_{\{\mathfrak{m}\}}M^{\bullet\sim}, J) \xrightarrow{\sim} \mathrm{Hom}_A(\operatorname*{colim}_{\lambda\in\Lambda} R^i\Gamma_{\{\mathfrak{m}\}}M^{\bullet\sim}_\lambda, J) \xrightarrow{\sim} \lim_{\lambda\in\Lambda} \mathrm{Hom}_A(R^i\Gamma_{\{\mathfrak{m}\}}M^{\bullet\sim}_\lambda, J).$$

Taking into account corollary 8.3.53, we are then reduced to proving the assertion for each $M^\bullet_\lambda$; but in this case, the sought isomorphism follows immediately from corollary 11.5.17(iii). ☐

Definition 11.5.19. Let A and $J(x)$ be as in (11.5.15), and E an A-module. We say that E is *finitely copresented* if there exist a finitely presented A-module M and an A-linear isomorphism $E \xrightarrow{\sim} \mathrm{Hom}_A(M, J(x))$.

Lemma 11.5.20. *Let A be as in* (11.5.15)*, and $I \subset A$ a finitely generated ideal, whose radical is the maximal ideal of A. For every A-module E, the following conditions are equivalent :*

(a) *E is finitely copresented and finitely generated.*
(b) *E is finitely copresented and $I^kE = 0$ for some $k \in \mathbb{N}$.*
(c) *E is finitely presented and $I^kE = 0$ for some $k \in \mathbb{N}$.*

Proof. To ease notation, for every ideal $L \subset A$ and every A-module M set

$$D(M) := \mathrm{Hom}_A(M, J(x)) \quad \text{and} \quad M[L] := \mathrm{Ann}_M(L).$$

Claim 11.5.21. Let E be any finitely copresented A-module. Then $E[I^k]$ is a finitely presented A-module for every $k \in \mathbb{N}$, and $E = \bigcup_{k\in\mathbb{N}} E[I^k]$.

Proof of the claim. We may assume that $E = D(M)$ for some finitely presented A-module M; then clearly every element of E is annihilated by some power of I, since the same holds for $J(x)$. Moreover, we have a natural identification

$$E[I^n] \xrightarrow{\sim} D(M/I^nM) \qquad \text{for every } n \in \mathbb{N}.$$

But M/I^kM is finitely presented and supported at $\{x\}$, so $D(M/I^kM)$ is finitely presented as well, by corollary 11.5.17(i). ♢

It follows immediately from claim 11.5.21 that (a)⇒(b)⇒(c).

(c)⇒(a): If E is finitely presented and $I^kE = 0$, then the same holds for $D(E)$, by corollary 11.5.17(i), and moreover $D \circ D(E) = E$, by the same token, whence (a). ☐

Proposition 11.5.22. *Let A be as in* (11.5.15)*, and $f : E \to N$ a homomorphism of A-modules, with E finitely copresented and N finitely presented. Then we have :*

(i) $\mathrm{Ker}\, f$ *is a finitely copresented A-module.*
(ii) $\mathrm{Im}\, f$ *and* $\mathrm{Coker}\, f$ *are finitely presented A-modules.*

Proof. Clearly, it suffices to show the assertions concerning $\mathrm{Ker}\, f$ and $\mathrm{Im}\, f$. To this aim, pick any finitely generated ideal $I \subset A$ such that $\mathrm{Supp}\, A/I = \{x\}$ (where x denotes the closed point of $\mathrm{Spec}\, A$); by corollary 11.4.41(ii) there exists $n \in \mathbb{N}$ such that $N[I^n] = N[I^m]$ for every integer $m \geq n$. In view of claim 11.5.21, we see that there exists $n \in \mathbb{N}$ such that $\mathrm{Im}\, f = (\mathrm{Im}\, f)[I^n]$. Taking into account corollary 11.4.41(i), we may then replace N by $N[I^n]$, and assume from start that $I^nN = 0$, so N is also finitely copresented, by lemma 11.5.20.

Now, more generally, let E and F be two finitely copresented A-modules, and say that $E = D(M)$, $F = D(P)$, where D is defined as in the proof of lemma 11.5.20; in view of claim

11.5.21 and corollary 11.5.17(i) we get natural identifications :

$$\begin{aligned}\mathrm{Hom}_A(E,F) &\stackrel{\sim}{\to} \lim_{n\in\mathbb{N}} \mathrm{Hom}_A(E[I^n],F[I^n]) \\ &\stackrel{\sim}{\to} \lim_{n\in\mathbb{N}} \mathrm{Hom}_A(P/I^nP,M/I^nM) \\ &\stackrel{\sim}{\to} \lim_{n\in\mathbb{N}} \mathrm{Hom}_A(P,M/I^nM) \\ &\stackrel{\sim}{\to} \lim_{n\in\mathbb{N}} \mathrm{Hom}_A(P,M^\wedge)\end{aligned}$$

where $M^\wedge$ denotes the I-adic completion of M. Recall that the natural map $M \to M^\wedge$ is injective (corollary 11.4.48(ii,iii)), so the same holds for the induced map

$$\mathrm{Hom}_A(P,M) \to \mathrm{Hom}_A(E,F) \qquad f \mapsto D(f). \tag{11.5.23}$$

Claim 11.5.24. With the foregoing notation, we have :

(i) Let $g : E \to F$ be any morphism. If g lies in the image of (11.5.23), then $\mathrm{Ker}\, g$, $\mathrm{Coker}\, g$ and $\mathrm{Im}\, g$ are all finitely copresented A-modules.

(ii) If either $I^kM = 0$ or $I^kP = 0$ for some $k \in \mathbb{N}$, then (11.5.23) is an isomorphism.

Proof of the claim. (i): Indeed, say that g is the image of $h : P \to M$ under (11.5.23); since $J(x)$ is coh-injective, we get natural identifications

$$\mathrm{Ker}\, g \stackrel{\sim}{\to} D(\mathrm{Coker}\, h) \qquad \mathrm{Coker}\, g \stackrel{\sim}{\to} D(\mathrm{Ker}\, h) \qquad \mathrm{Im}\, g \stackrel{\sim}{\to} D(\mathrm{Im}\, h)$$

whence the contention.

(ii): If $I^kM = 0$ for some $k \in \mathbb{N}$, then the natural map $M \to M^\wedge$ is an isomorphism, and the assertion follows. If $I^kP = 0$, then any morphism $P \to M^\wedge$ factors through $M^\wedge[I^k]$ (notation of the proof of lemma 11.5.20); however, corollaries 11.4.41(i) and 11.4.48(i) yield natural identifications

$$M[I^n] \stackrel{\sim}{\to} (M[I^n])^\wedge \stackrel{\sim}{\to} M^\wedge[I^n]$$

whence the contention (details left to the reader). ◊

Now, letting $F := N$ in claim 11.5.24, we deduce that both $\mathrm{Ker}\, f$ and $\mathrm{Im}\, f$ are finitely copresented. Lastly, since $I^n \cdot \mathrm{Im}\, f = 0$, lemma 11.5.20 says that $\mathrm{Im}\, f$ is finitely presented, as sought. □

Theorem 11.5.25. *In the situation of* (11.5.15)*, let $I \subset A$ be any finitely generated ideal, $C^\bullet$ any object of $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{coh}})$, and set $U := X\backslash\{x\}$. For every $i \in \mathbb{Z}$, the following conditions are equivalent :*

(a) *$I \cdot H^i(U, C^\bullet)$ is a finitely presented A-module.*

(b) *$I \cdot H^i(U, C^\bullet)$ is a finitely generated A-module.*

(c) *$I \cdot R^{i+1}\Gamma_{\{x\}}C^\bullet$ is a finitely presented A-module.*

(d) *$I \cdot R^{i+1}\Gamma_{\{x\}}C^\bullet$ is a finitely generated A-module.*

(e) *The radical of $\mathrm{Ann}_A(I \cdot R^{i+1}\Gamma_{\{x\}}C^\bullet)$ contains the maximal ideal of A.*

(f) *$I \cdot R^i\Gamma_{\{y\}}C^\bullet_{|X(y)} = 0$ for every closed point $y \in U$.*

Proof. Let $\omega^\bullet$ be a dualizing complex for X and $y \in X$ any point; then $\omega^\bullet_{|X(y)}$ is a dualizing complex for $X(y)$, and according to (11.5.15), there is a unique integer $c(y)$ such that $J(y) := R^{c(y)}\Gamma_{\{y\}}\omega^\bullet_{|X(y)} \neq 0$. If A is as in case (b) (resp. as in case (a)) of (11.5.15), we may invoke theorem 11.5.10 and lemma 11.5.8(i) (resp. lemma 11.3.50) to see that

$$c(y) + 1 = c := c(x) \quad \Leftrightarrow \quad y \text{ is a closed point of } U. \tag{11.5.26}$$

By corollary 11.5.17(i,ii), the rule

$$M \mapsto D_y(M) := \mathrm{Hom}_A(M, J(y)) \qquad \text{for every } \mathscr{O}_{X,y}\text{-module } M$$

restricts to an equivalence $\mathscr{O}_{X,y}\text{-}\mathbf{Mod}_{\mathrm{coh}} \xrightarrow{\sim} \mathscr{O}_{X,y}\text{-}\mathbf{Mod}^o_{\mathrm{coh}}$, and there is a natural isomorphism

$$(11.5.27)\qquad R^i\Gamma_{\{y\}}C^\bullet_{|X(y)} \xrightarrow{\sim} D_y(H^{c(y)-i}(X(y),(\mathscr{D}C^\bullet)_{|X(y)}))\qquad \text{in } \mathscr{O}_{X,y}\text{-}\mathbf{Mod}$$

where $\mathscr{D}$ is the duality functor corresponding to $\omega^\bullet$. Notice that $a\cdot\mathbf{1}_{D_yM} = D_y(a\cdot\mathbf{1}_M)$ for every $a\in\mathscr{O}_{X,y}$, so (11.5.27) and (11.5.26) imply that (f) holds if and only if

$$(11.5.28)\qquad I\cdot H^{c-i-1}(X(y),(\mathscr{D}C^\bullet)_{|X(y)}) = 0 \qquad \text{for every closed point } y \text{ of } U.$$

However, if A is as in case (b) (resp. as in case (a)) of (11.5.15), lemma 11.5.8(iii) (resp. theorem 11.3.52) says that every point of U specializes to a closed point, so (11.5.28) holds if and only if $I\cdot H^{c-i-1}(\mathscr{D}C^\bullet)_{|U}=0$. Since $\mathscr{D}C^\bullet$ is a complex of coherent $\mathscr{O}_X$-module, the latter condition is equivalent to saying that there exists an ideal I' whose radical is the maximal ideal of A, and such that $I'I\cdot H^{c-i-1}(\mathscr{D}C^\bullet)=0$. By invoking (11.5.27) with $y:=x$, we see that this holds if and only if $I'I\cdot R^{i+1}_{\{x\}}C^\bullet=0$. Summing up, we have shown that (e)⇔(f).

Claim 11.5.29. The A-module $I\cdot R^i\Gamma_{\{x\}}C^\bullet$ is finitely copresented, for every $i\in\mathbb{Z}$.

Proof of the claim. Notice first that, due to (11.5.27), the A-module $E := R^i\Gamma_{\{x\}}C^\bullet$ is finitely copresented, so the same holds for $E^{\oplus n}$, for every $n\in\mathbb{N}$. Since I is finitely generated, it is the image of a morphism $f: A^{\oplus n}\to A$, for some $n\in\mathbb{N}$, and then IE is naturally identified with the image of $f\otimes_A\mathbf{1}_E$. Say that $E=D_x(M)$ for a finitely presented A-module M; then clearly $f\otimes\mathbf{1}_E = D_x(f^\vee\otimes_A\mathbf{1}_M)$, where $f^\vee: A\to A^{\oplus n}$ is the transpose of f. Now the assertion follows from claim 11.5.24(i). ◊

Taking into account claim 11.5.29 and lemma 11.5.20, we deduce that (c)⇔(d)⇔(e).

Obviously, (a)⇒(b). Next, consider the exact sequence

$$H^i(X,C^\bullet)\xrightarrow{\alpha_i}H^i(U,C^\bullet)\xrightarrow{\beta_i}R^{i+1}\Gamma_{\{x\}}C^\bullet\xrightarrow{\gamma_{i+1}}H^{i+1}(X,C^\bullet)$$

(see (10.4.1)). Assume (b), which implies that $I\cdot\operatorname{Im}\beta_i$ is a finitely generated A-module, so there exists an ideal $I'\subset A$ whose radical is the maximal ideal, and such that $I'I\cdot\operatorname{Im}\beta_i=0$. On the other hand, by claim 11.5.29 and proposition 11.5.22 we know that $\operatorname{Im}\gamma_{i+1}$ is a finitely presented A-module, hence there exists an ideal $I''\subset A$ whose radical is the maximal ideal, and such that $I''\cdot\operatorname{Im}\gamma_{i+1}=0$. We conclude that $I''I'I\cdot R^{i+1}\Gamma_{\{x\}}C^\bullet=0$, whence (b)⇒(e).

Lastly, we suppose that (e) holds, and we show that (a) follows. To this aim, set $M := I\cdot H^i(U,C^\bullet)\cap\operatorname{Im}\alpha_i$, and consider the induced ladder with exact rows

$$(11.5.30)\qquad \begin{array}{ccccccccc} 0 & \longrightarrow & M & \longrightarrow & I\cdot H^i(U,C^\bullet) & \longrightarrow & I\cdot\operatorname{Ker}\gamma_{i+1} & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \operatorname{Coker}\gamma_i & \xrightarrow{\overline{\alpha}_i} & H^i(U,C^\bullet) & \longrightarrow & \operatorname{Ker}\gamma_{i+1} & \longrightarrow & 0. \end{array}$$

From (11.5.27) we know that $\operatorname{Ker}\gamma_{i+1}$ is finitely copresented and arguing as in the proof of claim 11.5.29, we conclude that the same holds for $I\cdot\operatorname{Ker}\gamma_{i+1}$. But (e) implies that the latter A-module is annihilated by a finitely generated ideal whose radical is the maximal ideal of A, so it is finitely presented, by lemma 11.5.20. We are thus reduced to checking that M is a finitely presented A-module. Now, set $N := \operatorname{Ker}(\overline{\alpha}_i\otimes_A\mathbf{1}_{A/I})$ and notice the short exact sequence

$$0\to I\cdot\operatorname{Coker}\gamma_i\to M\to N\to 0.$$

By proposition 11.5.22(ii) and (11.5.27), the A-module $\operatorname{Coker}\gamma_i$ is finitely presented, so the same holds for $I\cdot\operatorname{Coker}\gamma_i$, because A is coherent and I is finitely generated. So, we are further reduced to showing that N is finitely presented. However, N is naturally identified with the image of the map

$$\operatorname{Tor}_1^A(\operatorname{Ker}\gamma_{i+1},A/I)\to(\operatorname{Coker}\gamma_i)\otimes_A A/I$$

induced by the bottom row of (11.5.30). On the other hand, we have already noticed that $\mathrm{Coker}\,\gamma_i$ is finitely presented, so the same holds for $(\mathrm{Coker}\,\gamma_i) \otimes_A A/I$; also, proposition 11.5.22(i) and (11.5.27) say that $\mathrm{Ker}\,\gamma_{i+1}$ is finitely copresented. Taking into account proposition 11.5.22(ii) it finally suffices to show :

Claim 11.5.31. If Q is any finitely copresented A-module and P any finitely presented A-module, the A-module $\mathrm{Tor}_i^A(Q, P)$ is finitely copresented as well, for every $i \in \mathbb{N}$.

Proof of the claim. Since I is finitely generated and A is coherent, we may find a resolution $F_\bullet \xrightarrow{\sim} P[0]$ consisting of free A-modules of finite type (details left to the reader), and then $\mathrm{Tor}_i^A(Q, P) \simeq H_i(F_\bullet \otimes_A Q)$, so the assertion follows easily from claim 11.5.24(i) (details left to the reader). □

Proposition 11.5.32. *In the situation of* (11.5.15)*, let $d \in \mathbb{N}$ be any integer, and suppose additionally that :*

- (a') *If A is as in case* (a)*, then A is regular of dimension $d+1$.*
- (b') *If A is as in case* (b)*, the structure morphism $f : X \to S$ is flat, $f(x) = s$ and $f^{-1}(s)$ is a regular scheme of dimension d.*

Let $j : U := X\setminus\{x\} \to X$ be the open immersion, $\mathscr{F}$ a flat quasi-coherent $\mathscr{O}_U$-module. Then the following two conditions are equivalent :

- (c) *$\Gamma(U, \mathscr{F})$ is a flat A-module.*
- (d) *$\delta(x, j_*\mathscr{F}) \geq d+1$.*

Proof. If $d = 0$, then A is a valuation ring (proposition 9.1.34(ii)), and U is the spectrum of the field of fractions of A, in which case both (c) and (d) hold trivially. Hence we may assume that $d \geq 1$. Suppose now that (c) holds, and set $F := \Gamma(U, \mathscr{F})$. In view of (10.4.3), we need to show that $H^i(U, \mathscr{F}) = 0$ whenever $1 \leq i \leq d-1$. If $F^\sim$ denotes the $\mathscr{O}_X$-module determined by F, then $F^\sim_{|U} = \mathscr{F}$. Moreover, by [120, Ch.I, Th.1.2], F is the colimit of a filtered family $(L_i \mid i \in I)$ of free A-modules of finite rank, hence $H^i(U, \mathscr{F}) = \mathrm{colim}_{i\in I} H^i(U, L_i^\sim)$ by proposition 10.1.10(ii), so we are reduced to the case where $\mathscr{F} = \mathscr{O}_U$, and therefore $j_*\mathscr{F} = \mathscr{O}_X$ (corollary 11.3.9). In case (a'), assertion (d) follows already, by virtue of [126, Th.17.8]. So, suppose that (b') holds; since $f^{-1}(s)$ is regular, we have $\delta(x, \mathscr{O}_{f^{-1}(s)}) = d$; then, since the topological space underlying X is noetherian, lemma 10.4.20(ii) and corollary 10.4.47 imply that $\delta(x, \mathscr{O}_X) \geq d+1$, which is (d).

Conversely, suppose that (d) holds; we consider first the case (b'), and we shall derive (c) by induction on d, the case $d = 0$ having already been dealt with. Let $\mathfrak{m}_A$ (resp. $\overline{\mathfrak{m}}_A$) be the maximal ideal of A (resp. of $\overline{A} := A/\mathfrak{m}_K A$). Suppose then that $d \geq 1$ and that the assertion is known whenever $\dim f^{-1}(s) < d$. Pick $\overline{t} \in \overline{\mathfrak{m}}_A \setminus \overline{\mathfrak{m}}_A^2$, and let $t \in \mathfrak{m}_A$ be any lifting of $\overline{t}$. Since $f^{-1}(s)$ is regular, $\overline{t}$ is a regular element of $\overline{A}$, so that t is regular in A and the induced morphism $g : X' := \mathrm{Spec}\,A/tA \to S$ is flat ([65, Ch.IV, Th.11.3.8]). Let $j' : U' := U \cap X' \to X'$ be the restriction of j; our choice of $\overline{t}$ ensures that $g^{-1}(s)$ is a regular scheme, so the pair $(X', \mathscr{F}/t\mathscr{F}_{|U'})$ fulfills the conditions of the proposition, and $\dim g^{-1}(s) = d-1$. Furthermore, since $\mathscr{F}$ is a flat $\mathscr{O}_U$-module, the sequence $0 \to \mathscr{F} \xrightarrow{t} \mathscr{F} \to \mathscr{F}/t\mathscr{F} \to 0$ is short exact. Assumption (d) means that

$$H^i(U, \mathscr{F}) = 0 \qquad \text{whenever } 1 \leq i \leq d-1. \tag{11.5.33}$$

Therefore, from the long exact cohomology sequence we deduce that $H^i(U, \mathscr{F}/t\mathscr{F}) = 0$ for $1 \leq i \leq d-2$, *i.e.*

$$\delta(x, j'_*\mathscr{F}/t\mathscr{F}) \geq d. \tag{11.5.34}$$

The same sequence also yields a left exact sequence :

$$0 \to H^0(U, \mathscr{F}) \otimes_A A/tA \xrightarrow{\alpha} H^0(U, \mathscr{F}/t\mathscr{F}) \to H^1(U, \mathscr{F}). \tag{11.5.35}$$

Claim 11.5.36. $H^0(U, \mathscr{F}) \otimes_A A/tA$ is a flat A/tA-module.

Proof of the claim. By (11.5.34) and our inductive assumption, $H^0(U, \mathscr{F}/t\mathscr{F})$ is a flat A/tA-module. In case $d = 1$, proposition 9.1.34(ii) shows that A/tA is a valuation ring, and then the claim follows from (11.5.35), and [34, Ch.VI, §3, n.6, Lemma 1]. If $d > 1$, (11.5.33) implies that α is an isomorphism, so the claim holds also in such case. ◊

Set $V := \mathrm{Spec}\, A[t^{-1}] = X \setminus V(t) \subset U$; since $\mathscr{F}_{|V}$ is a flat $\mathscr{O}_V$-module, the $A[t^{-1}]$-module $H^0(U, \mathscr{F}) \otimes_A A[t^{-1}] \simeq H^0(V, \mathscr{F}_{|V})$ is flat. Moreover, since t is regular on both A and $H^0(U, \mathscr{F})$, an easy calculation shows that $\mathrm{Tor}_i^A(A/tA, H^0(U, \mathscr{F})) = 0$ for $i > 0$. Then the contention follows from claim 11.5.36 and [75, Lemma 5.2.1].

Lastly, in case (a') holds, one picks any element $t \in \mathfrak{m}_A \setminus \mathfrak{m}_A^2$ and argues in the same way (with some simplifications : details left to the reader). □

Remark 11.5.37. The special case of proposition 11.5.32 where A is regular local ring and $\mathscr{F}$ is a locally free $\mathscr{O}_U$-module of finite rank has been studied in detail in [97].

Lemma 11.5.38. *Let A be a noetherian ring, M an A-module endowed with a finite filtration $M_0 := 0 \subset M_1 \subset \cdots \subset M_k := M$, and denote by $\mathrm{gr}^\bullet M$ the associated graded A-module. Suppose that, for every $i = 1, \dots, k$, there exists an ideal $I_i \subset A$ such that $I_i \cdot \mathrm{gr}^i M$ is an A-module of finite type. Then $\prod_{i=1}^k I_i M$ is an A-module of finite type.*

Proof. A simple induction on the length of the filtration reduces the assertion to the following

Claim 11.5.39. Let A be a noetherian ring, $I, J \subset A$ two ideals, and

$$0 \to M_1 \to M_2 \to M_3 \to 0$$

a short exact sequence of A-modules, such that IM_1 and JM_3 are finitely generated. Then IJM_2 is finitely generated.

Proof of the claim. Indeed, the induced map $N := JM_2/(M_1 \cap JM_2) \to JM_3$ is injective, so N is finitely generated, and then the same holds for $I \otimes_A N$; but the latter maps surjectively onto $IJM_2/(IM_1 \cap IJM_2) \simeq (IJM_2 + IM_1)/IM_1$, so the latter is also of finite type, and therefore the same holds for $IJM_2 + IM_1$, whence the lemma. □

11.5.40. Let A be a noetherian ring, $\omega^\bullet$ a dualizing complex on $X := \mathrm{Spec}\, A$, and $I \subset A$ any ideal. Let also $U \subset X$ be any open subset, and $K^\bullet$ any object of $\mathsf{D}^b(\mathscr{O}_U\text{-}\mathbf{Mod})_{\mathrm{coh}}$. We denote :

- $\overline{U}$ the topological closure of U in X
- $Z := X \setminus U$ and $\partial U := \overline{U} \setminus U$, endowed with the reduced closed subscheme structures
- $U_1 := \{x \in U \mid$ there exists $y \in \partial U$ which is an immediate specialization of x in $\overline{U}\}$
- $\mathscr{D}_U : \mathsf{D}^b(\mathscr{O}_U\text{-}\mathbf{Mod})^o_{\mathrm{coh}} \to \mathsf{D}^b(\mathscr{O}_U\text{-}\mathbf{Mod})_{\mathrm{coh}}$ the duality functor associated with $\omega^\bullet_{|U}$
- $n(K^\bullet)$ the cardinality of $\{i \in \mathbb{Z} \mid H^i(\mathscr{D}_U K^\bullet) \neq 0\}$
- $d(K^\bullet) := \min(n(K^\bullet), 1 + \dim \partial U)$
- $\partial U(x) := \partial U \cap X(x)$ and $\delta(x) := \dim \partial U(x)$ for every $x \in X$
- $e(x) := \min(1 + \delta(y) \mid y$ is a specialization of x in $\overline{U})$ for every $x \in U_1$.

Here we use the convention that $\dim \partial U = -1$ if $\partial U = \varnothing$, and likewise we define the dimension of $\partial U(y)$, for any $y \in X$ such that this set is empty. On the other hand, the dimension of ∂U can be infinite, in the current setting. Notice that the integer $n(K^\bullet)$ depends only on $K^\bullet$, and does not depend on the choice of $\omega^\bullet$.

Lemma 11.5.41. *For every $x \in \partial U$, every closed point of $U \cap X(x)$ is an immediate generization of x in $X(x)$. Especially, every such point lies in U_1.*

Proof. Fix any $x \in \partial U$, set $A := \mathscr{O}_{X,x}$, and for any closed point z of $U \cap X(x)$, denote by $\mathfrak{p}_z \subset A$ the prime ideal corresponding to z, so that $\mathfrak{p}_z$ is strictly contained in the maximal ideal $\mathfrak{m}_A$ of A. Let also $I \subset A$ be any ideal such that $\mathrm{Spec}\, A/I = Z(x)$, so $I \not\subset \mathfrak{p}_z$ by construction. Set $B := A/\mathfrak{p}_z$, and denote by $\mathfrak{m}_B, \overline{I} \subset B$ the images of respectively $\mathfrak{m}_A$ and I. It suffices to show that $\dim B = 1$; suppose by contradiction that the latter fails, and pick any $f \in \overline{I} \setminus \{0\}$.

Claim 11.5.42. If $\dim B > 1$, there exists a prime ideal $\overline{\mathfrak{q}} \subset B$ of height 1, such that $f \notin \overline{\mathfrak{q}}$.

Proof of the claim. Clearly, every prime ideal of height one containing f is a maximal point of $\mathrm{Supp}\, B/fB$, hence it lies in $\mathrm{Ass}\, B/fB$ (lemma 10.5.3(i)); therefore, the set Σ of prime ideals of B of height one containing f is finite ([126, Th.6.5(i)]). If Σ is empty, Krull's *Hauptidealsatz* ([126, Th.13.5]) implies that f must be invertible, in which case the claim is obvious. If Σ contains a single prime ideal $\overline{\mathfrak{q}}_1$, notice that $\overline{\mathfrak{q}}_1 \neq \mathfrak{m}_B$, since $\dim B > 1$, and pick any $g \in \mathfrak{m}_B \setminus \mathfrak{q}_1$; again by Krull's theorem we know that there exists a prime ideal $\overline{\mathfrak{q}} \subset B$ of height one containing g, and by construction $\overline{\mathfrak{q}} \neq \overline{\mathfrak{q}}_1$, whence the claim, in this case. Otherwise, say that $\Sigma = \{\overline{\mathfrak{q}}_1, \cdots, \overline{\mathfrak{q}}_n\}$ for some $n \geq 2$. For every $i, j \leq n$ with $i \neq j$ we may find an element $g_{ij} \in \mathfrak{q}_i \setminus \mathfrak{q}_j$, and we set $g := \sum_{j=1}^n \prod_{i \neq j} g_{ij}$. It is easily seen that $g \in \mathfrak{m}_B \setminus (\overline{\mathfrak{q}}_1 \cup \cdots \cup \overline{\mathfrak{q}}_n)$, so we may apply again Krull's theorem to exhibit a prime ideal $\overline{\mathfrak{q}}$ which cannot lie in Σ, since it contains g. ◊

Let $\overline{\mathfrak{q}}$ be as in claim 11.5.42, and denote by $\mathfrak{q} \subset A$ the preimage of $\overline{\mathfrak{q}}$; then $\mathfrak{q}$ corresponds to a point $y \in U \cap X(x)$ which is different from x, and is a proper specialization of z in $X(x)$, which is impossible, since by assumption z is closed in U. □

Theorem 11.5.43. *In the situation of* (11.5.40)*, let $i \in \mathbb{Z}$ be any integer, and consider the following conditions :*

(a) $I \cdot R^i\Gamma_{\{x\}}K^\bullet_{|U(x)} = 0$ *for every* $x \in U_1$.
(b) $I^{d(K^\bullet)} \cdot H^i(U, K^\bullet)$ *is an A-module of finite type.*
(c) $I \cdot H^j(U, K^\bullet)$ *is an A-module of finite type, for every* $j \leq i$.
(d) $I^{e(x)} \cdot R^j\Gamma_{\{x\}}K^\bullet_{|U(x)} = 0$ *for every* $x \in U_1$ *and every* $j \leq i$.

Then (a)⇒(b) *and* (c)⇒(d).

Proof. (a)⇒(b): By corollary 10.3.39, we may find an object $L^\bullet$ of $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$ with an isomorphism $L^\bullet_{|U} \xrightarrow{\sim} K^\bullet$ in $\mathsf{D}^b(\mathscr{O}_U\text{-}\mathbf{Mod})_{\mathrm{coh}}$, whence an exact sequence

$$H^i(X, L^\bullet) \to H^i(U, K^\bullet) \to R^{i+1}\Gamma_Z L^\bullet \to H^{i+1}(X, L^\bullet)$$

(see (10.4.1)) whose first and last terms are finitely generated A-modules. By an easy diagram chase, it follows that condition (b) is equivalent to

(e) $I^{d(K^\bullet)} \cdot R^{i+1}\underline{\Gamma}_Z L^\bullet$ is a coherent $\mathscr{O}_X$-module.

It will therefore suffice to show that (a)⇒(e). However, from lemma 10.4.13(iii) we get a natural isomorphism

$$R\underline{\Gamma}_Z L^\bullet \xrightarrow{\sim} R\mathscr{H}om^\bullet_Z(\mathscr{D}_X L^\bullet, \omega^\bullet)$$

where $\mathscr{D}_X$ is the dualizing functor on $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}}$ defined by $\omega^\bullet$. By choosing an injective resolution for $\omega^\bullet$, we obtain a spectral sequence

$$E_2^{pq} := R^p\mathscr{H}om^\bullet_Z(H^{-q}(\mathscr{D}_X L^\bullet)[0], \omega^\bullet) \Rightarrow R^{p+q}\mathscr{H}om^\bullet_Z(\mathscr{D}_X L^\bullet, \omega^\bullet).$$

Now, for every $q \in \mathbb{Z}$, define the $\mathscr{O}_X$-module $\overline{H}^{-q}$ by the short exact sequence

$$0 \to \underline{\Gamma}_Z H^{-q}(\mathscr{D}_X L^\bullet) \to H^{-q}(\mathscr{D}_X L^\bullet) \to \overline{H}^{-q} \to 0.$$

There results an exact sequence

(11.5.44)
$$F^{pq} := R^p\mathscr{H}om^\bullet_Z(\overline{H}^{-q}[0], \omega^\bullet) \to E_2^{pq} \to G^{pq} := R^p\mathscr{H}om^\bullet_Z(\underline{\Gamma}_Z H^{-q}(\mathscr{D}_X L^\bullet)[0], \omega^\bullet)$$

Claim 11.5.45. For every $p, q \in \mathbb{Z}$ we have :

(i) E_2^{pq} and F^{pq} are quasi-coherent $\mathscr{O}_X$-modules.

(ii) G^{pq} and $\overline{H}^{-q}$ are coherent $\mathscr{O}_X$-modules.

Proof of the claim. The assertions about E_2^{pq} and F^{pq} follow immediately from lemmata 10.4.17(i) and 10.4.13(iii) and corollary 10.3.2(ii), and the assertion for $\overline{H}^{-q}$ follows from lemma 10.4.17(i). Next, notice that the natural map

$$\underline{\Gamma}_Z H^{-q}(\mathscr{D}_X L^\bullet) \to R\underline{\Gamma}_Z \circ \underline{\Gamma}_Z H^{-q}(\mathscr{D}_X L^\bullet)$$

is an isomorphism in $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})$, whence an isomorphism of $\mathscr{O}_X$-modules

$$G^{pq} \xrightarrow{\sim} R^p\mathscr{H}om^\bullet_{\mathscr{O}_X}(\underline{\Gamma}_Z H^{-q}(\mathscr{D}_X L^\bullet)[0], \omega^\bullet) \tag{11.5.46}$$

(lemma 10.4.13(vi)). But since X is noetherian, $\underline{\Gamma}_Z H^{-q}(\mathscr{D}_X L^\bullet)$ is a coherent $\mathscr{O}_X$-module, so the same holds for the target of (11.5.46) (proposition 10.3.3(i)), and the claim follows. ◊

Claim 11.5.47. In order to show (e), it suffices to check that :

(i) $I \cdot F^{pq} = 0$ for every $p, q \in \mathbb{Z}$ such that $p + q = i + 1$.

(ii) $F_x^{pq} = 0$ for every $x \in X$ and every $p \in \mathbb{Z}$ such that $p \notin [c_X(x) - \dim \partial U(x), c_X(x)]$.

Proof of the claim. Say that $\mathscr{D}_X L^\bullet \in \mathsf{D}^{[a,b]}(\mathscr{O}_X\text{-}\mathbf{Mod})$ for some $a, b \in \mathbb{Z}$ with $a \leq b$; to begin with, we show that – under assumptions (i) and (ii) of the claim – there exist for every $q = a, \dots, b$ and every $p = i+1-b, \dots, i+1-a$ and $x \in X$, integers $\nu(q), \mu(p, x) \in \mathbb{N}$ such that $I^{\nu(q)} F^{pq} = 0$ and $I^{\mu(p,x)} F_x^{pq} = 0$, and moreover

$$\sum_{q=a}^{b} \nu(q) \leq n(K^\bullet) \qquad \sum_{p=i+1-b}^{i+1-a} \mu(p, x) \leq 1 + \delta(x) \quad \text{for every } x \in X. \tag{11.5.48}$$

Indeed, if $q \in [a, b]$ is an index such that $H^{-q}(\mathscr{D}_U K^\bullet) = 0$, it follows that $H^{-q}(\mathscr{D}_X L^\bullet)_{|U} = 0$, so $\overline{H}^{-q} = 0$, therefore $F^{pq} = 0$ for every $p \in \mathbb{Z}$, and we may take $\nu(q) = 0$ in this case. But assumption (i) says that in any case we may take $\nu(q) \leq 1$ for every $q = a, \dots, b$. This already suffices to achieve the sought upper bound for the sum of the values $\nu(q)$. The other upper bound is treated similarly : we may in any case take $\mu(p, x) \leq 1$, due to condition (i), and moreover condition (ii) says that we may take $\mu(p, x) = 0$ for every $p \in \mathbb{Z}$ such that $p \notin [c_X(x) - \dim \partial U(x), c_X(x)]$, whence the contention.

Next, recall that $M := R^{i+1}\underline{\Gamma}_Z L^\bullet$ admits a finite filtration $\mathrm{Fil}^\bullet M$ whose associated graded $\mathscr{O}_X$-module is $\bigoplus_{p+q=i+1} E_\infty^{pq}$, and by construction, each term E_∞^{pq} is a quasi-coherent subquotient of E_2^{pq} (claim 11.5.45(i)), so $\mathrm{Fil}^q M$ is a quasi-coherent $\mathscr{O}_X$-module as well, for every $q = a, \dots, b$. Using claims 11.5.39 and 11.5.45(i,ii) we deduce that $I^{\nu(q)} E_2^{pq}$ is a coherent $\mathscr{O}_X$-module for every $q = a, \dots, b$, so the same holds for $I^{\nu(q)} E_\infty^{pq}$, and then (11.5.48) and lemma 11.5.38 imply that $I^{n(K^\bullet)} M$ is a coherent $\mathscr{O}_X$-module.

Set $\delta := \dim \partial U \in \mathbb{N} \cup \{\infty\}$; if $\delta \geq n(K^\bullet) - 1$, the proof is complete; otherwise $\delta \in \mathbb{N}$, and it remains only to check that $I^{1+\delta} M$ is also a coherent $\mathscr{O}_X$-module. To this aim, notice that (11.5.44) induces a short exact sequence

$$0 \to F_\infty^{pq} \to E_\infty^{pq} \to G_\infty^{pq} \to 0$$

where F_∞^{pq} (resp. G_∞^{pq}) is a certain quasi-coherent subquotient of F^{pq} (resp. of G^{pq}); from claim 11.5.45(ii) it follows that G_∞^{pq} is a coherent $\mathscr{O}_X$-module, and the foregoing implies that $I^{\mu(p,x)} F_{\infty,x}^{pq} = 0$ for every $x \in X$ and every $p = i+1-b, \dots, i+1-a$. We may then find, for every $q = a, \dots, b$ a coherent $\mathscr{O}_X$-submodule $N^q \subset \mathrm{Fil}^q M$ such that the induced morphism $\mathrm{Fil}^q M \to G_\infty^{pq}$ restricts to an epimorphism $N^q \to G_\infty^{pq}$. Set $N := \sum_{q=a}^{b} N^q \subset M$, and $P := M/N$, endow P with the filtration $\mathrm{Fil}^\bullet P$ induced by the filtration of M, and denote by $\mathrm{gr}^\bullet P$ the associated graded $\mathscr{O}_X$-module. By construction, we get an epimorphism $\psi_q : E_\infty^{pq} \to \mathrm{gr}^q P$ for every $q = a, \dots, b$, whose kernel contains the image of N^q in E_∞^{pq}. Consequently, the restriction of ψ_q to F_∞^{pq} is still an epimorphism, so that $I^{\mu(p,x)}\mathrm{gr}^{i+1-p}P_x = 0$ for every $x \in X$ and every $p = i+1-b, \dots, i+1-a$. In view of (11.5.48) we conclude that $I^{1+\delta(x)}P_x = 0$ for every $x \in X$, and since clearly $\delta(x) \leq \delta$ for every $x \in X$, it follows that $I^{1+\delta}P = 0$. Lastly, since N is a coherent $\mathscr{O}_X$-module, it suffices to invoke claim 11.5.39 to conclude the proof. ♢

Let $\mathscr{R}^\bullet$ be the residual complex arising from $\omega^\bullet$, introduced in (11.3.53). With this notation, F^{pq} is a subquotient of the A-module $\mathscr{H}om_{\mathscr{O}_X}(\overline{H}^{-q}, \underline{\Gamma}_Z\mathscr{R}^p)$. From lemma 10.4.4(iii.b), we get

$$\underline{\Gamma}_Z\mathscr{R}^p = \bigoplus_{x \in X_p \cap Z} E(x)^\sim. \qquad \text{with } X_p := \{x \in X \mid c_X(x) = p\} \text{ for every } p \in \mathbb{Z}$$

where $c_X : |X| \to \mathbb{Z}$ is the weak codimension function associated with $\omega^\bullet$ as in (11.3.49) and $E(x)$ is an injective hull of the A-module $\kappa(x)$, for every $x \in X$ (notation of (10.3)). Hence, denote by X_p^* the set of all specializations in X of the points of X_p; we deduce

$$\mathrm{Supp}\,\underline{\Gamma}_Z\mathscr{R}^p = Z \cap X_p^* \tag{11.5.49}$$

(we caution the reader that X_p is usually not a pro-constructible subset of X, so X_p^* is usually strictly contained in the topological closure of X_p in X). Moreover, since $\overline{H}^{-q}$ is a coherent $\mathscr{O}_X$-module (claim 11.5.45(ii)) and $\underline{\Gamma}_Z\mathscr{R}^p$ is quasi-coherent (lemma 10.4.17(i)), we also see that

$$\mathscr{H}om_{\mathscr{O}_X}(\overline{H}^{-q}, \underline{\Gamma}_Z\mathscr{R}^p)_x \simeq \mathrm{Hom}_{\mathscr{O}_{X,x}}(\overline{H}_x^{-q}, (\underline{\Gamma}_Z\mathscr{R}^p)_x) \qquad \text{for every } x \in X \tag{11.5.50}$$

([75, Lemma 2.4.29(i.a)]). Combining (11.5.49) and (11.5.50) we conclude that

$$\mathrm{Supp}\,F^{pq} \subset Z \cap X_p^* \cap \mathrm{Supp}\,\overline{H}^{-q}.$$

From this, we can already show condition (ii) of claim 11.5.47 : indeed, say that $F_x^{pq} \neq 0$; then $x \in X_p^*$, so $c_X(x) \geq p$, and on the other hand, by construction we have $\underline{\Gamma}_Z\overline{H}^{-q} = 0$, so $\mathrm{Supp}\,H^{-q}$ is the topological closure in X of $U \cap \mathrm{Supp}\,\overline{H}^{-q}$, therefore $x \in \partial U$ and furthermore there exists a generization z of x in X with $c_X(z) = p$, so $z \in X_p \cap \partial U(x)$, which forces the bound $c_X(x) \leq p + \dim \partial U(x)$, as required.

Lastly, to get condition (i) of claim 11.5.47 it suffices to check assertions (i) and (ii) of the following :

Claim 11.5.51. (i) $\mathrm{Supp}\,(I \cdot F^{pq}) \subset \mathrm{Supp}\,\mathscr{H}om_{\mathscr{O}_X}(I \cdot \overline{H}^{-q}, \underline{\Gamma}_Z\mathscr{R}^p)$ for every $p, q \in \mathbb{Z}$.
(ii) $\mathscr{H}om_{\mathscr{O}_X}(I \cdot \overline{H}^{-q}, \underline{\Gamma}_Z\mathscr{R}^p) = 0$ whenever $p + q = i + 1$.
(iii) $Z \cap X_p \cap \mathrm{Supp}\,(I \cdot \overline{H}^{-q}) = \varnothing$ whenever $p + q = i + 1$.

Proof of the claim. (i): Consider arbitrary $x \in X$, $a \in I$ and $f \in F_x^{pq}$; by virtue of (11.5.50), the element f is represented by an $\mathscr{O}_{X,x}$-linear map $\varphi : \overline{H}_x^{-q} \to \underline{\Gamma}_Z\mathscr{R}_x^p$, and therefore af is represented by $a\varphi$; the latter obviously factors through the submodule $I \cdot \overline{H}_x^{-q}$, so the contention follows from the natural identification

$$\mathscr{H}om_{\mathscr{O}_X}(I \cdot \overline{H}^{-q}, \underline{\Gamma}_Z\mathscr{R}^p)_x \simeq \mathrm{Hom}_{\mathscr{O}_{X,x}}(I \cdot \overline{H}_x^{-q}, (\underline{\Gamma}_Z\mathscr{R}^p)_x) \qquad \text{for every } x \in X \tag{11.5.52}$$

which is proven as (11.5.50).

(ii): Let $x \in X$ be any point, and $\varphi : I \cdot \overline{H}_x^{-q} \to (\underline{\Gamma}_Z\mathscr{R}^p)_x$ any $\mathscr{O}_{X,x}$-linear map; taking into account (11.5.52), we are reduced to showing that $\varphi = 0$. Now, notice that

$$(\underline{\Gamma}_Z\mathscr{R}^p)_x = \bigoplus_{y \in Z(x)_p} E(y) \qquad \text{where } Z(x)_p := X_p \cap Z \cap X(x).$$

If $Z(x)_p = \varnothing$, we are done; otherwise, for every $y \in Z(x)_p$ denote by $p_y : (\underline{\Gamma}_Z\mathscr{R}^p)_x \to E(y)$ the natural projection; it suffices to check that $p_y \circ \varphi = 0$ for every such y. However, $p_y \circ \varphi$ factors through an $\mathscr{O}_{X,y}$-linear map $I \cdot \overline{H}_y^{-q} \to (\underline{\Gamma}_Z\mathscr{R}^p)_y$, so we may replace x by y, and assume from start that $x \in X_p \cap Z$, in which case the contention will follow from assertion (iii) of the claim.

(iii): Fix any point $y \in X_p \cap Z$. We have already noticed that $\mathrm{Supp}\,\overline{H}^{-q}$ is the topological closure in X of $U \cap \mathrm{Supp}\,\overline{H}^{-q}$; we are then reduced to showing that $I \cdot \overline{H}^{-q}_z = 0$ for every closed point z of $X(y) \cap U$. But for any such z, we have an isomorphism

$$H^{-q}(\mathscr{D}_U K^\bullet)_z \xrightarrow{\sim} \overline{H}^{-q}_z \tag{11.5.53}$$

of $\mathscr{O}_{X,z}$-modules. On the other hand, corollary 11.5.17(iii) yields an isomorphism of $\mathscr{O}_{X,z}$-modules

$$\mathscr{O}^\wedge_{X,z} \otimes_{\mathscr{O}_{X,z}} H^{-q}(\mathscr{D}_U K^\bullet)_z \xrightarrow{\sim} D_z \circ R^{q+c_X(z)}\Gamma_{\{z\}} K^\bullet_{|U(z)} \tag{11.5.54}$$

where $\mathscr{O}^\wedge_{X,z}$ denotes the completion of the ring $\mathscr{O}_{X,z}$ and D_z denotes the local duality functor corresponding to the point z. We remark now that

$$c_X(z) = c_X(y) - 1 = p - 1. \tag{11.5.55}$$

Indeed, in view of lemma 11.3.50, identity (11.5.55) asserts that y is an immediate specialization of z in $X(y)$, and this is already known from lemma 11.5.41.

Finally, let $a \in I$ be any element; taking into account (11.5.53), we are reduced to checking that scalar multiplication by a is the zero endomorphism of $H^{-q}(\mathscr{D}_U K^\bullet)_z$, which – by virtue of (11.5.54) and (11.5.55) – is equivalent to showing that scalar multiplication by a is the zero endomorphism on $R^i\Gamma_{\{z\}} K^\bullet_{|U(z)}$, and the latter is ensured by our condition (a). ◊

(c)⇒(d): Let $x \in U_1$ be any point, pick any immediate specialization $y \in \partial U$ of x in X such that $1 + \dim \partial U(y) = e(x)$, let $U(y) := U \cap X(y)$, and notice that the natural map

$$H^j(U, K^\bullet) \otimes_A \mathscr{O}_{X,y} \to H^j(U(y), K^\bullet_{|U(y)})$$

is an isomorphism for every $j \in \mathbb{Z}$, so we may replace X by $X(y)$, U by $U(y)$ and $K^\bullet$ by $K^\bullet_{|U(y)}$, and assume from start that A is a local ring, and y is the closed point of X. In this situation, we need to show that $I^e R^j \Gamma_{\{x\}} K^\bullet_{|U(x)} = 0$, with $e := 1 + \dim \partial U$ and every $j \leq i$. Then, let $V := X \setminus \{y\}$, denote $j : U \to V$ the induced open immersion, and set

$$L^\bullet := \tau^{\leq i} Rj_* K^\bullet$$

(where $\tau^{\leq i}$ denotes the usual truncation functor), so that $L \in \mathrm{Ob}(\mathsf{D}^b(\mathscr{O}_V\text{-}\mathbf{Mod})_{\mathrm{qcoh}})$ and $L^\bullet_{|U} = \tau^{\leq i} K^\bullet$. Notice also that the natural morphism of $\mathscr{O}_X$-modules

$$H^j(U, K^\bullet)^\sim \to H^j L^\bullet$$

is an isomorphism for every $j \leq i$. Taking into account proposition 10.3.34(ii), it follows that we may find a morphism $\varphi^\bullet : C^\bullet \to L^\bullet$ in $\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})$ such that

- $C^\bullet \in \mathrm{Ob}(\mathsf{D}^b(\mathscr{O}_X\text{-}\mathbf{Mod})_{\mathrm{coh}})$.
- The induced morphism $C^\bullet_{|U} \to \tau^{\leq i} K^\bullet_{|U}$ is an isomorphism in $\mathsf{D}^b(\mathscr{O}_U\text{-}\mathbf{Mod})_{\mathrm{coh}}$.
- $H^j\varphi^\bullet : H^j C^\bullet \to H^j L^\bullet$ is a monomorphism for every $j \in \mathbb{Z}$, and its image contains the $\mathscr{O}_X$-submodule $I \cdot H^j(U, K^\bullet)^\sim$, for every $j \leq i$.

Set $D^\bullet := \mathrm{Cone}\,\varphi$; by construction, for every $j \in \mathbb{Z}$ we have

$$\mathrm{Supp}\, H^j L^\bullet \subset \overline{U} \cap V \quad \mathrm{Supp}\, H^j D^\bullet \subset Z \cap \mathrm{Supp}\, H^i L^\bullet \subset \partial U \cap V \quad I \cdot H^j D^\bullet = 0. \tag{11.5.56}$$

Now, consider the spectral sequence

$$E_2^{pq} := H^p(V, H^q D^\bullet) \Rightarrow H^{p+q}(V, D^\bullet).$$

It follows from (11.5.56) that $E_2^{pq} = 0$ for every $p > \dim \partial U \cap V = e - 2$, and $I \cdot E_2^{pq} = 0$ for every $p, q \in \mathbb{Z}$, whence

$$I^{e-1} H^j(V, D^\bullet) = 0 \qquad \text{for every } j \in \mathbb{Z}.$$

On the other hand, we have an exact sequence of A-modules

$$H^{j-1}(V, D^\bullet) \to H^j(V, C^\bullet) \to H^j(V, L^\bullet) = H^j(U, K^\bullet) \qquad \text{for every } j \leq i.$$

In view of lemma 11.5.38, we conclude that $I^e H^j(V, C^\bullet)$ is an A-module of finite type, whence $I^e \cdot R^j\Gamma_{\{x\}} C^\bullet_{|U(x)} = 0$ for every $j \leq i$ (theorem 11.5.25). To conclude the proof, it now suffices to observe that the natural map $R^j\Gamma_{\{x\}} C^\bullet_{|U(x)} \to R^j\Gamma_{\{x\}} K^\bullet_{|U(x)}$ is an isomorphism, for every $j \leq i$. □

The following corollary recovers the results of [85, Exp.VIII, §2].

Corollary 11.5.57. *In the situation of* (11.5.40)*, for every $i \in \mathbb{Z}$ we have :*
(i) *If $R^i\Gamma_{\{x\}} K^\bullet = 0$ for every $x \in U_1$, then $H^i(U, K^\bullet)$ is an A-module of finite type.*
(ii) *The following conditions are equivalent :*
  (a) *$R^j\Gamma_{\{x\}} K^\bullet = 0$ for every $x \in U_1$ and every $j \leq i$.*
  (b) *$H^j(U, K^\bullet)$ is an A-module of finite type for every $j \leq i$.*

Proof. It is the special case of theorem 11.5.43 with $I := A$. □

11.6. **Hochster's theorem and Stanley's theorem.** The two main results of this section are theorems 11.6.35 and 11.6.43, which were proved originally respectively by Hochster in [91], and by Stanley in [155]. Our proofs follow in the main the posterior methods presented by Bruns and Herzog in [43] (which in turns, partially rely on some ideas of Danilov). These results shall be used in section 12.5, in order to show that regular log schemes are Cohen-Macaulay. We begin with some preliminaries from algebraic topology, which we develop only to the extent that is required for our special purposes: a much more general theory exists, and is well known to experts (see *e.g.* [124, Ch.IX]).

For any topological space X, and any subset $T \subset X$, we denote by $\overline{T}$ the topological closure of T in X, endowed with the topology induced from X. We let $H_\bullet(X)$ (resp. $H_\bullet(X, T)$) be the singular homology groups of X (resp. of the pair (X, T)). Also, for every $n \in \mathbb{N}$ fix a Banach norm $\|\cdot\|$ on $\mathbb{R}^n$, and for every real number $\rho > 0$, let $\mathbb{B}^n(\rho) := \{v \in \mathbb{R}^n \mid \|v\| < \rho\}$, and set $\mathbb{S}^{n-1} := \overline{\mathbb{B}}^n(1) \setminus \mathbb{B}^n(1)$ (so $\mathbb{S}^{-1} = \varnothing$).

Definition 11.6.1. (i) A *finite regular cell complex* (or briefly : a *cell complex*) is the datum of a topological space X, together with a finite filtration

$$X^{-1} = \varnothing \subset X^0 \subset X^1 \subset X^2 \subset \cdots \subset X^k = X$$

consisting of closed subspaces, such that for every $i = 0, \dots, k$ we have a decomposition

$$X^i \setminus X^{i-1} = \bigcup_{\lambda \in \Lambda_i} e^i_\lambda$$

where :

(a) Λ_i is a finite set, and for every $\lambda \in \Lambda_i$ there exists a homeomorphism

$$f_\lambda : \overline{\mathbb{B}}^i(1) \xrightarrow{\sim} \overline{e}^i_\lambda \qquad \text{such that } f_\lambda^{-1}(e^i_\lambda) = \mathbb{B}^i(1).$$

(b) $e^i_\lambda \cap e^i_\mu = \varnothing$ for any two distinct indices $\lambda, \mu \in \Lambda_i$.
(c) $\overline{e}^i_\lambda \setminus e^i_\lambda \subset X^{i-1}$ for every $\lambda \in \Lambda_i$.

(ii) The smallest $k \in \mathbb{N}$ such that $X^k = X$ is called the *dimension* of $X^\bullet$, and is denoted $\dim X^\bullet$. For every $i = 0, \dots, k$, the subsets e^i_λ are called the *i-dimensional cells of $X^\bullet$*.

(iii) A *subcomplex* of the cell complex $X^\bullet$ is a closed subset $Y \subset X$ which is a union of cells of X. Then the filtration such that $Y^i := Y \cap X^i$ for every $i \geq -1$ defines a cell complex structure $Y^\bullet$ on Y.

Remark 11.6.2. With the notation of definition 11.6.1(i), notice that X^0 is a (finite) discrete topological space. Moreover, X is a Hausdorff space : indeed, more generally, the quotient of a compact Hausdorff space by a closed equivalence relation is Hausdorff, so in particular a space is Hausdorff, if it can be covered by finitely many closed compact Hausdorff subspaces.

Lemma 11.6.3. *With the notation of definition* 11.6.1*, we have :*

(i) *For every $i = 0, \dots, \dim X$ and $q \in \mathbb{Z}$, we have natural isomorphisms of abelian groups :*

$$H_q(X^i, X^{i-1}) \xrightarrow{\sim} \begin{cases} \mathbb{Z}^{\Lambda_i} & \text{if } q = i \\ 0 & \text{otherwise}. \end{cases}$$

(ii) *More precisely, let $(b_\lambda \mid \lambda \in \Lambda_i)$ be the canonical basis of the free $\mathbb{Z}$-module $\mathbb{Z}^{\Lambda_i}$; for every $\lambda \in \Lambda_i$, the isomorphism of* (i) *maps the image of the induced map*

$$H_i f_\lambda : H_i(\overline{\mathbb{B}}^i(1), \mathbb{S}^{i-1}) \to H_i(X^i, X^{i-1})$$

isomorphically onto the direct summand generated by b_λ.

Proof. (i): This is obvious for $i = 0$. For $i = 1, \dots, k := \dim X^\bullet$ and every $\lambda \in \Lambda_i$, set

$$Y^i_\lambda := f_\lambda(\overline{\mathbb{B}}^i(1/2)) \qquad Y^i := \bigcup_{\lambda \in \Lambda_i} Y^i_\lambda \qquad A^i := \bigcup_{\lambda \in \Lambda_i} \{f_\lambda(0)\}$$

and for any $q \in \mathbb{Z}$, consider the natural group homomorphisms

$$\begin{array}{ccccc} H_q(\overline{\mathbb{B}}^i(1/2), \overline{\mathbb{B}}^i(1/2) \setminus \{0\}) & \xrightarrow{\alpha'} & H_q(\overline{\mathbb{B}}^i(1), \overline{\mathbb{B}}^i(1) \setminus \{0\}) & \xleftarrow{\beta'} & H_q(\overline{\mathbb{B}}^i(1), \mathbb{S}^{i-1}) \\ \downarrow{\scriptstyle\gamma} & & \downarrow & & \downarrow \\ H_q(Y^i, Y^i \setminus A^i) & \xrightarrow{\alpha} & H_q(X^i, X^i \setminus A^i) & \xleftarrow{\beta} & H_q(X^i, X^{i-1}). \end{array} \tag{11.6.4}$$

The map α is an isomorphism, by excision; the same holds for β, since X^{i-1} is a deformation retract of $X^i \setminus A^i$. However, for every $\lambda \in \Lambda_i$ we have natural isomorphisms

$$H_q(Y^i_\lambda, Y^i_\lambda \setminus A) \xrightarrow{\sim} \begin{cases} \mathbb{Z} & \text{if } q = i \\ 0 & \text{otherwise.} \end{cases}$$

whence the contention.

(ii): Take $q := i$ in (11.6.4); then clearly γ is a monomorphism whose image is the direct summand $H_i(Y^i_\lambda, Y^i_\lambda \setminus A)$; on the other hand, arguing as in the foregoing, we see that both α' and β' are isomorphisms. The assertion follows easily. □

Remark 11.6.5. (i) In the situation of lemma 11.6.3, notice that there is a natural bijection from Λ_i to the set of connected components $\pi_0(X^i \setminus X^{i-1})$ of $X^i \setminus X^{i-1}$, for every $i = 0, \dots, \dim X$.

(ii) The direct sum decomposition of $H_i(X^i, X^{i-1})$ provided by lemma 11.6.3(i) depends only on the filtration $X^\bullet$ (and not on the choice of homeomorphisms f_λ). Indeed, this is clear, since the map $H_i f_\lambda$ factors as a composition :

$$H_i(\overline{\mathbb{B}}^i(1), \mathbb{S}^{i-1}) \xrightarrow{\sim} H_i(\overline{e}^i_\lambda, \overline{e}^i_\lambda \setminus e^i_\lambda) \xrightarrow{l_\lambda} H_i(X^i, X^{i-1})$$

where l_λ is the homomorphism induced by the obvious map of pairs $(\overline{e}^i_\lambda, \overline{e}^i_\lambda \setminus e^i_\lambda) \to (X^i, X^{i-1})$.

(iii) In view of (ii), the maps l_λ admit natural left inverse homomorphisms

$$p_\lambda : H_i(X^i, X^{i-1}) \to H_i(\overline{e}^i_\lambda, \overline{e}^i_\lambda \setminus e^i_\lambda)$$

such that

$$p_\mu \circ l_\lambda = 0 \qquad \text{for every } \lambda, \mu \in \Lambda_i \text{ with } \lambda \neq \mu. \tag{11.6.6}$$

These maps can be described as follows. For any $\lambda \in \Lambda_i$, the natural map of pairs $(X^i, X^{i-1}) \to (X^i, X^i \setminus e^i_\lambda)$ induces a homomorphism

$$m_\lambda : H_i(X^i, X^{i-1}) \to H_i(X^i, X^i \setminus e^i_\lambda).$$

Arguing by excision as in the proof of lemma 11.6.3(ii), it is easily seen that $q_\lambda := m_\lambda \circ l_\lambda$ is an isomorphism (details left to the reader), and we set $p_\lambda := q_\lambda^{-1} \circ m_\lambda$. Obviously p_λ is left inverse to l_λ, and in oder to check (11.6.6) it suffices to show that $m_\mu \circ l_\lambda = 0$ for every $\mu \neq \lambda$. However, $m_\mu \circ l_\lambda$ is the homomorphism arising from the map of pairs $(\overline{e}^i_\lambda, \overline{e}^i_\lambda \setminus e^i_\lambda) \to (X^i, X^i \setminus e^i_\mu)$, so the assertion follows, after remarking that $\overline{e}^i_\lambda \subset X^i \setminus e^i_\mu$.

11.6.7. We attach to any cell complex $X^\bullet$ a complex of abelian groups $\mathscr{C}_\bullet(X^\bullet)$, as follows.

- For $i < 0$ and for $i > k := \dim X^\bullet$, we set $\mathscr{C}_i(X^\bullet) := 0$, and for $i = 1, \dots, k$ we let

$$\mathscr{C}_i(X^\bullet) := H_i(X^i, X^{i-1}).$$

Sometimes we write just $\mathscr{C}_i(X)$, unless it is useful to stress which filtration $X^\bullet$ on X we are considering. For every $i > 0$, the differential $d_i : \mathscr{C}_i(X^\bullet) \to \mathscr{C}_{i-1}(X^\bullet)$ is the composition

$$H_i(X^i, X^{i-1}) \xrightarrow{\partial_i} H_{i-1}(X^{i-1}) \xrightarrow{j_{i-1}} H_{i-1}(X^{i-1}, X^{i-2})$$

where ∂_i is the boundary operator of the long exact homology sequence associated with the pair (X^i, X^{i-1}), and j_{i-1} is the homomorphism induced by the obvious map of pairs $(X^{i-1}, \varnothing) \to (X^{i-1}, X^{i-2})$. In order to check that $d_i \circ d_{i+1} = 0$ for every $i \in \mathbb{Z}$, recall that every element of $H_{i+1}(X^{i+1}, X^i)$ is the class $\overline{c}$ of a singular $(i+1)$-chain c of X^{i+1}, whose boundary $\partial_{i+1}c$ is a singular i-chain of X^i; then $d_{i+1}(\overline{c})$ is the class of $\partial_{i+1}c$ in $H_i(X^i, X^{i-1})$, and $d_i \circ d_{i+1}(\overline{c})$ is the class of $\partial_i \circ \partial_{i+1} c$ in $H_{i-1}(X^{i-1}, X^{i-2})$, so it vanishes.

- It is also useful to consider an augmented version of the above complex; namely, let us set

$$\overline{\mathscr{C}}_{-1}(X^\bullet) := \mathbb{Z} \qquad \text{and} \qquad \overline{\mathscr{C}}_i(X^\bullet) := \mathscr{C}_i(X^\bullet) \qquad \text{for every } i \neq -1$$

with differential d_0 given by the rule : $d_0(b^0_\lambda) = 1$ for every $\lambda \in \Lambda_0$.

Proposition 11.6.8. *With the notation of* (11.6.7)*, there exist natural isomorphisms of abelian groups*

$$H_q \mathscr{C}_\bullet(X^\bullet) \xrightarrow{\sim} H_q(X) \qquad \textit{for every } q \in \mathbb{N}.$$

Proof. For every topological space T, let $C_\bullet(T)$ denote the complex of singular chains of T. The filtration $X^\bullet$ induces a finite filtration of complexes

$$C_\bullet(X^0) \subset C_\bullet(X^1) \subset C_\bullet(X^2) \subset \cdots \subset C_\bullet(X)$$

whence a convergent spectral sequence

$$E^1_{pq} := H_{p+q}(X^p, X^{p-1}) \Rightarrow H_{p+q}(X)$$

(see [163, Th.5.5.1]). By direct inspection, it is easily seen that the differential $d^1_{p,0} : E^1_{p,0} \to E^1_{p-1,0}$ agrees with the differential d_p of $\mathscr{C}_\bullet(X^\bullet)$, for every $p \in \mathbb{N}$. On the other hand, lemma 11.6.3 shows that this spectral sequence degenerates, whence the contention. □

11.6.9. Keep the notation of definition 11.6.1, and set $\Lambda_0 := X^0$. For every $i = 0, \dots, \dim X$ and every $\lambda \in \Lambda_i$, the abelian group $H_{i,\lambda} := H_i(\overline{e}^i_\lambda, \overline{e}^i_\lambda \setminus e^i_\lambda)$ is free of rank one; if $i > 0$, we fix one of the two generators of this group, and we denote by b^i_λ its image in $\mathscr{C}_i(X^\bullet)$ (see remark 11.6.5(ii)). For $i = 0$, each e^0_λ is a point, hence $H_{0,\lambda}$ admits a canonical identification with $\mathbb{Z}$, and we let b^0_λ be the image of 1, under the resulting map $\mathbb{Z} \xrightarrow{\sim} H_{0,\lambda} \to \mathscr{C}_0(X^\bullet)$. The system of classes $(b^i_\lambda \mid 0 \leq i \leq \dim X, \lambda \in \Lambda_i)$ is called an *orientation* for $X^\bullet$. We may write

$$d_i(b^i_\lambda) = \sum_{\mu \in \Lambda_{i-1}} [b^i_\lambda : b^{i-1}_\mu] b^{i-1}_\mu \qquad \text{for every } i \leq \dim X^\bullet \text{ and every } \lambda \in \Lambda_i$$

for a system of uniquely determined integers $[b^i_\lambda : b^{i-1}_\mu]$, called the *incidence numbers* of the cells e^i_λ and e^{i-1}_μ (relative to the chosen orientation of $X^\bullet$). With this notation, we may state :

Lemma 11.6.10. *The incidence numbers of a cell complex $X^\bullet$ fulfill the following conditions :*

(i) $\sum_{\mu\in\Lambda_{i-1}}[b^i_\lambda : b^{i-1}_\mu]\cdot[b^{i-1}_\mu : b^{i-2}_\nu] = 0$ *for every $i \geq 2$, every $\lambda \in \Lambda_i$ and every $\nu \in \Lambda_{i-2}$.*

(ii) *Let $\lambda \in \Lambda_1$ be any index, and say that $\overline{e}^1_\lambda \setminus e^1_\lambda = e^0_\mu \cup e^0_\rho$. Then $[b^1_\lambda : b^0_\mu] + [b^1_\lambda : b^0_\rho] = 0$.*

Proof. Condition (i) translates the identity $d_{i-1} \circ d_i = 0$ for the differential $d_\bullet$ of the complex $\mathscr{C}_\bullet(X^\bullet)$. The identity of (ii) follows by a simple inspection of the definition of d_1 : details left to the reader. □

11.6.11. The generalities of the previous paragraphs shall be applied to the following situation. Let (V,σ) be a strictly convex polyhedral cone such that $\langle\sigma\rangle = V$, and set $d := \dim_{\mathbb{R}} V$. We attach to σ a cell complex $C^\bullet_\sigma$ as follows. Fix $u_0 \in \sigma^\vee$ such that $\sigma \cap \mathrm{Ker}\, u_0 = \{0\}$ (corollary 6.3.14), let σ° be the topological interior of σ (in V) and set

$$C_\sigma := \sigma \cap u_0^{-1}(1) \qquad C^\circ_\sigma := \sigma^\circ \cap u_0^{-1}(1).$$

Let $v_1, \dots, v_k$ be a minimal system of generators for σ; we may assume that $u_0(v_i) = 1$ for $i = 1, \dots, k$, in which case

$$C_\sigma = \left\{\sum_{i=1}^k \lambda_i v_i \mid \lambda_1, \dots, \lambda_k \geq 0 \quad \text{and} \quad \sum_{i=1}^k \lambda_i = 1\right\} \tag{11.6.12}$$

which shows that C_σ is a compact topological space (with the topology inherited from V).

Lemma 11.6.13. *There exists a homeomorphism $\overline{\mathbb{B}}^{d-1}(1) \xrightarrow{\sim} C_\sigma$ that maps $\mathbb{B}^{d-1}(1)$ onto C°_σ.*

Proof. Set $v_0 := k^{-1}\cdot(v_1 + \cdots + v_k)$ and $W := \mathrm{Ker}\, u_0$. It suffices to show that there exists a homeomorphism $\overline{\mathbb{B}}^{d-1}(1) \xrightarrow{\sim} D_\sigma := C_\sigma - v_0 \subset W$ that maps $\mathbb{B}^{d-1}(1)$ onto $D^\circ_\sigma := C^\circ_\sigma - v_0$. However, pick a minimal system $u_1, \dots, u_t$ of generators of $\sigma^\vee$ (corollary 6.3.12(i)); since σ spans V, for every $i = 1, \dots, t$ there exists $j \leq k$ such that $u_i(v_j) > 0$. Hence – after replacing the u_i by suitable scalar multiples – we may assume that $u_i(v_0) = 1$ for every $i = 1, \dots, t$, and then lemma 6.3.2 implies that

$$D_\sigma = \{v \in W \mid u_i(v) \geq -1 \quad \text{for every } i = 1, \dots, t\}.$$

Also, proposition 6.3.11(i) implies that

$$D^\circ_\sigma = \{v \in W \mid u_i(v) > -1 \quad \text{for every } i = 1, \dots, t\}.$$

For every $v \in W$, set $\mu(v) := \min(u_i(v)\,|i = 1, \dots, t)$. It is easily seen that $\mu(v) < 0$ for every $v \in W \setminus \{0\}$; indeed, if $\mu(w) \geq 0$, then the subset $\{\lambda w \mid \lambda \in \mathbb{R}_+\}$ lies in D_σ, and since the latter is compact, it follows that $w = 0$. Moreover we have

$$(\mathbb{R}_+ w) \cap D_\sigma = \{\lambda w \mid \lambda \in [0, -1/\mu(w)]\} \qquad \text{for every } w \in W \setminus \{0\}. \tag{11.6.14}$$

Fix a Banach norm $\|\cdot\|_V$ on V, and consider the mapping

$$\varphi : D_\sigma \to W \qquad \text{such that} \qquad \varphi(0) := 0 \quad \text{and} \quad \varphi(v) := -\frac{\mu(v)}{\|v\|}\cdot v \quad \text{for } v \neq 0.$$

It is easily seen that φ is injective; since μ is a continuous mapping, the same follows for φ, and since D_σ is compact, we conclude that φ induces a homeomorphism $D_\sigma \xrightarrow{\sim} \varphi(D_\sigma)$. However, from (11.6.14) it follows that

$$\varphi(D_\sigma) = \{v \in W \mid \|v\| \leq 1\} \qquad \text{and} \qquad \varphi(D^\circ_\sigma) = \{v \in W \mid \|v\| < 1\}$$

whence the claim. □

11.6.15. Keep the notation of (11.6.11); we consider the finite filtration $C_\sigma^\bullet$ of C_σ, defined as follows. For every $i = -1, \dots, d-1$, we let $C_\sigma^i \subset C_\sigma$ be the union of the subsets $\tau \cap u_0^{-1}(1)$, where τ ranges over the (finite) set of all faces of σ of dimension $i+1$. Clearly $C_\sigma^{-1} = \varnothing$, $C_\sigma^{d-1} = C_\sigma$, and C_σ^i is a closed subset of C_σ, for every $i = 0, \dots, d-1$. Moreover, it follows easily from lemma 11.6.13 and proposition 6.3.11(i) that the datum of C_σ and its filtration $C_\sigma^\bullet$ is a cell complex. With the notation of definition 11.6.1, the indexing set Λ_i can be taken to be the set of all $(i+1)$-dimensional faces of σ, for every $i = 0, \dots, d-1$: indeed, if τ is such a face, denote by τ° the relative interior of τ (see example 6.3.16(iii)); then it is clear that $e_\tau^i := \tau^\circ \cap C_\sigma \neq \varnothing$ and $\overline{e}_\tau^i = \tau \cap C_\sigma$.

Remark 11.6.16. (i) Notice that the cell complex $C_\sigma^\bullet$ is independent – up to homeomorphism – of the choice of u_0. Indeed, say that $u'_0 \in \sigma^\vee$ is any other linear form such that $\sigma \cap \mathrm{Ker}\, u'_0 = \{0\}$, and let $C'_\sigma := \sigma \cap u_0'^{-1}(1)$. We define a homeomorphism $\psi : C'_\sigma \stackrel{\sim}{\to} C_\sigma$, by the rule :

$$v \mapsto u_0(v)^{-1} \cdot v \qquad \text{for every } v \in C'_\sigma.$$

It is easily seen that ψ restricts to homeomorphisms $C_\sigma'^i \stackrel{\sim}{\to} C_\sigma^i$ for every $i = 0, \dots, d-1$.

(ii) For any integer $i = 0, \dots, d-3$, and any cells e_τ^i, e_λ^{i+2} of $C_\sigma^\bullet$ such that $e_\tau^i \subset \overline{e}_\lambda^{i+2}$, there exist exactly two $(i+1)$-dimensional cells e_μ^{i+1}, e_ρ^{i+1} such that $e_\tau^i \subset \overline{e}_\mu^{i+2} \cap \overline{e}_\rho^{i+1}$ and $e_\mu^{i+1} \cup e_\rho^{i+1} \subset \overline{e}_\lambda^{i+2}$: indeed, this assertion is a direct translation of claim 6.3.9(ii).

Proposition 11.6.17. *With the notation of* (11.6.9) *and* (11.6.15)*, the following holds for every* $i = 0, \dots, d-2$ *:*

(i) *If* $\tau \in \Lambda_{i+1}$ *and* $\mu \in \Lambda_i$ *is not a facet of* τ*, we have* $[b_\tau^{i+1} : b_\mu^i] = 0$.
(ii) *If* $\tau \in \Lambda_{i+1}$ *and* $\mu \in \Lambda_i$ *is a facet of* τ*, then* $[b_\tau^{i+1} : b_\mu^i] \in \{1, -1\}$.
(iii) *In the situation of remark* 11.6.16(ii)*, we have :*

$$[b_\lambda^{i+2} : b_\mu^{i+1}] \cdot [b_\mu^{i+1} : b_\tau^i] + [b_\lambda^{i+2} : b_\rho^{i+1}] \cdot [b_\rho^{i+1} : b_\tau^i] = 0.$$

Proof. (i): Consider the commutative diagram

$$(11.6.18)\qquad \begin{array}{ccccc} H_{i+1}(\overline{e}_\tau^{i+1}, \overline{e}_\tau^{i+1} \setminus e_\tau^{i+1}) & \xrightarrow{\partial} & H_i(\overline{e}_\tau^{i+1} \setminus e_\tau^{i+1}) & \xrightarrow{j_\tau} & H_i(C_\sigma^i, C_\sigma^i \setminus e_\mu^i) \\ \downarrow{\scriptstyle l_\tau} & & \downarrow{\scriptstyle g} & & \uparrow{\scriptstyle m_\mu} \\ H_{i+1}(C_\sigma^{i+1}, C_\sigma^i) & \xrightarrow{\partial'} & H_i(C_\sigma^i) & \xrightarrow{j_i} & H_i(C_\sigma^i, C_\sigma^{i-1}) \end{array}$$

where l_τ and m_μ are defined as in remark 11.6.5(ii,iii) and g is induced by the inclusion map $\overline{e}_\tau^{i+1} \setminus e_\tau^{i+1} \to C_\sigma^i$, the maps ∂ and ∂' are the boundary operators of the long exact sequences attached to the pairs $(\overline{e}_\tau^{i+1}, \overline{e}_\tau^{i+1} \setminus e_\tau^{i+1})$ and $(C_\sigma^{i+1}, C_\sigma^i)$, and j_i (resp. j_τ) is deduced from the obvious map of pairs $(\overline{e}_\tau^{i+1} \setminus e_\tau^{i+1}, \varnothing) \to (C_\sigma^i, C_\sigma^i \setminus e_\mu^i)$ (resp. $(C_\sigma^i, \varnothing) \to (C_\sigma^i, C_\sigma^{i-1})$). In light of remark 11.6.5(iii), we need to check that $m_\mu \circ j_{i-1} \circ \partial' \circ l_\tau = 0$, and to this aim, it suffices to show that $j_\tau = 0$. However, the assumption implies that $\mu \cap \tau$ is a (proper) face of both μ and τ; this translates as the identity $(\overline{e}_\tau^{i+1} \setminus e_\tau^{i+1}) \cap e_\mu^i = \varnothing$, whence the claim.

(ii): Clearly $C_\tau^\bullet$ is a cell subcomplex of $C_\sigma^\bullet$, and e_τ^{i+1} and e_μ^i are cells of this subcomplex. Moreover, any orientation for $C_\sigma^\bullet$ restricts to an orientation for $C_\tau^\bullet$, and the resulting incidence number of e_τ^{i+1} and e_μ^i is the same for either cell complex. Thus, we may replace σ by τ, in which case the map g of (11.6.18) is the identity.

Claim 11.6.19. If $\sigma = \tau$ and $i > 0$, both ∂ and $k_\mu := m_\mu \circ j_i$ in (11.6.18) are isomorphisms.

Proof of the claim. For ∂, we use the long exact homology sequence of the pair $(\overline{e}_\tau^{i+1}, \overline{e}_\tau^{i+1} \setminus e_\tau^{i+1})$: since $i \geq 0$, lemma 11.6.13 implies that $H_{i+1}(\overline{e}_\tau^{i+1}) = 0$, so ∂ is injective; since $i > 0$, the same argument shows that ∂ is surjective. Next, k_μ is the homomorphism deduced from the long exact homology sequence of the pair $(C_\tau^i, C_\tau^i \setminus e_\mu^i)$, and we remark that $C_\tau^i \setminus e_\mu^i$ is contractible :

indeed, e^i_μ is homeomorphic to $\mathbb{B}^i(1)$ (lemma 11.6.13), hence $C^i_\tau \setminus e^i_\mu$ is a retraction of $C^i_\tau \setminus \{x\}$, for any $x \in e^i_\mu$, and the latter is homeomorphic to $\mathbb{R}^i$ (again by lemma 11.6.13). If $i > 1$, we deduce already that k_μ is an isomorphism. For $i = 1$, the same argument shows that k_μ is injective, so its cokernel is a cyclic torsion group that injects into $H_0(C^1_\tau \setminus e^1_\mu) \simeq \mathbb{Z}$, hence it must vanish as well. ◊

Since (11.6.18) commutes, claim 11.6.19 yields the assertion, in case $i > 0$. If $i = 0$, C^1_τ is isomorphic to $\overline{\mathbb{B}}^1(1)$, and e^0_μ is one of the two points of $\overline{\mathbb{B}}^1(1) \setminus \mathbb{B}^1(1)$, so the assertion can be checked easily, by inspecting the definitions.

(iii) follows from (i), lemma 11.6.10(i) and remark 11.6.16(ii). □

The following result says that the properties of proposition 11.6.17 completely characterize the incidence numbers of $C^\bullet_\sigma$.

Proposition 11.6.20. *Keep the notation of* (11.6.15)*, and consider a system of integers*

$$(\beta^i_{\lambda\mu} \mid i = 1, \dots, d-1,\ \lambda \in \Lambda_i, \mu \in \Lambda_{i-1})$$

such that :

(a) *If $\lambda \in \Lambda_i$ and $\mu \in \Lambda_{i-1}$ is not a facet of λ, then $\beta^i_{\lambda\mu} = 0$.*

(b) *If $\lambda \in \Lambda_i$ and $\mu \in \Lambda_{i-1}$ is a facet of λ, then $\beta^i_{\lambda\mu} \in \{1, -1\}$.*

(c) *If μ and τ are the two 1-dimensional facets of the 2-dimensional face λ of σ, then*

$$\beta^1_{\lambda\mu} + \beta^1_{\lambda\tau} = 0.$$

(d) *Let $\lambda \in \Lambda_{i+1}$ and $\mu \in \Lambda_{i-1}$ be two faces, such that μ is a face of λ, and denote by τ and ρ the two facets of λ that contain μ. Then*

$$\beta^{i+1}_{\lambda\tau}\beta^i_{\tau\mu} + \beta^{i+1}_{\lambda\rho}\beta^i_{\rho\mu} = 0.$$

Then there exists a unique orientation of $C^\bullet_\sigma$

$$(b^i_\lambda \mid i = 0, \dots, d-1,\ \lambda \in \Lambda_i)$$

such that for every $i = 1, \dots, d-1$ we have :

(11.6.21) $$[b^i_\lambda : b^{i-1}_\mu] = \beta^i_{\lambda\mu} \qquad \text{for every } \lambda \in \Lambda_i,\ \mu \in \Lambda_{i-1}.$$

Proof. We construct the orientation classes b^i_λ fulfilling condition (11.6.21), by induction on i. For $i = 0$, the condition is empty, and the classes b^0_λ are prescribed by (11.6.9). For $i = 1$, and a given $\lambda \in \Lambda_1$, denote by τ and ρ the two faces of λ; clearly the condition $[b^1_\lambda : b^0_\tau] = \beta^1_{\lambda\tau}$ (and assumption (b)) determines b^1_λ univocally, and in view of (c) and lemma 11.6.10(ii), for this choice of orientation of e^1_λ we have as well $[b^1_\lambda : b^0_\rho] = \beta^1_{\lambda\rho}$. Moreover, if $\mu \in \Lambda_0 \setminus \{\tau, \rho\}$, then (11.6.21) is verified as well, by virtue of (a) and proposition 11.6.17(i).

Now, suppose that $i > 1$ and that we have already constructed orientation classes b^j_μ as sought, for every $j < i$ and every $\mu \in \Lambda_j$. Let $\lambda \in \Lambda_i$ be any face, and fix a facet τ of λ; again, the identity

(11.6.22) $$[b^i_\lambda : b^i_\tau] = \beta^i_{\lambda\tau}$$

determines b^i_λ, and it remains to check that – with this choice of b^i_λ – condition (11.6.21) holds for every $\mu \in \Lambda_{i-1} \setminus \{\tau\}$, and by virtue of (a) and proposition 11.6.17(i), it suffices to consider the facets μ of λ. However, notice that the system of orientation classes $(b^j_\mu \mid j = 0, \dots, i-1,\ \mu \subset \lambda)$ amounts to an orientation of C^{i-1}_λ (regarded as a cell subcomplex of $C^\bullet_\sigma$), and the incidence numbers for the complex $(C^{i-1}_\lambda)^\bullet$ relative to these classes agree with the incidence numbers of $C^\bullet_\sigma$, relative to the same classes. Especially, the sums

$$c := \sum_{\mu \in \Lambda_{i-1}} \beta^i_{\lambda\mu} b^{i-1}_\mu \qquad c' := \sum_{\mu \in \Lambda_{i-1}} [b^i_\lambda : b^{i-1}_\mu] b^{i-1}_\mu$$

are well defined elements of $\mathscr{C}_{i-1}(C_\lambda^{i-1})$, and in fact :

$$\begin{aligned} d_{i-1}(c) &= \sum_{\mu\in\Lambda_{i-1}} \beta^i_{\lambda\mu}\cdot d_{i-1}(b^{i-1}_\mu) \\ &= \sum_{\mu\in\Lambda_{i-1}} \beta^i_{\lambda\mu}\cdot \sum_{\rho\in\Lambda_{i-2}} [b^{i-1}_\mu : b^{i-2}_\rho]b^{i-2}_\rho \\ &= \sum_{\mu\in\Lambda_{i-1}}\sum_{\rho\in\Lambda_{i-2}} \beta^i_{\lambda\mu}\beta^{i-1}_{\mu\rho}b^{i-2}_\rho && \text{(by inductive assumption)} \\ &= 0 && \text{(by (d))} \end{aligned}$$

and a similar calculation yields $d_{i-1}(c')=0$ as well. However, C_λ^{i-1} is homeomorphic to $\mathbb{S}^{i-1}$ (lemma 11.6.13), hence

$$\mathrm{Ker}(d_{i-1}:\mathscr{C}_{i-1}(C_\lambda^{i-1})\to\mathscr{C}_{i-2}(C_\lambda^{i-1}))\simeq\mathbb{Z}$$

which, in view of (b), implies that $c=\pm c'$. Taking into account (11.6.22), we see that actually $c=c'$, whence the claim. The uniqueness of the orientation fulfilling condition (11.6.21) can be checked easily by induction on i : the details shall be left to the reader. □

11.6.23. Let now L be a free abelian group of finite rank d, and $(L_\mathbb{R},\sigma)$ a strictly convex L-rational polyhedral cone (see (6.3.20)), such that $\langle\sigma\rangle=L_\mathbb{R}$; set

$$P:=L\cap\sigma \qquad F_\lambda:=L\cap\lambda \qquad P_\lambda:=F_\lambda^{-1}P \qquad \text{for every face } \lambda \text{ of } \sigma$$

so P and its localization P_λ are fine and saturated monoids (proposition 6.3.22(i)), and F_λ is a face of P, for every such λ. Let R be any ring, and if $\lambda,\mu\subset\sigma$ are any two faces with $\lambda\subset\mu$, denote by

$$j_{\lambda\mu}:R[P_\lambda]\to R[P_\mu]$$

the natural localization map; notice that if $0\subset\sigma$ is the unique 0-dimensional face, then $P_0=P$, and $j_{0\mu}$ is the localization map $R[P]\to R[P_\mu]$. We attach to P the complex $\overline{\mathscr{C}}{}^\bullet_P$ of $R[P]$-modules such that :

$$\overline{\mathscr{C}}{}^0_P:=R[P] \qquad\text{and}\qquad \overline{\mathscr{C}}{}^i_P:=\bigoplus_{\lambda\in\Lambda_{i-1}}R[P_\lambda] \qquad \text{for every } i=1,\dots,\dim P$$

with differentials given by the rule :

$$d^i(x_\lambda):=\sum_{\substack{\mu\in\Lambda_i\\ \lambda\subset\mu}}[b^i_\mu:b^{i-1}_\lambda]\cdot j_{\lambda\mu}(x_\lambda) \qquad \text{for every } i\geq 1,\ \lambda\in\Lambda_{i-1} \text{ and } x_\lambda\in R[P_\lambda]$$

and

$$d^0(x):=\sum_{\mu\in\Lambda_0}j_{0\mu}(x) \qquad \text{for every } x\in R[P]$$

where $(b^j_\tau\mid j=0,\dots\dim\sigma-1,\ \tau\in\Lambda_j)$ is a chosen orientation for $C^\bullet_\sigma$. Taking into account lemma 11.6.10(ii) and proposition 11.6.17(iii), it is easily seen that $d^{i+1}\circ d^i=0$ for every $i\geq 0$ (essentially, the differential d^i is the transpose of the differential d_{i-1} of $\overline{\mathscr{C}}_\bullet(C^\bullet_\sigma)$).

Set as well $X:=\mathrm{Spec}\,R[P]$, and notice that $Z:=\mathrm{Spec}\,R\langle P/\mathfrak{m}_P\rangle\simeq\mathrm{Spec}\,R$ is a closed subset of X. For any $R[P]$-module M, we denote as usual by $M^\sim$ the quasi-coherent $\mathscr{O}_X$-module arising from M.

Theorem 11.6.24. *With the notation of* (11.6.23)*, for every $R[P]$-module M we have a natural isomorphism*

$$R\Gamma_Z M^\sim \xrightarrow{\sim} M\otimes_{R[P]}\overline{\mathscr{C}}{}^\bullet_P \qquad \textit{in } \mathsf{D}^+(R[P]\text{-}\mathbf{Mod}).$$

Proof. For every face λ of σ, set $U_\lambda := \mathrm{Spec}\, R[P_\lambda]$, and denote by $g_\lambda : U_\lambda \to X$ the open immersion. We consider the chain complex $\mathscr{R}_\bullet$ of $\mathbb{Z}_X$-modules such that :

$$\mathscr{R}_0 := \mathbb{Z}_X \qquad \mathscr{R}_i := \bigoplus_{\lambda\in\Lambda_{i-1}} g_{\lambda!}\mathbb{Z}_{U_\lambda} \qquad \text{for every } i = 1, \dots, \dim P.$$

The differential $d_1 : \mathscr{R}_1 \to \mathscr{R}_0$ is just the sum of the natural morphisms $g_{\lambda!}\mathbb{Z}_{U_\lambda} \to \mathbb{Z}_X$, for λ ranging over the one-dimensional faces of σ. For $i > 1$, the differential d_i is the sum of the maps

$$d_\lambda := \sum_{\substack{\mu\in\Lambda_i\\ \mu\subset\lambda}} [b^i_\lambda : b^{i-1}_\mu] \cdot d_{\lambda\mu!} : g_{\lambda!}\mathbb{Z}_{U_\lambda} \to \mathscr{R}_{n-1} \qquad \text{for every } \lambda \in \Lambda_{i-1}$$

where $d_{\lambda\mu} : g_{\lambda!}\mathbb{Z}_{U_\lambda} \to g_{\mu!}\mathbb{Z}_{U_\mu} \subset \mathscr{R}_{n-1}$ is induced by the inclusion $U_\lambda \subset U_\mu$. With this notation, a simple inspection of the definitions yields a natural identification

$$M \otimes_{R[P]} \overline{\mathscr{C}}^\bullet_P \xrightarrow{\sim} \mathrm{Hom}^\bullet_{\mathbb{Z}}(\mathscr{R}_\bullet, M^\sim[0]) \qquad \text{in } \mathsf{C}(R[P]\text{-}\mathbf{Mod}). \tag{11.6.25}$$

On the other hand, let $\lambda_1, \dots, \lambda_n$ be the one-dimensional faces of σ; then λ_i is L-rational (see (6.3.20)), and F_{λ_i} is a fine, sharp and saturated monoid of dimension one (propositions 6.3.22(i) and 6.4.9(ii)), so $F_{\lambda_i} \simeq \mathbb{N}$ for $i = 1, \dots, n$ (theorem 6.4.18(ii)). For each $i = 1, \dots, n$, let y_i be the unique generator of F_{λ_i}, and denote by $I \subset P$ the ideal generated by $y_1, \dots, y_n$; we remark

Claim 11.6.26. The radical of I is $\mathfrak{m}_P$.

Proof of the claim. For any $x \in \mathfrak{m}_P$, pick a subset $S \subset \{1, \dots, n\}$ such that $x = \sum_{i\in S} a_i y_i$, with $a_i > 0$ for every $i \in S$. Let $N \in \mathbb{N}$ be large enough such that $Na_i \geq 1$ for every $i \in S$, and pick $b_i \in \mathbb{N}$ such that $Na_i \geq b_i \geq 1$ for every $i \in S$. It follows that $Nx - \sum_{i\in S} b_i y_i \in P$, and the claim follows. ◊

Now, let $i : Z \to X$ be the closed immersion; we have :

Claim 11.6.27. The natural map $\mathbb{Z}_X \to i_*\mathbb{Z}_Z$ induces an isomorphism

$$\mathscr{R}_\bullet \xrightarrow{\sim} i_*\mathbb{Z}_Z[0] \qquad \text{in } \mathsf{D}^+(\mathbb{Z}_X\text{-}\mathbf{Mod}). \tag{11.6.28}$$

Proof of the claim. The assertion can be checked on the stalks at the points of X, hence let $x \in X$ be any such point; if $x \in Z$, claim 11.6.26 easily implies that $(\mathscr{R}_\bullet)_x$ is concentrated in degree zero, and then $(11.6.28)_x$ is clearly an isomorphism of complexes of $\mathbb{Z}$-modules. If $x \notin Z$, let $\mathfrak{p} \subset R[P]$ be the prime ideal corresponding to x, and $\lambda \subset \sigma$ the unique face such that $P \setminus F_\lambda = \mathfrak{p} \cap P$; a simple inspection of the construction shows that

$$(\mathscr{R}_\bullet)_x \xrightarrow{\sim} \overline{\mathscr{C}}_\bullet(C^\bullet_\lambda)$$

(notation of (11.6.7)). But proposition 11.6.8 and lemma 11.6.13 imply that $\overline{\mathscr{C}}_\bullet(C^\bullet_\lambda)$ is acyclic, whence the claim. ◊

In view of (11.6.25) and claim 11.6.27, we are reduced to showing that the natural map

$$\mathrm{Hom}^\bullet_{\mathbb{Z}}(\mathscr{R}_\bullet, M^\sim[0]) \to R\mathrm{Hom}^\bullet_{\mathbb{Z}}(\mathscr{R}_\bullet, M^\sim[0])$$

is an isomorphism in $\mathsf{D}^+(R[P]\text{-}\mathbf{Mod})$. This can be done by a spectral sequence argument, along the lines of proposition 10.4.18 (which indeed includes a special case of the situation we are considering here, namely the case where P is a free monoid : the details shall be left to the reader). □

11.6.29. Notice that $\overline{\mathscr{C}}^\bullet_P$ is a complex of L-graded R-modules, hence its cohomology is L-graded as well, and we wish next to compute the graded terms $\mathrm{gr}_\bullet H^\bullet(\overline{\mathscr{C}}^\bullet_P)$. To this aim, we make the following :

Definition 11.6.30. Let V be a finite dimensional $\mathbb{R}$-vector space, $X \subset V$ any subset, and $z \in V$ any point. Then :

(a) We say that a point $x \in X$ *is visibile from* z, if $\{tz + (1-t)x \mid 0 \leq t \leq 1\} \cap X = \{x\}$.
(b) We say that a subset $S \subset X$ *is visibile from* z, if every point of S is visible from z.

Lemma 11.6.31. *In the situation of* (11.6.15)*, let* $z \in V \setminus C_\sigma$ *be any point, and denote by* S *the set of points of* C_σ *that are visible from* z*. Then :*

(i) *S is a subcomplex of $C^\bullet_\sigma$.*
(ii) *S (with the topology induced from V) is homeomorphic to $\overline{\mathbb{B}}^e(1)$, for $e \in \{d-2, d-1\}$.*

Proof. Pick a system of generators $\rho_1, \dots, \rho_n$ for $\sigma^\vee$, and choose $\rho_0 \in \sigma^\vee$ so that $C_\sigma = \sigma \cap \rho_0^{-1}(1)$; we may assume that, for some integer $k \leq n$ we have

$$\rho_i(z) < 0 \qquad \text{if and only if} \qquad 1 \leq i \leq k.$$

Say that $y \in C_\sigma$, so that $\rho_i(y) \geq 0$ for every $i = 1, \dots, n$, and set $y_t := tz + (1-t)y$ for every $t \in [0,1]$; then clearly $\rho_i(y_t) \geq 0$ for every $i = k+1, \dots, n$. Now, if $\rho_0(z) \neq 1$, we get $\rho_0(y_t) \neq 1$ for every $t \neq 0$, therefore the whole of C_σ is visible from z, in which case (i) is trivial, and (ii) follows from 11.6.13. Hence we may assume that $\rho_0(z) = 1$, so $\rho_0(y_t) = 1$ for every $t \in [0,1]$. Suppose now that $\rho_i(y) > 0$ for some $i \leq k$; then there exists a unique $t_i \in]0,1[$ such that $\rho_i(y_{t_i}) = 0$. Hence, if $s := \min(\rho_i(y) \mid i = 1, \dots, k) > 0$, let $t := \min(t_i \mid i = 1, \dots, k)$; it follows that $\rho_i(y_t) \geq 0$ for every $i = 1, \dots, n$, so $y_t \in C_\sigma$, which says that y is not visible from z. Conversely, if $s = 0$, then it follows easily that y is visible from z. We conclude that

$$S = C_\sigma \cap \bigcup_{i=1}^k \mathrm{Ker}\, \rho_i$$

which shows (i). Next, set $W := \mathrm{Ker}\, \rho_0$, and denote by $\tau_z : \rho_0^{-1}(1) \xrightarrow{\sim} W$ the translation map given by the rule : $x \mapsto x - z$ for every $x \in \rho_0^{-1}(1)$. To conclude, it suffices to check that $S' := \tau_z(S)$ is homeomorphic to $\overline{\mathbb{B}}^{d-2}(1)$. To this aim, denote by λ the convex cone in W generated by $\tau_z(C_\sigma)$. Explicitly, if $v_1, \dots, v_k \in \sigma$ have been chosen so that (11.6.12) holds, then λ is the cone generated by $v_1 - z, \dots, v_k - z$; especially, λ is a polyhedral cone, and it is easily seen that $\langle \lambda \rangle = W$. Moreover, λ is strictly convex; indeed, otherwise there exist real numbers $a_1, \dots, a_k \geq 0$, with $a_i > 0$ for at least an index $i \leq k$, such that $\sum_{i=1}^k a_i \cdot (v_i - z) = 0$, *i.e.* $\sum_{i=1}^k a_i v_i = (\sum_{i=1}^k a_i) \cdot z$, which is absurd, since $z \notin \sigma$. Pick $u \in \lambda^\vee$ such that $\lambda \cap \mathrm{Ker}\, u = 0$, and set $C_\lambda := \lambda \cap u^{-1}(1)$; by lemma 11.6.13, the subset C_λ is homeomorphic to $\overline{\mathbb{B}}^{d-2}(1)$. Lastly, let $\pi : W \setminus \mathrm{Ker}\, u \to u^{-1}(1)$ be the radial projection (so $\pi(w)$ is the intersection point of $\mathbb{R}w$ with $u^{-1}(1)$, for every $w \in W \setminus \mathrm{Ker}\, u$). It is easily seen that π maps S' bijectively onto C_λ, so the restriction of π is a homeomorphism $S' \xrightarrow{\sim} C_\lambda$, as required. □

Lemma 11.6.32. *In the situation of* (11.6.23)*, let* $\lambda \subset \sigma$ *be any face. For every* $l \in L_\mathbb{R}$ *we have:*

(i) *The set of points of σ that are visible from l is a union of faces of σ.*
(ii) *Suppose $l \in L$, and endow $R[P_\lambda]$ with its natural L-grading. Then*

$$\mathrm{gr}_l R[P_\lambda] = \begin{cases} Rl & \textit{if } \lambda \subset \sigma \textit{ is not visible from } l \\ 0 & \textit{otherwise.} \end{cases}$$

Proof. Let $\rho_1, \dots, \rho_n$ be a system of generators of $\sigma^\vee$; we may assume that, for some integer $k \leq n$ we have

$$\rho_i(l) < 0 \qquad \text{if and only if } 1 \leq i \leq k.$$

Arguing as in the proof of lemma 11.6.31, we check easily that the set of points of σ visible from l equals $S := \sigma \cap \bigcup_{i=1}^k \mathrm{Ker}\, \rho_i$, which already shows (i).

(ii): Suppose first that $\lambda \subset \sigma$ is not visible from l; then there exists $x \in \lambda \setminus S$, and since F_λ generates λ (see (6.3.20)), we may assume that $x \in F_\lambda$ (details left to the reader). A simple inspection then shows that there exists a sufficiently large $N \in \mathbb{N}$ such that $l + Nx \in \sigma$, whence $l \in R[P_\lambda]$, and so $\mathrm{gr}_l R[P_\lambda] = Rl$. Conversely, if the latter identity holds, then there exists $x \in F_\lambda$ such that $l + x \in P$, whence $\rho_i(x) > 0$ for $i = 1, \dots, k$, so x is not visible from l. □

11.6.33. In the situation of (11.6.23), let us fix a linear form $u_0 \in \sigma^\vee$ such that $\sigma \cap \mathrm{Ker}\, u_0 = 0$, and define σ° and C_σ as in (11.6.11). For any $l \in L_\mathbb{R}$, denote by S_l the set of points of σ that are visible from l, so S_l is a union of faces of σ, by lemma 11.6.32(i), and therefore $C_l := S_l \cap C_\sigma$ is a subcomplex of $C_\sigma^\bullet$.

Proposition 11.6.34. *With the notation of* (11.6.33), *suppose $l \in L$. Then the following holds :*

(i) *If $-l \in \sigma^\circ$, the complex of R-modules $\mathrm{gr}_l \overline{\mathscr{C}}{}^\bullet_P$ is isomorphic to $R[-d]$.*

(ii) *If $-l \notin \sigma^\circ$, there is a natural isomorphism of complexes of R-modules :*

$$\mathrm{gr}_l \overline{\mathscr{C}}{}^\bullet_P \xrightarrow{\sim} \mathrm{Hom}^\bullet_\mathbb{Z}(\overline{\mathscr{C}}_\bullet(C_\sigma^\bullet)/\overline{\mathscr{C}}_\bullet(C_l^\bullet), R[-1]).$$

Moreover, in this case, both $\overline{\mathscr{C}}_\bullet(C_\sigma^\bullet)$ and $\overline{\mathscr{C}}_\bullet(C_l^\bullet)$ are acyclic complexes.

Proof. (i): If $-l \in \sigma^\circ$, then $l \in P_\lambda$ if and only if $\lambda = \sigma$, so the assertion is clear.

(ii): The sought identification of complexes follows from lemma 11.6.32(ii), by a direct inspection of the constructions (and indeed, this holds even if $-l \in \sigma^\circ$: details left to the reader). Moreover, it is already known from proposition 11.6.8 and lemma 11.6.13 that $\overline{\mathscr{C}}_\bullet(C_\sigma^\bullet)$ is acyclic.

• Next, if $l \in P$, then clearly $S_l = \varnothing$, so the assertion for $\overline{\mathscr{C}}_\bullet(C_l^\bullet)$ is trivial in this case.

• Thus, suppose that $l \notin P$; if furthermore $-l \notin P$, then the convex cone τ generated by P and l is still strictly convex, so we may find $u_1 \in \tau^\vee$ such that $u_1(l) = 1$ and $\sigma \cap \mathrm{Ker}\, u_1 = 0$. Set $C'_\sigma := \sigma \cap u_1^{-1}(1)$ and $C'_l := S_l \cap C'_\sigma$. In remark 11.6.16(i) we have exhibited a homeomorphism $C'^\bullet_\sigma \xrightarrow{\sim} C^\bullet_\sigma$ that preserves the respective cell complex structures, and a simple inspection shows that this homeomorphism maps C'_l onto C_l. On the other hand, it is easily seen that C'_l is also the set of points of C'_σ that are visible from l (indeed, the segment that joins any point of C'_σ to l lies in $u_1^{-1}(1)$, so its intersection with σ equals its intersection with C'_σ : details left to the reader). By virtue of lemma 11.6.31(ii) (and proposition 11.6.8), it follows that $\overline{\mathscr{C}}_\bullet(C'^\bullet_l)$ is acyclic, so the same holds for $\overline{\mathscr{C}}_\bullet(C^\bullet_l)$.

• Lastly, suppose $-l \in P \setminus \sigma^\circ$; we let $\rho_1, \dots, \rho_n$ be a system of generators of $\sigma^\vee$, and $k \leq n$ an integer such that $\rho_i(l) < 0$ if and only if $1 \leq i \leq k$. Denote by $\tau^\vee$ (resp. $\mu^\vee$) the convex cone in $L^\vee_\mathbb{R}$ generated by $(\rho_{k+1}, \dots, \rho_n)$ (resp. by $(-\rho_1, \dots, -\rho_k)$), and let τ (resp. μ) be the dual of $\tau^\vee$ (resp. of $\mu^\vee$) in $L_\mathbb{R}$; with this notation, we have $l \in \tau \cap \mu^\circ$. Especially, $\tau \cap \mu^\circ \neq \varnothing$, and since τ° is dense in τ (by proposition 6.3.11(i)), we deduce that $\tau^\circ \cap \mu^\circ \neq \varnothing$ as well. Pick $z \in \tau^\circ \cap \mu^\circ$; by inspecting the proof of lemma 11.6.32(i), it is easily seen that $S_l = S_z$. But by construction, $-z \notin \sigma$, therefore – arguing as in the previous case – we conclude that $\overline{\mathscr{C}}_\bullet(C^\bullet_z) = \overline{\mathscr{C}}_\bullet(C^\bullet_l)$ is acyclic. □

Theorem 11.6.35 (Hochster)**.** *Let R be a Cohen-Macaulay noetherian ring, P a fine, sharp and saturated monoid. Then $R[P]$ is a Cohen-Macaulay ring.*

Proof. In view of [126, p.181, Cor.] we may assume that R is a field. We argue by induction on $d := \dim P$. If $d = 0$, we have $P = 0$, and there is nothing to show. Suppose that $d > 0$

and that the assertion is already known for every Cohen-Macaulay ring R and every monoid as above, of dimension $< d$. Set $L := P^{\mathrm{gp}}$, and let $\sigma \subset L_{\mathbb{R}}$ be the unique convex polyhedral cone such that $P = L \cap \sigma$. The ideal $\mathfrak{n} := R[\mathfrak{m}_P]$ is maximal in $R[P]$, and proposition 11.6.34 and theorem 11.6.24 show that

$$\text{(11.6.36)} \qquad \operatorname{depth} R[P]_{\mathfrak{n}} = \dim P.$$

On the other hand, we have the more general :

Claim 11.6.37. Let F be a field, P a fine monoid, A an integral domain which is an F-algebra of finite type, and F' the field of fractions of A. Then we have :

(i) For every maximal ideal $\mathfrak{m} \subset A$, the Krull dimension of $A_{\mathfrak{m}}$ equals the transcendence degree of F' over F.

(ii) For every maximal ideal $\mathfrak{m} \subset F[P]$, the Krull dimension of $F[P]_{\mathfrak{m}}$ equals $\mathrm{rk}_{\mathbb{Z}} P^{\mathrm{gp}}$.

Proof of the claim. (i): This is a straightforward consequence of [126, Th.5.6].

(ii): Choose an isomorphism : $P^{\mathrm{gp}} \xrightarrow{\sim} L \oplus T$, where T is the torsion subgroup of P^{gp}, and L is a free abelian group of finite rank; there follows an induced isomorphism (4.8.52) :

$$F[P^{\mathrm{gp}}] \xrightarrow{\sim} F[L] \otimes_F F[T].$$

Let B be the maximal reduced quotient of $F[P^{\mathrm{gp}}]$ (so the kernel of the projection $F[P^{\mathrm{gp}}] \to B$ is the nilradical); we deduce that B is a direct product of the type $\prod_{i=1}^n F'_i[L]$, where each F'_i is a finite field extension of F. By (i), the Krull dimension of $F'_i[L]_{\mathfrak{m}}$ equals $r := \mathrm{rk}_{\mathbb{Z}} P^{\mathrm{gp}}$ for every maximal ideal $\mathfrak{m} \subset F'_i[L]$, hence every irreducible component of $\operatorname{Spec} B$ has dimension r. Let also C be the maximal reduced quotient of $F[P]$; the natural map $C \to B$ is an injective localization, obtained by inverting a finite system of generators of P, hence the induced morphism $\operatorname{Spec} B \to \operatorname{Spec} C$ is an open immersion with dense image. Let Z be any (reduced) irreducible component of $\operatorname{Spec} C$; again by (i) it follows that every non-empty open subset of Z has dimension equal to $\dim Z$, so necessarily the latter equals r. ◊

From (11.6.36), corollary 6.4.12(i) and claim 11.6.37(ii) we see already that $R[P]_{\mathfrak{n}}$ is a Cohen-Macaulay ring. Next, let $\lambda_1, \dots, \lambda_k$ be the one-dimensional faces of σ, and define P_{λ_i} as in (11.6.23), for every $i = 1, \dots, k$. In light of claim 11.6.26, we have

$$\operatorname{Spec} R[P] \setminus \{\mathfrak{n}\} = \bigcup_{i=1}^{k} \operatorname{Spec} R[P_{\lambda_i}]$$

so it remains to check that $R[P_{\lambda_i}]$ is Cohen-Macaulay for every $i = 1, \dots, k$. However, we may find a decomposition $P_{\lambda_i} \xrightarrow{\sim} Q_i \times G_i$, where G_i is a free abelian group of finite type, and Q_i is a fine, sharp and saturated monoid of dimension $d - 1$ (lemma 6.2.10). Set $S_i := R[G_i]$; then $R[P_{\lambda_i}] = S_i[Q_i]$, and S_i is a Cohen-Macaulay ring ([126, Th.17.7]), so the claim follows by inductive assumption. □

11.6.38. In the situation of (11.6.23), we endow $R[P]$ with its natural L-grading, and denote by $\underline{A} := (R[P], \mathrm{gr}_\bullet R[P])$ the resulting L-graded R-algebra. Let $(M, \mathrm{gr}_\bullet M)$ be an L-graded $\underline{A}$-module (see definition 7.6.1(ii)); we set

$$M^\dagger := \bigoplus_{l \in L} \mathrm{Hom}_R(\mathrm{gr}_l M, R)$$

which is naturally an R-submodule of $M^* := \mathrm{Hom}_R(M, R)$: indeed, any R-linear map $\mathrm{gr}_l M \to R$ yields a linear form $M \to R$, after composition with the projection $M \to \mathrm{gr}_l M$. Notice that M^* is naturally an $R[P]$-module; namely for any linear form $f : M \to R$ and any

$x \in P$, one defines $x \cdot f : M \to R$ by the rule : $x \cdot f(m) := f(xm)$ for every $m \in M$. Then, it is easily seen that $M^\dagger$ is an $R[P]$-submodule of M^*; more precisely, we have

$$x \cdot \mathrm{Hom}_R(\mathrm{gr}_l M, R) \subset \mathrm{Hom}_R(\mathrm{gr}_{l-x} M, R) \qquad \text{for every } x \in P. \tag{11.6.39}$$

In light of (11.6.39), it is convenient to define an L-grading on $M^\dagger$ by the rule :

$$\mathrm{gr}_l M^\dagger := \mathrm{Hom}_R(\mathrm{gr}_{-l} M, R) \qquad \text{for every } l \in L$$

and then $(M^\dagger, \mathrm{gr}_\bullet M^\dagger)$ is naturally an L-graded $\underline{A}$-module.

Remark 11.6.40. (i) Clearly, the rule $M \mapsto M^\dagger$ yields a functor from the category $\underline{A}$-$\mathbf{Mod}$ of L-graded $\underline{A}$-modules to $\underline{A}$-$\mathbf{Mod}^o$.

(ii) Let $\underline{A}$-$\mathbf{Mod}_{\mathrm{rflx}}$ denote the full subcategory of $\underline{A}$-$\mathbf{Mod}$ whose objects are all the L-graded $\underline{A}$-modules $(M, \mathrm{gr}_\bullet M)$ such that $\mathrm{gr}_l M$ is a projective R-module of finite type, for every $l \in L$. A simple inspection of the definition shows that the functor $(-)^\dagger$ of (i) restricts to an equivalence of categories :

$$\underline{A}\text{-}\mathbf{Mod}_{\mathrm{rflx}} \to (\underline{A}\text{-}\mathbf{Mod}_{\mathrm{rflx}})^o.$$

Example 11.6.41. If $S \subset L$ is any P-submodule, notice that $L \setminus (-S)$ is also a P-submodule of L, and set

$$S^\dagger := L/(L \setminus (-S))$$

where the quotient is a pointed P-module, as in remark 4.8.17(iii). Explicitly, $S^\dagger$ is the set $(-S) \cup \{0_{S^\dagger}\}$ (where the zero element $0_{S^\dagger}$ should not be confused with the neutral element 0 of the abelian group L); the P-module structure on $S^\dagger$ is determined by the rule :

$$x \cdot s := \begin{cases} x + s & \text{if } x + s \in -S \\ 0_{S^\dagger} & \text{otherwise} \end{cases} \qquad \text{for every } s \in -S.$$

Then it is easily seen that there exists a natural isomorphism of L-graded $\underline{A}$-modules :

$$R[S]^\dagger \xrightarrow{\sim} R\langle S^\dagger \rangle$$

(notation of (6.1.31)). On the other hand, the natural map $R[S] \to (R[S]^*)^*$ induces an isomorphism $R[S] \xrightarrow{\sim} (R[S]^\dagger)^\dagger$ whence an isomorphism of L-graded $\underline{A}$-modules

$$R[S] \xrightarrow{\sim} R\langle S^\dagger \rangle^\dagger. \tag{11.6.42}$$

Theorem 11.6.43 (Stanley, Danilov). *In the situation of* (11.6.23), *set $P^\circ := L \cap \sigma^\circ$. We have :*

(i) *There exists a natural isomorphism :*

$$R\mathrm{Hom}^\bullet_{R[P]}(R, R[P^\circ]) \xrightarrow{\sim} R[-d] \qquad \textit{in } \mathsf{D}(R[P]\text{-}\mathbf{Mod})$$

(here R is regarded as an $R[P]$-module, via the augmentation map $R[P] \to R$).

(ii) *If R is a Gorenstein noetherian ring, the complex of coherent $\mathscr{O}_X$-modules $R[P^\circ]^\sim[0]$ is dualizing on X.*

Proof. (i): From proposition 11.6.34 we deduce a map of complexes of L-graded $\underline{A}$-modules

$$\varphi^\bullet : \overline{\mathscr{C}}{}^\bullet_P \to R\langle (P^\circ)^\dagger \rangle[-d]$$

(notation of example 11.6.41) with $\mathrm{gr}_l \varphi^\bullet$ a quasi-isomorphism of complexes of R-modules, for every $l \in L$. Since $\mathrm{gr}_l \overline{\mathscr{C}}{}^\bullet_P$ is a finite dimensional R-vector space for every $l \in L$, there follows – in view of (11.6.42) – a quasi-isomorphism of complexes of L-graded $\underline{A}$-modules

$$R[P^\circ][0] \xrightarrow{\sim} (\overline{\mathscr{C}}{}^\bullet_P)^\dagger[-d]. \tag{11.6.44}$$

whence a convergent spectral sequence

$$E_1^{pq} := \mathrm{Ext}^p_{R[P]}(R, (\overline{\mathscr{C}}{}^{d-q}_P)^\dagger) \Rightarrow \mathrm{Ext}^{p+q}_{R[P]}(R, R[P^\circ]).$$

Hence, the assertion follows immediately from the :

Claim 11.6.45. With the foregoing notation, we have :

(i) $E_1^{pq} = 0$ whenever $q < d$.

(ii) $E_1^{0d} \simeq R$, and $E_1^{pd} = 0$ for every $p > 0$.

Proof of the claim. (i): Let $\lambda \subset \sigma$ be any face with $\dim \lambda > 0$; it suffices to check that $E^i := \mathrm{Ext}^i_{R(P]}(R, R[P_\lambda]^\dagger) = 0$ for every $i \in \mathbb{N}$. To this aim, pick any $x \in F_\lambda \setminus \{0\}$; since $R[P_\lambda]^\dagger = R\langle P_\lambda^\dagger \rangle$ (example 11.6.41), we see that scalar multiplication by x is an automorphism on $R[P_\lambda]^\dagger$, hence also on E^i. On the other hand, scalar multiplication by x is the zero endomorphism on R, hence also on E^i, and the claim follows.

(ii): Pick a resolution $F_\bullet$ of the P-graded $\mathbb{Z}[P]$-module $\mathbb{Z} := \mathbb{Z}[P]/\mathbb{Z}[\mathfrak{m}_P]$ as in remark 7.6.18(iii), so that F_n is a free $\mathbb{Z}[P]$-module of finite type for every $n \in \mathbb{N}$, and the differential $d_n : F_n \to F_{n-1}$ is a morphism of P-graded $\mathbb{Z}[P]$-modules, for every $n > 0$. Since the augmented complex $F_\bullet \to \mathbb{Z}$ is flat as a complex of $\mathbb{Z}$-modules, the complex of $R[P]$-modules $R \otimes_\mathbb{Z} F_\bullet$ is still a free resolution of the $R[P]$-module R, and we get natural isomorphisms

$$E_1^{pd} \xrightarrow{\sim} H^p\mathrm{Hom}^\bullet_{R[P]}(R \otimes_\mathbb{Z} F_\bullet, R[P]^\dagger[0]) \xrightarrow{\sim} H^p((R \otimes_\mathbb{Z} F_\bullet)^\dagger) \qquad \text{for every } p \in \mathbb{N}.$$

(where the differentials of the complex $(R\otimes_\mathbb{Z} F_\bullet)^\dagger$ are the maps $d_\bullet^\dagger$). However, remark 11.6.40(ii) implies that the complex $(R \otimes_\mathbb{Z} F_\bullet \to R)^\dagger$ is still acyclic, whence the contention. ◊

(ii): To ease notation, set $S := \mathrm{Spec}\, R$ and $\omega_P := R[P^\circ]^\sim$; in view of proposition 11.3.37, it suffices to check that the complex of coherent $\mathscr{O}_{X(x)}$-modules $\omega_P(x)[0]$ is dualizing on $X(x)$, for every $x \in X$ (notation of definition 4.9.17(iii)). Hence, fix any such point x, and let $\mathfrak{p} \subset R[P]$ be the prime ideal corresponding to x; after replacing R by its localization at the prime ideal $\mathfrak{p} \cap R$, we may assume that R is a local ring, and the structure morphism $X \to S$ maps x to the closed point of S, corresponding to the maximal ideal $\mathfrak{m}_R$ of R. Denote by $\lambda \subset \sigma$ the unique face such that $P \setminus F_\lambda = \mathfrak{p} \cap P$, so that $x \in U_\lambda := \mathrm{Spec}\, R[P_\lambda]$. We may find a decomposition $P \xrightarrow{\sim} F_\lambda^{\mathrm{gp}} \times Q$, where Q is also a fine, sharp and saturated monoid (lemma 6.2.10), whence an isomorphism of S-schemes

$$U_\lambda \xrightarrow{\sim} \mathrm{Spec}\, R[F_\lambda^{\mathrm{gp}}] \times_S Y \qquad \text{where } Y := \mathrm{Spec}\, R[Q]$$

and by construction, $F^{-1}(\mathfrak{p} \cap P)$ is the maximal ideal of P_λ, so the induced projection $p : U_\lambda \to Y$ maps x to the maximal ideal $R[\mathfrak{m}_Q] + \mathfrak{m}_R[Q] \subset R[Q]$. Let $\tau \subset Q^{\mathrm{gp}}_\mathbb{R}$ be the unique polyhedral cone such that $Q = \tau \cap Q^{\mathrm{gp}}$, set $Q^\circ := Q \cap \tau^\circ$, and define the coherent $\mathscr{O}_Y$-module $\omega_Q := R[Q^\circ]^\sim$. It is easily seen that there is a natural identification

$$\omega_{P|U_\lambda} \xrightarrow{\sim} p^*\omega_Q.$$

In view of proposition 11.3.34 and remark 11.3.32(i), it then suffices to check that $\omega_Q(p(x))$ is dualizing on $Y(p(x))$. Thus, we may replace P by Q, and assume from start that $\mathfrak{p} = R[\mathfrak{m}_P] + \mathfrak{m}_R[P] \subset R[P]$. In this case, set $S_0 := \mathrm{Spec}\, R/\mathfrak{m}_R$, and denote by $i_1 : S_0 \to S$ and $i_2 : S \to X(S)$ the closed immersions (where i_2 corresponds to the ring homomorphism $R(P]_\mathfrak{p} \to R$ deduced from augmentation map); according to (i) and corollary 10.3.2(ii), we have a natural identification

$$i_2^!\omega_P(x)[0] \simeq \mathscr{O}_S[-d].$$

On the other hand, since R is Gorenstein, $\mathscr{O}_S[-d]$ is a dualizing complex on S; from lemma 11.3.27(i) and proposition 11.1.7(i) it follows that $i_1^!\mathscr{O}_S[-d] \xrightarrow{\sim} (i_2 \circ i_1)^!\omega_P(x)[0]$ is dualizing on S_0, and therefore it is isomorphic to $\mathscr{O}_{S_0}[c]$ for some $c \in \mathbb{Z}$. Lastly, proposition 11.3.28(i) and corollary 10.3.2(ii) now say that $\omega_P(x)[0]$ is dualizing on $X(x)$. □

Remark 11.6.46. Suppose that R is a field; then example 7.11.33 shows that $(\overline{\mathscr{C}}^0_P)^\dagger$ is the injective hull of the $R[P]$-module R. In this case, claim 11.6.45(ii) is therefore a special case of claim 7.11.24. For a general R, the $R[P]$-module $(\overline{\mathscr{C}}^0_P)^\dagger$ shall not be injective, but it can be viewed as a graded variant of the injective hull construction.

12. LOGARITHMIC GEOMETRY

12.1. **Log topoi.** Henceforth, *all topoi under consideration will be locally ringed and with enough points, and all morphisms of topoi will be morphisms of locally ringed topoi* (see (4.9.13)). The purpose of this restriction is to insure that we obtain the right notions, when we specialize to the case of schemes.

Definition 12.1.1. Let $T := (T, \mathscr{O}_T)$ be a locally ringed topos.

(i) A *pre-log structure* on T is the datum of a pair

$$(\underline{M}, \alpha)$$

where $\underline{M}$ is a T-monoid, and $\alpha : \underline{M} \to \mathscr{O}_T$ is a morphism of T-monoids, called the *structure map* of $\underline{M}$, and where the monoid structure on $\mathscr{O}_T$ is induced by the multiplication law (hence, by the multiplication in the ring $\mathscr{O}_T(U)$, for every object U of T).

(ii) A morphism $(\underline{M}, \alpha) \to (\underline{N}, \beta)$ of pre-log structures on T, is a map $\gamma : \underline{M} \to \underline{N}$ of T-monoids, such that $\beta \circ \gamma = \alpha$. We denote by

$$\mathbf{pre\text{-}log}_T$$

the category of pre-log structures on T.

(iii) A pre-log structure $(\underline{M}, \alpha)$ on T is a *log structure* if α restricts to an isomorphism:

$$\alpha^{-1}\mathscr{O}_T^\times \xrightarrow{\sim} \underline{M}^\times \xrightarrow{\sim} \mathscr{O}_T^\times .$$

The datum of a locally ringed topos $(T, \mathscr{O}_T)$ and a log structure on T is also called, for short, a *log topos*. We denote by

$$\mathbf{log}_T$$

the full subcategory of $\mathbf{pre\text{-}log}_T$ consisting of all log structures on T. When there is no danger of ambiguity, we shall often omit mentioning explicitly the map α, and therefore only write $\underline{M}$ to denote a pre-log or a log structure.

12.1.2. The category $\mathbf{log}_T$ admits an initial object, namely the log structure $(\mathscr{O}_T^\times, j)$, where j is the natural inclusion; this is called the *trivial log structure*. $\mathbf{log}_T$ admits a final object as well: this is $(\mathscr{O}_T, \mathbf{1}_{\mathscr{O}_T})$. A morphism of locally ringed topoi $f : T \to S$ induces a pair of adjoint functors :

(12.1.3) $$f^* : \mathbf{pre\text{-}log}_S \to \mathbf{pre\text{-}log}_T \qquad f_* : \mathbf{pre\text{-}log}_T \to \mathbf{pre\text{-}log}_S .$$

Namely, let $(\underline{M}, \alpha)$ (resp. $(\underline{N}, \beta)$) be a pre-log structure on S (resp. on T) and

$$f^\flat : \mathscr{O}_S \to f_*\mathscr{O}_T \qquad f^\sharp : f^{-1}\mathscr{O}_S \to \mathscr{O}_T$$

the natural morphisms (corresponding to each other under the adjunction (f^{-1}, f_*) that defines the morphism f); then

$$f^{-1}\underline{M} \xrightarrow{f^{-1}\alpha} f^{-1}\mathscr{O}_S \xrightarrow{f^\sharp} \mathscr{O}_T$$

defines $f^*(\underline{M}, \alpha)$, and $f_*(\underline{N}, \beta)$ is the pair $(\underline{P}, \gamma)$, where $\underline{P}$ is the fibre product in the cartesian diagram

$$\begin{array}{ccc} \underline{P} & \xrightarrow{\gamma} & \mathscr{O}_S \\ \downarrow & & \downarrow{\scriptstyle f^\flat} \\ f_*\underline{N} & \xrightarrow{f_*\beta} & f_*\mathscr{O}_T . \end{array}$$

Lemma 12.1.4. *Let T be a topos with enough points, $\varphi : \mathscr{M} \to \mathscr{N}$ a morphism of integral T-monoids inducing isomorphisms $\mathscr{M}^\times \xrightarrow{\sim} \mathscr{N}^\times$ and $\mathscr{M}^\sharp \xrightarrow{\sim} \mathscr{N}^\sharp$. Then φ is an isomorphism.*

Proof. This can be checked on the stalks, hence we are reduced to the corresponding assertions for a morphism $M \to N$ of monoids. Moreover, $M^\sharp$ is just the set-theoretic quotient of M by the translation action of $M^\times$ (lemma 4.8.31(iii)), so the assertion is straightforward, and shall be left as an exercise for the reader. □

Definition 12.1.5. Let $\gamma : (\underline{M}, \alpha) \to (\underline{N}, \beta)$ be a morphism of pre-log structures on the locally ringed topos T, and ξ a T-point.

(i) We say that $(\underline{M}, \alpha)$ is *integral* (resp. *saturated*) if $\underline{M}$ is an integral (resp. integral and saturated) T-monoid.
(ii) We say that γ is *flat* (resp. *saturated*) *at the point* ξ, if $\gamma_\xi : \underline{M}_\xi \to \underline{N}_\xi$ is a flat morphism of monoids (resp. a saturated morphism of integral monoids) (see remark 4.8.23(vi)).
(iii) We say that γ is *flat* (resp. *saturated*), if γ is a flat morphism of T-monoids (resp. a saturated morphism of integral T-monoids) (see definition 6.2.28). In view of proposition 4.8.26 (resp. corollary 6.2.29), this is the same as saying that γ is flat (resp. saturated) at every T-point.

12.1.6. The forgetful functor :

$$\mathbf{log}_T \to \mathbf{pre\text{-}log}_T \quad : \quad \underline{M} \mapsto \underline{M}^{\text{pre-log}}$$

admits a left adjoint :

$$\mathbf{pre\text{-}log}_T \to \mathbf{log}_T \quad : \quad (\underline{M}, \alpha) \mapsto (\underline{M}, \alpha)^{\log}$$

such that the resulting diagram :

$$(12.1.7)\qquad \begin{array}{ccc} \alpha^{-1}(\mathscr{O}_T^\times) & \longrightarrow & \underline{M} \\ \downarrow & & \downarrow \\ \mathscr{O}_T^\times & \longrightarrow & \underline{M}^{\log} \end{array}$$

is cocartesian in the category of pre-log structures. One calls $\underline{M}^{\log}$ the *log structure associated* to $\underline{M}$. From this description, it is easily seen that the counit of adjunction

$$(12.1.8)\qquad (\underline{M}^{\text{pre-log}})^{\log} \to \underline{M}$$

is an isomorphism for every log structure $\underline{M}$ on T.

Composing with the adjunction (12.1.3), we deduce a pair of adjoint functors :

$$f^* : \mathbf{log}_S \to \mathbf{log}_T \qquad f_* : \mathbf{log}_T \to \mathbf{log}_S$$

for any map of locally ringed topoi $f : T \to S$. Explicitly, if $\underline{N}$ is any log structure on S, then $f^*\underline{N}$ is the push-out in the cocartesian diagram of T-monoids :

$$\begin{array}{ccc} f^*\mathscr{O}_S^\times & \longrightarrow & f^*(\underline{N}^{\text{pre-log}}) \\ \downarrow & & \downarrow \\ \mathscr{O}_T^\times & \longrightarrow & f^*\underline{N} \end{array}$$

and on the other hand, if $\underline{M}$ is any log structure on T, then it is easily seen that the pre-log structure $f_*(\underline{M}^{\text{pre-log}})$ is actually a log structure (this can be checked on the stalks over the points of T). It follows easily that the induced map of T-monoids :

$$(12.1.9)\qquad f^*(\underline{N}^\sharp) \to (f^*\underline{N})^\sharp$$

is an isomorphism. As a consequence, for every point ξ of T, the natural map $\underline{N}_{f(\xi)} \to (f^*\underline{N})_\xi$ is a local morphism of monoids.

Remark 12.1.10. The category $\mathbf{log}_T$ admits arbitrary colimits : indeed, since the counit (12.1.8) is an isomorphism, it suffices to construct such colimits in the category of pre-log structures, and then apply the functor $(-) \mapsto (-)^{\log}$ which preserves colimits, since it is a left adjoint.

12.1.11. Let $(\underline{M}, \alpha)$ be a pre-log structure on T. The morphism α extends to a unique morphism of pointed T-monoids $\alpha_\circ : \underline{M}_\circ \to \mathscr{O}_T$, whence a new pre-log structure

$$(\underline{M}, \alpha)_\circ := (\underline{M}_\circ, \alpha_\circ).$$

Clearly, $(\underline{M}, \alpha)$ is a log structure if and only if the same holds for $(\underline{M}, \alpha)_\circ$. More precisely, for any pre-log structure $\underline{M}$ there is a natural isomorphism of log structures :

$$(\underline{M}_\circ)^{\log} \xrightarrow{\sim} (\underline{M}^{\log})_\circ.$$

Furthermore, for any morphism $f : T \to S$ of topoi, we have natural isomorphisms of pre-log (resp. log) structures

$$f^*(\underline{N}_\circ) \xrightarrow{\sim} (f^*\underline{N})_\circ \qquad f_*(\underline{M}_\circ) \xrightarrow{\sim} (f_*\underline{M})_\circ$$

for every pre-log (resp. log) structure $\underline{N}$ on S and $\underline{M}$ on T (details left to the reader).

Example 12.1.12. (i) Let $T \to S$ be a morphism of topoi. Since the initial object of a category is the empty coproduct, it follows formally that the inverse image $f^*(\mathscr{O}_S^\times, j)$ of the trivial log structure on S, is the trivial log structure on T.

(ii) Let T be a topos, and $j_U : T/U \to T$ an open subtopos (see example 4.7.8(i)). Consider the subsheaf of monoids $\underline{M} \subset \mathscr{O}_T$ such that :

$$\underline{M}(V) := \{s \in \mathscr{O}_T(V) \mid s_{|U\times V} \in \mathscr{O}_T^\times(U \times V)\} \qquad \text{for every object } V \text{ of } T.$$

Then it is easily seen that the natural map $\underline{M} \to \mathscr{O}_T$ is a log structure on T. This log structure is (naturally isomorphic to) the extension $j_{U*}\mathscr{O}_U^\times$ of the trivial log structure on T/U.

(iii) Let U be any object of the topos T, and $\underline{M}$ a log structure on T. Since $\mathscr{O}_{T/U} = (\mathscr{O}_T)_{|U}$, it is easily seen that the natural morphism of pre-log structures

$$(\underline{M}^{\text{pre-log}})_{|U} \to (\underline{M}_{|U})^{\text{pre-log}}$$

is an isomorphism.

(iv) Let $\beta : \underline{M} \to \mathscr{O}_T$ be a pre-log structure on a topos T. Then $\beta^{-1}(0) \subset \underline{M}$ is an ideal, and β factors uniquely through the natural map $\underline{M} \to \underline{M}/\beta^{-1}(0)$, and a pre-log structure

$$(\underline{M}, \beta)_{\text{red}} := (\underline{M}/\beta^{-1}(0), \overline{\beta})$$

called the *reduced pre-log structure* associated to $\underline{M}$. As usual, we shall often write just $\underline{M}_{\text{red}}$ instead of $(\underline{M}, \beta)_{\text{red}}$. We say that β is *reduced* if the induced morphism of pre-log structures $\underline{M} \to \underline{M}_{\text{red}}$ is an isomorphism.

Suppose now that $\underline{M}$ is a log structure; then it is easily seen that the same holds for $\underline{M}_{\text{red}}$. More precisely, since the tensor product is right exact (see (4.8.19)), for any pre-log structure $\underline{M}$ the natural morphism of log structures

$$(\underline{M}_{\text{red}})^{\log} \to (\underline{M}^{\log})_{\text{red}}$$

is an isomorphism.

Lemma 12.1.13. *Let $\gamma : (\underline{M}, \alpha) \to (\underline{N}, \beta)$ be a morphism of pre-log structures on T. We have:*

(i) *If $\underline{M}$ is integral (resp. saturated), then the same holds for $\underline{M}^{\log}$.*

(ii) *The unit of adjunction $\underline{M} \to \underline{M}^{\log}$ is a flat morphism.*

(iii) *If γ is flat (resp. saturated) at a T-point ξ, the same holds for the induced morphism $\gamma^{\log} : \underline{M}^{\log} \to \underline{N}^{\log}$ of log structures.*

(iv) *Especially, if γ is flat (resp. saturated), the same holds for $\gamma^{\log}$.*

Proof. In view of lemma 4.8.46(ii) and proposition 4.8.26, both (i) and (ii) can be checked on stalks. Taking into account lemma 4.8.46(i), we are reduced to showing the following. Let P be a monoid, A a ring, $\beta : P \to (A, \cdot)$ a morphism of monoids; then the natural map $P \to P' := P \otimes_{\beta^{-1}A^\times} A^\times$ is flat, and if P is integral (resp. saturated), the same holds for P'. The first assertion follows easily from example 6.1.23(vi), and the second follows from remark 6.2.5(i) (resp. from corollary 6.2.25(ix) and proposition 6.2.26).

(iii): The map $\gamma^{\log}$ can be factored as the composition of

$$\gamma' := \gamma \otimes_{\beta^{-1}\mathscr{O}_T^\times} \mathscr{O}_T^\times : \underline{N}^{\log} \to \underline{P} := \underline{M} \otimes_{\beta^{-1}\mathscr{O}_T^\times} \mathscr{O}_T^\times$$

and the natural unit of adjunction $\gamma'' : \underline{P} \to \underline{P}^{\log} = \underline{M}^{\log}$. If γ_ξ is flat, the same clearly holds for γ'_ξ, and (ii) says that γ'' is flat, hence $\gamma_\xi^{\log}$ is flat in this case. Lastly, suppose that γ_ξ is saturated, and we wish to show that $\gamma_\xi^{\log}$ is saturated. Set $P := \alpha_\xi^{-1}\mathscr{O}_{T,\xi}^\times$ and $Q := \beta_\xi^{-1}\mathscr{O}_{T,\xi}^\times$. Then the induced map $(P^{-1}\underline{M}_\xi)^\sharp \to (Q^{-1}\underline{N}_\xi)^\sharp$ is saturated (lemma 6.2.12(ii,iii)). But the latter is the same as the morphism $(\gamma_\xi^{\log})^\sharp$, and then also γ_ξ is saturated, again by lemma 6.2.12(iii). □

Lemma 12.1.14. *Let $f : T' \to T$ be a morphism of topoi, ξ a T'-point, and $\gamma : (\underline{M}, \alpha) \to (\underline{N}, \beta)$ a morphism of integral log structures on T. The following conditions are equivalent :*

(a) *γ is flat (resp. saturated) at the T-point $f(\xi)$.*
(b) *$f^*\gamma$ is flat (resp. saturated) at the T'-point ξ.*
(c) *$\gamma_\xi^\sharp$ is a flat (resp. saturated) morphism of monoids.*

Proof. The equivalence of (a) and (c) follows from corollary 6.1.49 (resp. lemma 6.2.12(ii)). By the same token, (b) holds if and only if $(f^*\gamma)_\xi^\sharp$ is flat (resp. saturated); in light of the isomorphism (12.1.9), the latter condition is equivalent to (c). □

12.1.15. For any locally ringed topos T, let us write the objects of $\mathbf{Mnd}/\Gamma(T, \mathscr{O}_T)$ in the form (M, φ), where M is any monoid, and $\varphi : M \to \Gamma(T, \mathscr{O}_T)$ a morphism of monoids. There is an obvious global sections functor :

$$\Gamma(T, -) : \mathbf{pre\text{-}log}_T \to \mathbf{Mnd}/\Gamma(T, \mathscr{O}_T) \quad : \quad (\underline{N}, \alpha) \mapsto (\Gamma(T, \underline{N}), \Gamma(T, \alpha))$$

which admits a left adjoint :

$$\mathbf{Mnd}/\Gamma(T, \mathscr{O}_T) \to \mathbf{pre\text{-}log}_T \quad : \quad (M, \varphi) \mapsto (M, \varphi)_T := (M_T, \varphi_T).$$

Indeed, M_T is the constant sheaf on (T, C_T) with value M, and φ_T is the composition of the map of constant sheaves $M_T \to \Gamma(T, \mathscr{O}_T)_T$ induced by φ, with the natural map $\Gamma(T, \mathscr{O}_T)_T \to \mathscr{O}_T$. Again, we shall often just write M_T to denote this pre-log structure.

After taking associated log structures, we deduce a left adjoint :

$$\mathbf{Mnd}/\Gamma(T, \mathscr{O}_T) \to \mathbf{log}_T \quad : \quad (M, \varphi) \mapsto M_T^{\log} := (M, \varphi)_T^{\log} \tag{12.1.16}$$

to the global sections functor. $M_T^{\log}$ is called the *constant log structure* associated to (M, φ).

Definition 12.1.17. Let T be a locally ringed topos, $(\underline{M}, \alpha)$ a log structure on T.

(i) A *chart for $\underline{M}$* is an object (P, β) of $\mathbf{Mnd}/\Gamma(T, \mathscr{O}_T)$, together with a map of pre-log structures $\omega_P : (P, \beta)_T \to \underline{M}$, inducing an isomorphism on the associated log structures. (Notation of (12.1.15).)
(ii) We say that a chart (P, β) is *finite* (resp. *integral*, resp. *fine*, resp. *saturated*) if P is a finitely generated (resp. integral, resp. fine, resp. integral and saturated) monoid.

(iii) Let $\varphi : \underline{M} \to \underline{N}$ be a morphism of log structures on T. A *chart for* φ is the datum of charts :

$$\omega_P : (P, \beta)_T \to \underline{M} \quad \text{and} \quad \omega_Q : (Q, \gamma)_T \to \underline{N}$$

for $\underline{M}$, respectively $\underline{N}$, and a morphism of monoids $\vartheta : Q \to P$, fitting into a commutative diagram :

$$\begin{array}{ccc} Q_T & \xrightarrow{\vartheta_T^{\log}} & P_T^{\log} \\ {\scriptstyle \omega_Q}\downarrow & & \downarrow{\scriptstyle \omega_P} \\ \underline{N} & \xrightarrow{\varphi} & \underline{M}. \end{array}$$

We say that such a chart is *finite* (resp. *integral*, resp. *fine*, resp. *saturated*) if the monoids P and Q are finitely generated (resp. integral, resp. fine, resp. integral and saturated). We say that the chart is *flat* (resp. *saturated*), if ϑ is a flat morphism of monoids (resp. a saturated morphism of integral monoids).

(iv) We say that $\underline{M}$ is *quasi-coherent* (resp. *coherent*) if there exist a covering family $(U_\lambda \to 1_T \mid \lambda \in \Lambda)$ of the final object 1_T in (T, C_T), and for every $\lambda \in \Lambda$, a chart (resp. a finite chart) $(P_\lambda, \beta_\lambda)$ for $\underline{M}_{|U_\lambda}$.

(v) We say that $(\underline{M}, \alpha)$ is *quasi-fine* (resp. *fine*) if it is integral and quasi-coherent (resp. and coherent).

(vi) Let ξ be any T-point. We say that a chart (P, β) is *local* (resp. *sharp*) *at the point* ξ, if the morphism $\beta_\xi : P \to \mathscr{O}_{T,\xi}$ is local (resp. if P is sharp and β_ξ is local).

Lemma 12.1.18. *Let $f : T \to S$ be a morphism of locally ringed topoi, $\underline{Q}$ a log structure on S, and ξ any point of S. The following holds :*

(i) *If $\underline{Q}$ is quasi-coherent (resp. coherent, resp. integral, resp. saturated, resp. quasi-fine, resp. fine), then the same holds for $f^*\underline{Q}$.*

(ii) *Suppose that $\underline{Q}$ is an integral log structure. Then $\underline{Q}^\sharp$ is an integral S-monoid, and $\underline{Q}$ is saturated if and only if $\underline{Q}^\sharp$ is a saturated S-monoid.*

(iii) *Suppose that $\underline{Q}$ is quasi-coherent. Then $\underline{Q}$ is integral (resp. integral and saturated, resp. fine, resp. fine and saturated) if and only if there exist a covering family $(U_\lambda \to 1_S \mid \lambda \in \Lambda)$ of the final object of S, and for every $\lambda \in \Lambda$, an integral (resp. integral and saturated, resp. fine, resp. fine and saturated) chart $(P_\lambda)_{U_\lambda} \to \underline{Q}_{|U_\lambda}$.*

(iv) *If $\underline{P}$ is any coherent log structure on S, and $\omega : \underline{P}_\xi \to \underline{Q}_\xi$ is a map of monoids, then :*

  (a) *There exist a neighborhood U of ξ and a morphism $\vartheta : \underline{P}_{|U} \xrightarrow{\sim} \underline{Q}_{|U}$ of log structures, such that $\vartheta_\xi = \omega$.*

  (b) *Moreover, for any two morphisms $\vartheta, \vartheta' : \underline{P}_{|U} \xrightarrow{\sim} \underline{Q}_{|U}$ with the property of* (a), *we may find a smaller neighborhood $V \to U$ of ξ such that $\vartheta_{|V} = \vartheta'_{|V}$.*

  (c) *Especially, if $\underline{Q}$ is also coherent, and ω is an isomorphism, we may find ϑ and a small enough U as in* (a), *such that ϑ is an isomorphism.*

(v) *If M is a finitely generated monoid, and $\omega : M \to \mathscr{O}_{S,\xi}$ a morphism of monoids, then we may find a neighborhood U of ξ and a morphism $\vartheta : M_U \to \mathscr{O}_U$ of S/U-monoids, such that $\vartheta_\xi = \omega$.*

Proof. (i): If $\underline{Q}$ is the constant log structure associated to a map of monoids $\alpha : Q \to \Gamma(S, \mathscr{O}_S)$, then $f^*\underline{Q}$ is the constant log structure associated to $\Gamma(S, f^\natural) \circ \alpha$ (where $f^\natural : \mathscr{O}_S \to f_*\mathscr{O}_T$ is the natural map). The assertions concerning quasi-coherent or coherent log structures are a straightforward consequence. Next, suppose that $\underline{Q}$ is integral (resp. saturated); we wish to show that $f^*\underline{Q}$ is integral (resp. saturated). To this aim, let $\underline{M} := f^*(\underline{Q}^{\text{pre-log}})$; by lemma

4.8.45(i), $\underline{M}$ is an integral (resp. saturated) T-monoid; then the assertion follows from lemma 12.1.13(i).

(ii): By lemma 4.8.46(ii) the assertion can be checked on stalks. Hence, suppose that $\underline{Q}$ is integral; then $\underline{Q}_\xi$ is integral by *loc.cit.*, consequently, the same holds for $\underline{Q}_\xi/\underline{Q}_\xi^\times$ (lemma 4.8.38). The second assertion follows from lemma 6.2.9(ii).

(iii): Suppose first that $\underline{Q}$ is quasi-coherent and integral. Hence, there is a covering family $(U_\lambda \to 1_S \mid \lambda \in \Lambda)$, and for every $\lambda \in \Lambda$ a monoid M_λ, a pre-log structure $\alpha_\lambda : (M_\lambda)_{U_\lambda} \to \mathscr{O}_{U_\lambda}$, and an isomorphism $((M_\lambda)_{U_\lambda}, \alpha_\lambda)^{\log} \xrightarrow{\sim} \underline{Q}_{|U_\lambda}$; whence a cocartesian diagram of S-monoids, as in (12.1.7) :

$$\begin{array}{ccc} \underline{N} := \alpha_\lambda^{-1}(\mathscr{O}_{U_\lambda}^\times) & \longrightarrow & (M_\lambda)_{U_\lambda} \\ \downarrow & & \downarrow \\ \mathscr{O}_{U_\lambda}^\times & \longrightarrow & \underline{Q}_{|U_\lambda}. \end{array} \tag{12.1.19}$$

The induced diagram $(12.1.19)^{\mathrm{int}}$ of integral S-monoids is still cocartesian. Moreover, since $\underline{Q}_{|U_\lambda}$ is integral, α_λ factors through a unique map $\beta_\lambda : ((M_\lambda)_{U_\lambda})^{\mathrm{int}} \to \underline{Q}_{|U_\lambda} \to \mathscr{O}_{U_\lambda}$, and the morphism in S underlying the induced morphism of S-monoids $\underline{N}^{\mathrm{int}} \to \underline{N}' := \beta_\lambda^{-1}(\mathscr{O}_{U_\lambda}^\times)$ is an epimorphism (this can be checked easily on the stalks). Furthermore, $((M_\lambda)_{U_\lambda})^{\mathrm{int}} \simeq (M_\lambda^{\mathrm{int}})_{U_\lambda}$ (see (4.8.49)). It follows that the natural map

$$\underline{Q}_{|U_\lambda} \to \mathscr{O}_{U_\lambda}^\times \amalg_{\underline{N}'} (M_\lambda^{\mathrm{int}})_{U_\lambda} \simeq (M_\lambda^{\mathrm{int}})_{U_\lambda}^{\log}$$

is an isomorphism, so the claim holds with $P_\lambda := M_\lambda^{\mathrm{int}}$. If Q is fine, we can find M_λ as above which is also finitely generated, in which case the resulting P_λ shall be fine.

Suppose additionally, that $\underline{Q}$ is saturated. By the previous case, we may then find a covering family $(U_\lambda \to e_S \mid \lambda \in \Lambda)$, and for every $\lambda \in \Lambda$ an integral monoid M_λ, a pre-log structure $\alpha_\lambda : (M_\lambda)_{U_\lambda} \to \mathscr{O}_{U_\lambda}$, and an isomorphism $((M_\lambda)_{U_\lambda}, \alpha_\lambda)^{\log} \xrightarrow{\sim} \underline{Q}_{|U_\lambda}$; whence a cocartesian diagram (12.1.19) consisting of integral S-monoids. The induced diagram $(12.1.19)^{\mathrm{sat}}$ is still cocartesian; one may then argue as in the foregoing, to obtain a natural isomorphism : $\underline{Q}_{|U_\lambda} \xrightarrow{\sim} (M_\lambda^{\mathrm{sat}})_{U_\lambda}^{\log}$. Furthermore, if M_λ is finitely generated, the same holds for M_λ^{sat} (corollary 6.4.1(ii)), hence the chart thus obtained shall be fine and saturated, in this case.

Conversely, if a family $(P_\lambda \mid \lambda \in \Lambda)$ of integral (resp. saturated) monoids can be found fulfilling the condition of (iii), then $(P_\lambda)_{U_\lambda}$ is an integral (resp. saturated) pre-log structure on T/U_λ (example 4.8.47(ii)), hence the same holds for its associated log structure $\underline{Q}_{|U_\lambda}$ (lemma 12.1.13(i)), and thus also for $\underline{Q}$ (lemma 4.8.46(ii), example 4.7.12, and example 12.1.12(iii)). Moreover, if each P_λ is fine, then $\underline{Q}$ is fine as well.

(iv.a): We may assume that $\underline{P}$ admits a finite chart $\alpha : M_S \to \underline{P}$, for some finitely generated monoid M, denote by $\beta : \underline{Q} \to \mathscr{O}_S$ the structure map of $\underline{Q}$, and set $\omega' := \omega \circ \alpha_\xi : M \to \underline{Q}_\xi$. According to lemma 6.1.7(ii), the morphism ω' factors through a map $\omega'' : M \to \Gamma(U', \underline{Q})$, for some neighborhood U' of ξ. By adjunction, ω'' determines a morphism of S/U'-monoids $\psi : M_{U'} \to \underline{Q}_{|U'}$ whence a morphism of pre-log structures

$$(M_{U'}, \beta_{|U'} \circ \psi) \to (\underline{Q}_{|U'}, \beta_{|U'}). \tag{12.1.20}$$

Let us make the following general observation :

Claim 12.1.21. Let N be a finitely generated monoid, F any S-monoid, $f, g : N_S \to F$ two morphisms of S-monoids, such that $f_\xi = g_\xi$. Then there exists a neighborhood U of ξ in S such that $f_{|U} = g_{|U}$.

Proof of the claim. By adjunction, the morphisms f and g correspond to unique maps of monoids $\Gamma(f), \Gamma(g) : N \to \Gamma(S, F)$; since N is finitely generated and $f_\xi = g_\xi$, we may find a neighborhood U of ξ such that the maps $N \to F(U)$ induced by $\Gamma(f)$ and $\Gamma(g)$ coincide. Again by adjunction, we deduce a unique morphism of S/U-monoids $N_U \to F_{|U}$, which by construction is just the restriction of both f and g. ◊

Let $\gamma : \underline{P} \to \mathscr{O}_S$ be the structure map of $\underline{P}$; we apply claim 12.1.21 with S replaced by S/U', to deduce that there exists a small enough neighborhood $U \to U'$ of ξ such that the restriction $(\gamma \circ \alpha)_{|U} : M_{|U} \to \mathscr{O}_{S|U}$ agrees with $\beta_{|U} \circ \psi_{|U}$. Then it is clear that the morphism of log structure associated to (12.1.20)$_{|U}$ yields the sought extension ϑ of ω.

(iv.b): By assumption we have the identity : $\vartheta_\xi = \vartheta'_\xi$; however, any morphism of log structures $\underline{P}_{|U} \to \underline{Q}_{|U}$ is already determined by its restriction to the image of any finite local chart $M_U \to \underline{P}_{|U}$. Hence the assertion follows from claim 12.1.21.

(iv.c): We apply (iv.a) to ω^{-1} to deduce the existence of a morphism $\sigma : \underline{Q}_{|U} \to \underline{P}_{|U}$ such that $\sigma_\xi = \omega^{-1}$ on some neighborhood U of ξ. Hence, $(\vartheta \circ \sigma)_\xi = \mathbf{1}_{\underline{Q}_\xi}$ and $(\sigma \circ \vartheta)_\xi = \mathbf{1}_{\underline{P}_\xi}$. By (iv.b), these identities persist on some smaller neighborhood.

(v): The proof is similar to that of (iv.a), though simpler : we leave it as an exercise for the reader. □

Definition 12.1.22. (i) A *morphism* $(T, \underline{M}) \to (S, \underline{N})$ *of topoi with pre-log* (resp. *log*) *structures*, is a pair $f := (f, \log f)$ consisting of a morphism of locally ringed topoi $f : T \to S$, and a morphism

$$\log f : f^* \underline{N} \to \underline{M}$$

of pre-log structures (resp. log structures) on T. We say that f is *log flat* (resp. *saturated*) if $\log f$ is a flat (resp. saturated) morphism of pre-log structures.

(ii) Let $(f, \log f)$ as in (i) be a morphism of log topoi, ξ a T-point; we say that f is *strict at the point* ξ, if $\log f_\xi$ is an isomorphism. We say that f is *strict*, if it is strict at every T-point.

(iii) A *chart* for φ is the datum of charts

$$\omega_P : (P, \beta)_T \to \underline{M} \quad \text{and} \quad \omega_Q : (Q, \gamma)_S \to \underline{N}$$

for $\underline{M}$, respectively $\underline{N}$, and a morphism of monoids $\vartheta : Q \to P$, such that $(f^*\omega_Q, \omega_P, \vartheta)$ is a chart for the morphism $\log f$. We say that such a chart $(\omega_Q, \omega_P, \vartheta)$ is *finite* (resp. *fine*, resp. *flat*, resp. *saturated*) if the same holds for the corresponding chart $(f^*\omega_Q, \omega_P, \vartheta)$ of $\log f$.

Remark 12.1.23. (i) Let $f : (T, \underline{M}) \to (S, \underline{N})$ be a morphism of log topoi, $g : T' \to T$ a morphism of topoi, and $f' : (T', g^*\underline{M}) \to (S, \underline{N})$ the composition of f and the natural morphism of log topoi $(T', g^*\underline{M}) \to (T, \underline{M})$; let also ξ be a T'-point. Then f' is strict at the point ξ if and only if f is strict at the point $g(\xi)$. Indeed, f' is strict at ξ if and only if $(\log f')^\sharp_\xi$ is an isomorphism (lemma 12.1.4), if and only if $(\log f)^\sharp_{g(\xi)}$ is an isomorphism (by (12.1.9)), if and only if $\log f_{g(\xi)}$ is an isomorphism (again by lemma 12.1.4).

(ii) For any log topos $(T, \underline{M})$, let us set $(T, \underline{M})_\circ := (T, \underline{M}_\circ)$. Then $(T, \underline{M})_\circ$ is a log topos (see (12.1.11)), and clearly, every morphism $f : (T, \underline{M}) \to (S, \underline{N})$ of log topoi extends naturally to a morphism $f_\circ : (T, \underline{M})_\circ \to (S, \underline{N})_\circ$ of log topoi.

12.1.24. The 2-category of log topoi admits arbitrary 2-limits indexed by usual categories. Indeed, if $\mathscr{T} := ((T_\lambda, \underline{M}_\lambda) \mid \lambda \in \Lambda)$ is any pseudo-functor (from a small category Λ, to the category of log topoi), the 2-limit of $\mathscr{T}$ is the pair $(T, \underline{M})$, where T is the 2-limit of the system of ringed topoi $(T_\lambda \mid \lambda \in \Lambda)$, and $\underline{M}$ is the colimit of the induced system of log structures $(p^*_\lambda \underline{M}_\lambda \mid \lambda \in \Lambda)$ on T, where $p_\lambda : T \to T_\lambda$ denotes the natural projection, for every $\lambda \in \Lambda$ (see remark 12.1.10).

12.1.25. Consider a 2-cartesian diagram of log topoi :

$$\begin{array}{ccc} (T',\underline{M}') & \xrightarrow{g} & (T,\underline{M}) \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f} \\ (S',\underline{N}') & \xrightarrow{h} & (S,\underline{N}). \end{array}$$

The following result yields a relative variant of the isomorphism (12.1.9) :

Lemma 12.1.26. *In the situation of* (12.1.25)*, the morphism*

$$g^*\mathrm{Coker}(\log f) \to \mathrm{Coker}(\log f')$$

induced by $\log g$ *is an isomorphism of* T'*-monoids.*

Proof. Indeed, denote by $\beta : \underline{M} \to \mathscr{O}_T$ and $\gamma : \underline{N}' \to \mathscr{O}_{S'}$ the log structures of T and S'. Fix any T'-point ξ, let $\xi := g(\xi')$, and set

$$P := \underline{M}_\xi \otimes_{\underline{N}_{f(\xi)}} \underline{N}'_{f'(\xi')} \qquad \text{and} \qquad \rho := \beta_\xi \otimes \gamma_{f'(\xi')} : P \to \mathscr{O}_{T'}.$$

Then $\underline{M}'_{\xi'} = P \otimes_{\rho^{-1}\mathscr{O}_{T',\xi'}} \mathscr{O}^\times_{T',\xi'}$, and it is easily seen that $\rho^{-1}\mathscr{O}_{T',\xi'} = \mathscr{O}^\times_{T,\xi} \otimes_{\mathscr{O}^\times_{S,f(\xi)}} \mathscr{O}^\times_{S',f'(\xi')}$. Therefore $(\underline{M}'_{\xi'})^\sharp = P/\rho^{-1}\mathscr{O}_{T',\xi'} = \underline{M}^\sharp_\xi \otimes_{\underline{N}^\sharp_{f(\xi)}} \underline{N}'^\sharp_{f'(\xi')}$, and

$$\mathrm{Coker}(\log f'_{\xi'}) = \mathrm{Coker}(\underline{N}'^\sharp_{f'(\xi')} \to \underline{M}^\sharp_\xi \otimes_{\underline{N}^\sharp_{f(\xi)}} \underline{N}'^\sharp_{f'(\xi')}) = \mathrm{Coker}(\underline{N}^\sharp_{f(\xi)} \to \underline{M}^\sharp_\xi)$$

whence the contention. ◻

12.1.27. We consider now a special situation that we will encounter in proposition 12.1.30. Namely, let Q be a monoid, and $H \subset Q^\times$ a subgroup. Let also G be an abelian group, $\rho : G \to Q^{\mathrm{gp}}$ a group homomorphism, and set :

$$H_\rho := G \times_{Q^{\mathrm{gp}}} H \qquad Q_\rho := G \times_{Q^{\mathrm{gp}}} Q.$$

The natural inclusion $H \to Q$ and the projection $Q_\rho \to Q$ determine a unique morphism :

$$Q_\rho \otimes_{H_\rho} H \to Q. \tag{12.1.28}$$

Lemma 12.1.29. *In the situation of* (12.1.27)*, suppose furthermore that the composition :*

$$G \xrightarrow{\rho} Q^{\mathrm{gp}} \to (Q/H)^{\mathrm{gp}}$$

is surjective. Then (12.1.28) *is an isomorphism.*

Proof. Set $G' := G \oplus H$, and let $\rho' : G' \to Q^{\mathrm{gp}}$ be the unique group homomorphism that extends ρ and the natural map $H \to Q \to Q^{\mathrm{gp}}$. Under the standing assumptions, ρ' is clearly surjective. Define $Q_{\rho'}$ and $H_{\rho'}$ as in (12.1.27); there is a natural isomorphism of monoids : $Q_{\rho'} \xrightarrow{\sim} Q_\rho \oplus H$, inducing an isomorphism $H_{\rho'} \xrightarrow{\sim} H_\rho \oplus H$, and defined as follows. To every $g \in G$, $h \in H$, $q \in Q$ such that $[(g,h),q] \in Q_{\rho'}$, we assign the element $[(g,h^{-1}q),a] \in Q_\rho \oplus H$ (details left to the reader). Under this isomorphism, the projection $H_{\rho'} \to H$ is identified with the map $H_\rho \oplus H \to H$ given by the rule : $(h_1,h_2) \mapsto \pi_H(h_1)\cdot h_2$, where $\pi_H : H_\rho \to H$ is the projection. It then follows that the natural map :

$$Q_\rho \otimes_{H_\rho} H \to Q_{\rho'} \otimes_{H_{\rho'}} H$$

is an isomorphism. Thus, we may replace G and ρ by G' and ρ', which allows to assume from start that ρ is surjective. However, we have natural isomorphisms :

$$\mathrm{Ker}(Q_\rho \xrightarrow{\pi_Q} Q) \simeq \mathrm{Ker}\,\rho \simeq \mathrm{Ker}(H_\rho \xrightarrow{\pi_H} H).$$

Moreover, the set underlying Q (resp. H) is the set-theoretic quotient of the set Q_ρ (resp. H_ρ) by the translation action of $\mathrm{Ker}\,\rho$; hence the natural maps $Q_\rho/\mathrm{Ker}\,\pi_Q \to Q$ and $H_\rho/\mathrm{Ker}\,\pi_H \to H$ are isomorphisms (lemma 4.8.31(ii)). We can then compute :

$$Q_\rho \otimes_{H_\rho} H \simeq (Q_\rho/\mathrm{Ker}\,\pi_Q) \otimes_{H_\rho/\mathrm{Ker}\,\pi_H} H \simeq Q \otimes_H H \simeq Q$$

as stated. □

Proposition 12.1.30. *Let T be a locally ringed topos, ξ any T-point, and $\underline{M}$ a coherent (resp. fine) log structure on T. Suppose that G is a finitely generated abelian group with a group homomorphism $G \to \underline{M}^{\mathrm{gp}}_\xi$ such that the induced map $G \to (\underline{M}^\sharp)^{\mathrm{gp}}_\xi$ is surjective. Set*

$$P := G \times_{\underline{M}^{\mathrm{gp}}_\xi} \underline{M}_\xi.$$

Then the induced morphism $P \to \underline{M}_\xi$ extends to a finite (resp. fine) chart $P_U \to \underline{M}_{|U}$ on some neighborhood U of ξ.

Proof. We begin with the following :

Claim 12.1.31. Let Y be any locally ringed topos, ξ a Y-point, and $\alpha : Q_Y \to \mathscr{O}_Y$ the constant pre-log structure associated to a map of monoids $\vartheta : Q \to \Gamma(Y, \mathscr{O}_Y)$, where Q is finitely generated. Set $S := \alpha_\xi^{-1}\mathscr{O}^\times_{Y,\xi} \subset Q_{Y,\xi} = Q$. Then :

(i) S and $S^{-1}Q$ are finitely generated monoids.
(ii) There exists a neighborhood U of ξ such that $\alpha_{|U}$ factors as the composition of the natural map of sheaves of monoids $j_U : Q_U \to (S^{-1}Q)_U$, and a (necessarily unique) pre-log structure $\alpha_S : (S^{-1}Q)_U \to \mathscr{O}_U$.
(iii) The induced map of log structures $j_U^{\log} : Q_U^{\log} \to (S^{-1}Q)_U^{\log}$ is an isomorphism.
(iv) $\alpha^{-1}_{S,\xi}(\mathscr{O}^\times_{U,\xi}) = (S^{-1}Q)^\times$ is a finitely generated group.

Proof of the claim. (i) follows from lemma 6.1.20(iv).

(ii): Since $\mathscr{O}^\times_{Y,\xi}$ is the filtered colimit of the groups $\Gamma(U, \mathscr{O}^\times_U)$, where U ranges over the neighborhoods of ξ, lemma 6.1.7(ii) and (i) imply that the induced map $S \to \mathscr{O}^\times_{Y,\xi}$ factors through $\Gamma(U, \mathscr{O}^\times_Y)$ for some neighborhood U of ξ. Then the composition of ϑ and the natural map $\Gamma(Y, \mathscr{O}_Y) \to \Gamma(U, \mathscr{O}_U)$ extends to a unique map $S^{-1}Q \to \Gamma(U, \mathscr{O}_U)$, whence the sought pre-log structure α_S on U.

(iii): Let $\underline{N}$ be any log structure on U; it is clear that every morphism of pre-log structures $Q_U \to \underline{N}$ factors uniquely through $(S^{-1}Q)_U$, whence the contention.

(iv): Indeed, by construction we have : $\alpha^{-1}_{S,\xi}(\mathscr{O}^\times_{U,\xi}) = S^{\mathrm{gp}}$. ◊

Let Y be a neighborhood of ξ such that $\underline{M}_{|Y}$ admits a finite local chart $\alpha : Q_Y \to \mathscr{O}_Y$; we lift ξ to some Y-point, ξ_Y, and choose a neighborhood $U \in \mathrm{Ob}(T/Y)$ of ξ_Y, as provided by claim 12.1.31. We may then replace T by U, ξ by ξ_Y and α by the chart α_S of claim 12.1.31(ii), which allows to assume from start that $S := \alpha_\xi^{-1}(\mathscr{O}^\times_{T,\xi})$ is a finitely generated group. Moreover, let $H := \mathrm{Ker}(S \to \mathscr{O}^\times_{T,\xi})$; clearly $\alpha_\xi : Q \to \mathscr{O}_{T,\xi}$ factors through the quotient $Q' := Q/H$, hence we may find a neighborhood U of ξ such that $\alpha_{|U}$ factors through a (necessarily unique) map of pre-log structures $\alpha_H : Q'_U \to \mathscr{O}_U$. Furthermore, if $\underline{N}$ is any log structure on U, every map of pre-log structures $Q_U \to \underline{N}$ factors through Q'_U, so that α_H is a chart for $\underline{M}_{|U}$. We may therefore replace T by U and α by α_H, which allows to assume additionally, that α_ξ is injective on the subgroup S. Now, for any finitely generated subgroup $H \subset \mathscr{O}^\times_{T,\xi}$ with $S \subset H$, we set $\underline{M}_{\xi,H} := H \amalg_S Q$; clearly, the monoids $\underline{M}_{\xi,H}$ are finitely generated, and moreover :

$$\underline{M}_\xi = \operatorname*{colim}_{S \subset H \subset \mathscr{O}^\times_{T,\xi}} \underline{M}_{\xi,H}.$$

Furthermore, we deduce a natural sequence of maps of monoids :

$$\{1\} \to \underline{M}_{\xi,H} \xrightarrow{\varphi_H} \underline{M}_\xi \xrightarrow{\psi_H} \mathscr{O}^\times_{T,\xi}/H \to \{1\}. \qquad (12.1.32)$$

Claim 12.1.33. For every subgroup H as above, the sequence (12.1.32) is exact, *i.e.* $\underline{M}_{\xi,H}$ is the kernel of ψ_H, and $\mathscr{O}^\times_{T,\xi}/H$ is the cokernel of φ_H.

Proof of the claim. By lemma 4.8.29(iii), the assertion concerning $\operatorname{Ker}\psi_H$ can be verified on the underlying map of sets; however, lemma 4.8.31(ii) says that the set $\underline{M}_\xi$ is the set-theoretic quotient $(Q \times \mathscr{O}^\times_{T,\xi})/S$, for the natural translation action of S, and a similar description holds for $\underline{M}_{\xi,H}$, therefore $\operatorname{Ker}\varphi_H$ is the set-theoretic quotient $(H \times Q)/S$, as required.

The assertion concerning $\operatorname{Coker}\varphi_H$ holds by general categorical nonsense. ◊

Let $\varepsilon : \underline{M}_\xi \to \underline{M}^{\mathrm{gp}}_\xi$ be the natural map; claim 12.1.33 implies that the sequence of abelian groups (12.1.32)$^{\mathrm{gp}}$ is right exact, and then a little diagram chase shows that :

$$\varepsilon^{-1}(\operatorname{Im}\varphi^{\mathrm{gp}}_H) = \underline{M}_{\xi,H} \qquad \text{whenever } S \subset H \subset \mathscr{O}^\times_{T,\xi}. \tag{12.1.34}$$

Since G is finitely generated, we may find H as above, large enough, so that $\underline{M}^{\mathrm{gp}}_{\xi,H}$ contains the image of G. In view of (12.1.34), we deduce that the natural map

$$G \times_{\underline{M}^{\mathrm{gp}}_{\xi,H}} \underline{M}_{\xi,H} \to P$$

is an isomorphism, so P is finitely generated, by corollary 6.4.2; moreover P is integral whenever $\underline{M}_\xi$ is. Then, lemma 12.1.18(iv.a) implies that the natural map $P \to \underline{M}_\xi$ extends to a morphism of log structures $\vartheta : P^{\log}_U \to \underline{M}_{|U}$ on some neighborhood U of ξ. It remains to show that ϑ restricts to a chart for $\underline{M}_{|V}$, on some smaller neighborhood V of ξ. To this aim, it suffices to show that the map of stalks ϑ_ξ is an isomorphism (lemma 12.1.18(iv.c)). The latter assertion follows from lemma 12.1.29. □

Proposition 12.1.30 is the basis of several frequently used tricks that allow to construct “good” charts for a given coherent log structure (and for a morphism of such structures), or to “improve” given charts. We conclude this section with a selection of these tricks.

Corollary 12.1.35. *Let T be a topos, ξ a T-point, $\underline{M}$ a fine log structure on T. Then there exist a neighborhood U of ξ in T, and a chart $P_U \to \underline{M}_{|U}$ such that :*

(a) *P^{gp} is a free abelian group of finite rank.*
(b) *The induced morphism of monoids $P \to \mathscr{O}_{T,\xi}$ is local.*

Proof. Choose a group homomorphism $G := \mathbb{Z}^{\oplus n} \to \underline{M}^{\mathrm{gp}}_\xi$ (for some integer $n \geq 0$), such that the induced map $G \to (\underline{M}^\sharp)^{\mathrm{gp}}_\xi$ is surjective, and set $P := G \times_{\underline{M}^{\mathrm{gp}}_\xi} \underline{M}_\xi$. By proposition 12.1.30, the induced map $P \to \underline{M}_\xi$ extends to a chart $P_U \to \underline{M}_{|V}$, for some neighborhood U of ξ. According to example 4.8.36(v), P^{gp} is a subgroup of G, whence (a). Next, claim 12.1.31 implies that, after replacing P by some localization (which does not alter P^{gp}), and U by a smaller neighborhood of ξ, we may achieve (b) as well. □

Corollary 12.1.36. *Let T be a topos, ξ a T-point, $\underline{M}$ a coherent log structure on T, and suppose that $\underline{M}_\xi$ is integral and saturated. Then we have :*

(i) *There exist a neighborhood U of ξ in T, and a fine and saturated chart $P_U \to \underline{M}_{|U}$ which is sharp at the point ξ.*
(ii) *Especially, there exists a neighborhood U of ξ in T, such that $\underline{M}_{|U}$ is a fine and saturated log structure.*

Proof. (i): By lemma 6.2.10, we may find a decomposition $\underline{M}_\xi = P \times \underline{M}^\times_\xi$, for a sharp submonoid $P \subset \underline{M}_\xi$. Set $G := P^{\mathrm{gp}}$; we deduce an isomorphism $G \xrightarrow{\sim} \underline{M}^{\mathrm{gp}}_\xi/\underline{M}^\times_\xi$, and clearly $P = G \times_{\underline{M}^{\mathrm{gp}}_\xi} \underline{M}_\xi$. By proposition 12.1.30, it follows that the induced map $P \to \underline{M}_\xi$ extends to a chart $\beta : P_U \to \underline{M}_{|U}$ on a neighborhood U of ξ. By construction, β is sharp at the T-point ξ; moreover, since $\underline{M}_\xi$ is saturated, it is easily seen that the same holds for P. Finally, P is finitely generated, by corollary 6.4.2.

(ii): This follows immediately from (i) and lemma 12.1.18(iii). □

Theorem 12.1.37. *Let T be a locally ringed topos, ξ a T-point, $f : \underline{M} \to \underline{N}$ a morphism of coherent (resp. fine) log structures on T. Then :*

(i) *There exists a neighborhood U of ξ, such that $f_{|U}$ admits a finite (resp. fine) chart.*
(ii) *More precisely, given a finite (resp. fine) chart $\omega_P : P_T \to \underline{M}$, we may find a neighborhood U of ξ, a finite (resp. fine) monoid Q, and a chart of $f_{|U}$ of the form*

$$(\omega_{P|U}, \omega_Q : Q_U \to \underline{N}_{|U}, \vartheta : P \to Q).$$

(iii) *Moreover, if f is a flat (resp. saturated) morphism of fine log structures and $(\omega_P, \omega_Q, \vartheta)$ is a fine chart for f, then we may find a neighborhood U of ξ, a localization map $j : Q \to Q'$, and a flat (resp. saturated) and fine chart for $f_{|U}$ of the form $(\omega_{P|U}, \omega_{Q'}, j \circ \vartheta)$, such that*
  (a) $\omega_{Q|U} = \omega_{Q'} \circ j_U$.
  (b) *The chart $\omega_{Q'}$ is local at the point ξ.*

Proof. Up to replacing T by T/U'_i for a covering $(U'_i \to 1_T \mid i \in I)$ of the final object, we may assume that we have finite (resp. fine) charts $\omega_P : P_T \to \underline{M}$ and $Q'_T \to \underline{N}$ (lemma 12.1.18(iii)), whence a morphism of pre-log structures :

$$\omega : P_T \xrightarrow{\omega_P} \underline{M} \xrightarrow{f} \underline{N}.$$

Let ξ be any T-point; there follow maps of monoids $\varphi : P \to \underline{M}_\xi \to \underline{N}_\xi$ and $\psi : Q' \to \underline{N}_\xi$. Set $G := (P \oplus Q')^{\mathrm{gp}}$, and apply proposition 12.1.30 to the group homomorphism $G \to \underline{N}_\xi^{\mathrm{gp}}$ induced by φ and ψ; for $Q := G \times_{\underline{N}_\xi^{\mathrm{gp}}} \underline{N}_\xi$, we obtain a finite (resp. fine) local chart $Q_U \to \underline{N}_{|U}$ on some neighborhood U of ξ. Then, φ and the natural map $P \to G$ determine a unique map $P \to Q$, whence a morphism $\omega' : P_U \to Q_U \to \underline{N}_{|U}$ of pre-log structures; by construction, $\omega'_\xi : P = P_{U,\xi} \to \underline{N}_\xi$ is none else than φ. By lemma 12.1.18(iv.b), we may then find a smaller neighborhood $V \to U$ of ξ such that $\omega'_{|V} = \omega_{|V}$. This proves (i) and (ii).

Next, we suppose that f is flat (resp. saturated) and both $\underline{M}$, $\underline{N}$ are fine, and we wish to show (iii). In view of claim 12.1.31, we may find – after replacing T by a neighborhood of ξ – a fine chart for f of the form $(\omega_{P'}, \omega_{Q'}, \vartheta')$, such that :

- P' and Q' are localizations of P and Q, and ϑ' is induced by ϑ;
- $\omega_P = \omega_{P'} \circ (j_P)_T$ and $\omega_Q = \omega_{Q'} \circ (j_Q)_T$, where $j_P : P \to P'$ and $j_Q : Q \to Q'$ are the localization maps;
- the induced maps $Q'^\sharp \to \underline{M}_\xi^\sharp$ and $P'^\sharp \to \underline{N}_\xi^\sharp$ are isomorphisms.

Now, by proposition 4.8.26 (resp. corollary 6.2.29), the map f_ξ is flat (resp. saturated), hence the same holds for the induced map $\underline{M}_\xi^\sharp \to \underline{N}_\xi^\sharp$, by corollary 6.1.49(i) (resp. by lemma 6.2.12(iii)). Then the map $P'^\sharp \to Q'^\sharp$ induced by ϑ' is flat (resp. saturated) as well, so the same holds for ϑ', by corollary 6.1.49(ii) (resp. again by lemma 6.2.12(iii)). Finally, $j_P \circ \vartheta' : P \to Q'$ is flat (resp. saturated), by example 6.1.23(iii) (resp. by lemma 6.2.12(i)), and $(\omega_P, \omega_{Q'}, j_P \circ \vartheta')$ is a chart for f with the sought properties. □

Corollary 12.1.38. *Let T be a topos, ξ a T-point, and $\varphi : \underline{M} \to \underline{N}$ a saturated morphism of fine and saturated log structures on T. We have :*

(i) *There exist a neighborhood U of ξ, and a fine and saturate chart $(\omega_P, \omega_Q, \vartheta : P \to Q)$ of $\varphi_{|U}$, such that ω_P and ω_Q are sharp at the point ξ.*
(ii) *More precisely, suppose that $(\omega_P, \omega_Q, \vartheta : P \to Q)$ is a fine and saturated chart for φ, such that $\underline{M}$ is sharp at the point ξ, and ω_Q is local at ξ. Then there exists a section $\sigma : Q^\sharp \to Q$ of the projection $Q \to Q^\sharp$, such that $(\omega_P, \omega_Q \circ \sigma_T, \vartheta^\sharp)$ is a chart for φ.*

Proof. After replacing T by some neighborhood of ξ, we may assume that $\underline{M}$ admits a chart $\omega_P : P_T \to \underline{M}$ which is fine, saturated, and sharp at the point ξ (corollary 12.1.36(i)). Then, by theorem 12.1.37(iii), we may find a neighborhood U of ξ, and a fine and saturated chart $(\omega_{P|U}, \omega_Q, \vartheta : P \to Q)$ for $\varphi_{|U}$, such that ω_Q is local at ξ, so that ϑ is also a local morphism. Hence, it suffices to show assertion (ii).

(ii): We notice the following :

Claim 12.1.39. Let $\vartheta : P \to Q$ a local and saturated morphism of fine and saturated monoids, and suppose that P is sharp. Then there exists a section $\sigma : Q^\sharp \to Q$ of the projection $Q \to Q^\sharp$, such that $\vartheta(P)$ lies in the image of σ.

Proof of the claim. Pick an isomorphism $\beta : Q \xrightarrow{\sim} Q^\sharp \times Q^\times$ as in lemma 6.2.10, and denote by $\psi : P \to Q^\times$ the composition of ϑ with the induced projection $Q \to Q^\times$. The morphism $\vartheta^\sharp$ is still local and saturated (lemma 6.2.12(iii)), hence corollary 6.2.32(ii) implies that $\vartheta^{\sharp\mathrm{gp}}$ extends to an isomorphism $P^{\mathrm{gp}} \oplus L \xrightarrow{\sim} Q^{\sharp\mathrm{gp}}$, where L is a free abelian group of finite rank. Thus, we may extend ψ^{gp} to a group homomorphism $\psi' : Q^{\sharp\mathrm{gp}} \to Q^\times$. Define an automorphism α of $Q^\sharp \times Q^\times$, by the rule : $(x, g) \mapsto (x, g \cdot \psi'(x)^{-1})$. The restriction $\sigma : Q^\sharp \to Q$ of $(\alpha \circ \beta)^{-1}$ will do. ◊

With the notation of claim 12.1.39 it is easily seen that $\omega_Q \circ \sigma_T$ is still a chart for $\underline{N}$, hence $(\omega_P, \omega_Q \circ \sigma_T, \vartheta^\sharp)$ is a chart for φ as required. □

Corollary 12.1.40. *Let $f : (T, \underline{M}) \to (S, \underline{N})$ a morphism of log topoi with coherent (resp. fine) log structures, and suppose that $\underline{N}$ admits a finite (resp. fine) chart $\omega_Q : Q_S \to \underline{N}$. Let also ξ be any T-point; we have :*

- (i) *There exist a neighborhood U of ξ, and a finite (resp. fine) chart $(\omega_{Q|U}, \omega_P, \vartheta : Q \to P)$ for the morphism $f_{|U}$.*
- (ii) *Moreover, if $\underline{M}$ and $\underline{N}$ are fine and f is log flat (resp. saturated) then, on some neighborhood U of ξ, we may also find a chart $(\omega_{Q|U}, \omega_P, \vartheta)$ which is flat (resp. saturated) and fine.*

Proof. This is an immediate consequence of theorem 12.1.37. □

12.2. **Log schemes.** We specialize now to the case of a scheme X. Whereas in [75, §6.4] we considered only pre-log structures on the Zariski site of a scheme, hereafter we shall treat uniformly the categories of log structures on the topoi $X^\sim_{\text{ét}}$ and $X^\sim_{\mathrm{Zar}}$ (notation of (4.9.13)).

12.2.1. Henceforth, we choose $\tau \in \{\text{ét}, \mathrm{Zar}\}$ (see (4.9.19)), and whenever we mention a topology on a scheme X, it will be implicitly meant that this is the topology X_τ (unless explicitly stated otherwise). Let X be a scheme; a *pre-log structure* (resp. *a log structure*) on X is a pre-log structure (resp. a log structure) on the topos $X^\sim_\tau$. The datum of a scheme X and a log structure on X is called briefly a *log scheme*. It is known that a morphism of schemes $X \to Y$ is the same as a morphism of locally ringed topoi $X^\sim_\tau \to Y^\sim_\tau$, hence we may define a morphism of log schemes $(X, \underline{M}) \to (Y, \underline{N})$ as a morphism of log topoi $(X^\sim_\tau, \underline{M}) \to (Y^\sim_\tau, \underline{N})$ (and likewise for morphisms of schemes with pre-log structures). We denote by $\mathbf{pre\text{-}log}_\tau$ (resp. $\mathbf{log}_\tau$) the category of schemes with pre-log structures (resp. of log schemes) on the chosen topology τ. We denote by :

$$\mathbf{int.log}_\tau \qquad \mathbf{sat.log}_\tau \qquad \mathbf{qcoh.log}_\tau \qquad \mathbf{coh.log}_\tau$$

the full subcategory of the category $\mathbf{log}_\tau$, consisting of all log schemes with integral (resp. integral and saturated, resp. quasi-coherent, resp. coherent) log structures.

A scheme with a quasi-fine (resp. fine, resp. quasi-fine and saturated, resp. fine and saturated) log structure is called, briefly, a *quasi-fine log scheme* (resp. a *fine log scheme*, resp. a *qfs log* *scheme*, resp. a *fs log scheme*), and we denote by

$$\mathbf{qf.log}_\tau \qquad \mathbf{f.log}_\tau \qquad \mathbf{qfs.log}_\tau \qquad \mathbf{fs.log}_\tau$$

the full subcategory of $\mathbf{log}_\tau$ consisting of all quasi-fine (resp. fine, resp. qfs, resp. fs) log schemes on the topology τ. In case it is clear (or indifferent) which topology we are dealing with, we will usually omit the subscript τ. There is an obvious (forgetful) functor :

$$F : \mathbf{log} \to \mathsf{Sch}$$

to the category of schemes, and it is easily seen that this functor is a fibration. For every scheme X, we denote by $\mathbf{log}_X$ the fibre category $F^{-1}(X)$ *i.e.* the category of all log structures on X (or $\mathbf{log}_{X_\tau}$, if we need to specify the topology τ). The same notation shall be used also for the various subcategories : so for instance we shall write $\mathbf{int.log}_X$ for the full subcategory of all integral log structures on X. Moreover, we shall say that the log scheme $(X, \underline{M})$ is *locally noetherian* if the underlying scheme X is locally noetherian.

12.2.2. Most of the forthcoming assertions hold in both the étale and Zariski topoi, with the same proof. However, it may occasionally happen that the proof of some assertion concerning $X_\tau^\sim$ (for $\tau \in \{\text{ét}, \text{Zar}\}$), is easier for one choice or the other of these two topologies; in such cases, it is convenient to be able to change the underlying topology, to suit the problem at hand. This is sometimes possible, thanks to the following general considerations.

The morphism of locally ringed topoi $\widetilde{u}$ of (4.9.15) induces a pair of adjoint functors :

$$\widetilde{u}^* : \mathbf{log}_{\text{Zar}} \to \mathbf{log}_{\text{ét}} \qquad \widetilde{u}_* : \mathbf{log}_{\text{ét}} \to \mathbf{log}_{\text{Zar}}$$

as well as analogous adjoint pairs for the corresponding categories of sheaves of monoids (resp. of pre-log structures) on the two sites. It follows formally that $\widetilde{u}^*$ sends constant log structures to constant log structures, *i.e.* for every scheme X, and every object $M := (M, \varphi)$ of $\mathbf{Mnd}/\Gamma(X, \mathscr{O}_X)$ we have a natural isomorphism :

$$\widetilde{u}^*(X_{\text{Zar}}, M^{\log}_{X_{\text{Zar}}}) \simeq (X_{\text{ét}}, M^{\log}_{X_{\text{ét}}}).$$

More generally, lemma 12.1.18(i) shows that $\widetilde{u}^*$ preserves the subcategories of quasi-coherent (resp. coherent, resp. integral, resp. fine, resp. fine and saturated) log structures.

Proposition 12.2.3. (i) *The functor $\widetilde{u}^*$ on log structures is faithful and conservative.*

(ii) *The functor $\widetilde{u}^*$ restricts to a fully faithful functor :*

$$\widetilde{u}^* : \mathbf{int.log}_{\text{Zar}} \to \mathbf{int.log}_{\text{ét}}.$$

(iii) *Let $(X_{\text{ét}}, \underline{M})$ be any log scheme. Then the counit of adjunction $\widetilde{u}^*\widetilde{u}_*(X_{\text{ét}}, \underline{M}) \to (X_{\text{ét}}, \underline{M})$ is an isomorphism if and only if the same holds for the counit of adjunction $\widetilde{u}^*\widetilde{u}_*(\underline{M}^\sharp) \to \underline{M}^\sharp$.*

Proof. (i): Let $(X_{\text{Zar}}, \underline{M})$ be any log structure; set $(X_{\text{ét}}, \underline{M}_{\text{ét}}) := \widetilde{u}^*(X, \underline{M})$, and denote by $\widetilde{u}^\natural_X : \widetilde{u}^*\mathscr{O}_{X_{\text{Zar}}} \to \mathscr{O}_{X_{\text{ét}}}$ the natural map of structure rings. Since $\widetilde{u}$ is a morphism of locally ringed topoi, we have :

$$(\widetilde{u}^\natural_X)^{-1}\mathscr{O}^\times_{X_{\text{ét}}} = \widetilde{u}^*(\mathscr{O}^\times_{X_{\text{Zar}}}).$$

It follows easily that $\underline{M}_{\text{ét}}$ is the push-out in the cocartesian diagram :

$$\begin{array}{ccc} \widetilde{u}^*\underline{M}^\times & \xrightarrow{\alpha} & \mathscr{O}^\times_{X_{\text{ét}}} \\ \downarrow & & \downarrow \\ \widetilde{u}^*\underline{M} & \xrightarrow{\beta} & \underline{M}_{\text{ét}}. \end{array}$$

However, for every geometric point ξ of X, the natural map $\mathscr{O}_{X,|\xi|} \to \mathscr{O}_{X,\xi}$ is faithfully flat, hence α_ξ is injective, and therefore also β_ξ, in light of lemma 4.8.31(ii). The faithfulness of $\widetilde{u}^*$

is an easy consequence. Next, let $f : \underline{M} \to \underline{N}$ be a morphism of log structures on X_{Zar}, set $(X_{\text{ét}}, \underline{N}_{\text{ét}}) := \widetilde{u}^*(X, \underline{N})$, and suppose that $\widetilde{u}^* f : \underline{M}_{\text{ét}} \to \underline{N}_{\text{ét}}$ is an isomorphism; we wish to show that f is an isomorphism. However, β induces an isomorphism of monoids :

$$\widetilde{u}^*(\underline{M}^\sharp) \xrightarrow{\sim} \underline{M}^\sharp_{\text{ét}} \tag{12.2.4}$$

and likewise for $\underline{N}$; it follows already that f induces an isomorphism $\underline{M}^\sharp \xrightarrow{\sim} \underline{N}^\sharp$. To conclude, it suffices to invoke lemma 12.1.4.

(ii): Let us suppose that $\underline{M}$ is integral. According to [28, Prop.3.4.1], it suffices to show that the unit of adjunction $(X, \underline{M}) \to \widetilde{u}_*(X_{\text{ét}}, \underline{M}_{\text{ét}})$ is an isomorphism. Now, from the isomorphism (12.2.4) we deduce a commutative diagram :

$$\begin{array}{ccc} \underline{M}^\sharp & \longrightarrow & (\widetilde{u}_*\underline{M}_{\text{ét}})^\sharp \\ \downarrow & & \downarrow \\ \widetilde{u}_*\widetilde{u}^*(\underline{M}^\sharp) & \longrightarrow & \widetilde{u}_*(\underline{M}^\sharp_{\text{ét}}) \end{array}$$

whose bottom arrow is an isomorphism, and whose left vertical arrow is an isomorphism as well, by lemma 4.9.27(iii) (and again [28, Prop.3.4.1]). We claim that also the right vertical arrow is an isomorphism. Indeed, since $\widetilde{u}_*$ is left exact, the latter arrow is a monomorphism, hence it suffices to show it is an epimorphism; however, since $\underline{M}_{\text{ét}}$ is an integral log structure (lemma 12.1.18(i)), it is easily seen that the projection $\underline{M}_{\text{ét}} \to \underline{M}^\sharp_{\text{ét}}$ is a $\mathscr{O}^\times_{X_{\text{ét}}}$-torsor (in the topos $X^\sim_{\text{ét}}/\underline{M}^\sharp_{\text{ét}}$). Then the contention follows from the exact sequence of pointed sheaves (4.9.12), and the vanishing result of lemma 4.9.27(iv).

Summing up, we conclude that the top horizontal arrow in the above diagram is an isomorphism, so the assertion follows from lemma 12.1.4.

(iii): Set $(X_{\text{ét}}, (\widetilde{u}_*\underline{M})_{\text{ét}}) := \widetilde{u}^*\widetilde{u}_*(X_{\text{ét}}, \underline{M})$. To begin with, lemma 4.9.27(iv) easily implies that the natural morphism $(\widetilde{u}_*\underline{M})^\sharp \to \widetilde{u}_*(\underline{M}^\sharp)$ is an isomorphism; together with the general isomorphism (12.1.9), this yields a short exact sequence of $X_{\text{ét}}$-monoids :

$$0 \to \mathscr{O}^\times_{X_{\text{ét}}} \to (\widetilde{u}_*\underline{M})_{\text{ét}} \to \widetilde{u}^*\widetilde{u}_*(\underline{M}^\sharp) \to 0$$

which easily implies the assertion : the details shall be left to the reader. □

We shall prove later on some more results in the same vein (see corollary 12.2.24).

12.2.5. Arguing as in (12.1.24), we see easily that all finite limits are representable in the category of log schemes. The rule $X \mapsto (X, \mathscr{O}^\times_X)$ defines a fully faithful inclusion of the category of schemes into the category of log schemes. Hence, we shall regard a scheme as a log scheme with trivial log structure. Especially, if $(X, \underline{M})$ is any log scheme, and $Y \to X$ is any morphism of schemes, we shall often use the notation :

$$Y \times_X (X, \underline{M}) := (Y, \mathscr{O}^\times_Y) \times_{(X, \mathscr{O}^\times_X)} (X, \underline{M}). \tag{12.2.6}$$

Especially, if ξ is any τ-point of X, the *localization* of $(X, \underline{M})$ at ξ is the log scheme

$$(X(\xi), \underline{M}(\xi)) := X(\xi) \times_X (X, \underline{M})$$

(see definition 4.9.17(ii,iii)). If $\tau = \text{ét}$, this operation is also called the *strict henselization* of X at ξ.

Definition 12.2.7. (i) For every integer $n \in \mathbb{N}$, we have the subset :

$$(X, \underline{M})_n := \{x \in X \mid \dim \underline{M}_\xi \leq n \text{ for every } \tau\text{-point } \xi \to X \text{ localized at } x\}.$$

By remark 6.1.11(i), $(X, \underline{M})_0$ consists of all $x \in X$ such that $\underline{M}_\xi = \mathscr{O}^\times_{X,\xi}$ for every τ-point ξ of X localized at x; this subset is called the *trivial locus* of $(X, \underline{M})$, and is also denoted $(X, \underline{M})_{\mathrm{tr}}$.

(ii) If $f : (X, \underline{M}) \to (Y, \underline{N})$ is a morphism of log schemes, we denote by $\mathrm{Str}(f) \subset X$ the *strict locus* of f, which is the subset consisting of all points $x \in X$ such that f is strict at every τ-point localized at x (see definition 12.1.22(ii)).

Remark 12.2.8. Let $f : (X, \underline{M}) \to (Y, \underline{N})$ be any morphism of log schemes.

(i) Since $\log f$ induces local morphisms on stalks, it is easily seen that f restricts to a map

$$f_{\mathrm{tr}} : (X, \underline{M})_{\mathrm{tr}} \to (Y, \underline{N})_{\mathrm{tr}}.$$

(ii) Especially, we have $(X, \underline{M})_{\mathrm{tr}} \subset \mathrm{Str}(f)$.

12.2.9. Let $\underline{X} := (X_i \mid i \in I)$ be a cofiltered family of quasi-separated schemes, with affine transition morphisms $f_\varphi : X_j \to X_i$, for every morphism $\varphi : j \to i$ in I. Denote by X the limit of $\underline{X}$, and for each $i \in I$ let $\pi_i : X \to X_i$ be the natural projection.

Lemma 12.2.10. *In the situation of* (12.2.9)*, let* $\mathscr{X} := ((X_i, \underline{M}_i) \mid i \in I)$ *be a cofiltered system of log schemes, with transition morphisms* $(f_\varphi, \log f_\varphi) : (X_i, \underline{M}_i) \to (X_j, \underline{M}_j)$ *for every morphism* $\varphi : i \to j$ *in* I*. We have :*

(i) *The limit of the system* $\mathscr{X}$ *exists in the category* **log**.

(ii) *Let* $(X, \underline{M})$ *denote the limit of the system* $\mathscr{X}$*. If* X_i *is quasi-compact and quasi-separated for every* $i \in I$*, then the natural map*

$$\operatorname*{colim}_{i \in I} \Gamma(X_i, \underline{N}_i) \to \Gamma(X, \underline{N})$$

is an isomorphism.

Proof. (i): Let X be the limit of the system of schemes $\underline{X}$, and endow X with the sheaf of monoids $\underline{M} := \mathrm{colim}_{i \in I}\, \pi_i^* \underline{M}_i$, where π^* is the pull-back functor for sheaves of monoids (see (4.8.43)), and the transition maps $\pi_j^* \underline{M}_j \to \pi_i^* \underline{M}_i$ are induced by the morphisms $\log f_\varphi : f_\varphi^* \underline{M}_j \to \underline{M}_i$, for every $\varphi : i \to j$ in I. Then the structure maps of the log structures $\underline{M}_i$ induce a well defined morphism of X-monoids $\underline{M} \to \mathscr{O}_X$, and we claim that the resulting scheme with pre-log structure $(X, \underline{M})$ is actually a log scheme. Indeed, the assertion can be checked on the stalks, and notice that, for every τ-point ξ of X we have a natural identification

$$\mathscr{O}_{X,\xi} \xrightarrow{\sim} \operatorname*{colim}_{i \in I} \mathscr{O}_{X_i, \pi_i(\xi_i)}.$$

(This is clear for $\tau = \mathrm{Zar}$, and for $\tau = \text{ét}$ one uses [66, Ch.IV, Prop.18.8.18(ii)]); it then suffices to invoke lemma 4.8.46(i). Lastly, it is easily seen that $(X, \underline{M})$ is a limit of the system $\mathscr{X}$: the details shall be left to the reader.

(ii): In view of the explicit construction in (i), the assertion for $\tau = \mathrm{Zar}$ follows immediately from proposition 10.1.10, and for $\tau = \text{ét}$ it follows from [9, Exp.VII, Rem.5.14]. □

Example 12.2.11. Let X be a scheme. For the following example we choose to work with the étale topology $X_{\text{ét}}$ on X. A *divisor* on X is a closed subscheme $D \subset X$ which is regularly embedded in X and of codimension 1 ([66, Ch.IV, Déf.19.1.3, §21.2.12]). Suppose moreover that X is noetherian, let $D \subset X$ be a divisor, and denote by $(D_i \mid i \in I)$ the irreducible reduced components of D. We say that D is a *strict normal crossings* divisor, if :

- $\mathscr{O}_{X,x}$ is a regular ring, for every $x \in D$.
- D is a reduced subscheme.
- For every subset $J \subset I$, the (scheme theoretic) intersection $\bigcap_{j \in J} D_j$ is regular of pure codimension $\sharp J$ in X.

A closed subscheme D of a noetherian scheme X is a *normal crossings divisor* if, for every $x \in X$ there exists an étale neighborhood $f : U \to X$ of x such that $f^{-1}D$ is a strict normal crossings divisor in U.

Suppose that D is a normal crossings divisor of a noetherian scheme X, and let $j : U := X\setminus D \to X$ be the natural open immersion. We claim that the log structure $j_*\mathscr{O}_U^\times$ is fine (this is the direct image of the trivial log structure on $U_{\text{ét}}$: see example 12.1.12(ii)). To see this, let ξ be any geometric point of X localized at a point of D; up to replacing X by an étale neighborhood of ξ, we may assume that D is a strict normal crossings divisor; we can assume as well that X is affine and small enough, so that the irreducible components $(D_\lambda \mid \lambda \in \Lambda)$ are of the form $V(I_\lambda)$, where $I_\lambda \subset A := \Gamma(X, \mathscr{O}_X)$ is a principal divisor, say generated by an element $x_\lambda \in A$, for every $\lambda \in \Lambda$. We claim that $j_*\mathscr{O}_U^\times$ is the constant log structure associated to the pre-log structure :

$$\alpha : \mathbb{N}_X^{(\Lambda)} \to \mathscr{O}_X \quad : \quad e_\lambda \mapsto x_\lambda$$

where $(e_\lambda \mid \lambda \in \Lambda)$ is the standard basis of $\mathbb{N}^{(\Lambda)}$. Indeed, let $S \subset \Lambda$ be the largest subset such that the image of ξ lies in $D_S := \bigcap_{\lambda\in S} D_\lambda$, we have $x_\lambda \in \mathscr{O}_{X,x}^\times$ for all $\lambda \notin S$, so that the push-out of the induced diagram of stalks $\mathscr{O}_{X,\xi}^\times \leftarrow \alpha^{-1}\mathscr{O}_{X,\xi}^\times \to \mathbb{N}^{(\Lambda)}$ is the same as the push-out P_S of the analogous diagram $\mathscr{O}_{X,\xi}^\times \leftarrow \alpha_S^{-1}\mathscr{O}_{X,\xi}^\times \to \mathbb{N}^{(S)}$, where $\alpha_S : \mathbb{N}_X^{(S)} \to \mathscr{O}_X$ is the restriction of α. Suppose that $a \in \mathscr{O}_{X,\xi}$ and a is invertible on $X(\xi)\setminus D_S$; the minimal associated primes of $A/(a)$ are all of height one, and they must therefore be found among the prime ideals Ax_λ, with $\lambda \in S$. It follows easily that a is of the form $u \cdot \prod_{\lambda\in S} x_\lambda^{k_\lambda}$ for certain $k_\lambda \in \mathbb{N}$ and $u \in \mathscr{O}_{X,\xi}^\times$. Therefore, the natural map $\beta_\xi : P_S \to (j_*\mathscr{O}_U^\times)_\xi$ is surjective. Moreover, the family $(x_\lambda \mid \lambda \in S)$ is a regular system of parameters of $\mathscr{O}_{X,\xi}$ ([63, Ch.0, Prop.17.1.7]), therefore the natural map $\mathrm{Sym}^n_{\kappa(\xi)}(\mathfrak{m}_\xi/\mathfrak{m}_\xi^2) \to \mathfrak{m}_\xi^n/\mathfrak{m}_\xi^{n+1}$ is an isomorphism for every $n \in \mathbb{N}$ (here $\mathfrak{m}_\xi \subset \mathscr{O}_{X,\xi}$ is the maximal ideal); it follows easily that β_ξ is also injective.

Example 12.2.12. Suppose that X is a regular noetherian scheme, and $D \subset X$ a divisor on X; let $U := X\setminus D$. If D is not a normal crossings divisor, the log structure $\underline{M} := j_*\mathscr{O}_U^\times$ on $X_{\text{ét}}$ is not necessarily fine. For a counterexample, let K be an algebraically closed field, $C \subset \mathbb{A}^2_K$ a nodal cubic; take $D \subset X := \mathbb{A}^3_K$ to be the (reduced, affine) cone over the cubic C, with vertex $x_0 \in \mathbb{A}^3$, and pick a geometric point ξ localized at x_0. It is easily seen that, away from the vertex, D is a normal crossings divisor, hence $\underline{M}_{|X\setminus\{x_0\}}$ is a fine log structure on $X\setminus\{x_0\}$, by example 12.2.11. More precisely, let $y_0 \in C$ be the unique singular point, $L \subset D$ the line spanned by x_0 and y_0, and η a geometric point localized at the generic point of L. By inspecting the argument in example 12.2.11, we find that :

$$\underline{M}_\eta \simeq \mathbb{N}^{\oplus 2} \oplus \mathscr{O}_{X,\eta}^\times$$

(indeed, an isomorphism is obtained by choosing $a, b \in \mathscr{O}_{C,y_0}$ such that $V(a)$ and $V(b)$ are the two branches of the cubic C in an étale neighborhood of y_0). On the other hand, let $\mathfrak{p} \subset A := K[T_1, T_2, T_3]$ be the prime ideal corresponding to x_0, and $I \subset A_\mathfrak{p}$ the ideal defining the closed subscheme $X(x_0)\cap D$ in $X(x_0)$; we claim that $I\cdot\mathscr{O}_{X,\xi}$ is still a prime ideal, necessarily of height one. Indeed, let $B := A_\mathfrak{p}/I$, and denote by $A^\wedge$ (resp. $B^\wedge$) the $\mathfrak{p}$-adic completion of $A_\mathfrak{p}$ (resp. of B); then $B^\wedge$ is also the completion of the reduced ring $\mathscr{O}_{X,\xi}/I$, hence it suffices to show that $\mathrm{Spec}\, B^\wedge$ is irreducible. However, we may assume that $C \subset \mathrm{Spec}\, K[T_1, T_2]$ is the affine cubic defined by the ideal $J \subset K[T_1, T_2]$ generated by $T_1^3 - T_2^2 + T_1T_2$. Then I is generated by the element $f := T_1^3 - T_2^2T_3 + T_1T_2T_3$; also, $\mathfrak{p} = (T_1, T_2, T_3)$, so that $A^\wedge \simeq K[[T_1, T_2, T_3]]$ and $B^\wedge \simeq A^\wedge/(f)$. Suppose $\mathrm{Spec}\, B^\wedge$ is not irreducible. This means that $V(f) \subset \mathrm{Spec}\, A^\wedge$ is a union $V(f) = Z_1 \cup \cdots \cup Z_n$ of $n \geq 2$ irreducible components Z_i. Since $A^\wedge$ is a local regular ring, each such irreducible component Z_i is a divisor, defined by some principal prime ideal $\mathfrak{q}_i$ in $A^\wedge$. Let a_i be a generator for $\mathfrak{q}_i$; then f admits factorizations of the form $f = a_ib_i$ for some non-invertible $b_i \in A^\wedge$. Fix some i, and set $a := a_i$, $b := b_i$; since f is homogeneous of degree 3, we must have $a \in \mathfrak{p}^k\setminus\mathfrak{p}^{k+1}$ for either $k = 1$ or $k = 2$ ($k \neq 0$ since a is not a unit, and $k \neq 3$, since b is not a unit); then $b \in \mathfrak{p}^{3-k}\setminus\mathfrak{p}^{4-k}$. Write $a = a' + a''$ and $b = b' + b''$, where $a'' \in \mathfrak{p}^{k+1}$,

$b'' \in \mathfrak{p}^{4-k}$ and a' (resp. b') is homogeneous of degree k (resp. $3-k$). Then $f = ab = a'b' + c$, where $c \in \mathfrak{p}^4$ and $a'b'$ is homogeneous of degree 3. This means that $f = a'b'$ is a factorization of f in A. However, f is irreducible in A, a contradiction. (Instead of this elementary argument, one can appeal to [133, Th.43.20], which runs as follows. If R is a local domain, then there is a natural bijection between the set of minimal prime ideals of the henselization R^{h} of R and the set of maximal ideals of the normalization of R in its ring of fractions. In our case, the normalization D^ν of D is the cone over the normalization of C, hence the only point of D^ν lying over x_0 is the vertex of D^ν.)

It follows that any choice of a generator of I yields an isomorphism :

$$\underline{M}_\xi \simeq \mathbb{N} \oplus \mathscr{O}^\times_{X,\xi}.$$

Suppose now that – in an étale neighborhood V of ξ – the log structure $\underline{M}$ is associated to a pre-log structure $\alpha : P_V \to \mathscr{O}_V$, for some monoid P; hence $\underline{M}_{|V}$ is the push-out of the diagram $\mathscr{O}^\times_V \leftarrow \alpha^{-1}(\mathscr{O}^\times_V) \to P_V$, whence isomorphisms :

$$P/\alpha^{-1}_\xi(\mathscr{O}^\times_{X,\xi}) \simeq \underline{M}_\xi/\mathscr{O}^\times_{X,\xi} \simeq \mathbb{N} \qquad P/\alpha^{-1}_\eta(\mathscr{O}^\times_{X,\eta}) \simeq \underline{M}_\eta/\mathscr{O}^\times_{X,\eta} \simeq \mathbb{N}^{\oplus 2}.$$

But clearly $\alpha^{-1}_\xi(\mathscr{O}^\times_{X,\xi}) \subset \alpha^{-1}_\eta(\mathscr{O}^\times_{X,\eta})$, so we would have a surjection of monoids $\mathbb{N} \to \mathbb{N}^{\oplus 2}$, which is absurd.

On the other hand, we remark that the log structure $j_*\mathscr{O}^\times_U$ *on the Zariski site* X_{Zar} is fine : indeed, one has a global chart $\mathbb{N}_{X_{\mathrm{Zar}}} \to j_*\mathscr{O}^\times_U$, provided by the equation defining the divisor D.

12.2.13. Let R be a ring, M a monoid, and set $S := \operatorname{Spec} R[M]$. The unit of adjunction $\varepsilon_M : M \to R[M]$ can be regarded as an object (M, ε_M) of $\mathbf{Mnd}/\Gamma(S, \mathscr{O}_S)$, whence a constant log structure $M^{\log}_S$ on S (see (12.1.15)). The rule

$$M \mapsto \operatorname{Spec}(R, M) := (S, M^{\log}_S)$$

is clearly functorial in M. Namely, to any morphism $\lambda : M \to N$ of monoids, we attach the morphism of log schemes

$$\operatorname{Spec}(R, \lambda) := (\operatorname{Spec} R[\lambda], \lambda^{\log}_{\operatorname{Spec} R[N]}) : \operatorname{Spec}(R, N) \to \operatorname{Spec}(R, M).$$

Likewise, if P is a pointed monoid, $\operatorname{Spec} R\langle P\rangle$ is a closed subscheme of $\operatorname{Spec} R[P]$, and we may define

$$\operatorname{Spec}\langle R, P\rangle := \operatorname{Spec}(R, P) \times_{\operatorname{Spec} R[P]} \operatorname{Spec} R\langle P\rangle.$$

Lastly, if M is a non-pointed monoid, notice the natural isomorphism of log schemes

$$\operatorname{Spec}\langle R, M_\circ\rangle \xrightarrow{\sim} \operatorname{Spec}(R, M)_\circ.$$

(Notation of remark 12.1.23(ii) : the details shall be left to the reader.)

Lemma 12.2.14. *With the notation of* (12.2.13)*, let* $a \in M$ *be any element, and set* $M_a := S_a^{-1}M$*, where* $S_a := \{a^n \mid n \in \mathbb{N}\}$*. Then* $U_a := \operatorname{Spec} R[M_a]$ *is an open subscheme of* S*, and the induced morphism of log schemes :*

$$\operatorname{Spec}(R, M_a) \to \operatorname{Spec}(R, M) \times_S U_a$$

is an isomorphism.

Proof. Let $\beta_S : M_S \to \mathscr{O}_S$ and $\beta_{U_a} : (M_a)_{U_a} \to \mathscr{O}_{U_a}$ be the natural charts, and denote by $\varphi : M \to M_a$ the localization map. For every τ-point ξ of U_a, we have the identity :

$$\beta_{S,\xi} = \beta_{U_a,\xi} \circ \varphi : M \to \mathscr{O}_{S,\xi}.$$

Let $Q := \beta^{-1}_{U_a,\xi}\mathscr{O}^\times_{U_a,\xi}$. The assertion is a straightforward consequence of the following :

Claim 12.2.15. The induced commutative diagram of monoids :

$$\begin{array}{ccc} \varphi^{-1}Q & \longrightarrow & M \\ \downarrow & & \downarrow \\ Q & \longrightarrow & M_a \end{array}$$

is cocartesian.

Proof of the claim. Let $b \in M$, and suppose that $\beta_{U_a,\xi}(a^{-1}b) \in \mathscr{O}^\times_{U_a,\xi}$. Since $\beta_{U_a,\xi}(a) \in \mathscr{O}^\times_{U_a,\xi}$, we deduce that the same holds for $\beta_{U_a,\xi}(b)$, *i.e.* $b \in \varphi^{-1}Q$. Let $Q' := \varphi(\varphi^{-1}Q)$; we conclude that $Q = S_a^{-1}Q'$, the submonoid of M_a generated by Q' and a^{-1}. The claim follows easily. □

12.2.16. In the same vein, let X be a R-scheme, and (M, φ) any object of $\mathbf{Mnd}/\Gamma(X, \mathscr{O}_X)$. The map φ induces, via the adjunction of (4.8.50), a homomorphism of R-algebras $R[M] \to \Gamma(X, \mathscr{O}_X)$, whence a map of schemes $f : X \to S := \mathrm{Spec}\, R[M]$, inducing a morphism

$$X \times_S \mathrm{Spec}(R, M) \to (X, (M, \varphi)^{\log}_X) \qquad (12.2.17)$$

of log schemes.

Lemma 12.2.18. *In the situation of* (12.2.16)*, we have :*

(i) *The map* (12.2.17) *is an isomorphism.*
(ii) *The log scheme* $\mathrm{Spec}(R, M)$ *represents the functor*

$$\mathbf{log} \to \mathbf{Set} \quad : \quad (Y, \underline{N}) \mapsto \mathrm{Hom}_{\mathbb{Z}\text{-}\mathsf{Alg}}(R, \Gamma(Y, N)) \times \mathrm{Hom}_{\mathbf{Mnd}}(P, \Gamma(Y, \underline{N})).$$

Proof. (i): The log structure $f^*(M_S^{\log})$ of $\mathrm{Spec}(R, M) \times_S X$ represents the functor :

$$F : \mathbf{log}_X \to \mathbf{Set} \quad : \quad \underline{N} \mapsto \mathrm{Hom}_{\mathbf{Mnd}/\Gamma(S,\mathscr{O}_S)}((M, \varepsilon_M), \Gamma(S, f_*\underline{N})).$$

However, if $\underline{N}$ is any log structure on X, the pre-log structure $(f_*\underline{N})^{\text{pre-log}}$ is the same as $f_*(\underline{N}^{\text{pre-log}})$ (see [75, (6.4.8)]). From the explicit construction of direct images for pre-log structures, and since the global sections functor is left exact (because it is a right adjoint), we deduce a cartesian diagram of monoids :

$$\begin{array}{ccc} \Gamma(S, f_*\underline{N}) & \longrightarrow & \Gamma(S, \mathscr{O}_S) \\ \downarrow & & \downarrow \\ \Gamma(X, \underline{N}) & \longrightarrow & \Gamma(X, \mathscr{O}_X). \end{array}$$

It follows easily that F is naturally isomorphic to the functor given by the rule :

$$\underline{N} \mapsto \mathrm{Hom}_{\mathbf{Mnd}/\Gamma(X,\mathscr{O}_X)}((M, \varphi), \Gamma(X, \underline{N})).$$

The latter is of course the functor represented by $(M, \varphi)^{\log}_X$.

(ii) can now be deduced formally from (i), or proved directly by inspecting the definitions. □

12.2.19. From (12.2.13) it is also clear that the rule $(R, M) \mapsto \mathrm{Spec}(R, M)$ defines a functor

$$\mathbb{Z}\text{-}\mathsf{Alg}^o \times \mathbf{Mnd}^o \to \mathbf{log}$$

which commutes with fibre products; namely, say that

$$(R', M') \leftarrow (R, M) \to (R'', M'')$$

are two morphisms of $\mathbb{Z}\text{-}\mathsf{Alg} \times \mathbf{Mnd}$; then there is a natural isomorphism of log schemes :

$$\mathrm{Spec}(R' \otimes_R R'', M' \otimes_M M'') \xrightarrow{\sim} \mathrm{Spec}(R', M') \times_{\mathrm{Spec}(R,M)} \mathrm{Spec}(R'', M'').$$

For the proof, one compares the universal properties characterizing these log schemes, using lemma 12.2.18(ii) : details left to the reader.

12.2.20. Let X be a scheme, $\underline{M}$ a sheaf of monoids on X_τ. We say that $\underline{M}$ is *locally constant* if there exist a covering family $(U_\lambda \to X \mid \lambda \in \Lambda)$ and for every $\lambda \in \Lambda$, a monoid P_λ and an isomorphism of sheaves of monoids $\underline{M}_{|U_\lambda} \simeq (P_\lambda)_{U_\lambda}$. We say that $\underline{M}$ is *weakly constructible* if, for every affine open subset $U \subset X$ we can find finitely many locally closed constructible subsets $Z_1, \dots, Z_n \subset U$ such that :

- $U = Z_1 \cup \dots \cup Z_n$
- $\underline{M}_{|Z_i}$ is a locally constant sheaf of monoids, for every $i = 1, \dots, n$.

If moreover, $\underline{M}_\xi$ is a finitely generated monoid for every τ-point ξ of X, we say that $\underline{M}$ is *constructible*. If $\varphi : \underline{M} \to \underline{N}$ is a morphism of constructible sheaves of monoids on X_τ, then it is easily seen that $\mathrm{Ker}\,\varphi$, $\mathrm{Coker}\,\varphi$ and $\mathrm{Im}\,\varphi$ are constructible (corollary 6.4.3(i)). Moreover, constructibility is preserved under coequalizers; if $\underline{M}$ is weakly constructible with integral stalks $\underline{M}_\xi$ at every τ-point ξ of X, then a fibre product $\underline{M}' \times_{\underline{M}} \underline{M}''$ is constructible if the same holds for both $\underline{M}'$ and $\underline{M}''$; furthermore, under the same assumptions for $\underline{M}$, an equalizer $\mathrm{Equal}(\varphi, \varphi' : \underline{N} \to \underline{M})$ is constructible if the same holds for $\underline{N}$ (corollaries 6.4.2 and 6.4.3(ii)).

If X is locally noetherian and both $\underline{M}$ and $\underline{N}$ are weakly constructible, then the same holds for $\mathrm{Ker}\,\varphi$, $\mathrm{Coker}\,\varphi$ and $\mathrm{Im}\,\varphi$.

Suppose that $\underline{M}$ is a sheaf of monoids on X_τ, and for every $x \in X$ choose a τ-point $\overline{x}$ localized at x; the *rank* of $\underline{M}$ is the function

$$\mathrm{rk}_{\underline{M}} : X \to \mathbb{N} \cup \{\infty\} \qquad x \mapsto \dim_{\mathbb{Q}} \underline{M}^{\mathrm{gp}}_{\overline{x}} \otimes_{\mathbb{Z}} \mathbb{Q}.$$

It is clear from the definitions that the rank function of a constructible sheaf of monoid is constructible on X.

Lemma 12.2.21. *Let X be a scheme, $\varphi : \underline{Q} \to \underline{Q}'$ a morphism of coherent log structures on X_τ. Then :*

(i) *The sheaves $\underline{Q}^\sharp$ and* $\mathrm{Coker}\,\varphi$ *are constructible.*
(ii) *$(X, \underline{Q})_n$ is an open subset of X, for every integer $n \geq 0$. (See definition* 12.2.7(i)*.)*
(iii) *The rank functions of $\underline{Q}^\sharp$ and* $\mathrm{Coker}\,\varphi$ *are (constructible and) upper semicontinuous.*

Proof. (i): Suppose that $\underline{Q}$ admits a finite chart $\alpha : M_X \to \underline{Q}$. Pick a finite system of generators $\Sigma \subset M$, and for every $S \subset \Sigma$, set :

$$Z_S := \bigcap_{s \in S} D(s) \cap \bigcap_{t \in \Sigma \setminus S} V(t)$$

where, as usual $D(s)$ (resp. $V(s)$) is the open (resp. closed) subset of the points $x \in X$ such that the image $s(x) \in \kappa(x)$ of s is invertible (resp. vanishes). Clearly each Z_S is a constructible subset of X, and their union equals X. Moreover, for every $S \subset \Sigma$, and every τ-point ξ supported on Z_S, the submonoid $N_\xi := \alpha_\xi^{-1}(\mathscr{O}^\times_{X,\xi}) \subset M$ is a face of M (lemma 6.1.20(i)), hence it is the submonoid $\langle S \rangle$ generated by $\Sigma \cap N_\xi = S$ (lemma 6.1.20(ii)). It follows easily that $\underline{Q}^\sharp_{|Z_S} \simeq (M/\langle S \rangle)_{|Z_S}$.

More generally, suppose that $\underline{Q}$ is coherent. We may assume that X is affine. Then, by the foregoing, we may find a finite set Λ and a covering family $(f_\lambda : U_\lambda \to X \mid \lambda \in \Lambda)$ of X_τ, such that U_λ is affine and $\underline{Q}^\sharp_{|U_\lambda}$ is a constructible sheaf of monoids on $(U_\lambda)_\tau$, for every $\lambda \in \Lambda$. Since f_λ is finitely presented, it maps constructible subsets to constructible subsets ([66, Ch.IV, Th.1.8.4]); if $\tau = \mathrm{Zar}$, it follows easily that the restriction of $\underline{Q}^\sharp$ to $f_\lambda(U_\lambda)_\tau$ is constructible, therefore $\underline{Q}^\sharp$ is constructible. For $\tau = \text{ét}$ we remark :

Claim 12.2.22. Let $f : Y \to X$ a surjective morphism of schemes, locally of finite presentation, and $\mathscr{F}$ a sheaf of monoids on $X_{\text{ét}}$. Then $\mathscr{F}$ is constructible if and only if the same holds for $f^*_{\text{ét}}\mathscr{F}$.

Proof of the claim. This can be proved as [10, Exp.IX, Prop.2.8]. ◊

Hence, also for $\tau = \text{ét}$ we see that $\underline{Q}^\sharp$ is constructible. Next, notice that $\operatorname{Coker}\varphi = \operatorname{Coker}\varphi^\sharp$; by the foregoing, $\underline{Q}'^\sharp$ is constructible as well, so the same holds for $\operatorname{Coker}\varphi$.

(ii,iii): Let $x \in X$ be any point, and ξ a τ-point of X localized at x; by theorem 12.1.37(i) we may find a neighborhood $f : U \to X$ of ξ in X_τ and a finite chart $(\omega_P, \omega_{P'}, \vartheta)$ for $\varphi_{|U}$. By claim 12.1.31, we may assume, after replacing U by a smaller neighborhood of ξ, that ω_P and $\omega_{P'}$ are local at the point ξ, in which case $\underline{Q}^\sharp_\xi = P^\sharp$ and $\operatorname{Coker}\varphi_\xi = \operatorname{Coker}\vartheta$. Let $r : X \to \mathbb{N}$ (resp. $r' : U \to \mathbb{N}$) denote the rank function of $\underline{Q}^\sharp$ (resp. of $\underline{Q}^\sharp_{|U}$); then it is clear that $r' = r \circ f$. On the other hand, for every $y \in U$ and every τ-point η of U localized at y, the stalk $\underline{Q}^\sharp_\eta$ is a quotient of $P^\sharp$, hence $r'(y) \leq r(x)$ and $\dim \underline{Q}_\eta \leq \dim \underline{Q}_\xi$. Since f is an open mapping, this shows (ii), and also that the rank function of $\underline{Q}^\sharp$ is upper semicontinuous. Likewise, let s (resp. s') denote the rank function of $\operatorname{Coker}\varphi$ (resp. $\operatorname{Coker}\varphi_{|U}$); then $s' = s \circ f$, and $\operatorname{Coker}\varphi_\eta$ is a quotient of $\operatorname{Coker}\vartheta$ for every τ-point η of U; the latter implies that $s'(y) \leq s(x)$ for every $y \in U$, which shows that s is upper semicontinuous. □

Remark 12.2.23. By lemma 12.2.21(ii), if $\underline{Q}$ is any coherent log structure on a scheme X, then $(X, \underline{Q})_n$ is naturally an open subscheme of X for every $n \in \mathbb{N}$, and even naturally a log scheme, with the log structure inherited via the open immersion in X. Henceforth, for every such n and $\underline{Q}$, the notation $(X, \underline{Q})_n$ will refer to either the underlying open subscheme of X, or to the corresponding open log subscheme of $(X, \underline{Q})$, depending on the context.

Corollary 12.2.24. *Let X be a scheme, $\underline{M}$ a log structure on X_{Zar}, and set*

$$(X_{\text{ét}}, \underline{M}_{\text{ét}}) := \widetilde{u}^*(X_{\text{Zar}}, \underline{M}).$$

Then $\underline{M}$ is integral (resp. coherent, resp. fine, resp. fine and saturated) if and only if the same holds for $\underline{M}_{\text{ét}}$.

Proof. It has already been remarked that $(X_{\text{ét}}, \underline{M}_{\text{ét}})$ is coherent (resp. fine, resp. fine and saturated) whenever the same holds for $(X_{\text{Zar}}, \underline{M})$; furthermore, the proof of proposition 12.2.3(i) shows that the natural map on stalks $\underline{M}_{|\xi|} \to \underline{M}_{\text{ét},\xi}$ is injective for every geometric point ξ of X, therefore $\underline{M}$ is integral whenever the same holds for $\underline{M}_{\text{ét}}$.

Next, we suppose that $\underline{M}_{\text{ét}}$ is coherent, and we wish to show that $\underline{M}$ is coherent.

Let $x \in X$ be any point, ξ a geometric point localized at x. By assumption there exists a finitely generated monoid P', with a morphism $\alpha : P' \to \underline{M}_{\text{ét},\xi}$ inducing an isomorphism :

$$P' \otimes_{\beta^{-1}\underline{M}^\times_{\text{ét},\xi}} \underline{M}^\times_{\text{ét},\xi} \to \underline{M}_{\text{ét},\xi} \simeq \underline{M}_x \otimes_{\underline{M}^\times_x} \mathscr{O}^\times_{X,\xi}.$$

It follows easily that we may find a finitely generated submonoid $Q \subset \underline{M}_x$, such that the image of α lies in $(Q \cdot \underline{M}^\times_x) \otimes_{\underline{M}^\times_x} \mathscr{O}^\times_{X,\xi}$, and therefore the natural map :

$$(Q \cdot \underline{M}^\times_x) \otimes_{\underline{M}^\times_x} \mathscr{O}^\times_{X,\xi} \to \underline{M}_{\text{ét},\xi}$$

is surjective. Then lemma 4.8.31(ii) implies that $Q \cdot \underline{M}^\times_x = \underline{M}_x$, in other words, the induced map $Q \to \underline{M}^\sharp_x = \underline{M}^\sharp_{\text{ét},\xi}$ is surjective. Set

$$P := Q^{\text{gp}} \times_{\underline{M}^{\text{gp}}_{\text{ét},\xi}} \underline{M}_{\text{ét},\xi}.$$

In this situation, proposition 12.1.30 tells us that the induced map $\beta_\xi : P \to \underline{M}_{\text{ét},\xi}$ extends to an isomorphism of log structures $\beta^{\log} : P^{\log}_{U_{\text{ét}}} \to \underline{M}_{\text{ét}|U_{\text{ét}}}$ on some étale neighborhood $U \to X$ of

ξ. On the other hand, it is easily seen that the diagram of monoids :

$$\begin{array}{ccc} \underline{M}_x & \longrightarrow & \underline{M}_x^{\mathrm{gp}} \\ \downarrow & & \downarrow \\ \underline{M}_{\text{ét},\xi} & \longrightarrow & \underline{M}^{\mathrm{gp}}_{\text{ét},\xi} \end{array}$$

is cartesian, therefore β_ξ factors uniquely through a morphism $\beta'_x : P \to \underline{M}_x$. The latter extends to a morphism of log structures $\beta'^{\log} : P^{\log}_{U'_{\mathrm{Zar}}} \to \underline{M}_{|U'_{\mathrm{Zar}}}$ on some (Zariski) open neighborhood U' of x in X (lemma 12.1.18(iv.a),(v)). By inspecting the construction, we find a commutative diagram of monoids :

$$\begin{array}{ccc} (\widetilde{u}^* P^{\log}_{U'_{\mathrm{Zar}}})_\xi & \longrightarrow & P^{\log}_{U_{\text{ét}},\xi} \\ {\scriptstyle (\widetilde{u}^*\beta'^{\log})_\xi}\downarrow & & \downarrow{\scriptstyle \beta^{\log}_\xi} \\ (\widetilde{u}^*\underline{M})_\xi & = & \underline{M}_{\text{ét},\xi} \end{array}$$

(where $\widetilde{u}^*$ is the functor on log structures of (12.2.2)) whose horizontal arrows and right vertical arrow are isomorphisms; it follows that $(\widetilde{u}^*\beta'^{\log})_\xi$ is an isomorphism as well, therefore $\widetilde{u}^*\beta'^{\log}$ restricts to an isomorphism on some smaller étale neighborhood $f : U'' \to U'$ of ξ (lemma 12.1.18(iv.c)). Since f is an open morphism, we deduce that the restriction of $(\widetilde{u}^*\beta'^{\log})_\xi$ is already an isomorphism on $f(U'')_{\text{ét}}$, and $f(U'')$ is a (Zariski) open neighborhood of x in X. Finally, in light of proposition 12.2.3(i), we conclude that the restriction of $\beta'^{\log}$ is an isomorphism on $f(U'')_{\mathrm{Zar}}$, so $\underline{M}$ is coherent, as stated.

Lastly, we suppose that $\underline{M}_{\text{ét}}$ is fine and saturated, and we wish to show that $\underline{M}$ is saturated. However, the assertion can be checked on the stalks, hence let ξ be any geometric point of X; the proof of proposition 12.2.3 shows that the natural map $\underline{M}^\sharp_{|\xi|} \to \underline{M}^\sharp_{\text{ét},\xi}$ is bijective, so the assertion follows from lemma 6.2.9(ii). □

Corollary 12.2.25. *The category* **coh.log** *admits all finite limits. More precisely, the limit (in the category of log structures) of a finite system of coherent log structures, is coherent.*

Proof. Let Λ be a finite category, $\mathscr{X} := ((X_\lambda, \underline{M}_\lambda) \mid \lambda \in \Lambda)$ an inverse system of schemes with coherent log structures indexed by Λ. Denote by Y the limit of the system $(X_\lambda \mid \lambda \in \Lambda)$ of underlying schemes, and by $\pi_\lambda : Y \to X_\lambda$ the natural morphism, for every $\lambda \in \Lambda$. It is easily seen that the limit of $\mathscr{X}$ is naturally isomorphic to the limit of the induced system $\mathscr{Y} := ((Y, \pi^*_\lambda \underline{M}_\lambda) \mid \lambda \in \Lambda)$, and in view of lemma 12.1.18(i), we may therefore replace $\mathscr{X}$ by $\mathscr{Y}$, and assume that $\mathscr{X}$ is a finite inverse system in the category $\mathbf{log}_X$, for some scheme X (especially, the underlying maps of schemes are $\mathbf{1}_X$, for every morphism $\lambda \to \mu$ in Λ).

It suffices then to show that the push-out of two morphisms $g : \underline{N} \to \underline{M}$, $h : \underline{N} \to \underline{M}'$ of coherent log structures on X, is coherent. However, notice that the assertion is local on the site X_τ, hence we may assume that $\underline{N}$ admits a finite chart $Q_X \to \underline{N}$. Then, thanks to theorem 12.1.37(ii), we may further assume that both f and g admit finite charts of the form $Q_X \to P_X$ and respectively $Q_X \to P'_X$, for some finitely generated monoids P and P'. We deduce a natural map $(P \amalg_Q P')_X \xrightarrow{\sim} P_X \amalg_{Q_X} P'_X \to \underline{M} \amalg_{\underline{N}} \underline{M}'$, which is the sought finite chart. □

Lemma 12.2.26. *In the situation of* (12.2.9)*, suppose that X_i is quasi-compact and quasi-separated for every $i \in I$, and that there exist $i \in I$, and a coherent log structure $\underline{N}_i$ on X_i, such that the log structure $\underline{N} := \pi^*_i \underline{N}_i$ on X_τ has a finite chart $\beta : Q_X \to \underline{N}$. Then there exist a morphism $\varphi : j \to i$ in I and a chart $\beta_j : Q_{X_j} \to \underline{N}_j := f^*_\varphi \underline{N}_i$ for $\underline{N}_j$, such that $\pi^*_j \beta_j = \beta$.*

Proof. After replacing I by I/i, we may assume that $\underline{N}_j$ is well defined for every $j \in I$, and i is the final object of I. In this case, notice that $(X, \underline{N})$ is the limit of the cofiltered system of log schemes $((X_j, \underline{N}_j) \mid j \in I)$. We begin with the following :

Claim 12.2.27. In order to prove the lemma, it suffices to show that, for every τ-point ξ of X there exist $j(\xi) \in I$, a neighborhood $U_\xi \to X_{j(\xi)}$ of $\pi_{j(\xi)}(\xi)$ in $X_{j(\xi),\tau}$, and a chart $\beta_{j(\xi)} : Q_{U_\xi} \to \underline{N}_{j(\xi)|U_\xi}$ such that $(\mathbf{1}_{U_\xi} \times_{X_{j(\xi)}} \pi_{j(\xi)})^* \beta_{j(\xi)} = \beta$.

Proof of the claim. Clearly we may assume that U_ξ is an affine scheme, for every τ-point ξ of X. Under the stated assumptions, X is quasi-compact, hence we may find a finite set $\{\xi_1, \dots, \xi_n\}$ of τ-points of X, such that $(U_{\xi_k} \times_{X_{j(\xi_k)}} X \to X \mid k = 1, \dots, n)$ is covering in X_τ. Since I is cofiltered, we may then find $j \in I$ and morphisms $\varphi_k : j \to j(\xi_k)$ for every $k = 1, \dots, n$. After replacing each $\beta_{j(\xi_k)}$ by $f^*_{\varphi_k} \beta_{j(\xi_k)}$, we may assume that $j(\xi_k) = j$ for every $k \leq n$.

In this case, set $\beta_k := \beta_{j(\xi_k)}$, and $U_k := U_{\xi_k}$ for every $k \leq n$; let also $U_{kl} := U_k \times_{X_j} U_l$, $U^\sim_{kl} := U_{kl} \times_{X_j} X$ for every $k, l \leq n$, and denote by $\pi_{kl} : U^\sim_{kl} \to U_{kl}$ the natural projection. Hence, for every $k, l \leq n$ we have a morphism of U_{kl}-monoids :

$$\beta_{kl} := \beta_{k|U_{kl}} : Q_{U_{kl}} \to \underline{N}_{j|U_{kl}}$$

and by construction we have $\pi^*_{kl} \beta_{kl} = \pi^*_{lk} \beta_{lk}$ under the natural identification : $U^\sim_{kl} \xrightarrow{\sim} U^\sim_{lk}$. Notice now that U_{kl} is quasi-compact and quasi-separated for every $k, l \leq n$, hence the natural map

$$\operatorname*{colim}_{i \in I} \Gamma(U_{kl} \times_{X_j} X_i, \underline{N}_i) \to \Gamma(U^\sim_{kl}, \underline{N})$$

is an isomorphism (lemma 12.2.10(ii)). On the other hand, β_{kl} is given by a morphism of monoids $b_{kl} : Q \to \Gamma(U_{kl}, \underline{N}_j)$, and likewise $\pi^*_{kl} \beta_{kl}$ is given by the morphism $Q \to \Gamma(U^\sim_{kl}, \underline{N})$ obtained by composiiton of b_{kl} and the natural map $\Gamma(U_{kl}, \underline{N}_j) \to \Gamma(U^\sim_{kl}, \underline{N})$. By lemma 6.1.7(ii), we may then find a morphism $j' \to j$ in I such that the following holds. Set

$$V_k := U_k \times_{X_j} X_{j'} \qquad V_{kl} := V_k \times_{X_{j'}} V_l \qquad \text{for every } k, l \leq n$$

and let $p_k : V_k \to U_k$ be the projection for every $k \leq n$; let also $\beta'_k := p^*_k \beta_k$, which is a chart $Q_{V_k} \to \underline{N}_{j'|V_k}$ for the restriction of $\underline{N}_{j'}$. Then

$$\beta'_{k|V_{kl}} = \beta'_{l|V_{kl}} \qquad \text{for every } k, l \leq n \tag{12.2.28}$$

under the natural identification $V_{kl} \xrightarrow{\sim} V_{lk}$. By construction, the system of morphisms $(V_k \times_{X_{j'}} X \to X \mid k = 1, \dots, n)$ is covering in X_τ; after replacing j' by a larger index, we may then assume that the system of morphisms $(V_k \to X_{j'} \mid k = 1, \dots, n)$ is covering in $X_{j',\tau}$ ([65, Ch.IV, Th.8.10.5]). In this case, (12.2.28) implies that the local charts β'_k glue to a well defined chart $\beta_{j'} : Q_{X_{j'}} \to \underline{N}_{j'}$, and a direct inspection shows that we have indeed $\pi^*_{j'} \beta_{j'} = \beta$. ◊

Now, denote by $\alpha : Q_X \to \mathscr{O}_X$ the composition of β and the structure map of $\underline{N}$, and let ξ be a τ-point of X; we have a natural isomorphism

$$\underline{N}_\xi = \underline{N}_{i,\pi_i(\xi)} \otimes_{\underline{N}^\times_{i,\pi_i(\xi)}} \mathscr{O}^\times_{X,\xi} \xrightarrow{\sim} \operatorname*{colim}_{j \in I} \underline{N}_{i,\pi_i(\xi)} \otimes_{\underline{N}^\times_{i,\pi_i(\xi)}} \mathscr{O}^\times_{X_j,\pi_j(\xi_j)} \xrightarrow{\sim} \operatorname*{colim}_{j \in I} \underline{N}_{j,\pi_j(\xi)}$$

([66, Ch.IV, Prop.18.8.18(ii)]). It follows that β_ξ and α_ξ factor through morphisms of monoids $\beta_{\xi,j} : Q \to \underline{N}_{j,\pi_j(\xi)}$ and $\alpha_{\xi,j} : Q \to \mathscr{O}_{X_j,\pi_j(\xi)}$ for some $j \in I$ (lemma 6.1.7(ii)), and again we may replace I by I/j, after which we may assume that $\beta_{\xi,j}$ and $\alpha_{\xi,j}$ are defined for every $j \in I$. Then $\alpha_{\xi,j}$ extends to a pre-log structure $\alpha_j : Q_{U_j} \to \mathscr{O}_{U_j}$ on some neighborhood $U_j \to X_j$ of $\pi_j(\xi)$ in $X_{j,\tau}$ (lemma 12.1.18(v)), and we may also assume that $\beta_{\xi,j}$ extends to a morphism of pre-log structures $\beta_j : (Q_{U_j}, \alpha_j) \to \underline{N}_{j|U_j}$ (lemma 12.1.18(iv.a)). Notice as well that

$$\underline{N}^\sharp_{j,\xi} \simeq \underline{N}^\sharp_\xi \quad \text{and} \quad \beta^{-1}_{\xi,j} \underline{N}^\times_{j,\pi_j(\xi)} = \beta^{-1}_\xi \underline{N}^\times_\xi \qquad \text{for every } j \in I$$

and since β_ξ induces an isomorphism $Q/\beta^{-1}_\xi \underline{N}^\times_\xi \xrightarrow{\sim} \underline{N}^\sharp_\xi$, we deduce that $\beta_{j,\xi}$ (which is the same as $\beta_{\xi,j}$) induces an isomorphism $Q/\alpha^{-1}_{j,\xi} \mathscr{O}^\times_{X_j,\pi_j(\xi)} \xrightarrow{\sim} \underline{N}^\sharp_{j,\xi}$ for every $j \in I$. In turn, it then follows from lemma 12.1.4 that $\beta_{j,\xi}$ induces an isomorphism $(Q_{U_j}, \alpha_j)^{\log}_{\pi_j(\xi)} \xrightarrow{\sim} \underline{N}_{j,\pi_j(\xi)}$.

Next, by lemma 12.1.18(iv.b,c) we may find, for every $j \in I$, a neighborhood $U'_j \to U_j$ of ξ in X_τ, such that the restriction $(Q_{U'_j}, \alpha_{j|U'_j}) \to \underline{N}_{j|U'_j}$ of β_j is a chart for $\underline{N}_{j|U'_j}$.

By construction, the morphism $((\mathbf{1}_{U_j} \times_{X_j} \pi_j)^*\beta_j)_\xi : Q \to \underline{N}_\xi$ is the same as β_ξ, so by lemma 12.1.18(iv.b) we may find a neighborhood $V_j \to U'_j \times_{X_j} X$ of ξ in X_τ, such that

$$((\mathbf{1}_{U_j} \times_{X_j} \pi_j)^*\beta_j)_{|V_j} = \beta_{|V_j} \qquad \text{and} \qquad ((\mathbf{1}_{U_j} \times_{X_j} \pi_j)^*\alpha_j)_{|V_j} = \alpha_{|V_j}.$$

Claim 12.2.29. In the situation of (12.2.9), let $Y \to X$ be an object of the site X_τ, with Y quasi-compact and quasi-separated. We have :

- (i) There exist $i \in I$, an object $Y_i \to X_i$ of $X_{i,\tau}$, and an isomorphism of X-schemes $Y \xrightarrow{\sim} Y_i \times_{X_i} X$.
- (ii) Moreover, if $Y \to X$ is covering in X_τ, then we may find $i \in I$ and $Y_i \to X_i$ as in (i), which is covering in $X_{i,\tau}$.

Proof of the claim. (i) is obtained by combining [65, Ch.IV, Th.8.8.2(ii)] and [66, Ch.IV, Prop.17.7.8(ii)] (and [65, Ch.IV, Cor.8.6.4] if τ = Zar). Assertion (ii) follows from (i) and [65, Ch.IV, Th.8.10.5]. ◊

By claim 12.2.29(i), we may assume that $V_j = U''_j \times_{X_j} X$ for some neighborhood $U''_j \to U'_j$ of $\pi_j(\xi)$ in $X_{j,\tau}$. To conclude, it suffices to invoke claim 12.2.27. □

Proposition 12.2.30. *In the situation of* (12.2.9)*, suppose that X_i is quasi-compact and quasi-separated for every $i \in I$. Then the natural functor :*

$$\text{2-}\operatorname*{colim}_{I} \mathbf{coh.log}_{X_i} \to \mathbf{coh.log}_X \tag{12.2.31}$$

is an equivalence.

Proof. To begin with, we show :

Claim 12.2.32. The functor (12.2.31) is faithful. Namely, for a given $i \in I$, let $\underline{M}_i$ and $\underline{N}_i$ be two coherent log structures on X_i, and $f_i, g_i : \underline{M}_i \to \underline{N}_i$ two morphisms, such that $\pi_i^* f_i$ agrees with $\pi_i^* g_i$. Then there exists a morphism $\psi : j \to i$ in I such that $f_\psi^* f_i = f_\psi^* g_i$.

Proof of the claim. Set $\underline{M} := \pi_i^*\underline{M}_i$, and define likewise the coherent log structure $\underline{N}$ on X. For any τ-point ξ of X, pick a neighborhood $U_\xi \to X_i$ of $\pi_i(\xi)$ in X_i, and a finite chart $\beta : P_{U_\xi} \to \underline{M}_{i|U_\xi}$ for the restriction of $\underline{M}_i$. The morphisms $f_{i|U_\xi}$ and $g_{i|U_\xi}$ are determined by the induced maps $\varphi := \Gamma(U_\xi, f_i) \circ \beta$ and $\gamma := \Gamma(U_\xi, g_i) \circ \beta$, and the assumption means that the composition of φ and the natural map $\Gamma(U_\xi, \underline{N}_i) \to \Gamma(U_\xi \times_{X_i} X, \underline{N})$ equals the composition of γ with the same map.

It then follows from lemmata 12.2.10(ii) and 6.1.7(ii) that there exists a morphism $\psi : i(\xi) \to i$ in I such that the composition of φ with the natural map $\Gamma(U_\xi, \underline{N}_i) \to \Gamma(U_\xi \times_{X_i} X_{i(\xi)}, f_\psi^*\underline{N})$ equals the composition of γ with the same map; in other words, if we set $U'_\xi := U_\xi \times_{X_i} X_{i(\xi)}$, we have $f_\psi^* f_{i|U'_\xi} = f_\psi^* g_{i|U'_\xi}$. Next, since X is quasi-compact, we may find finitely many τ-points $\xi_1, \dots, \xi_n$ such that the family $(U'_{\xi_k} \times_{X_{i(\xi_k)}} X \to X)$ is covering in X_τ. Then, by [65, Ch.IV, Th.8.10.5] we may find $j \in I$ and morphisms $\psi_k : j \to i(\xi_k)$ in I, for $k = 1, \dots, n$, such that the induced family $(U''_k := U'_{\xi_k} \times_{X_{i(\xi_k)}} X_j \to X_j)$ is covering in $X_{j,\tau}$. By construction we have

$$f^*_{\psi_k \circ \psi} f_{i|U''_k} = f^*_{\psi_k \circ \psi} g_{i|U''_k} \qquad \text{for } k = 1, \dots, n$$

therefore $f^*_{\psi_k \circ \psi} f_i = f^*_{\psi_k \circ \psi} g_i$, as required. ◊

Claim 12.2.33. The functor (12.2.31) is full. Namely, let $i \in I$ and $\underline{M}_i$, $\underline{N}_i$ as in claim 12.2.32, and suppose that $f : \pi_i^*\underline{M}_i \to \pi_i^*\underline{N}_i$ is a given morphism of log structures; then there exist a morphism $\psi : j \to i$ in I, and a morphism of log structures $f_j : f_\psi^*\underline{M}_i \to f_\psi^*\underline{N}_i$ such that $\pi_j^* f_j = f$.

Proof of the claim. Indeed, by theorem 12.1.37(i) we may find a covering family $(U_\lambda \to X \mid \lambda \in \Lambda)$ in X_τ, and for each $\lambda \in \Lambda$ a finite chart

$$\beta_\lambda : P_{\lambda,U_\lambda} \to \underline{M}_{|U_\lambda} \quad \gamma_\lambda : Q_{\lambda,U_\lambda} \to \underline{N}_{|U_\lambda} \quad \vartheta_\lambda : P_\lambda \to Q_\lambda$$

for the restriction $f_{|U_\lambda}$. Clearly we may assume that each U_λ is affine, and since X is quasi-compact, we may assume as well that Λ is a finite set; in this case, claim 12.2.29 implies that there exist a morphism $j \to i$ in I, a covering family $(U_{j,\lambda} \to X_j \mid \lambda \in \Lambda)$, and isomorphism of X-schemes $U_\lambda \stackrel{\sim}{\to} U_{j,\lambda} \times_{X_j} X$ for every $\lambda \in \Lambda$. Next, lemma 12.2.26 says that, after replacing j by some larger index, we may assume that for every $\lambda \in \Lambda$ there exist charts

$$\beta_{j,\lambda} : P_{\lambda,U_{j,\lambda}} \to \underline{M}_j := f_\psi^* \underline{M}_i \qquad \text{and} \qquad \gamma_{j,\lambda} : Q_{\lambda,U_{j,\lambda}} \to \underline{N}_j := f_\psi^* \underline{N}_i$$

with $\pi_j^* \beta_{j,\lambda} = \beta_\lambda$ and $\pi_j^* \gamma_{j,\lambda} = \gamma_\lambda$. Set $f_{j,\lambda} := \vartheta^{\log}_{\lambda,U_{j,\lambda}} : \underline{M}_j \to \underline{N}_j$; by construction we have :

$$(\mathbf{1}_{U_{j,\lambda}} \times_{X_j} \pi_j)^* f_{j,\lambda} = f_{|U_\lambda} \qquad \text{for every } \lambda \in \Lambda.$$

Next, for every $\lambda, \mu \in \Lambda$, let $U_{j,\lambda\mu} := U_{j,\lambda} \times_{X_j} U_{j,\mu}$; we deduce, for every $\lambda, \mu \in \Lambda$, two morphisms of log structures $f_{j,\lambda|U_{j,\lambda\mu}}, f_{j,\mu|U_{\lambda\mu}} : \underline{M}_{j|U_{\lambda\mu}} \to \underline{N}_{j|U_{\lambda\mu}}$, which agree after pull back to $U_{j,\lambda\mu} \times_{X_j} X$. By applying claim 12.2.32 to the cofiltered system of schemes $(U_{j,\lambda\mu} \times_{X_j} X_{j'} \mid j' \in I/j)$, we may then achieve – after replacing j by some larger index – that $f_{j,\lambda|U_{j,\lambda\mu}} = f_{j,\mu|U_{\lambda\mu}}$, in which case the system $(f_{j,\lambda} \mid \lambda \in \Lambda)$ glues to a well defined morphism f_j as sought. ♢

Finally, let us show that (12.2.31) is essentially surjective. Indeed, let $\underline{M}$ be a coherent log structure on X; let us pick a covering family $\mathscr{U} := (U_\lambda \to X \mid \lambda \in \Lambda)$ and finite charts $\beta_\lambda : P_{\lambda,U_\lambda} \to \underline{M}_{|U_\lambda}$ for every $\lambda \in \Lambda$. As in the foregoing, we may assume that each U_λ is affine, and Λ is a finite set, in which case, according to claim 12.2.29(ii) we may find $i \in I$ and a covering family $(U_{i,\lambda} \to X_i \mid \lambda \in \Lambda)$ with isomorphisms of X-schemes $U_{i,\lambda} \times_{X_i} X \stackrel{\sim}{\to} U_\lambda$ for every $\lambda \in \Lambda$; for every $j \in I/i$ and every $\lambda \in \Lambda$, let us set $U_{j,\lambda} := U_{i,\lambda} \times_{X_i} X_j$. The composition $\alpha_\lambda : P_{\lambda,U_\lambda} \to \mathscr{O}_{U_\lambda}$ of β_λ and the structure map of $\underline{M}_{|U_\lambda}$ is determined by a morphism of monoids

$$P_\lambda \to \Gamma(U_\lambda, \mathscr{O}_{U_\lambda}) = \operatorname*{colim}_{i \in I/i} \Gamma(U_{j,\lambda}, \mathscr{O}_{U_{j,\lambda}}).$$

Then, as usual, lemma 6.1.7(ii) implies that there exists $j \in I/i$ such that α_λ descends to a pre-log structure $P_{\lambda,U_{j,\lambda}} \to \mathscr{O}_{U_{j,\lambda}}$ on $U_{j,\lambda}$, whose associated log structure we denote by $\underline{M}_{j,\lambda}$. For every $\lambda, \mu \in \Lambda$, let $U_{j,\lambda\mu} := U_{j,\lambda} \times_{X_j} U_{j,\mu}$; by construction we have isomorphisms

$$(12.2.34) \qquad (\mathbf{1}_{U_{j,\lambda\mu}} \times_{X_j} \pi_j)^* \underline{M}_{j,\lambda|U_{j,\lambda\mu}} \stackrel{\sim}{\to} (\mathbf{1}_{U_{j,\mu\lambda}} \times_{X_j} \pi_j)^* \underline{M}_{j,\mu|U_{j,\mu\lambda}} \qquad \text{for every } \lambda, \mu \in \Lambda.$$

By applying claim 12.2.33 to the cofiltered system $(U_{j,\lambda\mu} \times_{X_j} X_{j'} \mid j' \in I/j)$, we can then obtain – after replacing j by a larger index – isomorphisms $\omega_{\lambda\mu} : \underline{M}_{j,\lambda|U_{j,\lambda\mu}} \stackrel{\sim}{\to} M_{j,\mu|U_{j,\mu\lambda}}$ for every $\lambda, \mu \in \Lambda$, whose pull-back to $U_{j,\lambda\mu} \times_{X_j} X$ are the isomorphisms (12.2.34). Lastly, in view of claim 12.2.32, we may achieve – after further replacement of j by a larger index – that the system $\mathscr{D} := (\underline{M}_{j,\lambda}, \omega_{\lambda\mu} \mid \lambda, \mu \in \Lambda)$ is a descent datum for the fibration F of (12.2.1), whose pull-back to X is isomorphic to the natural descent datum for $\underline{M}$, associated to the covering family $\mathscr{U}$. Then $\mathscr{D}$ glues to a log structure $\underline{M}_j$, such that $\pi_j^* \underline{M}_j \simeq \underline{M}$. □

Corollary 12.2.35. *In the situation of* (10.1.8)*, suppose that* X_λ *is quasi-compact for every* $\lambda \in \mathrm{Ob}(\Lambda)$*, and that we have a morphism of log schemes with coherent log structures*

$$(g, \log g) : (Y, \underline{N}) \to (X, \underline{M}).$$

Then there exist $\lambda \in \Lambda$*, and a morphism of log schemes with coherent log structures*

$$(g_\lambda, \log g_\lambda) : (Y_\lambda, \underline{N}_\lambda) \to (X_\lambda, \underline{M}_\lambda) \qquad \textit{such that} \qquad \log g = \psi_\lambda^* \log g_\lambda.$$

Proof. The assertion is an immediate consequence of proposition 12.2.30. □

Corollary 12.2.36. *In the situation of* (10.1.8)*, let* $0 \in \mathrm{Ob}(\Lambda)$ *be an index such that* $\underline{N}_0$ *and* $\underline{M}_0$ *are coherent log structures on* Y_0*, and respectively* X_0*, and* $(g_0, \log g_0) : (Y_0, \underline{N}_0) \to (X_0, \underline{M}_0)$ *a morphism of log schemes. Suppose also that* X_λ *is quasi-compact (as well as quasi-separated) for every* $\lambda \in \mathrm{Ob}(\Lambda)$*; then we have :*

(i) *If the morphism of log schemes*

$$(g, \psi_0^* \log g_0) : Y \times_{Y_0} (Y_0, \underline{N}_0) \to X \times_{X_0} (X_0, \underline{M}_0)$$

admits a chart $(\omega, \omega', \vartheta : P \to Q)$*, there exists a morphism* $u : \lambda \to 0$ *in* Λ *such that the morphism of log schemes*

$$(g_\lambda, \psi_u^* \log g_0) : Y_\lambda \times_{Y_0} (Y_0, \underline{N}_0) \to X_\lambda \times_{X_0} (X_0, \underline{M}_0)$$

admits a chart $(\omega_\lambda, \omega'_\lambda, \vartheta)$.

(ii) *If* $(g, \psi_0^* \log g_0)$ *is a log flat (resp. saturated) morphism of fine log schemes, there exists a morphism* $u : \lambda \to 0$ *in* Λ *such that* $(g_\lambda, \psi_u^* \log g_0)$ *is a log flat (resp. saturated) morphism of fine log schemes.*

Proof. (i): Under the current assumptions, X and Y are quasi-compact. In view of lemma 12.2.26, we may then find a morphism $v : \mu \to 0$, such that ω and ω' descend to charts $\omega_v : P_{X_\mu} \to \varphi_v^* \underline{M}_0$ and $\omega'_v : Q_{Y_\mu} \to \psi_v^* \underline{N}_0$. We deduce two morphisms of pre-log structures $P_{Y_\mu} \to \psi_v^* \underline{N}_0$, namely

$$\beta_1 := \psi_v^*(\log g_0) \circ g_\mu^* \omega_v \qquad \text{and} \qquad \beta_2 := \omega'_v \circ \vartheta_{Y_\mu}$$

and by construction we have $\psi_\mu^* \beta_1^{\log} = \psi_\mu^* \beta_2^{\log}$. By proposition 12.2.30 it follows that there exists $w : \lambda \to \mu$ such that $\psi_w^* \beta_1^{\log} = \psi_w^* \beta_2^{\log}$. The latter means that $(\varphi_w^* \omega_v, \psi_w^* \omega'_v, \vartheta)$ is a chart for the morphism of log schemes $(g_\lambda, \psi_{v \circ w}^* \log g_0) : (Y_\lambda, \psi_{v \circ w}^* \underline{N}_0) \to (X_\lambda, \varphi_{v \circ w}^* \underline{M}_0)$, *i.e.* the claim holds with $u := v \circ w$.

(ii): Suppose therefore that $(g, \psi_0^* \log g_0)$ is a log flat (resp.saturated) morphism, and let $\mathscr{U} := (U_i \to X \mid i \in I)$ be a covering family for X_τ, such that $U_i \times_{X_0} (X_0, \underline{M}_0)$ admits a finite (resp. fine) chart, and U_i is affine for every $i \in I$. Since X is quasi-compact, we may assume that I is a finite set, and then there exists $\lambda \in \Lambda$ such that $\mathscr{U}$ descends to a covering family $\mathscr{U}_\lambda := (U_{\lambda,i} \to X_\lambda \mid i \in I)$ for $X_{\lambda,\tau}$ (claim 12.2.29(ii)). After replacing Λ by Λ/λ, we may assume that $\lambda = 0$, in which case we set $U_{\lambda,i} := U_{0,i} \times_{X_0} X_\lambda$ for every object λ of Λ, and every $i \in I$. Clearly, it suffices to show that there exists $u : \lambda \to 0$ such that $U_{\lambda,i} \times_{X_\lambda} (g_\lambda, \psi_u^* \log g_0)$ is flat (resp. saturated) for every $i \in I$. Set $Y'_{\lambda,i} := Y_\lambda \times_{X_\lambda} U_{\lambda,i}$ for every $\lambda \in \Lambda$; we may then replace the cofiltered system $\underline{X}$ and $\underline{Y}$, by respectively $(U_{\lambda,i} \mid \lambda \in \Lambda)$ and $(Y'_{\lambda,i} \mid \lambda \in \Lambda)$, which allows to assume from start, that $X \times_{X_0} (X_0, \underline{M}_0)$ admits a finite (resp. fine) chart. In this case, lemma 12.2.26 allows to further reduce to the case where $\underline{M}_0$ admits a finite (resp. fine) chart.

Then, by theorem 12.1.37(iii), we may find a covering family $\mathscr{V} := (V_j \to Y \mid j \in J)$ for Y_τ, consisting of finitely many affine schemes V_j, and for every $j \in J$, a flat (resp. saturated) and fine chart for the induced morphism $V_j \times_{Y_0} (Y_0, \underline{N}_0) \to X \times_{X_0} (X_0, \underline{M}_0)$. As in the foregoing, after replacing Λ by some category Λ/λ, we may assume that $\mathscr{V}$ descends to a covering family $\mathscr{V}_0 := (V_{0,j} \to Y_0 \mid j \in J)$ for $Y_{0,\tau}$, in which case we set $V_{\lambda,j} := V_{0,j} \times_{Y_0} Y_\lambda$ for every $\lambda \in \Lambda$. Clearly, it suffices to show that there exists $\lambda \in \Lambda$ such that the induced morphism $V_{\lambda,j} \times_{Y_0} (Y_0, \underline{N}_0) \to X_\lambda \times_{X_0} (X_0, \underline{M}_0)$ is log flat (resp. saturated). Thus, we may replace $\underline{Y}$ by the cofiltered system $(V_{\lambda,j} \mid \lambda \in \Lambda)$, which allows to assume that $(g, \psi_0^* \log g_0)$ admits a flat (resp. saturated) and fine chart. In this case, the assertion follows from (i). □

Proposition 12.2.37. *The inclusion functors :*

$$\mathbf{qf.log} \to \mathbf{qcoh.log} \qquad \mathbf{qfs.log} \to \mathbf{qf.log}$$

admit right adjoints :

$$\mathbf{qcoh}.\mathbf{log} \to \mathbf{qf}.\mathbf{log} \ : \ (X,\underline{M}) \mapsto (X,\underline{M})^{\mathrm{qf}} \qquad \mathbf{qf}.\mathbf{log} \to \mathbf{qfs}.\mathbf{log} \ : \ (X,\underline{M}) \mapsto (X,\underline{M})^{\mathrm{qfs}}.$$

Proof. Let $(X,\underline{M})$ be a scheme with quasi-coherent (resp. quasi-fine) log structure. We need to construct a morphism of log schemes

$$\varphi : (X,\underline{M})^{\mathrm{qf}} \to (X,\underline{M}) \qquad (\text{resp. } \varphi : (X,\underline{M})^{\mathrm{qfs}} \to (X,\underline{M}))$$

such that $(X,\underline{M})^{\mathrm{qf}}$ (resp. $(X,\underline{M})^{\mathrm{qfs}}$) is a quasi-fine (resp. qfs) log scheme, and the following holds. Every morphism of log schemes $\psi : (Y,\underline{N}) \to (X,\underline{M})$ with $(Y,\underline{N})$ quasi-fine (resp. qfs), factors uniquely through φ. To this aim, suppose first that $\underline{M}$ admits a chart (resp. a quasi-fine chart) $\alpha : P_X \to \underline{M}$. By lemma 12.2.18(i), α determines an isomorphism

$$(X,\underline{M}) \stackrel{\sim}{\to} \mathrm{Spec}(\mathbb{Z},P) \times_{\mathrm{Spec}\,\mathbb{Z}[P]} X.$$

Since $\underline{N}$ is integral (resp. and saturated), the morphism $(Y,\underline{N}) \to \mathrm{Spec}(\mathbb{Z},P)$ induced by ψ factors uniquely through $\mathrm{Spec}(\mathbb{Z},P^{\mathrm{int}})$ (resp. $\mathrm{Spec}(\mathbb{Z},P^{\mathrm{sat}})$) (lemma 12.2.18(ii)). Taking into account lemma 12.1.18(iii), it follows easily that we may take

$$(X,\underline{M})^{\mathrm{qf}} := \mathrm{Spec}(\mathbb{Z},P^{\mathrm{int}}) \times_{\mathbb{Z}[P]} X \qquad (X,\underline{M})^{\mathrm{qfs}} := \mathrm{Spec}(\mathbb{Z},P^{\mathrm{sat}}) \times_{\mathbb{Z}[P]} X$$

Next, notice that the universal property of $(X',\underline{M}') := (X,\underline{M})^{\mathrm{qf}}$ (resp. of $(X',\underline{M}') := (X,\underline{M})^{\mathrm{qfs}}$) is local on X_τ : namely, suppose that $(X',\underline{M}')$ has already been found, and let $U \to X$ be an object of X_τ, with a morphism $(Y,\underline{N}) \to (U,\underline{M}_{|U})$ from a quasi-fine (resp. qfs) log scheme; there follows a unique morphism

$$(Y,\underline{N}) \to (U,\underline{M}_{|U}) \times_{(X,\underline{M})} (X',\underline{M}') \stackrel{\sim}{\to} U \times_X (X',\underline{M}')$$

(notation of (12.2.6)). Thus $(U,\underline{M}_{|U})^{\mathrm{qf}} \simeq U \times_X (X,\underline{M})^{\mathrm{qf}}$ (resp. $(U,\underline{M}_{|U})^{\mathrm{qfs}} \simeq U \times_X (X,\underline{M})^{\mathrm{qfs}}$,) since the latter is a quasi-fine (resp. qfs) log scheme. Therefore, for a general quasi-coherent (resp. quasi-fine) log structure $\underline{M}$, choose a covering family $(U_\lambda \to X \mid \lambda \in \Lambda)$ such that $(U_\lambda,\underline{M}_{|U_\lambda})$ admits a chart for every $\lambda \in \Lambda$; it follows that the family $\mathscr{U} := ((U_\lambda,\underline{M}_{|U_\lambda})^{\mathrm{qf}} \mid \lambda \in \Lambda)$, together with the natural isomorphisms :

$$U_\mu \times_X (U_\lambda,\underline{M}_{|U_\lambda})^{\mathrm{qf}} \simeq U_\lambda \times_X (U_\mu,\underline{M}_{|U_\mu})^{\mathrm{qf}} \qquad \text{for every } \lambda,\mu \in \Lambda$$

is a descent datum for the fibred category over X_τ, whose fibre over any object $U \to X$ is the category of affine U-schemes endowed with a log structure (resp. likewise for the family $\mathscr{U} := ((U_\lambda,\underline{M}_{|U_\lambda})^{\mathrm{qfs}} \mid \lambda \in \Lambda)$). Using faithfully flat descent ([82, Exp.VIII, Th.2.1]), one sees that $\mathscr{U}$ comes from a quasi-fine (resp. qfs) log scheme which enjoys the sought universal property. □

Remark 12.2.38. (i) By inspecting the proof of proposition 12.2.37, we see that the quasi-fine log scheme associated to a coherent log scheme, is actually fine, and the qfs log scheme associated to a fine log scheme, is a fs log scheme (one applies corollary 6.4.1(i)). Hence we obtain functors

$$\mathbf{coh}.\mathbf{log} \to \mathbf{f}.\mathbf{log} \ : \ (X,\underline{M}) \mapsto (X,\underline{M})^{\mathrm{f}} \qquad \mathbf{f}.\mathbf{log} \to \mathbf{fs}.\mathbf{log} \ : \ (X,\underline{M}) \mapsto (X,\underline{M})^{\mathrm{fs}}$$

which are right adjoint to the inclusion functors $\mathbf{f}.\mathbf{log} \to \mathbf{coh}.\mathbf{log}$ and $\mathbf{fs}.\mathbf{log} \to \mathbf{f}.\mathbf{log}$.

(ii) Notice as well that, for every log scheme $(X,\underline{M})$ with quasi-coherent (resp. fine) log structure, the morphism of schemes underlying the counit of adjunction $(X,\underline{M})^{\mathrm{qf}} \to (X,\underline{M})$ (resp. $(X,\underline{M})^{\mathrm{fs}} \to (X,\underline{M})$) is a closed immersion (resp. is finite).

(iii) Furthermore, let $f : Y \to X$ be any morphism of schemes; the proof of proposition 12.2.37 also yields a natural isomorphism of $(Y,f^*\underline{M})$-schemes :

$$(Y,f^*\underline{M})^{\mathrm{qf}} \stackrel{\sim}{\to} Y \times_X (X,\underline{M})^{\mathrm{qf}} \qquad (\text{resp. } (Y,f^*\underline{M})^{\mathrm{qfs}} \stackrel{\sim}{\to} Y \times_X (X,\underline{M})^{\mathrm{qfs}}).$$

(iv) Let $(X, \underline{M})$ be a quasi-fine log scheme, and suppose that X is a normal, irreducible scheme, and $(X, \underline{M})_{\rm tr}$ is a dense subset of X. Denote by $X^{\rm qfs}$ the scheme underlying $(X, \underline{M})^{\rm qfs}$; then we claim that the projection $X^{\rm qfs} \to X$ (underlying the counit of adjunction) admits a natural section :

$$\sigma_X : X \to X^{\rm qfs}.$$

The naturality means that if $f : (X, \underline{M}) \to (Y, \underline{N})$ is any morphism of quasi-fine log schemes, where Y is also normal and irreducible, and $(Y, \underline{N})_{\rm tr}$ is dense in Y, then the induced diagram of schemes :

$$\begin{array}{ccc} X & \xrightarrow{\sigma_X} & X^{\rm qfs} \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f^{\rm qfs}} \\ Y & \xrightarrow{\sigma_Y} & Y^{\rm qfs} \end{array} \qquad (12.2.39)$$

commutes, and therefore it is cartesian, by virtue of (iii). Indeed, suppose first that X is affine, say $X = \operatorname{Spec} A$ for some normal domain A, and $\underline{M}$ admits an integral chart, given by a morphism $\beta : P \to A$, for some integral monoid P; we have to exhibit a ring homomorphism $P^{\rm sat} \otimes_P A \to A$, whose composition with the natural map $A \to P^{\rm sat} \otimes_P A$ is the identity of A. The latter is the same as the datum of a morphism of monoids $P^{\rm sat} \to A$ whose restriction to P agrees with β. However, since the trivial locus of $\underline{M}$ is dense in X, the image of P in A does not contain 0, hence β extends to a group homomorphism $\beta^{\rm gp} : P^{\rm gp} \to \operatorname{Frac}(A)^\times$; since A is integrally closed in $\operatorname{Frac}(A)$, we have $\beta^{\rm gp}(P^{\rm sat}) \subset A$, as required. Next, suppose that $U \to X$ is an object of X_τ, with U also affine and irreducible; then U is normal and the trivial locus of $(U, \underline{M}_{|U})$ is dense in U. Thus, the foregoing applies to $(U, \underline{M}_{|U})$ as well, and by inspecting the constructions we deduce a natural identification :

$$\sigma_U = \mathbf{1}_U \times_X \sigma_X.$$

Lastly, for a general $(X, \underline{M})$, we can find a covering family $(U_\lambda \to X \mid \lambda \to \Lambda)$ in X_τ, such that U_λ is affine, and $(U_\lambda, \underline{M}_{|U_\lambda})$ admits an integral chart for every $\lambda \in \Lambda$; proceeding as above, we obtain a system of morphisms $(\sigma_\lambda : U_\lambda \to U^{\rm qfs} \mid \lambda \in \Lambda)$, as well as natural identifications :

$$\mathbf{1}_{U_\mu} \times_X \sigma_\lambda = \mathbf{1}_{U_\lambda} \times_X \sigma_\mu \qquad \text{for every } \lambda, \mu \in \Lambda.$$

In other words, we have defined a descent datum for the category fibred over X_τ, whose fibre over any object $U \to X$ is the category of all morphisms of schemes $U \to U^{\rm qfs}$. By invoking faithfully flat descent ([82, Exp.VIII, Th.2.1]), we see that this descent datum yields a morphism $\sigma_X : X \to X^{\rm qfs}$ such that $\mathbf{1}_{U_\lambda} \times_X \sigma_X = \sigma_\lambda$ for every $\lambda \in \Lambda$. The verification that σ_X is a section of the projection $X^{\rm qfs} \to X$, and that (12.2.39) commutes, can be carried out locally on X_τ, in which case we can assume that $\underline{M}$ admits a chart as above, and one can check explicitly these assertions, by inspecting the constructions.

12.3. **Logarithmic differentials and smooth morphisms.** In this section we introduce the logarithmic version of the usual sheaves of relative differentials, and we study some special classes of morphisms of log schemes.

Definition 12.3.1. Let $(X, \underline{M} \stackrel{\alpha}{\to} \mathscr{O}_X)$ and $(Y, \underline{N} \stackrel{\beta}{\to} \mathscr{O}_Y)$ be two schemes with pre-log structures, and $f : (X, \underline{M}) \to (Y, \underline{N})$ a morphism of schemes with pre-log structures. Let also $\mathscr{F}$ be an $\mathscr{O}_X$-module. An *f-linear derivation of $\underline{M}$ with values in $\mathscr{F}$* is a pair $(\partial, \log \partial)$ consisting of maps of sheaves :

$$\partial : \mathscr{O}_X \to \mathscr{F} \qquad \log \partial : \log \underline{M} \to \mathscr{F}$$

such that :

- ∂ is a derivation (in the usual sense).
- $\log \partial$ is a morphism of sheaves of (additive) monoids on X_τ.

- $\partial \circ f^\natural = 0$ and $\log \partial \circ \log f = 0$.
- $\partial \circ \alpha(m) = \alpha(m) \cdot \log \partial(m)$ for every object U of X_τ, and every $m \in \underline{M}(U)$.

The set of all f-linear derivations with values in f shall be denoted by :

$$\mathrm{Der}_{(Y,\underline{N})}((X, \underline{M}), \mathscr{F}).$$

The f-linear derivations shall also be called $(Y, \underline{N})$-*linear derivations*, when there is no danger of ambiguity.

12.3.2. The set $\mathrm{Der}_{(Y,\underline{N})}((X, \underline{M}), \mathscr{F})$ is clearly functorial in $\mathscr{F}$, and moreover, for any object U of X_τ, any $s \in \mathscr{O}_X(U)$, and any f-linear derivation $(\partial, \log \partial)$, the restriction $(s\cdot\partial_{|U}, s\cdot\log \partial_{|U})$ is an element of $\mathrm{Der}_{(Y,\underline{N})}((U, \underline{M}_{|U}), \mathscr{F})$, hence the rule $U \mapsto \mathrm{Der}_{(Y,\underline{N})}((U, \underline{M}_{|U}), \mathscr{F})$ defines an $\mathscr{O}_X$-module :

$$\mathscr{D}er_{(Y,\underline{N})}((X, \underline{M}), \mathscr{F}).$$

In case $\underline{M} = \mathscr{O}_X^\times$ and $\underline{N} = \mathscr{O}_Y^\times$ are the trivial log structures, the f-linear derivations of $\underline{M}$ are the same as the usual f-linear derivations, *i.e.* the natural map

$$\mathscr{D}er_{(Y,\mathscr{O}_Y^\times)}((X, \mathscr{O}_X^\times), \mathscr{F}) \to \mathscr{D}er_Y(X, \mathscr{F}) \tag{12.3.3}$$

is an isomorphism. In the category of usual schemes, the functor of derivations is represented by the module of relative differentials. This construction extends to the category of schemes with pre-log structures. Namely, let us make the following :

Definition 12.3.4. Let $(X, \underline{M} \xrightarrow{\alpha} \mathscr{O}_X)$ and $(Y, \underline{N} \xrightarrow{\beta} \mathscr{O}_Y)$ be two schemes with pre-log structures, and $f : (X, \underline{M}) \to (Y, \underline{N})$ a morphism of schemes with pre-log structures. The *sheaf of logarithmic differentials* of f is the $\mathscr{O}_X$-module :

$$\Omega^1_{X/Y}(\log \underline{M}/\underline{N}) := (\Omega^1_{X/Y} \oplus (\mathscr{O}_X \otimes_{\mathbb{Z}} \log \underline{M}^{\mathrm{gp}}))/R$$

where R is the $\mathscr{O}_X$-submodule generated locally on X_τ by local sections of the form :

- $(d\alpha(a), -\alpha(a) \otimes \log a)$ with $a \in \underline{M}(U)$
- $(0, 1 \otimes \log a)$ with $a \in \mathrm{Im}((f^{-1}\underline{N})(U) \to \underline{M}(U))$

where U ranges over all the objects of X_τ (here we use the notation of (6.1)). For arbitrary $a \in \underline{M}(U)$, the class of $(0, 1 \otimes \log a)$ in $\Omega^1_{X/Y}(\log \underline{M}/\underline{N})$ shall be denoted by $d \log a$.

12.3.5. It is easy to verify that $\Omega^1_{X/Y}(\log \underline{M}/\underline{N})$ represents the functor

$$\mathscr{F} \mapsto \mathrm{Der}_{(Y,\underline{N})}((X, \underline{M}), \mathscr{F})$$

on $\mathscr{O}_X$-modules. Consequently, (12.3.3) translates as a natural isomorphism of $\mathscr{O}_X$-modules :

$$\Omega^1_{X/Y} \xrightarrow{\sim} \Omega^1_{X/Y}(\log \mathscr{O}_X^\times/\mathscr{O}_Y^\times). \tag{12.3.6}$$

Furthermore, let us fix a scheme with pre-log structure $(S, \underline{N})$, and define the category :

$$\mathbf{pre\text{-}log}/(S, \underline{N})$$

as in (1.1.1). Also, let $\mathbf{Mod.pre\text{-}log}/(S, \underline{N})$ be the category whose objects are all the pairs $((X, \underline{M}), \mathscr{F})$, where $(X, \underline{M})$ is a $(S, \underline{N})$-scheme, and $\mathscr{F}$ is an $\mathscr{O}_X$-module. The morphisms

$$((X, \underline{M}), \mathscr{F}) \to ((Y, \underline{N}), \mathscr{G})$$

in $\mathbf{Mod.pre\text{-}log}/(S, \underline{N})$ are the pairs (f, φ) consisting of a morphism $f : (X, \underline{M}) \to (Y, \underline{N})$ of $(S, \underline{N})$-schemes, and a morphism $\varphi : f^*\mathscr{G} \to \mathscr{F}$ of $\mathscr{O}_X$-modules. With this notation, we claim that the rule :

$$(X, \underline{M}) \mapsto ((X, \underline{M}), \Omega^1_{X/S}(\log \underline{M}/\underline{N})) \tag{12.3.7}$$

defines a functor $\mathbf{pre\text{-}log}/(S,\underline{N}) \to \mathbf{Mod}.\mathbf{pre\text{-}log}/(S,\underline{N})$. Indeed, slightly more generally, consider a commutative diagram of schemes with pre-log structures :

$$\begin{array}{ccc} (X,\underline{M}) & \xrightarrow{g} & (X',\underline{M}') \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f'} \\ (S,\underline{N}) & \xrightarrow{h} & (S',\underline{N}'). \end{array} \tag{12.3.8}$$

An $\mathscr{O}_X$-linear map :

$$g^*\Omega^1_{X'/S'}(\log \underline{M}'/\underline{N}') \xrightarrow{dg} \Omega_{X/S}(\log \underline{M}/\underline{N}) \tag{12.3.9}$$

is the same as a natural transformation of functors :

$$\mathscr{D}er_{(S,\underline{N})}((X,\underline{M}),\mathscr{F}) \to \mathscr{D}er_{(S',\underline{N}')}((X',\underline{M}'),g_*\mathscr{F}) \tag{12.3.10}$$

on all $\mathscr{O}_X$-modules $\mathscr{F}$. The latter can be defined as follows. Let $(\partial,\log\partial)$ be an $(S,\underline{N})$-linear derivation of $\underline{M}$ with values in $\mathscr{F}$; then we deduce morphisms :

$$\partial' : \mathscr{O}_{X'} \xrightarrow{g^\natural} g_*\mathscr{O}_X \xrightarrow{g_*\partial} g_*\mathscr{F} \qquad \log\partial' : \underline{M}' \xrightarrow{\log g} g_*\underline{M} \xrightarrow{g_*\log\partial} g_*\mathscr{F}$$

and it is easily seen that $(\partial',\log\partial')$ is a $(S',\underline{N}')$-linear derivation of $\underline{M}'$ with values in $g_*\mathscr{F}$.

12.3.11. Consider two morphisms $(X,\underline{M}) \xrightarrow{f} (Y,\underline{N}) \xrightarrow{g} (Z,\underline{P})$ of schemes with pre-log structures. A direct inspection of the definitions shows that :

$$\mathscr{D}er_{(Y,\underline{N})}((X,\underline{M}),\mathscr{F}) = \mathrm{Ker}(\mathscr{D}er_{(Z,\underline{P})}((X,\underline{M}),\mathscr{F}) \to \mathscr{D}er_{(Z,\underline{P})}((Y,\underline{N}),f_*\mathscr{F}))$$

for every $\mathscr{O}_X$-module $\mathscr{F}$, whence a right exact sequence of $\mathscr{O}_X$-modules :

$$f^*\Omega^1_{Y/Z}(\log \underline{N}/\underline{P}) \xrightarrow{df} \Omega^1_{X/Z}(\log \underline{M}/\underline{P}) \to \Omega^1_{X/Y}(\log \underline{M}/\underline{N}) \to 0 \tag{12.3.12}$$

extending the standard right exact sequence for the usual sheaves of relative differentials.

Proposition 12.3.13. *Suppose that the diagram* (12.3.8) *is cartesian. Then the map* (12.3.9) *is an isomorphism.*

Proof. If (12.3.8) is cartesian, X is the scheme $X' \times_{S'} S$, and $\underline{M}$ is the push-out of the diagram:

$$f^{-1}\underline{N} \leftarrow (f' \circ g)^{-1}\underline{N}' \xrightarrow{\varphi} g^*\underline{M}'.$$

Suppose now that $\log\partial : \underline{M}' \to g_*\mathscr{F}$ and $\partial : \mathscr{O}_{X'} \to g_*\underline{\mathscr{F}}$ define a f'-linear derivation of $\underline{M}'$. By adjunction, we deduce morphisms $\alpha : g^{-1}\mathscr{O}_{X'} \to \mathscr{F}$ and $\beta : g^{-1}\underline{M}' \to \mathscr{F}$. By construction, we have $\beta \circ \varphi = 0$, hence β extends uniquely to a morphism $\log\partial' : \underline{M} \to \mathscr{F}$ such that $\log\partial' \circ \log f = 0$. Likewise, α extends by linearity to a unique f-linear derivation $\partial : \mathscr{O}_X \to \mathscr{F}$. One checks easily that $(\partial',\log\partial')$ is a f-linear derivation of $\underline{M}$, and that every f-linear derivation of $\underline{M}$ with values in $\mathscr{F}$ is obtained in this fashion. ◻

12.3.14. The functor (12.3.7) admits a left adjoint. Indeed, let $((X,\underline{M} \xrightarrow{\alpha} \mathscr{O}_X),\mathscr{F})$ be any object of $\mathbf{Mod}.\mathbf{pre\text{-}log}/(S,\underline{N})$; we define an $(S,\underline{N})$-scheme $(X \oplus \mathscr{F},\underline{M} \oplus \mathscr{F})$ as follows. $X \oplus \mathscr{F}$ is the spectrum of the $\mathscr{O}_X$-algebra $\mathscr{O}_X \oplus \mathscr{F}$, whose multiplication law is given by the rule :

$$(s,t)\cdot(s',t') := (ss',st'+s't) \qquad \text{for every local section } s \text{ of } \mathscr{O}_X \text{ and } t \text{ of } \mathscr{F}.$$

Likewise, we define a composition law on the sheaf $\underline{M} \oplus \mathscr{F}$, by the rule :

$$(m,t)\cdot(m',t') := (mm',\alpha(m)\cdot t' + \alpha(m')\cdot t) \qquad \text{for every local section } m \text{ of } \underline{M} \text{ and } t \text{ of } \mathscr{F}.$$

Then $\underline{M} \oplus \mathscr{F}$ is a sheaf of monoids, and α extends to a pre-log structure $\alpha \oplus \mathbf{1}_\mathscr{F} : \underline{M} \oplus \mathscr{F} \to \mathscr{O}_X \oplus \mathscr{F}$. The natural map $\mathscr{O}_X \to \mathscr{O}_X \oplus \mathscr{F}$ is a morphism of algebras, whence a natural map of schemes $\pi : X \oplus \mathscr{F} \to X$, which extends to a morphism of schemes with pre-log structures $(X \oplus \mathscr{F}, \underline{M} \oplus \mathscr{F}) \to (X, \underline{M})$, by letting $\log \pi : \pi^* \underline{M} \to \underline{M} \oplus \mathscr{F}$ be the map induced by the natural monomorphism (notice that π^* induces an equivalence of sites $X_\tau \xrightarrow{\sim} (X \oplus \mathscr{F})_\tau$).

Now, let $(Y, \underline{P})$ be any $(S, \underline{N})$-scheme, and :

$$\varphi : \mathscr{F} := ((X, \underline{M}), \mathscr{F}) \to \Omega := ((Y, \underline{P}), \Omega^1_{Y/S}(\log \underline{P}/\underline{N}))$$

a morphism in $\mathbf{Mod.pre\text{-}log}/(S, \underline{N})$. By definition, φ consists of a morphism $f : (X, \underline{M}) \to (Y, \underline{P})$ and an $\mathscr{O}_X$-linear map $f^*\Omega^1_{Y/S}(\log \underline{P}/\underline{N}) \to \mathscr{F}$, which is the same as a $(S, \underline{N})$-linear derivation :

$$\partial : \mathscr{O}_Y \to f_*\mathscr{F} \qquad \log \partial : \underline{P} \to f_*\mathscr{F}.$$

In turns, the latter yields a morphism of $(S, \underline{N})$-schemes :

$$(Y \oplus f_*\mathscr{F}, \underline{P} \oplus f_*\mathscr{F}) \to (Y, \underline{P}) \tag{12.3.15}$$

determined by the map of algebras :

$$\mathscr{O}_Y \to \mathscr{O}_Y \oplus f_*\mathscr{F} \qquad s \mapsto (s, \partial s) \quad \text{for every local section } s \text{ of } \mathscr{O}_Y$$

and the map of monoids :

$$\underline{P} \mapsto \underline{P} \oplus f_*\mathscr{F} \qquad p \mapsto (p, \log \partial p) \quad \text{for every local section } p \text{ of } \underline{P}.$$

Finally, we compose (12.3.15) with the natural morphism

$$(X \oplus \mathscr{F}, \underline{M} \oplus \mathscr{F}) \to (Y \oplus f_*\mathscr{F}, \underline{P} \oplus f_*\mathscr{F})$$

that extends f, to obtain a morphism $g_\varphi : (X \oplus \mathscr{F}, \underline{M} \oplus \mathscr{F}) \to (Y, \underline{P})$. We leave to the reader the verification that the rule $\varphi \mapsto g_\varphi$ establishes a natural bijection :

$$\mathrm{Hom}_{\mathbf{Mod.pre\text{-}log}/(S,\underline{N})}(\mathscr{F}, \Omega) \xrightarrow{\sim} \mathrm{Hom}_{\mathbf{pre\text{-}log}/(S,\underline{N})}((X \oplus \mathscr{F}, \underline{M} \oplus \mathscr{F}), (Y, \underline{P})).$$

12.3.16. In the situation of definition 12.3.4, let $(\partial, \log \partial)$ be an f-linear derivation of $\underline{M}$ with values in an $\mathscr{O}_X$-module $\mathscr{F}$. Consider the map :

$$\partial' : \mathscr{O}_X^\times \to \mathscr{F} \quad : \quad u \mapsto u^{-1} \cdot \partial u \quad \text{for all local sections } u \text{ of } \mathscr{O}_X^\times.$$

By definition, $\partial' \circ \alpha : \alpha^{-1}\underline{M} \to \mathscr{F}$ agrees with the restriction of $\log \partial$; in view of the cocartesian diagram (12.1.7), we deduce that $\log \partial$ extends uniquely to an f-linear derivation $\log \partial^{\log}$ of $\underline{M}^{\log}$. Let $f^{\log} : (X, \underline{M}^{\log}) \to (Y, \underline{N}^{\log})$ be the map deduced from f; a similar direct verification shows that $\log \partial^{\log}$ is a $f^{\log}$-linear derivation. There follow natural identifications :

$$\Omega^1_{X/Y}(\log(\underline{M}/\underline{N})) = \Omega^1_{X/Y}(\log(\underline{M}^{\log}/\underline{N})) = \Omega^1_{X/Y}(\log(\underline{M}^{\log}/\underline{N}^{\log})). \tag{12.3.17}$$

Moreover, if $\underline{M}$ and $\underline{N}$ are log structures, the natural map :

$$\mathscr{O}_X \otimes_\mathbb{Z} \log \underline{M}^{\mathrm{gp}} \to \Omega^1_{X/Y}(\log(\underline{M}/\underline{N})) \qquad a \otimes b \mapsto a \cdot d\log(b) \tag{12.3.18}$$

is an epimorphism. Indeed, we have $da = d(a+1)$ for every local section $a \in \mathscr{O}_X(U)$ (for any étale X-scheme U), and locally on X_τ, either a or $1 + a$ is invertible in $\mathscr{O}_X$ (this holds certainly on the stalks, hence on appropriate small neighborhoods $U' \to U$); hence da lies in the image of (12.3.18).

Example 12.3.19. Let R be a ring, $\varphi : N \to M$ be any map of monoids, and set :

$$S := \mathrm{Spec}\, R \qquad S[M] := \mathrm{Spec}\, R[M] \qquad S[N] := \mathrm{Spec}\, R[N].$$

Also, let $f : \mathrm{Spec}(R, M) \to \mathrm{Spec}(R, N)$ be the morphism of log schemes induced by φ (see (12.2.13)). With this notation, we claim that (12.3.18) induces an isomorphism :

$$\mathscr{O}_{S[M]} \otimes_\mathbb{Z} \mathrm{Coker}\, \varphi^{\mathrm{gp}} \xrightarrow{\sim} \Omega^1_{S[M]/S[N]}(\log M^{\log}_{S[M]}/N^{\log}_{S[N]})$$

To see this, we may use (12.3.12) to reduce to the case where $N = \{1\}$. Next, notice that the functor

$$\mathbf{Mnd}^o \to \mathbf{pre\text{-}log}/(S, \mathscr{O}_S^\times) \quad : \quad M \mapsto \mathrm{Spec}(R, M)$$

commutes with limits, and the same holds for the functor (12.3.7), since the latter is a right adjoint. Hence, we may assume that M is finitely generated; then lemma 6.1.7(i) further reduces to the case where $M = \mathbb{N}^{\oplus n}$ for some integer $n \geq 0$, and even to the case where $n = 1$. Set $X := S[\mathbb{N}]$; it is easy to see that a S-linear derivation of $\mathbb{N}_X^{\log}$ with values in an $\mathscr{O}_X$-module $\mathscr{F}$, is completely determined by a map of additive monoids $\mathbb{N} \to \Gamma(X, \mathscr{F})$, and the latter is the same as an $\mathscr{O}_X$-linear map $\mathscr{O}_X \to \mathscr{F}$, whence the contention.

Lemma 12.3.20. *Let $f : (X, \underline{M}) \to (Y, \underline{N})$ be a morphism of schemes with quasi-coherent log structures. Then :*

(i) *The $\mathscr{O}_X$-module $\Omega^1_{X/Y}(\log \underline{M}/\underline{N})$ is quasi-coherent.*
(ii) *If $\underline{M}$ is coherent, X is noetherian, and $f : X \to Y$ is locally of finite type, then $\Omega^1_{X/Y}(\log \underline{M}/\underline{N})$ is a coherent $\mathscr{O}_X$-module.*
(iii) *If both $\underline{M}$ and $\underline{N}$ are coherent, and $f : X \to Y$ is locally of finite presentation, then $\Omega^1_{X/Y}(\log \underline{M}/\underline{N})$ is a quasi-coherent $\mathscr{O}_X$-module of finite presentation.*

Proof. Applying the right exact sequence (12.3.12) to the sequence $(X, \underline{M}) \xrightarrow{f} (Y, \underline{N}) \to (Y, \mathscr{O}_Y^\times)$, we may easily reduce to the case where $\underline{N} = \mathscr{O}_Y^\times$ is the trivial log structure on Y. In this case, $\underline{N}$ admits the chart given by the unique map of monoids : $\{1\} \to \Gamma(Y, \mathscr{O}_Y)$, and f admits the chart $\{1\} \to P$, whenever $\underline{M}$ admits a chart $P \to \Gamma(X, \mathscr{O}_X)$.

Hence, everything follows from the following assertion, whose proof shall be left to the reader. Suppose that $\varphi : A \to B$ is a ring homomorphism, $\underline{M}$ (resp. $\underline{N}$) is the constant log structure on $X := \mathrm{Spec}\, B$ (resp. on $Y := \mathrm{Spec}\, A$) associated to a map of monoids $\alpha : P \to B$ (resp. $\beta : Q \to A$), and $f : (X, \underline{M}) \to (Y, \underline{N})$ is defined by φ admits a chart $\vartheta : Q \to P$. Then $\Omega^1_{X/Y}(\log \underline{M}/\underline{N})$ is the quasi-coherent $\mathscr{O}_X$-module $L^\sim$, associated to the B-module $L := (\Omega^1_{B/A} \oplus (B \otimes_\mathbb{Z} P^{\mathrm{gp}}))/R$, where R is the submodule generated by the elements of the form $(0, 1 \otimes \log \vartheta(q))$ for all $q \in Q$, and those of the form $(d\alpha(m), -\alpha(m) \otimes \log m)$, for all $m \in M$. $\square$

12.3.21. Let us fix a log scheme $(Y, \underline{N})$. To any pair of $(Y, \underline{N})$-schemes $X := (X, \underline{M})$, $X' := (X', \underline{M}')$, we attach a contravariant functor

$$\mathscr{H}_Y(X', X) : (X'_\tau)^o \to \mathbf{Set}$$

by assigning, to every object U of X'_τ, the set of all morphisms $(U, \underline{M}'_{|U}) \to (X, \underline{M})$ of $(Y, \underline{N})$-schemes. It is easily seen that $\mathscr{H}_Y(X', X)$ is a sheaf on X'_τ. Any morphism $\varphi : (X'', \underline{M}'') \to (X', \underline{M}')$ (resp. $\psi : (X, \underline{M}) \to (X'', \underline{M})$) of $(Y, \underline{N})$-schemes induces a map of sheaves :

$$\varphi^* : \varphi^* \mathscr{H}_Y(X', X) \to \mathscr{H}_Y(X'', X) \qquad (\text{resp. } \psi_* : \mathscr{H}_Y(X', X) \to \mathscr{H}_Y(X', X''))$$

in the obvious way.

Definition 12.3.22. With the notation of (12.3.21) :

(i) We say that a morphism $i : (T', \underline{L}') \to (T, \underline{L})$ of log schemes is a *closed immersion* (resp. an *exact closed immersion*) if the underlying morphism of schemes $T' \to T$ is a closed immersion, and $\log i : i^*\underline{L} \to \underline{L}'$ is an epimorphism (resp. an isomorphism) of T'_τ-monoids.
(ii) We say that a morphism $i : (T', \underline{L}') \to (T, \underline{L})$ of log schemes is an *exact nilpotent immersion* if i is an exact closed immersion, and the ideal $\mathscr{I} := \mathrm{Ker}(\mathscr{O}_T \to i_*\mathscr{O}_{T'})$ is nilpotent.

(iii) We say that a morphism $f : (X, \underline{M}) \to (Y, \underline{N})$ of log schemes is *formally smooth* (resp. *formally unramified*, resp. *formally étale*) if, for every exact nilpotent immersion $i : T' \to T$ of fine $(Y, \underline{N})$-schemes, the induced map of sheaves $i^* : i^*\mathscr{H}_Y(T, X) \to \mathscr{H}_Y(T', X)$ is an epimorphism (resp. a monomorphism, resp. an isomorphism).

(iv) We say that a morphism $f : (X, \underline{M}) \to (Y, \underline{N})$ of log schemes is *smooth* (resp. *unramified*, resp. *étale*) if the underlying morphism $X \to Y$ is locally of finite presentation, and f is formally smooth (resp. formally unramified, resp. formally étale).

Example 12.3.23. Let $(S, \underline{P})$ be a log scheme, $(f, \log f) : (X, \underline{M}) \to (Y, \underline{N})$ be a morphism of S-schemes, such that Y is a separated S-scheme. The pair $(\mathbf{1}_{(X,\underline{M})}, (f, \log f))$ induces a morphism

$$\Gamma_f : (X, \underline{M}) \to (X', \underline{M}') := (X, \underline{M}) \times_S (Y, \underline{N})$$

the *graph* of f. Then it is easily seen that Γ_f is a closed immersion of log schemes. Indeed, the morphism of schemes underlying Γ_f is a closed immersion ([59, Ch.I, 5.4.3]) and it is easily seen that the morphism $\log \Gamma_f : \Gamma_f^*\underline{M}' \to \underline{M}$ is an epimorphism on the underlying sheaves of sets, so it is *a fortiori* an epimorphism of X_τ-monoids.

Proposition 12.3.24. *Let $f : (X, \underline{M}) \to (Y, \underline{N})$, $g : (Y, \underline{N}) \to (Z, \underline{P})$, and $h : (Y', \underline{N}') \to (Y, \underline{N})$ be morphisms of log schemes. Denote by $\mathbf{P}$ either one of the properties : "formally smooth", "formally unramified", "formally étale", "smooth", "unramified", "étale". The following holds :*

(i) *If f and g enjoy the property $\mathbf{P}$, then the same holds for $g \circ f$.*

(ii) *If $(f, \log f)$ enjoys the property $\mathbf{P}$, then the same holds for*

$$(f, \log f) \times_{(Y,\underline{N})} (Y', \underline{N}') : (X, \underline{M}) \times_{(Y,\underline{N})} (Y', \underline{N}') \to (Y', \underline{N}').$$

(iii) *Let $(j_\lambda : U_\lambda \to X \mid \lambda \in \Lambda)$ be a covering family in X_τ; endow U_λ with the log structure $(\underline{M})_{|U_\lambda}$ and suppose that $f_\lambda := (f \circ j_\lambda, (\log f)_{|U_\lambda}) : (U_\lambda, (\underline{M})_{|U_\lambda}) \to (Y, \underline{N})$ enjoys the property $\mathbf{P}$, for every $\lambda \in \Lambda$. Then f enjoys the property $\mathbf{P}$ as well.*

(iv) *An open immersion of log schemes is étale.*

(v) *A closed immersion of log schemes is formally unramified.*

Proof. (i), (ii) and (iv) are left to the reader.

(iii): To begin with, if each f_λ is locally of finite presentation, the same holds for f, by [66, Ch.IV, lemme 17.7.5], hence we may assume that $\mathbf{P}$ is either "formally smooth" or "formally unramified". (Clearly, the case where $\mathbf{P}$ is "formally étale" will follow.)

Now, let $i : T' \to T$ be an exact nilpotent immersion of $(Y, \underline{N})$-schemes, and ξ a τ-point of T'. By inspecting the definitions, it is easily seen that the stalk $\mathscr{H}_Y(T, X)_\xi$ is the union of the images of the stalks $\mathscr{H}_Y(T, U_\lambda)_\xi$, for every $\lambda \in \Lambda$, and likewise for $\mathscr{H}_Y(T', X)_\xi$. It readily follows that f is formally smooth whenever all the f_λ are formally smooth.

Lastly, suppose that all the f_λ are formally unramified, and let $s_\xi, t_\xi \in \mathscr{H}_Y(T, X)_{i(\xi)}$ be two sections whose images in $\mathscr{H}_Y(T', X)_\xi$ agree; after replacing T by a neighborhood of $i(\xi)$ in T_τ, we may assume that s_ξ, t_ξ are represented by two $(Y, \underline{N})$-morphisms $s, t : T \to (X, \underline{M})$ such that $s \circ i = t \circ i$. Choose $\lambda \in \Lambda$ such that U_λ is a neighborhood of $s \circ i(\xi) = t \circ i(\xi)$; this means that there exist a neighborhood $p' : U' \to T'$ of ξ, and a morphism $s_{U'} : U' \to U_\lambda$ lifiting $s \circ i$ (and thus, also $t \circ i$). Then we may find a neighborhood $p : U \to T$ of $i(\xi)$ which identifies p' with $p \times_T \mathbf{1}_{T'}$ ([66, Ch.IV, Th.18.1.2]), and since j_λ is étale, we may furthermore find morphisms $s_U, t_U : U \to U_\lambda$ such that $j_\lambda \circ s_U = s \circ i = t \circ i = j_\lambda \circ t_U$. Set $i_U := i \times_T \mathbf{1}_U : U' \to U$; by construction, s_U and t_U yield two sections of $i_U^*\mathscr{H}_Y(U, U_\lambda)_\xi$, whose images in $\mathscr{H}_Y(U', U_\lambda)_\xi$ coincide. Since f_λ is formally unramified, it follows that – up to replacing U by a neighborhood of $i(\xi)$ in U_τ – we must have $s_U = t_U$, so $s_\xi = t_\xi$, and we conclude that f is formally unramified.

(v): Consider a commutative diagram of log schemes :

$$\begin{array}{ccc} (T',\underline{L}') & \xrightarrow{h'} & (X,\underline{M}) \\ {\scriptstyle i}\downarrow & & \downarrow{\scriptstyle f} \\ (T,\underline{L}) & \xrightarrow{h} & (Y,\underline{N}) \end{array}$$

where f is a closed immersion, and i is an exact closed immersion. We are easily reduced to showing that there exists at most a morphism $(g, \log) : (T, \underline{L}) \to (X, \underline{M})$ such that $f \circ g = h$ and $h' = g \circ i$. Since $f : X \to Y$ is a closed immersion of schemes, there exists at most one morphism of schemes $g : T \to X$ lifting h and extending h' ([66, Ch.IV, Prop.17.1.3(i)]). Hence we may assume that such a g is given, and we need to check that there exists at most one morphism $\log g : g^*\underline{M} \to \underline{L}$ whose composition with $g^*(\log f) : h^*\underline{N} \to g^*\underline{M}$ equals $\log h$. However, by assumption $\log f$ is an epimorphism, hence the same holds for $g^*(\log f)$ (proposition 1.3.25(iv)), whence the contention. □

Corollary 12.3.25. *Let f and g be as proposition* 12.3.24. *We have :*

(i) *If $g \circ f$ is formally unramified, the same holds for f.*
(ii) *If $g \circ f$ is formally smooth (resp. formally étale) and g is formally unramified, then f is formally smooth (resp. formally étale).*
(iii) *Suppose that g is formally étale. Then f is formally smooth (resp. formally unramified, resp. formally étale) if and only if the same holds for $g \circ f$.*

Proof. (i): Let $Y = \bigcup_{\lambda\in\Lambda}$ be an affine open covering of Y, and for each $\lambda \in \Lambda$, let $f_\lambda : U_\lambda \times_Y (X, \underline{M}) \to (U_\lambda, \underline{N}_{|U_\lambda})$ be the restriction of f; in light of proposition 12.3.24(iii) it suffices to show that each f_λ is formally unramified, and on the other hand, the restriction $g \circ f_\lambda : U_\lambda \times_Y (X, \underline{M}) \to (Z, \underline{P})$ of $g \circ f$ is formally unramified, by proposition 12.3.24(i),(iv). It follows that we may replace f and g respectively by f_λ and g_λ, which allows to assume that Y is affine, especially separated, so that g is a separated morphism of schemes. In such situation, one may – in view of example 12.3.23 – argue as in the proof of [66, Ch.IV, Prop.17.1.3] : the details shall be left to the reader.

(ii) is a formal consequence of the definitions (cp. the proof of [66, Ch.IV, Prop.17.1.4]), and (iii) follows from (ii) and proposition 12.3.24(i). □

Proposition 12.3.26. *Let $f : (X, \underline{M}) \to (Y, \underline{N})$ be a morphism of log schemes, and i an exact closed immersion of $(Y, \underline{N})$-schemes, defined by an ideal $\mathscr{I} := \mathrm{Ker}(\mathscr{O}_T \to i_*\mathscr{O}_{T'})$ with $\mathscr{I}^2 = 0$. For any global section $s : T' \to \mathscr{H}_Y(T', X)$, denote by $\mathscr{T}_s$ the morphism :*

$$i^*\mathscr{H}_Y(T, X) \times_{\mathscr{H}_Y(T',X)} T' \to T'$$

deduced from $i^* : i^*\mathscr{H}_Y(T, X) \to \mathscr{H}_Y(T', X)$. Let also $U \subset T'$ be the image *of $\mathscr{T}_s$* (i.e. *the subset of all $t' \in T'$ such that $\mathscr{T}_{s,\xi} \neq \varnothing$ for every τ-point ξ localized at t'), and suppose that $U \neq \varnothing$. We have :*

(i) *U is an open subset of T', and $\mathscr{T}_{s|U}$ is a torsor for the abelian sheaf*

$$\mathscr{G} := \mathscr{H}om_{\mathscr{O}_{T'}}(s^*\Omega^1_{X/Y}(\log(\underline{M}/\underline{N})), \mathscr{I})_{|U}.$$

(ii) *If f is a smooth morphism of log schemes with coherent log structures, we have :*
 (a) *The $\mathscr{O}_X$-module $\Omega^1_{X/Y}(\log(\underline{M}/\underline{N}))$ is locally free of finite type.*
 (b) *If T' is affine, $\mathscr{T}_s$ is a trivial $\mathscr{G}$-torsor.*

Proof. (i): To any τ-point ξ of U, and any two given local sections h and g of $\mathscr{T}_{s,\xi}$, we assign the f-linear derivation of $\underline{M}_{s(\xi)}$ with values in $s_*\mathscr{I}_\xi$ given by the rule :

$$\begin{aligned} a &\mapsto h^*(a) - g^*(a) && \text{for every } a \in \mathscr{O}_{X,s(\xi)} \\ d\log m &\mapsto \log u(m) := u(m) - 1 && \text{for every } m \in \underline{M}_{s(\xi)} \end{aligned}$$

where $u(m)$ is the unique local section of $\mathrm{Ker}(\mathscr{O}_{T,\xi} \to i_*\mathscr{O}_{T',\xi})$ such that

$$\log(g(m) \cdot u(m)) = \log h(m).$$

We leave to the reader the laborious, but straightforward verification that the above map is well-defined, and yields the sought bijection between $\mathscr{T}_{s,\xi}$ and $\mathscr{G}_\xi$.

(ii.b) is standard : first, since f is smooth, we have $U = T'$; by lemma 12.3.20(iii), the $\mathscr{O}_X$-module $\Omega^1_{X/Y}(\log(\underline{M}/\underline{N}))$ is quasi-coherent and finitely presented, hence $\mathscr{G}$ is quasi-coherent; however, the obstruction to gluing local sections of a $\mathscr{G}$-torsor lies in $H^1(T_\tau, \mathscr{G})$ (see (4.9.11)); the latter vanishes whenever T is affine.

(ii.a) We may assume that X is affine, say $X = \mathrm{Spec}\, A$; then $\Omega^1_{X/Y}(\log(\underline{M}/\underline{N}))$ is the quasi-coherent $\mathscr{O}_X$-module arising from a finitely presented A-module Ω (lemma 12.3.20(iii)). Let I be any A-module, and set :

$$T_I := X \oplus I^\sim \qquad \underline{L}_I := \underline{M} \oplus I^\sim$$

(notation of (12.3.14)). Let $i : X \to T_I$ (resp. $\pi : T_I \to X$) be the natural closed immersion (resp. the natural projection); then $(T_I, \underline{L}_I)$ is a fine log scheme, and π (resp. i) extends to a morphism of log schemes $(\pi, \log \pi) : (T_I, \underline{L}_I) \to (X, \underline{M})$ (resp. $(i, \log i) : (X, \underline{M}) \to (T_I, \underline{L}_I)$) with $\log \pi : \pi^*\underline{M} \to \underline{L}_I$ (resp. $\log i : i^*\underline{L}_I \to \underline{M}$) induced by the obvious inclusion (resp. projection) map. Notice that $(i, \log i)$ is an exact immersion and $(I^\sim)^2 = 0$, hence (i) says that the set $\mathscr{T}(T_I)$ of all morphisms $g : (T_I, \underline{L}_I) \to (X, \underline{M})$ such that

$$f \circ g = f \circ \pi \qquad g \circ i = \mathbf{1}_{(X,\underline{M})}$$

is in bijection with $\mathrm{Hom}_A(\Omega, I)$. Moreover, any map $\varphi : I \to J$ of A-modules induces a morphism $i_\varphi : (T_J, \underline{L}_J) \to (T_I, \underline{L}_I)$ of log schemes, and if φ is surjective, i_φ is an exact nilpotent immersion. Furthermore, we have a commutative diagram of sets :

$$\begin{array}{ccc} \mathscr{T}(T_I) & \xrightarrow{\ i^*_\varphi\ } & \mathscr{T}(T_J) \\ \downarrow & & \downarrow \\ \mathrm{Hom}_A(\Omega, I) & \xrightarrow{\ \varphi_*\ } & \mathrm{Hom}_A(\Omega, J) \end{array}$$

whose vertical arrows are bijections, and where i^*_φ (resp. φ_*) is given by the rule $g \mapsto g \circ i_\varphi$, (resp. $\psi \mapsto \varphi \circ \psi$). Assertion (ii.b) implies that ι^*_φ is surjective when f is smooth and φ is surjective, hence the same holds for φ_*, *i.e.* Ω is a projective A-module, as stated. □

Corollary 12.3.27. *Let $(f, \log f) : (X, \underline{M}) \to (Y, \underline{N})$ be a morphism of log schemes. We have:*

(i) *If $\underline{M}$ and $\underline{N}$ are fine log structures, and f is strict (see definition* 12.1.22(ii)*), then $(f, \log f)$ is smooth (resp. étale) if and only if the underlying morphism of schemes $f : X \to Y$ is smooth (resp. étale).*

(ii) *Suppose that $(f, \log f)$ is a smooth (resp. étale) morphism of log schemes on the Zariski sites of X and Y, and either :*

  (a) *$\underline{M}$ and $\underline{N}$ are both integral log structures,*

  (b) *or else $\underline{N}$ is coherent (on Y_{Zar}) and $\underline{M}$ is fine (on X_{Zar}).*

  Then the induced morphism of log schemes on étale sites :

$$\widetilde{u}^*(f, \log f) := (f, \widetilde{u}^*_X \log f) : \widetilde{u}^*_X(X, \underline{M}) \to \widetilde{u}^*_Y(Y, \underline{N})$$

is smooth (resp. étale). (Notation of (12.2.2).*)*

(iii) *Suppose that* $(f, \log f)$ *is a morphism of log schemes on the Zariski sites of* X *and* Y*, and* $\underline{M}$ *is an integral log structure on* X_{Zar}*. Suppose also that* $\widetilde{u}^*(f, \log f)$ *is smooth (resp. étale). Then the same holds for* $(f, \log f)$*.*

Proof. (i): Suppose first that $(f, \log f)$ is smooth (resp. étale). Let $i : T' \to T$ be a nilpotent immersion of affine schemes, defined by an ideal $\mathscr{I} \subset \mathscr{O}_T$ such that $\mathscr{I}^2 = 0$; let $s : T' \to X$ and $t : T \to Y$ be morphisms of schemes such that $f \circ s = t \circ i$. By lemma 12.1.18(i), the log structures $\underline{L} := t^*\underline{N}$ and $\underline{L}' := s^*\underline{M}$ are fine, and by choosing the obvious maps $\log s$ and $\log t$, we deduce a commutative diagram :

$$\begin{array}{ccc} (T', \underline{L}') & \xrightarrow{s} & (X, \underline{M}) \\ {\scriptstyle i}\downarrow & & \downarrow{\scriptstyle f} \\ (T, \underline{L}) & \xrightarrow{t} & (Y, \underline{N}). \end{array} \tag{12.3.28}$$

Then proposition 12.3.26(ii.b) says that there exists a morphism (resp. a unique morphism) of schemes $g : T \to X$ such that $g \circ i = s$ and $f \circ g = t$, *i.e.* f is smooth (resp. étale).

The converse is easy, and shall be left as an exercise for the reader.

(ii): Suppose first that $(f, \log f)$ is smooth, $\underline{N}$ is coherent and $\underline{M}$ is fine. By proposition 12.3.24(iii), the assertion to prove is local on $X_{\text{ét}}$, hence we may assume that f admits a chart, given by a morphism of finitely generated monoids $P \to P'$ and commutative diagrams :

$$P'_{X_{\mathrm{Zar}}} \to \underline{M} \qquad \omega : P_{Y_{\mathrm{Zar}}} \to \underline{N}$$

(theorem 12.1.37(i)). Now, consider a commutative diagram of log schemes on étale sites :

$$\begin{array}{ccc} (T', \underline{L}') & \xrightarrow{s} & \widetilde{u}^*_X(X, \underline{M}) \\ {\scriptstyle i}\downarrow & & \downarrow{\scriptstyle \widetilde{u}^* f} \\ (T, \underline{L}) & \xrightarrow{t} & \widetilde{u}^*_Y(Y, \underline{N}) \end{array} \tag{12.3.29}$$

where i is an exact nilpotent immersion of fine log schemes, defined by an ideal $\mathscr{I} \subset \mathscr{O}_T$ such that $\mathscr{I}^2 = 0$. Since the assertion to prove is local on $T_{\text{ét}}$, we may assume that T is affine and – in view of theorem 12.1.37(ii) – that t admits a chart, given by a morphism of finitely generated monoids $\varphi : P \to Q$, and commutative diagrams :

$$\begin{array}{ccc} P_{T_{\text{ét}}} = t^*P_{Y_{\text{ét}}} & \xrightarrow{t^*u^*_Y\omega} & t^*\widetilde{u}^*_Y\underline{N} \\ {\scriptstyle \varphi_T}\downarrow & & \downarrow{\scriptstyle \log t} \\ Q_{T_{\text{ét}}} & \xrightarrow{\beta} & \underline{L} \end{array} \qquad \begin{array}{ccc} P & \longrightarrow & \Gamma(Y, \mathscr{O}_Y) \\ {\scriptstyle \varphi}\downarrow & & \downarrow{\scriptstyle t^\natural} \\ Q & \xrightarrow{\psi} & \Gamma(T, \mathscr{O}_T) \end{array} \tag{12.3.30}$$

Since i is an exact closed immersion, it follows that the morphism :

$$Q_{T'_{\text{ét}}} \xrightarrow{i^*\beta} i^*\underline{L} \xrightarrow{\log i} \underline{L}'$$

is a chart for $\underline{L}'$. Especially, $(T', \underline{L}')$ is isomorphic to $(T'_{\text{ét}}, Q^{\log}_{T'})$, the constant log structure deduced from the morphism $i^\natural \circ \psi : Q \to \Gamma(T', \mathscr{O}_{T'})$. The latter is also the log scheme $\widetilde{u}^*_{T'}(T_{\mathrm{Zar}}, Q^{\log}_{T'})$. From proposition 12.2.3(ii) we deduce that there exists a unique morphism $s_{\mathrm{Zar}} : (T_{\mathrm{Zar}}, Q^{\log}_{T'}) \to (X, \underline{M})$, such that $\widetilde{u}^* s_{\mathrm{Zar}} = s$. On the other hand, by inspecting (12.3.30) we find that there exists a unique morphism $t_{\mathrm{Zar}} : (T_{\mathrm{Zar}}, Q^{\log}_T) \to (Y, \underline{N})$ such that $\widetilde{u}^* t_{\mathrm{Zar}} = t$.

These morphisms can be assembled into a diagram :

$$(12.3.31)\qquad \begin{array}{ccc} (T'_{\mathrm{Zar}}, Q^{\log}_{T'}) & \xrightarrow{s_{\mathrm{Zar}}} & (X, \underline{M}) \\ {\scriptstyle i_{\mathrm{Zar}}}\downarrow & & \downarrow{\scriptstyle f} \\ (T_{\mathrm{Zar}}, Q^{\log}_{T}) & \xrightarrow{t_{\mathrm{Zar}}} & (Y, \underline{N}) \end{array}$$

where i_{Zar} is an exact closed immersion. By construction, the diagram $\widetilde{u}^*$(12.3.31) is naturally isomorphic to (12.3.29); especially, (12.3.31) commutes (proposition 12.2.3(i)). Now, since f is smooth, proposition 12.3.26(ii.b) implies that there exists a morphism $v : (T_{\mathrm{Zar}}, Q^{\log}_T) \to (X, \underline{M})$ such that $f \circ v = t_{\mathrm{Zar}}$ and $v \circ i_{\mathrm{Zar}} = s_{\mathrm{Zar}}$; then $\widetilde{u}^* v$ provides an appropriate lifting of t, which allows to conclude that $\widetilde{u}^*(f, \log f)$ is smooth.

Next, suppose that $(f, \log f)$ is étale (and we are still in case (b) of the corollary); then there exists a unique morphism v with the properties stated above. However, from proposition 12.2.3(i),(ii) we deduce easily that the natural map :

$$\mathscr{H}_Y((T_{\mathrm{Zar}}, Q^{\log}_T), (X, \underline{M}))(T) \to \mathscr{H}_{\widetilde{u}^*(Y,\underline{N})}((T, \underline{L}), \widetilde{u}^*(X, \underline{M}))(T)$$

is a bijection, and the same holds for the analogous map for T'. In view of the foregoing, this shows that the map $\mathscr{H}_{\widetilde{u}^*(Y,\underline{N})}((T, \underline{L}), \widetilde{u}^*(X, \underline{M}))(T) \to \mathscr{H}_{\widetilde{u}^*(Y,\underline{N})}((T', \underline{L}'), \widetilde{u}^*(X, \underline{M}))(T')$ is bijective, whenever t admits a chart and T is affine. We easily conclude that $\widetilde{u}^*(f, \log f)$ is étale.

The case where both $\underline{N}$ and $\underline{M}$ are both integral, is similar, though easier : we may assume that $\underline{L}$ admits a chart, in which case $(T, \underline{L})$ is of the form $\widetilde{u}^*(T_{\mathrm{Zar}}, Q^{\log}_T)$ for some finite integral monoid Q; then $(T', \underline{L}')$ admits a similar description, and again, by appealing to proposition 12.2.3(ii) we deduce that (12.3.29) is of the form $\widetilde{u}^*$(12.3.31), in which case we conclude as in the foregoing.

Conversely, if $\widetilde{u}^*(f, \log f)$ is smooth, consider again a commutative diagram (12.3.28) of log schemes on Zariski sites, with i an exact closed immersion, defined by a sheaf of ideals $\mathscr{I} \subset \mathscr{O}_T$ such that $\mathscr{I}^2 = 0$. By applying everywhere the pull-back functors from Zariski to étale sites, we deduce a commutative diagram $\widetilde{u}^*$(12.3.28) of log schemes on étale sites, and it is easy to see that $\widetilde{u}^*(i, \log i)$ is again an exact nilpotent immersion. According to proposition 12.3.26(ii.b), after replacing T by any affine open subset, we may find a morphism of log schemes $g : \widetilde{u}^*_T(T, \underline{L}) \to \widetilde{u}^*_X(X, \underline{M})$, such that $g \circ \widetilde{u}^* i = \widetilde{u}^* s$ and $\widetilde{u}^* f \circ g = t$. By proposition 12.2.3(i),(ii) there exists a unique morphism $g' : (T, \underline{L}) \to (X, \underline{M})$ such that $\widetilde{u}^* g' = g$, and necessarily $g' \circ i = s$ and $f \circ g' = t$. We conclude that $(f, \log f)$ is smooth.

Finally, if $\widetilde{u}^*(f, \log f)$ is étale, the morphism g exhibited above is unique, and therefore the same holds for g', so $(f, \log f)$ is étale as well. □

Proposition 12.3.32. *In the situation of* (12.3.11)*, suppose that the log structures* $\underline{M}, \underline{N}, \underline{P}$ *are coherent, and consider the following conditions :*

(a) *f is smooth (resp. étale).*
(b) *df is a locally split monomorphism (resp. an isomorphism).*

Then (a)⇒(b)*, and if $g \circ f$ is smooth, then* (b)⇒(a).

Proof. We may assume that the schemes under consideration are affine, say $X = \operatorname{Spec} A$, $Y = \operatorname{Spec} B$, $Z = \operatorname{Spec} C$; then (12.3.12) amounts to an exact sequence of A-modules :

$$A \otimes_B \Omega(g) \xrightarrow{df} \Omega(g \circ f) \xrightarrow{\omega} \Omega(f) \to 0.$$

On the other hand, let $i : (T'\underline{L}') \to (T, \underline{L})$ be an exact closed immersion of $(Y, \underline{N})$-schemes, defined by an ideal $\mathscr{I} \subset \mathscr{O}_T$ with $\mathscr{I}^2 = 0$. Suppose that $s : T' \to \mathscr{H}_Y(T', X)$ is a global section, *i.e.* a given morphism of $(Y,\underline{N})$-schemes $(T'\underline{L}') \to (X,\underline{M})$. In this situation, we have a natural sequence of morphisms :

$$\mathscr{H}_1 := \mathscr{H}_Y(T,X) \xrightarrow{\alpha} \mathscr{H}_2 := \mathscr{H}_Z(T,X) \xrightarrow{f_*} \mathscr{H}_3 := \mathscr{H}_Z(T,Y)$$

where α is the obvious monomorphism. Let us consider the pull-back of these sheaves along the global section s :

$$\mathscr{T} := T' \times_{\mathscr{H}_Y(T',X)} i^*\mathscr{H}_1 \qquad \mathscr{T}' := T' \times_{\mathscr{H}_Z(T',X)} i^*\mathscr{H}_2 \qquad \mathscr{T}'' := T' \times_{\mathscr{H}_Z(T',Y)} i^*\mathscr{H}_3.$$

By proposition 12.3.26(i), any choice of a global section of $\mathscr{T}(T)$ determines a commutative diagram of sets :

$$\begin{array}{ccccc} \mathrm{Hom}_A(\Omega(f),\mathscr{I}(T)) & \xrightarrow{\omega^*} & \mathrm{Hom}_A(\Omega(g\circ f),\mathscr{I}(T)) & \xrightarrow{df^*} & \mathrm{Hom}_B(\Omega(g),\mathscr{I}(T)) \\ \downarrow & & \downarrow & & \downarrow \\ \mathscr{T}(T) & \longrightarrow & \mathscr{T}'(T) & \xrightarrow{f_*} & \mathscr{T}''(T) \end{array} \tag{12.3.33}$$

whose vertical arrows are bijections.

In order to show that df is a locally split monomorphism (resp. an isomorphism), it suffices to show that the map $df^* := \mathrm{Hom}_A(df, I)$ is surjective for every A-module I. To this aim, we take $(T,L) := (T_I,\underline{L}_I)$, $(T',\underline{L}') := (X,\underline{M})$, and let i be the nilpotent immersion defined by the ideal $I \subset A \oplus I$, as in the proof of proposition 12.3.26(ii.a). If $\mathscr{I} \subset \mathscr{O}_T$ is the corresponding sheaf of ideals, then $\mathscr{I}(T) = I$; moreover, the inclusions $A \to A \oplus I$ and $\underline{M} \subset \underline{M} \oplus \mathscr{I}$ determine a morphism $h : (T_I,\underline{L}_I) \to (X,\underline{M})$, which is a global section of $\mathscr{T}(T)$. Having made these choices, consider the resulting diagram (12.3.33) : if f is étale, f_* is an isomorphism, and when f is smooth, f_* is surjective (proposition 12.3.26(ii.b)), whence the contention.

For the converse, we may suppose that df is a split monomorphism, hence df^* in (12.3.33) is a split surjection. We have to show that $\mathscr{T}(T)$ is not empty, and by assumption (and proposition 12.3.26(ii.b)) we know that $\mathscr{T}'(T) \neq \varnothing$. Choose any $\widetilde{h} \in \mathscr{T}'(T)$; then t and $f_*\widetilde{h}$ are two elements of $\mathscr{T}''(T)$, so we may find $\varphi \in \mathrm{Hom}_B(\Omega(g),\mathscr{I}(T))$ such that $\varphi + f_*\widetilde{h} = t$ (where the sum denotes the action of $\mathrm{Hom}_B(\Omega(g),\mathscr{I}(T))$ on its torsor $\mathscr{T}''$). Then we may write $\varphi = \psi \circ df$ for some $\psi : \Omega(g\circ f) \to \mathscr{I}(Y)$, and it follows easily that $\psi + \widetilde{h}$ lies in $\mathscr{T}(T)$. Finally, if df is an isomorphism, we have $\Omega(f) = 0$, hence $\mathscr{T}(T)$ contains exactly one element. □

Proposition 12.3.34. *Let R be a ring, $\varphi : P \to Q$ a morphism of finitely generated monoids, such that* $\mathrm{Ker}\,\varphi^{\mathrm{gp}}$ *and the torsion subgroup of* $\mathrm{Coker}\,\varphi^{\mathrm{gp}}$ *(resp.* $\mathrm{Ker}\,\varphi^{\mathrm{gp}}$ *and* $\mathrm{Coker}\,\varphi^{\mathrm{gp}}$*) are finite groups whose orders are invertible in R. Then, the induced morphism*

$$\mathrm{Spec}(R,\varphi) : \mathrm{Spec}(R,Q) \to \mathrm{Spec}(R,P)$$

is smooth (resp. étale).

Proof. To ease notation, set

$$f := \mathrm{Spec}(R,\varphi) \qquad (X,\underline{M}) := \mathrm{Spec}(R,Q) \qquad (Y,\underline{N}) := \mathrm{Spec}(R,P).$$

Clearly f is finitely presented. We have to show that, for every commutative diagram like (12.3.28) with i an exact nilpotent immersion of fine log schemes, there is, locally on T_τ at least one morphism (resp. a unique morphism) $h : (T,\underline{L}) \to (X,\underline{M})$ such that $f \circ h = h \circ i$.

Let $\mathscr{I} := \mathrm{Ker}(\mathscr{O}_T \to i_*\mathscr{O}_{T'})$; by considering the $\mathscr{I}$-adic filtration on $\mathscr{O}_T$, we reduce easily to the case where $\mathscr{I}^2 = 0$, and then we may embed $\mathscr{I}$ in $\underline{L}$ via the morphism :

$$\mathscr{I} \to \mathscr{O}_T^\times \subset \underline{L} \qquad x \mapsto 1 + x.$$

(Here $\mathscr{I}$ is regarded as a sheaf of abelian groups, via its addition law.) Since i is exact, the natural morphism $\underline{L}/\mathscr{I} \to i_*\underline{L}'$ is an isomorphism, whence a commutative diagram :

$$\begin{array}{ccc} \underline{L} & \xrightarrow{\log i} & i_*\underline{L}' \\ \downarrow & & \downarrow \\ \underline{L}^{\mathrm{gp}} & \xrightarrow{(\log i)^{\mathrm{gp}}} & i_*(\underline{L}')^{\mathrm{gp}} \simeq \underline{L}^{\mathrm{gp}}/\mathscr{I} \end{array} \tag{12.3.35}$$

and since $\underline{L}$ is integral, one sees easily that (12.3.35) is cartesian (it suffices to consider the stalks over the τ-points).

• On the other hand, suppose first that both $\mathrm{Ker}\,\varphi^{\mathrm{gp}}$ and $\mathrm{Coker}\,\varphi^{\mathrm{gp}}$ are finite groups whose order is invertible in R, hence in $\mathscr{I}$; then a standard diagram chase shows that we may find a unique map $g : P_T^{\mathrm{gp}} \to L^{\mathrm{gp}}$ of abelian sheaves that fits into a commutative diagram :

$$\begin{array}{ccccc} Q_T^{\mathrm{gp}} & \longrightarrow & t^*\underline{N}^{\mathrm{gp}} & \xrightarrow{(\log t)^{\mathrm{gp}}} & \underline{L}^{\mathrm{gp}} \\ {\scriptstyle \varphi_T^{\mathrm{gp}}}\downarrow & & {\scriptstyle g}\nearrow & & \downarrow{\scriptstyle (\log i)^{\mathrm{gp}}} \\ P_T^{\mathrm{gp}} & \longrightarrow & i_*s^*\underline{M}^{\mathrm{gp}} & \xrightarrow{i_*(\log s)^{\mathrm{gp}}} & i_*(\underline{L}')^{\mathrm{gp}}. \end{array} \tag{12.3.36}$$

• More generally, we may write : $\mathrm{Coker}\,\varphi^{\mathrm{gp}} \simeq G \oplus H$, where H is a finite group with order invertible in R, and G is a free abelian group of finite rank. The direct summand G lifts to a direct summand $G' \subset P^{\mathrm{gp}}$. Extend φ^{gp} to a map $\psi : Q^{\mathrm{gp}} \oplus G' \to P^{\mathrm{gp}}$, by the rule : $(x, g) \mapsto \varphi^{\mathrm{gp}}(x) \cdot g$. Given any τ-point ξ of T, we may extend the morphism $Q^{\mathrm{gp}} = Q^{\mathrm{gp}}_{T,\xi} \to \underline{L}^{\mathrm{gp}}_\xi$ in $(12.3.36)_\xi$, to a map $\omega : Q^{\mathrm{gp}} \oplus G' \to \underline{L}^{\mathrm{gp}}_\xi$ whose composition with $(\log i)^{\mathrm{gp}}_\xi$ agrees with the composition of ψ and the bottom map $P^{\mathrm{gp}} = P^{\mathrm{gp}}_{T,\xi} \to i_*(\underline{L}')^{\mathrm{gp}}_\xi$ of $(12.3.36)_\xi$. By the usual arguments, ω extends to a map of abelian sheaves $\vartheta : (Q^{\mathrm{gp}} \oplus G')_U \to (\underline{L}^{\mathrm{gp}})_{|U}$ on some neighborhood $U \to T$ of ξ, and if U is small enough, the composition $(\log i)^{\mathrm{gp}}_{|U} \circ \vartheta$ agrees with the composition of ψ_U and the bottom map $\beta : P_U^{\mathrm{gp}} \to i_*(\underline{L}'^{\mathrm{gp}})_{|U}$ of $(12.3.36)_{|U}$. We may then replace T by U, and since $\mathrm{Ker}\,\psi = \mathrm{Ker}\,\varphi^{\mathrm{gp}}$, and $\mathrm{Coker}\,\psi = H$, the same diagram chase as in the foregoing shows that we may again find a morphism $g : P_T^{\mathrm{gp}} \to \underline{L}^{\mathrm{gp}}$ fitting into a commutative diagram :

$$\begin{array}{ccc} (Q^{\mathrm{gp}} \oplus G')_T & \xrightarrow{\vartheta} & \underline{L}^{\mathrm{gp}} \\ {\scriptstyle \psi_T}\downarrow & {\scriptstyle g}\nearrow & \downarrow{\scriptstyle (\log i)^{\mathrm{gp}}} \\ P_T^{\mathrm{gp}} & \xrightarrow{\beta} & i_*\underline{L}'^{\mathrm{gp}} \end{array}$$

In either case, in view of (12.3.35), the morphisms

$$P_T \to P_T^{\mathrm{gp}} \xrightarrow{g} \underline{L}^{\mathrm{gp}} \qquad \text{and} \qquad P_T \to i_*s^*\underline{M} \xrightarrow{i_* \log s} i_*\underline{L}'$$

determine a unique morphism $P_T \to \underline{L}$, which induces a morphism of log schemes $(T, \underline{L}) \to (X, \underline{M})$ with the sought property. □

Theorem 12.3.37. *Let $f : (X, \underline{M}) \to (Y, \underline{N})$ be a morphism of fine log schemes. Assume we are given a fine chart $\beta : Q_Y \to \underline{N}$ of $\underline{N}$. Then the following conditions are equivalent :*

(a) *f is smooth (resp. étale).*

(b) *There exist a covering family $(g_\lambda : U_\lambda \to X \mid \lambda \in \Lambda)$ in $X_{\text{ét}}$, and for every $\lambda \in \Lambda$, a fine chart $(\beta, (P_\lambda)_{U_\lambda} \to g_\lambda^*\underline{M}, \varphi_\lambda : Q \to P_\lambda)$ of the induced morphism of log schemes*

$$f_{|U_\lambda} := (f \circ g_\lambda, g_\lambda^* \log f) : (U_\lambda, g_\lambda^*\underline{M}) \to (Y, \underline{N})$$

such that :

(i) $\operatorname{Ker}\varphi_\lambda^{\mathrm{gp}}$ *and the torsion subgroup of* $\operatorname{Coker}\varphi_\lambda^{\mathrm{gp}}$ *(resp.* $\operatorname{Ker}\varphi_\lambda^{\mathrm{gp}}$ *and* $\operatorname{Coker}\varphi_\lambda^{\mathrm{gp}}$*) are finite groups of orders invertible in* $\mathscr{O}_{U_\lambda}$.
(ii) *The natural morphism of* Y*-schemes* $p_\lambda : U_\lambda \to Y \times_{\operatorname{Spec}\mathbb{Z}[Q]} \operatorname{Spec}\mathbb{Z}[P_\lambda]$ *is étale.*

Proof. Suppose first that $\tau = \text{ét}$, so $\underline{M}$ and $\underline{N}$ are log structures on étale sites. Then the log structure $g_\lambda^*\underline{M}$ on $(U_\lambda)_{\text{ét}}$ is just the restriction of $\underline{M}$, and $g_\lambda^* \log f$ is the restriction of $\log f$ to $(U_\lambda)_{\text{ét}}$. In case $\tau = \text{Zar}$, the log structure $g_\lambda^*\underline{M}$ can be described as follows. Form the log scheme $(X, \underline{M}') := \widetilde{u}_X^*(X, \underline{M})$ (notation of (12.2.2)), take the restriction $\underline{M}'_{|U_\lambda}$ of $\underline{M}'$ to $(U_\lambda)_{\text{ét}}$, and push forward to the Zariski site to obtain $\widetilde{u}_{X*}(\underline{M}'_{|U_\lambda}) = g_\lambda^*\underline{M}$ (by proposition 12.2.3(ii)). Since f is smooth (resp. étale) if and only if $\widetilde{u}^*f$ is (corollary 12.3.27(ii),(iii)), we conclude that the assertion concerning f holds if and only if the corresponding assertion for $\widetilde{u}^*f$ does. Hence, it suffices to consider the case of log structures on étale sites. Set $S := \operatorname{Spec}\mathbb{Z}[Q]$.

(b)⇒(a): Taking into account lemma 12.2.18(i), we deduce a commutative diagram of log schemes :

$$\begin{array}{ccccc}
(U_\lambda, \underline{M}_{|U_\lambda}) & \xrightarrow{\sim} & \operatorname{Spec}(\mathbb{Z}, P_\lambda) \times_{\operatorname{Spec}\mathbb{Z}[P_\lambda]} U_\lambda & \xrightarrow{p_\lambda} & \operatorname{Spec}(\mathbb{Z}, P_\lambda) \times_{\operatorname{Spec}\mathbb{Z}[Q]} Y \\
{\scriptstyle g_\lambda}\downarrow & & & & \downarrow{\scriptstyle \pi_\lambda} \\
(X, \underline{M}) & \xrightarrow{f} & (Y, \underline{N}) & \xrightarrow{\sim} & \operatorname{Spec}(\mathbb{Z}, Q) \times_{\operatorname{Spec}\mathbb{Z}[Q]} Y.
\end{array}$$

It follows by corollary 12.3.27(i) (resp. by propositions 12.3.24(ii) and 12.3.34) that p_λ (resp. π_λ) is smooth. Hence $f \circ g_\lambda$ is smooth, by proposition 12.3.24(i). Finally, f is smooth, by proposition 12.3.24(iii).

(a)⇒(b): Suppose that f is smooth, and fix a geometric point ξ of X. Since $(12.3.18)_\xi$ is a surjection, we may find elements $t_1, \dots, t_r \in \underline{M}_\xi$ such that $(d\log t_i \mid i = 1, \dots, r)$ is a basis of the free $\mathscr{O}_{X,\xi}$-module $\Omega^1_{X/Y}(\log \underline{M}/\underline{N})_\xi$ (proposition 12.3.26(ii.a)). Moreover, the kernel of $(12.3.18)_\xi$ is generated by sections of the form :

- $1 \otimes \log a$ where $a \in N' := \operatorname{Im}(\log f_\xi : \underline{N}_{f(\xi)} \to \underline{M}_\xi)$
- $\sum_{j=1}^s \alpha(m_i) \otimes \log m_i$ where $m_1, \dots, m_s \in \underline{M}_\xi$ and $\sum_{j=1}^s d\alpha(m_j) = 0$ in $\Omega^1_{X/Y}$

whence a well-defined $\mathscr{O}_{X,\xi}$-linear map :

$$\Omega^1_{X/Y}(\log \underline{M}/\underline{N})_\xi \to \kappa(\xi) \otimes_\mathbb{Z} (\underline{M}_\xi^{\mathrm{gp}}/(\underline{M}_\xi^\times \cdot N')) \quad : \quad d\log a \mapsto 1 \otimes a. \tag{12.3.38}$$

Consider the map of monoids :

$$\varphi : P_1 := \mathbb{N}^{\oplus r} \oplus Q \to \underline{M}_\xi$$

which is given by the rule : $e_i \mapsto t_i$ on the canonical basis $e_1, \dots, e_r$ of $\mathbb{N}^{\oplus r}$, and on the summand Q it is given by the map $Q \xrightarrow{\beta_\xi} \underline{N}_{f(\xi)} \xrightarrow{\log f_\xi} \underline{M}_\xi$. Since (12.3.38) is a surjection, we see that the same holds for the induced map

$$\kappa(\xi) \otimes_\mathbb{Z} P_1^{\mathrm{gp}} \xrightarrow{\mathbf{1}_{\kappa(\xi)} \otimes_\mathbb{Z} \varphi^{\mathrm{gp}}} \kappa(\xi) \otimes_\mathbb{Z} \underline{M}_\xi^{\mathrm{gp}} \to \kappa(\xi) \otimes_\mathbb{Z} (\underline{M}_\xi^{\mathrm{gp}}/\underline{M}_\xi^\times).$$

It follows that the cokernel of the map $\overline{\varphi} : P_1^{\mathrm{gp}} \to \underline{M}_\xi^{\mathrm{gp}}/\underline{M}_\xi^\times$ induced by φ^{gp}, is a finite group (lemma 12.2.21(i)) annihilated by an integer n which is invertible in $\mathscr{O}_{X,\xi}$. Let $m_1, \dots, m_s \in \underline{M}_\xi^{\mathrm{gp}}$ be finitely many elements, whose images in $\underline{M}_\xi^{\mathrm{gp}}/\underline{M}_\xi^\times$ generate $\operatorname{Coker}\overline{\varphi}$; therefore we may find $u_1, \dots, u_s \in \underline{M}_\xi^\times$, and $x_1, \dots, x_s \in P_1^{\mathrm{gp}}$, such that $m_i^n \cdot u_i = \overline{\varphi}(x_i)$ for every $i \leq s$. However, since $\mathscr{O}_{X,\xi}$ is strictly henselian, $\underline{M}_\xi^\times \simeq \mathscr{O}_{X,\xi}^\times$ is n-divisible, hence we may find $v_1, \dots, v_s$ in $\underline{M}_\xi^\times$ such that $u_i = v_i^n$ for $i = 1, \dots, n$. Define group homomorphisms :

$$\mathbb{Z}^{\oplus s} \xrightarrow{\gamma} \mathbb{Z}^{\oplus s} \oplus P_1^{\mathrm{gp}} \xrightarrow{\delta} \underline{M}_\xi^{\mathrm{gp}}$$

by the rules : $\gamma(e_i) = (-ne_i, x_i)$ and $\delta(e_i, y) = m_i v_i \cdot \varphi(y)$ for every $i = 1, \dots, s$ and every $y \in P_1^{\mathrm{gp}}$. It is easily seen that δ factors through a group homomorphism $h : G := \operatorname{Coker}\gamma \to$

$\underline{M}_\xi$; moreover the natural map $P_1^{\mathrm{gp}} \to G$ is injective, and its cokernel is annihilated by n; furthermore, the induced map $G \to \underline{M}_\xi^\sharp$ is surjective. Let $P := h^{-1}\underline{M}_\xi$. Then, the natural map $Q^{\mathrm{gp}} \to P^{\mathrm{gp}}$ is injective, and the torsion subgroup of $P^{\mathrm{gp}}/Q^{\mathrm{gp}}$ is annihilated by n. We deduce that the rule : $x \mapsto d\log h(x)$ for every $x \in P^{\mathrm{gp}}$, induces an isomorphism :

$$\mathscr{O}_{X,\xi} \otimes_{\mathbb{Z}} (P^{\mathrm{gp}}/Q^{\mathrm{gp}}) \xrightarrow{\sim} \Omega^1_{X/Y}(\log \underline{M}/\underline{N})_\xi. \tag{12.3.39}$$

It follows that we may find an étale neighborhood $U \to X$ of ξ, such that (12.3.39) extends to an isomorphism of $\mathscr{O}_U$-modules :

$$\mathscr{O}_U \otimes_{\mathbb{Z}} (P^{\mathrm{gp}}/Q^{\mathrm{gp}}) \xrightarrow{\sim} \Omega^1_{U/Y}(\log \underline{M}_{|U}/\underline{N}). \tag{12.3.40}$$

Next, proposition 12.1.30 says that, after replacing U by a smaller étale neighborhood of ξ, the restriction $h_{|P} : P \to \underline{M}_\xi$ extends to a chart $P_U \to \underline{M}_{|U}$, whence a strict morphism

$$p : (U, \underline{M}_{|U}) \to (Y', P^{\log}_{Y'}) := (Y, \underline{N}) \times_{\mathrm{Spec}(\mathbb{Z},Q)} \mathrm{Spec}(\mathbb{Z}, P).$$

as sought. Taking into account corollary 12.3.27(i), it remains only to show :

Claim 12.3.41. p is étale.

Proof of the claim. By proposition 12.3.13 and example 12.3.19, we have natural isomorphisms

$$\Omega^1_{Y'/Y}(\log P^{\log}_{Y'}/\underline{N}) \xrightarrow{\sim} \mathscr{O}_{Y'} \otimes_{\mathbb{Z}} (P^{\mathrm{gp}}/Q^{\mathrm{gp}}).$$

In view of (12.3.40), it follows that the map

$$dp : p^*\Omega^1_{Y'/Y}(\log P^{\log}_{Y'}/\underline{N}) \to \Omega^1_{U/Y}(\log \underline{M}_{|U}/\underline{N})$$

is an isomorphism, and then the claim follows from proposition 12.3.32. □

Corollary 12.3.42. *Keep the notation of theorem* 12.3.37. *Suppose that f is a smooth morphism of fs log schemes, and that Q is fine, sharp and saturated. Then there exist a covering family $(g_\lambda : U_\lambda \to X)$ in $X_{\mathrm{ét}}$, and fine and saturated charts $(\beta, (P_\lambda)_{U_\lambda} \to g_\lambda^*\underline{M}, \varphi_\lambda : Q \to P_\lambda)$ of $f_{|U_\lambda}$ fulfilling conditions* (b.i) *and* (b.ii) *of the theorem, and such that moreover φ_λ is injective, and $P_\lambda^\times$ is a torsion-free abelian group, for every $\lambda \in \Lambda$.*

Proof. Notice that, under the stated assumptions, Q^{gp} is a torsion-free abelian group; hence theorem 12.3.37 already implies the existence of a covering family $(g_\lambda : U_\lambda \to X)$ in $X_{\mathrm{ét}}$, and of fine charts $(\beta, \omega'_\lambda : (P'_\lambda)_{U_\lambda} \to g_\lambda^*\underline{M}, \varphi'_\lambda : Q \to P'_\lambda)$ such that φ'_λ is injective and $\mathrm{Coker}(\varphi'_\lambda)^{\mathrm{gp}}$ is a finite group of order invertible in $\mathscr{O}_{U_\lambda}$, for every $\lambda \in \Lambda$. Since $g_\lambda^*\underline{M}$ is saturated (lemma 12.1.18(i)), it is clear that ω'_λ factors through a morphism $(P'_\lambda)^{\mathrm{sat}}_{U_\lambda} \to g_\lambda^*\underline{M}$ of pre-log structures, which is again a chart, so we may assume that P'_λ is fine and saturated, for every $\lambda \in \Lambda$ (corollary 6.4.1(ii)), in which case we may find an isomorphism of monoids $P'_\lambda = P_\lambda \times G$, where $P_\lambda^\times$ is torsion-free, and G is a finite group (lemma 6.2.10). Let d be the order of $\mathrm{Coker}(\varphi'_\lambda)^{\mathrm{gp}}$, and denote by φ_λ the composition of φ'_λ and the projection $P'_\lambda \to P_\lambda$; since Q^{gp} is a torsion-free abelian group, we deduce a short exact sequence :

$$0 \to G \to \mathrm{Coker}(\varphi'_\lambda)^{\mathrm{gp}} \to \mathrm{Coker}\,\varphi_\lambda^{\mathrm{gp}} \to 0 \tag{12.3.43}$$

and notice that φ_λ is also injective. We may assume that U_λ and Y are affine, say $U_\lambda = \mathrm{Spec}\, B_\lambda$ and $Y = \mathrm{Spec}\, A$, and since d is invertible in $\mathscr{O}_{U_\lambda}$, we reduce easily – via base change by a finite morphism $Y' \to Y$ – to the case where A contains the subgroup $\boldsymbol{\mu}_d \subset \overline{\mathbb{Q}}^\times$ of d-th power roots of 1. The chart ω'_λ determines a morphism of monoids $P'_\lambda \to B_\lambda$, and the map $f^\sharp : A \to B_\lambda$ factors through the natural ring homomorphism

$$A \to A \otimes_{R[Q]} R[P'_\lambda] \xrightarrow{\sim} A \otimes_{R[Q]} (R[P_\lambda] \otimes_R R[G]) \qquad \text{where} \qquad R := \mathbb{Z}[d^{-1}, \boldsymbol{\mu}_d].$$

On the other hand, let $\Gamma := \mathrm{Hom}_{\mathbb{Z}}(G, \boldsymbol{\mu}_d)$; then we have a natural decomposition

$$R[G] \simeq \prod_{\chi\in\Gamma} e_\chi R[G]$$

where e_χ is the idempotent of $R[G]$ defined as in (14.6.11) (cp. the proof of theorem 14.6.23(i)); each factor is a ring isomorphic to R, whence a corresponding decomposition of U_λ as a disjoint union of Y-schemes $U_\lambda = \coprod_{\chi\in\Gamma} U_{\lambda,\chi}$. We are then further reduced to the case where $U_\lambda = U_{\lambda,\chi}$ for some character χ of G. In view of (12.3.43), it is easily seen that the composition

$$Q^{\mathrm{gp}} \xrightarrow{(\varphi'_\lambda)^{\mathrm{gp}}} (P'_\lambda)^{\mathrm{gp}} \to G \xrightarrow{\chi} \boldsymbol{\mu}_d$$

extends to a well defined group homomorphism $\overline{\chi} : P_\lambda^{\mathrm{gp}} \to \boldsymbol{\mu}_d$, whence a map $\overline{\chi}_{U_\lambda} : P_{\lambda,U_\lambda} \to \mu_{d,U_\lambda} \subset g_\lambda^*\underline{M}$ of sheaves on $U_{\lambda,\tau}$. Define $\omega_\lambda : P_{\lambda,U_\lambda} \to g_\lambda^*\underline{M}$ by the rule : $s \mapsto \omega'_\lambda(s)\cdot\overline{\chi}_{U_\lambda}(s)$ for every local section s of P_{λ,U_λ}. It is easily seen that ω_λ is again a chart for $g_\lambda^*\underline{M}$ (*e.g.* one may apply lemma 12.1.4). Lastly, a direct inspection shows that $(\beta, \omega_\lambda, \varphi_\lambda)$ is a chart of $f_{|U_\lambda}$ with the sought properties. □

12.3.44. Let $(Y_i \mid i \in I)$ be a cofiltered system of quasi-compact and quasi-separated schemes, with affine transition morphisms, and suppose that 0 is an initial object of the indexing category I. Suppose also that $g_0 : X_0 \to Y_0$ is a finitely presented morphism of schemes. Let $X_i := X_0 \times_{Y_0} Y_i$ for every $i \in I$, and denote $g_i : X_i \to Y_i$ the induced morphism. Let also $g : X \to Y$ be the limit of the family of morphisms $(g_i \mid i \in I)$.

Corollary 12.3.45. *In the situation of* (12.3.44)*, suppose that* $(g, \log g) : (X, \underline{M}) \to (Y, \underline{N})$ *is a smooth morphism of fine log schemes. Then there exist* $i \in I$*, and a smooth morphism* $(g_i, \log g_i) : (X_i, \underline{M}_i) \to (Y_i, \underline{N}_i)$ *of fine log schemes, such that* $\log g = \pi_i^* \log g_i$.

Proof. First, using corollary 12.2.35, we may find $i \in I$ such that $(g, \log g)$ descends to a morphism $(g_i, \log g_i)$ of log schemes with coherent log structures. After replacing I by I/i, we may then suppose that $i = 0$, in which case we set $(X_i, \underline{M}_i) := X_i \times (X_0, \underline{M}_0)$, and define likewise $(Y_i, \underline{N}_i)$ for every $i \in I$.

Next, arguing as in the proof of corollary 12.2.36(ii), we may assume that $\underline{N}_0$ admits a fine chart. In this case, also $\underline{N}$ admits a fine chart, and then we my find a covering family $\mathscr{U} := (U_\lambda \to X \mid \lambda \in \Lambda)$ for X_τ, such that the induced morphism $(U_\lambda, \underline{M}_{|U_\lambda}) \to (Y, \underline{N})$ admits a chart fulfilling conditions (i) and (ii) of theorem 12.3.37. Moreover, under the current assumptions, X is quasi-compact, hence we may assume that Λ is a finite set, in which case there exists $i \in I$ such that $\mathscr{U}$ descends to a covering family $(U_{i,\lambda} \to X_i \mid \lambda \in \Lambda)$ for $X_{i,\tau}$ (claim 12.2.29(ii)), and as usual, we may then reduce to the case where $i = 0$. It then suffices to show that there exists $i \in I$ such that the induced morphism $U_{0,\lambda} \times_{X_0} (X_i, \underline{M}_i) \to (Y_i, \underline{N}_i)$ is smooth (proposition 12.3.24(iii)). Thus, we may replace the system $(X_i \mid i \in I)$ by the system of schemes $(U_{0,\lambda} \times_{X_0} X_i \mid i \in I)$, and assume from start that $(g, \log g)$ admits a fine chart fulfilling conditions (i) and (ii) of theorem 12.3.37. In this case, corollary 12.2.36(i) and [65, Ch.IV, Prop.17.7.8(ii)] imply more precisely that there exists $i \in I$ such that the morphism $(X_i, \underline{M}_i) \to (Y_i, \underline{N}_i)$ fulfills conditions (i) and (ii) of theorem 12.3.37, whence the contention. □

12.4. **Logarithmic blow up of a coherent ideal.** This section introduces the logarithmic version of the scheme-theoretic blow up of a coherent ideal, which will be exhibited as the logarithmic homogeneous spectrum of a certain graded algebra, naturally attached to any sheaf of ideals in a log structure.

12.4.1. We shall consider first the logarithmic counterparts of the notions introduced in section 10.6. To begin with, let X be any scheme, N a monoid, and $\underline{P}$ a (commutative) N-graded monoid of the topos X_τ (see definition 4.8.8). Notice that $\underline{P}^\times = \coprod_{n\in N}(\underline{P}^\times \cap \underline{P}_n)$, hence the sheaf of invertible sections of a N-graded monoid on X is a N-graded abelian sheaf.

Definition 12.4.2. Let X be a scheme, and $\beta : \underline{M} \to \mathscr{O}_X$ a log structure on X_τ.

(i) A $\mathbb{N}$-*graded* $\mathscr{O}_{(X,\underline{M})}$-*algebra* is a datum $(\mathscr{A}, \underline{P}, \alpha, \beta_\mathscr{A})$ consisting of a $\mathbb{N}$-graded $\mathscr{O}_X$-algebra $\mathscr{A} := \oplus_{n\in\mathbb{N}}\mathscr{A}_n$ (on the site X_τ), a graded monoid $\underline{P}$ on X_τ, and a commutative diagram :

$$\begin{CD} \underline{M} @>\alpha>> \underline{P} \\ @V\beta VV @VV\beta_\mathscr{A}V \\ \mathscr{O}_X @>>> \mathscr{A} \end{CD}$$

where $\beta_\mathscr{A}$ restricts to a morphism of graded monoids $\underline{P} \to \coprod_{n\in\mathbb{N}} \mathscr{A}_n$ (and the composition law on the target is induced by the multiplication law of $\mathscr{A}$), α is a morphism of monoids $\underline{M} \to (\underline{P})_0$, and the bottom map is the natural morphism $\mathscr{O}_X \to \mathscr{A}_0$. We say that the $\mathbb{N}$-graded $\mathscr{O}_{(X,\underline{M})}$-algebra $(\mathscr{A}, \underline{P}, \alpha, \beta_\mathscr{A})$ is *quasi-coherent*, if $\mathscr{A}$ is a quasi-coherent $\mathscr{O}_X$-algebra.

(ii) A *morphism* $(g, \log g) : (\mathscr{A}, \underline{P}, \alpha, \beta_\mathscr{A}) \to (\mathscr{A}', \underline{P}', \alpha', \beta'_\mathscr{A})$ *of* $\mathbb{N}$-*graded* $\mathscr{O}_{(X,\underline{M})}$-*algebras* is a commutative diagram :

$$\begin{CD} \underline{P} @>\log g>> \underline{P}' \\ @V\beta_\mathscr{A} VV @VV\beta'_\mathscr{A}V \\ \mathscr{A} @>g>> \mathscr{A}' \end{CD}$$

where $\log g$ is a morphism of $\mathbb{N}$-graded monoid such that $\log g \circ \alpha = \alpha'$, and g is a morphism of $\mathscr{O}_Z$-algebras.

12.4.3. Let M be a monoid, S an M-module; we say that an element $s \in S$ is *invertible*, if the translation map $M \to S : m \mapsto m \cdot s$ (for all $m \in M$) is an isomorphism. It is easily seen that the subset $S^\times$ consisting of all invertible elements of S, is naturally an $M^\times$-module.

Let $\underline{M}$ be a sheaf of monoids on X_τ, and $\mathscr{N}$ an $\underline{M}$-module; by restriction of scalars, $\mathscr{N}$ is naturally an $\underline{M}^\times$-module. We define the $\underline{M}^\times$-submodule $\mathscr{N}^\times \subset \mathscr{N}$, by the rule :

$$\mathscr{N}^\times(U) := \mathscr{N}(U)^\times \qquad \text{for every object } U \text{ of } X_\tau.$$

Conversely, for any $\underline{M}^\times$-module $\mathscr{P}$, the extension of scalars $\mathscr{N} \otimes_{\underline{M}^\times} \underline{M}$ defines a functor $\underline{M}^\times\text{-}\mathbf{Mod} \to \underline{M}\text{-}\mathbf{Mod}$. It is easily seen that the latter restricts to an equivalence from the full subcategory $\underline{M}^\times\text{-}\mathbf{Inv}$ of $\underline{M}^\times$-torsors to the subcategory $(\underline{M}\text{-}\mathbf{Inv})^\times$ of $\underline{M}\text{-}\mathbf{Mod}$ whose objects are all invertible $\underline{M}$-modules, and whose morphisms are the isomorphisms of $\underline{M}$-modules (see definition 4.8.6(iv)); the functor $\mathscr{N} \mapsto \mathscr{N}^\times$ provides a quasi-inverse $(\underline{M}\text{-}\mathbf{Inv})^\times \to \underline{M}^\times\text{-}\mathbf{Inv}$.

Especially, if $(X, \underline{M})$ is a log scheme, we see that the category of invertible $\underline{M}$-modules is equivalent to that of invertible $\mathscr{O}_X^\times$-modules, hence also to that of invertible $\mathscr{O}_X$-modules.

If $\varphi : (Z, \underline{N}) \to (X, \underline{M})$ is a morphism of log schemes, and $\mathscr{N}$ a $\underline{M}$-module, we let :

$$\varphi^*\mathscr{N} := \varphi^{-1}\mathscr{N} \otimes_{\varphi^{-1}\underline{M}} \underline{N}. \tag{12.4.4}$$

Clearly, $\varphi^*\mathscr{N}$ is an invertible $\underline{N}$-module, whenever $\mathscr{N}$ is an invertible $\underline{M}$-module.

12.4.5. Keep the notation of definition 12.4.2(i); by faithfully flat descent, the restriction of $\mathscr{A}$ to the Zariski site of X is again a quasi-coherent $\mathscr{O}_X$-algebra, which we denote again by $\mathscr{A}$. We may then set $Y := \mathrm{Proj}\,\mathscr{A}$, and let $\pi : Y \to X$ be the natural morphism. The composition of $\pi^{-1}\beta_{\mathscr{A}}$ and the morphism (10.6.24), yields a map on the site Y_τ :

$$\pi^{-1}\underline{P}_n \to \mathscr{O}_Y(n) \qquad \text{for every } n \in \mathbb{N}. \tag{12.4.6}$$

Set $\mathscr{O}_Y(\bullet) := \coprod_{n\in\mathbb{Z}} \mathscr{O}_Y(n)$; it is easily seen that the morphisms (10.6.21) induce a natural $\mathbb{Z}$-graded monoid structure on $\mathscr{O}_Y(\bullet)$, and the coproduct of the maps (12.4.6) amounts to a morphism of graded monoids :

$$\omega_\bullet : \pi^{-1}\underline{P} \to \mathscr{O}_Y(\bullet).$$

We let $\underline{Q}$ be the push-out in the cocartesian diagram :

$$\begin{array}{ccc} \omega_\bullet^{-1}(\mathscr{O}_Y(\bullet)^\times) & \longrightarrow & \pi^{-1}\underline{P} \\ \downarrow & & \downarrow \\ \mathscr{O}_Y(\bullet)^\times & \longrightarrow & \underline{Q}. \end{array} \tag{12.4.7}$$

Clearly $\underline{Q}$ is naturally a $\mathbb{Z}$-graded monoid, in such a way that all the arrows in (12.4.7) are morphisms of $\mathbb{Z}$-graded monoids. For every $n \in \mathbb{Z}$, let $\underline{Q}_n$ be the degree n subsheaf of $\underline{Q}$; the map $\omega_\bullet$ and the natural inclusion $\mathscr{O}_Y(\bullet)^\times \to \mathscr{O}_Y(\bullet)$ determine a unique morphism $\underline{Q} \to \mathscr{O}_Y(\bullet)$, whose restriction in degree zero is a pre-log structure :

$$\beta^\sim_{\mathscr{A}} : \underline{Q}_0 \to \mathscr{O}_Y.$$

Clearly α induces a unique morphism $\alpha^\sim : \pi^{-1}\underline{M} \to \underline{Q}_0$, such that the diagram of monoids :

$$\begin{array}{ccc} \pi^{-1}\underline{M} & \xrightarrow{\alpha^\sim} & \underline{Q}_0 \\ {\scriptstyle \pi^{-1}\beta}\downarrow & & \downarrow{\scriptstyle \beta^\sim_{\mathscr{A}}} \\ \pi^{-1}\underline{\mathscr{O}}_X & \xrightarrow{\pi^\natural} & \mathscr{O}_Y \end{array}$$

commutes. Denote by $\underline{P}^\sim$ the log structure associated to $\beta^\sim_{\mathscr{A}}$; the *homogeneous spectrum* of the quasi-coherent $\mathbb{N}$-graded algebra $(\mathscr{A}, \underline{P}, \alpha, \beta_{\mathscr{A}})$ is defined as the $(X, \underline{M})$-scheme :

$$\mathrm{Proj}(\mathscr{A}, \underline{P}) := (Y, \underline{P}^\sim).$$

We also let :

$$U_1(\mathscr{A}, \underline{P}) := U_1(\mathscr{A}) \times_Y \mathrm{Proj}(\mathscr{A}, \underline{P}).$$

Furthermore, for every $n \in \mathbb{Z}$ we have a natural morphism of $\underline{Q}_0$-monoids :

$$\underline{Q}_0 \otimes_{\mathscr{O}_Y^\times} \mathscr{O}_Y(n)^\times \to \underline{Q}_n \tag{12.4.8}$$

and it is easily seen that $(12.4.8)_{|U_1(\mathscr{A})}$ is an isomorphism. We set :

$$\underline{P}^\sim(n) := (\underline{P}^\sim \otimes_{\underline{Q}_0} \underline{Q}_n)_{|U_1(\mathscr{A})} \qquad \text{for every } n \in \mathbb{Z}.$$

Hence (12.4.8) induces a natural isomorphism :

$$(\underline{P}^\sim \otimes_{\mathscr{O}_Y^\times} \mathscr{O}_Y(n)^\times)_{|U_1(\mathscr{A})} \xrightarrow{\sim} \underline{P}^\sim(n). \tag{12.4.9}$$

Especially, $\underline{P}^\sim(n)$ is an invertible $\underline{P}^\sim_{|U_1(\mathscr{A})}$-module, for every $n \in \mathbb{Z}$. From (12.4.9), we also deduce natural isomorphisms of $\underline{P}^\sim_{|U_1(\mathscr{A})}$-modules :

$$\underline{P}^\sim(n) \otimes_{\underline{P}^\sim} \underline{P}^\sim(m) \xrightarrow{\sim} \underline{P}^\sim(n+m) \qquad \text{for every } n, m \in \mathbb{Z} \tag{12.4.10}$$

and of $\mathscr{O}_{U_1(\mathscr{A})}$-modules :

$$\underline{P}^\sim(n) \otimes_{\underline{P}^\sim} \mathscr{O}_{U_1(\mathscr{A})} \xrightarrow{\sim} \mathscr{O}_Y(n)_{|U_1(\mathscr{A})} \qquad \text{for every } n \in \mathbb{Z}. \tag{12.4.11}$$

Additionally, the morphism $\pi^{-1}\underline{P}_n \to \underline{Q}_n$ deduced from (12.4.7), yields a natural map of $\underline{P}^\sim_{|U_1(\mathscr{A})}$-modules :

(12.4.12) $$\lambda_n : (\pi^*\underline{P}_n)_{|U_1(\mathscr{A})} \to \underline{P}^\sim(n) \qquad \text{for every } n \in \mathbb{N}.$$

Example 12.4.13. Let $(Z, \gamma : \underline{N} \to \mathscr{O}_Z)$ be a log scheme, $\mathscr{L}$ an invertible $\underline{N}$-module, and set :

$$\beta_{\mathscr{A}(\mathscr{L})} := \mathrm{Sym}^\bullet_{\underline{N}}\mathscr{L} \otimes_{\underline{N}} \gamma : \mathrm{Sym}^\bullet_{\underline{N}}\mathscr{L} \to \mathscr{A}(\mathscr{L}) := \mathrm{Sym}^\bullet_{\mathscr{O}_Z}(\mathscr{L} \otimes_{\underline{N}} \mathscr{O}_Z)$$

which is a morphisms of $\mathbb{N}$-graded monoids (notation of example 4.8.10). Clearly $\mathscr{A}(\mathscr{L})$ is also a $\mathbb{N}$-graded quasi-coherent $\mathscr{O}_Z$-algebra. Denote also :

$$\alpha_{\mathscr{L}} : \underline{N} \to \mathrm{Sym}^\bullet_{\underline{N}}\mathscr{L}$$

the natural morphism that identifies $\underline{N}$ to $\mathrm{Sym}^0_{\underline{N}}\mathscr{L}$; then the datum

$$(\mathscr{A}(\mathscr{L}), \mathrm{Sym}^\bullet_{\underline{N}}\mathscr{L}, \alpha_{\mathscr{L}}, \beta_{\mathscr{A}(\mathscr{L})})$$

is a quasi-coherent $\mathscr{O}_{(Z,\underline{N})}$-algebra, and a direct inspection of the definitions shows that the induced morphism of log schemes :

(12.4.14) $$\pi_{(Z,\underline{N})} : \mathbb{P}(\mathscr{L}) := \mathrm{Proj}(\mathscr{A}(\mathscr{L}), \mathrm{Sym}^\bullet_{\underline{N}}\mathscr{L}) \to (Z, \underline{N})$$

is an isomorphism. Furthermore, we have natural isomorphisms as in (10.6.34) :

$$\pi^*_{(Z,\underline{N})}(\mathscr{L}^{\otimes n} \otimes_{\underline{N}} \mathscr{O}_Z) \xrightarrow{\sim} \mathscr{O}_{\mathbb{P}(\mathscr{L})}(n) \qquad \text{for every } n \in \mathbb{Z}.$$

Let $\underline{P}^\sim_{\mathscr{L}} \to \mathscr{O}_{\mathbb{P}(\mathscr{L})}$ be the log structure of $\mathbb{P}(\mathscr{L})$; there follows a natural identification :

(12.4.15) $$\pi^*_{(Z,\underline{N})}\mathscr{L}^{\otimes n} \xrightarrow{\sim} \underline{P}^\sim_{\mathscr{L}} \otimes_{\mathscr{O}^\times_{\mathbb{P}(\mathscr{L})}} \mathscr{O}_{\mathbb{P}(\mathscr{L})}(n)^\times \xrightarrow{\sim} \underline{P}^\sim_{\mathscr{L}}(n) \qquad \text{for every } n \in \mathbb{Z}$$

where the last isomorphism is (12.4.9), in view of the fact that $U_1(\mathscr{A}(\mathscr{L})) = \mathrm{Proj}\,\mathscr{A}(\mathscr{L})$.

Example 12.4.16. (i) Let $(Z, \underline{N})$ be a log scheme, and $n \in \mathbb{N}$ any integer. We define an $\mathbb{N}$-grading on $\mathbb{N}^{\oplus n}$, by setting

$$\mathrm{gr}^k\mathbb{N}^{\oplus n} := \{a_\bullet := (a_1, \dots, a_n) \mid a_1 + \cdots + a_n = k\} \qquad \text{for every } k \in \mathbb{N}.$$

We then define the $\mathbb{N}$-graded monoid

$$\mathrm{Sym}^\bullet_{\underline{N}}\underline{N}^{\oplus n} := \mathbb{N}^{\oplus n}_Z \times \underline{N}$$

whose $\mathbb{N}$-grading is deduced in the obvious way from the foregoing grading of $\mathbb{N}^{\oplus n}$. The log structure $\gamma : \underline{N} \to \mathscr{O}_Z$ extends naturally to a map of $\mathbb{N}$-graded Z-monoids :

$$\mathrm{Sym}^\bullet_{\underline{N}}\gamma^{\oplus n} : \mathrm{Sym}^\bullet_{\underline{N}}\underline{N}^{\oplus n} \to \mathrm{Sym}^\bullet_{\mathscr{O}_Z}\mathscr{O}_Z^{\oplus n}.$$

Namely, if $e_1, \dots, e_n$ is the canonical basis of the free $\mathscr{O}_Z$-module $\mathscr{O}_Z^{\oplus n}$, then $\mathrm{Sym}^k_{\mathscr{O}_Z}\mathscr{O}_Z^{\oplus n}$ is a free $\mathscr{O}_Z$-module with basis

$$\{e_{a_\bullet} := e_1^{a_1} \cdots e_n^{a_n} \mid a_\bullet \in \mathrm{gr}^k\mathbb{N}^{\oplus n}\}$$

and $\mathrm{Sym}^\bullet_{\underline{N}}\gamma^{\oplus n}$ is given by the rule : $(a_\bullet, x) \mapsto \gamma(x)\cdot e_{a_\bullet}$ for every $a_\bullet \in \mathbb{N}^{\oplus n}$, every τ-open subset of Z, and every section $x \in \underline{N}(U)$. Clearly $\mathrm{Sym}^\bullet_{\underline{N}}\gamma^{\oplus n}$ defines an $\mathbb{N}$-graded $\mathscr{O}_{(Z,\underline{N})}$-algebra

$$\mathrm{Sym}^\bullet_{(\mathscr{O}_Z,\underline{N})}(\mathscr{O}_Z, \underline{N})^{\oplus n} := (\mathrm{Sym}^\bullet_{\mathscr{O}_Z}\mathscr{O}_Z^{\oplus n}, \mathrm{Sym}^\bullet_{\underline{N}}\underline{N}^{\oplus n}) \qquad \text{for every } n \in \mathbb{N}.$$

We set :

$$\mathbb{P}^n_{(Z,\underline{N})} := \mathrm{Proj}\,\mathrm{Sym}^\bullet_{(\mathscr{O}_Z,\underline{N})}(\mathscr{O}_Z, \underline{N})^{\oplus n+1}$$

and we call it the *projective n-dimensional space* over $(Z, \underline{N})$.

(ii) Denote by $\underline{N}^\sim$ the log structure of $\mathbb{P}^n_{(Z,\underline{N})}$, and by $\underline{N}^\sim(k)$ the $\underline{N}^\sim$-modules defined as in (12.4.9), for every $k \in \mathbb{Z}$. By simple inspection we get a commutative diagram of monoids :

$$\begin{array}{ccc} \Gamma(Z, \mathrm{Sym}^k_{\underline{N}} \underline{N}^{\oplus n+1}) & \xrightarrow{\Gamma(Z,\mathrm{Sym}^k_{\underline{N}}\gamma^{\oplus n+1})} & \Gamma(Z, \mathrm{Sym}^k_{\mathscr{O}_Z} \mathscr{O}_Z^{\oplus n+1}) \\ \downarrow & & \downarrow \\ \Gamma(\mathbb{P}^n_{(Z,\underline{N})}, \underline{N}^\sim(k)) & \longrightarrow & \Gamma(\mathbb{P}^n_{(Z,\underline{N})}, \mathscr{O}_{\mathbb{P}^n_{(Z,\underline{N})}}(k)) \end{array} \qquad \text{for every } k \in \mathbb{N}$$

whose right vertical arrow is an isomorphism. Especially, the natural basis of the free $\underline{N}(Z)$-module $\Gamma(Z, \mathrm{Sym}^1_{\underline{N}} \underline{N}^{\oplus n+1}) = \underline{N}(Z)^{\oplus n+1}$ yields a distinguished system of $n+1$ elements

$$\varepsilon_0, \dots, \varepsilon_n \in \Gamma(\mathbb{P}^n_{(Z,\underline{N})}, \underline{N}^\sim(1)).$$

On the other hand, we have as well the distinguished system of global sections

$$T_0, \dots, T_n \in \Gamma(\mathbb{P}^n_{(Z,\underline{N})}, \mathscr{O}_{\mathbb{P}^n_{(Z,\underline{N})}}(1))$$

corresponding to the natural basis of $\Gamma(Z, \mathrm{Sym}^1_{\mathscr{O}_Z} \mathscr{O}_Z^{\oplus n+1}) = \mathscr{O}_Z(Z)^{\oplus n+1}$. For each $i = 0, \dots, n$, the largest open subset $U_i \subset \mathbb{P}^n_{(Z,\underline{N})}$ such that $T_i \in \Gamma(U_i, \mathscr{O}_{\mathbb{P}^n_{(Z,\underline{N})}}(1)^\times)$ is the complement of the hyperplane where T_i vanishes. Moreover, notice that

$$T_i^{-1} T_j \in \underline{N}^\sim(U_i) \qquad \text{for every } i, j = 0, \dots, n.$$

With this notation, the isomorphism (12.4.9) yields the identification :

$$\varepsilon_j = T_i^{-1} T_j \otimes T_i \qquad \text{on } U_i \qquad \text{for every } i, j = 0, \dots, n$$

from which we also see that, for every $i = 0, \dots, n$, the open subset U_i is the largest such that $\varepsilon_i \in \Gamma(U_i, \underline{N}^\sim(1)^\times)$. By the same token, we obtain :

(12.4.17) $$(\mathbb{P}^n_{(Z,\underline{N})}, \underline{N}^\sim)_{\mathrm{tr}} = U_0 \cap \dots \cap U_n \simeq \mathbb{G}^n_{m,Z}.$$

12.4.18. Let $(Z, \underline{N})$ be a log scheme, $(\varphi, \log \varphi) : (\mathscr{A}, \underline{P}) \to (\mathscr{A}', \underline{P}')$ a morphism of quasi-coherent $\mathbb{N}$-graded $\mathscr{O}_{(Z,\underline{N})}$-algebras. We let (notation of (10.6.26)) :

$$G(\varphi, \log \varphi) := G(\varphi) \times_{\mathrm{Proj}\,\mathscr{A}'} \mathrm{Proj}(\mathscr{A}', \underline{P}').$$

Denote also by $\pi : Y := \mathrm{Proj}\,\mathscr{A} \to Z$ and $\pi' : Y' := \mathrm{Proj}\,\mathscr{A}' \to Z'$ the natural projections; there follows, on the one hand, a morphism of $\mathbb{N}$-graded monoids :

(12.4.19) $$\pi'^{-1}(\log \varphi) : (\mathrm{Proj}\,\varphi)^{-1}(\pi^{-1}\underline{P}) \to (\pi'^{-1}\underline{P}')_{|G(\varphi)}$$

and on the other hand, a morphism of $\mathbb{Z}$-graded monoids :

(12.4.20) $$(\mathrm{Proj}\,\varphi)^{-1}\mathscr{O}_Y(\bullet)^\times \to \mathscr{O}_{Y'}(\bullet)^\times_{|G(\varphi)}$$

deduced from (10.6.28). Define the $\mathbb{Z}$-graded monoid $\underline{Q}$ on Y_τ as in (12.4.7), and the analogous $\mathbb{Z}$-graded monoid $\underline{Q}'$ on Y'_τ. Then (12.4.19) and (12.4.20) determine a unique morphism of $\mathbb{Z}$-graded monoids :

$$\vartheta : (\mathrm{Proj}\,\varphi)^{-1}\underline{Q} \to \underline{Q}'_{|G(\varphi)}$$

and by construction, the restriction of ϑ in degree zero is a morphism of pre-log structures :

$$\vartheta_0 : (\mathrm{Proj}\,\varphi)^*((\underline{Q})_0, \beta^\sim_{\mathscr{A}}) \to ((\underline{Q}')_0, \beta^\sim_{\mathscr{A}'})$$

whence a morphism of $(Z, \underline{N})$-schemes :

$$\mathrm{Proj}(\varphi, \log \varphi) : G(\varphi, \log \varphi) \to \mathrm{Proj}(\mathscr{A}, \underline{P}).$$

Moreover, on the one hand, (10.6.28) induces an isomorphism of $\mathscr{O}^\times_{Y'}$-modules :

$$\nu^\times_{\mathscr{A}(n)} : (\mathscr{O}^\times_{Y'} \otimes_{(\mathrm{Proj}\,\varphi)^{-1}\mathscr{O}^\times_Y} (\mathrm{Proj}\,\varphi)^{-1}\mathscr{O}_Y(n)^\times)_{|G_1(\varphi)} \xrightarrow{\sim} \mathscr{O}_{Y'}(n)^\times_{|G_1(\varphi)} \qquad \text{for every } n \in \mathbb{Z}$$

(notation of (10.6.27)). On the other hand, for every $n \in \mathbb{Z}$, the morphism of $(\mathrm{Proj}\,\varphi)^{-1}(\underline{Q})_0$-modules ϑ_n determines a morphism of $\underline{P}'^{\sim}$-modules :

$$\vartheta_n^{\sim} : \mathrm{Proj}(\varphi, \log\,\varphi)^* \underline{P}^{\sim}(n)_{|G_1(\varphi)} \to \underline{P}'^{\sim}(n)_{|G_1(\varphi)} \tag{12.4.21}$$

and by inspecting the construction, it is easily seen that the isomorphism (12.4.9) (and the corresponding one for $\underline{P}'^{\sim}(n)$) identifies $\vartheta_n^{\sim}$ with $\nu^{\times}_{\mathscr{A}(n)} \otimes_{\mathscr{O}^{\times}_{Y'}} \underline{P}'^{\sim}$; especially, $\vartheta_n^{\sim}$ is an isomorphism.

12.4.22. Let $\psi : (Z', \underline{N}') \to (Z, \underline{N})$ be a morphism of log schemes, and $(\mathscr{A}, \underline{P}, \alpha, \beta_{\mathscr{A}})$ a $\mathbb{N}$-graded quasi-coherent $\mathscr{O}_{(Z,\underline{N})}$-algebra. We may view $\underline{P}$ as a $\underline{N}$-module, via the morphism α, hence we may form the $\underline{N}'$-module $\psi^*\underline{P}$, as in (12.4.4). Moreover, by remark (6.1.25)(i), $\psi^*\underline{P}$ is a $\mathbb{N}$-graded sheaf of monoids on Z'_τ, such that

$$\psi^*(\mathscr{A}, \underline{P}) := (\psi^*\mathscr{A}, \psi^*\underline{P}, \psi^*\alpha, \psi^*\beta_{\mathscr{A}}) \tag{12.4.23}$$

is a $\mathbb{N}$-graded quasi-coherent $\mathscr{O}_{(Z',\underline{N}')}$-algebra, and in view of the isomorphism (6.1.26), we obtain a natural isomorphism of $(Z', \underline{N}')$-schemes:

$$\mathrm{Proj}\,\psi^*(\mathscr{A}, \underline{P}) \xrightarrow{\sim} (Z', \underline{N}') \times_{(Z,\underline{N})} \mathrm{Proj}(\mathscr{A}, \underline{P}). \tag{12.4.24}$$

Furthermore, denote by $\pi_{(\mathscr{A},\underline{P})} : U_1(\psi^*(\mathscr{A}, \underline{P})) \to U_1(\mathscr{A}, \underline{P})$ the morphism deduced from (12.4.24), and by $\pi_Y : Y' := \mathrm{Proj}\,\psi^*\mathscr{A} \to Y := \mathrm{Proj}\,\mathscr{A}$ the underlying morphism of schemes. From (10.6.31) we obtain natural isomorphisms :

$$(\mathscr{O}^{\times}_{Y'} \otimes_{\pi_Y^{-1}\mathscr{O}^{\times}_Y} \pi_Y^{-1}\mathscr{O}_Y(n)^{\times})_{|U_1(\psi^*\mathscr{A})} \xrightarrow{\sim} \mathscr{O}_{Y'}(n)^{\times}_{|U_1(\psi^*\mathscr{A})} \qquad \text{for every } n \in \mathbb{Z}$$

and the latter induce natural identifications :

$$\pi^*_{(\mathscr{A},\underline{P})}\underline{P}^{\sim}(n) \xrightarrow{\sim} (\psi^*\underline{P})^{\sim}(n) \qquad \text{for every } n \in \mathbb{Z}. \tag{12.4.25}$$

12.4.26. Keep the notation of (12.4.5), and let $\log\mathscr{C}_{(X,\underline{M})}$ be the category whose objects are the pairs $((Z, \underline{N}), \mathscr{L})$, where $(Z, \underline{N})$ is a $(X, \underline{M})$-scheme, and $\mathscr{L}$ is an invertible $\underline{N}$-module. The morphisms $((Z, \underline{N}), \mathscr{L}) \to ((Z', \underline{N}'), \mathscr{L}')$ are the pairs (φ, h), where $\varphi : (Z, \underline{N}) \to (Z', \underline{N}')$ is a morphism of $(X, \underline{M})$-schemes, and $h : \varphi^*\mathscr{L}' \xrightarrow{\sim} \mathscr{L}$ is an isomorphism of $\underline{N}$-modules (with composition of morphisms defined in the obvious way). There is an obvious forgetful functor :

$$\mathsf{p} : \log\mathscr{C}_{(X,\underline{M})} \to \mathscr{C}_X \quad : \quad ((Z, \underline{N}), \mathscr{L}) \mapsto (Z, \mathscr{L} \otimes_{\underline{N}} \mathscr{O}_Z)$$

and the functor $F_{\mathscr{A}}$ can be lifted to a functor :

$$F_{(\mathscr{A},\underline{P})} : \log\mathscr{C}_{(X,\underline{M})} \to \mathbf{Set}$$

which assigns to any object $((Z, \gamma : \underline{N} \to \mathscr{O}_Z), \mathscr{L})$ the set consisting of all morphisms of $\mathbb{N}$-graded quasi-coherent $\mathscr{O}_{(Z,\underline{N})}$-algebras :

$$\begin{array}{ccc} \psi^*\underline{P} & \xrightarrow{\log g} & \mathrm{Sym}^{\bullet}_{\underline{N}}\mathscr{L} \\ {\scriptstyle \psi^*\beta_{\mathscr{A}}}\downarrow & & \downarrow{\scriptstyle \beta_{\mathscr{A}(\mathscr{L})}} \\ \psi^*\mathscr{A} & \xrightarrow{g} & \mathscr{A}(\mathscr{L}) \end{array}$$

where $\psi : (Z, \underline{N}) \to (X, \underline{M})$ is the structural morphism, and g is an epimorphism on the underlying $\mathscr{O}_Z$-modules.

Proposition 12.4.27. $(U_1(\mathscr{A}, \underline{P}), \underline{P}^{\sim}(1)) \in \mathrm{Ob}(\log\mathscr{C}_{(X,\underline{M})})$ *represents the functor* $F_{(\mathscr{A},\underline{P})}$.

Proof. Given $((Z, \underline{N}) \xrightarrow{\psi} (X, \underline{M}), \mathscr{L}) \in \mathrm{Ob}(\log\mathscr{C}_{(X,\underline{M})})$ and $(g, \log g) \in F_{(\mathscr{A},\underline{P})}((Z, \underline{N}), \mathscr{L})$, define $\mathbb{P}(\mathscr{L})$ as in (12.4.14); there follows a morphism of $(Z, \underline{N})$-schemes :

$$\mathrm{Proj}(g, \log g) : \mathbb{P}(\mathscr{L}) \to \mathrm{Proj}\,\psi^*(\mathscr{A}, \underline{P}).$$

In view of (12.4.14) and (12.4.24), this is the same as a morphism of $(X,\underline{M})$-schemes :

$$\mathbb{P}(g,\log g):(Z,\underline{N})\to \mathrm{Proj}(\mathscr{A},\underline{P})$$

and arguing as in the proof of lemma 10.6.33, we see that the image of $\mathbb{P}(g,\log g)$ lands in $U_1(\mathscr{A},\underline{P})$. Next, combining (12.4.15), (12.4.21) and (12.4.25), we deduce a natural isomorphism :

$$\begin{aligned}\pi^*_{(Z,\underline{N})}\circ\mathbb{P}(g,\log g)^*\underline{P}^\sim(1) &\xrightarrow{\sim} \mathrm{Proj}(g,\log g)^*\circ\pi^*_{(\mathscr{A},\underline{P})}\underline{P}^\sim(1)\\ &\xrightarrow{\sim} \mathrm{Proj}(g,\log g)^*(\psi^*\underline{P})^\sim(1)\\ &\xrightarrow{\sim} \underline{P}^\sim_{\mathscr{L}}(1)\\ &\xrightarrow{\sim} \pi^*_{(Z,\underline{N})}\mathscr{L}\end{aligned}$$

whence an isomorphism $h(g,\log g):\mathbb{P}(g,\log g)^*\underline{P}^\sim(1)\xrightarrow{\sim}\mathscr{L}$, and the datum :

$$(\mathbb{P}(g,\log g),h(g,\log g)):((Z,\underline{N}),\mathscr{L})\to(U_1(\mathscr{A},\underline{P}),\underline{P}^\sim(1))$$

is a well defined morphism of $\log\mathscr{C}_{(X,\underline{M})}$.

Conversely, let $\varphi:=(\beta,\log\beta):(Z,\underline{N})\to U_1(\mathscr{A},\underline{P})$ be a morphism of $(X,\underline{M})$-schemes, and $h:\varphi^*\underline{P}^\sim(1)\xrightarrow{\sim}\mathscr{L}$ an isomorphism of $\underline{N}$-modules. In view of (12.4.10), we deduce an isomorphism :

$$h^{\otimes n}:\varphi^*\underline{P}^\sim(n)\xrightarrow{\sim}\mathscr{L}^{\otimes n}\qquad\text{for every } n\in\mathbb{Z}.$$

Combining with (12.4.12), we may define the map of $\underline{N}$-modules :

$$\log\widehat{g}(\varphi,h):=\bigoplus_{n\in\mathbb{N}}h^{\otimes n}\circ\beta^*(\lambda_n):\psi^*\underline{P}\to\mathrm{Sym}^\bullet_{\underline{N}}\mathscr{L}.$$

On the other hand, in view of (12.4.11), we have an isomorphism of $\mathscr{O}_Z$-modules :

$$h\otimes_{\underline{N}}\mathscr{O}_Z:\beta^*\mathscr{O}_Y(1)_{|U_1(\mathscr{A})}\xrightarrow{\sim}\varphi^*\underline{P}^\sim(1)\otimes_{\underline{N}}\mathscr{O}_Z\xrightarrow{\sim}\mathscr{L}\otimes_{\underline{N}}\mathscr{O}_Z$$

(where, as usual, $Y:=\mathrm{Proj}\,\mathscr{A}$). We let (notation of (10.6.36)) :

$$\widehat{g}(\varphi,h):=g(\beta,h\otimes_{\underline{N}}\mathscr{O}_Z)$$

and notice that the pair $(\widehat{g}(\varphi,h),\log\widehat{g}(\varphi,h))$ is an element of $F_{(\mathscr{A},\underline{P})}((Z,\underline{N}),\mathscr{L})$. Summing up, we have exhibited two natural transformations :

$$\vartheta:F_{(\mathscr{A},\underline{P})}\Rightarrow\mathrm{Hom}_{\log\mathscr{C}_{(X,\underline{M})}}(-,(U_1(\mathscr{A},\underline{P}),\underline{P}^\sim(1)))\quad(g,\log g)\mapsto\mathbb{P}(g,\log g)$$
$$\sigma:\mathrm{Hom}_{\log\mathscr{C}_{(X,\underline{M})}}(-,(U_1(\mathscr{A},\underline{P}),\underline{P}^\sim(1)))\Rightarrow F_{(\mathscr{A},\underline{P})}\qquad(\varphi,h)\mapsto(\widehat{g}(\varphi,h),\log\widehat{g}(\varphi,h))$$

and it remains to show that these transformations are isomorphisms of functors. However, the latter fit into an essentially commutative diagram of natural transformations :

$$\begin{array}{ccccc}F_{(\mathscr{A},\underline{P})} & \xRightarrow{\vartheta} & \mathrm{Hom}_{\log\mathscr{C}_{(X,\underline{M})}}(-,(U_1(\mathscr{A},\underline{P}),\underline{P}^\sim(1))) & \xRightarrow{\sigma} & F_{(\mathscr{A},\underline{P})}\\ \Downarrow & & \Downarrow & & \Downarrow\\ F_{\mathscr{A}}\circ\mathsf{p} & \Longrightarrow & \mathrm{Hom}_{\mathscr{C}_X}(\mathsf{p}(-),(U_1(\mathscr{A}),\mathscr{O}_Y(1)_{|U_1(\mathscr{A})})) & \Longrightarrow & F_{\mathscr{A}}\circ\mathsf{p}\end{array}$$

whose bottom line is given by the natural transformations (10.6.37). Moreover, given an isomorphism h of invertible $\underline{N}$-modules, the discussion in (12.4.3) leads to the identity :

$$h=(h\otimes_{\underline{N}}\mathscr{O}_Z)^\times\otimes_{\mathscr{O}_{Z^\times}}\underline{N}. \qquad (12.4.28)$$

Likewise, we have natural identifications :

$$\mathrm{Sym}^n_{\underline{N}}\mathscr{L}=(\mathrm{Sym}^n_{\mathscr{O}_Z}\mathscr{L}\otimes_{\underline{N}}\mathscr{O}_Z)^\times\otimes_{\mathscr{O}_Z^\times}\underline{N}\qquad\text{for every } n\in\mathbb{Z}$$

which show that $\beta_{\mathscr{A}}$ and g determine uniquely $\log g$. This – and an inspection of the proof of lemma 10.6.33 – already implies that $\sigma\circ\vartheta$ is the identity automorphism of the functor

$F_{(\mathscr{A},\underline{P})}$. Finally, let $\varphi = (\beta, \log \beta)$ and h as in the foregoing, so that (φ, h) is a morphism in $\log \mathscr{C}_{(X,\underline{M})}$; to conclude we have to show that $(\varphi', h') := \vartheta \circ \sigma(\varphi, h)$ equals (φ, h). Say that $\varphi' := (\beta', \log \beta')$; by the above (and by the proof of lemma 10.6.33) we already know that $\beta = \beta'$, and (12.4.28) implies that $h = h'$. Hence, it remains only to show that $\log \beta = \log \beta'$, which can be checked directly on the stalks over the τ-points of Z : we leave the details to the reader. $\square$

Example 12.4.29. (i) Let $\psi : (Z', \underline{N}') \to (Z, \underline{N})$ be a morphism of log schemes, $n \in \mathbb{N}$ any integer, and $\mathbb{P}^n_{(Z,\underline{N})}$ the n-dimensional projective space over $(Z, \underline{N})$, defined as in example 12.4.16. A simple inspection of the definitions yields a natural isomorphism of $\mathscr{O}_{(Z',\underline{N}')}$-algebras

$$\mathrm{Sym}^\bullet_{(\mathscr{O}_{Z'},\underline{N}')}(\mathscr{O}_{Z'}, \underline{N}')^{\oplus n} \xrightarrow{\sim} \psi^*\mathrm{Sym}^\bullet_{(\mathscr{O}_Z,\underline{N})}(\mathscr{O}_Z, \underline{N})^{\oplus n} \qquad \text{for every } n \in \mathbb{N}$$

whence a natural isomorphism of $(Z', \underline{N}')$-schemes :

$$\mathbb{P}^n_{(Z',\underline{N}')} \xrightarrow{\sim} (Z', \underline{N}') \times_{(Z,\underline{N})} \mathbb{P}^n_{(Z,\underline{N})} \qquad \text{for every } n \in \mathbb{N}.$$

(ii) Let $\mathscr{L}$ be any invertible $\underline{N}$-module; notice that a morphism of $\mathbb{N}$-graded monoids

$$\mathrm{Sym}^\bullet_{\underline{N}} \underline{N}^{\oplus n} \to \mathrm{Sym}^\bullet_{\underline{N}} \mathscr{L}$$

which is the identity map in degree zero, is the same as the datum of a sequence

$$(\beta_i : \underline{N} \to \mathscr{L} \mid i = 1, , \dots, n)$$

of morphisms of $\underline{N}$-modules, and the latter is the same as a sequence $(b_1, \dots, b_n)$ of global sections of $\mathscr{L}$. Since $\mathrm{Sym}^1_{\mathscr{O}_Z} \mathscr{O}_Z^{\oplus n+1}$ generates $\mathrm{Sym}^\bullet_{\mathscr{O}_Z} \mathscr{O}_Z^{n+1}$, proposition 12.4.27 and (i) imply that $\mathbb{P}^n_{(Z,\underline{N})}$ represents the functor $\log \mathscr{C}_{(Z,\underline{N})} \to \mathbf{Set}$ that assigns to any pair $((X, \underline{M}), \mathscr{L})$ the set of all sequences $(b_0, \dots, b_n)$ of global sections of $\mathscr{L}$. The bijection

$$\text{(12.4.30)} \qquad \mathrm{Hom}_{\log \mathscr{C}_{(Z,\underline{N})}}(((X, \underline{M}), \mathscr{L}), (\mathbb{P}^n_{(Z,\underline{N})}, \underline{N}^\sim(1))) \xrightarrow{\sim} \Gamma(X, \mathscr{L})^{n+1}$$

can be explicited as follows. Let $(\varphi, h) : ((X, \underline{M}), \mathscr{L}) \to (\mathbb{P}^n_{(Z,\underline{N})}, \underline{N}^\sim(1))$ be a given morphism in $\log \mathscr{C}_{(Z,\underline{N})}$; then $h : \varphi^*\underline{N}^\sim(1) \to \mathscr{L}$ is an isomorphism of $\underline{M}$-modules, which induces a map on global sections

$$\Gamma(h) : \Gamma(\mathbb{P}^n_{(Z,\underline{N})}, \underline{N}^\sim(1))) \to \Gamma(X, \mathscr{L}).$$

Now, $\underline{N}^\sim(1)$ admits a distiguished system of global sections $\varepsilon_0, \dots, \varepsilon_n$ (example 12.4.16(ii)), and the bijection (12.4.30) assigns to (φ, h) the sequence $(\Gamma(h)(\varepsilon_0), \dots, \Gamma(h)(\varepsilon_n))$.

(iii) Given a sequence $b_\bullet := (b_0, \dots, b_n)$ as in (ii), denote by

$$f_{b_\bullet} : (X, \underline{M}) \to \mathbb{P}^n_{(Z,\underline{N})}$$

the corresponding morphism. A direct inspection of the definitions shows that the formation of $f_{b_\bullet}$ is compatible with arbitrary base changes $h : (Z', \underline{N}') \to (Z, \underline{N})$. Namely, set $(X', \underline{M}') := (Z', \underline{N}') \times_{(Z,\underline{N})} (X, \underline{M})$, let $g : (X', \underline{M}') \to (X, \underline{M})$ be the induced morphism, $\mathscr{L}' := g^*\mathscr{L}$, and suppose that $\mathscr{L}'$ is also invertible (which always holds, if $\underline{M}'$ is an integral log structure); the sequence $b_\bullet$ pulls back to a corresponding sequence $b'_\bullet := (b'_0, \dots, b_n)$ of global sections of $\mathscr{L}'$, and there follows a cartesian diagram of log schemes :

$$\begin{array}{ccc} (X', \underline{M}') & \xrightarrow{f_{b'_\bullet}} & \mathbb{P}^n_{(Z',\underline{N}')} \\ {\scriptstyle g}\downarrow & & \downarrow{\scriptstyle \mathbb{P}^n_h} \\ (X, \underline{M}) & \xrightarrow{f_{b_\bullet}} & \mathbb{P}^n_{(Z,\underline{N})}. \end{array}$$

The details shall be left to the reader.

Definition 12.4.31. Let $(X, \underline{M})$ be a log scheme, and $\mathscr{I} \subset \underline{M}$ an ideal of $\underline{M}$ (see (3.7.22)).

(i) Let $f : (Y, \underline{N}) \to (X, \underline{M})$ be a morphism of log schemes; then $f^{-1}\mathscr{I}$ is an ideal in the sheaf of monoids $f^{-1}\underline{M}$; we let :

$$\mathscr{I}\underline{N} := \log f(f^{-1}\mathscr{I}) \cdot \underline{N}$$

which is the smallest ideal of $\underline{N}$ containing the image of $f^{-1}\mathscr{I}$.

(ii) A *logarithmic blow up* of the ideal $\mathscr{I}$ is a morphism of log schemes

$$\varphi : (X', \underline{M}') \to (X, \underline{M})$$

which enjoys the following universal property. The ideal $\mathscr{I}\underline{M}'$ is invertible, and every morphism of log schemes $(Y, \underline{N}) \to (X, \underline{M})$ such that $\mathscr{I}\underline{N} \subset \underline{N}$ is invertible, factors uniquely through φ.

Remark 12.4.32. (i) Keep the notation of definition 12.4.31. By the usual general nonsense, it is clear that the blow up $(X', \underline{M}')$ is determined up to unique isomorphism of $(X, \underline{M})$-schemes.

(ii) Moreover, let $f : Y \to X$ be a morphism of schemes. Then we claim that the natural projection :

$$(Y', \underline{M}'_Y) := Y \times_X (X', \underline{M}') \to (Y, \underline{M}_Y) := Y \times_X (X, \underline{M})$$

is a logarithmic blow up of $\mathscr{I}\underline{M}_Y$, provided $\mathscr{I}\underline{M}'_Y$ is an invertible ideal; especially, this holds whenever $\underline{M}'$ is an integral log structure (lemma 12.1.18(i)). The proof is left as an exercise for the reader.

12.4.33. Let $(X, \underline{M})$ be a log scheme, $\mathscr{I} \subset \underline{M}$ an ideal; we shall show the existence of the logarithmic blow up of $\mathscr{I}$, under fairly general conditions. To this aim, we introduce the graded *blow up $\mathscr{O}_X$-algebra* :

$$\mathsf{B}(X, \underline{M}, \mathscr{J}) := \bigoplus_{n\in\mathbb{N}} \mathscr{I}^n \otimes_{\underline{M}} \mathscr{O}_X$$

where $\mathscr{I}^n \otimes_{\underline{M}} \mathscr{O}_X$ is the sheaf associated to the presheaf $U \mapsto \mathscr{I}^n(U) \otimes_{\underline{M}(U)} \mathscr{O}_X(U)$ on X_τ. Here $\mathscr{I}^0 := \underline{M}$, and for every $n > 0$ we let $\mathscr{I}^n$ be the sheaf associated to the presheaf $U \mapsto \mathscr{I}(U)^n$ on X_τ. The graded multiplication law of the blow up $\mathscr{O}_X$-algebra is induced by the multiplication $\mathscr{I}^n \times \mathscr{I}^m \to \mathscr{I}^{n+m}$, for every $n, m \in \mathbb{N}$.

The natural map $\mathscr{I}^n \to \mathscr{I}^n \otimes_{\underline{M}} \mathscr{O}_X$ induces a morphism of sheaves of monoids :

$$\coprod_{n\in\mathbb{N}} \mathscr{I}^n \to \mathsf{B}(X, \underline{P}, \mathscr{J}).$$

The latter defines a $\mathbb{N}$-graded $\mathscr{O}_{(X,\underline{M})}$-algebra, which we denote $\mathscr{B}(X, \underline{M}, \mathscr{I})$.

12.4.34. Suppose first that $\mathscr{I}$ is invertible; then it is easily seen that, locally on X_τ, $\mathscr{I}$ is generated by a regular local section (see example 4.8.36(i)), hence the same holds for the power $\mathscr{I}^n$, for every $n \in \mathbb{N}$. Therefore $\mathscr{I}^n$ is a locally free $\underline{M}$-module of rank one, and we have a natural isomorphism :

$$\mathscr{B}(X, \underline{M}, \mathscr{I}) \stackrel{\sim}{\to} (\mathscr{A}(\mathscr{I}), \mathrm{Sym}^\bullet_{\underline{M}}\mathscr{I})$$

(notation of example (12.4.13)). It follows that in this case, the natural projection :

$$\pi_{(X,\underline{M},\mathscr{I})} : \mathrm{Proj}\, \mathscr{B}(X, \underline{M}, \mathscr{I}) \to (X, \underline{M})$$

is an isomorphism of log schemes.

12.4.35. The formation of $\mathscr{B}(X, \underline{M}, \mathscr{I})$ is obviously functorial with respect to morphisms of log schemes; more precisely, such a morphism $f : (Y, \underline{N}) \to (X, \underline{M})$ induces a morphism of $\mathbb{N}$-graded $\mathscr{O}_{(Y,\underline{N})}$-algebras:

$$\mathscr{B}(f, \mathscr{I}) : f^*\mathscr{B}(X, \underline{M}, \mathscr{I}) \to \mathscr{B}(Y, \underline{N}, \mathscr{I}\underline{N})$$

(notation of (12.4.23)) which is an epimorphism on the underlying $\mathscr{O}_Y$-modules. Moreover, if $g : (Z, \underline{Q}) \to (Y, \underline{N})$ is another morphism, we have the identity :

$$\mathscr{B}(f \circ g, \mathscr{I}) = \mathscr{B}(g, \mathscr{I}\underline{N}) \circ g^*\mathscr{B}(f, \mathscr{I}). \tag{12.4.36}$$

Furthermore, the construction of the blow up algebra is local for the topology of X_τ : if $U \to X$ is any object of X_τ, we have a natural identification

$$\mathscr{B}(U, \underline{M}_{|U}, \mathscr{I}_{|U}) \xrightarrow{\sim} \mathscr{B}(X, \underline{M}, \mathscr{I})_{|U}.$$

In the presence of charts for the log structure $\underline{M}$, we can give a handier description for the blow up algebra; namely, we have the following :

Lemma 12.4.37. *Let X be a scheme, $\alpha : \underline{P} \to \mathscr{O}_X$ a pre-log structure, $\beta : \underline{P} \to \underline{P}^{\log}$ the natural morphism of pre-log structures. Let also $\mathscr{I} \subset \underline{P}$ be an ideal, and set $\mathscr{I}\underline{P}^{\log} := \beta(\mathscr{I}) \cdot \underline{P}^{\log}$ (which is the ideal of $\underline{P}^{\log}$ generated by the image of $\mathscr{I}$). Then :*

(i) *There is a natural isomorphism of graded $\mathscr{O}_X$-algebras :*

$$\bigoplus_{n\in\mathbb{N}} \mathscr{I}^n \otimes_{\underline{P}} \mathscr{O}_X \xrightarrow{\sim} \mathsf{B}(X, \underline{P}^{\log}, \mathscr{I}\underline{P}^{\log}).$$

(ii) *Especially, suppose $(X, \underline{M})$ is a log scheme that admits a chart $\beta : P_X \to \underline{M}$, let $I \subset P$ be an ideal, and set $I\underline{M} := \beta(I_X) \cdot \underline{M}$. Then $\mathscr{B}(X, \underline{M}, I\underline{M})$ is a $\mathbb{N}$-graded quasi-coherent $\mathscr{O}_{(X,\underline{M})}$-algebra.*

(iii) *In the situation of* (ii)*, set $(S, P_S^{\log}) := \mathrm{Spec}(\mathbb{Z}, P)$ (see* (12.2.13)*), and denote by $f : (X, \underline{M}) \to (S, P_S^{\log})$ the natural morphism. Then the map :*

$$\mathscr{B}(f, IP_S^{\log}) : f^*\mathscr{B}(S, P_S^{\log}, IP_S^{\log}) \to \mathscr{B}(X, \underline{M}, I\underline{M})$$

is an isomorphism of $\mathbb{N}$-graded $\mathscr{O}_{(X,\underline{M})}$-algebras.

Proof. (i): Since the functor (4.8.51) commutes with all colimits, we have a natural isomorphism of sheaves of rings on X_τ :

$$\mathbb{Z}[\underline{P}^{\log}] \xrightarrow{\sim} \mathbb{Z}[\underline{P}] \otimes_{\mathbb{Z}[\alpha^{-1}\mathscr{O}_X^\times]} \mathbb{Z}[\mathscr{O}_X^\times].$$

We are therefore reduced to showing that the natural morphism

$$\mathbb{Z}[\mathscr{I}^n] \otimes_{\mathbb{Z}[\alpha^{-1}\mathscr{O}_X^\times]} \mathbb{Z}[\mathscr{O}_X^\times] \to \mathscr{I}^n\mathbb{Z}[\underline{P}^{\log}]$$

is an isomorphism for every $n \in \mathbb{N}$. The latter assertion can be checked on the stalks over the τ-points of X; to this aim, we invoke the more general :

Claim 12.4.38. Let G be an abelian group, $\varphi : H \to P'$ and $\psi : H \to G$ two morphisms of monoids, $I \subset P'$ an ideal. Then the natural map

$$\mathbb{Z}[I] \otimes_{\mathbb{Z}[H]} \mathbb{Z}[G] \to I\mathbb{Z}[P' \otimes_H G] \tag{12.4.39}$$

is an isomorphism.

Proof of the claim. Recall that $\mathbb{Z}[I] = I\mathbb{Z}[P']$, and the map (12.4.39) is induced by the natural identification: $\mathbb{Z}[P'] \otimes_{\mathbb{Z}[H]} \mathbb{Z}[G] \xrightarrow{\sim} \mathbb{Z}[P' \otimes_H G]$ (see (4.8.52)). Especially, (12.4.39) is clearly surjective, and it remains to show that it is also injective. To this aim, notice first that ψ factors through the unit of adjunction $\eta : H \to H^{\mathrm{gp}}$; the morphism $\mathbb{Z}[\eta] : \mathbb{Z}[H] \to \mathbb{Z}[H^{\mathrm{gp}}] = H^{-1}\mathbb{Z}[H]$ is a localization map (see (4.8.53)), especially it is flat, hence (12.4.39) is injective when $G =$

$H^{\rm gp}$ and $\psi = \eta$. It follows easily that we may replace H by $H^{\rm gp}$, P' by $P' \otimes_H H^{\rm gp}$, I by $I \cdot (P' \otimes_H H^{\rm gp})$, and therefore assume that H is a group. Let $L := \psi(H)$; arguing as in the foregoing, we may consider separately the case where ψ is the surjection $H \to L$ and the case where ψ is the injection $i : L \to G$. However, one sees easily that $\mathbb{Z}[i] : \mathbb{Z}[L] \to \mathbb{Z}[G]$ is a flat morphism, hence it suffices to consider the case where ψ is a surjective group homomorphism. Set $K := \operatorname{Ker}\psi$; we have a natural identification : $P' \otimes_H G \simeq P' \otimes_K \{1\}$, hence we may further reduce to the case where $G = \{1\}$. Then the contention is that the augmentation map $\mathbb{Z}[K] \to \mathbb{Z}$ induces an isomorphism $\omega : \mathbb{Z}[I] \otimes_{\mathbb{Z}[K]} \mathbb{Z} \xrightarrow{\sim} I\mathbb{Z}[P'/K]$. From lemma 4.8.31(ii), we derive easily that $I\mathbb{Z}[P'/K] = \mathbb{Z}[I/K]$, where I/K is the set-theoretic quotient of I for the K-action deduced from φ. However, any set-theoretic section $I/K \to I$ of the natural projection $I \to I/K$ yields a well-defined surjection $\mathbb{Z}[I/K] \to \mathbb{Z}[I] \otimes_{\mathbb{Z}[K]} \mathbb{Z}$ whose composition with ω is the identity map. The claim follows. ◊

(ii): Let U be an affine object of X_τ, say $U = \operatorname{Spec} A$; from (i), we see that $\mathscr{B}(X, \underline{M}, I\underline{M})_{|U}$ is the quasi-coherent $\mathscr{O}_U$-algebra associated to the A-algebra $\oplus_{n\in\mathbb{N}}\mathbb{Z}[I^n] \otimes_{\mathbb{Z}[P]} A$.

(iii): In view of (i) we know already that $\mathscr{B}(f, IP_S^{\log})$ induces an isomorphism on the underlying $\mathscr{O}_X$-algebras; hence, by lemma 12.2.18(i), it remains to show that $\mathscr{B}(f, IP_S^{\log})$ induces an isomorphism :

$$f^*(I^n P_S^{\log}) \xrightarrow{\sim} I^n f^*(P_S^{\log}) \qquad \text{for every } n \in \mathbb{N}.$$

Let $\gamma : f^{-1}P_S^{\log} \to f^{-1}\mathscr{O}_S \to \mathscr{O}_X$ be the natural map; after replacing I by I^n, we come down to showing that the natural map :

$$f^{-1}(IP_S^{\log}) \otimes_{\gamma^{-1}\mathscr{O}_X^\times} \mathscr{O}_X^\times \to I \cdot (f^{-1}P_S^{\log} \otimes_{\gamma^{-1}\mathscr{O}_X^\times} \mathscr{O}_X^\times)$$

is an isomorphism. This assertion can be checked on the stalks over the τ-points of X; if x is such a point, let $G := \mathscr{O}_{X,x}^\times$, $H := \gamma_x^{-1}G$ and $P' := P_{S,f(x)}^{\log}$. The map under consideration is the natural morphism of P'-modules :

$$\omega : (IP') \otimes_H G \to I(P' \otimes_H G)$$

and it suffices to show that $\mathbb{Z}[\omega]$ is an isomorphism; however, the latter is none else than (12.4.39), so we may appeal to claim 12.4.38 to conclude. □

12.4.40. We wish to generalize lemma 12.4.37(ii) to log structures that do not necessarily admit global charts. Namely, suppose now that $\underline{M}$ is a quasi-coherent log structure on X, and $\mathscr{I} \subset \underline{M}$ is a coherent ideal (see definition 4.8.6(v)). For every τ-point ξ of X, we may then find a neighborhood U of ξ in X_τ, a chart $\beta : P_U \to \underline{M}_{|U}$, and local sections $s_1, \dots, s_n \in \mathscr{I}(U)$ which form a system of generators for $\mathscr{I}_{|U}$. We may then write $s_{i,\xi} = u_i \cdot \beta(x_i)$ for certain $x_1, \dots, x_n \in P$ and $u_1, \dots, u_n \in \mathscr{O}_{X,\xi}^\times$. Up to shrinking U, we may assume that $u_1, \dots, u_n \in \mathscr{O}_X^\times(U)$, and it follows that $\mathscr{I}_{|U} = I \cdot \underline{M}_{|U}$, where $I \subset P$ is the ideal generated by $x_1, \dots, x_n$. In other words, locally on X_τ, the datum $(X, \underline{M}, \mathscr{I})$ is of the type considered in lemma 12.4.37(ii); therefore the blow up $\mathscr{O}_X$-algebra $\mathscr{B}(X, \underline{M}, \mathscr{I})$ is quasi-coherent. We may then consider the natural projection :

$$\pi_{(X,\underline{M},\mathscr{I})} : \mathrm{Bl}_{\mathscr{I}}(X, \underline{M}) := \operatorname{Proj} \mathscr{B}(X, \underline{M}, \mathscr{I}) \to (X, \underline{M}). \tag{12.4.41}$$

Next, let $f : (Y, \underline{N}) \to (X, \underline{M})$ be a morphism of log schemes; it is easily seen that $\mathscr{I}\underline{N}$ is a coherent ideal of $\underline{N}$, hence $\mathscr{B}(Y, \underline{N}, \mathscr{I}\underline{N})$ is quasi-coherent as well, and since the map $\mathscr{B}(f, \mathscr{I})$ of (12.4.35) is an epimorphism on the underlying $\mathscr{O}_Y$-modules, we have :

$$G(\mathscr{B}(f, \mathscr{I})) = \mathrm{Bl}_{\mathscr{I}\underline{N}}(Y, \underline{N})$$

(notation of (12.4.18)) whence a closed immersion of $(Y, \underline{N})$-schemes :

$$\operatorname{Proj} \mathscr{B}(f, \mathscr{I}) : \mathrm{Bl}_{\mathscr{I}\underline{N}}(Y, \underline{N}) \to (Y, \underline{N}) \times_{(X,\underline{M})} \mathrm{Bl}_{\mathscr{I}}(X, \underline{M})$$

([60, Ch.II, Prop.3.6.2(i)] and (12.4.24)), which is the same as a morphism of $(X, \underline{M})$-schemes :

$$\varphi(f, \mathscr{I}) : \mathrm{Bl}_{\mathscr{I}\underline{N}}(Y, \underline{N}) \to \mathrm{Bl}_{\mathscr{I}}(X, \underline{M}).$$

Moreover, if $g : (Z, \underline{Q}) \to (Y, \underline{N})$ is another morphism, (12.4.36) induces the identity :

$$\varphi(f, \mathscr{I}) \circ \varphi(g, \mathscr{I}\underline{N}) = \varphi(f \circ g, \mathscr{I}). \tag{12.4.42}$$

Example 12.4.43. In the situation of lemma 12.4.37(iii), notice that $\mathscr{O}_S$ is a flat $\mathbb{Z}[P_S]$-algebra, and therefore :

$$\mathsf{B}(S, P_S^{\log}, IP_S^{\log}) = \bigoplus_{n \in \mathbb{N}} I^n \mathscr{O}_S.$$

Moreover, (12.4.24) specializes to a natural isomorphism of $(X, \underline{M})$-schemes :

$$\mathrm{Bl}_{I\underline{M}}(X, \underline{M}) \stackrel{\sim}{\to} X \times_S \mathrm{Bl}_{IP_S^{\log}}(S, P_S^{\log}). \tag{12.4.44}$$

We wish to give a more explicit description of the log structure of $\mathrm{Bl}_{IP_S^{\log}}(S, P_S^{\log})$. To begin with, recall that $S' := \mathrm{Proj}\, \mathsf{B}(S, P_S^{\log}, IP_S^{\log})$ admits a distinguished covering by (Zariski) affine open subsets : namely, for every $a \in I$, consider the localization

$$P_a := T_a^{-1} P \qquad \text{where} \qquad T_a := \{a^n \mid n \in \mathbb{N}\}$$

and let $Q_a \subset P_a$ be the submonoid generated by the image of P and the subset $\{a^{-1}b \mid b \in I\}$; then

$$S' = \bigcup_{a \in I} \mathrm{Spec}\, \mathbb{Z}[Q_a].$$

Hence, let us set

$$U_a := \mathrm{Spec}(\mathbb{Z}, Q_a) \qquad \text{for every } a \in I.$$

We claim that these locally defined log structures glue to a well defined log structure $\underline{Q}$ on the whole of S'_τ. Indeed, let $a, b \in I$; we have

$$U_{a,b} := \mathrm{Spec}\, \mathbb{Z}[Q_a] \cap \mathrm{Spec}\, \mathbb{Z}[Q_b] = \mathrm{Spec}\, \mathbb{Z}[Q_a \otimes_P Q_b]$$

and it is easily seen that $Q_a \otimes_P Q_b = Q_a[b^{-1}a]$, *i.e.* the localization of Q_a obtained by inverting its element $a^{-1}b$, and this is of course the same as $Q_b[a^{-1}b]$. Then lemma 12.2.14 implies that the log structures of U_a and U_b agree on $U_{a,b}$, whence the contention. It is easy to check that the resulting log scheme is precisely $\mathrm{Bl}_{IP_S^{\log}}(S, P_S^{\log})$: the details shall be left to the reader.

Proposition 12.4.45. *Let $(X, \underline{M})$ be a log scheme with quasi-coherent log structure, and $\mathscr{I} \subset \underline{M}$ a coherent ideal. Then, the morphism* (12.4.41) *is a logarithmic blow up of $\mathscr{I}$.*

Proof. Let $f : (Y, \underline{N}) \to (X, \underline{M})$ be a morphism of log schemes, and suppose that $\mathscr{I}\underline{N}$ is an invertible ideal of $\underline{N}$; in this case, we have already remarked (see (12.4.34)) that the projection $\pi_{(Y, \underline{N}, \mathscr{I}\underline{N})} : \mathrm{Bl}_{\mathscr{I}\underline{N}}(Y, \underline{N}) \to (Y, \underline{N})$ is an isomorphism. We deduce a morphism :

$$\varphi(f, \mathscr{I}) \circ \pi^{-1}_{(Y, \underline{N}, \mathscr{I}\underline{N})} : (Y, \underline{N}) \to \mathrm{Bl}_{\mathscr{I}}(X, \underline{M}). \tag{12.4.46}$$

To conclude, it remains to show that (12.4.46) is the only morphism of log schemes whose composition with $\pi_{(X, \underline{M}, \mathscr{I})}$ equals f. The latter assertion can be checked locally on X_τ, hence we may assume that $\underline{M}$ admits a chart $P_X \to \underline{M}$, such that $\mathscr{I} = I\underline{M}$ for some finitely generated ideal $I \subset P$. In this case, in view of (12.4.44), the set of morphisms of $(X, \underline{M})$-schemes $(Y, \underline{N}) \to \mathrm{Bl}_{\mathscr{I}}(X, \underline{M})$ is in natural bijection with the set of $(S, P_S^{\log})$-morphisms $(Y, \underline{N}) \to B := \mathrm{Bl}_{IP_S^{\log}}(S, P_S^{\log})$ (notation of example 12.4.43). In other words, we may assume that $(X, \underline{M}) = (S, P_S^{\log})$, and $\mathscr{I} = IP_S^{\log}$. Then f is determined by $\log f$, *i.e.* by a map $\beta : P \to$

$\underline{N}(Y)$. Let $a_1, \dots, a_k$ be a system of generators for I; for each $i = 1, \dots, k$, we let $U_i \subset Y$ be the subset of all $y \in Y$ for which there exists a τ-point ξ of Y with $|\xi| = y$ and

$$a_i \underline{N}_\xi = I \underline{N}_\xi . \tag{12.4.47}$$

Notice that if $y \in U_i$, then (12.4.47) holds for every τ-point ξ of Y localized at y (details left to the reader).

Claim 12.4.48. The subset U_i is open in Y_i for every $i = 1, \dots, k$, and $Y = \bigcup_{i=1}^k U_i$.

Proof of the claim. Say that $y \in U_i$, and let ξ be a τ-point of Y localized at y, such that (12.4.47) holds. This means that, for every $j = 1, \dots, k$, there exists $u_j \in \underline{N}_\xi$ such that $a_j = u_j a_i$. Then, we may find a τ-neighborhood $h : U' \to$ of ξ such that this identity persists in $\underline{N}(U')$; thus, $h(U') \subset U_i$. Since h is an open map, this shows that U_i is an open subset.

Next, let ξ be any τ-point of Y; by assumption, we have $I\underline{N}_\xi = b\underline{N}_\xi$ for some $b \in \underline{N}_\xi$; this means that for every $i = 1, \dots, k$ there exists $u_i \in \underline{N}_\xi$ such that $a_i = u_i b$. Since $a_1, \dots, a_k$ generate I, we must have $u_i \in \underline{N}_\xi^\times$ for at least an index $i \leq k$, in which case $|\xi| \in U_i$, and this shows that the U_i cover the whole of Y, as claimed. ◊

It is easily seen that, for every $i = 1, \dots, k$, any morphism $(U_i, \underline{N}_{|U_i}) \to B$ of $(S, P_S^{\log})$-schemes factors through the open immersion $\mathrm{Spec}\,(Z, Q_{a_i}) \to B$ (where Q_a, for an element $a \in P$, is defined as in example 12.4.43). Conversely, by construction β extends to a unique morphism of monoids $Q_{a_i} \to \underline{N}(U_i)$. Summing up, there exists at most one morphism of $(S, P_S^{\log})$-schemes $(U_i, \underline{N}_{|U_i}) \to B$. In light of claim 12.4.48, the proposition follows. □

12.4.49. Keep the notation of proposition 12.4.45; by inspecting the construction, it is easily seen that the log structure $\underline{M}'$ of $\mathrm{Bl}_{\mathscr{I}}(X, \underline{M})$ is quasi-coherent, and if $\underline{M}$ is coherent (resp. quasi-fine, resp. fine), then the same holds for $\underline{M}'$. However, simple examples show that $\underline{M}'$ may fail to be saturated, even in cases where $(X, \underline{M})$ is a fs log scheme. Due to the prominent role played by fs log schemes, it is convenient to introduce the special notation :

$$\mathrm{sat.Bl}_{\mathscr{I}}(X, \underline{M}) := (\mathrm{Bl}_{\mathscr{I}}(X, \underline{M}))^{\mathrm{qfs}}$$

for the *saturated logarithmic blow up* of a coherent ideal $\mathscr{I}$ in a quasi-fine log structure $\underline{M}$ (notation of proposition 12.2.37). Clearly the projection $\mathrm{sat.Bl}_{\mathscr{I}}(X, \underline{M}) \to (X, \underline{M})$ is a final object of the category of saturated $(X, \underline{M})$-schemes in which the preimage of $\mathscr{I}$ is invertible. If $(X, \underline{M})$ is a fine log scheme, $\mathrm{sat.Bl}_{\mathscr{I}}(X, \underline{M})$ is a fs log scheme. Moreover, for any morphism of schemes $f : Y \to X$, let $\underline{M}_Y := f^*\underline{M}$; from remarks (12.4.32)(ii) and 12.2.38(iii), we deduce a natural isomorphism of $(Y, \underline{M}_Y)$-schemes :

$$\mathrm{sat.Bl}_{\mathscr{I}\underline{M}_Y}(Y, \underline{M}_Y) \xrightarrow{\sim} Y \times_X \mathrm{sat.Bl}_{\mathscr{I}}(X, \underline{M}). \tag{12.4.50}$$

Theorem 12.4.51. *Let $(X, \underline{M})$ be a quasi-fine log scheme with saturated log structure, $\mathscr{I} \subset \underline{M}$ an ideal, ξ a τ-point of X. Suppose that, in a neighborhood of ξ, the ideal $\mathscr{I}$ is generated by at most two sections, and denote :*

$$\varphi : \mathrm{Bl}_{\mathscr{I}}(X, \underline{M}) \to (X, \underline{M}) \qquad \textit{(resp. } \varphi_{\mathrm{sat}} : \mathrm{sat.Bl}_{\mathscr{I}}(X, \underline{M}) \to (X, \underline{M})\textit{)}$$

the logarithmic (resp. saturated logarithmic) blow up of $\mathscr{I}$. Then :

(i) *If $\mathscr{I}_\xi$ is an invertible ideal of $\underline{M}_\xi$, the natural morphisms*

$$\varphi^{-1}(\xi) \to \mathrm{Spec}\,\kappa(\xi) \qquad \varphi_{\mathrm{sat}}^{-1}(\xi) \to \mathrm{Spec}\,\kappa(\xi)$$

are isomorphisms.

(ii) *Otherwise, $\varphi^{-1}(\xi)$ is a $\kappa(\xi)$-scheme isomorphic to $\mathbb{P}^1_{\kappa(\xi)}$; furthermore, the same holds for the reduced fibre $\varphi_{\mathrm{sat}}^{-1}(\xi)_{\mathrm{red}}$, provided $\underline{M}$ is fine.*

Proof. After replacing X by a τ-neighborhood of ξ, we reduce to the case where $\underline{M}$ admits an integral and saturated chart $\alpha : P_X \to \underline{M}$ (lemma 12.1.18(iii)), and if $\underline{M}$ is a fs log structure, we may also assume that the chart α is fine and sharp at ξ (corollary 12.1.36(i)). Furthermore, we may assume that $\mathscr{I}$ is generated by at most two elements of $\underline{M}(X)$, and if $\mathscr{I}_\xi$ is principal, we may assume that the same holds for $\mathscr{I}$. In the latter case, since $\underline{M}$ is integral, $\mathscr{I}$ is invertible, hence φ and φ_{sat} are isomorphisms, so (i) follows already.

Now, suppose that $\mathscr{I}_\xi$ is not invertible, and let $a', b' \in \underline{M}(X)$ be a system of generators for $\mathscr{I}$; we can write $a' = \alpha(a) \cdot u$, $b' = \alpha(b) \cdot v$ for some $a, b \in P$ and $u, v \in \kappa^\times$. Set $t := a^{-1}b$, and let $J \subset P$ be the ideal generated by a and b; clearly $J\underline{M} = \mathscr{I}$, and $Pa, Pb \neq J$.

Consider first the case where $X = \operatorname{Spec} \kappa$, where κ is a field (resp. a separably closed field, in case $\tau =$ ét). In this situation, a pre-log structure on X_τ is the same as a morphism of monoids $\beta : P \to \kappa$, the associated log structure is the induced map of monoids

$$\beta^{\log} : P \otimes_{P_0} \kappa^\times \to \kappa \qquad \text{where} \qquad P_0 := \beta^{-1}\kappa^\times$$

and α is the natural map $P \to P \otimes_{P_0} \kappa^\times$. After replacing P by its localization $P_0^{-1}P$, we may also assume that $P_0 = P^\times$. Let

$$(S, P_S^{\log}) := \operatorname{Spec}(\kappa, P) \qquad J^\sim := JP_S^{\log} \qquad (Y, \underline{N}) := \mathrm{Bl}_{J^\sim}(S, P_S^{\log}).$$

Denote by $\varepsilon : \kappa[P] \to \kappa$ the homomorphism of κ-algebras induced by β via the adjunction (4.8.50), and set $I := \operatorname{Ker} \varepsilon$. In view of lemma 12.4.37(i) and (12.4.50), we have natural cartesian diagrams of κ-schemes :

(12.4.52)
$$\begin{array}{ccc} \varphi^{-1}(\xi) & \longrightarrow & (Y, \underline{N}) \\ \downarrow & & \downarrow \\ |\xi| & \xrightarrow{\operatorname{Spec} \varepsilon} & S \end{array} \qquad \begin{array}{ccc} \varphi_{\mathrm{sat}}^{-1}(\xi) & \longrightarrow & (Y, \underline{N})^{\mathrm{sat}} \\ \downarrow & & \downarrow \\ |\xi| & \xrightarrow{\operatorname{Spec} \varepsilon} & S. \end{array}$$

On the other hand, (a, b) can be regarded as a pair of global sections of $J^\sim\underline{N}$, so the universal property of example 12.4.29(ii) yields a morphism of $(S, P_S^{\log})$-schemes :

$$f_{(a,b)} : (Y, \underline{N}) \to \mathbb{P}^1_{(S, P_S^{\log})}.$$

In light of example 12.4.29(i), the assertion concerning $\varphi^{-1}(\xi)$ will then follow from the :

Claim 12.4.53. The morphism $|\xi| \times_S f_{(a,b)}$ is an isomorphism of κ-schemes.

Proof of the claim. Let $Q_a \subset P^{\mathrm{gp}}$ (resp. $Q_b \subset P^{\mathrm{gp}}$) be the submonoid generated by P and t (resp. by P and t^{-1}); by inspecting example 12.4.43, we see that Y is covered by two affine open subsets :

$$U_a := \operatorname{Spec} \kappa[Q_a] \qquad U_b := \operatorname{Spec} \kappa[Q_b]$$

and $U_a \cap U_b = \operatorname{Spec} \kappa[Q_a \otimes_P Q_b]$. On the other hand, $\mathbb{P}^1_{(S, P_S^{\log})}$ is covered as well by two affine open subsets U'_0 and U'_∞, both isomorphic to $\operatorname{Spec} \kappa[P \oplus \mathbb{N}]$, and such that $U'_0 \cap U'_\infty = \operatorname{Spec} \kappa[P \oplus \mathbb{Z}]$, as usual. Moreover, a direct inspection shows that $f_{(a,b)}$ restricts to morphisms

$$U_a \to U'_0 \qquad U_b \to U'_\infty$$

induced respectively by the maps of κ-algebras

$$\omega_0 : \kappa[P \oplus \mathbb{N}] \to \kappa[Q_a] \qquad \omega_\infty : \kappa[P \oplus \mathbb{N}] \to \kappa[Q_b]$$

such that $\omega_0(x, n) = x \cdot t^n$ and $\omega_\infty(x, n) = x \cdot t^{-n}$ for every $(x, n) \in P \oplus \mathbb{N}$. We show that $\overline{\omega}_0 := \omega_0 \otimes_{\kappa[P]} \kappa[P]/I$ is an isomorphism; the same argument will apply also to ω_∞, so the claim shall follow.

Indeed, clearly the $\kappa[P]$-algebra $\kappa[Q_a]$ is generated by t, hence ω_0 is surjective, and then the same holds for $\overline{\omega}_0$. Next, set $H_a := I \cdot \kappa[Q_a]$; it is easily seen that H_a consists of all sums of the form $\sum_{j=0}^n c_j t^j$, for arbitrary $n \in \mathbb{N}$, with $c_j \in I$ for every $j = 0, \dots, n$. Clearly, an element $p(T) \in \kappa[\mathbb{N}] = \kappa[T]$ lies in $\mathrm{Ker}\, \overline{\omega}_0$ if and only if $p(t) \in H_a$, so we come down to the following assertion. Let $c_0, \dots, c_n \in \kappa[P]$ such that

$$\sum_{j=0}^{n} c_j t^j = 0 \tag{12.4.54}$$

in $\kappa[Q_a]$; then c_j lies in the ideal $\kappa[\beta^{-1}(0)]$ of $\kappa[P]$, for every $j = 0, \dots, n$. Since P is integral, (12.4.54) is equivalent to the identity : $\sum_{j=0}^n c_j a^{n-j} b^j = 0$ in $\kappa[P]$. For every $x \in P$, denote by $\pi_x : \kappa[P] \to \kappa$ the κ-linear projection such that $\pi_x(x) = 1$, and $\pi_x(y) = 0$ for every $y \in P \backslash \{x\}$.

Suppose, by way of contradiction, that $c_i \notin \kappa[\beta^{-1}(0)]$ for some $i \leq n$, hence $\pi_x(c_i) \neq 0$ for some $x \in P_0$; since $P_0 = P^\times$, we may replace c_j by $x^{-1}c_j$, for every $j \leq n$, and assume that $\pi_1(c_i) \neq 0$, hence $\pi_{a^{n-i}b^i}(c_i a^{n-i} b^i) \neq 0$ (again, using the assumption that P is integral). Thus, there exists $j \neq i$ with $j \leq n$, such that $\pi_{a^{n-i}b^i}(c_j a^{n-j} b^j) \neq 0$, and we may then find an element $c \in P$ such that $\pi_{a^{n-i}b^i}(c a^{n-j} b^j) = 1$, *i.e.* $c a^{n-j} b^j = a^{n-i} b^i$; up to swapping the roles of a and b, we may assume that $i > j$, in which case we may write $t^{i-j} = c$; since P is saturated, it follows that $t \in P$, hence J is generated by a, which is excluded. ◊

Next, we assume that $\underline{M}$ is a fs log structure (and X is still $\mathrm{Spec}\, \kappa$), and we consider the morphism φ_{sat}. As already remarked, we may assume that α is sharp at ξ, and P fine and saturated; the sharpness condition amounts to saying that $\beta(x) = 0$ for every $x \in P \setminus \{1\}$, therefore I is the augmentation ideal of the graded κ-algebra $\kappa[P]$. By inspecting the proof of proposition 12.2.37, we see that $(Y, \underline{N})^{\mathrm{sat}}$ is covered by two affine open subsets

$$U_a^{\mathrm{fs}} := \mathrm{Spec}\, \kappa[Q_a^{\mathrm{sat}}] \qquad U_b^{\mathrm{fs}} := \mathrm{Spec}\, \kappa[Q_b^{\mathrm{sat}}]$$

and $U_a^{\mathrm{fs}} \cap U_b^{\mathrm{fs}} = \mathrm{Spec}\, \kappa[Q_a^{\mathrm{sat}} \otimes_P Q_b^{\mathrm{sat}}]$. Since J is not principal, we have $t \notin P$, and since P is saturated, we deduce that t is not a torsion element of P^{gp}; as the latter is a finitely generated abelian group, it follows that we may find a *unimodular* element $u \in P^{\mathrm{gp}}$ such that t lies in the submonoid $\mathbb{N}u \subset P^{\mathrm{gp}}$ generated by u; this condition means that $t = u^k$ for some $k \in \mathbb{N}$, and $\mathbb{N}u$ is not properly contained in another rank one free submonoid of P^{gp}. Write $u = a'^{-1}b'$ for some $a', b' \in P$, let $J' \subset P$ be the ideal generated by a' and b', and $R_{a'}$ (resp. $R_{b'}$) the submonoid of P^{gp} generated by P and u (resp. by P and u^{-1}); clearly $R_{a'}^{\mathrm{sat}} = Q_a^{\mathrm{sat}}$, and $R_{b'}^{\mathrm{sat}} = Q_b^{\mathrm{sat}}$. Denote by $\underline{N}'$ the log structure of $(Y, \underline{N})^{\mathrm{sat}}$, and $\mathscr{J}' := J'\underline{N}'$; it is easily seen that

$$\mathscr{J}'_{|U_a^{\mathrm{fs}}} = a'\underline{N}'_{|U_a^{\mathrm{fs}}} \qquad \mathscr{J}'_{|U_b^{\mathrm{fs}}} = b'\underline{N}'_{|U_b^{\mathrm{fs}}}$$

hence $\mathscr{J}'$ is invertible, and example 12.4.29(ii) yields a morphism of $(S, P_S^{\log})$-schemes

$$f_{(a',b')} : (Y, \underline{N})^{\mathrm{sat}} \to \mathbb{P}^1_{(S, P_S^{\log})}.$$

In light of example 12.4.29(i), the assertion concerning $\varphi_{\mathrm{sat}}^{-1}(\xi)$ will then follow from the :

Claim 12.4.55. $(|\xi| \times_S f_{(a',b')})_{\mathrm{red}} : \varphi_{\mathrm{sat}}^{-1}(\xi)_{\mathrm{red}} \to \mathbb{P}^1_\kappa$ is an isomorphism of κ-schemes.

Proof of the claim. As in the proof of claim 12.4.53, the morphism $f_{(a',b')}$ restricts to morphisms $U_a^{\mathrm{fs}} \to U'_0$ and $U_b^{\mathrm{fs}} \to U'_\infty$ induced by maps of κ-algebras :

$$\omega_0 : \kappa[P \oplus \mathbb{N}] \to \kappa[Q_a^{\mathrm{sat}}] \qquad \omega_\infty : \kappa[P \oplus \mathbb{N}] \to \kappa[Q_b^{\mathrm{sat}}]$$

such that $\omega_0(x, n) = x \cdot u^n$ and $\omega_\infty(x, n) = x \cdot u^{-n}$ for every $(x, n) \in P \oplus \mathbb{N}$, and again, it suffices to show that

$$(\omega_0 \otimes_{\kappa[P]} \kappa[P]/I)_{\mathrm{red}} : \kappa[T] \to (\kappa[R_a^{\mathrm{sat}}]/I\kappa[R_a^{\mathrm{sat}}])_{\mathrm{red}}$$

is an isomorphism (where for any ring A, we denote A_{red} be the maximal reduced quotient of A, *i.e.* $A_{\mathrm{red}} := A/\mathrm{nil}(A)$, where $\mathrm{nil}(A)$ is the nilradical of A). We break the latter verification in two steps : first, let us check that the map

$$\overline{\omega}'_0 : \kappa[T] \to \kappa[R_a]/I\kappa[R_a] \qquad p(T) \mapsto p(u) \pmod{I\kappa[R_a]}$$

is an isomorphism. Indeed, $\overline{\omega}'_0$ is induced by the map of monoids $\varphi : \mathbb{N} \to R_a$ such that $n \mapsto u^n$ for every $n \in \mathbb{N}$; if $t = u^k$, the map φ fits into the cocartesian diagram :

$$\begin{array}{ccc} \mathbb{N} & \xrightarrow{\psi} & Q_a \\ {\scriptstyle \boldsymbol{k}_{\mathbb{N}}}\downarrow & & \downarrow{\scriptstyle j} \\ \mathbb{N} & \xrightarrow{\varphi} & R_a \end{array}$$

where $\boldsymbol{k}_{\mathbb{N}}$ is the k-Frobenius map, ψ is given by the rule : $n \mapsto t^n$ for every $n \in \mathbb{N}$, and j is the natural inclusion. Hence :

$$\overline{\omega}'_0 = (\kappa[\psi] \otimes_{\kappa[P]} \kappa[P]/I) \otimes_{\kappa[T^k]} \kappa[T].$$

However, the proof of claim 12.4.53 shows that $\kappa[\psi] \otimes_{\kappa[P]} \kappa[P]/I$ is an isomorphism, whence the contention. Lastly, let show that the natural map

$$\overline{\omega}''_0 : \kappa[R_a]/I\kappa[R_a] \to (\kappa[R_a^{\mathrm{sat}}]/I\kappa[R_a^{\mathrm{sat}}])_{\mathrm{red}}$$

is an isomorphism. Indeed, it is clear that the natural map $\omega''_0 : \kappa[R_a] \to \kappa[R_a^{\mathrm{sat}}]$ is integral and injective, hence $\mathrm{Spec}\,\omega''_0$ is surjective; therefore $\mathrm{Spec}\,\overline{\omega}''_0$ is still surjective and integral. However, the foregoing shows that $\kappa[R_a]/I\kappa[R_a]$ is reduced, so we deduce that $\overline{\omega}''_0$ is injective. To show that $\overline{\omega}''_0$ is surjective, it suffices to show that the classes of the generating system $R_a^{\mathrm{sat}} \subset \kappa[R_a^{\mathrm{sat}}]$ lie in the image of $\overline{\omega}''_0$. Hence, let $x \in R_a^{\mathrm{gp}}$, with $x^m \in R_a$ for some $m > 0$, so that $x^m = y \cdot u^n$ for some $n \in \mathbb{N}$ and $y \in P$. If $y \neq 1$, we have $y \in I$, hence the image of x^m vanishes in $\kappa[R_a^{\mathrm{sat}}]/I\kappa[R_a^{\mathrm{sat}}]$, and the image of x vanishes in the reduced quotient; finally, if $y = 1$, the identity $x^m = u^n$ implies that m divides n, since u is unimodular; hence $x = u^{n/m}$ and the image of x agrees with $\overline{\omega}''_0(u^{n/m})$. $\diamondsuit$

Finally, let us return to a general quasi-fine log scheme $(X, \underline{M})$; the theorem will follow from the more precise :

Claim 12.4.56. In the situation of the theorem, suppose moreover that

(a) $\underline{M}$ admits a saturated chart $\alpha : P_X \to \underline{M}$
(b) $\mathscr{I} = J\underline{M}$, where $J \subset P$ is an ideal generated by two elements $a, b \in P$
(c) $\mathscr{I}_\xi$ is not invertible.

Then we have :

(i) There exists a morphism of $(X, \underline{M})$-schemes : $\mathrm{Bl}_{\mathscr{I}}(X, \underline{M}) \to \mathbb{P}^1_{(X,\underline{M})}$ inducing an isomorphism of $\kappa(\xi)$-schemes $\varphi^{-1}(\xi) \xrightarrow{\sim} \mathbb{P}^1_{\kappa(\xi)}$.
(ii) If furthermore, P is fine (and saturated) and α is sharp at ξ, then there exists a morphism of $(X, \underline{M})$-schemes : $\mathrm{sat}.\mathrm{Bl}_{\mathscr{I}}(X, \underline{M}) \to \mathbb{P}^1_{(X,\underline{M})}$ inducing an isomorphism of $\kappa(\xi)$-schemes $\varphi_{\mathrm{sat}}^{-1}(\xi)_{\mathrm{red}} \xrightarrow{\sim} \mathbb{P}^1_{\kappa(\xi)}$.

Proof of the claim. (i): Denote by $\underline{N}$ the log structure of $\mathrm{Bl}_{\mathscr{I}}(X, \underline{M})$; the elements a, b define global sections of the invertible $\underline{N}$-module $\mathscr{I}\underline{N}$, and we claim that the corresponding morphism of $(X, \underline{M})$-schemes $f_{(a,b)} : \mathrm{Bl}_{\mathscr{I}}(X, \underline{M}) \to \mathbb{P}^1_{(X,\underline{M})}$ will do. Indeed, set $(|\xi|, \underline{M}_\xi) := |\xi| \times_X (X, \underline{M})$, and recall that there exists natural isomorphisms

$$|\xi| \times_X \mathbb{P}^1_{(X,\underline{M})} \xrightarrow{\sim} \mathbb{P}^1_{(|\xi|,\underline{M}_\xi)} \qquad |\xi| \times_X \mathrm{Bl}_{\mathscr{I}}(X, \underline{M}) \xrightarrow{\sim} \mathrm{Bl}_{\mathscr{I}\underline{M}_\xi}(|\xi|, \underline{M}_\xi)$$

(example 12.4.29(i) and remark 12.4.32(ii)). Denote by $\underline{N}_\xi$ the log structure of $\mathrm{Bl}_{\mathscr{I}\underline{M}_\xi}(|\xi|, \underline{M}_\xi)$; by example 12.4.29(iii), the base change

$$|\xi| \times_X f : \mathrm{Bl}_{\mathscr{I}\underline{M}_\xi}(|\xi|, \underline{M}_\xi) \to \mathbb{P}^1_{(|\xi|, \underline{M}_\xi)}$$

is the unique morphism $f_{(\overline{a},\overline{b})}$ of $(|\xi|, \underline{M}_\xi)$-schemes corresponding to the pair $(\overline{a}, \overline{b})$ of global sections of $\mathscr{I}\underline{N}_\xi$ obtained by pulling back the pair (a, b). Therefore, in order to check that $|\xi| \times_X f$ is an isomorphism, we may replace from start $(X, \underline{M})$ by $(|\xi|, \underline{M}_\xi)$ (whose log structure is still quasi-fine, by lemma 12.1.18(i), and assume that $X = \mathrm{Spec}\, \kappa$, where κ is a field (resp. a separably closed field, in case $\tau = \text{ét}$), in which case the assertion is just claim 12.4.53.

(ii): Denote by $\underline{N}'$ the log structure of $\mathrm{sat.Bl}_{\mathscr{I}}(X, \underline{M})$, define a', b' and J' as in the foregoing, and set again $\mathscr{J}' := J'\underline{N}'$. Again, it is easily seen that $\mathscr{J}'$ is an invertible $\underline{N}'$-module, and the pair (a', b') yields a morphism $f_{(a',b')} : \mathrm{sat.Bl}_{\mathscr{I}}(X, \underline{M}) \to \mathbb{P}^1_{(X,\underline{M})}$ which fulfills the sought condition. Indeed, denote by $\underline{N}'_\xi$ the log structure of $\mathrm{sat.Bl}_{\mathscr{I}\underline{M}_\xi}(|\xi|, \underline{M}_\xi)$; in light of (12.4.50) and example 12.4.29(iii), the base change

$$|\xi| \times_X f_{(a',b')} : \mathrm{sat.Bl}_{\mathscr{I}\underline{M}_\xi}(|\xi|, \underline{M}_\xi) \to \mathbb{P}^1_{(|\xi|, \underline{M}_\xi)}$$

is the unique morphism $f_{(\overline{a}',\overline{b}')}$ of $(|\xi|, \underline{M}_\xi)$-schemes corresponding to the pair $(\overline{a}', \overline{b}')$ of global sections of $\mathscr{J}'\underline{N}'_\xi$ obtained by pulling back the pair (a', b'). Thus, the assertion is just claim 12.4.55. □

12.5. **Regular log schemes.** In this section we introduce the logarithmic version of the classical regularity condition for locally noetherian schemes. This theory is essentially due to K.Kato ([112]), and we mainly follow his exposition, except in a few places where his original arguments are slightly flawed, in which cases we supply the necessary corrections.

Lemma 12.5.1. *Let A be a noetherian local ring, N an A-module of finite type, $\alpha : P \to A$ and $\beta : Q \to A$ two morphisms of pointed monoids, with $P^\sharp$ and $Q^\sharp$ both fine. Suppose that α and β induce the same constant log structure on* $\mathrm{Spec}\, A$ *(see* (12.1.15)*). Then N is α-flat if and only if it is β-flat.*

Proof. Let ξ be a τ-point localized at the closed point of $X := \mathrm{Spec}\, A$, set $B := \mathscr{O}_{X,\xi}$ and let $\varphi : A \to B$ be the natural map. Let also M be the push-out of the diagram of monoids $P \leftarrow (\varphi \circ \alpha)^{-1}B^\times \to B^\times$ deduced from α; then $M \simeq P^{\log}_{X,\xi}$, the stalk at the point ξ of the constant log structure on X_τ associated to α. Since φ is faithfully flat, it is easily seen that N is α-flat if and only if $N \otimes_A B$ is $\varphi \circ \alpha$-flat.

Hence we may replace A by B, α by $\varphi \circ \alpha$, N by $N \otimes_A B$, and Q by M, after which we may assume that $Q = P \amalg_{\alpha^{-1}(A^\times)} A^\times$; especially, there exists a morphism of monoids $\gamma : P \to Q$ such that $\alpha = \beta \circ \gamma$, and moreover β is a local morphism.

Next, set $S := \alpha^{-1}(A^\times)$; clearly γ extends to a morphism of monoids $\gamma' : S^{-1}P \to Q$, and α and $\beta \circ \gamma'$ induce the same constant log structure on X_τ. Arguing as in the proof of proposition 6.4.31, we see that N is P-flat if and only if it is $S^{-1}P$-flat. Hence, we may replace P by $S^{-1}P$, which allows to assume that γ induces an isomorphism $P \amalg_{P^\times} A^\times \xrightarrow{\sim} Q$, therefore also an isomorphism $P^\sharp \xrightarrow{\sim} Q^\sharp$. The latter implies that $\mathfrak{m}_Q = \mathfrak{m}_P Q$; moreover, notice that the morphism of monoids $P^\times \to A^\times$ is faithfully flat, so the natural map :

$$\mathrm{Tor}_1^{\mathbb{Z}\langle P\rangle}(N, \mathbb{Z}\langle P/\mathfrak{m}_P\rangle) \to \mathrm{Tor}_1^{\mathbb{Z}\langle Q\rangle}(N, \mathbb{Z}\langle (P/\mathfrak{m}_P) \otimes_P Q\rangle) \to \mathrm{Tor}_1^{\mathbb{Z}\langle Q\rangle}(N, \mathbb{Z}\langle Q/\mathfrak{m}_Q\rangle)$$

is an isomorphism. The assertion follows. □

Lemma 12.5.2. *Let M be an integral monoid, A a ring, $\varphi : M \to A$ a morphism of monoids, and set $S :=$ $\mathrm{Spec}\, A$. Suppose that A is φ-flat. Then the log structure $(M, \varphi)^{\log}_S$ on S_τ is the subsheaf of monoids of $\mathscr{O}_S$ generated by $\mathscr{O}_S^\times$ and the image of M.*

Proof. To ease notation, set $\underline{M} := (M,\varphi)^{\log}_S$; let ξ be any τ-point of S. Then the stalk $\underline{M}_\xi$ is the push-out of the diagram : $\mathscr{O}^\times_{S,\xi} \leftarrow \varphi^{-1}_\xi(\mathscr{O}^\times_{S,\xi}) \to M$ where $\varphi_\xi : M \to \mathscr{O}_{S,\xi}$ is deduced from φ. Hence $\underline{M}_\xi$ is generated by $\mathscr{O}^\times_{S,\xi}$ and the image of M, and it remains only to show that the structure map $\underline{M}_\xi \to \mathscr{O}_{S,\xi}$ is injective. Therefore, let $a, b \in M$ and $u, v \in \mathscr{O}^\times_{S,\xi}$ such that :

(12.5.3) $$\varphi_\xi(a)\cdot u = \varphi_\xi(b)\cdot v.$$

We come down to showing :

Claim 12.5.4. There exist $c, d \in M$ such that :

$$\varphi_\xi(c), \varphi_\xi(d) \in \mathscr{O}^\times_{S,\xi} \qquad ac = bd \qquad \varphi_\xi(c)\cdot v = \varphi_\xi(d)\cdot u.$$

Proof of the claim. Let $\mathfrak{m}_\xi \subset \mathscr{O}_{S,\xi}$ be the maximal ideal, and set $\mathfrak{p} := \varphi^{-1}_\xi(\mathfrak{m}_\xi)$, so that φ_ξ extends to a local morphism $\varphi_\mathfrak{p} : M_\mathfrak{p} \to \mathscr{O}_{S,\xi}$. Since $\mathscr{O}_{S,\xi}$ is a flat A-algebra, $\mathscr{O}_{S,\xi}$ is φ-flat, and consequently it is faithfully $\varphi_\mathfrak{p}$-flat (lemma 6.1.36). Then, assumption (12.5.3) leads to the identity:

$$aM_\mathfrak{p} \otimes_{M_\mathfrak{p}} \mathscr{O}_{S,\xi} = \varphi_\xi(a)\cdot\mathscr{O}_{S,\xi} = \varphi_\xi(b)\cdot\mathscr{O}_{S,\xi} = bM_\mathfrak{p} \otimes_{M_\mathfrak{p}} \mathscr{O}_{S,\xi}$$

whence $aM_\mathfrak{p} = bM_\mathfrak{p}$, by faithful $\varphi_\mathfrak{p}$-flatness. It follows that there exist $x, y \in M_\mathfrak{p}$ such that $ax = b$ and $by = a$, hence $axy = a$, which implies that $xy = 1$, since $M_\mathfrak{p}$ is an integral module. The latter means that there exist $c, d \in M\backslash\mathfrak{p}$ such that $ac = bd$ in M. We deduce easily that

$$\varphi_\xi(a)\cdot\varphi_\xi(c)\cdot v = \varphi_\xi(a)\cdot\varphi_\xi(d)\cdot u.$$

Thus, to complete the proof, it suffices to show that $\varphi_\xi(a)$ is regular in $\mathscr{O}_{S,\xi}$. However, the morphism of M-modules $\mu_a : M \to M : m \mapsto am$ (for all $m \in M$) is injective, hence the same holds for the map $\mu_a \otimes_M \mathscr{O}_{S,\xi} : \mathscr{O}_{S,\xi} \to \mathscr{O}_{S,\xi}$, which is just multiplication by $\varphi(a)$. ☐

12.5.5. Let $(X, \underline{M})$ be a locally noetherian log scheme, with coherent log structure (on the site X_τ, see (12.2.1)), and let ξ be any τ-point of X. We denote by $I(\xi, \underline{M}) \subset \mathscr{O}_{X,\xi}$ the ideal generated by the image of the maximal ideal of $\underline{M}_\xi$, and we set :

$$d(\xi, \underline{M}) := \dim \mathscr{O}_{X,\xi}/I(\xi, \underline{M}) + \dim \underline{M}_\xi.$$

Lemma 12.5.6. *In the situation of* (12.5.5)*, suppose furthermore that* $(X, \underline{M})$ *is a fs log scheme. Then we have the inequality :*

$$\dim \mathscr{O}_{X,\xi} \le d(\xi, \underline{M}).$$

Proof. According to corollary 12.1.36(i), there exist a neighborhood $U \to X$ of ξ in X_τ, and a fine and saturated chart $\alpha : P_U \to \underline{M}_{|U}$, which is sharp at the point ξ. Especially, $P \simeq \underline{M}^\sharp_\xi$, therefore $\dim P = \dim \underline{M}_\xi$ (corollary 6.4.12(ii)). Notice that $\mathscr{O}_{X,\xi}$ is a noetherian local ring (this is obvious for $\tau =$ Zar, and follows from [66, Ch.IV, Prop.18.8.8(iv)] for $\tau =$ ét), hence to conclude it suffices to apply corollary 6.4.27(i) to the induced map of monoids $P \to \mathscr{O}_{X,\xi}$. ☐

Definition 12.5.7. Let $(X, \underline{M})$ be a locally noetherian fs log scheme, ξ a τ-point of X.

(i) We say that $(X, \underline{M})$ is *regular at the point* ξ, if the following holds :
  (a) the inequality of lemma (12.5.6) is actually an equality, and
  (b) the local ring $\mathscr{O}_{X,\xi}/I(\xi, \underline{M})$ is regular.
(ii) We denote by $(X, \underline{M})_{\mathrm{reg}} \subset X$ the set of points x such that $(X, \underline{M})$ is regular at any (hence all) τ-points of X localized at x.
(iii) We say that $(X, \underline{M})$ is *regular*, if $(X, \underline{M})_{\mathrm{reg}} = X$.
(iv) Let K be a field, and X a K-scheme. We say that the K-log scheme $(X, \underline{M})$ is *geometrically regular*, if $E \times_K (X, \underline{M})$ is regular, for every finite field extension E of K.

Remark 12.5.8. (i) Certain constructions produce log structures $\underline{M} \to \mathscr{O}_X$ that are morphisms of pointed monoids. It is then useful to extend the notion of regularity to such log structures. We shall say that $(X, \underline{M})$ is a *pointed regular* log scheme, if there exists a log structure $\underline{N}$ on X, such that $\underline{M} = \underline{N}_\circ$ (notation of (12.1.11)), and $(X, \underline{N})$ is a regular log scheme.

(ii) Likewise, if K is a field, X a K-scheme, and $\underline{M}$ a log structure on X, we shall say that the K-log scheme $(X, \underline{M})$ is *geometrically pointed regular*, if $\underline{M} = \underline{N}_\circ$ for some log structure $\underline{N}$ on X, such that $(X, \underline{N})$ is geometrically regular.

12.5.9. Let $(X, \underline{M})$ be a locally noetherian fs log scheme, ξ a τ-point of X, and $\mathscr{O}^\wedge_{X,\xi}$ the completion of $\mathscr{O}_{X,\xi}$. The next result is the logarithmic version of the classical characterization of complete regular local rings ([126, Th.29.7 and Th.29.8]).

Theorem 12.5.10. *With the notation of* (12.5.9)*, the log scheme* $(X, \underline{M})$ *is regular at the point* ξ *if and only if there exist :*

(a) *a complete regular local ring* $(R, \mathfrak{m}_R)$*, and a local ring homomorphism* $R \to \mathscr{O}^\wedge_{X,\xi}$*;*
(b) *a fine and saturated chart* $P_{X(\xi)} \to \underline{M}(\xi)$ *which is sharp at the closed point* ξ *of* $X(\xi)$*, such that the induced continuous ring homomorphism*

$$R[[P]] \to \mathscr{O}^\wedge_{X,\xi}$$

is an isomorphism if $\mathscr{O}_{X,\xi}$ *contains a field, and otherwise it is a surjection, with kernel generated by an element* $\vartheta \in R[[P]]$ *whose constant term lies in* $\mathfrak{m}_R \backslash \mathfrak{m}_R^2$.

Proof. Suppose first that (a) and (b) hold. If R contains a field, then it follows that

$$\dim \mathscr{O}_{X,\xi} = \dim \mathscr{O}^\wedge_{X,\xi} = \dim R + \dim P$$

by corollary 6.4.27(ii); moreover, in this case $I(\xi, \underline{M}) = \mathfrak{m}_P \mathscr{O}_{X,\xi}$, hence $\mathscr{O}_{X,\xi}/I(\xi, \underline{M}) = \mathscr{O}_{X,\xi}/\mathfrak{m}_P \mathscr{O}_{X,\xi}$, whose completion is $\mathscr{O}^\wedge_{X,\xi}/\mathfrak{m}_P \mathscr{O}^\wedge_{X,\xi} \simeq R$ so that $\mathscr{O}_{X,\xi}/I(\xi, \underline{M})$ is regular ([63, Ch.0, Prop.17.3.3(i)]). Furthermore,

$$\dim R = \dim \mathscr{O}^\wedge_{X,\xi}/\mathfrak{m}_P \mathscr{O}^\wedge_{X,\xi} = \dim \mathscr{O}_{X,\xi}/I(\xi, \underline{M})$$

([126, Th.15.1]). Hence $(X, \underline{M})$ is regular at the point ξ. If R does not contain a field, we obtain $\dim \mathscr{O}_{X,\xi} = \dim R + \dim P - 1$. On the other hand, let ϑ_0 be the image of ϑ in $\mathfrak{m}_R$; then we have $\mathscr{O}^\wedge_{X,\xi}/\mathfrak{m}_P \mathscr{O}^\wedge_{X,\xi} \simeq R/\vartheta_0 R$, which is regular of dimension $\dim\, R - 1$, and again we invoke [63, Ch.0, Prop.17.3.3(i)] to see that $(X, \underline{M})$ is regular at ξ.

Conversely, suppose that $(X, \underline{M})$ is regular at ξ. Suppose first that $\mathscr{O}_{X,\xi}$ contains a field; then we may find a field $k \subset \mathscr{O}^\wedge_{X,\xi}$ mapping isomorphically to the residue field of $\mathscr{O}^\wedge_{X,\xi}$ ([126, Th.28.3]). Pick a sequence $(t_1, \dots, t_r)$ of elements of $\mathscr{O}_{X,\xi}$ whose image in the regular local ring $\mathscr{O}_{X,\xi}/I(\xi, \underline{M})$ forms a regular system of parameters. Let also P a fine saturated monoid for which there exist a neighborhood $U \to X$ of ξ and a chart $P_U \to \underline{M}_{|U}$, sharp at the point ξ. There follows a map of monoids $\alpha : P \to \mathscr{O}_{X,\xi}$, and necessarily the image of $\mathfrak{m}_P$ lies in the maximal ideal of $\mathscr{O}_{X,\xi}$, and generates $I(\xi, \underline{M})$. We deduce a continuous ring homomorphism

$$k[[P \times \mathbb{N}^{\oplus r}]] \to \mathscr{O}^\wedge_{X,\xi}$$

which extends α, and which maps the generators $T_1, \dots, T_r$ of $\mathbb{N}^{\oplus r}$ onto respectively $t_1, \dots, t_r$. This map is clearly surjective, and by comparing dimensions (using corollary 6.4.27(ii)) one sees that it is an isomorphism. Then the theorem holds in this case, with $R := k[[\mathbb{N}^{\oplus r}]]$.

Next, if $\mathscr{O}_{X,\xi}$ does not contain a field, then its residue characteristic is a positive integer p, and we may find a complete discrete valuation ring $V \subset \mathscr{O}^\wedge_{X,\xi}$ whose maximal ideal is pV, and such that V/pV maps isomorphically onto the residue field of $\mathscr{O}^\wedge_{X,\xi}$ ([126, Th.29.3]). Again, we choose a morphism of monoids $\alpha : P \to \mathscr{O}_{X,\xi}$ as in the foregoing, and a sequence $(t_1, \dots, t_r)$

of elements of $\mathscr{O}_{X,\xi}$ lifting a regular system of parameters for $\mathscr{O}_{X,\xi}/I(\xi,\underline{M})$, by means of which we define a continuous ring homomorphism

$$\varphi : V[[P \times \mathbb{N}^{\oplus r}]] \to \mathscr{O}^{\wedge}_{X,\xi}$$

as in the previous case. Again, it is clear that φ is surjective. The image of the ideal J generated by the maximal ideal of $P \times \mathbb{N}^{\oplus r}$ is the maximal ideal of $\mathscr{O}^{\wedge}_{X,\xi}$; in particular, there exists $x \in J$ such that $\vartheta := p - x$ lies in $\mathrm{Ker}\,\varphi$. If we let $R := V[[\mathbb{N}^{\oplus r}]]$, it is clear that $\vartheta \in \mathfrak{m}_R \setminus \mathfrak{m}_R^2$.

Claim 12.5.11. Let A be a ring, π a regular element of A such that $A/\pi A$ is an integral domain, P a fine and sharp monoid. Let also ϑ be an element of $A[[P]]$ whose constant term is π (see (6.4.25)). Then $A[[P]]/(\vartheta)$ is an integral domain.

Proof of the claim. To ease notation, set $A_0 := A/\pi A$, $B := A[[P]]$ and $C := B/\vartheta B$. Choose a decomposition (6.4.26), and set $\mathrm{Fil}^\gamma_n B := \prod_{i\geq n} A[[\mathrm{gr}^\gamma_i P]]$ for every $n \in \mathbb{N}$. $\mathrm{Fil}^\gamma_\bullet B$ is a separated filtration by ideals of B, and we may consider the induced filtration $\mathrm{Fil}^\gamma_\bullet C$ on C. First, we remark that $\mathrm{Fil}^\gamma_\bullet C$ is also separated. This comes down to checking that

$$\bigcap_{n\geq 0} \vartheta B + \mathrm{Fil}^\gamma_n B = \vartheta B.$$

To this aim, suppose that, for a given $x \in B$ we have identities of the type $x = \vartheta y_n + z_n$, with $y_n \in B$ and $z_n \in \mathrm{Fil}^\gamma_n B$ for every $n \in \mathbb{N}$. Then, since π is regular, an easy induction shows that $\mathrm{gr}^\gamma_i(y_n) = \mathrm{gr}^\gamma_i(y_m)$ whenever $n, m > i$, and moreover $x = \vartheta \cdot \sum_{i\in\mathbb{N}} \mathrm{gr}^\gamma_i(y_{i+1})$, which shows the contention. It follows that, in order to show that C is a domain, it suffices to show that the same holds for the graded ring $\mathrm{gr}^\gamma_\bullet C$ associated to $\mathrm{Fil}^\gamma_\bullet C$. However, notice that :

$$\mathrm{Fil}^\gamma_n B \cap \vartheta B = \vartheta \cdot \mathrm{Fil}^\gamma_n B \qquad \text{for every } n \in \mathbb{N}.$$

(Indeed, this follows easily from the fact that π is a regular element : the verification shall be left to the reader). Hence, we may compute :

$$\mathrm{gr}^\gamma_n C = \frac{\mathrm{Fil}^\gamma_n B + \vartheta B}{\mathrm{Fil}^\gamma_{n+1} + \vartheta B} \simeq \frac{\mathrm{Fil}^\gamma_n B}{\mathrm{Fil}^\gamma_{n+1} + \vartheta \mathrm{Fil}^\gamma_n} \simeq A[\mathrm{gr}^\gamma_n P]/\vartheta A[\mathrm{gr}^\gamma_n P] \simeq A_0[\mathrm{gr}^\gamma_n P].$$

Thus, $\mathrm{gr}^\gamma_\bullet A \simeq A_0[P]$, which is a domain, since by assumption A_0 is a domain. ◊

From claim 12.5.11(ii) we deduce that $R[[P]]/(\vartheta)$ is an integral domain. Then, again by comparing dimensions, we see that φ factors through an isomorphism $R[[P]]/(\vartheta) \xrightarrow{\sim} \mathscr{O}^{\wedge}_{X,\xi}$. □

Remark 12.5.12. Resume the notation of (12.5.9), and suppose that $\mathscr{O}_{X,\xi}/I(\xi,\underline{M})$ is a regular local ring. Let $P_{X(\xi)} \to \underline{M}(\xi)$ be a chart as in theorem 12.5.10(b), and $\alpha : P \to \mathscr{O}_{X,\xi}$ the corresponding morphism of monoids. Moreover, if $\mathscr{O}_{X,\xi}$ contains a field, let V denote a coefficient field of $\mathscr{O}^{\wedge}_{X,\xi}$, and otherwise, let V be a complete discrete valuation ring whose maximal ideal is generated by p, the residue characteristic of $\mathscr{O}_{X,\xi}$. In either case, pick a ring homomorphism $V \to \mathscr{O}^{\wedge}_{X,\xi}$ inducing an isomorphism of V/pV onto the residue field of $\mathscr{O}_{X,\xi}$. Let as well $t_1, \dots, t_r \in \mathscr{O}_{X,\xi}$ be any sequence of elements whose image in $\mathscr{O}_{X,\xi}/I(\xi,\underline{M})$ forms a regular system of parameters, and extend the map α to a morphism of monoids $P \times \mathbb{N}^{\oplus r} \to \mathscr{O}_{X,\xi}$, by the rule : $e_i \mapsto t_i$, where $e_1, \dots, e_r$ is the natural basis of $\mathbb{N}^{\oplus r}$. Then by inspecting the proof of theorem 12.5.10, we see that the induced continuous ring homomorphism :

$$V[[P \times \mathbb{N}^{\oplus r}]] \to \mathscr{O}^{\wedge}_{X,\xi}$$

is always surjective, and if V is not a field, its kernel contains an element ϑ whose constant term in V is $\vartheta_0 = p$. If V is a field (resp. if V is a discrete valuation ring) then $(X, \underline{M})$ is regular at the point ξ, if and only if this map is an isomorphism (resp. if and only if the kernel of this map is generated by ϑ).

Corollary 12.5.13. *Let $(X, \underline{M})$ be a regular log scheme. Then the scheme X is normal and Cohen-Macaulay.*

Proof. Let $x \in X$ be any point, and ξ a τ-point localized at x; we have to show that $\mathscr{O}_{X,x}$ is Cohen-Macaulay; in light of [66, Ch.IV, Cor.18.8.13(a)] (when $\tau = \text{ét}$), it suffices to show that the same holds for $\mathscr{O}_{X,\xi}$. Then [126, Th.17.5] further reduces to showing that the completion $\mathscr{O}^{\wedge}_{X,\xi}$ is Cohen-Macaulay; the latter follows easily from theorems 12.5.10 and 11.6.35(i). Next, in order to prove that X is normal, it suffices to show that $\mathscr{O}_{X,x}$ is regular, whenever x has codimension one in X ([126, Th.23.8]). Again, by [66, Ch.IV, Cor.18.8.13(c)] (when $\tau = \text{ét}$) and [63, Ch.0, Prop.17.1.5], we reduce to showing that $\mathscr{O}^{\wedge}_{X,\xi}$ is regular for such a point x. However, for a point of codimension one we have $r := \dim \underline{M}_\xi \leq 1$. If $r = 0$, then $I(\xi, \underline{M}) = \{0\}$, hence $\mathscr{O}_{X,\xi}$ is regular. Lastly, if $r = 1$, we see that $\underline{M}^\sharp_\xi \simeq \mathbb{N}$ (theorem 6.4.18(iii)); consequently, there exist a regular local ring R and an isomorphism $\mathscr{O}^{\wedge}_{X,\xi} \simeq R[[\mathbb{N}]]/(\vartheta)$, where $\vartheta = 0$ if $\mathscr{O}_{X,\xi}$ contains a field, and otherwise the constant term of ϑ lies in $\mathfrak{m}_R \setminus \mathfrak{m}_R^2$. Since $R[[\mathbb{N}]]$ is again regular, the assertion follows in either case. □

Corollary 12.5.14. *Let $i : (X', \underline{M}') \to (X, \underline{M})$ be an exact closed immersion of regular log schemes (see definition* 12.3.22(i)*). Then the underlying morphism of schemes $X' \to X$ is a regular closed immersion.*

Proof. Let ξ be a τ-point of X, and denote by J the kernel of $i^\natural_\xi : \mathscr{O}_{X,\xi} \to \mathscr{O}_{X',\xi}$. To ease notation, let as well $A := \mathscr{O}_{X,\xi}/I(\xi, \underline{M})$ and $A' := \mathscr{O}_{X',\xi}/I(\xi, \underline{M}')$ Since $\log i : i^*\underline{M} \to \underline{M}'$ is an isomorphism, $i^\natural_\xi$ induces an isomorphism :

$$\mathscr{O}_{X,\xi}/(J + I(\xi, \underline{M})) \xrightarrow{\sim} A'.$$

Since A and A' are regular, there exists a sequence of elements $t_1, \dots, t_k \in J$, whose image in A forms the beginning of a regular system of parameters and generate the kernel of the induced map $A \to A'$ ([63, Ch.0, Cor.17.1.9]). Extend this sequence by suitable elements of $\mathscr{O}_{X,\xi}$, to obtain a sequence $(t_1, \dots, t_r)$ whose image in A is a regular system of parameters. We deduce a surjection $\varphi : V[[P \times \mathbb{N}^{\oplus r}]] \to \mathscr{O}^{\wedge}_{X,\xi}$ as in remark 12.5.12, where V is either a field or a complete discrete valuation ring. Denote by $(e_1, \dots, e_r)$ the natural basis of $\mathbb{N}^{\oplus r}$. Now, suppose first that V is a complete discrete valuation ring; then $\mathrm{Ker}\, \varphi$ is generated by an element $\vartheta \in V[[P \times \mathbb{N}^{\oplus r}]]$, whose constant term is a uniformizer in V; we deduce easily from claim 12.5.11 that $(e_1, \dots, e_r, \vartheta)$ is a regular sequence in $V[[P \times \mathbb{N}^{\oplus r}]]$; hence the same holds for the sequence $(\vartheta, e_1, \dots, e_r)$, in view of [126, p.127, Cor.]. This implies that $(t_1, \dots, t_r)$ is a regular sequence in $\mathscr{O}^{\wedge}_{X,\xi}$, hence $(t_1, \dots, t_k)$ is a regular sequence in $\mathscr{O}_{X,\xi}$, which is the contention. The case where V is a field is analogous, though simpler : the details shall be left to the reader. □

Remark 12.5.15. In the situation of remark 12.5.12, suppose that P is a free monoid of finite rank d, let $\{f_1, \dots, f_d\} \subset \mathscr{O}_{X,\xi}$ be the image of the (unique) basis of P, and for every $i \leq d$ let $Z_i \subset X$ be the zero locus of f_i; then $\bigcup_{i=1}^d Z_i$ is a strict normal crossings divisor in the sense of example 12.2.11. The proof is analogous to that of corollary 12.5.14 : the sequence $(f_1, \dots, f_d, \vartheta)$ is regular in $V[[P \oplus \mathbb{N}^{\oplus r}]]$, hence also its permutation $(\vartheta, f_1, \dots, f_d)$ is regular, whence the claim (the details shall be left to the reader).

Proposition 12.5.16. *Resume the situation of* (12.5.9). *We have :*

- (i) *The log scheme $(X, \underline{M})$ is regular at the τ-point ξ if and only if the following two conditions hold :*
  - (a) *The ring $\mathscr{O}_{X,\xi}/I(\xi, \underline{M})$ is regular.*
  - (b) *There exists a morphism of monoids $P \to \mathscr{O}_{X,\xi}$ from a fine monoid P, whose associated constant log structure on $X(\xi)$ is the same as $\underline{M}(\xi)$, and such that $\mathscr{O}_{X,\xi}$ is P-flat.*

(ii) *Moreover, if the equivalent conditions of* (i) *hold, and* $Q_X \to \underline{M}(\xi)$ *is any fine chart, then* $\mathscr{O}_{X,\xi}$ *is Q-flat, for the induced map of monoids* $Q \to \mathscr{O}_{X,\xi}$.

Proof. (i): Suppose first that $(X, \underline{M})$ is regular at the point ξ; then by definition (a) holds. Next, we may find a fine monoid P and a local morphism $\alpha : P \to A := \mathscr{O}_{X,\xi}$ whose associated constant log structure on $X(\xi)$ is the same as $\underline{M}(\xi)$, and a regular local ring R, with a ring homomorphism $R \to A$ such that the induced continuous map $R[[P]] \to A^\wedge$ fulfills condition (b) of theorem 12.5.10 (where $A^\wedge$ is the completion of A). Since the completion map $\varphi : A \to A^\wedge$ is faithfully flat, A is α-flat if and only if $A^\wedge$ is $\varphi \circ \alpha$-flat; in light of proposition 6.1.39(i), it then suffices to show that, for every ideal $I \subset P$, the natural map

$$A^\wedge \overset{\mathbf{L}}{\otimes}_P P/I \to A^\wedge \otimes_P P/I$$

is an isomorphism in $\mathsf{D}^-(A^\wedge\text{-}\mathbf{Mod})$ (notation of (6.1.33)). To this aim we remark :

Claim 12.5.17. For any ideal $I \subset P$, the natural morphism

$$R[P] \overset{\mathbf{L}}{\otimes}_P P/I \to R\langle P/I \rangle$$

is an isomorphism in $\mathsf{D}^-(R[P]\text{-}\mathbf{Mod})$.

Proof of the claim. We consider the change of rings spectral sequence for Tor :

$$E^2_{ij} := \mathrm{Tor}_i^{\mathbb{Z}[P]}(\mathrm{Tor}_j^{\mathbb{Z}}(R, \mathbb{Z}[P]), \mathbb{Z}\langle P/I \rangle) \Rightarrow \mathrm{Tor}^{\mathbb{Z}}_{i+j}(R, \mathbb{Z}\langle P/I \rangle)$$

([163, Th.5.6.6]). Clearly $E^2_{ij} = 0$ whenever $j > 0$, whence isomorphisms :

$$\mathrm{Tor}_i^{\mathbb{Z}\langle P \rangle}(R\langle P \rangle, \mathbb{Z}\langle P/I \rangle) \xrightarrow{\sim} \mathrm{Tor}_i^{\mathbb{Z}}(R, \mathbb{Z}\langle P/I \rangle)$$

for every $i \in \mathbb{N}$. The claim follows easily. ◊

In light of claim 12.5.17 we deduce natural isomorphisms :

$$A^\wedge \overset{\mathbf{L}}{\otimes}_P P/I \xrightarrow{\sim} A^\wedge \overset{\mathbf{L}}{\otimes}_{R[P]} (R[P] \overset{\mathbf{L}}{\otimes}_P P/I) \xrightarrow{\sim} A^\wedge \overset{\mathbf{L}}{\otimes}_{R[P]} R\langle P/I \rangle$$

in $\mathsf{D}^-(A^\wedge\text{-}\mathbf{Mod})$. Now, if A contains a field, we have $A^\wedge \simeq R[[P]]$, which is a flat $R[P]$-algebra ([126, Th.8.8]), and the contention follows. If A does not contain a field, the complex

$$0 \to R[[P]] \xrightarrow{\vartheta} R[[P]] \to A^\wedge \to 0$$

is a $R[P]$-flat resolution of $A^\wedge$. Since $R[[P]]/IR[[P]] \simeq \lim_{n \in \mathbb{N}} R\langle P/(I \cup \mathfrak{m}_P^n) \rangle$, we come down to the following :

Claim 12.5.18. Let $\vartheta \in R[P]$ be any element whose constant term ϑ_0 is a regular element in R. Then, for every ideal $I \subset P$, the image of ϑ in $R\langle P/I \rangle$ is a regular element.

Proof of the claim. In view of (6.4.22), P can be regarded as a graded monoid $P = \coprod_{n \in \mathbb{N}} P_n$, so $R[P]$ is a graded algebra, and $I = \coprod_{n \in \mathbb{N}} (I \cap P_n)$ is a graded ideal. Thus, $\langle P/I \rangle$ is a graded R-algebra as well, and the claim follows easily (details left to the reader). ◊

Conversely, suppose that conditions (a) and (b) hold. By virtue of lemma 12.5.1, we may assume that P is fine, sharp and saturated, and that the map $P \to \mathscr{O}_{X,\xi}$ is local. According to remark 12.5.12, we may find a regular local ring R of dimension $\leq 1 + \dim A/\mathfrak{m}_P A$, and a surjective ring homomorphism :

$$\varphi : R[[P]] \to A^\wedge$$

Suppose first that $\dim R = 1 + \dim A/\mathfrak{m}_P A$; then $\mathrm{Ker}\,\varphi$ contains an element ϑ whose constant term ϑ_0 lies in $\mathfrak{m}_R \setminus \mathfrak{m}_R^2$, and φ induces an isomorphism $R_0 := R/\vartheta_0 R \xrightarrow{\sim} A^\wedge/\mathfrak{m}_P A^\wedge$. We have to show that φ induces an isomorphism $\overline{\varphi} : R[[P]]/(\vartheta) \xrightarrow{\sim} A^\wedge$. To this aim, we consider the $\mathfrak{m}_P$-adic filtrations on these rings; for the associated graded rings we have :

$$\mathrm{gr}_n R[[P]]/(\vartheta) \simeq R_0\langle \mathfrak{m}_P^n/\mathfrak{m}_P^{n+1}\rangle \qquad \mathrm{gr}_n A^\wedge = \mathfrak{m}_P^n A^\wedge/\mathfrak{m}_P^{n+1}A^\wedge.$$

Hence $\mathrm{gr}_n\overline{\varphi}$ is the natural map $A^\wedge/\mathfrak{m}_P A^\wedge \otimes_P (\mathfrak{m}_P^n/\mathfrak{m}_P^{n+1}) \to \mathfrak{m}_P^n A^\wedge/\mathfrak{m}_P^{n+1}A^\wedge$, and the latter is an isomorphism, since $A^\wedge$ is P-flat. The assertion follows in this case. The remaining case where $\dim R = \dim A/\mathfrak{m}_P A$ is similar, but easier, so shall be left to the reader, as an exercise.

(ii) follows immediately from (i) and lemma 12.5.1. □

Corollary 12.5.19. *Let $(X, \underline{M})$ be a log scheme, ξ a τ-point of X, and suppose that $(X, \underline{M})$ is regular at ξ. Then the following conditions are equivalent :*

(a) *$\mathscr{O}_{X,\xi}$ is a regular local ring.*

(b) *$\underline{M}_\xi^\sharp$ is a free monoid of finite rank.*

Proof. (b)⇒(a) : Indeed, it suffices to show that $\mathscr{O}_{X,\xi}^\wedge$ is regular ([63, Ch.0, Prop.17.3.3(i)]); by theorem 12.5.10, the latter is isomorphic to either $R[[P]]$ or $R[[P]]/\vartheta R[[P]]$, where R is a regular local ring, $P := \underline{M}_\xi$, and the constant term of ϑ lies in $\mathfrak{m}_R \setminus \mathfrak{m}_R^2$. Since, by assumption, P is a free monoid of finite rank, it is easily seen that rings of the latter kind are regular ([63, Ch.0, Cor.17.1.8]).

(a)⇒(b) : By proposition 12.5.16(ii), $R := \mathscr{O}_{X,\xi}$ is P-flat, for a morphism $P := \underline{M}_\xi^\sharp \to R$ that induces the log structure $\underline{M}(\xi)$ on $X(\xi)$. It follows that

$$\mathfrak{m}_P R/\mathfrak{m}_P^2 R = (\mathfrak{m}_P/\mathfrak{m}_P^2) \otimes_P R = R^{\oplus r}$$

where $r := \mathrm{rk}^\circ_{P^\times}\mathfrak{m}_P/\mathfrak{m}_P^2$ is the cardinality of $\mathfrak{m}_P \setminus \mathfrak{m}_P^2$. In view of [66, Ch.IV, Prop.16.9.3, Cor.16.9.4, Cor.19.1.2], we deduce that the image of $\mathfrak{m}_P \setminus \mathfrak{m}_P^2$ is a regular sequence of R of length r, hence $\dim P = \dim R - \dim R/\mathfrak{m}_P R = r$, since $(X, \underline{M})$ is regular at ξ. Then the assertion follows from proposition 6.4.23. □

Corollary 12.5.20. *Let $(X, \underline{M})$ be a regular log scheme, ξ any τ-point of X, and $\mathfrak{p} \subset \underline{M}_\xi$ an ideal. We have :*

(i) *If $\mathfrak{p}$ is a prime ideal, $\mathfrak{p}\mathscr{O}_{X,\xi}$ is a prime ideal of $\mathscr{O}_{X,\xi}$, and* $\mathrm{ht}\,\mathfrak{p} = \mathrm{ht}\,\mathfrak{p}\mathscr{O}_{X,\xi}$.

(ii) *If $\mathfrak{p}$ is a radical ideal, $\mathfrak{p}\mathscr{O}_{X,\xi}$ is a radical ideal of $\mathscr{O}_{X,\xi}$.*

Proof. To ease notation, set $A := \mathscr{O}_{X,\xi}$. Pick a chart $\beta : P_{X(\xi)} \to \underline{M}(\xi)$ with P fine, sharp and saturated (corollary 12.1.36(i)); by proposition 12.5.16(ii), the ring A is P-flat for the resulting map $P \to A$. Let $\mathfrak{q} := \beta^{-1}\mathfrak{p} \subset P$; then $\mathfrak{p}A = \mathfrak{q}A$.

(i): Since $\mathfrak{p}$ is a prime ideal, $\mathfrak{q}$ is a prime ideal of P, and in order to prove that $\mathfrak{p}A$ is a prime ideal, it suffices therefore to show that the completion $(A/\mathfrak{q}A)^\wedge$ of $A/\mathfrak{q}A$ is an integral domain. However, remark 12.5.12 implies that $(A/\mathfrak{q}A)^\wedge \simeq B/\vartheta B$, where $B := R[[P\backslash\mathfrak{q}]]$, with $(R, \mathfrak{m}_R)$ a regular local ring, and ϑ is either zero, or else it is an element whose constant term $\vartheta_0 \in R$ lies in $\mathfrak{m}_R\backslash\mathfrak{m}_R^2$. The assertion is obvious when $\vartheta = 0$, and otherwise it follows from claim 12.5.11. Next, by going down (corollary 6.4.34), we see that :

$$\mathrm{ht}\,\mathfrak{p}A \geq \mathrm{ht}\,\mathfrak{p}.$$

On the other hand, notice that we have a natural identification $\mathrm{Spec}\,\underline{M}_\xi \xrightarrow{\sim} \mathrm{Spec}\,P$, especially $\mathrm{ht}\,\mathfrak{p} = \mathrm{ht}\,\mathfrak{q}$, hence $\dim A/\mathfrak{p}A = \dim(A/\mathfrak{q}A)^\wedge = \dim R + \dim(P\backslash\mathfrak{q}) - \varepsilon$, where ε is either 0 or 1 depending on whether R does or does not contain a field (corollary 6.4.27(ii)). Thus :

$$\mathrm{ht}\,\mathfrak{p}A \leq \dim A - \dim A/\mathfrak{p}A = \dim P - \dim(P\backslash\mathfrak{q}) = \mathrm{ht}\,\mathfrak{p}$$

(corollary 6.4.12(iii)), which completes the proof.

(ii): In this case, $\mathfrak{q}$ is a radical ideal of P, so it can be written as a finite intersection of prime ideals of P (lemmata 6.1.16 and 6.1.20(iii)); then the assertion follows from (i) and lemma 6.1.37 (details left to the reader). □

Lemma 12.5.21. *Let X be a scheme, $\underline{M}$ a fs log structure on X_{Zar}, and ξ a geometric point of X. Then $(X, \underline{M})$ is regular at the point $|\xi|$ if and only if $\widetilde{u}_X^*(X, \underline{M})$ is regular at ξ.*

Proof. Set $(Y, \underline{N}) := \widetilde{u}_X^*(X, \underline{M})$ (notation of (12.2.2) : of course $Y = X$, but the sheaf $\mathscr{O}_Y$ is defined on the site $X_{\text{ét}}$, hence $B := \mathscr{O}_{Y,\xi}$ is the strict henselization of $A := \mathscr{O}_{X,|\xi|}$), and let $\alpha : \underline{M}_{|\xi|} \to B$ be the induced morphism of monoids; since α is local, it is easily seen that $\underline{N}_\xi$ is isomorphic to the push-out of the diagram $\underline{M}_{|\xi|} \leftarrow \underline{M}^\times_{|\xi|} \to B^\times$, especially $\dim \underline{M}_{|\xi|} = \dim \underline{N}_\xi$. Moreover, $I(\xi, \underline{N}) = I(|\xi|, \underline{M})B$, so that $B_0 := B/I(\xi, \underline{N})$ is the strict henselization of $A_0 := A/I(|\xi|, \underline{M})$ ([66, Ch.IV, Prop.18.6.8]); hence A_0 is regular if and only if the same holds for B_0 ([66, Ch.IV, Cor.18.8.13]). Finally, $\dim A = \dim B$ and $\dim A_0 = \dim B_0$ ([126, Th.15.1]). The lemma follows. ☐

12.5.22. Let $(Y, \underline{N})$ be a log scheme, $\overline{y}$ a τ-point of Y, and $\alpha : Q_Y^{\log} \to \underline{N}$ a fine and saturated chart which is sharp at $\overline{y}$. Let also $\varphi : Q \to P$ be an injective morphism of monoids, with P fine and saturated, and such that $P^\times$ is a torsion-free abelian group. Define $(X, \underline{M})$ as the fibre product in the cartesian diagram of log schemes :

$$(12.5.23)\qquad \begin{array}{ccc} (X, \underline{M}) & \xrightarrow{\ f\ } & (Y, \underline{N}) \\ \downarrow & & \downarrow{\scriptstyle h} \\ \mathrm{Spec}(\mathbb{Z}, P) & \xrightarrow{\mathrm{Spec}(\mathbb{Z}, \varphi)} & \mathrm{Spec}(\mathbb{Z}, Q) \end{array}$$

where h is induced by α; especially, h is strict.

Lemma 12.5.24. *In the situation of* (12.5.22)*, let $\overline{x}$ be any τ-point of X such that $f(\overline{x}) = \overline{y}$, and suppose that $(Y, \underline{N})$ is regular at $\overline{y}$. Then $(X, \underline{M})$ is regular at $\overline{x}$.*

Proof. To begin with, we show :

Claim 12.5.25. The natural map :

$$\mathscr{O}_{X,\overline{x}} \overset{\mathbf{L}}{\otimes}_P P/I \to \mathscr{O}_{X,\overline{x}} \otimes_P P/I$$

is an isomorphism in $\mathsf{D}^-(\mathscr{O}_{X,\overline{x}}\text{-}\mathbf{Mod})$, for every ideal $I \subset P$ (notation of (6.1.33)).

Proof of the claim. It suffices to show that this map is an isomorphism in $\mathsf{D}^-(\mathscr{O}_{Y,\overline{y}}\text{-}\mathbf{Mod})$, and in the latter category we have a commutative diagram :

$$(12.5.26)\qquad \begin{array}{ccccc} (\mathscr{O}_{Y,\overline{y}} \overset{\mathbf{L}}{\otimes}_Q P) \overset{\mathbf{L}}{\otimes}_P P/I & \longrightarrow & & & \mathscr{O}_{Y,\overline{y}} \overset{\mathbf{L}}{\otimes}_Q P/I \\ \downarrow & & & & \downarrow \\ (\mathscr{O}_{Y,\overline{y}} \otimes_Q P) \overset{\mathbf{L}}{\otimes}_P P/I & \longrightarrow & (\mathscr{O}_{Y,\overline{y}} \otimes_Q P) \otimes_P P/I & \xrightarrow{\sim} & \mathscr{O}_{Y,\overline{y}} \otimes_Q P/I. \end{array}$$

Since $\mathscr{O}_{X,\overline{x}}$ is a localization of $\mathscr{O}_{Y,\overline{y}} \otimes_Q P$, we are reduced to showing that the bottom arrow of (12.5.26) is an isomorphism. However, the top arrow of (12.5.26) is always an isomorphism. Moreover, on the one hand, since $(Y, \underline{N})$ is regular at $\overline{y}$, the ring $\mathscr{O}_{Y,\overline{y}}$ is Q-flat (proposition 12.5.16(ii)), and on the other hand, since φ is injective, P/I is an integral Q-module, so the two vertical arrows are isomorphisms as well, and the claim follows. ◊

Claim 12.5.27. $\mathscr{O}_{X,\overline{x}}/I(\overline{x}, \underline{M})$ is a regular ring.

Proof of the claim. Let $\beta : P \to A := \mathscr{O}_{X,\overline{x}}$ be the morphism deduced from h, and set :

$$S := \beta^{-1}(\mathscr{O}^\times_{X,\overline{x}}) \qquad I(\overline{x}, P) := P \backslash S.$$

Then the $\mathbb{Z}[P]$-algebra A is a localization of the $\mathbb{Z}[P]$-algebra

$$B := S^{-1}(\mathscr{O}_{Y,\overline{y}} \otimes_Q P)$$

and it suffices to show that $B/I(\overline{x}, \underline{M})$ is regular.

It is easily seen that $I(\overline{x}, \underline{M}) = I(\overline{x}, P)A$ and $\varphi(\mathfrak{m}_Q) \subset I(\overline{x}, P)$; on the other hand, since α is sharp at the point $\overline{y}$, we have $I(\overline{y}, \underline{N}) = \mathfrak{m}_Q \mathscr{O}_{Y,\overline{y}}$, and $Q \setminus \mathfrak{m}_Q = \{1\}$. Let p be the residue characteristic of $\mathscr{O}_{Y,\overline{y}}$; there follow isomorphisms of $\mathbb{Z}_{(p)}$-algebras :

$$B/I(\overline{x}, \underline{M})B \simeq S^{-1}\mathscr{O}_{Y,\overline{y}} \otimes_Q P/I(\overline{x}, P) \simeq \mathscr{O}_{Y,\overline{y}}/I(\overline{y}, \underline{N}) \otimes_{\mathbb{Z}_{(p)}} \mathbb{Z}_{(p)}[S^{\mathrm{gp}}].$$

By assumption, $\mathscr{O}_{Y,\overline{y}}/I(\overline{y}, \underline{N})$ is regular, hence we are reduced to showing that $\mathbb{Z}_{(p)}[S^{\mathrm{gp}}]$ is a smooth $\mathbb{Z}_{(p)}$-algebra ([66, Ch.IV, Prop.17.5.8(iii)]). However, under the current assumptions P^{gp} is a free abelian group of finite rank, hence the same holds for S^{gp}, and the contention follows easily. ◊

In light of proposition 6.1.40(i), claims 12.5.25 and 12.5.27 assert that conditions (a) and (b) of proposition 12.5.16(i) are satisfied for the τ-point $\overline{x}$ of $(X, \underline{M})$, so the latter is regular at $\overline{x}$, as stated. □

Theorem 12.5.28. *Let $f : (X, \underline{M}) \to (Y, \underline{N})$ be a smooth morphism of locally noetherian fs log schemes, ξ a τ-point of X, and suppose that $(Y, \underline{N})$ is regular at the point $f(\xi)$. Then $(X, \underline{M})$ is regular at the point ξ.*

Proof. In case $\tau = \mathrm{Zar}$, lemma 12.5.21 and corollary 12.3.27(ii) reduce the assertion to the corresponding one for $\widetilde{u}^* f$. Hence, we may assume that $\tau = \text{ét}$. Next, since the assertion is local on X_τ, we may assume that $\underline{N}$ admits a fine and saturated chart $\alpha : Q_Y^{\log} \to \underline{N}$ which is sharp at $f(\xi)$ (corollary 12.1.36(i)); then, by corollary 12.3.42, we may further assume that there exist an injective morphism of fine and saturated monoids $\varphi : Q \to P$, such that $P^\times$ is torsion-free, and a cartesian diagram as in (12.5.23). Then the assertion follows from lemma 12.5.24. □

Corollary 12.5.29. *Let $f : (X, \underline{M}) \to (Y, \underline{N})$ be a smooth morphism of locally noetherian fine log schemes. Then, for every $y \in (Y, \underline{N})_{\mathrm{tr}}$, the log scheme $\mathrm{Spec}\, \kappa(y) \times_Y (X, \underline{M})$ is geometrically regular.*

Proof. The trivial log structure on $\mathrm{Spec}\, \kappa(y)$ is obviously saturated, so the same holds for the log structure of $\mathrm{Spec}\, \kappa(y) \times_Y (X, \underline{M})$. Hence, the assertion is an immediate consequence of theorem 12.5.28. □

In the same vein we have :

Proposition 12.5.30. *Let $f : (X, \underline{M}) \to (Y, \underline{N})$ be a strict morphism of locally noetherian fs log schemes, ξ a τ-point of X, and suppose that the morphism of schemes $f_\xi : X(\xi) \to Y(f(\xi))$ is flat. The following holds :*

(i) *If $(X, \underline{M})$ is regular at the point ξ, then $(Y, \underline{N})$ is regular at the point $f(\xi)$.*
(ii) *Conversely, if $(Y, \underline{N})$ is regular at the point $f(\xi)$, and the fibre $f_\xi^{-1}(f(\xi))$ is a regular scheme (notation of (4.9.20)), then $(X, \underline{M})$ is regular at the point ξ.*

Proof. Set $A := \mathscr{O}_{Y,f(\xi)}$ and $B := \mathscr{O}_{X,\xi}$, let $g : A \to B$ be the induced ring homomorphism, pick a fine chart $\beta : P \to A$ for the log structure $\underline{N}(f(\xi))$, and denote by $I \subset A$ the ideal generated by the image of the maximal ideal of $\underline{N}_{f(\xi)}$.

(i): By proposition 12.5.16(ii), the local ring B/IB is regular, $g \circ \beta : P \to B$ is a fine chart for the log structure $\underline{M}(\xi)$, and B is $(g \circ \beta)$-flat. Since the induced map $A/I \to B/IB$ is flat and local, also A/I is regular ([63, Ch.0, Prop.17.3.3(i)]), and since g is faithfully flat, A is β-flat (remark 6.1.35(iii)). Then the assertion follows from proposition 12.5.16(i).

(ii): By proposition 12.5.16(ii), the local ring A/I is regular, and A is β-flat. Since g is flat, the same holds for the induced map $A/I \to B/IB$; it follows that also B/IB is regular ([63, Ch.0, Prop.17.3.3(ii)]), the induced map $P \to B$ is a chart for $\underline{M}(\xi)$ and B is $(g \circ \beta)$-flat, whence the contention, again by proposition 12.5.16(i). □

Theorem 12.5.31. *Let $(X, \underline{M})$ be a locally noetherian fs log scheme. Then the subset $(X, \underline{M})_{\mathrm{reg}}$ is closed under generization.*

Proof. Let ξ be a τ-point of X, with support $x \in (X, \underline{M})_{\mathrm{reg}}$, and let η be a generization of ξ, whose support is a strict generization y of x. We have to show that $(X, \underline{M})$ is regular at the point η. Since the assertion is local on X, we may assume that $(X, \underline{M})$ admits a fine and saturated chart $\beta : P_X \to \underline{M}$, sharp at the point ξ (corollary 12.1.36(i)). Let $\alpha : P \to \mathscr{O}_{X,\eta}$ be the morphism deduced from β_η, and set $\mathfrak{p} := \alpha^{-1}\mathfrak{m}_\eta$, where $\mathfrak{m}_\eta \subset \mathscr{O}_{X,\eta}$ is the maximal ideal. We consider the cartesian diagram of log schemes :

$$\begin{array}{ccc} (X', \underline{M}')_\circ & \longrightarrow & (X, \underline{M}) \\ \big\downarrow & & \big\downarrow{\scriptstyle g} \\ \mathrm{Spec}\langle \mathbb{Z}, P/\mathfrak{p}\rangle & \longrightarrow & \mathrm{Spec}(\mathbb{Z}, P) \end{array}$$

where g is induced by β (notation of (12.2.13)). Clearly ξ and η induce τ-points on X', which we denote by the same names. We have natural identifications:

$$\mathscr{O}_{X,\xi}/I(\xi, \underline{M}) \xrightarrow{\sim} \mathscr{O}_{X',\xi}/I(\xi, \underline{M}') \qquad \underline{M}'_\eta = \mathscr{O}^\times_{X',\eta} \qquad \mathscr{O}_{X,\eta}/I(\eta, \underline{M}) \xrightarrow{\sim} \mathscr{O}_{X',\eta}$$

([66, Ch.IV, Prop.18.6.8]). Moreover, from proposition 12.5.16(ii) we know that $\mathscr{O}_{X,\xi}$ is P-flat; then corollary 6.4.34 yields the inequality :

$$\dim \mathscr{O}_{X',\xi} = \dim \mathscr{O}_{X,\xi} \otimes_P P/\mathfrak{p} \geq \dim \mathscr{O}_{X,\xi} - \mathrm{ht}(\mathfrak{p}) = \dim \mathscr{O}_{X,\xi}/I(\xi, \underline{M}) + \dim P/\mathfrak{p}$$

in other words : $\dim \mathscr{O}_{X',\xi} = d(\xi, \underline{M}')$ (notation of definition 12.5.7), so $(X', \underline{M}')$ is regular at ξ. By the same token, $\mathscr{O}_{X,\eta}$ is $P_\mathfrak{p}$-flat; from proposition 12.5.16(i), it follows that $(X, \underline{M})$ is regular at η if and only if the same holds for $(X', \underline{M}')$.

Hence we may replace $(X, \underline{M})$ by $(X', \underline{M}')$, and P by $P \setminus \mathfrak{p}$, after which we may assume that $y \in (X, \underline{M})_{\mathrm{tr}}$. In this case :

$$\alpha(P) \subset \mathscr{O}^\times_{X,\eta} \tag{12.5.32}$$

and we have to show that $\mathscr{O}_{X,\eta}$ is a regular local ring, or equivalently, that $\mathscr{O}_{X,y}$ is regular ([66, Ch.IV, Cor.18.8.13(c)]). Now, if $P = 0$, then $\mathscr{O}_{X,x}$ is regular, and the assertion follows from [126, Th.19.3]; thus, we may assume that $P \neq 0$.

Denote by Y the topological closure of y in X, endowed with its reduced subscheme structure. According to [60, Ch.II, Prop.7.1.7] (and [66, Ch.IV, Prop.18.8.8(iv)] in case $\tau = \text{ét}$), we may find a local injective ring homomorphism $j : \mathscr{O}_{Y,\xi} \to V$, where V is a discrete valuation ring. Let also $\overline{\beta} : P \to \mathscr{O}_{Y,\xi}$ be the morphism deduced from β. Then (12.5.32) implies that $j \circ \overline{\beta}(P) \subset V \setminus \{0\}$, hence $j \circ \overline{\beta}$ extends to a homomorphism of groups $P^{\mathrm{gp}} \to K^\times$, where $K^\times := (V \setminus \{0\})^{\mathrm{gp}}$ is the multiplicative group of the field of fractions of V; after composition with the valuation $K^\times \to \mathbb{Z}$ of V, there follows a group homomorphism

$$\varphi : P^{\mathrm{gp}} \to \mathbb{Z}.$$

Notice also that $j \circ \overline{\beta}$ is a local morphism, since the same holds for j and $\overline{\beta}$; consequently, $\varphi(P^{\mathrm{gp}}) \neq \{0\}$. Set $Q := \varphi^{-1}\mathbb{N}$; then $\varphi(Q)$ is a non-trivial submonoid of $\mathbb{N}$, and $\dim Q = \dim Q/\mathrm{Ker}\,\varphi = \dim \varphi(Q) = 1$. Set

$$T := \mathrm{Spec}\, V \qquad (S, \underline{Q}) := \mathrm{Spec}(\mathbb{Z}, Q).$$

Notice that Q is saturated and fine (corollary 6.4.2), so there exists an isomorphism :

$$\mathbb{Z}^{\oplus r} \times \mathbb{N} \xrightarrow{\sim} Q \qquad \text{for some } r \in \mathbb{N}$$

(theorem 6.4.18(iii)); the latter determines a chart :

$$\mathbb{N}_S \to \underline{Q} \tag{12.5.33}$$

which is sharp at every τ-point of S localized outside the trivial locus $\mathrm{Spec}(\mathbb{Z}, Q)_{\mathrm{tr}}$. We consider the cartesian diagram of log schemes :

$$\begin{array}{ccc} (X', g'^*\underline{Q}) & \xrightarrow{g'} & \mathrm{Spec}(\mathbb{Z}, \underline{Q}) \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f} \\ (X, \underline{M}) & \xrightarrow{g} & \mathrm{Spec}(\mathbb{Z}, P) \end{array}$$

where f is the morphism of log schemes induced by the inclusion map $\psi : P \to Q$. Notice that f is a smooth morphism (proposition 12.3.34); moreover, the restriction

$$f_{\mathrm{tr}} : \mathrm{Spec}(\mathbb{Z}, Q)_{\mathrm{tr}} \to \mathrm{Spec}(\mathbb{Z}, P)_{\mathrm{tr}}$$

of f, is just the morphism $\mathrm{Spec}\,\mathbb{Z}[\psi^{\mathrm{gp}}] : \mathrm{Spec}\,\mathbb{Z}[Q^{\mathrm{gp}}] \to \mathrm{Spec}\,\mathbb{Z}[P^{\mathrm{gp}}]$, hence it is an isomorphism of schemes. It follows that f' is a smooth morphism (proposition 12.3.24(ii)), and its restriction f'_{tr} to the trivial loci, is an isomorphism.

The homomorphism j induces a morphism $h : T \to X$, such that the closed point of T maps to x and the generic point maps to y. By construction $g \circ h$ lifts to a morphism of schemes $h' : T \to S$, and the pair (h, h') determines a morphism $T \to X'$. Let $x', y' \in X'$ be the images of respectively the closed point and the generic point of T, and choose τ-points ξ' and η' localized at x' and respectively y'; then the image of x' in X is the point x, therefore $(X', g'^*\underline{Q})$ is regular at the point ξ', by theorem 12.5.28. Furthermore, $g'(\xi')$ lies outside $\mathrm{Spec}(\mathbb{Z}, Q)_{\mathrm{tr}}$, hence (12.5.33) induces a chart $\mathbb{N}_{X'} \to g'^*\underline{Q}$, which is sharp at ξ'. In light of corollary 12.5.19, we deduce that $\mathscr{O}_{X',x'}$ is a regular ring, and then the same holds also for $\mathscr{O}_{X',y'}$ ([63, Ch.0, Cor.17.3.2]). However, y' lies in the trivial locus of $(X', g'^*\underline{Q})$, and its image in X is y, so by the foregoing the natural map $\mathscr{O}_{X,y} \to \mathscr{O}_{X',y'}$ is an isomorphism, and the contention follows. $\square$

Remark 12.5.34. Notice that the proof of [60, Chap.II, Prop.7.1.7] (that is invoked in the proof of theorem 12.5.31) is slightly incorrect : indeed, with the notation of the proof of *loc.cit.*, it is implicitly assumed that $B/\mathfrak{m}B \neq 0$, which may fail, *e.g.* take $A := k[[x_2]]$ (for any field k), whose maximal ideal is generated by $x_1 := x_2^2$ and x_2, so that $B = k((x_2))$ in this case. The proof can be amended by considering the scheme $X := \mathrm{Spec}\,A$ and the blow-up $\pi : E \to X$ of the coherent ideal $\mathfrak{m}\mathscr{O}_X$; since π is proper and surjective, we see that there exists $i \in \{1, \dots, n\}$ such the image of the restriction $\mathrm{Spec}\,A[x_1/x_i, \dots, x_n/x_i] \to X$ of π contains $\mathfrak{m}$, and the argument then carries through with $B := A[x_1/x_i, \dots, x_n/x_i]$. See also [102, Th.6.4.3].

12.5.35. Let $(X, \underline{M})$ be any log scheme, ξ a τ-point of X. There follows a continuous map

$$\psi_\xi : X(\xi) \to T_\xi := \mathrm{Spec}\,\underline{M}_\xi$$

that sends the closed point of $X(\xi)$ to the closed point of T_ξ. For every point $\mathfrak{p} \in T_\xi$, let $\overline{\{\mathfrak{p}\}}$ be the topological closure of $\{\mathfrak{p}\}$ in T_ξ; then

$$X(\mathfrak{p}) := \psi_\xi^{-1}\overline{\{\mathfrak{p}\}}$$

is a closed subset of $X(\xi)$, which we endow with its reduced subscheme structure, and we set

$$(X(\mathfrak{p}), \underline{M}(\mathfrak{p})) := ((X(\xi), \underline{M}(\xi)) \times_X X(\mathfrak{p}))_{\mathrm{red}}$$

(notation of example 12.1.12(iv)). Notice that $U_\mathfrak{p} := \psi_\xi^{-1}(\mathfrak{p})$ is an open subset of $X(\mathfrak{p})$, for every $\mathfrak{p} \in T_\xi$. We call the family

$$(U_\mathfrak{p} \mid \mathfrak{p} \in T_\xi)$$

of locally closed subschemes of $X(\xi)$, the *logarithmic stratification* of $(X(\xi), \underline{M}(\xi))$. For instance, $U_\varnothing = (X(\overline{x}), \underline{M}(\overline{x}))_{\mathrm{tr}}$. More generally, it is clear from the definition that

$$U_\mathfrak{p} = (X(\mathfrak{p}), \underline{M}(\mathfrak{p}))_{\mathrm{tr}} \qquad \text{for every } \mathfrak{p} \in T_\xi. \tag{12.5.36}$$

Corollary 12.5.37. *In the situation of* (12.5.35)*, suppose that* $(X, \underline{M})$ *is regular at* ξ*. Then :*

(i) *The log scheme* $(X(\mathfrak{p}), \underline{M}(\mathfrak{p}))$ *is pointed regular, for every* $\mathfrak{p} \in T_\xi$*.*

(ii) *The scheme* $X(\mathfrak{p})$ *is irreducible, and its codimension in* X *equals the height of* $\mathfrak{p}$ *in* T_ξ*, for every* $\mathfrak{p} \in T_\xi$*.*

(iii) *The scheme* $U_\mathfrak{p}$ *is regular and irreducible, for every* $\mathfrak{p} \in T_\xi$*.*

Proof. (i): By theorem 12.5.31, it suffices to show that $(X(\mathfrak{p}), \underline{M}(\mathfrak{p}))$ is pointed regular at ξ, for every $\mathfrak{p} \in T_\xi$. However, say that $X(\xi) = \mathrm{Spec}\, A$, and let $P \to \underline{M}(\xi)$ be a fine and saturated chart, sharp at the τ-point ξ. Then $X(\mathfrak{p}) = \mathrm{Spec}\, A_0$, where $A_0 := A/\mathfrak{p}A$, and $\underline{M}(\mathfrak{p}) = \underline{N}_\circ$, where $\underline{N}$ is the fs log structure deduced from the induced map $\beta : P\backslash\mathfrak{p} \to A_0$. By proposition 12.5.16(ii), the ring A is P-flat; then A_0 is β-flat, and the assertion follows from proposition 12.5.16(i).

Next, (ii) is a rephrasing of corollary 12.5.20(i), and (iii) follows from (i),(ii) and (12.5.36), by virtue of corollary 12.5.19. □

Proposition 12.5.38. *Let* $(X, \beta : \underline{M} \to \mathscr{O}_X)$ *be a regular log scheme, set* $U := (X, \underline{M})_{\mathrm{tr}}$*, and denote by* $j : U \to X$ *the open immersion. Then the morphism* β *induces identifications:*

$$\underline{M} \xrightarrow{\sim} j_*\mathscr{O}_U^\times \cap \mathscr{O}_X \qquad \underline{M}^{\mathrm{gp}} \xrightarrow{\sim} j_*\mathscr{O}_U^\times.$$

Proof. Notice that the scheme X is normal (corollary 12.5.13), hence both $j_*\mathscr{O}_U^\times$ and $\mathscr{O}_X$ are subsheaves of the sheaf $i_*\mathscr{O}_{X_0}$, where X_0 is the subscheme of maximal points of X, and $i : X_0 \to X$ is the natural morphism; so we may intersect these two sheaves inside the latter.

In view of lemma 12.5.2 and proposition 12.5.16(ii), we know already that β is injective, and clearly the image of β lands in $j_*\mathscr{O}_U^\times$, so it remains only to show that β (resp. β^{gp}) induces an epimorphism onto $j_*\mathscr{O}_U^\times \cap \mathscr{O}_X$ (resp. onto $j_*\mathscr{O}_U^\times$). The assertions can be checked on the stalks, hence let ξ be any τ-point of X; to begin with, we show :

Claim 12.5.39. The induced map $\beta_\xi^{\mathrm{gp}} : \underline{M}_\xi^{\mathrm{gp}} \to (j_*\mathscr{O}_U^\times)_\xi$ is a surjection.

Proof of the claim. Set $A := \mathscr{O}_{X,\xi}$; notice that $(X(\xi), \underline{M}(\xi))_{\mathrm{tr}}$ is the complement of the union of the finitely many closed subsets of the form $Z_\mathfrak{p} := \mathrm{Spec}\, A/\mathfrak{p}A$, where $\mathfrak{p} \subset \underline{M}_\xi$ runs over the prime ideals of height one. Due to corollary 12.5.20(i), each $Z_\mathfrak{p}$ is an irreducible divisor in $\mathrm{Spec}\, A$. Now, let $s \in (j_*\mathscr{O}_U^\times)_\xi$; then the divisor of s is of the form $\sum_{\mathrm{ht}\mathfrak{p}=1} n_\mathfrak{p}[\mathfrak{p}]$, for some $n_\mathfrak{p} \in \mathbb{Z}$. By lemmata 12.1.18(ii) and 12.2.21(i), $\underline{M}_\xi^\sharp$ is a fine and saturated monoid; then lemma 6.4.39 and proposition 6.4.50 say that the fractional ideal $I := \bigcap_{\mathrm{ht}\,\mathfrak{p}=1} \mathfrak{m}_\mathfrak{p}^{n_\mathfrak{p}}$ of $\underline{M}_\xi$ is reflexive, and therefore the fractional ideal IA of A is reflexive as well (lemma 6.4.45(ii)). Since A is normal, by considering the localizations of $I\mathscr{O}_{X,\xi}$ at the prime ideals of height one of A, we deduce easily that $IA = sA$ ([34, Ch.VII, §4, n.2, Cor. du Th.2]). Thus, we may write $s = \sum_{i=1}^n \beta_\xi^{\mathrm{gp}}(x_i)a_i$ for certain $a_i \in A$ and $x_i \in I$ (for $i = 1, \dots, n$). Then we must have $\beta_\xi^{\mathrm{gp}}(x_i)a_i \notin s \cdot \mathfrak{m}_\xi$ for at least one index $i \leq n$ (where $\mathfrak{m}_\xi \subset A$ is the maximal ideal); for such i, it follows that $s^{-1} \cdot \beta_\xi^{\mathrm{gp}}(x_i) \in A^\times$, whence $s \in \underline{M}_\xi^{\mathrm{gp}}$, as required. ◊

Now, let $s \in (j_*\mathscr{O}_U^\times)_\xi \cap A$; by claim 12.5.39, we may find $x \in \underline{M}_\xi^{\mathrm{gp}}$ such that $\beta_\xi^{\mathrm{gp}}(x) = s$. To conclude, it suffices to show that $x \in \underline{M}_\xi$. By theorem 6.4.18(i), we are reduced to showing that $x \in (\underline{M}_\xi)_\mathfrak{p}$ for every prime ideal $\mathfrak{p} \subset \underline{M}_\xi$ of height one. Set $\mathfrak{q} := \mathfrak{p}A$; then $\mathfrak{q}$ is a prime ideal of height one (corollary 12.5.20(i)), and β_ξ extends to a well defined map of monoids $\beta_\mathfrak{p} : (\underline{M}_\xi)_\mathfrak{p} \to A_\mathfrak{q}$. Furthermore, $A_\mathfrak{q}$ is a discrete valuation ring (corollary 12.5.13), whose valuation we denote $v : A_\mathfrak{q} \setminus \{0\} \to \mathbb{N}$. In view of theorem 6.4.18(ii), we see that $x \in (\underline{M}_\xi)_\mathfrak{p}$ if and only if $(v \circ \beta_\mathfrak{p})^{\mathrm{gp}}(x) \geq 0$. However, clearly $v(s) \geq 0$, whence the contention. □

Remark 12.5.40. Let $\mathbf{reg.log}_\tau$ denote the full subcategory of $\mathbf{log}_\tau$ whose objects are the regular log schemes. As an immediate consequence of proposition 12.5.38 (and of remark 12.2.8(i)) we see that the forgetful functor F of (12.2.1) restricts to a fully faithful functor

$$\mathbf{reg.log}_\tau \to \mathbf{Open} \qquad (X, \underline{M}) \mapsto ((X, \underline{M})_{\mathrm{tr}} \to X)$$

where $\mathbf{Open}$ is full subcategory of $\mathsf{Morph}(\mathsf{Sch})$ whose objects are the open immersions.

12.5.41. Let $(X, \underline{M})$ be a quasi-compact and regular log scheme. Set $Z := X \setminus (X, \underline{M})_{\mathrm{tr}}$; then Z is a closed subset of X (lemma 12.2.21(ii)), and we endow it with its reduced subscheme structure. Denote by $\omega_X \subset \mathscr{O}_X$ the sheaf of ideals corresponding to Z. We have :

Theorem 12.5.42. *In the situation of* (12.5.41)*, the complex* $\omega_X[0]$ *is dualizing on* X*. (See definition* 11.3.16.*)*

Proof. In light of proposition 11.3.37, we may assume that X is local, say $X = \operatorname{Spec} A$, for a local noetherian ring A. Next, pick any τ-point ξ localized at the closed point of X; by virtue of proposition 11.3.34 and [66, Ch.IV, Prop.18.8.8(iv) and Prop.18.8.12(ii)], we may further reduce to the case where $(X, \underline{M}) = (X(\xi), \underline{M}(\xi))$. Let $X^\wedge := \operatorname{Spec} A^\wedge$, where $A^\wedge$ denotes the completion of the local ring A, and denote by $f : X^\wedge \to X$ the natural morphism; by applying again proposition 11.3.34, we reduce to checking that $f^*\omega_X[0]$ is dualizing on $X^\wedge$. However, theorem 12.5.10 says that there exist a local ring homomorphism $R \to A^\wedge$, with R a complete regular local ring, and a fine and saturated chart $P_X \to \underline{M}$, sharp at the closed point of X, such that the induced continuous ring homomorphism $\varphi : R[[P]] \to A^\wedge$ is an isomorphism if A contains a field, and otherwise it is a surjection, whose kernel is generated by a regular element $\vartheta \in R[[P]]$. With this notation, a simple inspection shows that Z is the union of the closed subsets $X(\mathfrak{p}) \subset X$, where $\mathfrak{p} \subset P$ ranges over all prime ideals $\mathfrak{p} \neq \varnothing$ (notation of (12.5.35)). Then, corollary 12.5.20(i) says that ω_X is the intersection of the ideals of $\mathscr{O}_X$ of the form $\mathfrak{p}\mathscr{O}_X$, where $\mathfrak{p} \subset P$ is an arbitrary non-empty prime ideal. Denote by $P^\circ \subset P$ the intersection of all the (finitely many) non-empty prime ideals of P; lemma 6.1.37 and proposition 12.5.16(ii) imply that $\omega_X = P^\circ \cdot \mathscr{O}_X$ (details left to the reader), and since f is a flat morphism, we deduce that $f^*\omega_X = P^\circ \cdot \mathscr{O}_{X^\wedge}$. The ideal P° can also be described as follows. Set $V := P^{\mathrm{gp}}_\mathbb{R}$, denote by σ the unique strictly convex polyhedral cone such that $P = \sigma \cap P^{\mathrm{gp}}$, and let σ° be the topological interior of σ in V; then it is easily seen that $P^\circ = P \cap \sigma^\circ$.

Set $Y := \operatorname{Spec} R[P]$, $\omega_Y := P^\circ \cdot \mathscr{O}_Y$, and let $y \in Y$ be the image of the closed point of $Y^\wedge := \operatorname{Spec} R[[P]]$, under the natural morphism $g : Y^\wedge \to Y$. Theorem 11.6.43(ii) says that $\omega_Y[0]$ is dualizing on Y; then, since g is flat, propositions 11.3.34 and 11.3.37 imply that $g^*\omega_Y[0]$ is dualizing on $Y^\wedge$.

Now, suppose that A contains a field; then φ induces an isomorphism $X^\wedge \xrightarrow{\sim} Y^\wedge$ which identifies $f^*\omega_X$ with $g^*\omega_Y$, whence the contention.

Lastly, if A does not contain a field, φ induces a regular closed immersion $i : X^\wedge \to Y^\wedge$, so $i^!(g^*\omega_Y[0])$ is dualizing on $X^\wedge$ (lemma 11.3.27(i)). The latter is the complex of $\mathscr{O}_{X^\wedge}$-modules arising from the complex of $A^\wedge$-modules $L^\bullet := R\mathrm{Hom}^\bullet_{R[[P]]}(A^\wedge[0], R[[P^\circ]])$ (corollary 10.3.2(ii); here $R[[P^\circ]] := P^\circ \cdot R[[P]]$). However, $A^\wedge[0]$ is naturally isomorphic (in $\mathsf{D}(R[[P]]\text{-}\mathbf{Mod})$) to the Koszul complex $\mathbf{K}_\bullet(\vartheta)$ (notation of remark 7.8.1(ii) : this is a bounded complex of free $R[[P]]$-modules), so we see that

$$L^\bullet \simeq (R[[P^\circ]] \otimes_{R[[P]]} A^\wedge)[-1].$$

However, we have natural $A^\wedge$-linear isomorphisms :

$$\begin{aligned} R[[P^\circ]] \otimes_{R[[P]]} A^\wedge &\stackrel{\sim}{\to} R[P^\circ] \otimes_{R[P]} A^\wedge && \text{(since } g \text{ is flat)} \\ &\stackrel{\sim}{\to} \mathbb{Z}[P^\circ] \otimes_{\mathbb{Z}[P]} A \otimes_A A^\wedge \\ &\stackrel{\sim}{\to} (P^\circ \cdot A) \otimes_A A^\wedge && \text{(by proposition 12.5.16(ii))} \end{aligned}$$

which shows that $i^!(g^*\omega_Y[0]) \simeq f^*\omega_X[-1]$, and concludes the proof of the theorem. □

12.6. **Resolution of singularities of regular log schemes.** Most of this section concerns results that are special to the class of log schemes over the Zariski topology; these are then applied to étale fs log structures, after we have shown that every such log structure admits a logarithmic blow up which descends to the Zariski topology (proposition 12.6.52). The same statement – with an unnecessary restriction to regular log schemes – can be found in the article [135] by W.Niziol : see theorem 5.6 of *loc.cit.* We mainly follow her treatment, except for fleshing out some details, and correcting some inaccuracies.

Therefore, *we let here* $\tau = \mathrm{Zar}$, *and all log structures considered in this section until* (12.6.48) *are defined on the Zariski sites of their underlying schemes.*

12.6.1. Let $f : (Y, \underline{N}) \to (X, \underline{M})$ be any morphism of log schemes; we remark that f is a morphism of monoidal spaces, *i.e.* for every $y \in Y$, the map $\underline{M}_{f(y)} \to \underline{N}_y$ induced by $\log f$, is local. Indeed, it has been remarked in (12.1.6) that the natural map $\underline{M}_{f(y)} \to (f^*\underline{M})_y$ is local, and on the other hand, a section $s \in (f^*\underline{M})_y$ is invertible if and only if its image in $\mathscr{O}_{Y,y}$ is invertible, if and only if $\log f_y(s)$ is invertible in $\underline{N}_y$, whence the contention. We shall denote

$$f^\sharp : (Y, \underline{N})^\sharp \to (X, \underline{M})^\sharp$$

the morphism of sharp monoidal spaces induced by f in the obvious way (*i.e.* the underlying continuous map is the same as the continuous map underlying f, and $\log f^\sharp : f^*\underline{M}^\sharp \to \underline{N}^\sharp$ is $(\log f)^\sharp$: see definition 6.5.1).

12.6.2. We let $\mathscr{K}$ be the category whose objects are all data of the form $\underline{X} := ((X, \underline{M}), F, \psi)$, where $(X, \underline{M})$ is a log scheme, F is a fan, and $\psi : (X, \underline{M})^\sharp \to F$ is a morphism of sharp monoidal spaces, such that $\log \psi : \psi^*\mathscr{O}_F \to \underline{M}^\sharp$ is an isomorphism. The morphisms :

$$((Y, \underline{N}), F', \psi') \to \underline{X}$$

in $\mathscr{K}$ are all the pairs (f, φ), where $f : (Y, \underline{N}) \to (X, \underline{M})$ is a morphism of log schemes, and $\varphi : F' \to F$ is a morphism of fans, such that the diagram

$$\begin{array}{ccc} (Y, \underline{N})^\sharp & \xrightarrow{f^\sharp} & (X, \underline{M})^\sharp \\ {\scriptstyle \psi'}\downarrow & & \downarrow{\scriptstyle \psi} \\ F' & \xrightarrow{\varphi} & F \end{array}$$

commutes. Especially, notice that lemma 12.1.4 implies the identity :

$$\mathrm{Str}(f) = \psi'^{-1}\mathrm{Str}(\varphi). \qquad (12.6.3)$$

(notation of definitions 6.5.1(ii) and 12.2.7(ii)). We shall say that an object $\underline{X}$ is *locally noetherian*, if the same holds for the scheme X. Likewise, a morphism (f, φ) in $\mathscr{K}$ is *quasi-compact*, (resp. *quasi-separated*, resp. *separated*, resp. *locally of finite type*, resp. *of finite type*) if the same holds for the morphism of schemes underlying f. We say that f is *étale*, if the same holds for the morphism of log schemes underlying f. Also, the *trivial locus* of $\underline{X}$ is defined as the subset $(X, \underline{M})_{\mathrm{tr}}$ of X.

12.6.4. There is an obvious (forgetful) functor :

$$F : \mathscr{K} \to \mathsf{Sch} \qquad ((X, \underline{M}), F, \psi) \mapsto X$$

which is a fibration. More precisely, every morphism of schemes $S' \to S$ induces a *base change* functor (notation of (1.1.27)) :

$$F\mathscr{K}/S \to F\mathscr{K}/S' \qquad \underline{X} \mapsto S' \times_S \underline{X}$$

unique up to natural isomorphism of functors. Namely, for $\underline{X} := ((X, \underline{M}), F, \psi)$ one lets

$$S' \times_S \underline{X} := (S' \times_S (X, \underline{M}), F, \psi')$$

where $\psi' := \psi \circ \pi^\sharp$, and $\pi : S' \times_S (X, \underline{M}) \to (X, \underline{M})$ is the natural projection.

Example 12.6.5. (i) Let P be a monoid, R a ring, and set $(S, P_S^{\log}) := \mathrm{Spec}(R, P)$ (see (12.2.13)). The unit of adjunction $\varepsilon_P : P \to R[P]$ determines a unique morphism of sharp monoidal spaces

$$\psi_P : \mathrm{Spec}(R, P)^\sharp \to T_P := (\mathrm{Spec}\, P)^\sharp$$

(proposition 6.5.6), and we claim that $\underline{S} := (\mathrm{Spec}(R, P), T_P, \psi_P)$ is an object of $\mathscr{K}$.

The assertion can be checked on the stalks, hence let ξ be a point of S; then ξ corresponds to a prime ideal $\mathfrak{p}_\xi \subset R[P]$, and by inspecting the definitions, we see that $\psi_P(\xi) = \varepsilon_P^{-1}(\mathfrak{p}_\xi) = \mathfrak{q}_\xi := P \cap \mathfrak{p}_\xi \in \mathrm{Spec}\, P$. Again, a direct inspection shows that the morphism

$$(\log \psi_P)_\xi : \mathscr{O}_{T_P, \mathfrak{q}_\xi} \to (P_S^{\log})^\sharp_\xi$$

is none else than the natural isomorphism $P^\sharp_{\mathfrak{q}_\xi} \xrightarrow{\sim} P^{\log}_{S,\xi}/\mathscr{O}^\times_{S,\xi}$ deduced from ε_P and the natural identifications

$$P^{\log}_{S,\xi} = \mathscr{O}^\times_{S,\xi} \otimes_{P \setminus \mathfrak{q}_\xi} P = \mathscr{O}^\times_{S,\xi} \otimes_{P^\times_{\mathfrak{q}_\xi}} P_{\mathfrak{q}_\xi}.$$

(ii) The construction of $\underline{S}$ is clearly functorial in P. Namely, say that $\lambda : P \to Q$ is a morphism of monoids, and set $S' := \mathrm{Spec}\, R[Q]$, $T_Q := (\mathrm{Spec}\, Q)^\sharp$. There follows a morphism

$$\underline{S}' := (\mathrm{Spec}(R, Q), T_Q, \psi_Q) \to \underline{S} \qquad (12.6.6)$$

in $\mathscr{K}$, whose underlying morphism of log schemes is $\mathrm{Spec}(R, \lambda)$, and whose underlying morphism of fans is just $(\mathrm{Spec}\, \lambda)^\sharp$.

12.6.7. Example 12.6.5 can be globalized to more general log schemes, at least under some additional assumptions. Namely, let $(X, \underline{M})$ be a regular log scheme. For every point x of X, let $\mathfrak{m}_x \subset \mathscr{O}_{X,x}$ be the maximal ideal; we set :

$$F(X) := \{x \in X \mid I(x, \underline{M}) = \mathfrak{m}_x\}$$

(notation of (12.5.5)), and we endow $F(X)$ with the topology induced from X. The *fan of* $(X, \underline{M})$ is the sharp monoidal space

$$F(X, \underline{M}) := (F(X), \underline{M}_{|F(X)})^\sharp.$$

We wish to show that $F(X, \underline{M})$ is indeed a fan. Let $U \subset X$ be any open subset; to begin with, it is clear that $F(U, \underline{M}_{|U})$ is naturally an open subset of $F(X, \underline{M})$; hence the contention is local on X, so we may assume that X is affine, say $X = \mathrm{Spec}\, A$ for a noetherian ring A, and that $\underline{M}$ admits a finite chart $P_X \to \underline{M}$; denote by $\beta : P \to A$ the induced morphism of monoids. Let now ξ be a point of X, and $\mathfrak{p}_\xi \subset A$ the corresponding prime ideal; set $\mathfrak{q}_\xi := \beta^{-1}\mathfrak{p}_\xi \in \mathrm{Spec}\, P$. By inspecting the definitions, it is easily seen that $I(\xi, \underline{M}) = \mathfrak{q}_\xi A_{\mathfrak{p}_\xi}$. Therefore, for any prime ideal $\mathfrak{q} \subset P$, let $V(\mathfrak{q})_{\max}$ be the finite set consisting of all the maximal points of the closed subset $V(\mathfrak{q}) := \mathrm{Spec}\, A/\mathfrak{q}A$ (*i.e.* the minimal prime ideals of $A/\mathfrak{q}A$); in light of corollary 12.5.20(i), it follows easily that

$$F(X) = \bigcup_{\mathfrak{q}\in\mathrm{Spec}\, P} V(\mathfrak{q})_{\max} \tag{12.6.8}$$

especially, $F(X)$ is a finite set (lemma 6.1.20(iii)). Let $t \in F(X)$ be any element, and denote by $U(t) \subset F(X)$ the subset of all generizations of t in $F(X)$; as a corollary, we see that $U(t)$ is an open subset of $F(X)$. Moreover, (12.6.8) also implies that :

$$U(t) = \bigcup_{\mathfrak{q}\in\mathrm{Spec}\, P} (\mathrm{Spec}\, \mathscr{O}_{X,t}/\mathfrak{q}\mathscr{O}_{X,t})_{\max}.$$

However, corollary 12.5.20(i) says that $\mathrm{Spec}\, \mathscr{O}_{X,t}/\mathfrak{q}\mathscr{O}_{X,t}$ is irreducible for every $\mathfrak{q} \in \mathrm{Spec}\, P$, therefore the set $U(t)$ is naturally identified with a subset of $\mathrm{Spec}\, P$. Furthermore, arguing as in example 12.6.5(i) we find a natural isomorphism $P^\sharp_{\mathfrak{q}_t} \xrightarrow{\sim} \mathscr{O}_{F(X,\underline{M}),t}$. Moreover, if $t' \in U(t)$ is any other point, the specialization map $\mathscr{O}_{F(X,\underline{M}),t} \to \mathscr{O}_{F(X,\underline{M}),t'}$ corresponds – under the above isomorphism – to the natural morphism $P^\sharp_{\mathfrak{q}_t} \to P^\sharp_{\mathfrak{q}'_t}$ induced by the localization map $P_{\mathfrak{q}_t} \to P_{\mathfrak{q}'_t}$. This shows that the open monoidal subspace $(U(t), \underline{M}_{|U(t)})$ is naturally isomorphic to $(\mathrm{Spec}\, P_{\mathfrak{q}_t})^\sharp$, hence $F(X, \underline{M})$ is a fan, as stated.

Remark 12.6.9. (i) The discussion in (12.6.7) shows more precisely that if :

- (a) $(U, \underline{M})$ is a log scheme with $U = \mathrm{Spec}\, A$ affine,
- (b) there exists a morphism $\beta : P \to A$ from a finitely generated monoid P, inducing the log structure $\underline{M}$ on U, and
- (c) $\beta(\mathfrak{q})A$ is a prime ideal for every $\mathfrak{q} \in \mathrm{Spec}\, P$

then $F(U, \underline{M})$ is naturally identified with $(\mathrm{Spec}\, P)^\sharp$. In this situation, denote by

$$f_\beta : (U, \underline{M})^\sharp \to T_P := (\mathrm{Spec}\, P)^\sharp$$

the morphism of sharp monoidal spaces deduced from β (proposition 6.5.6); by inspecting the definitions, we see that the associated map $\log f_\beta : f^*_\beta \mathscr{O}_{T_P} \to \underline{M}^\sharp$ is an isomorphism. Via the foregoing natural identification, there results a morphism $\pi_U : (U, \underline{M})^\sharp \to F(U, \underline{M})$ which can be described without reference to P. Indeed, let $x \in U$ be any point, and $\mathfrak{p} \in \mathrm{Spec}\, A$ the corresponding prime ideal; by inspecting the definitions we find that

$$\pi_U(x) = I(x, \underline{M}) \ \text{ which is the largest prime ideal in } \mathrm{Spec}\, A_\mathfrak{p} \cap F(U, \underline{M}).$$

Especially, $\pi_U(x)$ is a generization of x, and the inverse of $(\log \pi_U)_x : \mathscr{O}_{F(U,\underline{M}),\pi_U(x)} \xrightarrow{\sim} \underline{M}^\sharp_x$ is induced by the specialization map $\underline{M}_x \to \underline{M}_{\pi_U(x)}$ (which induces an isomorphism on the associated sharp quotient monoids).

(ii) Finally, it follows easily from corollary 12.5.20(i) and [65, Ch.IV, Cor.8.4.3], that every regular log scheme $(X, \underline{M})$ admits an affine open covering $X = \bigcup_{i\in I} U_i$, such that each $(U_i, \underline{M}_{|U_i})$ fulfills conditions (a)–(c) above, and the intrinsic description in (i) shows that the morphisms π_{U_i} glue to a well defined morphism $\pi_X : (X, \underline{M})^\sharp \to F(X, \underline{M})$ of sharp monoidal spaces, such that the datum

$$\mathscr{K}(X, \underline{M}) := ((X, \underline{M}), F(X, \underline{M}), \pi_X)$$

is an object of $\mathscr{K}$.

(iii) Notice that $\pi_X^{-1}(t)$ is an irreducible locally closed subset of X of codimension equal to the height of t, for every $t \in F(X, \underline{M})$; also $\pi_X^{-1}(t)$ is a regular scheme, for its reduced subscheme structure. Indeed, we have already observed that t is the unique maximal point of $\pi_X^{-1}(t)$, and then the assertion follows immediately from corollary 12.5.37(ii,iii). Furthermore, the inclusion map $j : F(X, \underline{M}) \to X$ is a continuous section of π_X, and notice that $j \circ \pi_X(U) =$

$j^{-1}U$ for every open subset $U \subset X$, since j maps every $t \in F(X, \underline{M})$ to the unique maximal point of $\pi_X^{-1}(t)$. It follows easily that π_X is an open map.

12.6.10. Denote by $\mathscr{K}_{\rm int}$ the full subcategory of $\mathscr{K}$ whose objects are the data $((X, \underline{M}), F, \psi)$ such that $\underline{M}$ is an integral log structure, and F is an integral fan. There is an obvious functor

$$\mathscr{K}_{\rm int} \to \mathbf{int.Fan} \quad : \quad ((X, \underline{M}), F, \psi) \mapsto F$$

to the category of integral fans, which shall be used to construct useful morphisms of log schemes, starting from given morphisms of fans. This technique rests on the following three results :

Lemma 12.6.11. *Let $((X, \underline{M}), F, \psi)$ be an object of $\mathscr{K}_{\rm int}$, with F locally fine. Then, for each point $x \in X$ there exist an open neighborhood $U \subset X$ of x, a fine chart $Q_U \to \underline{M}_{|U}$ (for some fine monoid Q depending on x), and an isomorphism of monoids $Q^\sharp \stackrel{\sim}{\to} \mathscr{O}_{F,\psi(x)}$.*

Proof. The assertion is local on X, hence we may assume that $F = (\mathrm{Spec}\, P)^\sharp$ for a fine monoid P. In this case, ψ is determined by the corresponding map

$$\overline{\beta} : P_X \to \underline{M}^\sharp.$$

Indeed, for any $x \in X$, the point $\psi(x)$ is the prime ideal $\overline{\beta}_x^{-1}(\mathfrak{m}_x) \subset P$, where $\mathfrak{m}_x \subset \underline{M}_x^\sharp$ is the maximal ideal; moreover :

$$\mathscr{O}_{F,\psi(x)} = P/\overline{S}_x \qquad \text{where} \qquad \overline{S}_x := \overline{\beta}_x^{-1}(1)$$

and – under this identification – the isomorphism $\log \psi_x : \mathscr{O}_{F,\psi(x)} \stackrel{\sim}{\to} \underline{M}_x^\sharp$ is deduced from $\overline{\beta}_x$ in the obvious way.

Now, let $x \in X$ be any point; after replacing X by the open subset $\psi^{-1}U(\psi(x))$, we may assume that $P = \mathscr{O}_{F,\psi(x)}$ (notation of (6.5.16)), and by assumption $\log \psi_x : P \to \underline{M}_x^\sharp$ is an isomorphism. Pick a surjection $\alpha : \mathbb{Z}^{\oplus r} \to P^{\rm gp}$, and let Q be the pull-back in the cartesian diagram :

$$\begin{array}{ccc} Q & \longrightarrow & \mathbb{Z}^{\oplus r} \\ \downarrow & & \downarrow {\scriptstyle (\log \psi_x)^{\rm gp} \circ \alpha} \\ \underline{M}_x^\sharp & \longrightarrow & \underline{M}_x^{\rm gp}/\underline{M}_x^\times. \end{array}$$

By construction, α restricts to a morphism of monoids $\vartheta : Q \to P$, inducing an isomorphism $Q^\sharp \stackrel{\sim}{\to} P$, whence an isomorphisms of fans $(\mathrm{Spec}\, P)^\sharp \stackrel{\sim}{\to} (\mathrm{Spec}\, Q)^\sharp$, and Q is fine, by corollary 6.4.2. Moreover, the choice of a lifting $\mathbb{Z}^{\oplus r} \to \underline{M}_x^{\rm gp}$ of $(\log \psi_x)^{\rm gp} \circ \alpha$ determines a morphism

$$\beta_x : Q \to \underline{M}_x^\sharp \times_{\underline{M}_x^{\rm gp}/\underline{M}_x^\times} \underline{M}_x^{\rm gp} = \underline{M}_x$$

which lifts $\log \psi_x \circ \vartheta$ (here it is needed that $\underline{M}$ is integral). Next, after replacing X by an open neighborhood of x, we may assume that β_x extends to a map of pre-log structures $\beta : Q_X \to \underline{M}$ lifting $\overline{\beta}$ (lemma 12.1.18(iv.b),(v)). It remains only to show that β is a chart for $\underline{M}$, which can be checked on the stalks. Thus, let $y \in X$ be any point, and set $S_y := \beta_y^{-1}\underline{M}_y^\times$; with the foregoing notation, the stalk $Q_{X,y}^{\log}$ of the induced log structure is naturally isomorphic to $(S_y^{-1}Q \times \mathscr{O}_{X,y}^\times)/S_y^{\rm gp}$, therefore

$$(Q_{X,y}^{\log})^\sharp \simeq Q/S_y \simeq P/\overline{S}_y$$

and the induced map $P/\overline{S}_y \to \underline{M}_y^\sharp$ is again deduced from $\overline{\beta}_y$, so it is an isomorphism; then the same holds for $\beta_y^{\log} : Q_{X,y}^{\log} \to \underline{M}_y$ (lemma 12.1.4). □

Lemma 12.6.12. *Let $\mu : P \to P'$ be a morphism of integral monoids such that μ^{gp} is surjective, $\varphi : (\operatorname{Spec} P')^\sharp \to (\operatorname{Spec} P)^\sharp$ the induced morphism of affine fans, and denote by*

$$\lambda : P \to Q := P^{\mathrm{gp}} \times_{P'^{\mathrm{gp}}} P'$$

the map of monoids determined by μ and the unit of adjunction $P \to P^{\mathrm{gp}}$. Then :

(i) *The natural projection $Q \to P'$ induces an isomorphism $\omega : (\operatorname{Spec} P')^\sharp \to (\operatorname{Spec} Q)^\sharp$ of affine fans, such that $(\operatorname{Spec} \lambda)^\sharp \circ \omega = \varphi$.*
(ii) *The induced morphism (12.6.6) in $\mathscr{K}_{\mathrm{int}}$ (with $R := \mathbb{Z}$) is $\mathbf{int}.\mathbf{Fan}$-cartesian.*
(iii) *If P and P' are fine, the morphism (12.6.6) is étale.*

Proof. (See (3.1) for generalities concerning inverse images and cartesian morphisms relative to a functor.) Notice first that, since μ^{gp} is surjective, the projection $Q \to P'$ induces an isomorphism $Q^\sharp \xrightarrow{\sim} P'^\sharp$, whence (i).

(ii): Notice that the log structure of $\operatorname{Spec}(\mathbb{Z}, Q)$ is integral, by lemma 12.1.18(iii). Next, set

$$F' := (\operatorname{Spec} P')^\sharp.$$

Define $\underline{S}$, $\underline{S}'$ as in example 12.6.5(ii) (with $R := \mathbb{Z}$), let $g : ((Y, \underline{N}), F'', \psi_Y) \to \underline{S}$ be any morphism of $\mathscr{K}_{\mathrm{int}}$, and $\varphi' : F'' \to F'$ a morphism of integral fans, such that the image of g in $\mathbf{int}.\mathbf{Fan}$ equals $\varphi \circ \varphi'$; we must show that g factors through a unique morphism $h : ((Y, \underline{N}), F'', \psi_Y) \to \underline{S}'$, whose image in $\mathbf{int}.\mathbf{Fan}$ equals φ'. As usual, we may reduce to the case where $Y = \operatorname{Spec} A$ is affine, $F'' = \operatorname{Spec} P''$ is an affine fan for a sharp integral monoid P'', and ψ_Y is given by a map of sheaves $P''_Y \to \underline{N}^\sharp$. In such situation, the morphism $(Y, \underline{N}) \to \operatorname{Spec}(\mathbb{Z}, P)$ underlying g is determined by a morphism of monoids $P \to \underline{N}(Y)$, or which is the same, a map of sheaves $\gamma_Y : P_Y \to \underline{N}$; likewise, φ' is given by a morphism of monoids $P' \to P''$, and composing with ψ_Y, we get a map of sheaves $\alpha_Y : P'_Y \to \underline{N}^\sharp$. Finally, the condition that g lies over $\varphi \circ \varphi'$ translates as the commutativity of the following diagram of sheaves :

$$\begin{array}{ccccc} P_Y^{\mathrm{gp}} & \longrightarrow & P_Y'^{\mathrm{gp}} & \longleftarrow & P'_Y \\ {\scriptstyle \gamma_Y^{\mathrm{gp}}}\downarrow & & \downarrow & & \downarrow{\scriptstyle \alpha_Y} \\ \underline{N}^{\mathrm{gp}} & \longrightarrow & \underline{N}^{\mathrm{gp}}/\underline{N}^\times & \longleftarrow & \underline{N}^\sharp. \end{array}$$

There follows a unique morphism of sheaves :

$$Q_Y \to \underline{N}^{\mathrm{gp}} \times_{\underline{N}^{\mathrm{gp}}/\underline{N}^\times} \underline{N}^\sharp = \underline{N} \tag{12.6.13}$$

(here it is needed that $\underline{N}$ is integral) such that the diagram :

$$\begin{array}{ccccc} P_Y & \longrightarrow & Q_Y & \longrightarrow & P'_Y \\ {\scriptstyle \gamma_Y}\downarrow & & \downarrow & & \downarrow{\scriptstyle \alpha_Y} \\ \underline{N} & = & \underline{N} & \longrightarrow & \underline{N}^\sharp \end{array}$$

commutes. Then (12.6.13) determines a morphism of log schemes $h_Y : (Y, \underline{N}) \to \operatorname{Spec}(\mathbb{Z}, Q)$, such that the pair (h_Y, φ') is the unique morphism h in $\mathscr{K}_{\mathrm{int}}$ with the sought properties.

(iii): If both P and P' are fine, so is Q (corollary 6.4.2), and by construction, λ^{gp} is an isomorphism. Then the assertion follows from theorem 12.3.37. □

Proposition 12.6.14. *Let $\underline{X} := ((X, \underline{M}), F, \psi)$ be an object of $\mathscr{K}_{\mathrm{int}}$. Let also $\varphi : F' \to F$ be an integral partial subdivision, with F locally fine and F' integral. We have :*

(i) *$(X, \underline{M})$ is a fine log scheme.*
(ii) *If F is saturated, $(X, \underline{M})$ is a fs log scheme.*
(iii) *$\underline{X}$ admits an inverse image over φ (relative to the functor of (12.6.10)).*
(iv) *If φ is finite, then the cartesian morphism $(f, \varphi) : \varphi^* \underline{X} \to \underline{X}$, is quasi-compact.*

(v) *If F' is locally fine, the morphism (f, φ) is quasi-separated and étale.*

Proof. (i): This is just a restatement of lemma 12.6.11.

(ii): In light of (i), we only have to show that $\underline{M}_x$ is a saturated monoid, for every $x \in X$. Since by assumption $\underline{M}^\sharp_x$ is saturated, the assertion follows from lemma 6.2.9(ii).

Claim 12.6.15. In order to show (iii)–(v), we may assume that :

(a) $F = (\operatorname{Spec} P)^\sharp$ for a fine monoid P, and X is an affine scheme.
(b) The map of global sections $P \to \Gamma(X, \underline{M}^\sharp)$ determined by ψ, comes from a morphism of pre-log structures $\beta : P_X \to \underline{M}$ which is a fine chart for $\underline{M}$.

Proof of the claim. To begin with, suppose that $((X', \underline{M}'), F', \psi')$ is the sought preimage of $\underline{X}$; let $U \subset X$ be any open subset, and $V \subset F$ an open subset such that $\psi(U) \subset V$. Then it is easily seen that the object

$$\varphi^* \underline{X} \times_{\underline{X}} (U, V) := ((f^{-1}U, \underline{M}'_{|f^{-1}U}), \varphi^{-1}V, \psi'_{|f^{-1}U})$$

is a preimage of $((U, \underline{M}_{|U}), V, \psi_{|U})$ over the restriction $\varphi^{-1}V \to V$ of φ. Now, suppose that we have found an affine open covering $X = \bigcup_{i \in I} U_i$, and for every $i \in I$ an affine open subset $V_i \subset F$ with $\psi(U_i) \subset V_i$, such that the object $\underline{U}_i := ((U_i, \underline{M}_{|U_i}), V_i, \psi_{|U_i})$ admits a preimage over the restriction $\varphi_i : \varphi^{-1}V_i \to V_i$ of φ; then the foregoing implies that there are natural isomorphisms:

$$\varphi_i^* \underline{U}_i \times_{\underline{U}_i} (U_{ij}, V_{ij}) \xrightarrow{\sim} \varphi_j^* \underline{U}_j \times_{\underline{U}_j} (U_{ij}, V_{ij})$$

for every $i, j \in I$, where $U_{ij} := U_i \cap U_j$ and $V_{ij} := V_i \cap V_j$. Thus, we may glue all these inverse images along these isomorphisms, to obtain the sought inverse image of $\underline{X}$.

Moreover, if φ is finite, the same will hold for the restrictions φ_i, and if each cartesian morphism $\varphi_i^* \underline{U}_i \to \underline{U}_i$ is quasi-compact, the same will hold also for (f, φ) ([58, Ch.I, §6.1]). Likewise, if each morphism $\varphi_i^* \underline{U}_i \to \underline{U}_i$ is étale and quasi-separated, then the same will hold for (f, φ) ([58, Ch.I, Prop.6.1.11] and proposition 12.3.24(iii)).

Therefore, we may replace X by any U_i, and F by the corresponding V_i, which reduces the proof of (iii)–(v) to the case where condition (a) is fulfilled. Lastly, in light of lemma 12.6.11 we may suppose that the open subsets U_i are small enough, so that also condition (b) is fulfilled. $\Diamond$

In view of claim 12.6.15, we shall assume henceforth that conditions (a) and (b) are fulfilled. Let $\underline{S} := (\operatorname{Spec}(\mathbb{Z}, P), T_P, \psi_P)$ be the object of $\mathscr{K}_{\mathrm{int}}$ considered in example 12.6.5(i) (with $R := \mathbb{Z}$); in this situation, β determines a morphism of schemes $f_\beta : X \to S$, and in view of lemma 12.2.14 we have $\underline{X} \simeq X \times_S \underline{S}$ (notation of (12.6.4)). Therefore, if we find an inverse image $\underline{S}'$ for $\underline{S}$ over φ, the object $X \times_S \underline{S}'$ will provide the sought inverse image of $\underline{X}$. Thus, in order to show (iii)–(v), we may further reduce to the case where $\underline{X} = \underline{S}$ ([58, Ch.I, Prop.6.1.5(iii), Prop.6.1.9(iii)] and proposition 12.3.24(ii)).

Claim 12.6.16. In order to prove (iii)–(v), we may assume that F' is affine.

Proof of the claim. Indeed, say that $F' = \bigcup_{i \in I} V_i$ is an open covering, and let $\varphi_i : V_i \to T_P$ be the restriction of φ; suppose that we have found, for each $i \in I$, an inverse image $\varphi_i^* \underline{S}$ of $\underline{S}$ over φ_i; again, it follows easily that an inverse image for $\underline{S}$ over φ can be constructed by gluing the objects $\varphi_i^* \underline{S}$. This already implies that, in order to show (iii), we may assume that F' is affine.

Now, suppose that φ is finite, so we may find an open covering as above, such that furthermore each V_i is affine, and I is a finite set. Suppose that each of the corresponding morphisms $\varphi_i^* \underline{S} \to \underline{S}$ is quasi-compact; by the foregoing, the schemes underlying the objects $\varphi_i^* \underline{S}$ give a finite open covering of the scheme underlying $\varphi^* \underline{S}$, and then it is clear that (iv) holds.

Next, suppose furthermore that each morphism $\varphi_i^* \underline{S} \to \underline{S}$ is étale. It follows that the morphism $\varphi^* \underline{S} \to \underline{S}$ is also étale (proposition 12.3.24(ii)); then, since S is noetherian, the scheme underlying $\varphi^*\underline{S}$ is locally noetherian ([58, Ch.I, Prop.6.2.2]), and therefore the morphism $\varphi^*\underline{S} \to \underline{S}$ is quasi-separated ([58, Ch.I, Cor.6.1.13]). ◊

In view of claim 12.6.16, we shall assume that $F' = (\operatorname{Spec} P')^\sharp$ is affine as well, for a sharp and integral P', and that φ is given by a morphism $\lambda : P \to P'$ inducing a surjection on the associated groups (details left to the reader). Then assertions (iii) and (iv) are now straightforward consequences of lemma 12.6.12(i,ii), and (v) follows from lemma 12.6.12(iii), after one remarks that, when F' is fine, one may choose for P' a fine monoid. □

Remark 12.6.17. Keep the assumptions of proposition 12.6.14, and let $t \in F_0$ a point of F of height zero (see (6.5.16)). Notice that the inclusion map $j_t : \{t\} \to F$ is an open immersion, hence the fibre $X_t := \psi^{-1}(t) \subset X$ is open; indeed, it is clear from the definitions, that $\psi^{-1}(F_0)$ is precisely the trivial locus of $\underline{X}$. Moreover, let $t' \in \varphi^{-1}(t)$ since the group homomorphism $\mathscr{O}^{\mathrm{gp}}_{F,t} \to \mathscr{O}^{\mathrm{gp}}_{F',t'}$ is surjective, we see that t' is of height zero in F', and φ restricts to an isomorphism of fans $(\{t'\}, \mathscr{O}_{F,t'}) \xrightarrow{\sim} (\{t\}, \mathscr{O}_{F,t})$. Set $\underline{X}_t := j_t^*\underline{X}$ (whose underlying scheme is X_t), and define likewise $\varphi^*\underline{X}_{t'} := (\varphi \circ j_{t'})^*\underline{X}$ (whose underlying scheme is an open subset of the trivial locus of $\varphi^*\underline{X}$). We deduce that :

- The trivial locus of $\varphi^*\underline{X}$ is the preimage of $(X, \underline{M})_{\mathrm{tr}}$.
- For every $t' \in F'_0$, the restriction of $(f, \varphi) : \varphi^*\underline{X}_{t'} \to \underline{X}_t$ is an isomorphism.

Corollary 12.6.18. *In the situation of proposition* 12.6.14*, let* $((X', \underline{M}'), F', \psi') := \varphi^*\underline{X}$*. The following holds :*

(i) *If* $F' = F^{\mathrm{sat}}$*, and* $\varphi : F^{\mathrm{sat}} \to F$ *is the counit of adjunction, then* $(X', \underline{M}') = (X, \underline{M})^{\mathrm{fs}}$*, and* f *is the counit of adjunction.*

(ii) *If* φ *is the blow up of a coherent ideal* $\mathscr{I}$ *of* $\mathscr{O}_F$*, then* f *is the blow up of* $\mathscr{I}\underline{M}$*, the unique ideal of* $\underline{M}$ *whose image in* $\underline{M}^\sharp$ *equals* $\psi^{-1}\mathscr{I}$*.*

(iii) *Suppose moreover, that* $(X, \underline{M})$ *is regular,* F' *is saturated , and* $\underline{X} = \mathscr{K}(X, \underline{M})$ *(notation of remark* 12.6.9(iii)*). Then* $(X', \underline{M}')$ *is regular, and* $\varphi^*\underline{X}$ *is isomorphic to* $\mathscr{K}(X', \underline{M}')$*.*

Proof. To start with, we remark that the assertions are local on X. Indeed, this is clear for (i), and for (iii) it follows easily from remark 12.6.9(i,,ii); concerning (ii), suppose that $X = \bigcup_{i\in I} U_i$ is an open covering, such that $\varphi^*(U_i, \underline{M}_{|U_i})$ is the blow up of the ideal $\mathscr{I}\underline{M}_{|U_i}$, for every $i \in I$. For every $i, j \in I$ set $U_{ij} := U_i \cap U_j$; by the universal property of the blow up, there are unique isomorphisms of $(U_{ij}, \underline{M}_{|U_{ij}})$-schemes :

$$U_{ij} \times_{U_i} \varphi^*(U_i, \underline{M}_{|U_i}) \xrightarrow{\sim} U_{ij} \times_{U_j} \varphi^*(U_j, \underline{M}_{|U_j}).$$

Then both $\varphi^*(X, \underline{M})$ and the blow up of $\mathscr{I}\underline{M}$ are necessarily obtained by gluing along these isomorphisms, so they are isomorphic.

Thus, we may assume that $F = (\operatorname{Spec} P)^\sharp$ for some fine monoid P, and $(X, \underline{M}) = X \times_S (S, P^{\log}_S)$ for some morphism of schemes $X \to S$, where as usual $(S, P^{\log}_S, F, \psi_P)$ is defined as in example 12.6.5(i). In this case, (i) follows from remarks 12.2.38(iii), 6.5.8(ii) and lemma 12.6.12(ii).

Likewise, remark 12.4.32(ii) allows to reduce (ii) to the case where $\underline{X} = (S, P^{\log}_S, F, \psi_P)$, and $\mathscr{I} = I^\sim$ for some ideal $I \subset P$; in which case we conclude by inspecting the explicit description in example 12.4.43.

(iii): From proposition 12.6.14(ii,v) and theorem 12.5.28 we already see that $(X', \underline{M}')$ is regular. Next, we are easily reduced to the case where X is affine, say $X = \operatorname{Spec} A$, and $F' = (\operatorname{Spec} Q)^\sharp$, for some saturated monoid Q, and by lemma 12.6.12, we may assume that φ is induced by a morphism of monoids $\lambda : P \to Q$ such that λ^{gp} is an isomorphism, and $(X', \underline{M}') = \varphi^*\underline{X} = X \times_S \underline{S}'$, where $\underline{S}' := (\operatorname{Spec}(\mathbb{Z}, Q), F', \psi_Q)$ is defined as in example

12.6.5(ii). Let $\mathfrak{q} \subset Q$ be any prime ideal, and set $\mathfrak{p} := \mathfrak{q} \cap P$; in light of remark 12.6.9(i), it then suffices to show that $Q/\mathfrak{q} \otimes_P A = Q/\mathfrak{q} \otimes_{P/\mathfrak{p}} A/\mathfrak{p}A$ is an integral domain. To this aim, let us remark :

Claim 12.6.19. Let $\lambda : P \to Q$ be a morphism of fine monoids, such that λ^{gp} is an isomorphism, $F \subset Q$ any face, and denote $\lambda_F : F \cap P \to P$ the inclusion map. Then :

(i) The natural map $\mathrm{Coker}\, \lambda_F^{\mathrm{gp}} \to P^{\mathrm{gp}}/(F \cap P)^{\mathrm{gp}}$ is injective.

(ii) If moreover, P is saturated, then $\mathrm{Coker}\, \lambda_F^{\mathrm{gp}}$ is a free abelian group of finite rank.

Proof of the claim. The map of (i) is obtained via the snake lemma, applied to the ladder of abelian groups :

$$\begin{array}{ccccccccc} 0 & \longrightarrow & (F \cap P)^{\mathrm{gp}} & \longrightarrow & P^{\mathrm{gp}} & \longrightarrow & P^{\mathrm{gp}}/(F \cap P)^{\mathrm{gp}} & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \lambda_F^{\mathrm{gp}}} & & \downarrow{\scriptstyle \lambda^{\mathrm{gp}}} & & \downarrow & & \\ 0 & \longrightarrow & F^{\mathrm{gp}} & \longrightarrow & Q^{\mathrm{gp}} & \longrightarrow & Q^{\mathrm{gp}}/F^{\mathrm{gp}} & \longrightarrow & 0. \end{array}$$

taking into account that both $\mathrm{Ker}\, \lambda^{\mathrm{gp}}$ and $\mathrm{Coker}\, \lambda^{\mathrm{gp}}$ vanish. Then (i) is obvious, and (ii) comes down to checking that $P^{\mathrm{gp}}/(F \cap P)^{\mathrm{gp}}$ is torsion-free, in case P is fine and saturated. But since $F \cap P$ is a face of P, the latter assertion is an easy consequence of proposition 6.4.9. ◊

Now, set $F := Q \setminus \mathfrak{q}$; we come down to checking that $B := F \otimes_{F \cap P} A/\mathfrak{p}A$ is an integral domain, and remark 12.6.9(i) tells us that $A/\mathfrak{p}A$ is a domain. However, $A/\mathfrak{p}A$ is $(F \cap P)$-flat (proposition 12.5.16(ii)), hence the natural map

$$B \to C := F^{\mathrm{gp}} \otimes_{(F \cap P)^{\mathrm{gp}}} \mathrm{Frac}(A/\mathfrak{p}A)$$

is injective; on the other hand, claim 12.6.19(ii) implies that $C = A[\mathrm{Coker}\, \lambda_F^{\mathrm{gp}}]$ is a free (polynomial) A-algebra, whence the contention. □

Example 12.6.20. In the situation of example 6.5.27, take $T := \mathrm{Spec}\, P$ for a fine monoid P, and define $\underline{S}$ as in example 12.6.5(i). The k-Frobenius map $\boldsymbol{k}_P$ (example 6.5.10(i)) induces an endomorphism $\boldsymbol{k}_{\underline{S}} := (\mathrm{Spec}(R, \boldsymbol{k}_P), \boldsymbol{k}_T)$ of $\underline{S}$ in $\mathscr{K}$. By proposition 12.6.14(iii) and example 6.5.27, there exists a unique morphism $\underline{g}$ fitting into a commutative diagram of $\mathscr{K}_{\mathrm{int}}$:

(12.6.21)
$$\begin{array}{ccc} \varphi^*\underline{S} & \longrightarrow & \underline{S} \\ \downarrow{\scriptstyle \underline{g}} & & \downarrow{\scriptstyle \boldsymbol{k}_{\underline{S}}} \\ \varphi^*\underline{S} & \longrightarrow & \underline{S} \end{array}$$

(where the horizontal arrows are the cartesian morphisms). Say that $\varphi^*\underline{S} = ((Y, \underline{N}), F, \psi)$; then we have $\underline{g} = (g, \boldsymbol{k}_F)$ for a unique endomorphism $g := (g, \log g)$ of the log scheme $(Y, \underline{N})$. Let $U := \mathrm{Spec}\, P' \subset F$ be any open affine subset ; since $\boldsymbol{k}_F$ is the identity on the underlying topological spaces, g restricts to an endomorphism $g_{|\psi^{-1}U}$ of $\psi^{-1}U \times_Y (Y, \underline{N})$. In view of lemma 12.6.12, the latter log scheme is of the form $\underline{S}'$ as in example 12.6.5(ii), with $Q := P^{\mathrm{gp}} \times_{P'^{\mathrm{gp}}} P'$. Then $g_{|\psi^{-1}U}$ is induced by an endomorphism ν of Q, fitting into a commutative diagram :

$$\begin{array}{ccc} P & \longrightarrow & Q \\ \downarrow{\scriptstyle \boldsymbol{k}_P} & & \downarrow{\scriptstyle \nu} \\ P & \longrightarrow & Q \end{array}$$

whose horizontal arrows are the natural injections. Since $Q \subset P^{\mathrm{gp}}$, it is clear that $\nu = \boldsymbol{k}_Q$. Especially, $g : Y \to Y$ is a finite morphism of schemes. Furthermore, for every point $y \in Y$, we have a commutative diagram of monoids :

$$\begin{array}{ccccc} \underline{N}_{g(y)} & \longrightarrow & \underline{N}^\sharp_{g(y)} & \xleftarrow{\sim} & \mathscr{O}_{F,\psi(y)} \\ \downarrow{\scriptstyle \log g_y} & & \downarrow{\scriptstyle \log g^\sharp_y} & & \downarrow{\scriptstyle \boldsymbol{k}_{\psi(y)}:=(\log \boldsymbol{k}_F)_{\psi(y)}} \\ \underline{N}_y & \longrightarrow & \underline{N}^\sharp_y & \xleftarrow{\sim} & \mathscr{O}_{F,\psi(y)}. \end{array} \qquad (12.6.22)$$

12.6.23. Let $(K, |\cdot|)$ be a valued field, Γ and K^+ respectively the value group and the valuation ring of $|\cdot|$; denote by $1 \in \Gamma$ the neutral element, and by $\Gamma_+ \subset \Gamma$ the submonoid consisting of all elements ≤ 1. Set $S := \operatorname{Spec} K^+$; we consider the log scheme $(S, \mathscr{O}^*_S)$, where $\mathscr{O}^*_S \subset \mathscr{O}_S$ is the subsheaf such that $\mathscr{O}^*_S(U) := \mathscr{O}_S(U)\backslash\{0\}$ for every open subset $U \subset S$. To this log scheme we associate the object of $\mathscr{K}_{\mathrm{int}}$:

$$\mathsf{f}(K, |\cdot|) := ((S, \mathscr{O}^*_S), \operatorname{Spec} \Gamma_+, \psi_\Gamma)$$

where ψ_Γ is the morphism of monoidal spaces arising from the isomorphism

$$\Gamma_+ \xrightarrow{\sim} (K^+\backslash\{0\})/(K^+)^\times$$

deduced from the valuation $|\cdot|$. It is well known that ψ_Γ is a homeomorphism (see *e.g.* [75, §6.1.26]). We shall use objects of this kind to state some separation and properness criteria for log schemes whose existence is established via proposition 12.6.14. To this aim, we need to digress a little, to prove the following auxiliary results, which are refinements of the standard valuative criteria for morphisms of schemes.

12.6.24. Let $f : X \to Y$ be a morphism of schemes, R an integral ring, and K the field of fractions of R. Let us denote by $X(R)_{\max} \subset X(R)$ the set of morphisms $\operatorname{Spec} R \to X$ which map $\operatorname{Spec} K$ to a maximal point of X. There follows a commutative diagram of sets :

$$\begin{array}{ccc} X(R)_{\max} & \longrightarrow & X(K)_{\max} \\ \downarrow & & \downarrow \\ Y(R) & \longrightarrow & Y(K). \end{array} \qquad (12.6.25)$$

Proposition 12.6.26. *Let $f : X \to Y$ be a morphism of schemes. The following conditions are equivalent :*

(a) *f is separated.*

(b) *f is quasi-separated, and for every valued field $(K, |\cdot|)$, the map of sets :*

$$X(K^+)_{\max} \to X(K)_{\max} \times_{Y(K)} X(K^+)_{\max} \qquad (12.6.27)$$

deduced from diagram (12.6.25) *(with $R := K^+$, the valuation ring of $|\cdot|$), is injective.*

Proof. (a) ⇒ (b) by the valuative criterion of separation ([58, Ch.I, Prop.5.5.4]). Conversely, we shall show that if (b) holds, then the assumptions of the criterion of *loc.cit.* are fulfilled. Indeed, let $(L, |\cdot|_L)$ be any valued field, with valuation ring L^+, and suppose we have two morphisms $\sigma_1, \sigma_2 : \operatorname{Spec} L^+ \to X$ whose restrictions to $\operatorname{Spec} L$ agree, and such that $f \circ \sigma_1 = f \circ \sigma_2$.

Let $s, \eta \in \operatorname{Spec} L^+$ be respectively the closed point and the generic point, set $x := \sigma_1(\eta) = \sigma_2(\eta) \in X$, and denote by $\varphi : \mathscr{O}_{X,x} \to L$ the ring homomorphism corresponding to the restriction of σ_1 (and σ_2); then x admits two specializations $x_i := \sigma_i(s) \in X$ (for $i = 1, 2$) such that φ sends the image $A_i \subset \mathscr{O}_{X,x}$ of the specialization map $\mathscr{O}_{X,x_i} \to \mathscr{O}_{X,x}$, into L^+, and the maximal ideal of A_i into the maximal ideal $\mathfrak{m}_L$ of L^+, for both $i = 1, 2$. Moreover, $y := f(x_1) = f(x_2)$.

Denote by $B \subset \mathscr{O}_{X,x}$ the smallest subring containing A_1 and A_2, and set $\mathfrak{p} := B \cap \varphi^{-1}\mathfrak{m}_L$. Then $\varphi(B_\mathfrak{p}) \subset L^+$ as well, and $B_\mathfrak{p}$ dominates both A_1 and A_2. Now, let $t \in X$ be a maximal point which specializes to x; by [58, Ch.I, Prop.5.5.2] we may find a valued field $(E, |\cdot|_E)$

with a local ring homomorphism $\mathscr{O}_{X,t} \to E$, such that the valuation ring E^+ of $|\cdot|_E$ dominates the image of the specialization map $\mathscr{O}_{X,x} \to \mathscr{O}_{X,t}$. Let $\kappa(E)$ be the residue field of E^+, and $\overline{B}_\mathfrak{p} \subset \kappa(E)$ the image of $B_\mathfrak{p}$. By the same token, we may find a valuation ring $V \subset \kappa(E)$ with fraction field $\kappa(E)$, and dominating $\overline{B}_\mathfrak{p}$; then it is easily seen that the preimage $K^+ \subset E^+$ of V is a valuation ring with field of fractions $K = E$, which dominates the image of $B_\mathfrak{p}$ in $\mathscr{O}_{X,t}$ ([126, Th.10.1(iv)]). Hence, K^+ dominates the images of $\mathscr{O}_{X,x_i}$, for both $i = 1, 2$, and therefore, also the image of $\mathscr{O}_{Y,y}$; in other words, in this way we obtain two elements in $X(K^+)_{\max}$ whose images agree in $Y(K^+)$, and whose restrictions $\operatorname{Spec} K \to X$ coincide. By assumption, these two K^+-points must then coincide, especially $x_1 = x_2$, and therefore $\sigma_1 = \sigma_2$, as required. □

Proposition 12.6.28. *Let $f : X \to Y$ be a quasi-compact morphism of schemes. The following conditions are equivalent :*

(a) *f is universally closed.*
(b) *For every valued field $(K, |\cdot|)$, the corresponding map* (12.6.27) *is surjective.*

Proof. (a) ⇒ (b) by the valuative criterion of [58, Ch.I, Prop.5.5.8]. Conversely, we will show that (b) implies that the conditions of *loc.cit.* are fulfilled. Hence, let $(L, |\cdot|_L)$ be any valued field, with valuation ring L^+, and suppose that we have a morphism $\sigma : \operatorname{Spec} L \to X$, whose composition with f extends to a morphism $\operatorname{Spec} L^+ \to Y$; we have to show that σ extends to a morphism $\operatorname{Spec} L^+ \to X$. Denote by $\eta, s \in \operatorname{Spec} L^+$ respectively the generic and the closed point, let $x \in X$ be the image of η, and $y \in Y$ the image of s. Then σ corresponds to a ring homomorphism $\sigma^\natural : \mathscr{O}_{X,x} \to L$, and L^+ dominates the image of the map $\mathscr{O}_{Y,y} \to \mathscr{O}_{X,x}$ determined by f. Moreover, $\sigma^\natural$ factors through the residue field $\kappa(x)$ of $\mathscr{O}_{X,x}$. Then $\kappa(x)^+ := \kappa(x) \cap L^+$ is a valuation ring with fraction field $\kappa(x)$, and we are reduced to showing that there exists a specialization $x' \in X$ of x, such that $f(x') = y$, and such that $\kappa(x)^+$ dominates the image of the specialization map $\mathscr{O}_{X,x'} \to \mathscr{O}_{X,x}$.

Let now $t \in X$ be a maximal point which specializes to x; by [58, Ch.I, Prop.5.5.8] we may find a valued field $(E, |\cdot|_E)$ with a local ring homomorphism $\mathscr{O}_{X,t} \to E$, whose valuation ring E^+ dominates the image of the specialization map $\mathscr{O}_{X,x} \to \mathscr{O}_{X,t}$. Let $\kappa(E)$ be the residue field of E^+; the induced map $\mathscr{O}_{X,x} \to \kappa(E)$ factors through $\kappa(x)$, and by [126, Th.10.2] we may find a valuation ring $V \subset \kappa(E)$ with field of fractions $\kappa(E)$, which dominates $\kappa(x)^+$. The preimage $K^+ \subset E^+$ of V is a valuation ring with field of fractions $K = E$ ([126, Th.10.1]). By construction, K^+ dominates the image of $\mathscr{O}_{X,y}$, in which case assumption (b) says that there exists a specialization x' of x such that $f(x') = y$, and such that K^+ dominates the image of the specialization map $\mathscr{O}_{X,x'} \to \mathscr{O}_{X,t}$. A simple inspection then shows that $\kappa(x)^+$ dominates the image of $\mathscr{O}_{X,x'}$ in $\mathscr{O}_{X,x}$, as required. □

Corollary 12.6.29. *Let $f : X \to Y$ be a morphism of schemes which is quasi-separated and of finite type. Then the following conditions are equivalent :*

(a) *f is proper.*
(b) *For every valued field $(K, |\cdot|)$, the corresponding diagram* (12.6.25) *(with $R := K^+$ the valuation ring of $|\cdot|$) is cartesian.*

Proof. It is immediate from propositions 12.6.26 and 12.6.28. □

12.6.30. We are now ready to return to log schemes. Resume the situation of (12.6.23), let $\underline{X} := ((X, \underline{M}), F, \psi)$ be any object of $\mathscr{K}$, and denote by $\alpha : \underline{M} \to \mathscr{O}_X$ the structure map of $\underline{M}$.

Suppose we are given a morphism $\sigma : S \to X$ of schemes, and we ask whether there exists a morphism of log structures $\beta : \sigma^*\underline{M} \to \mathscr{O}_S^*$, such that the pair (σ, β) is a morphism of log schemes $(S, \mathscr{O}_S^*) \to (X, \underline{M})$. By definition, this holds if and only if the composition

$$\overline{\beta} : \sigma^*\underline{M} \xrightarrow{\sigma^*\alpha} \sigma^*\mathscr{O}_X \xrightarrow{\sigma^\natural} \mathscr{O}_S$$

factors through $\mathscr{O}_S^*$. Moreover, in this case the factorization is unique, so that σ determines β uniquely. Let $\eta \in S$ be the generic point; we claim that the stated condition is fulfilled, if and only if $t := \sigma(\eta)$ lies in $(X, \underline{M})_{\mathrm{tr}}$ (see definition 12.2.7(i)). Indeed, if t lies in the trivial locus, $\underline{M}_t = \mathscr{O}_{X,t}^\times$, so certainly the image of $\overline{\beta}_t : \underline{M}_t \to \mathscr{O}_{S,\eta}$ lies in $\mathscr{O}_{S,\eta}^* = K^\times$. Now, if $s \in S$ is any other point, the composition

$$\underline{M}_{\sigma(s)} \xrightarrow{\overline{\beta}_{\sigma(s)}} \mathscr{O}_{S,s} \to \mathscr{O}_{S,\eta} = K$$

factors through $\underline{M}_t$, hence its image lies in $K^\times \cap \mathscr{O}_{S,s} = \mathscr{O}_{S,s}^*$, whence the contention. Conversely, if $\overline{\beta}$ factors through $\mathscr{O}_S^*$, it follows especially that the image of the stalk of the structure map $\underline{M}_t \to \mathscr{O}_{X,t}$ lies in the preimage of $\mathscr{O}_{S,\eta}^* = \mathscr{O}_{S,\eta}^\times$, and the latter is just $\mathscr{O}_{X,t}^\times$, so t lies in the trivial locus.

Next, let $f : (S, \mathscr{O}_S^*) \to (X, \underline{M})$ be any morphism of log schemes. We claim that there exists a unique morphism of fans $\varphi := (\varphi, \log\varphi) : \mathrm{Spec}\,\Gamma_+ \to F$, such that the pair (f, φ) is a morphism $\mathsf{f}(K, |\cdot|) \to \underline{X}$ in $\mathscr{K}$. Indeed, since ψ_Γ is a homeomorphism, there exists a unique continuous map φ on the underlying topological spaces, such that $\varphi \circ \psi_\Gamma = \psi \circ f$, and for the same reason, the map $\log f^\sharp : f^*\underline{M}/\mathscr{O}_S^\times \to \mathscr{O}_S^*/\mathscr{O}_S^\times$ is of the form $\psi_\Gamma^*(\log\varphi)$ for a unique morphism of sheaves $\log\varphi$ as sought. Then $\log\varphi$ will be a local morphism, since the same holds for $\log f$ (see (12.6.1)).

Summing up, we have shown that the natural map

$$\mathrm{Hom}_{\mathscr{K}}(\mathsf{f}(K, |\cdot|), \underline{X}) \to X(K^+) \quad : \quad (\sigma, \varphi) \mapsto \sigma$$

is injective, and its image is the set of all the morphisms $S \to X$ which map η into $(X, \underline{M})_{\mathrm{tr}}$.

Proposition 12.6.31. *Let $\underline{X} := ((X, \underline{M}), F, \psi)$ be an object of $\mathscr{K}_{\mathrm{int}}$, and $\varphi : F' \to F$ an integral partial subdivision, with F and F' locally fine. We have :*

(i) *If the induced map $F'(\mathbb{N}) \to F(\mathbb{N})$ is injective, the cartesian morphism $\varphi^*\underline{X} \to \underline{X}$ is separated.*

(ii) *If φ is a proper subdivision, the cartesian morphism $\varphi^*\underline{X} \to \underline{X}$ is proper, and induces an isomorphism of schemes $(\varphi^*\underline{X})_{\mathrm{tr}} \xrightarrow{\sim} (X, \underline{M})_{\mathrm{tr}}$.*

Proof. The assertions are local on X (cp. the proof of claim 12.6.15), so we may assume – by lemma 12.6.11 – that $\underline{M}$ admits a chart $P_X \to \underline{M}$, and $F = (\mathrm{Spec}\,P)^\sharp$. In this case, let $S := \mathrm{Spec}\,\mathbb{Z}[P]$, and denote by $\underline{S}$ the object of $\mathscr{K}_{\mathrm{int}}$ attached to P, as in example 12.6.5(i) (with $R := \mathbb{Z}$); then $(X, \underline{M})$ is isomorphic to $X \times_S (S, P_S^{\log})$, and if $f_S : \varphi^*\underline{S} \to \underline{S}$ is the cartesian morphism over φ, then the cartesian morphism $f : \varphi^*\underline{X} \to \underline{X}$ is given by the pair $(\mathbf{1}_X \times_S f_S, \varphi)$ (see the proof of proposition 12.6.14(iii)). Thus, we may replace $\underline{X}$ by $\underline{S}$ ([58, Ch.I, Prop.5.3.1(iv)]), in which case lemma 12.6.12 shows that the log scheme $(X', \underline{M}')$ underlying $\varphi^*\underline{S}$ admits an open covering consisting of affine log schemes of the form $\mathrm{Spec}(\mathbb{Z}, Q)$, for a fine monoid Q. Notice that, for such Q we have :

$$\mathrm{Spec}(\mathbb{Z}, Q)_{\mathrm{tr}} = \mathbb{Z}[Q^{\mathrm{gp}}]$$

which is a dense open subset of $\mathrm{Spec}\,\mathbb{Z}[Q]$.

(i): According to proposition 12.6.14(v), the morphism f is quasi-separated, so we may apply the criterion of proposition 12.6.26. Indeed, let $(K, |\cdot|)$ be any valued field, and suppose that $\sigma_i \in X'(K^+)_{\max}$ (for $i = 1, 2$) are two sections, whose images in $X'(K)_{\max} \times_{S(K)} S(K^+)$ coincide; we have to show that $\sigma_1 = \sigma_2$. However, we have just seen that the maximal points of X' lie in $(X', \underline{M}')_{\mathrm{tr}}$, so the discussion of (12.6.30) shows that both σ_i extend uniquely to morphisms $\sigma'_i : \mathsf{f}(K, |\cdot|) \to \varphi^*\underline{S}$ in $\mathscr{K}$, and it suffices to show that $\sigma'_1 = \sigma'_2$. By definition, the datum of σ'_i is equivalent to the datum of a morphism $\sigma''_i : \mathsf{f}(K, |\cdot|) \to \underline{S}$, and a morphism of fans $\varphi'_i : \mathrm{Spec}\,\Gamma_+ \to F'$. Again by (12.6.30), the morphisms σ''_1 and σ''_2 agree if and only if they induce the same morphisms of schemes; the latter holds by assumption, since σ_1 and σ_2 yield the same element of $S(K^+)$. On the other hand, in view of (b) and proposition 6.5.24, the elements $\varphi_1, \varphi_2 \in F'(\Gamma_+)$ coincide if and only if their images in $F(\Gamma_+)$ coincide; but again, this last condition holds since the images of both σ_i agree in $S(K^+)$.

(ii): In view of (i) and proposition 12.6.14(iv),(v) we know already that f is separated and of finite type, so we may apply the criterion of corollary 12.6.29. Hence, let $\sigma \in S(K^+)$ be a section, and $x \in X'(K)_{\max}$ a K-rational point such that $f(x)$ is the image of σ in $S(K)$; in view of (i), it suffices to show that σ lifts to a section $\widetilde{\sigma} \in X'(K^+)_{\max}$, whose image in $X'(K)$ is x. Since $x \in (X', \underline{M}')_{\mathrm{tr}}$, remark 12.6.17 implies that $f(x) \in (S, P_S^{\log})_{\mathrm{tr}}$, and then the discussion in (12.6.30) says that σ underlies a unique morphism $(\sigma', \beta) : \mathsf{f}(K, |\cdot|) \to \underline{S}$. By proposition 6.5.26, the element $\beta \in F(\Gamma_+)$ lifts to an element $\beta' \in F'(\Gamma_+)$, and finally the pair $((\sigma, \beta), \beta')$ determines a unique morphism $\mathsf{f}(K, |\cdot|) \to \varphi^*\underline{S}$, whose underlying morphism of schemes is the sought $\widetilde{\sigma}$. Lastly, notice that the map $F'(\{1\}) \to F(\{1\})$ induced by φ, is bijective by propositions 6.5.24 and 6.5.26 (where $\{1\}$ is the monoid with one element), which means that φ restricts to a bijection on the points of height zero; then remark 12.6.17 implies the second assertion of (ii). ☐

Theorem 12.6.32. *Let $(X, \underline{M})$ be a regular log scheme. Then there exists a smooth morphism of log schemes $f : (X', \underline{M}') \to (X, \underline{M})$, whose underlying morphism of schemes is proper and birational, and such that X' is a regular scheme. More precisely, f restricts to an isomorphism of schemes $f^{-1}X_{\mathrm{reg}} \to X_{\mathrm{reg}}$ on the preimage of the open locus of regular points of X.*

Proof. We use the object $\underline{X} := ((X, \underline{M}), F(X, \underline{M}), \pi_X)$ attached to $(X, \underline{M})$ as in remark 12.6.9(ii). Indeed, it is clear that $F(X, \underline{M})$ is locally fine and saturated, hence theorem 6.6.31 yields an integral, proper, simplicial subdivision $\varphi : F' \to F(X, \underline{M})$ which restricts to an isomorphism $\varphi^{-1}F(X, \underline{M})_{\mathrm{sim}} \xrightarrow{\sim} F(X, \underline{M})_{\mathrm{sim}}$. Take $(f, \varphi) : \varphi^*\underline{X} \to \underline{X}$ to be the cartesian morphism over φ, and denote by $(X', \underline{M}')$ the log scheme underlying $\varphi^*\underline{X}$; it follows already from proposition 12.6.31(ii) that f is proper on the underlying schemes. Next, corollary 12.5.19 shows that X_{reg} is $\pi^{-1}F(X, \underline{M})_{\mathrm{sim}}$, so f restricts to an isomorphism $f^{-1}X_{\mathrm{reg}} \xrightarrow{\sim} X_{\mathrm{reg}}$. Furthermore, f is étale, by proposition 12.6.14(v), hence the log scheme $(X', \underline{M}')$ is regular (theorem 12.5.28). Finally, again by corollary 12.5.12 we see that X' is regular. ☐

12.6.33. Let now $(Y, \underline{N})$ be a regular log scheme, such that $F(Y, \underline{N})$ is affine (notation of remark 12.6.9(ii)), say isomorphic to $(\mathrm{Spec}\, P)^\sharp$, for some fine, sharp and saturated monoid P. Let $I \subset P$ be an ideal generated by two elements $a, b \in P$, and denote by $f : (Y', \underline{N}') \to (Y, \underline{N})$ the saturated blow up of the ideal $I\underline{N}$ of $\underline{N}$ (see (12.4.49)). Set $U' := (Y', \underline{N}')_{\mathrm{tr}}$, $U := (Y, \underline{N})_{\mathrm{tr}}$, and denote $j : U \to Y$, $j' : U' \to Y'$ the open immersions. In this situation we have :

Lemma 12.6.34. (i) $H^1(Y', \underline{N}'^{\sharp\mathrm{gp}}) = 0$.

(ii) *Suppose moreover, that $R^1 j'_* \mathscr{O}_{U'}^\times = 0$. Then $R^1 j_* \mathscr{O}_U^\times = 0$.*

Proof. (i): Since $\underline{N}'^{\sharp\mathrm{gp}} = \pi_X^* \mathscr{O}^{\mathrm{gp}}_{F(Y', \underline{N}')}$, claim 12.6.39(ii) and remark 12.6.9(iii) reduce to showing

$$H^1(F(Y', \underline{N}'), \mathscr{O}^{\mathrm{gp}}_{F(Y', \underline{N}')}) = 0. \tag{12.6.35}$$

However, by corollary 12.6.18(iii), the fan $F(Y', \underline{N}')$ is the saturated blow up of the ideal $I\mathscr{O}_{F(Y,\underline{N})}$ of $\mathscr{O}_{F(Y,\underline{N})}$, hence it admits the affine covering

$$F(Y', \underline{N}') = (\mathrm{Spec}\, P[a^{-1}b]^{\mathrm{sat}})^\sharp \cup (\mathrm{Spec}\, P[b^{-1}a]^{\mathrm{sat}})^\sharp.$$

Notice now that every affine fan is a local topological space, hence the left hand-side of (12.6.35) is computed by the Čech cohomology of $\mathscr{O}^{\mathrm{gp}}_{F(Y', \underline{N}')}$ relative to this covering (theorem 10.2.24(ii)).

However, the intersection of the two open subsets is $(\mathrm{Spec}\, P[a^{-1}b, b^{-1}a])^\sharp$, and clearly the restriction map

$$H^0(\mathrm{Spec}\, P[a^{-1}b]^{\mathrm{sat}}, \mathscr{O}^{\mathrm{gp}}_{F(Y',\underline{N}')}) \to H^0(\mathrm{Spec}\, P[a^{-1}b, b^{-1}a], \mathscr{O}^{\mathrm{gp}}_{F(Y',\underline{N}')})$$

is surjective. The assertion is an immediate consequence.

(ii): Let $y \in Y$ be any point; according to (12.4.50), the morphism

$$f \times_Y Y(y) : (Y', \underline{N}') \times_Y Y(y) \to (Y(y), \underline{N}(y))$$

is the saturated blow up of the ideal $I\underline{N}(y)$; on the other hand, let $U(y) := U \times_Y Y(y)$, $U'(y) := U' \times_Y Y(y)$ and denote by $j_y : U(y) \to Y(y)$ and $j'_y : U'(y) \to Y' \times_Y Y(y)$ the open immersions; in light of proposition 10.1.10(ii), it suffices to show that $R^1 j_{y*}\mathscr{O}_{U(y)} = 0$, and the assumption implies that $R^1 j'_{y*}\mathscr{O}_{U'(y)} = 0$. Summing up, we may replace Y be $Y(y)$, and assume from start that Y is local, and y is its closed point. From the assumption we get :

$$H^1(Y', j'_*\mathscr{O}^\times_{U'}) = H^1(U', \mathscr{O}^\times_{Y'}) = \mathrm{Pic}\, U'.$$

On the other hand, recall that $\underline{N}'^{\sharp\mathrm{gp}} = j'_*\mathscr{O}^\times_{U'}/\mathscr{O}^\times_{Y'}$ (proposition 12.5.38); combining with (i), we deduce that the natural map

$$\mathrm{Pic}\, Y' \to \mathrm{Pic}\, U'$$

is surjective. Set $Y'_0 := f^{-1}(y) \subset Y'$, endow Y'_0 with its reduced subscheme structure, and let $i : Y'_0 \to Y'$ be the closed immersion. If I is an invertible ideal of P, then f is an isomorphism, in which case the assertion is obvious. We may then assume that I is not invertible, in which case claim 12.4.56(ii) says that there exists a morphism of $(Y, \underline{N})$-schemes $h : (Y', \underline{N}') \to \mathbb{P}^1_{(Y,\underline{N})}$ inducing an isomorphism of $\kappa(y)$-schemes

(12.6.36) $$(h \times_Y \mathrm{Spec}\, \kappa(y))_{\mathrm{red}} : Y'_0 \xrightarrow{\sim} \mathbb{P}^1_{\kappa(y)}.$$

Let us remark :

Claim 12.6.37. Let S be a noetherian local scheme, s the closed point of S, and $f : X \to S$ a proper morphism of schemes. Suppose that $\dim X(s) \leq 1$, and $H^1(X(s), \mathscr{O}_{X(s)}) = 0$. Then the natural map

$$\mathrm{Pic}\, X \to \mathrm{Pic}\, X(s)$$

is injective.

Proof of the claim. Say that $S = \mathrm{Spec}\, A$ for a local ring A, and denote by $\mathfrak{m}_A \subset A$ the maximal ideal. For every $k \in \mathbb{N}$, set $S_n := \mathrm{Spec}\, A/\mathfrak{m}_A^{k+1}$, and let $i_n : X_n := X \times_S S_n \to X$ be the closed immersion. Let $\mathscr{L}$ be any invertible $\mathscr{O}_X$-module, and suppose that $i_0^*\mathscr{L} \simeq \mathscr{O}_{X_0}$; we have to show that $\mathscr{L} \simeq \mathscr{O}_X$. We notice that, for every $k \in \mathbb{N}$, the natural map

$$H^0(X_{k+1}, i_{k+1}^*\mathscr{L}) \to H^0(X_k, i_k^*\mathscr{L})$$

is surjective : indeed, its cokernel is an A-submodule of $H^1(X_0, \mathfrak{m}_A^k\mathscr{L}/\mathfrak{m}_A^{k+1}\mathscr{L})$, and since $\dim X_0 \leq 1$, the natural map

$$(\mathfrak{m}_A^k/\mathfrak{m}_A^{k+1}) \otimes_{\kappa(s)} H^1(X_0, i_0^*\mathscr{L}) \xrightarrow{\sim} H^1(X_0, (\mathfrak{m}_A^k/\mathfrak{m}_A^{k+1}) \otimes_{\kappa(s)} \mathscr{L}) \to H^1(X_0, \mathfrak{m}_A^k\mathscr{L}/\mathfrak{m}_A^{k+1}\mathscr{L})$$

is surjective; on the other hand, our assumptions imply that $H^1(X_0, i_0^*\mathscr{L}) = 0$, whence the contention. Let $A^\wedge$ be the $\mathfrak{m}_A$-adic completion of A; taking into account [61, Ch.III, Th.4.1.5], we deduce that the natural map

$$H^0(X, \mathscr{L}) \otimes_A A^\wedge \to H := H^0(X_0, i^*\mathscr{L})$$

is a continuous surjection, for the $\mathfrak{m}_A$-adic topologies. Since H is a discrete space for this topology, and since the image of $H^0(X, \mathscr{L})$ is dense in the $\mathfrak{m}_A$-adic topology of $H^0(X, \mathscr{L}) \otimes_A A^\wedge$, we conclude that the restriction map $H^0(X, \mathscr{L}) \to H$ is surjective as well. Let $\overline{s} \in H$ be a global section of $i_0^*\mathscr{L}$ whose image in $i_0^*\mathscr{L}_x$ is a generator of the latter A_0-module, for every

$x \in X_0$, and pick $s \in H^0(X, \mathscr{L})$ whose image in H equals $\overline{s}$. It remains only to check that, for every $x \in X$, the A-module $\mathscr{L}_x$ is generated by the image s_x of s. However, since X is proper, every $x \in X$ specializes to a point of X_0, hence we may assume that $x \in X_0$, in which case one concludes easily, by appealing to Nakayama's lemma (details left to the reader). $\diamondsuit$

Combining claim 12.6.37 and [122, Prop.11.1(i)], we see that the induced map

$$i^* : \mathrm{Pic}\, Y' \to \mathrm{Pic}\, Y'_0$$

is injective. Let now $\mathscr{L}$ be any invertible $\mathscr{O}_U$-module; we have to show that $\mathscr{L}$ extends to an invertible $\mathscr{O}_Y$-module (which is then isomorphic to $\mathscr{O}_Y$). However, notice that f restricts to an isomorphism $g : U' \xrightarrow{\sim} U$, hence $g^*\mathscr{L}$ is an invertible $\mathscr{O}_{U'}$-module, and by the foregoing there exists an invertible $\mathscr{O}_{Y'}$-module $\mathscr{L}'$ such that $\mathscr{L}'_{|U'} \simeq g^*\mathscr{L}$. In light of the isomorphism (12.6.36), there exists an invertible $\mathscr{O}_{\mathbb{P}^1_Y}$-module $\mathscr{L}''$ such that $i^*\mathscr{L}' \simeq i^*h^*\mathscr{L}''$. Therefore

$$\mathscr{L}' \simeq h^*\mathscr{L}''.$$

Now, on the one hand, claim 12.6.37 implies that $\mathscr{L}'' = \mathscr{O}_{\mathbb{P}^1_Y}(n)$ for some $n \in \mathbb{N}$; on the other hand, (12.4.17) implies that h restricts to a morphism of schemes $h_{\mathrm{tr}} : U' \to \mathbb{G}_{m,Y}$, and $\mathscr{L}''_{|\mathbb{G}_{m,Y}} = \mathscr{O}_{\mathbb{P}^1_Y}(n)_{|\mathbb{G}_{m,Y}} = \mathscr{O}_{\mathbb{G}_{m,Y}}$, so finally $g^*\mathscr{L} = \mathscr{O}_{U'}$, hence $\mathscr{L} = \mathscr{O}_U$, whence the contention. $\square$

The following result complements proposition 12.5.38.

Theorem 12.6.38. *Let $(X, \underline{M})$ be any regular log scheme, set $U := (X, \underline{M})_{\mathrm{tr}}$ and denote by $j : U \to X$ the open immersion. Then we have :*

$$R^1 j_* \mathscr{O}_U^\times = 0.$$

Proof. We begin with the following general :

Claim 12.6.39. Let $\pi : T_1 \to T_2$ be a continuous open and surjective map of topological spaces, such that $\pi^{-1}(t)$ is an irreducible topological space (with the subspace topology) for every $t \in T_2$. Then, we have :

(i) For every sheaf S on T_2, the natural map $S \to \pi_*\pi^*S$ is an isomorphism.
(ii) For every abelian sheaf S on T_2, the natural map $S[0] \to R\pi_*\pi^*S$ is an isomorphism in $\mathsf{D}(\mathbb{Z}_{T_2}\text{-}\mathbf{Mod})$.

Proof of the claim. (i): Since π is open, π^*S is the sheaf associated to the presheaf : $U \mapsto S(\pi U)$, for every open subset U of T_1. We show, more precisely, that this presheaf is already a sheaf; since π is surjective, the claim shall follow immediately. Now, let $U \subset T_1$ be an open subset, and $(U_i \mid i \in I)$ a family of open subsets of X covering U; for every $i, j \in I$, set $U_{ij} := U_i \cap U_j$. It suffices to show that $S(\pi U)$ is the equalizer of the two maps :

$$\prod_{i \in I} S(\pi U_i) \rightrightarrows \prod_{i,j \in I} S(\pi U_{ij}).$$

Since S is a sheaf, the latter will hold, provided we know that $\pi U_i \cap \pi U_j = \pi U_{ij}$ for every $i, j \in I$. Hence, let $t \in \pi U_i \cap \pi U_j$; this means that $\pi^{-1}(t) \cap U_i \neq \varnothing$ and $\pi^{-1}(t) \cap U_j \neq \varnothing$. Since $\pi^{-1}(t)$ is irreducible, we deduce that $\pi^{-1}(t) \cap U_{ij} \neq \varnothing$, as required.

(ii): The proof of (i) also shows that, for every flabby abelian sheaf J on T_2, the abelian sheaf π^*J is flabby on T_1. Hence, if S is any abelian sheaf on T_2, we obtain a flabby resolution of π^*S of the form $\pi^*J_\bullet$, by taking a flabby resolution $S \to J_\bullet$ of S on T_2. According to remark 7.3.31(vi), there is a natural isomorphism

$$\pi_*\pi^*J \xrightarrow{\sim} R\pi_*\pi^*S$$

in $\mathsf{D}(\mathbb{Z}_{T_2}\text{-}\mathbf{Mod})$. Then the assertion follows from (i). $\diamondsuit$

After these preliminaries, let us return to the log scheme $(X, \underline{M})$, and its associated object $\underline{X} := ((X, \underline{M}), F(X, \underline{M}), \pi_X)$. The assertion to prove is local on X, hence we may assume that $F(X, \underline{M}) = (\operatorname{Spec} P)^\sharp$, for some sharp, fine and saturated monoid P. Next, by theorem 12.6.32 (and its proof) there exists an integral proper simplicial subdivision $\varphi : F' \to F(X, \underline{M})$, such that the log scheme $(X', \underline{M}')$ underlying $\varphi^*\underline{X}$ is regular, X' is regular, and the morphism $X' \to X$ restricts to an isomorphism $U' := (X', \underline{M}')_{\mathrm{tr}} \to U$. In this situation, we may find a further subdivision $\varphi' : F'' \to F'$ such that both φ' and $\varphi \circ \varphi'$ are compositions of saturated blow up of ideals generated by at most two elements of P (example 6.6.15(iii)). Say that $\varphi \circ \varphi' = \varphi_r \circ \varphi_{r-1} \cdots \circ \varphi_1$, where each φ_i is a saturated blow up of the above type. By proposition 12.6.14(iii), we deduce a sequence of morphisms of log schemes

$$(X_1, \underline{M}_1) \xrightarrow{g_1} \cdots \to (X_{r-1}, \underline{M}_{r-1}) \xrightarrow{g_{r-1}} (X_r, \underline{M}_r) \xrightarrow{g_r} (X_{r+1}, \underline{M}_{r+1}) := (X, \underline{M})$$

each of which is the blow up of a corresponding ideal, and by the same token, φ' induces a morphism $g : (X_1, \underline{M}_1) \to (X', \underline{M}')$ of $(X, \underline{M})$-schemes. For every $i = 1, \cdots, r+1$, set $U_i := (X_i, \underline{M}_i)_{\mathrm{tr}}$, and let $j_i : U_i \to X_i$ be the open immersion; especially, $U_{r+1} = U$. We shall show, by induction on i, that

$$R^1 j_{i*}\mathscr{O}^\times_{U_i} = 0 \qquad \text{for } i = 1, \dots, r+1. \tag{12.6.40}$$

Notice first that the stated vanishing translates the following assertion. For every $x \in X_i$ and every invertible $\mathscr{O}_{U_i}$-module $\mathscr{L}$, there exists an open neighborhood U_x of x in X_i such that $\mathscr{L}_{|U_x \cap U_i}$ extends to an invertible $\mathscr{O}_{U_x}$-module. However, it follows immediately from propositions 11.3.8 and 11.3.15, that every invertible $\mathscr{O}_{U'}$-module extends to an invertible $\mathscr{O}_{X'}$-module. Since g restricts to an isomorphism $U_1 = g^{-1}U' \xrightarrow{\sim} U'$, we easily deduce that every invertible $\mathscr{O}_{U_1}$-module extends to an invertible $\mathscr{O}_{X_1}$-module (namely : if $\mathscr{L}$ is such a module, extend $g_{|U_1*}\mathscr{L}$ to an invertible $\mathscr{O}_{X'}$-module, and pull the extension back to X_1, via g^*). Summing up, we see that (12.6.40) holds for $i = 1$.

Next, suppose that (12.6.40) has already been shown to hold for a given $i \leq r$; by lemma 12.6.34(ii), it follows that (12.6.40) holds for $i + 1$, so we are done. □

12.6.41. Let X be a scheme, $\underline{M}$ a fine log structure on the Zariski site of X, x a point of X, and notice that every fractional ideal of $\underline{M}_x$ is finitely generated (lemma 6.4.39(iv)). Say that $X(x) = \operatorname{Spec} A$; in view of lemma 6.4.45(ii) there is a natural map of abelian groups

$$\operatorname{Div}(\underline{M}_x) \to \operatorname{Div}(A).$$

Composing with the map $I \mapsto I^\sim$ as in (11.3.12), we get, by virtue of *loc.cit.*, a map

$$\operatorname{Div}(\underline{M}_x) \to \operatorname{Div} X(x). \tag{12.6.42}$$

Corollary 12.6.43. *With the notation of* (12.6.41)*, suppose furthermore that* $(X, \underline{M})$ *is regular at the point* x*. Then* (12.6.42) *induces an isomorphism*

$$\overline{\operatorname{Div}}(\underline{M}_x) \xrightarrow{\sim} \overline{\operatorname{Div}}(X(x)).$$

Proof. By virtue of proposition 6.4.55(ii) (and remark 11.3.11(i)), the map under investigation is already known to be injective. To show surjectivity, let K be the field of fractions of A, and $L \subset K$ any reflexive fractional ideal of A; we may then regard $\mathscr{L} := L^\sim$ as a coherent $\mathscr{O}_X$-submodule of $i_*\mathscr{O}_{X_0}$, where $i : X_0 \to X$ is the inclusion map of the subscheme $X_0 := \operatorname{Spec} K$. By proposition 11.3.15, the $\mathscr{O}_U$-module $\mathscr{L}_{|U}$ is invertible, hence it extends to an invertible $\mathscr{O}_{X(x)}$-module $\mathscr{L}'$, by virtue of theorem 12.6.38. Since $X(x)$ is local, $\mathscr{L}'$ is a free $\mathscr{O}_{X(x)}$-module, and therefore $\mathscr{L}_{|U} \simeq \mathscr{O}_U$. Thus, pick $a \in \mathscr{L}(U) \subset K$ which generates $\mathscr{L}_{|U}$; after replacing L by $a^{-1}L$, we may assume that $\mathscr{L}_{|U} = \mathscr{O}_U$ as subsheaves of $i_*\mathscr{O}_{X_0}$. Let Σ be the set of points of height one of $X(x)$ contained in $X(x) \setminus U$; for each $y \in \Sigma$, the maximal ideal $\mathfrak{m}_y$ of $\mathscr{O}_{X(x),y}$ is generated by a single element a_y, and there exists $k_y \in \mathbb{Z}$ such that $a_y^{k_y}$ generates the $\mathscr{O}_{X(x),y}$-submodule $\mathscr{L}_y$ of K. To ease notation, let $P := \underline{M}_x$, and denote $\psi : X(x) \to \operatorname{Spec} P$ the natural continuous map; also, let $\mathfrak{m}_{\psi(y)}$ be the maximal ideal of the localization $P_{\psi(y)}$ for every $y \in X(x)$, and set

$$I := \bigcap_{y\in\Sigma} \mathfrak{m}_{\psi(y)}^{k_y}.$$

In light of lemma 6.4.39(i,ii) and proposition 6.4.50, it is easily seen that $I/P^\times$ is a reflexive fractional ideal of the fine and saturated monoid $P^\sharp$, so I is a reflexive fractional ideal of P. Then $IA \subset K$ is a reflexive fractional ideal of A. Set $\mathscr{L}'' := (IA)^\sim \subset i_*\mathscr{O}_{X_0}$; then $\mathscr{L}''_{|U} = \mathscr{L}_{|U}$ and $\mathscr{L}''_y = \mathscr{L}_y$ for every $y \in \Sigma$. It follows that, for every $y \in \Sigma$, there exists an open neighborhood U_y of y in $X(x)$ such that $\mathscr{L}''_{|U_y} = \mathscr{L}_{|U_y}$. Let $U' := U \cup \bigcup_{y\in\Sigma} U_y$, and denote by $j' : U' \to X(x)$ the open immersion. Notice that $\delta'(y, \mathscr{O}_X) \geq 2$ for every $y \in X \setminus U'$ (corollary 12.5.13). In light of proposition 11.3.8(ii) (and remark 11.3.11(i)), we deduce

$$\mathscr{L} = j'_*\mathscr{L}_{|U'} = j'_*\mathscr{L}''_{|U'} = \mathscr{L}''$$

whence the contention. □

12.6.44. Let $\underline{M}$ be a log structure on the Zariski site of a local scheme X, such that $(X, \underline{M})$ is a regular log scheme. Let $x \in X$ be the closed point, say that $X = \operatorname{Spec} B$ for some local ring B, and let $\beta : P \to B$ a chart for $\underline{M}$ which is sharp at x. As usual, if M is any B-module, we denote $M^\sim$ the quasi-coherent $\mathscr{O}_X$-module arising from M.

Theorem 12.6.45. *In the situation of* (12.6.44)*, suppose as well that* $\dim P = 2$ *and* $\dim X = 2$*. Then every indecomposable reflexive* $\mathscr{O}_X$*-module is isomorphic to* $(IB)^\sim$*, for some reflexive fractional ideal* I *of* P*. (Notation of* (6.4.44)*.)*

Proof. Set $Q := \operatorname{Div}_+(P)$ and define $\varphi : P \to Q$ as in example 6.4.64. The chart β defines a morphism $\psi : (X, \underline{M}) \to \operatorname{Spec}(\mathbb{Z}, P)$, and we let $(X', \underline{M}')$ be the fibre product in the cartesian diagram

$$\begin{array}{ccc} (X', \underline{M}') & \longrightarrow & \operatorname{Spec}(\mathbb{Z}, Q) \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle \operatorname{Spec}(\mathbb{Z},\varphi)} \\ (X, \underline{M}) & \xrightarrow{\psi} & \operatorname{Spec}(\mathbb{Z}, P). \end{array}$$

Arguing as in the proof of claim 13.3.37, it is easily seen that X' is a local scheme and $(X', \underline{M}')$ is regular. Moreover, X' is a regular scheme, since Q is a free monoid (corollary 12.5.19), and f is a finite morphism of Kummer type (lemma 13.3.6).

Claim 12.6.46. The $\mathscr{O}_X$-module $f_*\mathscr{O}_{X'}$ is isomorphic to a finite direct sum $(I_1B \oplus \cdots \oplus I_kB)^\sim$, where $I_1, \dots, I_k$ are reflexive fractional ideals of P, and $\mathscr{O}_X$ is a direct summand of $f_*\mathscr{O}_{X'}$.

Proof of the claim. In view of example 6.4.64, we see that $f_*\mathscr{O}_{X'} = (Q \otimes_P B)^\sim$ is the direct sum of the $\mathscr{O}_X$-modules $(\operatorname{gr}_\gamma Q \otimes_P B)^\sim$, where γ ranges over the elements of $Q^{\mathrm{gp}}/P^{\mathrm{gp}}$, and $\operatorname{gr}_\bullet Q$ denotes the φ-grading of Q. But for each such γ, the natural map $\operatorname{gr}_\gamma Q \otimes_P B \to \operatorname{gr}_\gamma Q \cdot B$ is an isomorphism, since B is P-flat (proposition 12.5.16(ii)). This shows the first assertion, and the second is clear as well, since $\operatorname{gr}_0 Q = P$. ◊

Denote by x' the closed point of X'; from corollary 12.5.20(i) we see that $U := (X, \underline{M})_1$ is the complement of $\{x\}$ and $U' := (X', \underline{M}')_1$ is the complement of $\{x'\}$ (notation of definition 12.2.7(i)). Let also $j : U \to X$ and $j' : U' \to X'$ be the open immersions.

Claim 12.6.47. (i) The restriction $g : U' \to U$ of f is a flat morphism of schemes.

(ii) The functor $j^* : \mathscr{O}_X\text{-}\mathbf{Rflx} \to \mathscr{O}_U\text{-}\mathbf{Rflx}$ is an equivalence (see definition 11.3.1(iii)).

Proof of the claim. (i): It suffices to check that the restriction $\mathrm{Spec}(\mathbb{Z}, Q)_1 \to \mathrm{Spec}(\mathbb{Z}, P)_1$ of $\mathrm{Spec}(\mathbb{Z}, \varphi)$ is flat. However, we have the affine open covering

$$\mathrm{Spec}(\mathbb{Z}, P)_1 = \mathrm{Spec}\,\mathbb{Z}[P_{\mathfrak{p}_1}] \cup \mathrm{Spec}\,\mathbb{Z}[P_{\mathfrak{p}_2}]$$

where $\mathfrak{p}_1, \mathfrak{p}_2 \subset P$ are the two prime ideals of height one (see example 6.4.19(i)). Hence, we are reduced to showing that the morphism of log schemes underlying

$$\mathrm{Spec}(\mathbb{Z}, \varphi_{\mathfrak{p}_i}) : \mathrm{Spec}(\mathbb{Z}, Q_{\mathfrak{p}_i}) \to \mathrm{Spec}(\mathbb{Z}, P_{\mathfrak{p}_i})$$

is flat for $i = 1, 2$. However, it is clear that $Q_{\mathfrak{p}_i}$ is an integral $P_{\mathfrak{p}_i}$-module, hence it suffices to check that $Q_{\mathfrak{p}_i}$ is a flat $P_{\mathfrak{p}_i}$-module, for $i = 1, 2$ (proposition 6.1.52), or equivalently, that $Q^\sharp_{\mathfrak{p}_i}$ is a flat $P^\sharp_{\mathfrak{p}_i}$-module (corollary 6.1.49(ii)). The latter assertion follows immediately from the discussion of (6.4.61).

(ii): From proposition 11.3.8 we see that j^* is full and essentially surjective. Moreover, it follows from remark 11.3.5 that every reflexive $\mathscr{O}_X$-module is S_1, so j^* is also faithful (details left to the reader). ♢

In light of claim 12.6.47(ii), it suffices to show that every indecomposable reflexive $\mathscr{O}_U$-module $\mathscr{F}$ is isomorphic to $(IB)^\sim_{|U}$, for some reflexive fractional ideal I of P. However, for such $\mathscr{F}$, claim 12.6.47(i) and lemma 11.3.7(i) imply that $g^*\mathscr{F}$ is a reflexive $\mathscr{O}_{U'}$-module. From proposition 11.3.8 and corollary 10.4.23 we deduce that $\delta'(x', j'_*g^*\mathscr{F}) \geq 2$, so $j'_*g^*\mathscr{F}$ is a free $\mathscr{O}_{X'}$-module of finite rank ([63, Ch.0, Prop.17.3.4]), and finally, $g^*\mathscr{F}$ is a free $\mathscr{O}_{U'}$-module of finite rank. Taking into account claim 12.6.46, it follows that $g_*g^*\mathscr{F} = \mathscr{F} \otimes_{\mathscr{O}_U} g_*\mathscr{O}_{U'}$ is a direct sum of $\mathscr{O}_U$-modules of the type $(IB)^\sim_{|U}$, for various $I \in \mathrm{Div}(P)$; moreover, $\mathscr{F}$ is a direct summand of $g_*g^*\mathscr{F}$. Then, we may find a decomposition $g_*g^*\mathscr{F} = \mathscr{F}_1 \oplus \cdots \oplus \mathscr{F}_t$ such that $\mathscr{F}_i$ is an indecomposable $\mathscr{O}_U$-module for $i = 1, \dots, t$, and $\mathscr{F}_1 = \mathscr{F}$ (details left to the reader : notice that – since reflexive $\mathscr{O}_U$-modules are S_1 – the length t of such a decomposition is bounded by the dimension of the $\kappa(\eta)$-vector space $(g_*g^*\mathscr{F})_\eta$, where η is the maximal point of X). On the other hand, notice that

$$\begin{aligned}
\mathrm{End}_{\mathscr{O}_U}((IB)^\sim_{|U}) &= \mathrm{End}_B(IB) && \text{(claim 12.6.47(ii))}\\
&= (IB : IB) && \text{(by (6.4.53))}\\
&= (I : I)B && \text{(lemma 6.4.45(i))}\\
&= B && \text{(proposition 6.4.55(i))}
\end{aligned}$$

for every $I \in \mathrm{Div}(P)$. Now the contention follows from theorem 7.11.3. □

12.6.48. Let now $(X_{\text{ét}}, \underline{M})$ be a quasi-coherent log scheme on the étale site of X. Pick a covering family $(U_\lambda \mid \lambda \in \Lambda)$ of X in $X_{\text{ét}}$, and for every $\lambda \in \Lambda$, a chart $P_{\lambda,U_\lambda} \to \underline{M}_{|U_\lambda}$. The latter induce isomorphisms of log schemes $(U_\lambda, \underline{M}_{|U_\lambda}) \xrightarrow{\sim} \widetilde{u}^*(U_{\lambda,\mathrm{Zar}}, P^{\log}_{U_{\lambda,\mathrm{Zar}}})$ (see (12.2.2)); in other words, every quasi-coherent log structure on $X_{\text{ét}}$ descends, locally on $X_{\text{ét}}$, to a log structure on the Zariski site. However, $(X_{\text{ét}}, \underline{M})$ may fail to descend to a unique log structure on the whole of X_{Zar}. Our present aim is to show that, at least under a few more assumptions on $\underline{M}$, we may find a blow up $(X'_{\text{ét}}, \underline{M}') \to (X_{\text{ét}}, \underline{M})$ such that $(X'_{\text{ét}}, \underline{M}')$ descends to a log structure on X'_{Zar}. To begin with, for every $\lambda \in \Lambda$ let

$$T_\lambda := (\mathrm{Spec}\, P_\lambda)^\sharp \qquad \text{and} \qquad S_\lambda := \mathrm{Spec}\,\mathbb{Z}[P_\lambda].$$

Also, let $\underline{S}_\lambda := (\mathrm{Spec}(\mathbb{Z}, P_\lambda), T_\lambda, \psi_{P_\lambda})$ be the object of $\mathscr{K}$ attached to P_λ, as in example 12.6.5(i). From the isomorphism

$$(U_{\lambda,\mathrm{Zar}}, \widetilde{u}_*\underline{M}_{|U_\lambda}) \xrightarrow{\sim} U_\lambda \times_{S_\lambda} \mathrm{Spec}(\mathbb{Z}, P_\lambda)$$

we deduce an object

$$\underline{U}_\lambda := U_\lambda \times_{S_\lambda} \underline{S}_\lambda = ((U_{\lambda,\mathrm{Zar}}, \widetilde{u}_*\underline{M}_{|U_\lambda}), T_\lambda, \psi_\lambda).$$

Suppose now that $\underline{M}$ is a fs log structure; then we may choose for each P_λ a fine and saturated monoid (lemma 12.1.18(iii)). Next, suppose that X is quasi-compact; in this case we may assume that Λ is a finite set, hence $\mathscr{S} := \{P_\lambda \mid \lambda \in \Lambda\}$ is a finite set of monoids, and consequently we may choose a finite sequence of integers $\underline{c}(\mathscr{S})$ fulfilling the conditions of (6.6.25) relative to the category $\mathscr{S}$-**Fan**. Then, for every $\lambda \in \Lambda$ we have a well defined integral roof $\rho_\lambda : T_\lambda(\mathbb{Q}_+) \to \mathbb{Q}_+$, and we denote by $f_\lambda : T(\rho_\lambda) \to T_\lambda$ the corresponding subdivision. There follows a cartesian morphism

$$f_\lambda^* \underline{U}_\lambda \to \underline{U}_\lambda$$

whose underlying morphism of log schemes is a saturated blow up of the ideal $\mathscr{I}_{\rho_\lambda} \widetilde{u}_*\underline{M}_{|U_\lambda}$ (proposition 6.6.13 and corollary 12.6.18). Next, for $\lambda, \mu \in \Lambda$, set $U_{\lambda\mu} := U_\lambda \times_X U_\mu$ and let

$$\underline{U}_{\lambda\mu} := ((U_{\lambda\mu}, \widetilde{u}_*\underline{M}_{|U_{\lambda\mu}}), T_\lambda, \psi_{\lambda\mu})$$

where $\psi_{\lambda\mu}$ is the composition of ψ_λ and the projection $U_{\lambda\mu} \to U_\lambda$. Denote by $(U_\lambda^\sim, \underline{M}_\lambda^\sim)$ (resp. $(U_{\lambda\mu}^\sim, \underline{M}_{\lambda\mu}^\sim)$) the log scheme underlying $f_\lambda^* \underline{U}_\lambda$ (resp. $f_\lambda^* \underline{U}_{\lambda\mu}$). Also, for any $\lambda, \mu, \gamma \in \Lambda$, let $\pi_{\lambda\mu\gamma} : U_{\lambda\mu} \times_X U_\gamma \to U_{\lambda\mu}$ be the natural projection.

Lemma 12.6.49. *In the situation of* (12.6.48)*, we have :*

(i) *There exists a unique isomorphism of log schemes* $g_{\lambda\mu} : (U_{\lambda\mu}^\sim, \underline{M}_{\lambda\mu}^\sim) \xrightarrow{\sim} (U_{\mu\lambda}^\sim, \underline{M}_{\mu\lambda}^\sim)$ *fitting into a commutative diagram :*

$$\begin{array}{ccc} (U_{\lambda\mu}^\sim, \underline{M}_{\lambda\mu}^\sim) & \xrightarrow{g_{\lambda\mu}} & (U_{\mu\lambda}^\sim, \underline{M}_{\mu\lambda}^\sim) \\ \downarrow & & \downarrow \\ U_{\lambda\mu} & = & U_{\mu\lambda} \end{array}$$

whose vertical arrows are the saturated blow up morphisms.

(ii) *There exist natural isomorphisms of* $\mathscr{O}_{U_{\lambda\mu}}$*-modules*

$$\omega_{\lambda\mu} : g_{\lambda\mu}^* \mathscr{O}_{U_{\mu\lambda}}(1) \xrightarrow{\sim} \mathscr{O}_{U_{\lambda\mu}}(1)$$

such that $(\pi_{\mu\gamma\lambda}^* \omega_{\mu\lambda}) \circ (\pi_{\lambda\mu\gamma}^* \omega_{\lambda\mu}) = \pi_{\lambda\gamma\mu}^* \omega_{\lambda\gamma}$ *for every* $\lambda, \mu, \gamma \in \Lambda$.

Proof. (i): By the universal property of the saturated blow up, it suffices to show that :

$$\mathscr{I}_{\rho_\lambda} \widetilde{u}_*\underline{M}_{|U_{\lambda\mu}} = \mathscr{I}_{\rho_\mu} \widetilde{u}_*\underline{M}_{|U_{\mu\lambda}} \qquad \text{on } U_{\lambda\mu} = U_{\mu\lambda}. \tag{12.6.50}$$

The assertion is local on $U_{\lambda\mu}$, hence let $x \in U_{\lambda\mu}$ be any point; we get an isomorphism of $\widetilde{u}_*\underline{M}_x$-monoids :

$$\mathscr{O}_{T_\lambda, \psi_{\lambda\mu}(x)} \xrightarrow{\sim} \mathscr{O}_{T_\mu, \psi_{\mu\lambda}(x)}$$

whence an isomorphism of fans $U(\psi_{\lambda\mu}(x)) \xrightarrow{\sim} U(\psi_{\mu\lambda}(x))$ (notation of (6.5.16)). Therefore, the subset $U(x) := \psi_{\lambda\mu}^{-1} U(\psi_{\lambda\mu}(x)) \cap \psi_{\mu\lambda}^{-1} U(\psi_{\mu\lambda}(x))$ is an open neighborhood of x in $U_{\lambda\mu}$, and both $\psi_{\lambda\mu}$ and $\psi_{\mu\lambda}$ factor through the same morphism of monoidal spaces :

$$\psi(x) : (U(x), (\widetilde{u}_*\underline{M}^\sharp)_{|U(x)}) \to F(x) := (\operatorname{Spec} \widetilde{u}_*\underline{M}_x)^\sharp$$

and open immersions $F(x) \to T_\lambda$ and $F(x) \to T_\mu$. It then follows from (6.6.25) that the preimage of $\mathscr{I}_{\rho_\lambda}$ on $F(x)$ agrees with the preimage of $\mathscr{I}_{\rho_\mu}$, whence the contention.

(ii): By inspecting the definitions, it is easily seen that the epimorphism (10.6.24) identifies naturally $\mathscr{O}_{U_{\lambda\mu}^\sim}(1)$ to the ideal $\mathscr{I}_{\rho_{\lambda\mu}} \mathscr{O}_{U_{\lambda\mu}^\sim}$ of $\mathscr{O}_{U_{\lambda\mu}^\sim}$ generated by the image of $\mathscr{I}_{\rho_\lambda} \widetilde{u}_*\underline{M}_{|U_{\lambda\mu}}$. Hence the assertion follows again from (12.6.50). □

12.6.51. Lemma 12.6.49 implies that

$$((U^\sim_\lambda, \mathscr{O}_{U^\sim_\lambda}(1)), (g_{\lambda\mu}, \omega_{\lambda\mu}) \mid \lambda, \mu \in \Lambda)$$

is a descent datum – relative to the faithfully flat and quasi-compact morphism $\coprod_{\lambda\in\Lambda} U_\lambda \to X$ – for the fibred category of schemes endowed with an ample invertible sheaf. According to [82, Exp.VIII, Prop.7.8], such a datum is effective, hence it yields a projective morphism $\pi : X^\sim \to X$ together with an ample invertible sheaf $\mathscr{O}_{X^\sim}(1)$ on $X^\sim$, with isomorphisms $g_\lambda : X^\sim \times_X U_\lambda \stackrel{\sim}{\to} U^\sim_\lambda$ of U_λ-schemes and $\pi^*_\lambda \mathscr{O}_{X^\sim}(1) \stackrel{\sim}{\to} g^*_\lambda \mathscr{O}_{U^\sim_\lambda}(1)$ of invertible modules.

Then the datum $(\widetilde{u}^* \underline{M}^\sim_\lambda, \widetilde{u}^* \log g_{\lambda\mu} \mid \lambda, \mu \in \Lambda)$ likewise determines a unique sheaf of monoids $\underline{M}^\sim$ on $X^\sim_{\text{ét}}$, and the structure maps of the log structures $\underline{M}_\lambda$ glue to a well defined morphism of sheaves of monoids $\underline{M}^\sim \to \mathscr{O}_{X^\sim_{\text{ét}}}$, so that $(X^\sim_{\text{ét}}, \underline{M}^\sim)$ is a log scheme, and the projection π extends to a morphism of log schemes $(\pi, \log \pi) : (X^\sim_{\text{ét}}, \underline{M}^\sim) \to (X_{\text{ét}}, \underline{M})$.

Proposition 12.6.52. *In the situation of* (12.6.51)*, the counit of adjunction*

$$\widetilde{u}^* \widetilde{u}_*(X^\sim_{\text{ét}}, \underline{M}^\sim) \to (X^\sim_{\text{ét}}, \underline{M}^\sim)$$

is an isomorphism.

Proof. (This is the counit of the adjoint pair $(\widetilde{u}^*, \widetilde{u}_*)$ of (12.1.6), relating the categories of log structures on $X^\sim_{\text{Zar}}$ and $X^\sim_{\text{ét}}$.) Recall that there exist natural epimorphisms $(\mathbb{Q}^{\oplus d}_+)_{T(\rho_\lambda)} \to \mathscr{O}_{T(\rho_\lambda),\mathbb{Q}}$ (see (6.6.27)), which induce epimorphisms of $U^\sim_{\lambda,\text{Zar}}$-monoids

$$\vartheta_\lambda : (\mathbb{Q}^{\oplus d}_+)_{U^\sim_{\lambda,\text{Zar}}} \to (\underline{M}^\sim_\lambda)^\sharp_\mathbb{Q} \qquad \text{for every } \lambda \in \Lambda.$$

The compatibility with open immersions expressed by (6.6.28) implies that the system of maps $(\widetilde{u}^* \vartheta_\lambda \mid \lambda \in \Lambda)$ glues to a well defined epimorphism of $X^\sim_{\text{ét}}$-monoids :

$$\vartheta : (\mathbb{Q}^{\oplus d}_+)_{X^\sim_{\text{ét}}} \to (\underline{M}^\sim)^\sharp_\mathbb{Q}.$$

In view of lemma 4.9.27(ii), it follows that the counit of adjunction :

$$\widetilde{u}^* \widetilde{u}_* (\underline{M}^\sim)^\sharp_\mathbb{Q} \to (\underline{M}^\sim)^\sharp_\mathbb{Q}$$

is an isomorphism. By applying again lemma 4.9.27(ii) to the monomorphism $(\underline{M}^\sim)^\sharp \to (\underline{M}^\sim)^\sharp_\mathbb{Q}$, we deduce that also the counit

$$\widetilde{u}^* \widetilde{u}_* (\underline{M}^\sim)^\sharp \to (\underline{M}^\sim)^\sharp$$

is an isomorphism. Then the assertion follows from proposition 12.2.3(iii). □

Corollary 12.6.53. *Let $(X_{\text{ét}}, \underline{M})$ be a quasi-compact regular log scheme. Then there exists a smooth morphism of log schemes $(X'_{\text{ét}}, \underline{M}') \to (X_{\text{ét}}, \underline{M})$ whose underlying morphism of schemes is proper and birational, and such that X' is a regular scheme. More precisely, f restricts to an isomorphism $(X'_{\text{ét}}, \underline{M}')_{\text{tr}} \to (X_{\text{ét}}, \underline{M})_{\text{tr}}$ on the trivial loci.*

Proof. Given such $(X_{\text{ét}}, \underline{M})$, we construct first the morphism $\pi : (X^\sim_{\text{ét}}, \underline{M}^\sim) \to (X_{\text{ét}}, \underline{M})$ as in (12.6.51). Since $\pi \times_X \mathbf{1}_{U_\lambda}$ is proper for every $\lambda \in \Lambda$, if follows that π is proper ([64, Ch.IV, Prop.2.7.1]). Likewise, notice that each morphism $U^\sim_\lambda \to U_\lambda$ induces an isomorphism $(U^\sim_\lambda, \underline{M}^\sim_\lambda)_{\text{tr}} \stackrel{\sim}{\to} (U_\lambda, \widetilde{u}_* \underline{M}_{|U_\lambda})_{\text{tr}}$ (remark 12.6.17). It follows easily that π restricts an isomorphism on the trivial loci. Hence, we may replace $(X_{\text{ét}}, \underline{M})$ by $(X^\sim_{\text{ét}}, \underline{M}^\sim_{\text{ét}})$. Then, by corollary 12.3.27(ii) and proposition 12.6.52 we are further reduced to showing that there exists a proper morphism $\pi' : (X'_{\text{Zar}}, \underline{M}') \to \widetilde{u}_*(X^\sim_{\text{ét}}, \underline{M}^\sim)$ with X' regular, restricting to an isomorphism on the trivial loci. However, in light of lemma 12.5.21 (and again, proposition 12.6.52), the sought π' is provided by the more precise theorem 12.6.32. □

12.7. **Local properties of the fibres of a smooth morphism.** Resume the situation of example 12.6.5(ii), and to ease notation set $\varphi := (\mathrm{Spec}\,\lambda)^\sharp$, and $(f, \log f) := \mathrm{Spec}(R, \lambda)$. Suppose now, that $\lambda : P \to Q$ is an integral, local and injective morphism of fine monoids. Then $f : S' \to S$ is flat and finitely presented (theorem 6.2.3). Moreover :

Lemma 12.7.1. *In the situation of* (12.7)*, for every point $s \in S$, the fibre $f^{-1}(s)$ is either empty, or else it is pure-dimensional, of dimension*

$$\dim f^{-1}(s) = \dim Q - \dim P = \mathrm{rk}_{\mathbb{Z}}\,\mathrm{Coker}\,\lambda^{\mathrm{gp}}.$$

Proof. To begin with, notice that $\lambda^{-1}Q^\times = P^\times$, whence the second stated identity, in view of corollary 6.4.12(i). To prove the first stated identity, we easily reduce to the case where R is a field. Notice that the image of f is an open subset $U \subset S$ ([64, Ch.IV, Th.2.4.6]), especially U (resp. S') is pure-dimensional of dimension $\mathrm{rk}_{\mathbb{Z}} P^{\mathrm{gp}}$ (resp. $\mathrm{rk}_{\mathbb{Z}} Q^{\mathrm{gp}}$) by claim 11.6.37(ii). Hence, fix any closed point $s \in S$, and set $X := f^{-1}(s)$. From [64, Ch.IV, Cor.6.1.2] we deduce that, for every closed point $s' \in X$, the Krull dimension of $\mathscr{O}_{X,s'}$ equals $r := \mathrm{rk}_{\mathbb{Z}}\mathrm{Coker}\,\lambda^{\mathrm{gp}}$. More precisely, say that $Z \subset X$ is any irreducible component; we may find a closed point $s' \in Z$ which does not lie on any other irreducible component of X, and then the foregoing implies that the dimension of Z equals r, as stated.

Next, let $s \in U$ be any point, and denote K the residue field of $\mathscr{O}_{U,s}$, and $\pi : R[P] \to K$ the natural map. Let $y \in \mathrm{Spec}\,K[P]$ be the K-rational closed point such that $a(y) = \pi(a)$ for every $a \in P$; then the image of y in S equals s, and if we let $f_K := \mathrm{Spec}\,K[\lambda]$, we have an isomorphism of K-schemes $f_K^{-1}(y) \stackrel{\sim}{\to} f^{-1}(s)$. The foregoing shows that $f_K^{-1}(y)$ is pure-dimensional of dimension r, hence the same holds for $f^{-1}(s)$. □

Now, let us fix $s \in S$, such that $f^{-1}(s) \neq \varnothing$, and suppose that $\psi_P(s) = \mathfrak{m}_P$ is the closed point of T_P. For every $\mathfrak{q} \in \varphi^{-1}(\mathfrak{m}_P)$, the closure $\overline{\{\mathfrak{q}\}}$ of $\{\mathfrak{q}\}$ in T_Q is the image of the natural map $\mathrm{Spec}\,Q/\mathfrak{q} \to T_Q$. We deduce natural isomorphisms of schemes :

$$S_0 := \psi_P^{-1}\{\mathfrak{m}_\mathfrak{p}\} \stackrel{\sim}{\to} \mathrm{Spec}\,R\langle P/\mathfrak{m}_P\rangle \qquad S'_\mathfrak{q} := \psi_Q^{-1}\overline{\{\mathfrak{q}\}} \stackrel{\sim}{\to} \mathrm{Spec}\,R\langle Q/\mathfrak{q}\rangle$$

under which, the restriction $f_\mathfrak{q} : S'_\mathfrak{q} \to S_0$ of f is identified with $\mathrm{Spec}\,R\langle\lambda_\mathfrak{q}\rangle$, where $\lambda_\mathfrak{q} : P/\mathfrak{m}_P \to Q/\mathfrak{q}$ is induced by λ. The latter is an integral and injective morphism as well (corollary 6.1.51). Explicitly, set $F := Q\setminus\mathfrak{q}$, and let $\lambda_F : P^\times \to F$ be the restriction of λ; then $\lambda_\mathfrak{q} = (\lambda_F)_\circ$, and lemma 12.7.1 yields the identity :

$$\dim f_\mathfrak{q}^{-1}(s) = \dim Q/\mathfrak{q} = \dim Q - \mathrm{ht}\,\mathfrak{q}. \tag{12.7.2}$$

Also, notice that T_Q is a finite set under the current assumptions (lemma 6.1.20(iii)), and clearly

$$f^{-1}(s) = \bigcup_{\mathfrak{q}\in\mathrm{Max}(\varphi^{-1}\mathfrak{m}_P)} f_\mathfrak{q}^{-1}(s)$$

where, for a topological space T, we denote by $\mathrm{Max}(T)$ the set of maximal points of T. Therefore, for every irreducible component Z of $f^{-1}(s)$ there must exist $\mathfrak{q} \in \mathrm{Max}(\varphi^{-1}\mathfrak{m}_P)$ such that $Z \subset f_\mathfrak{q}^{-1}(s)$, and especially,

$$\dim f^{-1}(s) = \dim f_\mathfrak{q}^{-1}(s). \tag{12.7.3}$$

Conversely, we claim that (12.7.3) holds for every $\mathfrak{q} \in \mathrm{Max}(\varphi^{-1}\mathfrak{m}_P)$. Indeed, suppose that $\dim f_\mathfrak{q}^{-1}(s) < \dim f^{-1}(s)$ for one such $\mathfrak{q}$, and let Z be an irreducible component of $f_\mathfrak{q}^{-1}(s)$; let also Z' be an irreducible component of $f^{-1}(s)$ containing Z. By the foregoing, there exists $\mathfrak{q}' \in \mathrm{Max}(\varphi^{-1}\mathfrak{m}_P)$ with $Z' \subset f_{\mathfrak{q}'}^{-1}(s)$. Set $\mathfrak{q}'' := \mathfrak{q} \cup \mathfrak{q}'$; then clearly $\mathfrak{q}'' \in \varphi^{-1}(\mathfrak{m}_P)$, and

$$\overline{\{\mathfrak{q}''\}} = \overline{\{\mathfrak{q}\}} \cap \overline{\{\mathfrak{q}'\}}.$$

Especially, $Z \subset f_{\mathfrak{q}''}^{-1}(s)$; however, it follows from (12.7.2) that $\dim f_{\mathfrak{q}''}^{-1}(s) < \dim f_{\mathfrak{q}}^{-1}(s)$ (since $\mathrm{ht}\,\mathfrak{q} < \mathrm{ht}\,\mathfrak{q}''$); but this is absurd, since $\dim Z = \dim f_{\mathfrak{q}}^{-1}(s)$ (lemma 12.7.1). The same counting argument also shows that every maximal point of $f^{-1}(s)$ gets mapped necessarily to a maximal point of $\varphi^{-1}(\mathfrak{m}_P)$; in other words, we have shown that ψ_Q restricts to a surjective map :

$$\mathrm{Max}(f^{-1}s) \to \mathrm{Max}(\varphi^{-1}\mathfrak{m}_P).$$

More precisely, let $s' \in f^{-1}(s)$ be a point such that $\psi_Q(s') = \mathfrak{m}_Q$, the closed point of T_Q. Then clearly $s' \in f_{\mathfrak{q}}^{-1}(s)$ for every $\mathfrak{q} \in \mathrm{Max}(\varphi^{-1}\mathfrak{m}_P)$, and it follows that the foregoing surjection restricts further to a surjective map :

$$f_{s'}^{-1}(s) \to \mathrm{Max}(\varphi^{-1}\mathfrak{m}_P). \qquad (12.7.4)$$

On the other hand, since $\log \psi_Q$ is an isomorphism, we have

$$(Q_{S'}^{\log})^\sharp_{\overline{s}'} = \mathscr{O}_{T_Q,\mathfrak{q}} = Q^\sharp_{\mathfrak{q}} \qquad \text{for every } s' \in \psi_Q^{-1}(\mathfrak{q})$$

(where $\overline{s}'$ denotes any τ-point of S' localized at s'); explicitly, if $F = Q \setminus \mathfrak{q}$, then $Q^\sharp_{\mathfrak{q}} = Q/F$; likewise, we get $(P_S^{\log})^\sharp_{\overline{s}} = P/\varphi^{-1}F$. Taking into account (12.7.2), we deduce :

$$\dim f^{-1}(f(s')) - \dim f_{\mathfrak{q}}^{-1}(f(s')) = \mathrm{rk}_{\mathbb{Z}}\,\mathrm{Coker}\,(\log f)^{\mathrm{gp}}_{\overline{s}'} \qquad \text{for every } s' \in \psi_Q^{-1}(\mathfrak{q}).$$

Thus, for every $n \in \mathbb{N}$, let

$$U_n := \{s' \in S' \mid \mathrm{rk}_{\mathbb{Z}}\,\mathrm{Coker}\,(\log f)^{\mathrm{gp}}_{\overline{s}'} = n\}.$$

The foregoing implies that for every $s \in S$, the subset $U_0 \cap f^{-1}(s)$ is open and dense in $f^{-1}(s)$, and $U_n \cap f^{-1}(s)$ is either empty, or else it is a subset of pure codimension n in $f^{-1}(s)$.

12.7.5. In the situation of (12.7), suppose moreover that $\log f$ is saturated; notice that this condition holds if and only if $\log\varphi$ is saturated, if and only if the same holds for λ (lemma 6.2.12(iii)). Then, corollary 6.2.32(ii) says that $\mathrm{Coker}(\log f^\sharp)^{\mathrm{gp}}_{\overline{s}'}$ is torsion-free for every $s' \in S'$; especially, $\mathrm{Coker}(\log f^\sharp)^{\mathrm{gp}}_{\overline{s}'}$ vanishes for every $s' \in U_0$. Then corollary 6.2.32(i) implies that $\log f^\sharp_{\overline{s}'}$ is an isomorphism for every $s' \in U_0$, in which case the same holds for $\log f_{\overline{s}'}$ (lemma 12.1.4); in other words, U_0 is the strict locus of f (see definition 12.2.7(ii)).

Lemma 12.7.6. *Let K be an algebraically closed field of characteristic p, and $\chi : P \to (K, \cdot)$ a local morphism of monoids. Let also $\lambda : P \to Q$ be as in* (12.7.5). *We have :*

(i) *The K-algebra $Q \otimes_P K$ is Cohen-Macaulay.*
(ii) *If moreover, either $p = 0$, or else the order of the torsion subgroup of $\Gamma := \mathrm{Coker}\,\lambda^{\mathrm{gp}}$ is not divisible by p, then $Q \otimes_P K$ is reduced (*i.e. *its nilradical is trivial).*

Proof. (i): Since χ is a local morphism, we have $\chi^{-1}(0) = \mathfrak{m}_P$, and χ is determined by its restriction $P^\times \to K^\times$, which is a homomorphism of abelian groups. Notice that $K^\times$ is divisible, hence it is injective in the category of abelian groups; since the unit of adjunction $P \to P^{\mathrm{sat}}$ is local (lemma 6.2.9(iii)), it follows that χ extends to a local morphism $\chi' : P^{\mathrm{sat}} \to K$. Notice that $Q \otimes_P K = Q^{\mathrm{sat}} \otimes_{P^{\mathrm{sat}}} K$ (lemma 6.2.12(iv)), hence we may replace P by P^{sat} and Q by Q^{sat}, which allows to assume from start that Q is saturated. In this case, by theorem 11.6.35(i), both $K[P]$ and $K[Q]$ are Cohen-Macaulay; since $K[\lambda]$ is flat, theorem 10.4.38 and [64, Ch.IV, Cor.6.1.2] imply that $Q \otimes_P K$ is Cohen-Macaulay as well.

(ii): Let $Q = \bigoplus_{\gamma\in\Gamma} Q_\gamma$ be the λ-grading of Q (see remark 6.2.5(iii)). Under the current assumptions, λ is exact (lemma 6.2.30(ii)), consequently $Q_0 = P$ (remark 6.2.5(v)). Moreover, Q_γ is a finitely generated P-module, for every $\gamma \in \Gamma$ (corollary 6.4.5), hence either $Q_\gamma = \varnothing$, or else Q_γ is a free P-module of rank one, say generated by an element u_γ (remark 6.2.5(iv)). Furthermore, $Q_\gamma^k = Q_{k\gamma}$ for every integer $k > 0$ and every $\gamma \in \Gamma$ (proposition 6.2.31). Thus, whenever $Q_\gamma \neq \varnothing$, the element $u_\gamma \otimes 1$ is a basis of the K-vector space $Q_\gamma \otimes_P K$, and $(u_\gamma \otimes 1)^k$ is a basis of $Q_{k\gamma} \otimes_P K$, for every $k > 0$; especially, $u_\gamma \otimes 1$ is not nilpotent. In view of proposition 7.6.28(ii), the contention follows. □

12.7.7. Let $f : (X, \underline{M}) \to (Y, \underline{N})$ be a smooth and log flat morphism of fine log schemes. For every $n \in \mathbb{N}$, let $U(f, n) \subset X$ be the subset of all $x \in X$ such that $\mathrm{rk}_{\mathbb{Z}}\mathrm{Coker}\,(\log f^\sharp_{\overline{x}})^{\mathrm{gp}} = n$, for any τ-point $\overline{x}$ localized at x. By lemma 12.2.21(iii), $U(f, n)$ is a locally closed subset (resp. an open subset) of X, for every $n > 0$ (resp. for $n = 0$).

Theorem 12.7.8. *In the situation of* (12.7.7)*, we have :*

(i) *f is a flat morphism of schemes.*
(ii) *For all $y \in Y$, every connected component of $f^{-1}(y)$, is pure dimensional, and $f^{-1}(y) \cap U_n$ is either empty, or else it has pure codimension n in $f^{-1}(y)$, for every $n \in \mathbb{N}$.*
(iii) *Moreover, if f is saturated, we have :*
  (a) *The strict locus* $\mathrm{Str}(f)$ *of f is open in X, and* $\mathrm{Str}(f) \cap f^{-1}(y)$ *is a dense subset of $f^{-1}(y)$, for every $y \in Y$.*
  (b) *$f^{-1}(y)$ is geometrically reduced and Cohen-Macaulay, for every $y \in Y$.*
  (c) $\mathrm{Coker}(\log f^\sharp_{\overline{x}})^{\mathrm{gp}}$ *is a free abelian group of finite rank, for every τ-point $\overline{x}$ of X.*

Proof. Let ξ be any τ-point of X; according to corollary 12.1.35, there exist a neighborhood V of ξ, and a fine chart $P_V \to \underline{N}_{|V}$, such that P^{gp} is a free abelian group of finite rank, and the induced morphism of monoids $P \to \mathscr{O}_{Y,\xi}$ is local.

By lemma 12.1.14, [64, Ch.IV, Th.2.4.6, Prop.2.5.1] and [66, Ch.IV, Prop.17.5.7], it suffices to prove the theorem for the morphism $f \times_Y V : (X, \underline{M}) \times_Y V \to (V, \underline{N}_{|V})$. Hence we may assume from start that $\underline{N}$ admits a fine chart $\beta : P_Y \to \underline{N}$, such that P^{gp} is torsion-free and the induced map $P \to \mathscr{O}_{Y,\xi}$ is local.

By theorem 12.3.37, remark 12.1.23(i), [64, Ch.IV, Th.2.4.6] and [66, Ch.IV, Prop.17.5.7] (and again lemma 12.1.14) we may further assume that f admits a fine chart $(\beta, \omega_Q : Q_X \to \underline{M}, \lambda)$, such that λ is injective, the torsion subgroup of $\mathrm{Coker}\,\lambda^{\mathrm{gp}}$ is a finite group whose order is invertible in $\mathscr{O}_X$, and the induced morphism of schemes $X \to Y \times_{\mathrm{Spec}\,\mathbb{Z}[Q]} \mathrm{Spec}\,\mathbb{Z}[P]$ is étale. Moreover, by theorem 12.1.37(iii), we may assume – after replacing Q by a localization, and X by a neighborhood of ξ in X_τ – that the morphism $\lambda : P \to Q$ is integral (resp. saturated, if f is saturated), and the morphism $Q \to \mathscr{O}_{X,\xi}$ induced by $\omega_{P,\xi}$ is local, so λ is local as well.

In this case, the same sort of reduction as in the foregoing shows that, in order to prove (i) and (ii), it suffices to consider a morphism f as in (12.7), for which these assertions have already been established. Likewise, in order to show (iii), it suffices to consider a morphism f as in (12.7.5). For such a morphism, assertions (iii.a) and (iii.c) are already known, and (iii.b) is an immediate consequence of lemma 12.7.6. □

Theorem 12.7.8(iii) admits the following partial converse :

Proposition 12.7.9. *Let $f : (X, \underline{M}) \to (Y, \underline{N})$ be a smooth and log flat morphism of fs log schemes, such that $f^{-1}(y)$ is geometrically reduced, for every $y \in Y$. Then f is saturated.*

Proof. Fix a τ-point ξ of X; the assertion can be checked on stalks, hence we may assume that $\underline{N}$ admits a fine and saturated chart $\beta : P_Y \to \underline{N}$ (lemma 12.1.18(iii)), such that the induced morphism $\alpha_P : P \to \mathscr{O}_{Y,f(\xi)}$ is local (claim 12.1.31). Then, by corollary 12.3.42, we may find an étale morphism $g : U \to X$ and a τ-point ξ' of U with $g(\xi') = \xi$, such that the induced morphism of log schemes $f_U : (U, g^*\underline{M}) \to (Y, \underline{N})$ admits a fine and saturated chart $(\beta, \omega_Q : Q_U \to g^*\underline{M}, \lambda)$, where λ is injective, and the induced ring homomorphism

(12.7.10) $$Q \otimes_P \mathscr{O}_{Y,f(\xi)} \to \mathscr{O}_{U,\xi'}$$

is étale. By [66, Ch.IV, Prop.17.5.7], the fibres of f_U are still geometrically reduced, hence we are reduced to the case where $U = X$ and $\xi = \xi'$. Furthermore, after replacing Q by a localization, and X by a neighborhood of ξ, we may assume that the map $\alpha_Q : Q \to \mathscr{O}_{X,\xi}$ induced by $\omega_{Q,\xi}$ is local and λ is integral (theorem 12.1.37(iii) and lemma 6.2.9(i)). Lastly, let K be the residue field of $\mathscr{O}_{Y,f(\xi)}$; our assumption on $f^{-1}(y)$ means that the ring $A := \mathscr{O}_{X,\xi} \otimes_{\mathscr{O}_{Y,f(\xi)}} K$ is reduced.

We shall apply the criterion of proposition 6.2.31. Thus, let $Q = \bigoplus_{\gamma \in \Gamma} Q_\gamma$ be the λ-grading of Q and notice as well that λ is a local morphism (since the same holds for α_P and α_Q), therefore it is exact (lemma 6.2.30(ii)); consequently $Q_0 = P$ (remark 6.2.5(v)). Moreover, Q_γ is a finitely generated P-module, for every $\gamma \in \Gamma$ (corollary 6.4.5), hence either $Q_\gamma = \varnothing$, or else Q_γ is a free P-module of rank one.

We have to prove that $Q_\gamma^k = Q_{k\gamma}$ for every integer $k > 0$ and every $\gamma \in \Gamma$. In case $Q_\gamma = \varnothing$, this is the assertion that $Q_{k\gamma} = \varnothing$ as well. However, since Q is saturated, the same holds for $\Gamma' := (\lambda P)^{-1} Q / (\lambda P)^{\mathrm{gp}}$ (lemma 6.2.9(i,ii)), so it suffices to remark that $\Gamma' \subset \Gamma$ is precisely the submonoid consisting of all those $\gamma \in \Gamma$ such that $Q_\gamma \neq \varnothing$.

Therefore, fix a generator u_γ for every P-module $Q_\gamma \neq \varnothing$, and by way of contradiction, suppose that there exist $\gamma \in \Gamma'$ and $k > 0$ such that u_γ^k does not generate the P-module $Q_{k\gamma}$; this means that there exists $a \in \mathfrak{m}_P$ such that $u_\gamma^k = a \cdot u_{k\gamma}$. Now, notice that the induced morphism of monoids $\beta : P \to K$ is local, especially $\beta(a) = 0$, therefore $(u_\gamma \otimes 1)^k = 0$ in the K-algebra $Q \otimes_P K$. Denote by $I \subset Q \otimes_P K$ the annihilator of $u_\gamma \otimes 1$, and notice that, since (12.7.10) is flat, IA is the annihilator of the image u' of $u_\gamma \otimes 1$ in A.

On the other hand, it is easily seen that I is the graded ideal generated by $(u_\mu \otimes 1 \mid \mu \in \Gamma'')$ where $\Gamma'' \subset \Gamma'$ is the subset of all μ such that $u_\gamma \cdot u_\mu$ is not a generator of the P-module $Q_{\gamma+\mu}$. Clearly $u_\mu \notin Q^\times$ for every $\mu \in \Gamma''$, therefore the image of $u_\mu \otimes 1$ in A lies in the maximal ideal. Therefore $IA \neq A$, *i.e.* u' is a non-zero nilpotent element, a contradiction. □

12.7.11. Let $(X, \underline{M})$ be any log scheme, and $\overline{x}$ any geometric point, localized at a point $x \in X$. Suppose that $y \in X$ is a generization of x, and $\overline{y}$ a geometric point localized at y, and assume first that the log structure $\underline{M}$ is defined on the étale site $X_{\mathrm{\acute{e}t}}$; then, arguing as in (4.9.23), we may extend uniquely any strict specialization morphism $X(\overline{y}) \to X(\overline{x})$ to a morphism of log schemes $(X(\overline{y}), \underline{M}(\overline{y})) \to (X(\overline{x}), \underline{M}(\overline{x}))$ fitting into a commutative diagram

$$\begin{array}{ccc} (X(\overline{y}), \underline{M}(\overline{y})) & \longrightarrow & (X(y), \underline{M}(y)) \\ \downarrow & & \downarrow \\ (X(\overline{x}), \underline{M}(\overline{x})) & \longrightarrow & (X(x), \underline{M}(x)) \end{array}$$

whose right vertical arrow is induced by the natural isomorphism

$$(X(y), \underline{M}(y)) \xrightarrow{\sim} (X(x), \underline{M}(x)) \times_{X(x)} X(y).$$

A simple inspection shows that the induced morphism

$$\Gamma(X(\overline{x}), \underline{M}(\overline{x}))^\sharp \to \Gamma(X(\overline{y}), \underline{M}(\overline{y}))^\sharp$$

is naturally identified with the morphism $\underline{M}^\sharp_{\overline{x}} \to \underline{M}^\sharp_{\overline{y}}$ obtained from the specialization map $\underline{M}_{\overline{x}} \to \underline{M}_{\overline{y}}$. In case $\underline{M}$ is defined on the Zariski site X_{Zar}, we may apply the foregoing construction to the log scheme $\widetilde{u}^*(X, \underline{M})$, to obtain again the strictly local log schemes $(X(\overline{x}), \underline{M}(\overline{x}))$ and $(X(\overline{y}), \underline{M}(\overline{y}))$ a corresponding commutative diagram, as in the foregoing case.

12.7.12. Let $g : (X, \underline{M}) \to (Y, \underline{N})$ be a morphism of log schemes, $\overline{x}$ any geometric point of X, and set $\overline{y} := g(\overline{x})$. The log structures $\underline{M} \to \mathscr{O}_X$ and $\underline{N} \to \mathscr{O}_Y$, and the map $\log g_{\overline{x}}$ induce a commutative diagram of continuous maps

$$\begin{array}{ccc} X(\overline{x}) & \xrightarrow{g_{\overline{x}}} & Y(\overline{y}) \\ {\scriptstyle\psi_{\overline{x}}}\downarrow & & \downarrow{\scriptstyle\psi_{\overline{y}}} \\ \mathrm{Spec}\,\underline{M}_{\overline{x}} & \xrightarrow{\varphi_{\overline{x}}} & \mathrm{Spec}\,\underline{N}_{\overline{y}} \end{array} \tag{12.7.13}$$

(notation of 4.9.20), and notice that $\psi_{\overline{x}}$ (resp. $\psi_{\overline{y}}$) maps the closed point of $X(\overline{x})$ (resp. of $Y(\overline{y})$) to the closed point $t_{\overline{x}} \in \mathrm{Spec}\,\underline{M}_{\overline{x}}$ (resp. $t_{\overline{y}} \in \mathrm{Spec}\,\underline{N}_{\overline{y}}$).

Proposition 12.7.14. *In the situation of* (12.7.12)*, suppose that g is a smooth morphism of fine log schemes, and moreover :*

(a) *either g is a saturated morphism*
(b) *or $(X, \underline{M})$ is a fs log scheme.*

Then the following holds :

(i) *The map $\psi_{\overline{x}}$ restricts to a bijection :*
$$\mathrm{Max}(g_{\overline{x}}^{-1}(\overline{y})) \xrightarrow{\sim} \mathrm{Max}(\varphi_{\overline{x}}^{-1}(t_{\overline{y}})).$$
(ii) *For every irreducible component Z of $g_{\overline{x}}^{-1}(\overline{y})$, set*
$$(Z, \underline{M}(Z)) := (X(\overline{x}), \underline{M}(\overline{x})) \times_{X(\overline{x})} Z.$$
Then the $\kappa(\overline{y})$-log scheme $(Z, \underline{M}(Z)_{\mathrm{red}})$ is geometrically pointed regular. (Notation and terminology of example 12.1.12(iv) *and remark* 12.5.8(ii)*.)*

Proof. By corollary 12.1.35, there exist a neighborhood $U \to Y$ of $\overline{y}$, and a fine chart $\beta : P_U \to \underline{N}_{|U}$ such that $\beta_{\overline{y}}$ is a local morphism, and P^{gp} is torsion-free. Now, let
$$g_{\overline{x}} := (g_{\overline{x}}, \log g_{\overline{x}}) : (X(\overline{x}), \underline{M}(\overline{x})) \to (Y(\overline{y}), \underline{N}(\overline{y}))$$
be the morphism of log schemes induced by g, as in 12.7.11; by theorem 12.3.37, we may find a fine chart for $g_{\overline{x}}$ of the type $(i_{\overline{y}}^*\beta, \omega, \lambda : P \to Q)$, where λ is injective, and the order of the torsion subgroup of $\mathrm{Coker}\,\lambda^{\mathrm{gp}}$ is invertible in $\mathscr{O}_{X,x}$. Moreover, set $R := \mathscr{O}_{Y(\overline{y}),\overline{y}}$; then the induced map $X(\overline{x}) \to \mathrm{Spec}\,Q \otimes_P R$ is pro-étale, and – after replacing Q by some localization – we may assume that $\omega_{\overline{x}} : Q \to \mathscr{O}_{X(\overline{x}),\overline{x}}$ is local (claim 12.1.31), hence the same holds for λ. Furthermore, under assumption (a) (resp. (b)), we may also suppose that Q is saturated, by lemmata 6.2.9(ii) and 12.1.18(ii) (resp. that λ is saturated, by theorem 12.1.37(iii)).

Let us now define $f : S' \to S$ as in (12.7); notice that $\omega_{\overline{x}}$ induces a closed immersion $Y(\overline{y}) \to S$, and we have a natural identification of $Y(\overline{y})$-schemes :
$$\mathrm{Spec}\,Q \otimes_P R = Y(\overline{y}) \times_S S'.$$
Denote by $\overline{s}$ the image of $\overline{y}$ in S, and $\overline{s}'$ the image of $\overline{x}$ in $Y(\overline{y}) \times_S S' \subset S'$; there follows an isomorphism of $Y(\overline{y})$-schemes :
$$X(\overline{x}) \xrightarrow{\sim} Y(\overline{y}) \times_{S(\overline{s})} S'(\overline{s}')$$
([66, Ch.IV, Prop.18.8.10]). Moreover, our chart induces isomorphisms :
$$\mathrm{Spec}\,\underline{M}_{\overline{x}} \xrightarrow{\sim} T_Q \qquad \mathrm{Spec}\,\underline{N}_{\overline{y}} \xrightarrow{\sim} T_P$$
which identify $\varphi_{\overline{x}}$ to the map $\varphi : T_Q \to T_P$ of (12.7). In view of these identifications, we see that (12.7.13) is the restriction to the closed subset $X(\overline{x})$, of the analogous diagram :

$$\begin{array}{ccc} S'(\overline{s}') & \xrightarrow{f_{\overline{s}'}} & S(\overline{s}) \\ {\scriptstyle\psi_{\overline{s}'}}\downarrow & & \downarrow{\scriptstyle\psi_{\overline{s}}} \\ T_Q & \xrightarrow{\varphi} & T_P. \end{array}$$

We may thus assume that $X = S'$, $Y = S$ and $g = f$. Moreover, let s (resp. s') be the support of $\overline{s}$ (resp. of $\overline{s}'$); the morphism $\pi : S'(\overline{s}') \to S'(s')$ is flat, hence it restricts to a surjection

$$\mathrm{Max}(f_{\overline{s}'}^{-1}\overline{s}) \to \mathrm{Max}(f_{s'}^{-1}s).$$

In order to prove (i), it suffices then to show that the map $\mathrm{Max}(f_{\overline{s}'}^{-1}\overline{s}) \to \mathrm{Max}(\varphi^{-1}\mathfrak{m}_P)$, defined as the composition of the foregoing map and the surjection (12.7.4), is injective. This boils down to the assertion that, for every $\mathfrak{q} \in \mathrm{Max}(\varphi^{-1}\mathfrak{m}_P)$ the point s' lies on a unique irreducible component of the fibre $\pi^{-1}(f_{\mathfrak{q},s'}^{-1}s)$. However, let $\overline{\beta} : P \to \kappa(s)$ be the composition of the chart $P \to R$ and the projection $R \to \kappa(s)$; then $f_{\mathfrak{q}}^{-1}(s) = \mathrm{Spec}\, Q/\mathfrak{q} \otimes_P \kappa(s)$. Since π is pro-étale, the assertion will follow from [66, Ch.IV, Prop.17.5.7] and corollary 12.5.13, together with :

Claim 12.7.15. The log scheme $W_{\mathfrak{q}} := \mathrm{Spec}\langle\mathbb{Z}, Q/\mathfrak{q}\rangle \times_{\mathrm{Spec}\,\mathbb{Z}[P]} \mathrm{Spec}\,\kappa(s)$ is geometrically pointed regular.

Proof of the claim. To ease notation, set $F := Q \setminus \mathfrak{q}$; by assumption $\lambda^{-1}F = P^\times$, so that

$$W_{\mathfrak{q}} = (W'_{\mathfrak{q}})_\circ \qquad \text{where} \qquad W'_{\mathfrak{q}} := \mathrm{Spec}(\mathbb{Z}, F) \times_{\mathrm{Spec}(\mathbb{Z},P^\times)} \mathrm{Spec}\,\kappa(s)$$

(notation of (12.2.13); notice that the log structures of $\mathrm{Spec}(\mathbb{Z}, P^\times)$ and $\mathrm{Spec}\,\kappa(s)$ are trivial). Moreover, let $\lambda_F : P^\times \to F$ be the restriction of λ; then λ_F^{gp} is injective, and

$$\mathrm{Coker}\,\lambda_F^{\mathrm{gp}} \subset \mathrm{Coker}\,\lambda^{\mathrm{gp}}$$

(corollary 6.2.33(i)), hence the order of the torsion subgroup of $\mathrm{Coker}\lambda_F^{\mathrm{gp}}$ is invertible in $\mathscr{O}_{S,s}$. Moreover, if λ is saturated, then the same holds for λ_F (corollary 6.2.33(ii)), and it is easily seen that if Q is saturated, the same holds for F. Consequently, the morphism $\mathrm{Spec}(\mathbb{Z}, \lambda_F)$ is smooth (proposition 12.3.34). The same then holds for the morphism $W'_{\mathfrak{q}} \to \mathrm{Spec}\,\kappa(s)$ obtained after base change of $\mathrm{Spec}(\mathbb{Z}, \lambda_F)$ along the morphism $h : \mathrm{Spec}(\mathbb{Z}, P^\times) \to \mathrm{Spec}\,\kappa(s)$ induced by $\overline{\beta}$ (proposition 12.3.24(ii)).

Now we notice that under either of the assumptions (a) or (b), $W'_{\mathfrak{q}}$ is a fs log scheme. Indeed, under assumption (b), this follows by remarking that $\mathrm{Spec}\,\kappa(s)$ is trivially a fs log scheme, and $\mathrm{Spec}(\mathbb{Z}, \lambda_F)$ is saturated. Under assumption (a), $\mathrm{Spec}(\mathbb{Z}, F)$ is a fs log scheme, and it suffices to observe that h is a strict morphism. Lastly, since the morphism $W'_{\mathfrak{q}} \to \mathrm{Spec}\,\kappa(s)$ is obviously saturated, we apply corollary 12.5.29 to conclude. ◊

(ii): In light of the foregoing, we see that, for any irreducible component Z of $g_{\overline{x}}^{-1}(\overline{y})$, there exists a unique $\mathfrak{q}(Z) \in \mathrm{Max}(\varphi^{-1}\mathfrak{m}_P)$ such that Z is isomorphic to the strict henselization of $f_{\mathfrak{q}(Z)}^{-1}(s)$, at the geometric point $\overline{s}'$. Notice now that the log structure of $W_{\mathfrak{q}(Z)}$ is reduced, by virtue of claim 12.7.15 and proposition 12.5.38; then, a simple inspection of the definitions shows that $(Z, \underline{M}(Z)_{\mathrm{red}})$ is isomorphic to the strict henselization $W_{\mathfrak{q}(Z)}(\overline{s}')$. Invoking again claim 12.7.15, we deduce the contention. □

12.7.16. In the situation of (12.7.12), suppose that Y is a normal scheme, and $(Y, \underline{N})_{\mathrm{tr}}$ is a dense subset of Y. Let $\overline{\eta}$ be a geometric point of $Y(\overline{y})$, localized at the generic point η, and

$$(U_{\mathfrak{q}} \mid \mathfrak{q} \in \mathrm{Spec}\,\underline{M}_{\overline{x}})$$

the logarithmic stratification of $(X(\overline{x}), \underline{M}(\overline{x}))$ (see (12.5.35)). Notice that $\psi_{\overline{x}}(g^{-1}(\eta))$ lies in the preimage $\Sigma \subset \mathrm{Spec}\,\underline{M}_{\overline{x}}$ of the maximal point $\varnothing$ of $\mathrm{Spec}\,\underline{N}_{\overline{y}}$; therefore, $g_{\overline{x}}^{-1}(\eta)$ is the union of the subsets $U_{\mathfrak{q}} \times_Y |\eta|$, for all $\mathfrak{q} \in \Sigma$.

Proposition 12.7.17. *In the situation of* (12.7.16)*, suppose that g is a smooth morphism of fine log schemes. Then the following holds :*

(i) *X is a normal scheme.*
(ii) *The scheme $g_{\overline{x}}^{-1}(\overline{\eta})$ is normal and irreducible.*

(iii) *For every* $\mathfrak{q} \in \Sigma$, *the* $\kappa(\eta)$*-scheme* $U_\mathfrak{q} \times_Y |\eta|$ *is non-empty, geometrically normal and geometrically irreducible, of pure dimension* $\dim g_{\overline{x}}^{-1}(\eta) - \mathrm{ht}\,\mathfrak{q}$.

(iv) *Especially, set* $W := (X(\overline{x})\backslash U_\varnothing) \times_Y |\overline{\eta}|$*; then* $\psi_{\overline{x}}$ *induces a bijection :*

$$\mathrm{Max}(W) \xrightarrow{\sim} \{\mathfrak{q} \in \Sigma \mid \mathrm{ht}\mathfrak{q} = 1\}.$$

(v) *For every* $w \in \mathrm{Max}(W)$, *the stalk* $\mathscr{O}_{g_{\overline{x}}^{-1}(\overline{\eta}),w}$ *is a discrete valuation ring.*

Proof. Set $R := \mathscr{O}_{Y(\overline{y}),\overline{y}}$; arguing as in the proof of proposition 12.7.14, we may find :

- a local, flat and saturated morphism $\lambda : P \to Q$ of fine monoids, such that the order of the torsion subgroup of $\mathrm{Coker}\,\lambda^{\mathrm{gp}}$ is invertible in R;
- local morphisms of monoids $P \to R$, $Q \to \mathscr{O}_{X(\overline{x}),\overline{x}}$ which are charts for the log structures deduced from $\underline{N}$ and respectively $\underline{M}$, and such that the induced morphism of $Y(\overline{y})$-schemes $X(\overline{x}) \to \mathrm{Spec}\, Q \otimes_P R$ is pro-étale.

By [66, Ch.IV, Prop.17.5.7], we may then assume that $(X, \underline{M})$ (resp. $(Y, \underline{N})$) is the scheme $\mathrm{Spec}\, Q \otimes_P R$ (resp. $\mathrm{Spec}\, R$), endowed with the log structure deduced from the natural map $Q \to Q \otimes_P R$ (resp. the chart $P \to R$), and g is the natural projection. Suppose first that R is excellent, and let R' be the normalization of R in a finite extension K' of $\mathrm{Frac}(R)$; then R' is also strictly local and noetherian, and if y' denotes the closed point of $Y' := \mathrm{Spec}\, R'$, then the residue field extension $\kappa(y) \subset \kappa(y')$ is purely inseparable. Set

$$(X', \underline{M}') := (X, \underline{M}) \times_Y Y' \qquad (Y', \underline{N}') := (Y, \underline{N}) \times_Y Y'$$

and let $g' : (X', \underline{M}') \to (Y', \underline{N}')$ be the induced morphism of log schemes; it follows especially that the restriction $g'^{-1}(y') \to g^{-1}(y)$ is a homeomorphism on the underlying topological spaces. Hence, there is a geometric point $\overline{x}'$ of X', unique up to isomorphism, whose image in X agrees with $\overline{x}$, and we easily deduce an isomorphism of Y-schemes ([66, Ch.IV, Prop.18.8.10])

$$X'(\overline{x}') \xrightarrow{\sim} X(\overline{x}) \times_Y Y'. \tag{12.7.18}$$

Let η' be the generic point of Y'; by assumption, $\underline{N}'$ is trivial in a Zariski neighborhood of η', hence $(X', \underline{N}') \times_{Y'} |\eta'|$ is a fs log schemes (since g is saturated), and then the same log scheme is also regular (theorem 12.5.28), therefore $g'^{-1}(\eta')$ is a normal scheme (corollary 12.5.13). On the other hand, R' is a Krull domain ([133, Th.33.10]), and g' is flat with reduced fibres (theorem 12.7.8(iii.b)), so X' is a noetherian normal scheme (lemma 9.8.2), consequently the same holds for $X'(\overline{x}')$ ([66, Ch.IV, Prop.18.8.12(i)]); especially, the latter is irreducible, so the same holds for $X'(\overline{x}') \times_{Y'} |\eta'|$. In view of (12.7.18), it follows that $X(\overline{x}) \times_Y |\eta'|$ is also normal and irreducible. Since K' is arbitrary, this completes the proof of (i) and (ii), in this case.

Next, if R is any normal ring, we may write R as the union of a filtered family $(R_i \mid i \in I)$ of excellent normal local subrings ([64, Ch.IV, (7.8.3)(ii,vi)]). For each $i \in I$, denote by $\overline{y}_i$ the image of $\overline{y}$ in $\mathrm{Spec}\, R_i$; then the strict henselization R_i^{sh} of R_i at $\overline{y}_i$ is also a subring of R, so we may replace R_i by R_i^{sh}, which allows to assume that each R_i is strictly local, normal and noetherian ([66, Ch.IV, Prop.18.8.8(iv), Prop.18.8.12(i)]). Up to replacing I by a cofinal subset, we may assume that the image of P lies in R_i, for every $i \in I$. For each $i \in I$, set $X_i := \mathrm{Spec}\, Q \otimes_P R_i$, $Y_i := \mathrm{Spec}\, R_i$, and endow X_i (resp. Y_i) with the log structure $\underline{M}_i$ (resp. $\underline{N}_i$) deduced from the natural map $Q \to Q \otimes_P R_i$ (resp. $P \to R_i$). There follows a system of morphisms of log schemes $g_i : (X_i, \underline{M}_i) \to (Y_i, \underline{N}_i)$ for every $i \in I$, whose limit is the morphism g. Moreover, since $(Y, \underline{N})_{\mathrm{tr}}$ is dense in Y, the image of P lies in $R\backslash\{0\}$, hence it lies in $R_i \backslash \{0\}$ for every $i \in I$, and the latter means that $(Y_i, \underline{N}_i)_{\mathrm{tr}}$ is dense in Y_i, for every $i \in I$. Let $\overline{\eta}_i$ (resp. $\overline{x}_i$) be the image of $\overline{\eta}$ (resp. of $\overline{x}$) in Y_i (resp. in X_i); moreover, for each $i \in I$, let $x_i \in X_i$ be the support of $\overline{x}_i$. By the previous case, we know that $g_{i,\overline{x}_i}^{-1}(\overline{\eta}_i)$ is normal and irreducible. However, X (resp. $g_{\overline{x}}^{-1}(\overline{\eta})$) is the limit of the system of schemes $(X_i \mid i \in I)$ (resp.

$(g^{-1}_{i,\overline{x}_i}(\overline{\eta}_i) \mid i \in I))$, so (i) and (ii) follow. (Notice that the colimit of a filtered system of integral (resp. normal) domains, is an integral (resp. normal) domain : exercise for the reader.)

(iii): For every $\mathfrak{q} \in \operatorname{Spec} Q = \operatorname{Spec} \underline{M}_{\overline{x}}$, set $X_\mathfrak{q} := \operatorname{Spec} Q/\mathfrak{q} \otimes_P R$; since the chart $Q \to \mathscr{O}_{X(\overline{x}),\overline{x}}$ is local, it is clear that $x \in X_\mathfrak{q}$ for every such $\mathfrak{q}$, and :

$$X_\mathfrak{q}(\overline{x}) = \bigcup_{\mathfrak{p} \in \operatorname{Spec} Q/\mathfrak{q}} U_\mathfrak{p}.$$

If $\varphi(\mathfrak{q}) = \varnothing$, the induced map $P \to Q/\mathfrak{q}$ is still flat (corollary 6.1.51), hence the projection $X_\mathfrak{q}(\overline{x}) \to Y$ is a flat morphism of schemes, especially $g^{-1}_{\overline{x}}(\eta) \cap X_\mathfrak{q}(\overline{x}) \neq \varnothing$. Furthermore, the subset $X_\mathfrak{q}(\overline{x})$ is pure-dimensional, of codimension $\operatorname{ht} \mathfrak{q}$ in $g^{-1}_{\overline{x}}(\eta)$, by (12.7.2) and [64, Ch.IV, Cor.6.1.4]. It follows that $U_\mathfrak{q}$ is a dense open subset of $X_\mathfrak{q}(\overline{x})$. To conclude, it remains only to show that each $X_\mathfrak{q}(\overline{x})$ is geometrically normal and geometrically irreducible; however, let $j_\mathfrak{q} : X_\mathfrak{q} \to X$ be the closed immersion; the induced morphism of log schemes $g_\mathfrak{q} : (X_\mathfrak{q}, j^*_\mathfrak{q}\underline{M}) \to (Y, \underline{N})$ is also smooth, hence the assertion follows from (ii).

(iv) is a straightforward consequence of (iii).

(v): Notice that $A := \mathscr{O}_{g^{-1}_{\overline{x}}(\overline{\eta}),w}$ is ind-étale over the noetherian ring $Q \otimes_P \kappa(\overline{\eta})$, hence its strict henselization is noetherian, and then A itself is noetherian ([66, Ch.IV, Prop.18.8.8(iv)]). Since X is normal, and w is a point of height one in $g^{-1}_{\overline{x}}(\overline{\eta})$, we conclude that A is a discrete valuation ring. □

13. Étale coverings of schemes and log schemes

13.1. **Acyclic morphisms of schemes.** For any scheme X, we shall denote by :

$$\mathsf{Cov}(X)$$

the category whose objects are the finite étale morphisms $E \to X$; the morphisms $(E \to X) \to (E' \to X)$ are the X-morphisms of schemes $E \to E'$. By faithfully flat descent, $\mathsf{Cov}(X)$ is naturally equivalent to the subcategory of $X^\sim_{\text{ét}}$ consisting of all locally constant constructible sheaves. If $f : X \to Y$ is any morphism of schemes, and $\varphi : E \to Y$ is an object $\mathsf{Cov}(Y)$, then $f^*\varphi := \varphi \times_Y X : E \times_Y X \to X$ is an object of $\mathsf{Cov}(X)$; more precisely, we have a fibration :

$$\mathsf{Cov} \to \mathsf{Sch} \qquad (13.1.1)$$

over the category of schemes, whose fibre, over any scheme X, is the category $\mathsf{Cov}(X)$.

Lemma 13.1.2. *Let f be a morphism of schemes, and suppose that either one of the following conditions holds :*

(a) *f is integral and surjective.*
(b) *f is faithfully flat.*
(c) *f is proper and surjective.*

Then f is of universal 2-descent for the fibred category (13.1.1).

Proof. This is [9, Exp.VIII, Th.9.4]. □

Lemma 13.1.3. *In the situation of definition* 10.5.42*, let $U \subset X$ be any open subset with $Y \subset U$. If $\operatorname{Lef}(X, Y)$ holds, the closed immersion $j : Y \to U$ induces a fully faithful functor*

$$j^* : \mathsf{Cov}(U) \to \mathsf{Cov}(Y).$$

Proof. Let $\mathsf{Cov}(\mathfrak{X})$ be the full subcategory of $\mathscr{O}_\mathfrak{X}$-$\mathsf{Alg}_{\text{lfft}}$ consisting of all finite étale $\mathscr{O}_\mathfrak{X}$-algebras (notation of lemma 10.5.43(ii)); the category $\mathsf{Cov}(U)$ is a full subcategory of $\mathscr{O}_U$-$\mathsf{Alg}_{\text{lfft}}$, so lemma 10.5.43(ii) already implies that the functor $\mathsf{Cov}(U) \to \mathsf{Cov}(\mathfrak{X})$ is fully faithful, hence we are reduced to showing that the functor :

$$\mathsf{Cov}(\mathfrak{X}) \to \mathsf{Cov}(Y) \qquad \mathscr{A} \mapsto \operatorname{Spec} \mathscr{A} \otimes_{\mathscr{O}_\mathfrak{X}} \mathscr{O}_Y$$

is fully faithful. To this aim, let $\mathscr{I} \subset \mathscr{O}_X$ be the ideal defining the closed immersion $Y \subset X$; consider the direct system of schemes

$$(Y_n := \mathrm{Spec}\,\mathscr{O}_X/\mathscr{I}^{n+1} \mid n \in \mathbb{N})$$

and let $\mathsf{Cov}(Y_\bullet)$ be the category consisting of all direct systems $(E_n \mid n \in \mathbb{N})$ of schemes, such that E_n is finite étale over Y_n, and such that the transition maps $E_n \to E_{n+1}$ induce isomorphisms $E_n \stackrel{\sim}{\to} E_{n+1} \times_{Y_{n+1}} Y_n$ for every $n \in \mathbb{N}$. The morphisms in $\mathsf{Cov}(Y_\bullet)$ are the morphisms of direct systems of schemes. We have a natural fully faithful functor :

$$\mathsf{Cov}(\mathfrak{X}) \to \mathsf{Cov}(Y_\bullet) \qquad \mathscr{A} \mapsto (\mathrm{Spec}\,\mathscr{A}/\mathscr{I}^{n+1}\mathscr{A} \mid n \in \mathbb{N})$$

([59, Ch.I, Cor.10.6.10(ii)]). Finally, the functor $\mathsf{Cov}(Y_\bullet) \to \mathsf{Cov}(Y)$ given by the rule : $(E_n \mid n \in \mathbb{N}) \to E_0$ is an equivalence, by [66, Ch.IV, Th.18.1.2]. The claim follows. □

13.1.4. Consider a cofiltered system $X_\bullet := (X_\lambda \mid \lambda \in \Lambda)$ of quasi-compact and quasi-separated schemes, with affine transition morphisms; let X be the limit of $X_\bullet$, and for every $\lambda \in \Lambda$, let $p_\lambda : X \to X_\lambda$ be the natural morphism. The functors $p^*_\lambda : \mathsf{Cov}(X_\lambda) \to \mathsf{Cov}(X)$ define a pseudo-cocone in the 2-category $\mathbf{Cat}$, whence a functor :

$$\text{(13.1.5)} \qquad 2\text{-}\underset{\lambda\in\Lambda}{\mathrm{colim}}\,\mathsf{Cov}(X_\lambda) \to \mathsf{Cov}(X).$$

Lemma 13.1.6. *In the situation of* (13.1.4)*, the functor* (13.1.5) *is an equivalence.*

Proof. It is a rephrasing of [65, Ch.IV, Th.8.8.2, Th.8.10.5] and [66, Ch.IV, Prop.17.7.8(ii)]. □

Lemma 13.1.7. *Let X be a scheme, $j : U \to X$ an open immersion with dense image, and $f : X' \to X$ an integral surjective and radicial morphism. The following holds :*

(i) *The morphism f induces an equivalence of sites*

$$f^* : X'_{\text{ét}} \to X_{\text{ét}}$$

and the functor $f^* : \mathsf{Cov}(X) \to \mathsf{Cov}(X')$ is an equivalence.

(ii) *The functor $j^* : \mathsf{Cov}(X) \to \mathsf{Cov}(U)$ is faithful.*

(iii) *Suppose that X is reduced and normal, and moreover :*
   (a) *either X has finitely many maximal points*
   (b) *or else, j is a quasi-compact open immersion.*

Then j^* is fully faithful, and its essential image consists of all the objects φ of $\mathsf{Cov}(U)$ such that $\varphi \times_X X(\overline{x})$ lies in the essential image of the pull-back functor :

$$\mathsf{Cov}(X(\overline{x})) \to \mathsf{Cov}(X(\overline{x}) \times_X U)$$

for every geometric point $\overline{x}$ of X. (Notation of definition 4.9.17(ii).*)*

(iv) *Furthermore, if X is locally noetherian and regular, and $X\setminus U$ has codimension ≥ 2 in X, then j^* is an equivalence.*

Proof. (i) follows from [9, Exp.VIII, Th.1.1].

(ii): Indeed, let $\varphi : E \to X$ and $\varphi' : E' \to X$ be any two finite étale morphisms, and $f, g : E \to E'$ two morphisms of X-schemes such that $f \times_X U = g \times_X U$; let $\Delta_{E'} \to E' \times_X E'$ be the open and closed diagonal immersion, $(f, g) : E \to E' \times_X E'$ the morphism deduced from f and g, and set $D := (f, g)^{-1}\Delta_{E'}$. Then D is the largest open subset of E' such that $f_{|D} = g_{|D}$; on the other hand, by assumption $\varphi^{-1}U \subset D$, and since φ is an open map, $\varphi^{-1}U$ is dense in E. Lastly, D is also a closed subset of E, so $D = E$, whence the claim.

(iii): Choose a covering $X = \bigcup_{i\in I} V_i$ consisting of affine open subsets, let

$$X' := \coprod_{i\in I} V_i \qquad X'' := X' \times_X X'$$

and denote by $g : X' \to X$ the induced morphism; set also $j'_i := j \times_X V_i$ for every $i \in I$. By lemma 13.1.2, g is of universal 2-descent for the fibred category Cov. On the other hand, the induced open immersion $j'' : U \times_X X'' \to X''$ has dense image, hence the corresponding functor j''^* is faithful, by (ii). By corollary 3.5.30(ii), the full faithfulness of j^* follows from the full faithfulness of the pull-back functor j'^* corresponding to the open immersion $j' := j \times_X X'$. The latter holds if and only if the same holds for all the pull-back functors $j_i'^*$. Hence, we may replace X by V_i, and assume from start that X is affine, say $X = \operatorname{Spec} A$. Let $E \to X$ and $E' \to X$ be two objects of $\mathsf{Cov}(X)$, and $h : E \times_X U \to E' \times_X U$ a morphism, and write $E = \operatorname{Spec} B$, $E' = \operatorname{Spec} B'$ for finite étale A-algebras B and B'; we have to check that h extends to a morphism $E \to E'$.

• To this aim, consider first the case where X has finitely many maximal points $\eta_1, \dots, \eta_s$. Under the current assumptions, A is the product of s domains, and its total ring of fractions $\operatorname{Frac} A$ is the product of fields $\kappa(\eta_1) \times \cdots \times \kappa(\eta_s)$. The restrictions $h_{\eta_i} := h \times_U X(\eta_i) : E(\eta_i) \to E'(\eta_i)$ induce a map of $\operatorname{Frac} A$-algebras

$$h^\natural_\eta := \prod_{i=1}^s h^\natural_{\eta_i} : B' \otimes_A \operatorname{Frac} A \to B \otimes_A \operatorname{Frac} A.$$

On the other hand, by proposition 9.8.3, B (resp. B') is the normalization of A in $B \otimes_A \operatorname{Frac} A$ (resp. in $B' \otimes_A \operatorname{Frac} A$). It follows that $h^\natural_\eta$ restricts to a map $B' \to B$, and the corresponding morphism $E \to E'$ is necessarily an extension of h. This shows that j^* is fully faithful in this case.

• Next, suppose that assumption (b) holds, and set $\mathscr{E} := B^\sim$, $\mathscr{E}' := B'^\sim$; then $\mathscr{E}$ and $\mathscr{E}'$ are étale $\mathscr{O}_X$-algebras and locally free $\mathscr{O}_X$-modules of finite type, and h corresponds to a morphism $h^\sharp : \mathscr{E} \to \mathscr{E}'$. Under the current assumptions, $j_*\mathscr{O}_U$ is a quasi-coherent $\mathscr{O}_X$-algebra, and $\mathscr{O}_{X,x}$ is integrally closed in $(j_*\mathscr{O}_U)_x$, for every $x \in X$ ([75, Prop.8.2.31(i)]). Likewise, $j_*j^*\mathscr{E} = \mathscr{E} \otimes_{\mathscr{O}_X} j_*\mathscr{O}_U$, so $\mathscr{E}'_x$ is the integral closure of $\mathscr{O}_{X,x}$ in $(j_*j^*\mathscr{E})_x$, for every $x \in X$. Lastly, $\mathscr{E}_x$ is integral over $\mathscr{O}_{X,x}$, so the map $(j_*j^*h^\sharp)_x : (j_*j^*\mathscr{E})_x \to (j_*j^*\mathscr{E}')_x$ restricts to a map $\mathscr{E}_x \to \mathscr{E}'_x$, and the assertion follows.

To proceed, we make the following general remark.

Claim 13.1.8. Let Z be a scheme, $V_0 \subset Z$ an open subset, and $\varphi : E \to V_0$ an object of $\mathsf{Cov}(V_0)$. Suppose that, for every open subset $V \subset Z$ containing V_0, the pull-back functor $j_V^* : \mathsf{Cov}(V) \to \mathsf{Cov}(V_0)$ is fully faithful. Let $\mathscr{F}$ be the family consisting of all the data (V, ψ, α) where $V \subset X$ is any open subset with $V_0 \subset V$, $\psi : E_V \to V$ is a finite étale morphism, and $\alpha : \psi^{-1}V_0 \xrightarrow{\sim} E$ is an isomorphism of V_0-schemes. $\mathscr{F}$ is preordered (see example 1.1.6(iii)) by the relation such that $(V, \psi, \alpha) \geq (V', \psi', \alpha')$ if and only if $V' \subset V$ and there is an isomorphism $\beta : \psi^{-1}V' \xrightarrow{\sim} E_{V'}$ of V'-schemes, such that $\alpha' \circ j_{V'}^*(\beta) = \alpha$. Then the partially ordered quotient $\mathscr{F}'$ of $\mathscr{F}$ admits a supremum (see example 1.1.16). (Notice that $\mathscr{F}$ is a proper class, but it can be replaced by a subset that meets every isomorphism class.)

Proof of the claim. Using Zorn's lemma, it is easily seen that every element of $\mathscr{F}'$ can be dominated by a maximal element, and it remains to show that any two maximal elements (V, ψ, α) and (V', α', ψ) of $\mathscr{F}$ are isomorphic; to see this, set $V'' := V \cap V'$: by assumption, the isomorphism $\alpha'^{-1} \circ \alpha : \psi^{-1}V_0 \xrightarrow{\sim} \psi'^{-1}V_0$ extends to an isomorphism of V''-schemes $\psi^{-1}V'' \xrightarrow{\sim} \psi'^{-1}V''$, using which one can glue E_V and $E_{V'}$ to obtain a datum $(V \cup V', \psi'', \alpha'')$ which is larger than both our maximal elements, hence it is isomorphic to both. ◇

Claim 13.1.9. In the situation of claim 13.1.8, suppose that Z is reduced and normal, V_0 is dense in Z, and either one of the assumptions (iii.a) or (iii.b) hold for Z and the open immersion $V_0 \to Z$. Let $(V_{\max}, \psi, \alpha)$ be a supremum for $\mathscr{F}$, and $\overline{z}$ a geometric point of Z, such that $\varphi \times_Z Z(\overline{z})$ extends to a finite étale covering of $Z(\overline{z})$; then the support of $\overline{z}$ lies in $V_{\max}$.

Proof of the claim. By lemma 13.1.6, there exist an étale neighborhood $g : Y \to Z$ of $\overline{z}$, with Y affine, a finite étale morphism $\varphi_Y : E_Y \to Y$, and an isomorphism $h : \varphi \times_{V_0} Y \simeq \varphi_Y \times_Z V_0$. We have a natural essentially commutative diagram :

$$\begin{array}{ccccc} \mathsf{Cov}(gY) & \xrightarrow{\alpha} & \mathsf{Desc}(\mathsf{Cov}, g) & \longrightarrow & \mathsf{Cov}(Y) \\ \downarrow & & \downarrow & & \downarrow \\ \mathsf{Cov}(V_0 \cap gY) & \xrightarrow{\beta} & \mathsf{Desc}(\mathsf{Cov}, g \times_Z V_0) & \longrightarrow & \mathsf{Cov}(Y \times_Z V_0) \end{array}$$

where α and β are equivalences, by lemma 13.1.2. Moreover, let $Y' := Y \times_Z Y$ and $Y'' := Y' \times_Z Y$; it is easily seen that if assumption (iii.a) (resp. (iii.b)) holds for Z and V_0, the same holds for Y' and $Y' \times_Z V_0$, and also for Y'' and $Y'' \times_Z V_0$. By the foregoing, it follows that the functors

$$\mathsf{Cov}(Y') \to \mathsf{Cov}(Y' \times_Z V_0) \qquad \text{and} \qquad \mathsf{Cov}(Y'') \to \mathsf{Cov}(Y'' \times_Z V_0)$$

are fully faithful, hence the right square subdiagram is 2-cartesian (corollary 3.5.30(iii)). Thus, the datum $(\varphi \times_Z gY, \varphi_Y, h)$ determines an object φ' of $\mathsf{Cov}(gY)$, together with an isomorphism $\varphi' \times_Z V_0 \simeq \varphi \times_Z gY$, which we may use to glue φ and φ' to a single object φ'' of $\mathsf{Cov}(V_0 \cup gY)$. The claim follows. ◊

The foregoing shows that the assumptions of claim 13.1.8 are fulfilled, with $Z := X$, $V_0 := U$ and any object φ of $\mathsf{Cov}(U)$, hence there exists a largest open subset $U_{\max} \subset X$ over which φ extends. However, claim 13.1.9 shows that $U_{\max} = X$, so the proof of (iii) is complete.

(iv): In view of (iii) and [66, Ch.IV, Cor.18.8.13], we are reduced to the case where X is a regular local scheme, and it suffices to show that j^* is essentially surjective. We argue by induction on the dimension n of $X \setminus U$. If $n = 0$, then $X \setminus U$ is the closed point, in which case it suffices to invoke the Zariski-Nagata purity theorem ([85, Exp.X, Th.3.4(i)]). Suppose $n > 0$ and that the assertion is already known for smaller dimensions. Let φ be a given finite étale covering of U, and x a maximal point of $X \setminus U$; then $X(x) \setminus U = \{x\}$, so $\varphi_{|U \cap X(x)}$ extends to a finite étale morphism φ_x over $X(x)$. In turns, φ_x extends to an affine open neighborhood $V \subset X$ of X, and up to shrinking V, this extension φ' agrees with φ on $U \cap V$, by lemma 13.1.6. Hence we can glue φ and φ', and replace U by $U \cup V$. Repeating the procedure for every maximal point of $X \setminus U$, we reduce the dimension of $X \setminus U$; then we conclude by the inductive assumption. □

Definition 13.1.10. Let $f : X \to S$ be a morphism of schemes, $\overline{x}$ a geometric point of X localized at $x \in X$; set $s := f(x)$, $\overline{s} := f(\overline{x})$, and denote by $f_{\overline{x}} : X(\overline{x}) \to S(\overline{s})$ the morphism of strictly local schemes induced by f. Let also $\mathbb{L} \subset \mathbb{N}$ be any non-empty set of prime numbers.

(i) Let also $\mathbf{P}$ be any property of schemes (such as : connected, irreducible, integral, normal, . . .); we shall say that *the Milnor fibres of f at the point x have property* $\mathbf{P}$, if the scheme $f_{\overline{x}}^{-1}(\xi)$ has property $\mathbf{P}$, for every strict geometric point ξ of $S(\overline{s})$ (see definition 4.9.17(i)).

(ii) We say that f is *locally (-1)-acyclic at the point x*, if the Milnor fibres of f at the point x are non-empty.

(iii) We say that f is *locally 0-acyclic at the point x*, if the Milnor fibres of f at the point x are connected (and in particular, non-empty).

(iv) We say that a group G is a *finite $\mathbb{L}$-group* if G is finite and all the primes dividing the order of G lie in $\mathbb{L}$. We say that G is an *$\mathbb{L}$-group* if it is a filtered union of finite $\mathbb{L}$-groups.

(v) We say that f is *locally 1-aspherical for $\mathbb{L}$ at the point x*, if we have :

$$H^1(f_{\overline{x}}^{-1}(\xi)_{\text{ét}}, G) = \{1\}$$

for every strict geometric point ξ of $S(\overline{s})$, and every $\mathbb{L}$-group G (where 1 denotes the trivial G-torsor).

(vi) We say that f is *locally* (-1)*-acyclic* (resp. *locally* 0*-acyclic*, resp. *locally* 1*-aspherical for* $\mathbb{L}$), if f is locally (-1)-acyclic (resp. locally 0-acyclic, resp. locally 1-aspherical for $\mathbb{L}$) at every point of X.

(vii) We say that f is (-1)*-acyclic* (resp. 0*-acyclic*) if the unit of adjunction : $\mathscr{F} \to f_*f^*\mathscr{F}$ is a monomorphism (resp. an isomorphism) for every sheaf $\mathscr{F}$ on $S_{\text{ét}}$.

See section 4.1 for generalities about G-torsors for a group object G on a topos T. Here we shall be mainly concerned with the case where T is the étale topos $X^\sim_{\text{ét}}$ of a scheme X, and G is representable by a group scheme, finite and étale over X. In this case, using faithfully flat descent one can show that any G-torsor is representable by a *principal G-homogeneous space*, *i.e.* a finite, surjective, étale morphism $E \to X$ with a G-action $G \to \mathrm{Aut}_X(E)$ such that the induced morphism of X-schemes

$$G \times E \to E \times_X E$$

is an isomorphism.

13.1.11. If G_X is the constant $X^\sim_{\text{ét}}$-group arising from a finite group G and X is non-empty and connected, right G_X-torsors are also understood as G-valued characters of the étale fundamental group of X. Indeed, let ξ be a geometric point of X; recall ([82, Exp.V, §7]) that $\pi := \pi_1(X_{\text{ét}}, \xi)$ is defined as the automorphism group of the fibre functor

$$F_\xi : \mathsf{Cov}(X) \to \mathbf{Set} \qquad (E \xrightarrow{f} X) \mapsto f^{-1}\xi.$$

We endow π with its natural profinite topology, as in (3.6.7), so that F_ξ can be viewed as an equivalence of categories

$$F_\xi : \mathsf{Cov}(X) \to \pi\text{-}\mathbf{Set}.$$

Lemma 13.1.12. *In the situation of* (13.1.11)*, there exists a natural bijection of pointed sets :*

$$H^1(X_{\text{ét}}, G_X) \xrightarrow{\sim} H^1_{\text{cont}}(\pi, G)$$

from the pointed set of right G_X-torsors, to the first non-abelian continuous cohomology group of P with coefficients in G (see (3.6.1)*).*

Proof. Let $f : E \to X$ be a right G_X-torsor, and fix a geometric point $s \in F_\xi(E)$; given any $\sigma \in \pi$, there exists a unique $g_{s,\sigma} \in G$ such that

$$s \cdot g_{s,\sigma} = \sigma_E(s).$$

Any $g \in G$ determines a X-automorphism $g_E : E \to E$, and by definition, the automorphism $F_\xi(g_E)$ on $F_\xi(E)$ commutes with the left action of any element $\tau \in \pi$; however $F_\xi(g_E)$ is just the right action of g on $F_\xi(E)$, hence we may compute :

$$s \cdot g_{s,\tau} \cdot g_{s,\sigma} = (\tau_E(s)) \cdot g_{s,\sigma} = \tau_E(s \cdot g_{s,\tau}) = \tau_E \cdot \sigma_E(s)$$

so the rule $\sigma \mapsto g_{s,\sigma}$ defines a group homomorphism $\rho_{s,f} : \pi \to G$ which is clearly continuous. We claim that the conjugacy class of $\rho_{s,f}$ does not depend on the choice of s. Indeed, if $s' \in F_\xi(E)$ is another choice, there exists a (unique) element $h \in G$ such that $h(s) = s'$; arguing as in the foregoing we see that σ_E commutes with the right action of h on $F_\xi(E)$. In other words, $\sigma_E(s) = h^{-1} \circ \sigma_E(s')$, so that $g_{s',\sigma} = h \circ g_{s,\sigma} \circ h^{-1}$.

Therefore, denote by ρ_f the conjugacy class of $\rho_{s,f}$; we claim that ρ_f depends only on the isomorphism class of the G_X-torsor E. Indeed, any isomorphism $t : E \xrightarrow{\sim} E'$ of right G_X-torsors induces a bijection $F_\xi(t) : F_\xi(E) \xrightarrow{\sim} F_\xi(E')$, equivariant for the action of G, and for any $\sigma \in \pi$ we have $F_\xi(t) \circ \sigma_E = \sigma_{E'} \circ F_\xi(t)$, whence the assertion.

Conversely, given a continuous group homomorphism $\rho : \pi \to G$, let us endow G with the induced left π-action, and right G-action. Then G is an object of π-$\mathbf{Set}$, to which there corresponds a finite étale morphism $E_\rho \to X$, with an isomorphism $E_\rho \times_X |\xi| \stackrel{\sim}{\to} G$ of sets with left π-action. Since the right action of G is π-equivariant, we have a corresponding G-action by X-automorphisms on E_ρ, so E_ρ is G-torsor, and its image under the map of the lemma is clearly the conjugacy class of ρ.

Finally, in order to show that the map of the lemma is injective, it suffices to prove that, for any right G_X-torsor $(f : E \to X, \varphi : E \times G \to E)$ and any $s \in F_\xi(E)$, there exists an isomorphism of right G_X-torsors $E_{\rho_{s,f}} \stackrel{\sim}{\to} E$. However, s and $\rho_{s,f}$ determine an identification of sets with left π-action :

$$G \stackrel{\sim}{\to} F_\xi(E) \tag{13.1.13}$$

whence an isomorphism $t : E_{\rho_{s,f}} \stackrel{\sim}{\to} E$ in $\mathsf{Cov}(X)$. Moreover, (13.1.13) also identifies the right G-action on $F_\xi(E)$ to the natural right G-action on G; the latter is π-equivariant, hence it induces a right G-action $\varphi' : E \times G \to E$, such that t is G-equivariant. To conclude, it suffices to show that $\varphi = \varphi'$. In view of [66, Ch.IV, Cor.17.4.8], the latter assertion can be checked on the stalks over the geometric point ξ, where it holds by construction. ☐

Remark 13.1.14. (i) In the situation of (13.1.11), let $E \to X$ be any right G_X-torsor, and $\rho_E : \pi \to G$ the corresponding representation. Then the proof of lemma 13.1.12 shows that the left π-action on $F_\xi(E)$ is isomorphic to the left π-action on G induced by ρ_E; especially, ρ_E is surjective if and only if π acts transitively on $F_\xi(E)$, if and only if the scheme E is connected (since a decomposition of E into connected components corresponds to a decomposition of $F_\xi(E)$ into orbits for the π-action).

(ii) Let $\varphi : G' \to G$ be a homomorphism of finite groups, and

$$H^1_{\mathrm{cont}}(\pi, \varphi) : H^1_{\mathrm{cont}}(\pi, G') \to H^1_{\mathrm{cont}}(\pi, G)$$

the induced map. Denote by r (resp. l) the right (resp. left) translation action of G on itself. Let also $E' \to X$ be a principal G'-homogeneous space, given by a map $\rho : G' \to \mathrm{Aut}_X(E')$, and denote by $c' \in H^1_{\mathrm{cont}}(\pi, G')$ the class of E'. Then the class $c := H^1_{\mathrm{cont}}(\pi, \varphi)(c)$ can be described geometrically as follows. The scheme $E' \times G$ admits an obvious right G-action, induced by r. Moreover, it admits as well a right G'-action : namely, to any element $g \in G'$, we assign the X-automorphism $\rho_g \times l_{\varphi(g^{-1})} : E' \times G \stackrel{\sim}{\to} E' \times G$. Set $E := (E \times G)/G'$; it is easily seen that E is a principal G-homogeneous space, and its class is precisely c (the detailed verification shall be left as an exercise for the reader).

(iii) Consider a commutative diagram of schemes

$$\begin{array}{ccc} E' & \xrightarrow{\ g\ } & E \\ & {\scriptstyle f'}\searrow \quad \swarrow{\scriptstyle f} & \\ & X & \end{array}$$

where f (resp. f') is a G-torsor (resp. a G'-torsor) for a given finite group G (resp. G'). Denote by $\rho : G \to \mathrm{Aut}_X(E)$ and $\rho' : G' \to \mathrm{Aut}_X(E')$ the respective actions. We have :

(a) Suppose that there exists a group homomorphism $\varphi : G' \to G$, such that $\rho \circ \varphi = g \circ \rho'$. Then g induces a G'-equivariant map

$$F_\xi(E') \to \mathrm{Res}(\varphi) F_\xi(E)$$

whence an isomorphism $(E' \times G)/G' \stackrel{\sim}{\to} G$ of G-torsors. Hence, let c (resp. c') denote any representative of the equivalence class of E (resp. E') in $H^1_{\mathrm{cont}}(\pi, G)$ (resp.

$H^1_{\mathrm{cont}}(\pi, G'))$; in view of (ii), it follows that

$$H^1(\pi, \varphi)(c') = c.$$

In other words, the induced diagram of continuous group homomorphisms

$$\begin{array}{ccc} & \pi_1(X_{\text{ét}}, \xi) & \\ {}^{c'}\swarrow & & \searrow^{c} \\ G' & \xrightarrow{\ \varphi\ } & G \end{array}$$

commutes, up to composition with an inner automorphism of G. (Details left to the reader.)

(b) If E is connected, a group homomorphism $\varphi : G \to G'$ fulfilling the condition of (a) exists and is unique up to composition with an inner automorphism of G. Indeed, fix any $e' \in F_\xi(E')$ and let $e := f(e')$; if $g' \in G'$, define $\varphi(g')$ as the unique $g \in G$ such that $f(e' \cdot g') = e \cdot g$; also, in view of (i) we may pick $\sigma_{g'} \in \pi_1(X, \xi)$ such that $\sigma_{g'} \cdot e' = e' \cdot g'$, and notice that $\sigma_{g'} \cdot e = e \cdot \varphi(g')$ for every $g' \in G'$. Now, if $h' \in G'$ is any other element, we may compute :

$$f(e' \cdot g'h') = f(\sigma_{g'} \cdot e' \cdot h') = \sigma_{g'} \cdot f(e' \cdot h') = \sigma_{g'} \cdot e \cdot \varphi(h') = e \cdot \varphi(g') \cdot \varphi(h')$$

whence $\varphi(g'h') = \varphi(g') \cdot \varphi(h')$, as required.

Lemma 13.1.15. *Let $f : X \to Y$ be a morphism of schemes, $\mathscr{F}$, $\mathscr{G}$ two sheaves on $Y_{\text{ét}}$. Then :*

(i) *If $\mathscr{F}$ is locally constant and constructible, the natural map :*

$$\vartheta_f : f^*\mathscr{H}om_{Y^\sim_{\text{ét}}}(\mathscr{F}, \mathscr{G}) \to \mathscr{H}om_{X^\sim_{\text{ét}}}(f^*\mathscr{F}, f^*\mathscr{G})$$

is an isomorphism.

(ii) *If f is 0-acyclic, it induces a fully faithful functor*

$$f^* : \mathsf{Cov}(Y) \to \mathsf{Cov}(X) \quad : \quad (E \to Y) \mapsto (E \times_Y X \to X).$$

Proof. (i): Suppose we have a cartesian diagram of schemes :

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow{g} & Y. \end{array}$$

Then, according to (4.8.2), we have a natural isomorphism :

$$\vartheta_{g'} \circ g'^*\vartheta_f \Rightarrow \vartheta_{f'} \circ f'^*\vartheta_g$$

(an invertible 2-cell, in the terminology of (2.1)). Now, if g – and therefore g' – is a covering morphism, ϑ_g and $\vartheta_{g'}$ are isomorphisms, and $g'^*\vartheta_f$ is an isomorphism if and only if the same holds for ϑ_f. Summing up, in this case ϑ_f is an isomorphism if and only if the same holds for $\vartheta_{f'}$. Thus, we may choose g such that g^* is a constant sheaf, and after replacing f by f', we may assume that $\mathscr{F} = S_Y$ is the constant sheaf associated with a finite set S. Since the functors

$$\mathscr{H}om_{Y^\sim_{\text{ét}}}(-, \mathscr{G}) : (Y^\sim_{\text{ét}})^o \to Y^\sim_{\text{ét}} \quad \text{and} \quad f^* : Y^\sim_{\text{ét}} \to X^\sim_{\text{ét}}$$

are left exact, we may further reduce to the case where $S = \{1\}$ is the set with one element, in which case $\mathscr{F} = 1_Y$ is the final object of $Y^\sim_{\text{ét}}$, and $f^*\mathscr{F} = 1_X$ is the final object of $X^\sim_{\text{ét}}$. Moreover, we have a natural identification :

$$\mathscr{H}om_{Y^\sim_{\text{ét}}}(1_Y, \mathscr{G}) \xrightarrow{\sim} \mathscr{G} \quad : \quad \sigma \mapsto \sigma(1)$$

and likewise for $\mathscr{H}om_{X^\sim_{\text{ét}}}(1_Y, f^*\mathscr{G})$. Using the foregoing characterization, it is easily checked that, under these identifications, ϑ_f is the identity map of $f^*\mathscr{G}$, whence the claim.

(ii): It has already been remarked that $\mathsf{Cov}(Y)$ is equivalent to the category of locally constant constructible sheaves on $Y_{\text{ét}}$, and likewise for $\mathsf{Cov}(X)$. Let E and F be two objects of $\mathsf{Cov}(Y)$; we have natural bijections :

$$\begin{aligned}\mathrm{Hom}_{\mathsf{Cov}(X)}(f^*E, f^*F) &\xrightarrow{\sim} \Gamma(X, \mathscr{H}om_{X^{\sim}_{\text{ét}}}(f^*E, f^*F)) \\ &\xrightarrow{\sim} \Gamma(Y, f_*f^*\mathscr{H}om_{Y^{\sim}_{\text{ét}}}(E, F)) && \text{by (i)} \\ &\xrightarrow{\sim} \Gamma(Y, \mathscr{H}om_{Y^{\sim}_{\text{ét}}}(E, F)) && \text{since } f \text{ is 0-acyclic} \\ &\xrightarrow{\sim} \mathrm{Hom}_{\mathsf{Cov}(Y)}(E, F)\end{aligned}$$

as stated. □

Lemma 13.1.16. *Let $f : X \to S$ be a quasi-compact morphism of schemes, and suppose that :*

(a) *f is locally (-1)-acyclic.*
(b) *For every strict geometric point ξ of S, the induced morphism $f_\xi : f^{-1}(\xi) \to |\xi|$ is 0-acyclic (*i.e. *f has non-empty geometrically connected fibres).*

Then f is 0-acyclic.

Proof. Let $\mathscr{F}$ be a sheaf on $S_{\text{ét}}$. For every strict geometric point ξ of S, we have a commutative diagram :

$$\begin{array}{ccc}\mathscr{F}_\xi & \xrightarrow{\varepsilon_\xi} & (f_*f^*\mathscr{F})_\xi \\ {\scriptstyle\alpha}\downarrow & & \downarrow \\ \Gamma(|\xi|, \xi^*\mathscr{F}) & \xrightarrow{f^*_\xi} & \Gamma(f^{-1}(\xi), f^*_\xi \circ \xi^*\mathscr{F})\end{array} \tag{13.1.17}$$

where $\varepsilon : \mathscr{F} \to f_*f^*\mathscr{F}$ is the unit of adjunction. The map α is an isomorphism, and the same holds for f^*_ξ, since f_ξ is 0-acyclic. Hence ε_ξ is injective, which shows already that f is (-1)-acyclic. It remains to show that ε_ξ is surjective. Hence, let $t \in (f_*f^*\mathscr{F})_\xi$ be any section. From (13.1.17) we see that there exists a section $t' \in \mathscr{F}_\xi$ such that the images of t and $\varepsilon_\xi(t')$ agree on $\Gamma(f^{-1}(\xi), f^*_\xi \circ \xi^*\mathscr{F})$. We may find an étale neighborhood $g : U \to S$ of ξ, such that t' (resp. t) extends to a section $t'_U \in \mathscr{F}(U)$ (resp. $t_U \in \Gamma(X \times_S U, f^*\mathscr{F})$). Let $X_U := X \times_S U$, $f_U := f \times_S U : X_U \to U$, and for every geometric point $\overline{x}$ of X_U, denote by $f^*_{\overline{x}} : \mathscr{F}_{f_U(\overline{x})} \to f^*_U\mathscr{F}_{\overline{x}}$ the natural isomorphism (4.9.22). We set

$$V := \{x \in X_U \mid t_{U,\overline{x}} = f^*_{\overline{x}}(t'_{U,f(\overline{x})})\}$$

where $\overline{x}$ is any geometric point of X localized at x, and $t_{U,\overline{x}} \in f^*\mathscr{F}_{\overline{x}}$ (resp. $t'_{U,f(\overline{x})} \in \mathscr{F}_{f_U(\overline{x})}$) denotes the image of t_U (resp. of t'_U). Clearly V is an open subset of X_U, and we have :

Claim 13.1.18. (i) $V = f_U^{-1}f_U(V)$.
(ii) $f_U(V) \subset U$ is an open subset.

Proof of the claim. (i): Given a point $u \in U$, choose a strict geometric point $\overline{u}$ localized at u, and set $\overline{s} := g(\overline{u})^{\text{st}}$; by assumption, the morphism $f_{\overline{s}} : f^{-1}(\overline{s}) \to |\overline{s}|$ is 0-acyclic, hence the image of t_U in $\Gamma(f^{-1}(\overline{s}), f^*_{\overline{s}} \circ \overline{s}^*\mathscr{F})$ is of the form $f^*_{\overline{s}}t''$, for some $t'' \in \mathscr{F}_{\overline{s}}$. It follows that $V \cap f_U^{-1}(u)$ is either the whole of $f_U^{-1}(u)$ or the empty set, according to whether t'' agrees or not with the image of t'_U in $\mathscr{F}_{\overline{s}} = g^*\mathscr{F}_{\overline{u}}$.

(ii): The subset $X \setminus V$ is closed, especially pro-constructible; since f is quasi-compact, we deduce that $f_U(X \setminus V)$ is a pro-constructible subset of U (corollary 8.1.50). It then follows from (i) that $f_U(V)$ is ind-constructible, hence we are reduced to showing that $f_U(V)$ is closed under generizations (proposition 8.1.47(ii)). To this aim, since V is open, it suffices to show that f_U is *generizing*, *i.e.* that the induced maps $X_U(x) \to U(u)$ are surjective, for every $u \in U$ and every $x \in f_U^{-1}(u)$. However, choose a geometric point $\overline{x}$ localized at x, and let $\overline{u} := f_U(\overline{x})$; since the natural maps $X_U(\overline{x}) \to X_U(x)$ and $U(\overline{u}) \to U(u)$ are surjective, it suffices to show that the same holds for the map $f_{U,\overline{x}} : X_U(\overline{x}) \to U(\overline{u})$. The image of $\overline{x}$ (resp. $\overline{U}$) in X (resp. in S) is a geometric point which we denote by the same name; since the natural maps $X_U(\overline{x}) \to X(\overline{x})$ and $U(\overline{u}) \to S(\overline{u})$ are isomorphisms, we are reduced to showing that $f_{\overline{x}} : X(\overline{x}) \to S(\overline{u})$ is surjective, which holds, since f is locally (-1)-acyclic. ♢

Set $W := f_U(V)$; in view of claim 13.1.18, W is an étale neighborhood of ξ, and the natural map $\mathscr{F}(W) \to f^*\mathscr{F}(U)$ sends the restriction $t'_{U|W}$ of t'_U to the restriction $t_{U|V}$ of t_U, whence the claim. □

13.1.19. Consider now a cartesian diagram of schemes :

(13.1.20)
$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f} \\ S' & \xrightarrow{g} & S \end{array}$$

where g is a local morphism of strictly local schemes, and denote by s (resp. by s') the closed point of S (resp. of S'). Let $x' \in f'^{-1}(s')$ be any point, $\overline{x}'$ a geometric point of X' localized at x', and set $x := g'(x')$, $\overline{x} := g'(\overline{x}')$. Then g' induces a morphism of S'-schemes :

(13.1.21) $$X'(\overline{x}') \to X(\overline{x}) \times_S S'.$$

Lemma 13.1.22. *In the situation of* (13.1.19)*, suppose that g is an integral morphism. Then :*

(i) *The induced morphism $f'^{-1}(s') \to f^{-1}(s)$ induces a homeomorphism on the underlying topological spaces.*
(ii) (13.1.21) *is an isomorphism.*

Proof. If g is integral, $\kappa(s')$ is a purely inseparable algebraic extension of $\kappa(s)$, hence the morphism $T' := \operatorname{Spec}\kappa(s') \to T := \operatorname{Spec}\kappa(s)$ is radicial, and the same holds for the induced morphisms :

$$f'^{-1}(s') \xrightarrow{\sim} f^{-1}(s) \times_T T' \to f^{-1}(s) \qquad f_x^{-1}(s) \times_T T' \to f_x^{-1}(s)$$

([59, Ch.I, Prop.3.5.7(ii)]). Especially (i) holds, and therefore the natural map $X'(x') \to X(x) \times_S S'$ is an isomorphism; we see as well that $f_x^{-1}(s) \times_T T'$ is a local scheme. Then the assertion follows from [66, Ch.IV, Rem.18.8.11]. □

Proposition 13.1.23. *Let $f : X \to S$ and $g : S' \to S$ be morphisms of schemes, with g quasi-finite, and set $X' := X \times_S S'$. Suppose that f is locally (-1)-acyclic (resp. locally 0-acyclic); then the same holds for $f' := f \times_S S' : X' \to S'$.*

Proof. Let $\overline{s}'$ be any geometric point of S', and set $\overline{s} := g(\overline{s}')$. Denote by $s \in S$ (resp. $s' \in S'$) the support of $\overline{s}$ (resp. $\overline{s}'$); then f is locally (-1)-acyclic at the points of $f^{-1}(s)$, if and only if $f_{\overline{s}} := f \times_S S(\overline{s}) : X \times_S S(\overline{s}) \to S(\overline{s})$ enjoys the same property at the points of $f_{\overline{s}}^{-1}(\overline{s})$. Likewise, f' is locally (-1)-acyclic (resp. locally 0-acyclic) at the points of $f'^{-1}(s')$, if and only if $f'_{\overline{s}'} : X' \times_{S'} S'(\overline{s}') \to S'(\overline{s}')$ enjoys the same property at the points of $f_{\overline{s}}^{-1}(\overline{s})$. Hence, we may replace g by $g_{\overline{s}'} : S'(\overline{s}') \to S(\overline{s})$, and f by the induced morphism $X \times_S S(\overline{s}) \to S(\overline{s})$, which allows to assume that g is finite ([66, Ch.IV, Th.18.5.11]), hence integral. Let ξ' (resp. $\overline{x}'$) be any strict geometric point of S' (resp. of $f'^{-1}(s')$), and let $\xi := g(\xi')^{\mathrm{st}}$, (resp. let $\overline{x}$ be the image of $\overline{x}'$ in X); we have natural morphisms :

$$f'^{-1}_{\overline{x}'}(\xi') \xrightarrow{\alpha} X(\overline{x}) \times_S \xi' \xrightarrow{\beta} f_{\overline{x}}^{-1}(\xi).$$

However, α is an isomorphism, by lemma 13.1.22(ii), and β is a radicial morphism, since the field extension $\kappa(\xi) \subset \kappa(\xi')$ is purely inseparable ([59, Ch.I, Prop.3.5.7(ii)]). The claim follows. □

Lemma 13.1.24. (i) *Let S be a strictly local scheme, $s \in S$ the closed point, $f : X \to S$ a morphism of schemes, $\overline{x}$ (resp. ξ) a strict geometric point of $f^{-1}(s)$ (resp. of S). We may find :*

(a) *A cartesian diagram* (13.1.20)*, with S' strictly local, irreducible and normal.*
(b) *A strict geometric point $\overline{x}'$ of $f'^{-1}(s')$ with $g'(\overline{x}')^{\mathrm{st}} = \overline{x}$.*
(c) *A strict geometric point ξ' of S' localized at the generic point η' of S', with $g(\xi')^{\mathrm{st}} = \xi$, and such that* (13.1.21) *induces an isomorphism :*

$$f'^{-1}_{\overline{x}'}(\xi') \stackrel{\sim}{\to} f^{-1}_{\overline{x}}(\xi). \qquad (13.1.25)$$

(ii) *Moreover, if S is noetherian, we may find S' as in* (i)*, such that $\mathscr{O}_{S'}(S')$ is a Krull domain.*
(iii) *Alternatively, we may find S' as in* (i)*, with separably closed residue field $\kappa(\eta')$.*

Proof. (i): Denote by $Z \subset S$ the closure of the image of ξ, endow Z with its reduced subscheme structure, set $Y := X \times_S Z \subset X$, and let $h_{\overline{x}} : Y(\overline{x}) \to Z$ be the natural morphism. Then Z is a strictly local scheme ([66, Ch.IV, Prop.18.5.6(i)]). Moreover, the closed immersion $Y \to X$ induces an isomorphism $Y(\overline{x}) \stackrel{\sim}{\to} X(\overline{x}) \times_S Z$ of Z-schemes (lemma 13.1.22(ii)). By construction, ξ factors through a strict geometric point ξ' of Z, and we deduce an isomorphism $h^{-1}_{\overline{x}}(\xi') \stackrel{\sim}{\to} f^{-1}_{\overline{x}}(\xi)$ of Z-schemes. Thus, we may replace (S, X, ξ) by (Z, Y, ξ'), and assume that S is the spectrum of a strictly local domain, and ξ is localized at the generic point of S.

Claim 13.1.26. Let A be a strictly local domain, and A^ν the normalization of A in an algebraic extension K of $F := \mathrm{Frac}\, A$. Then A^ν is strictly local.

Proof of the claim. A^ν is the union of a filtered family $(A_\lambda \mid \lambda \in \Lambda)$ of finite A-subalgebras of F; since A is henselian, each A_λ is a product of henselian local rings, hence it is a local henselian ring, so the same holds for A^ν. Moreover, the residue field of A^ν is separably closed, since it is an algebraic extension of the residue field of A, which is separably closed by assumption. ◊

Say that $S = \mathrm{Spec}\, A$, and denote by A^ν the normalization of A in its field of fractions F. By claim 13.1.26, A^ν is strictly henselian, so we may fulfill condition (a) by taking $S' := \mathrm{Spec}\, A^\nu$. Condition (b) holds as well, due to lemma 13.1.22(i). Finally, it is clear that ξ lifts to a unique strict geometric point ξ' of S', and it follows from lemma 13.1.22(ii) that (13.1.25) is an isomorphism, as required.

(ii): A direct inspection of the proof of (i) reveals that if S is noetherian, the scheme S' exhibited is the spectrum of the normalization of a noetherian domain; the assertion then follows from [133, Th.33.10].

(iii): Let A^ν_K be the normalization of A in a separable closure K of F; the proof of (i) applies as well with $S' := \mathrm{Spec}\, A^\nu_K$, whence the assertion. □

13.1.27. Consider now a cofiltered family $\mathscr{S} := (S_\lambda \mid \lambda \in \Lambda)$ of affine schemes. Denote by S the limit of $\mathscr{S}$, and suppose moreover that Λ admits a final element $0 \in \Lambda$. Let $f_0 : X_0 \to S_0$ be a finitely presented morphism of schemes, and set :

$$X_\lambda := X_0 \times_{S_0} S_\lambda \qquad f_\lambda := f_0 \times_{S_0} S_\lambda : X_\lambda \to S_\lambda \qquad \text{for every } \lambda \in \Lambda.$$

Set as well $X := X_0 \times_{S_0} S$ and $f := f_0 \times_{S_0} S : X \to S$. Let $x \in X$ be any point, and $s := f(x)$. Let also ξ be a strict geometric point of S. We deduce a compatible system of points $x_\lambda := p'_\lambda(x) \in X_\lambda$, whence a cofiltered system of local schemes

$$\mathscr{X} := (X_\lambda(x_\lambda) \mid \lambda \in \Lambda).$$

Moreover, we get a compatible system of strict geometric points $(\xi_\lambda := p_\lambda(\xi)^{\mathrm{st}} \mid \lambda \in \Lambda)$, with :

$$\xi \stackrel{\sim}{\to} \lim_{\lambda \in \Lambda} \xi_\lambda.$$

Choose a geometric point $\overline{x}$ of X localized at x, and set likewise $\overline{x}_\lambda := p'_\lambda(\overline{x})$; then $\mathscr{X}$ lifts to a system $\mathscr{X}^{\mathrm{sh}} := (X_\lambda(\overline{x}_\lambda) \mid \lambda \in \Lambda)$, whose limit is naturally isomorphic to $X(\overline{x})$ ([66, Ch.IV, Prop.18.8.18(ii)]). Furthermore, $\mathscr{X}^{\mathrm{sh}}$ induces a natural isomorphism of $\kappa(\xi)$-schemes :

$$f_{\overline{x}}^{-1}(\xi) \xrightarrow{\sim} \lim_{\lambda \in \Lambda} f_{\lambda,\overline{x}_\lambda}^{-1}(\xi_\lambda) \tag{13.1.28}$$

where, as usual, $f_{\overline{x}} : X(\overline{x}) \to S$ (resp. $f_{\lambda,\overline{x}_\lambda} : X_\lambda(\overline{x}_\lambda) \to S_\lambda$) is deduced from f (resp. from f_λ). These remarks, together with the following lemma 13.1.29, and the previous lemma 13.1.24, will allow in many cases, to reduce the study of the fibres of $f_{\overline{x}}$, to the case where the base S is strictly local, excellent and normal.

Lemma 13.1.29. *Let S be a strictly local normal scheme. Then there exists a cofiltered family $\mathscr{S} := (S_\lambda \mid \lambda \in \Lambda)$ consisting of strictly local normal excellent schemes, such that :*

(a) *S is isomorphic to the limit of $\mathscr{S}$.*

(b) *The natural morphism $S \to S_\lambda$ is dominant for every $\lambda \in \Lambda$.*

Proof. Say that $S = \operatorname{Spec} A$, and write A as the union of a filtered family $\mathscr{A} := (A_\lambda \mid \lambda \in \Lambda)$ of excellent noetherian local subrings, which we may assume to be normal, by [64, Ch.IV, (7.8.3)(ii),(vi)]. Proceeding as in (13.1.27), we choose a compatible family of geometric points $\overline{s}_\lambda$ localized at the closed points of $\operatorname{Spec} A_\lambda$, for every $\lambda \in \Lambda$; using these geometric points, we lift $\mathscr{A}$ to a filtered family $(A_\lambda^{\mathrm{sh}} \mid \lambda \in \Lambda)$ of strict henselizations, whose colimit is naturally isomorphic to A. Moreover, each A_λ^{sh} is noetherian, normal and excellent ([66, Ch.IV, Prop.18.8.8(iv), Prop.18.8.12(i)] and proposition 9.7.19(ii)). Let η be the generic point of S, $h_\lambda : S \to S_\lambda := \operatorname{Spec} A_\lambda^{\mathrm{sh}}$ the natural morphism, and $\eta_\lambda^{\mathrm{sh}} := h_\lambda(\eta)$ for every $\lambda \in \Lambda$. The cofiltered system $(S_\lambda \mid \lambda \in \Lambda)$ fulfills condition (a). Moreover, by construction, the image of $\eta_\lambda^{\mathrm{sh}}$ in $\operatorname{Spec} A_\lambda$ is the generic point η_λ; then $\eta_\lambda^{\mathrm{sh}}$ is the generic point of S_λ, since the latter is the only point of S_λ lying over η_λ. Hence (b) holds as well. □

Part (ii) of the following proposition improves upon [10, Exp.XV, Th.4.1].

Proposition 13.1.30. *Let $f : X \to S$ be a flat morphism of schemes. We have :*

(i) *f is locally (-1)-acyclic.*

(ii) *Suppose moreover, that f has geometrically reduced fibres, and :*

  (a) *either f is locally finitely presented,*

  (b) *or else, S is locally noetherian.*

  Then f is locally 0-acyclic.

(iii) *Furthermore, if f is locally finitely presented and has geometrically normal fibres, then the Milnor fibres of f at every point of X are geometrically normal and irreducible.*

Proof. Let $x \in X$ be any point, set $s := f(x)$, choose a geometric point $\overline{x}$ of X localized at x, set $\overline{s} := f(\overline{x})$, and let ξ be any strict geometric point of $S(\overline{s})$.

(i): If f is flat, the induced morphism $f_{\overline{x}} : X(\overline{x}) \to S(\overline{s})$ is faithfully flat; especially, $f_{\overline{x}}$ is surjective ([126, Th.7.3(i)]).

(ii),(iii): Set $X' := X \times_S S(\overline{s})$. The natural morphism $X(\overline{x}) \to X$ factors uniquely through a morphism of $S(\overline{s})$-schemes $j : X(\overline{x}) \to X'$, and if we denote by $\overline{x}'$ the image in X' of $\overline{x}$, then j induces an isomorphism of $S(\overline{s})$-schemes : $X(\overline{x}) \xrightarrow{\sim} X'(\overline{x}')$. Hence we may replace S by $S(\overline{s})$, and assume that S is strictly local, when (a) holds, and even strictly local and noetherian, when (b) holds. By lemma 13.1.24, we are further reduced to the case where $S = S(\overline{s}) = \operatorname{Spec} A$ is strictly local and normal, ξ is localized at the generic point of S, and :

(a') either f is finitely presented,

(b') or else, A is a (not necessarily noetherian) Krull domain.

Claim 13.1.31. (i) In case (b') holds, $f_{\overline{x}}^{-1}(\xi)$ is connected.

(ii) If (a') holds and f has geometrically normal fibres, then $f_{\overline{x}}^{-1}(\xi)$ is normal and irreducible.

Proof of the claim. Let F be the field of fractions of A; the field $\kappa(\xi)$ is algebraic over F, hence, in order to show (i), it suffices to check that $X(\overline{x}) \times_S \operatorname{Spec} K$ is connected for every finite field extension $F \subset K$ ([65, Ch.IV, Prop.8.4.1(ii)]). Likewise, in order to show (ii), it suffices to check that $X(\overline{x}) \times_S \operatorname{Spec} K$ is normal and irreducible for every such K. Let A_K be the normalization of A in K, set $S_K := \operatorname{Spec} A_K$, $X_K := X \times_S S_K$, let $f_K : X_K \to S_K$ be the induced morphism, and pick any geometric point $\overline{x}_K$ of X_K whose image in X agrees with $\overline{x}$. By claim 13.1.26, S_K is strictly local, and if (b') holds, then A_K is again a Krull domain ([34, Ch.VII, §1, n.8, Prop.12]). Moreover, lemma 13.1.22(ii) yields a natural identification :

$$X_K(\overline{x}_K) \times_{S_K} \operatorname{Spec} K \xrightarrow{\sim} X(\overline{x}) \times_S \operatorname{Spec} K.$$

Clearly, if f has geometrically reduced (resp. geometrically normal) fibres, the same holds for f_K, hence we may replace f by f_K, and reduce to checking the claim for $K = F$.

Now, $B := \mathscr{O}_{X,\overline{x}}$ is clearly a flat A-algebra, and notice that the geometric fibres $f_{\overline{x}}$ are cofiltered limits of schemes that are étale over the fibres of f; if the fibres of f are geometrically reduced (resp. geometrically normal), it follows that the same holds for the fibres of $f_{\overline{x}}$. In case A is a Krull domain, B is integrally closed in $B \otimes_A F$ (lemma 9.8.2); especially these two rings have the same idempotents, whence (i).

Lastly, if the assumptions of (ii) hold, then we know already that the fibres of $f_{\overline{x}}$ are geometrically normal, so that $X(\overline{x})$ is normal, by [65, Ch.IV, Prop.11.3.13(ii)], and therefore $B \otimes_A F$ is a normal domain, whence (ii). ◊

Claim 13.1.31 yields already (iii), and also shows that (ii) holds when (b') holds.

Finally, let us check that (ii) holds when (a') holds. By lemma 13.1.29, the scheme S is the limit of a cofiltered family $(S_\lambda \mid \lambda \in \Lambda)$ of strictly local excellent and normal schemes, such that the natural morphisms $p_\lambda : S \to S_\lambda$ are dominant. By claim 9.8.4, there exists $\lambda \in \Lambda$ and a flat morphism of schemes $f_\lambda : X_\lambda \to S_\lambda$ with geometrically reduced fibres, with an isomorphism of S-schemes $S \times_{S_\lambda} X_\lambda \xrightarrow{\sim} X$; then, for every $\mu \in \Lambda$ with $\mu \geq \lambda$, set $X_\mu := S_\mu \times_{S_\lambda} X_\lambda$ and $f_\mu := S_\mu \times_{S_\lambda} f_\lambda : X_\mu \to S_\mu$. After replacing Λ by a coinitial subset, we may assume that f_μ is defined for every $\lambda \in \Lambda$. For every such λ, let $x_\lambda \in X_\lambda$ be the image of x. Arguing as in (13.1.27), we obtain a compatible system of strict geometric points ξ_λ of S_λ (resp. $\overline{x}_\lambda$ of X_λ), such that $p_\lambda(\xi)$ factors through ξ_λ; whence an isomorphism (13.1.28). Thus, $f_{\overline{x}}^{-1}(\xi)$ is reduced if and only if $f_{\lambda,\overline{x}_\lambda}^{-1}(\xi_\lambda)$ is reduced for every sufficiently large $\lambda \in \Lambda$ ([65, Ch.IV, Prop.8.7.2]). Furthermore, since p_λ is dominant, ξ_λ is localized at the generic point of S_λ, for every $\lambda \in \Lambda$. Thus, we are reduced to the case where $S = S(s)$ is the spectrum of a strictly local noetherian normal domain A, and ξ is localized at the generic point of S; since such A is a Krull domain ([126, Th.12.4(i)]), this is covered by claim 13.1.31. □

Remark 13.1.32. In the statement and proof of proposition 13.1.30(iii) we use a definition of *geometrically normal scheme* (over a given field) which is more general than that introduced originally in [64, Ch.IV, Def.6.7.6] (which includes some unnecessary noetherian assumptions), and agrees *e.g.* with the definition in [107, Tag 0380, Tag 038M].

Example 13.1.33. (i) Let A be an excellent local ring, and $A^\wedge$ the completion of A. Then the natural morphism :

$$f : \operatorname{Spec} A^\wedge \to \operatorname{Spec} A$$

is locally 0-acyclic. Indeed, this follows from proposition 13.1.30(ii) (and from the excellence assumption, which includes the geometric regularity of the formal fibres of A).

(ii) Suppose additionally, that A is strictly local. Then f is 0-acyclic. To see this, we apply the criterion of lemma 13.1.16 : indeed, since f is flat, it is (-1)-acyclic (proposition 13.1.30(i)); it remains to show that f has geometrically connected fibres, and since $A^\wedge$ is strictly local ([66, Ch.IV, Prop.18.5.14]), this is the same as showing that f is locally 0-acyclic at the closed point of $\operatorname{Spec} A^\wedge$, which has already been remarked in (i).

(iii) More generally, f is 0-acyclic whenever A is excellent and henselian. Indeed, in this case the argument of (ii) again reduces to showing that f has geometrically connected fibres. However, consider the natural commutative diagram :

$$\begin{array}{ccc} \mathrm{Spec}\,(A^\wedge)^{\mathrm{sh}} & \longrightarrow & \mathrm{Spec}\,A^\wedge \\ {\scriptstyle f^{\mathrm{sh}}}\downarrow & & \downarrow{\scriptstyle f} \\ \mathrm{Spec}\,A^{\mathrm{sh}} & \longrightarrow & \mathrm{Spec}\,A. \end{array} \tag{13.1.34}$$

Since A is henselian, A^{sh} is the colimit of a filtered family of finite étale and local A-algebras. Since A and $A^\wedge$ have the same residue field, it follows easily that $A^\wedge \otimes_A A^{\mathrm{sh}}$ is the colimit of a filtered family of finite étale and local $A^\wedge$-algebras, hence it is strictly henselian, and therefore (13.1.34) is cartesian, especially the geometric fibres of f are connected if and only if the same holds for the geometric fibres of f^{sh}, and the latter are reduced (even regular), since A is excellent. Hence, we come down to showing that f^{sh} is locally 0-acyclic at the closed point of $\mathrm{Spec}\,(A^\wedge)^{\mathrm{sh}}$, which holds again by proposition 13.1.30(ii).

Proposition 13.1.35. *Let $f : X \to S$ be a morphism of schemes locally of finite type, and suppose that either one of the following conditions holds :*

(a) *For some $d \in \mathbb{N}$, the fibres of f are all of pure dimension d.*
(b) *f is* quasi-flat*, in the sense of* [64, Ch.IV, (2.3.3)] i.e. *there exists a quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ of finite type which is S-flat and with* $\mathrm{Supp}\,\mathscr{F} = X$ *(notation of definition* 10.1.1(iv)*).*

Then the Milnor fibres of f at every point of X have finitely many irreducible components.

Proof. Suppose first that (a) holds. We may assume that $X = \mathrm{Spec}\,B$ is affine, and by lemma 13.1.24(iii), we may also assume that $S = \mathrm{Spec}\,A$ is strictly local and normal, and the field of fractions F of A is separably closed. In this situation, we need to check that $X(\overline{x}) \times_S \mathrm{Spec}\,F$ has finitely many irreducible components, for every geometric point $\overline{x}$ of X whose image in S is localized at the maximal ideal $\mathfrak{m} \subset A$. By assumption, $B/\mathfrak{m}B$ is of pure dimension d; by the Nother normalization lemma, we may then find a finite map $\kappa(\mathfrak{m})[T_1, \dots, T_d] \to B/\mathfrak{m}B$ of $\kappa(\mathfrak{m})$-algebras, and lift it to a map of A-algebras $\varphi : A[T_1, \dots, T_d] \to B$ which will be quasi-finite at the support $x \in \mathrm{Spec}\,B$ of $\overline{x}$. After replacing X by an affine open neighborhood of x, we may therefore assume that the morphism $g : X \to \mathbb{A}^d_S$ induced by φ is quasi-finite ([65, Ch.IV, Cor.13.1.4]). Then, since $X_F := X \times_S \mathrm{Spec}\,F$ is of pure dimension d, it follows easily that the restriction $g_F : X_F \to \mathbb{A}^d_F$ of g is maximizing (see definition 8.1.46(ii)). Set $\overline{y} := g(\overline{x})$, let $h : X(\overline{x}) \to \mathbb{A}^d_S(\overline{y})$ be the induced morphism, and consider the commutative diagram of schemes :

$$\begin{array}{ccc} X(\overline{x}) \times_S \mathrm{Spec}\,F & \longrightarrow & X_F \\ {\scriptstyle h \times_S \mathrm{Spec}\,K}\downarrow & & \downarrow{\scriptstyle g_F} \\ \mathbb{A}^d_S(\overline{y}) \times_S \mathrm{Spec}\,F & \longrightarrow & \mathbb{A}^d_F. \end{array}$$

Notice that both horizontal arrows are flat morphisms, hence they are generizing, and the fibres of the bottom horizontal arrows are 0-dimensional; since g_F is maximizing, it then follows that the same holds for $h \times_S \mathrm{Spec}\,K$. On the other hand, h is a finite morphism, by Zariski's main theorem, so it has finite fibres, and $\mathbb{A}^d_S(\overline{y}) \times_S \mathrm{Spec}\,K$ is an integral scheme, by proposition 13.1.30(iii), whence the assertion.

Next, suppose that (b) holds; again, we fix a geometric point $\overline{x}$ of X, and we are easily reduced to the case where S is strictly local, X is affine, and the image $\overline{s}$ of $\overline{x}$ in S is localized at the closed point. Then we may find a closed immersion $i : X \to Y := \mathbb{A}^n_S$, for some $n \in \mathbb{N}$; according to [86, Part I, Th.3.4.1], the $\mathscr{O}_Y$-module $i_*\mathscr{F}$ is finitely presented in an affine open neighborhood U of the support of $\overline{y} := i(\overline{x})$, hence we may replace Y by U and X by $X \times_Y U$, and assume that $i_*\mathscr{F}$ is a finitely presented Y-scheme. Let $\mathscr{I} \subset \mathscr{O}_Y$ be the 0-th Fitting ideal of $i_*\mathscr{F}$, set $X' := \mathrm{Spec}\,\mathscr{O}_Y/\mathscr{I}$, and let $g : X' \to S$ be the induced projection; then X' is a closed subscheme of Y, and $i(X) = \mathrm{Supp}_Y(i_*\mathscr{F}) = X'$, hence the maximal reduced subschemes of X and X' are S-isomorphic. It follows easily that the $S(\overline{s})$-schemes $X(\overline{x})$ and $X'(\overline{y})$ have isomorphic maximal reduced subschemes. Hence, for every strict geometric point ξ of $S(\overline{s})$, the fibres $f_{\overline{x}}^{-1}(\xi)$ and $g_{\overline{x}}^{-1}(\xi)$ are homeomorphic. Thus, we may replace $f : X \to S$ by $g : X' \to S$, and assume from start that X is a finitely presented S-scheme.

Claim 13.1.36. There exist finitely many closed subschemes $Z_1, \dots, Z_k \subset X$ such that $X = Z_1 \cup \cdots \cup Z_k$, and integers $d_1, \dots, d_k \in \mathbb{N}$ such that for every $i = 1, \dots, k$, all the fibres of the restriction $Z_i \to S$ of f are of pure dimension d_i.

Proof of the claim. Say that $S = \mathrm{Spec}\,A$, $X = \mathrm{Spec}\,B$ and $\mathscr{F} = M^\sim$ for a finitely presented A-algebra B and an A-flat B-module M of finite presentation. Then we may find a noetherian subring $A_0 \subset A$, an A_0-algebra B_0 of finite type, and a B_0-module M_0 with an isomorphism of A-algebras $A \otimes_{A_0} B_0 \xrightarrow{\sim} B$ and of B-modules $B \otimes_{B_0} M_0 \xrightarrow{\sim} M$. Moreover, we may assume that M_0 is a flat A_0-module ([65, Ch.IV, Cor.11.2.6.1]), and that $\mathrm{Supp}_{B_0} M_0 = \mathrm{Spec}\,B_0$ ([65, Ch.IV, Cor.8.3.3]). In view of [64, Ch.IV, Cor.4.1.4], we are easily reduced to checking the assertion for the corresponding morphism $\mathrm{Spec}\,B_0 \to \mathrm{Spec}\,A_0$. The latter is provided by [65, Ch.IV, Prop.12.1.1.5]. ◊

To a decomposition $X = Z_1 \cup \cdots \cup Z_k$ as in claim 13.1.36, there corresponds a decomposition $X(\overline{x}) = Z_1(\overline{x}) \cup \cdots \cup Z_k(\overline{x})$ for every geometric point $\overline{x}$ of X, hence it suffices to check the assertion for each of the restrictions $Z_i \to S$ of f, so we may assume that condition (a) holds, in which case the assertion is already known. □

For future use, we point out the following

Proposition 13.1.37. *Let $g : X \to Y$ be a flat morphism of excellent noetherian schemes, with X strictly local, and Y normal. Let $U \subset X$ be an open subset, and $Z \subset Y$ a closed subscheme. Suppose that :*

(i) *$g^{-1}(z) \subset U$ for every maximal point z of Z.*
(ii) *$U \cap g^{-1}(z)$ is a dense open subset of $g^{-1}(z)$, for every $z \in Z$.*
(iii) *The fibres $g^{-1}(z)$ are reduced, for every $z \in Z$.*

Then the induced functor $\mathsf{Cov}(U) \to \mathsf{Cov}(U \times_Y Z)$ is fully faithful.

Proof. Indeed, say that $X = \mathrm{Spec}\,B$, $Y = \mathrm{Spec}\,A$, $Z = V(I)$ for some ideal $I \subset A$, and denote by $B^\wedge$ the $\mathfrak{m}_B$-adic completion of the local ring B (where $\mathfrak{m}_B \subset B$ denotes the maximal ideal). Let also $f : \mathrm{Spec}\,B^\wedge \to Y$ be the induced morphism, and $U^\wedge \subset \mathrm{Spec}\,B^\wedge$ the preimage of U. In light of example 13.1.33(ii) and lemma 13.1.15(ii), it suffices to show that the induced functor $\mathsf{Cov}(U^\wedge) \to \mathsf{Cov}(U^\wedge \times_Y Z)$ is fully faithful. In view of lemma 13.1.3, we are further reduced to checking that conditions (a)–(c) of proposition 10.5.46 hold for the induced ring homomorphism $\varphi : A \to B^\wedge$, the open subset $U^\wedge$, and the ideal I. However, by example 10.5.41, we have $\mathrm{Ass}_A(I, A) = \mathrm{Max}(Z)$, hence (c) follows trivially from our assumption (i). Next, since $B^\wedge$ is a faithfully flat B-algebra, assumption (ii) implies that $U^\wedge \cap f^{-1}(z)$ is a dense open subset of $f^{-1}(z)$, for every $z \in Z$. Moreover, since B is excellent, the natural morphism $\mathrm{Spec}\,B^\wedge \to X$ is regular, so the same holds for the induced morphism $f^{-1}(z) \to g^{-1}(z)$, and then our assumption (iii) implies – together with [126, Th.32.3(i)] – that $f^{-1}(z)$ is reduced, for every $z \in Z$, whence condition (b). Lastly, we check condition (a), *i.e.* we show that $B^\wedge$ is I-adically complete. Indeed, let C be the I-adic completion of $B^\wedge$; the natural map $B^\wedge \to C$ is injective, and it admits a left inverse, constructed as follows. Let $\underline{a} := (a_n \mid n \in \mathbb{N})$ be a given sequence of elements of $B^\wedge$, which is Cauchy for the I-adic topology; then $\underline{a}$ is also Cauchy for the $\mathfrak{m}_B$-adic topology, and it is easily seen that the limit l of $\underline{a}$ in the $\mathfrak{m}_B$-adic topology depends only on the class $[\underline{a}]$ of $\underline{a}$ in C, so we get a well defined ring homomorphism $\lambda : C \to B^\wedge$ by the rule : $[\underline{a}] \mapsto l$, and clearly λ is the sought left inverse. It remains to check that λ is injective; thus, suppose that $l = 0$, and that $[\underline{a}] \neq 0$; this means that there exists $N \in \mathbb{N}$ such that $a_n \notin I^N$, for every $n \in \mathbb{N}$. Now, the induced sequence $(\overline{a}_n \mid n \in \mathbb{N})$ of elements of $B^\wedge/I^N$ is stationary, and on the other hand, it converges $\mathfrak{m}_B$-adically to 0; therefore $\overline{a}_n = 0$ for every sufficiently large $n \in \mathbb{N}$, a contradiction. □

13.1.38. Let A be a noetherian normal ring, and endow the A-algebra $A[[t]]$ with its t-adic topology. Let

$$\varphi : \mathfrak{X} := \operatorname{Spf} A[[t]] \to X := \operatorname{Spec} A[[t]] \qquad \pi : X \to S := \operatorname{Spec} A \qquad i : S \to X$$

be respectively the natural morphism of locally ringed spaces, the natural projection, and the closed immersion determined by the ring homomorphism $A[[t]] \to A$ given by the rule : $f(t) \mapsto f(0)$, for every $f(t) \in A[[t]]$. Let also $U_0 \subset \operatorname{Spec} A$ be an open subset, $U := \pi^{-1}U_0$ and $\mathfrak{U} := \varphi^{-1}U$. Finally, denote by $\mathscr{E}$ a locally free $\mathscr{O}_U$-module of finite rank, and set $\mathscr{E}^\wedge := \varphi^*_{|\mathfrak{U}}\mathscr{E}$, which is a locally free $\mathscr{O}_{\mathfrak{U}}$-module of finite rank.

Lemma 13.1.39. *In the situation of* (13.1.38)*, suppose that $S \setminus U_0$ has codimension ≥ 2 in S. Then:*

(i) *The natural map*
$$\Gamma(U, \mathscr{E}) \to \Gamma(\mathfrak{U}, \mathscr{E}^\wedge)$$
is an isomorphism of $A[[t]]$-modules.

(ii) *The restriction $i_{|U_0} : U_0 \to U$ of i induces an equivalence :*
$$i^*_{|U_0} : \mathsf{Cov}(U) \to \mathsf{Cov}(U_0) \quad : \quad (E \to U) \mapsto (E \times_U U_0 \to U_0).$$

Proof. (i): To begin with, set $Z := S \setminus U_0$; since the morphism π is flat, hence generizing ([126, Th.9.5]), the closed subset $X \setminus U = \pi^{-1}Z$ has codimension ≥ 2 in X. Since A and $A[[t]]$ are both normal, we deduce :

$$\operatorname{depth}_{X \setminus V}\mathscr{O}_X \geq 2 \qquad \operatorname{depth}_Z \mathscr{O}_S \geq 2 \tag{13.1.40}$$

(theorem 10.4.21 and [126, Th.23.8]); therefore (corollary 10.4.23) :

$$\Gamma(U, \mathscr{O}_X) = \Gamma(X, \mathscr{O}_X) = A[[t]]. \tag{13.1.41}$$

Next, the short exact sequences of $\mathscr{O}_X$-modules :

$$0 \to i_*\mathscr{O}_S \to \mathscr{O}_X/t^{n+1}\mathscr{O}_X \to \mathscr{O}_X/t^n\mathscr{O}_X \to 0 \qquad \text{for every } n \in \mathbb{N}$$

induce exact sequences

$$R^j\Gamma_Z i_*\mathscr{O}_S \to R^j\Gamma_Z \mathscr{O}_X/t^{n+1}\mathscr{O}_X \to R^j\Gamma_Z \mathscr{O}_X/t^n\mathscr{O}_X \qquad \text{for every } n, j \in \mathbb{N}. \tag{13.1.42}$$

Then (13.1.40) and (13.1.42) yield inductively :

$$\operatorname{depth}_Z \mathscr{O}_X/t^n\mathscr{O}_X \geq 2 \qquad \text{for every } n \in \mathbb{N}$$

and again corollary 10.4.23 implies :

$$\Gamma(U, \mathscr{O}_X/t^n\mathscr{O}_X) = A[t]/t^nA[t] \qquad \text{for every } n \in \mathbb{N}. \tag{13.1.43}$$

Since U is quasi-compact, we may find a left exact sequence $P := (0 \to \mathscr{E} \to \mathscr{O}_U^{\oplus m} \to \mathscr{O}_U^{\oplus n})$ of $\mathscr{O}_U$-modules (corollary 10.3.28). Since φ is a flat morphism of locally ringed spaces, the sequence φ^*P is still left exact. Since the global section functors are left exact, we are then reduced to the case where $\mathscr{E} = \mathscr{O}_U$. Then we may write :

$$\mathscr{E}^\wedge = \mathscr{O}_{\mathfrak{U}} = \lim_{n \in \mathbb{N}} \mathscr{O}_U/t^n\mathscr{O}_U$$

where, for each $n \in \mathbb{N}$, we regard $\mathscr{O}_U/t^n\mathscr{O}_U$ as a sheaf of (pseudo-discrete) rings on $\mathfrak{U} = V(t) \subset U$. The functor $\Gamma(\mathfrak{U}, -)$ is a right adjoint, hence commutes with limits, and we deduce an isomorphism :

$$\Gamma(\mathfrak{U}, \mathscr{E}^\wedge) \stackrel{\sim}{\to} \lim_{n\in\mathbb{N}} \Gamma(U, \mathscr{O}_U/t^n\mathscr{O}_U).$$

(This is even a homeomorphism, provided we view the target as a limit of rings with the discrete topology.) Taking (13.1.43) into account, we obtain $\Gamma(\mathfrak{U}, \mathscr{E}^\wedge) = A[[t]]$ which, together with (13.1.41), implies the contention.

(ii): Notice that (i) and lemma 10.5.44 imply that $\mathrm{Lef}(U, i(U_0))$ holds (see definition 10.5.42). Since the pull-back functor $\pi^*_{|U} : \mathsf{Cov}(U_0) \to \mathsf{Cov}(U)$ is a right quasi-inverse to $i^*_{|U_0}$, the latter is essentially surjective. The full faithfulness is a special case of lemma 13.1.3. □

13.2. **Local asphericity of smooth morphisms of schemes.** Let S be a strictly local scheme, $s \in S$ the closed point, $f : X \to S$ a smooth morphism, $\overline{x}$ any geometric point of $f^{-1}(s)$, and denote by $f_{\overline{x}} : X(\overline{x}) \to S$ the induced morphism of strictly local schemes. For any open subset $U \subset S$ we have a base change functor :

(13.2.1) $$f^*_{\overline{x}} : \mathsf{Cov}(U) \to \mathsf{Cov}(f^{-1}_{\overline{x}}U) \qquad (E \to U) \mapsto (E \times_U f^{-1}_{\overline{x}}U).$$

Theorem 13.2.2. *In the situation of* (13.2)*, we have :*

(i) *The functor* (13.2.1) *is fully faithful.*
(ii) *Suppose moreover that S is excellent and normal, and that $S\backslash U$ has codimension ≥ 2 in S. Then* (13.2.1) *is an equivalence of categories.*

Proof. (i): In view of lemma 13.1.15(ii) it suffices to show that $f_{\overline{x}}$ is 0-acyclic (since in that case, the same will obviously hold also for its restriction $f^{-1}_{\overline{x}}U \to U$). To begin with, $f_{\overline{x}}$ is locally (-1)-acyclic, by proposition 13.1.30(i), hence it remains only to show that f is locally 0-acyclic at the point x (lemma 13.1.16). The latter assertion follows from proposition 13.1.30(ii) and [66, Ch.IV, Th.17.5.1].

(ii): In light of (i), it suffices to show that (13.2.1) is essentially surjective, under the assumptions of (ii). We argue by induction on the relative dimension n of f. Let $x \in X$ be the support of $\overline{x}$. We may find an open neighborhood $U \subset X$ of x, and an étale morphism of S-schemes $\varphi : U \to \mathbb{A}^n_S$ ([66, Ch.IV, Cor.17.11.4]). Let $\overline{x}' := \varphi(\overline{x})$; there follows an isomorphism of S-schemes : $X(\overline{x}) \stackrel{\sim}{\to} \mathbb{A}^n_S(\overline{x}')$, hence we may assume from start that $X = \mathbb{A}^n_S$, and f is the natural projection. Especially, the theorem holds for $n = 0$. Suppose then, that $n > 0$, and that the theorem is already known when the relative dimension is $< n$. Write $f = h \circ g$, where

$$g : X \simeq \mathbb{A}^{n-1}_S \times_S \mathbb{A}^1_S \to \mathbb{A}^1_S \qquad \text{and} \qquad h : \mathbb{A}^1_S \to S$$

are the natural projections; set $\overline{x}_1 := g(\overline{x})$, and $U_1 := h^{-1}_{\overline{x}_1}U$, (where $h_{\overline{x}_1} : S_1 := \mathbb{A}^1_S(\overline{x}_1) \to S$ is the morphism induced by h). We have $S_1\backslash U_1 = h^{-1}_{\overline{x}_1}(S\backslash U)$, and since flat maps are generizing ([126, Th.9.5]) we easily see that the codimension of $S_1\backslash U_1$ in S_1 equals the codimension of $S\backslash U$ in S. From our inductive assumption, we deduce that the base change functor $\mathsf{Cov}(U_1) \to \mathsf{Cov}(f^{-1}_{\overline{x}}U)$ is essentially surjective, and hence it suffices to show that the same holds for the functor $\mathsf{Cov}(U) \to \mathsf{Cov}(U_1)$. Thus, we are reduced to the case where $X = \mathbb{A}^1_S$. Suppose now, that $E \to f^{-1}_{\overline{x}}U$ is a finite étale morphism; we can write $f_{\overline{x}}$ as the limit of a cofiltered family of smooth morphisms $(f_\lambda : Y_\lambda \to S \mid \lambda \in \Lambda)$, where each Y_λ is an affine étale $\mathbb{A}^1_S$-scheme. Then $f^{-1}_{\overline{x}}U$ is the limit of the family $(Y_\lambda \times_S U \mid \lambda \in \Lambda)$. By [65, Ch.IV, Th.8.8.2(ii), Th.8.10.5] and [66, Ch.IV, Prop.17.7.8], we may find a $\lambda \in \Lambda$, a finite étale morphism $E_\lambda \to Y_\lambda \times_S U$ and an isomorphism of $f^{-1}_{\overline{x}}U$-schemes : $E_\lambda \times_{Y_\lambda} \mathbb{A}^1_S(\overline{x}) \stackrel{\sim}{\to} E$. Denote by $y \in Y_\lambda$ the image of the closed point of $\mathbb{A}^1_S(\overline{x})$, and by $\overline{y}$ the geometric point of Y_λ obtained as the image of $\overline{x}$ (the latter is viewed naturally as a geometric point of $\mathbb{A}^1_S(\overline{x})$); by construction, y lies in the closed fibre $Y_0 := Y_\lambda \times_S \mathrm{Spec}\,\kappa(s)$, which is an étale $\mathbb{A}^1_{\kappa(s)}$-scheme, and we may therefore find a specialization $z \in Y_0$ of y, with z a closed point. Pick a geometric point $\overline{z}$ of Y_0 localized at z, and a strict specialization map $Y_\lambda(\overline{z}) \to Y_\lambda(\overline{y})$ as in (4.9.23); there follows a commutative diagram :

$$\begin{array}{ccc} \mathbb{A}^1_S(\overline{x}) \simeq Y_\lambda(\overline{y}) & \longrightarrow & Y_\lambda(\overline{z}) \\ \downarrow & & \downarrow \\ Y_\lambda(y) & \longrightarrow & Y_\lambda(z). \end{array}$$

The finite étale covering $E_\lambda \times_{Y_\lambda} Y_\lambda(y) \to Y_\lambda(y) \times_S U$ lies in the essential image of the functor

$$\mathsf{Cov}(Y_\lambda(z) \times_S U) \to \mathsf{Cov}(Y_\lambda(y) \times_S U) \qquad C \mapsto C \times_{Y_\lambda(z)} Y_\lambda(y).$$

It follows that $E \to f_{\overline{x}}^{-1}U$ lies in the essential image of the functor

$$\mathsf{Cov}(f^{-1}_{\lambda,\overline{z}}U) \to \mathsf{Cov}(f^{-1}_{\overline{x}}U) \qquad C \mapsto C \times_{Y(\overline{z})} Y(\overline{y}) \simeq C \times_{Y(\overline{z})} \mathbb{A}^1_S(\overline{x})$$

and therefore it suffices to show that the pull-back functor $\mathsf{Cov}(U) \to \mathsf{Cov}(f_{\overline{z}}^{-1}U)$ is essentially surjective. In other words, we may replace x by z, and assume throughout that x is a closed point of $\mathbb{A}^1_S$.

Claim 13.2.3. Under the current assumptions, we may find a strictly local normal scheme T, with closed point t, a finite surjective morphism $g : T \to S$, and a finite morphism of $\mathrm{Spec}\,\kappa(s)$-schemes :

$$\mathrm{Spec}\,\kappa(t) \to \mathrm{Spec}\,\kappa(x).$$

Proof of the claim. Since $\kappa(x)$ is a finite extension of $\kappa(s)$, it is generated by finitely many algebraic elements $u_1, \dots u_n$, and an easy induction allows to assume that $n = 1$. In this case, one constructs first a scheme T' by taking any lifting of the minimal polynomial of u_1 : for the details, see e.g. [61, Ch.0, (10.3.1.2.)], which shows that the resulting T is local, finite and flat over S, so T' maps surjectively onto S. Next, we may replace T' by its maximal reduced subscheme, which is still strictly local and finite over S. Next, since S is excellent, the normalization $(T')^\nu$ of T' is finite over S ([64, Ch.IV, Scholie 7.8.3(vi)]); let T be any irreducible component of $(T')^\nu$; by [66, Ch.IV, Prop.18.8.10], T fulfills all the sought conditions. ◊

Choose $g : T \to S$ as in claim 13.2.3; since the residue field extension $\kappa(s) \to \kappa(t)$ is algebraic and purely inseparable, there exists a unique point $x' \in \mathbb{A}^1_S(\overline{x}) \times_S T$ lying over t, and we may find a unique strict geometric point $\overline{x}'$ of $\mathbb{A}^1_S(\overline{x}) \times_S T$ localized at x', and lying over $\overline{x}$. In view of [66, Ch.IV, Prop.18.8.10], there follows a natural isomorphism of T-schemes :

$$\mathbb{A}^1_S(\overline{x}) \times_S T \xrightarrow{\sim} \mathbb{A}^1_T(\overline{x}').$$

Denote by $f_{\overline{x}'} := f_{\overline{x}} \times_S T : \mathbb{A}^1_T(\overline{x}') \to T$ the natural projection, and set $U_T := g^{-1}U$; since the morphism $g : T \to S$ is generizing ([126, Th.9.4(ii)]), it is easily seen that $T \setminus U_T$ has codimension ≥ 2 in T.

Let $F : \mathsf{Cov} \to \mathbf{Sch}$ be the fibred category (13.1.1). We have a natural essentially commutative diagram of categories :

$$\begin{array}{ccc} \mathsf{Cov}(U) & \longrightarrow & \mathsf{Desc}(F, g \times_S U) \\ \downarrow & & \downarrow \delta \\ \mathsf{Cov}(f^{-1}_{\overline{x}}U) & \longrightarrow & \mathsf{Desc}(F, g \times_S f^{-1}_{\overline{x}}U) \end{array} \tag{13.2.4}$$

where, for any morphism of schemes h, we have denoted by $\mathsf{Desc}(F, h)$ the category of descent data for the fibred category F, relative to the morphism h.

According to lemma 13.1.2, the morphism g is of universal 2-descent for the fibred category F, so the horizontal arrows in (13.2.4) are equivalences. Hence, the theorem will follow, once we know that δ is essentially surjective. However, we have :

Claim 13.2.5. (i) Set $U'_T := U_T \times_S T$ and $U''_T := U'_T \times_S T$. The pull-back functors :

$$\mathsf{Cov}(U'_T) \to \mathsf{Cov}(\mathbb{A}^1_T(\overline{x}') \times_T U'_T) \qquad \mathsf{Cov}(U''_T) \to \mathsf{Cov}(\mathbb{A}^1_T(\overline{x}') \times_T U''_T)$$

are fully faithful.

(ii) Suppose that the pull-back functor

$$\mathsf{Cov}(U_T) \to \mathsf{Cov}(f^{-1}_{\overline{x}'} U_T)$$

is essentially surjective. Then the same holds for the functor δ.

Proof of the claim. (i): Let $\overline{z}''$ be any geometric point of $X'' := \mathbb{A}^1_T \times_S T \times_S T$ whose strict image in $\mathbb{A}^1_T$ is $\overline{x}'$, and let $\overline{z}'$ be the image of $\overline{z}''$ in $X' := \mathbb{A}^1_T \times_S T$; by lemma 13.1.22(ii), the natural morphisms :

$$X'(\overline{z}') \to \mathbb{A}^1_T(\overline{x}') \times_S T \qquad X''(\overline{z}'') \to \mathbb{A}^1(\overline{x}') \times_S T \times_S T$$

are isomorphisms (notice that $T \times_S T$ is also strictly local). Then the claim follows from assertion (i) of the theorem, applied to the projections $X' \to T \times_S T$ and $X'' \to T \times_S T \times_S T$.

(ii): Recall that an object of $\mathsf{Desc}(F, g \times_S f^{-1}_{\overline{x}'} U)$ consists of a finite étale morphism $E'_T \to f^{-1}_{\overline{x}'} U_T$ and a X'-isomorphism $\beta' : E'_T \times_S T \xrightarrow{\sim} T \times_S E'_T$ fulfilling a cocycle condition on $E \times_S T \times_S T$. By assumption, E_T descends to a finite étale morphism $E_T \to U_T$; then (i) implies that β' descends to a U'_T-isomorphism $\beta : E_T \times_S T \xrightarrow{\sim} T \times_S E_T$, and the cocycle identity for β' descends to a cocycle identity for β. ◊

In view of claim 13.2.5, we may replace (S, U, x) by (T, U_T, x'), and therefore assume that x is a $\kappa(s)$-rational point of $\mathbb{A}^1_{\kappa(s)}$. In this case, any choice of coordinate t on $\mathbb{A}^1_S$ yields a section $\sigma_{\overline{x}} : S \to \mathbb{A}^1_S(\overline{x})$ of the natural projection, such that $\sigma_{\overline{x}}(s) = x$. To conclude the proof of the theorem, it suffices to show that the pull-back functor :

$$\mathsf{Cov}(f^{-1}_{\overline{x}} U) \xrightarrow{\sigma^*_{\overline{x}}} \mathsf{Cov}(U)$$

is fully faithful.

Say that $S = \operatorname{Spec} A$; then the scheme $\mathbb{A}^1_S(\overline{x})$ is the spectrum of $A\{t\}$, the henselization of $A[t]$ along the ideal $\mathfrak{m}\{t\}$ generated by t and the maximal ideal $\mathfrak{m}$ of A. Let $A^\wedge$ (resp. $A\{t\}^\wedge$) be the $\mathfrak{m}$-adic (resp. $\mathfrak{m}\{t\}$-adic) completion of A (resp. of $A\{t\}$), and notice the natural isomorphism:

$$A\{t\}^\wedge / tA\{t\}^\wedge \xrightarrow{\sim} A^\wedge$$

(indeed, it is easy to check that $A\{t\}^\wedge \simeq A^\wedge[[t]]$), whence a natural diagram of schemes :

$$\begin{array}{ccc} X^\wedge := \operatorname{Spec} A\{t\}^\wedge & \xrightarrow{g'} & \operatorname{Spec} A\{t\} \\ {\scriptstyle \pi} \downarrow \uparrow {\scriptstyle \sigma} & & {\scriptstyle f_{\overline{x}}} \downarrow \uparrow {\scriptstyle \sigma_{\overline{x}}} \\ S^\wedge := \operatorname{Spec} A^\wedge & \xrightarrow{g} & \operatorname{Spec} A \end{array}$$

(where π is the natural projection) whose horizontal arrows commute with both the downward arrows and the upward ones. Set $U^\wedge := g^{-1} U$; by example 13.1.33(ii) and lemma 13.1.15(ii), the pull-back functors

$$g^* : \mathsf{Cov}(U) \to \mathsf{Cov}(U^\wedge) \qquad g'^* : \mathsf{Cov}(f^{-1}_{\overline{x}} U) \to \mathsf{Cov}(\pi^{-1} U^\wedge)$$

are fully faithful. Consequently, we are easily reduced to showing that the pull-back functor : $\mathsf{Cov}(\pi^{-1} U^\wedge) \xrightarrow{\sigma^*} \mathsf{Cov}(U^\wedge)$ is an equivalence. The latter holds by lemma 13.1.39(ii). □

Example 13.2.6. As an application of theorem 13.2.2, suppose that $K \subset E$ is an extension of separably closed fields, V_K a geometrically normal and strictly local K-scheme, $U \subset V_K$ an open subset, and ξ a geometric point of $V_E := V_K \times_K E$, whose image in V_K is supported on the closed point. Then the induced functor

$$\mathsf{Cov}(U) \to \mathsf{Cov}(U \times_{V_K} V_E(\xi))$$

is fully faithful, and it is an equivalence in case V_K is excellent and $V_K \setminus U$ has codimension ≥ 2 in V_K. Indeed, let K^{a} (resp. E^{a}) be an algebraic closure of K (resp. E), and choose a homomorphism $K^{\mathrm{a}} \to E^{\mathrm{a}}$ extending the inclusion of K into E. Then both $V_{K^{\mathrm{a}}} := V_K \times_K K^{\mathrm{a}}$ and $V_{E^{\mathrm{a}}}(\xi) := V_E(\xi) \times_E E^{\mathrm{a}}$ are still normal and strictly local (lemma 13.1.22(ii)), and the induced functors

$$\mathsf{Cov}(U) \to \mathsf{Cov}(U \times_K K^{\mathrm{a}}) \qquad \mathsf{Cov}(U \times_{V_K} V_E(\xi)) \to \mathsf{Cov}(U \times_{V_K} V_{E^{\mathrm{a}}}(\xi))$$

are equivalences (lemma 13.1.7(i)). It then suffices to show that the induced functor

$$\mathsf{Cov}(U \times_K K^{\mathrm{a}}) \to \mathsf{Cov}(U \times_{V_K} V_{E^{\mathrm{a}}}(\xi))$$

has the asserted properties. Hence, we may replace K by K^{a} and E by E^{a}, and assume from start that $K \subset E$ is an extension of algebraically closed fields. In this case, E can be written as the colimit of a filtered family $(R_\lambda \mid \lambda \in \Lambda)$ of smooth K-algebras; correspondingly, V_E is the limit of a cofiltered system $(V_\lambda \mid \lambda \in \Lambda)$ of smooth V_K-schemes, and – by lemma 13.1.6 – $\mathsf{Cov}(U \times_{V_K} V_E(\xi))$ is the 2-colimit of the system of categories

$$\mathsf{Cov}(U \times_{V_K} V_\lambda(\xi_\lambda)) \qquad (\lambda \in \Lambda)$$

(where, for each $\lambda \in \Lambda$, we denote by ξ_λ the image of ξ in V_λ). Now the contention follows directly from theorem 13.2.2.

Theorem 13.2.7. *Let $f : X \to S$ is a smooth morphism of schemes, $\mathbb{L} \subset \mathbb{N}$ be a set of primes, and suppose that all the elements of $\mathbb{L}$ are invertible in $\mathscr{O}_S$. Then f is 1-aspherical for $\mathbb{L}$.*

Proof. Let $\overline{x}$ be any geometric point of X, $\overline{s} := f(\overline{x})$, and $\overline{\eta}$ a strict geometric point of $S(\overline{s})$. To ease notation, set $T := X(\overline{x})$, let $f_{\overline{x}} : T \to S(\overline{s})$ be the natural map, and $T_{\overline{\eta}} := f_{\overline{x}}^{-1}(\overline{\eta})$; we have to show that $H^1(T_{\overline{\eta},\text{ét}}, G) = \{1\}$ for every $\mathbb{L}$-group G. Arguing as in the proof of proposition 13.1.30, we reduce to the case where $S = S(\overline{s})$. Then, by lemma 13.1.24, we can further assume that S is normal and $\overline{\eta}$ is localized at the generic point η of S. By lemma 13.1.29, S is the limit of a cofiltered system $(S_\lambda \mid \lambda \in \Lambda)$ of strictly local, normal and excellent schemes, with dominant transition maps, and as usual, after replacing Λ by a coinitial subset, we may assume that f (resp. $\overline{\eta}$) descends to a compatible system of morphisms $(f_\lambda : X_\lambda \to S_\lambda \mid \lambda \in \Lambda)$, (resp. of strict geometric points $\overline{\eta}_\lambda$ localized at the generic point of S_λ). By [66, Ch.IV, Prop.17.7.8(ii)], there exists $\lambda \in \Lambda$ such that f_μ is smooth for every $\mu \geq \lambda$. Then, in view of [9, Exp.VII, Rem.5.14] and the isomorphism (13.1.28), we may replace f by f_λ, and $\overline{\eta}$ by $\overline{\eta}_\lambda$, and assume from start that S is strictly local, normal and excellent, and G is a finite $\mathbb{L}$-group.

Let $(\varphi : E_{\overline{\eta}} \to T_{\overline{\eta}}, \rho : G \to \mathrm{Aut}_{T_{\overline{\eta}}}(E_{\overline{\eta}}))$ be a principal G-homogeneous space; we come down to showing that $E_{\overline{\eta}}$ has a section $T_{\overline{\eta}} \to E_{\overline{\eta}}$. By [66, Ch.IV, Prop.17.7.8(ii)] and [65, Ch.IV, Th.8.8.2(ii), Th.8.10.5], we may find a finite separable extension $\kappa(\eta) \subset L$, and a principal G-homogeneous space

$$\varphi_L : E_L \to T_L := T \times_S \operatorname{Spec} L \qquad \rho_L : G \to \mathrm{Aut}_{T_L}(E_L)$$

such that

$$\varphi = \varphi_L \times_{\operatorname{Spec} L} \operatorname{Spec} \kappa(\overline{\eta}) \qquad \rho = \rho_L \times_{\operatorname{Spec} L} \operatorname{Spec} \kappa(\overline{\eta}).$$

Say that $S = \operatorname{Spec} A$, denote by A_L the normalization of A in L, and set $S_L := \operatorname{Spec} A_L$. Then S_L is again normal and excellent ([64, Ch.IV, (7.8.3)(ii,vi)]), and the residue field of A_L is an algebraic extension of the residue field of A, hence it is separably closed, so S_L is strictly local as well. Thus, we may replace S by S_L, and assume that $E_{\overline{\eta}}$ descends to a principal G-homogeneous space $E_\eta \to T_\eta := f_{\overline{x}}^{-1}(\eta)$ on T_η. Next, we may write η as the limit of the filtered system of affine open subsets of S, so that – by the same arguments – we find an affine open subset $U \subset S$ and a principal G-homogeneous space $E_U \to T_U := f_{\overline{x}}^{-1}U$, with a G-equivariant isomorphism of T_η-schemes : $E_U \times_{T_U} T_\eta \xrightarrow{\sim} E_\eta$. Denote by $D_1, \dots, D_n$ the irreducible components of $S \backslash U$ which have codimension one in S, and for every $i \leq n$, endow D_i with its reduced closed subscheme structure, and set $D'_i := D_i \times_S T$. Let also η_T be the generic point of T.

Claim 13.2.8. For given $i \leq n$, let y be the generic point of D_i. We have:

(i) T and E_U are noetherian normal schemes, and $T(y) := T \times_S S(y)$ is regular.
(ii) D'_i is an integral scheme of pure codimension one in T, and $D'(y) := D'_i \times_{D_i} D_i(y)$ is regular (and irreducible).
(iii) Let also $z \in D'_i$ be the generic point, and $\mathfrak{m}_y$ (resp. $\mathfrak{m}_z$) the maximal ideal of $\mathscr{O}_{S,y}$ (resp. of $\mathscr{O}_{T,z}$); then $\mathscr{O}_{S,y}$ and $\mathscr{O}_{T,z}$ are discrete valuation rings, and $\mathfrak{m}_y \cdot \mathscr{O}_{T,z} = \mathfrak{m}_z$.
(iv) Let $t \in A$ be any element such that $t \cdot \mathscr{O}_{S,y} = \mathfrak{m}_y$. Then there exist an integer $m > 0$ such that $(m, \mathrm{char}\,\kappa(s)) = 1$, a finite étale covering

$$E_y \to T(y)[t^{1/m}] := T(y) \times_S \mathrm{Spec}\,A[T]/(T^m - t)$$

and an isomorphism of $T(y)[t^{1/m}] \times_T T_U$-schemes :

$$E_y \times_T T_U \xrightarrow{\sim} E_U \times_T T(y)[t^{1/m}].$$

Proof of the claim. (i): Since S is normal by assumption, the assertion for T and E_U follows from [66, Ch.IV, Prop.17.5.7, Prop.18.8.12(i), Prop.18.8.8(iv)]. Let $u \in T(y)$ be any point; denote by $w \in X$ the image of u. Since $\mathscr{O}_{S,y}$ is a discrete valuation ring, $\mathscr{O}_{X,w}$ is a regular local ring ([66, Ch.IV, Prop.17.5.8(iii)]); moreover, the natural map $\mathscr{O}_{X,w} \to \mathscr{O}_{T(y),u}$ induces isomorphisms on strict henselizations, therefore $\mathscr{O}_{T(y),u}$ is regular ([66, Ch.IV, Prop.18.8.13]).

(ii): By virtue of proposition 13.1.30(ii), the geometric generic fibre of the induced morphism $D'_i \to D_i$ is connected, hence the same holds for its generic fibre. But arguing as in the proof of (i), we see that this generic fibre is noetherian and regular, so it is irreducible and reduced. Since moreover the morphism $D'_i \to D_i$ is flat, it follows easily that D'_i is irreducible and reduced as well. Lastly, D'_i is of pure codimension one in T, by virtue of [64, Ch.IV, Cor.6.1.4].

(iii): From (i) and (ii) we see that $\mathscr{O}_{S,y}$ and $\mathscr{O}_{T,z}$ are discrete valuation rings; since moreover D'_i is reduced, the same holds for $\mathscr{O}_{T,z}/\mathfrak{m}_y\mathscr{O}_{T,z}$, so $\mathfrak{m}_y \cdot \mathscr{O}_{T,z} = \mathfrak{m}_z$.

(iv): By (iii) we have $t \cdot \mathscr{O}_{T,z} = \mathfrak{m}_z$. Notice that $T(z) \times_T T_U = T(\eta_T)$, and $E_{\eta_T} := E_U \times_T T(z)$ is a disjoint union of spectra of finite separable extensions $L_1, \dots, L_k$ of $\kappa(\eta_T)$. Moreover, E_{η_T} is a principal G-homogeneous space over $T(\eta_T)$, *i.e.* every L_j is a Galois extension of $\kappa(\eta_T)$, with Galois group $G_j := \mathrm{Gal}(L_j/\kappa(\eta_T)) \subset G$. Since G is an $\mathbb{L}$-group, the same holds for G_j, hence $E_U \times_T T(y)$ is tamely ramified along the divisor $\overline{\{z\}}$ (the topological closure of $\{z\}$ in $T(y)$), and the assertion follows from Abhyankar's lemma [82, Exp.XIII, Prop.5.2]. ◊

Claim 13.2.9. There exist :

(a) a finite dominant morphism $S' \to S$, such that both S' and $T' := T \times_S S'$ are strictly local and normal;
(b) an open subset $U' \subset S'$, such that $S' \backslash U'$ has codimension ≥ 2 in S';
(c) a finite étale morphism $E' \to T'_{U'} := T \times_S U'$, with an isomorphism of $T'_{U'}$-schemes :

$$E' \times_T T_\eta \simeq E_\eta \times_T T'_{U'}.$$

Proof of the claim. For every $i \leq n$, let y_i be the maximal point of D_i, and choose $t_i \in A$ whose image in $\mathscr{O}_{S,y_i}$ generates the maximal ideal. Choose also $m_i \in \mathbb{N}$ with $(m_i, \mathrm{char}\,\kappa(s)) = 1$

and such that there exists a finite étale covering $E_i \to T(y_i)[t_i^{1/m_i}]$ extending the étale covering $E_U \times_T T(y_i)[t_i^{1/m_i}]$ (claim 13.2.8(iv)). Fix an algebraic closure K of $\mathrm{Frac}\, A$, pick for each $i = 1, \dots, n$ an m_i-th root τ_i of t_i in K, and let S' be the normalization of $\mathrm{Spec}\, A[\tau_1, \dots, \tau_n]$. Then S' is finite over S, hence it is excellent ([64, Ch.IV, (7.8.3)(ii,vi)]), and strictly local (cp. the proof of lemma 13.1.24). Set $E'_\eta := E_\eta \times_S S'$, $T' := T \times_S S'$; since the geometric fibres of $f_{\overline{x}}$ are connected (proposition 13.1.30(ii)), the same holds for the geometric fibres of the induced morphism $T' \to S'$, therefore T' is connected, and then it is also strictly local, by the usual arguments. Notice also that T' is the limit of a cofiltered family of smooth S'-schemes, hence it is reduced and normal ([66, Ch.IV, Prop.17.5.7]). Say that $E'_\eta = \mathrm{Spec}\, C$, $T = \mathrm{Spec}\, B$, $T' = \mathrm{Spec}\, B'$, and let C' be the integral closure of B' in C. Notice that $C \otimes_B \kappa(\eta_T)$ is a finite product of finite separable extensions of the field $B' \otimes_B \kappa(\eta_T)$, and consequently the natural morphism $\varphi' : E_{T'} := \mathrm{Spec}\, C' \to T'$ is finite ([126, §33, Lemma 1]). Define :

$$U' := \{y \in S' \mid \varphi' \times_{S'} S'(y) : E_{T'}(y) \to T'(y) \text{ is étale}\}.$$

Let now $y \in U'$ any point; then $S'(y)$ is the limit of the cofiltered family $(U_\lambda \mid \lambda \in \Lambda)$ of affine open neighborhoods of y in S', and $\varphi' \times_{S'} S'(y)$ the limit of the system of morphisms $(\varphi'_\lambda := \varphi' \times_{S'} U_\lambda \mid \lambda \in \Lambda)$; we may then find $\lambda \in \Lambda$ such that φ'_λ is étale ([66, Ch.IV, Prop.17.7.8(ii)]), hence $U_\lambda \subset U'$, which shows that U' is open. Furthermore, from [66, Ch.IV, Prop.17.5.7] it follows that $E_U \times_T T'$ is normal, whence an isomorphism of T'-schemes :

$$E_{T'} \times_S U \simeq E_U \times_T T'$$

(cp. the proof of lemma 13.1.7(iii)) especially, $U \times_S S' \subset U'$. Likewise, by construction we have natural morphisms : $T'(y_i) \to T(y_i)[t_i^{1/m_i}]$, and using the fact that all the schemes in view are normal we deduce isomorphisms of $T'(y_i)$-schemes :

$$E_{T'}(y_i) \xrightarrow{\sim} E_i \times_{T(y_i)[t_i^{1/m_i}]} T'(y_i).$$

Thus, U' contains all the points of S' of codimension ≤ 1, since the image in S of any such point lies in $U \cup \{y_1, \dots, y_n\}$. The morphism $E' := E_{T'} \times_{S'} U' \to T'_{U'}$ fulfills conditions (a)-(c). $\diamondsuit$

Now, choose $S' \to S$, $U' \subset S'$, and $E' \to T'_{U'}$ as in claim 13.2.9; since the corresponding T' is local, there exists a unique point $x' \in X' := X \times_S S'$ lying over x; pick a geometric point $\overline{x}'$ of X' localized at x', and lying over $\overline{x}$; it then follows from [66, Ch.IV, Prop.18.8.10] that the natural morphism $X'(\overline{x}') \to T'$ is an isomorphism. In such situation, theorem 13.2.2 says that there exists a finite étale covering $E \to U'$ with an isomorphism of $T'_{U'}$-schemes : $E \times_{U'} T'_{U'} \xrightarrow{\sim} E'$, whence an isomorphism of $T_{\overline{\eta}}$-schemes :

$$E_{\overline{\eta}} \simeq E(\overline{\eta}) \times_{\mathrm{Spec}\, \kappa(\overline{\eta})} T_{\overline{\eta}}.$$

Since $\kappa(\overline{\eta})$ is separably closed, the étale morphism $E(\overline{\eta}) \to \mathrm{Spec}\, \kappa(\overline{\eta})$ admits a section, hence the same holds for φ, as claimed. $\square$

13.2.10. Let $f : X \to S$ be a morphism of schemes, and $j : U \subset X$ an open immersion, and set $U_\eta := U \cap f^{-1}(\eta)$ for every $\eta \in S_{\max}$, where $S_{\max} \subset S$ denotes the subset of all maximal points of S. We deduce a natural essentially commutative diagram of functors :

$$\mathscr{D}(S,f,U) \quad : \quad \begin{array}{ccc} \mathsf{Cov}(X) & \xrightarrow{\quad j^* \quad} & \mathsf{Cov}(U) \\ {\scriptstyle \prod_\eta \iota^*_\eta}\downarrow & & \downarrow{\scriptstyle \prod_\eta \iota^*_{\eta|U}} \\ \prod_{\eta \in S_{\max}} \mathsf{Cov}(f^{-1}\eta) & \xrightarrow{\prod_\eta j^*_\eta} & \prod_{\eta \in S_{\max}} \mathsf{Cov}(U_\eta) \end{array}$$

where $j_\eta : U_\eta \to f^{-1}(\eta)$ is the restriction of j and $\iota_\eta : f^{-1}(\eta) \to X$ is the natural immersion. Let us say that $U \subset X$ is *fibrewise dense*, if $f^{-1}(s) \cap U$ is dense in $f^{-1}(s)$, for every $s \in S$. Then we have :

Theorem 13.2.11. *In the situation of* (13.2.10)*, suppose that f is smooth, and U is fibrewise dense. The following holds :*

(i) *The restriction functor j^* is fully faithful.*
(ii) *The diagram $\mathscr{D}(S, f, U)$ is 2-cartesian.*
(iii) *If furthermore, $f^{-1}S_{\max} \subset U$, then j^* is an equivalence.*

Proof. Assertion (ii) means that the functors j^* and ι_η^* induce an equivalence $(j, \iota_\bullet)^*$ from $\mathsf{Cov}(X)$ to the category $\mathscr{C}(X, U)$ of data

(13.2.12) $$\underline{E} := (\varphi, (\psi_\eta, \alpha_\eta \mid \eta \in S_{\max}))$$

where φ (resp. ψ_η) is an object of $\mathsf{Cov}(U)$ (resp. of $\mathsf{Cov}(f^{-1}\eta)$, for every $\eta \in S_{\max}$), and $\alpha_\eta : \varphi \times_U \operatorname{Spec} \kappa(\eta) \xrightarrow{\sim} \psi_\eta \times_{f^{-1}\eta} U_\eta$ is an isomorphism of U-schemes, for every $\eta \in S_{\max}$ (see example 3.3.12(ii)). On the basis of this description, it is easily seen that (i),(ii)⇒(iii). Furthermore, we remark :

Claim 13.2.13. (i) If j^* is fully faithful, then the same holds for $(j, \iota_\bullet)^*$.

(ii) For every open subset $U' \subset X$ containing U, suppose that :
 (a) The pull-back functor $\mathsf{Cov}(U') \to \mathsf{Cov}(U)$ is fully faithful.
 (b) If $f^{-1}S_{\max} \subset U'$, the pull-back functor $\mathsf{Cov}(X) \to \mathsf{Cov}(U')$ is an equivalence.
Then assertion (ii) holds.

Proof of the claim. (i): Since $f^{-1}\eta$ is a normal (even regular) scheme ([66, Ch.IV, Prop.17.5.7]), the pull-back functors ι_η^* are fully faithful (lemma 13.1.7(iii)); the assertion is an immediate consequence.

(ii): In light of (i), it remains only to check that $(j, \iota_\bullet)^*$ is essentially surjective. Thus, let $\varphi : E \to U$ be a finite étale morphism, such that $i_\eta^* \varphi$ extends to a finite étale morphism $\varphi'_\eta : E'_\eta \to f^{-1}(\eta)$, for every maximal point $\eta \in S$. By claim 13.1.8, there is a largest open subset $U_{\max}$ containing U, over which φ extends to a finite étale morphism $\varphi_{\max}$. To conclude, we have to show that $U_{\max} = X$. However, for any maximal point η, let $i_\eta : f^{-1}(\eta) \to X(\eta)$ be the natural closed immersion. By lemma 13.1.7(i), i_η^* is an equivalence, hence we may find a finite étale morphism $\varphi'_{(\eta)} : E'(\eta) \to X(\eta)$ such that $i_\eta^* \varphi'_{(\eta)} \simeq \varphi'_\eta$. By the same token, we also see that $E'(\eta) \times_{X(\eta)} U(\eta)$ is $U(\eta)$-isomorphic to $E \times_U U(\eta)$.

Next, $S(\eta)$ is the limit of the filtered system $\mathscr{V}$ of all open subsets $V \subset S$ with $\eta \in V$, hence lemma 13.1.6 ensures that we may find $V \in \mathscr{V}$ and an object $\varphi'_V : E'_V \to f^{-1}V$ of $\mathsf{Cov}(f^{-1}V)$ such that $\varphi'_V \times_V S(\eta) \simeq \varphi'_{(\eta)}$, and after shrinking V, we may also assume (again by lemma 13.1.6) that $E'_V \times_X U$ is U-isomorphic to $E \times_S V$. Hence we may glue E' and E along the common intersection, to deduce a finite étale morphism $E' \to U' := U \cup f^{-1}V$ that extends φ. It follows that $f^{-1}(\eta) \subset f^{-1}V \subset U_{\max}$. Since η is arbitrary, (b) implies that the pull-back functor $\mathsf{Cov}(X) \to \mathsf{Cov}(U_{\max})$ is an equivalence, especially φ lies in the essential image of j^*, as claimed. ◊

Claim 13.2.14. (i) Suppose that S is noetherian and normal, and X is separated. Then (i) holds.

(ii) If furthermore, S is also excellent, then (ii) holds as well.

Proof of the claim. (i): Under the assumptions of the claim, X is normal and noetherian ([66, Ch.IV, Prop.17.5.7]), so (i) follows from lemma 13.1.7(iii), which also says – more generally – that assumption (a) of claim 13.2.13(ii) holds in this case, hence in order to show (ii) it suffices to check that assumption (b) of claim 13.2.13(ii) holds whenever $U \cup f^{-1}S_{\max} \subset U' \subset X$, especially $X\setminus U'$ has codimension ≥ 2 in X. Suppose first that S is regular; then the same holds for X ([66, Ch.IV, Prop.17.5.8]), and the contention follows from lemma 13.1.7(iv).

In the general case, let $S_{\mathrm{reg}} \subset S$ be the regular locus, which is open since S is excellent, and contains all the points of codimension ≤ 1, by Serre's normality criterion ([64, Ch.IV, Th.5.8.6]). Consider the restriction $f^{-1}S_{\mathrm{reg}} \to S_{\mathrm{reg}}$ of f, and the fibrewise dense open immersion $j_{\mathrm{reg}} : U' \cap f^{-1}S_{\mathrm{reg}} \subset f^{-1}S_{\mathrm{reg}}$; by the foregoing, the functor j^*_{reg} is an equivalence, hence we are easily reduced to showing that the functor $\mathsf{Cov}(X) \to \mathsf{Cov}(U' \cup f^{-1}S_{\mathrm{reg}})$ is an equivalence, *i.e.* we may assume that $V := f^{-1}S_{\mathrm{reg}} \subset U'$. Moreover, since the full faithfulness of j^* is already known, we only need to show that any finite étale morphism $\varphi : E \to U'$ extends to an object of $\mathsf{Cov}(X)$. To this aim, by lemma 13.1.7(iii), it suffices to prove that $\varphi \times_{U'} (X(\overline{x}) \times_X U')$ extends to an object of $\mathsf{Cov}(X(\overline{x}))$, for every geometric point $\overline{x}$ of X. Let $\overline{s} := f(\overline{x})$, and denote by $s \in S$ the support of $\overline{s}$; by assumption, we may find a geometric point ξ of $f^{-1}(s)$, whose support lies in $U' \cap f^{-1}(s)$, and a strict specialization morphism $X(\xi) \to X(\overline{x})$. There follows an essentially commutative diagram :

$$\begin{array}{ccccc} \mathsf{Cov}(X(\overline{x})) & \xrightarrow{\ \rho\ } & \mathsf{Cov}(X(\overline{x}) \times_X V) & \xleftarrow{\ \alpha\ } & \mathsf{Cov}(S(\overline{s}) \times_S S_{\mathrm{reg}}) \\ \downarrow{\scriptstyle \delta} & & \downarrow{\scriptstyle \gamma} & \swarrow{\scriptstyle \beta} & \\ \mathsf{Cov}(X(\xi)) & \xrightarrow{\ \tau\ } & \mathsf{Cov}(X(\xi) \times_X V) & & \end{array}$$

where α and β are both equivalences, by theorem 13.2.2(ii); hence γ is an equivalence as well. Moreover, both $\mathsf{Cov}(X(\overline{x}))$ and $\mathsf{Cov}(X(\xi))$ are equivalent to the category of finite sets, and δ is obviously an equivalence. By construction, $\gamma(\varphi \times_{U'} (X(\xi) \times_X V))$ lies in the essential image of τ, hence $\varphi \times_{U'} (X(\xi) \times_X V)$ lies in the essential image of ρ, so say it is isomorphic to $\rho(\varphi')$ for some object φ' of $\mathsf{Cov}(X(\overline{x}))$. Using (i) (and [66, Ch.IV, Prop.18.8.12]) one checks easily that $\varphi' \times_X U' \simeq \varphi \times_{U'} (X(\xi) \times_X U')$, whence the contention. $\Diamond$

Claim 13.2.15. Let $m \in \mathbb{N}$ be any integer. Assertions (i) and (ii) hold if S and X are affine schemes of finite type over $\mathrm{Spec}\,\mathbb{Z}$, the fibres of f have pure dimension m, and furthermore :

$$\dim f^{-1}(s)\setminus U < m \qquad \text{for every } s \in S. \tag{13.2.16}$$

Proof of the claim. Indeed, in this situation, S admits finitely many maximal points, hence the normalization morphism $S^\nu \to S$ is integral and surjective. Set :

$$S_2 := S^\nu \times_S S^\nu \qquad U_1 := U \times_S S^\nu \qquad U_2 := U \times_S S_2.$$

Let $\beta : X_1 := X \times_S S^\nu \to X$, $f_1 : X_1 \to S^\nu$ and $j_2 : U_2 \to X_2 := X \times_S S_2$ be the induced morphisms; clearly $f_1^{-1}(s')$ has pure dimension m for every $s' \in S^\nu$, and from (13.2.16) we deduce that $\dim f_1^{-1}(s') \setminus U_1 < m$, especially, U_1 is dense in every fibre of f_1; by the same token, U_2 is dense in X_2. Then j_2^* is faithful (lemma 13.1.7(ii)), and lemma 13.1.2 and corollary 3.5.30(ii) imply that j^* is fully faithful, provided the same holds for the functor $j_1^* : \mathsf{Cov}(X_1) \to \mathsf{Cov}(U_1)$. In other words, in order to prove assertion (i), we may replace (f, U) by (f_1, U_1), which allows to assume that S is an affine normal scheme, and then it suffices to invoke claim 13.2.14, to conclude.

Concerning assertion (ii) : by the foregoing, we already know that j^* is fully faithful, so the same holds for $(j, \iota_\bullet)^*$ (claim 13.2.13(i)). To show that $(j, \iota_\bullet)^*$ is essentially surjective, let $\underline{E}$ be an object as in (13.2.12) of the category $\mathscr{C}(X, U)$; the normalization morphism induces a bijection $S^\nu_{\max} \xrightarrow{\sim} S_{\max} : \eta^\nu \mapsto \eta$, and clearly $\kappa(\eta^\nu) = \kappa(\eta)$ for every $\eta \in S_{\max}$, whence a datum

$$\underline{E}^\nu := (\varphi_1 := \varphi \times_U U_1, (\psi_\eta, \alpha_\eta \mid \eta^\nu \in S^\nu_{\max}))$$

of the analogous category $\mathscr{C}(X_1, U_1)$; by claim 13.2.14(ii), we may find $\varphi'_1 \in \mathrm{Ob}(\mathsf{Cov}(X_1))$ and an isomorphism $\alpha : \varphi'_1 \times_{X_1} U_1 \xrightarrow{\sim} \varphi_1$. Let $U_3 := U_2 \times_U U_1$, and denote by $j_3 : U_3 \to$

$X_3 := X_2 \times_X X_1$ the natural open immersion; by the foregoing, we know already that both j_2^* and j_3^* are fully faithful; then corollary 3.5.30(iii) says that the natural essentially commutative diagram :

$$\begin{array}{ccc} \mathsf{Desc}(\mathsf{Cov}, \beta) & \longrightarrow & \mathsf{Desc}(\mathsf{Cov}, \beta \times_X U) \\ \downarrow & & \downarrow \\ \mathsf{Cov}(X_1) & \longrightarrow & \mathsf{Cov}(U_1) \end{array}$$

is 2-cartesian. Thus, let $\rho : \mathsf{Cov}(U) \to \mathsf{Desc}(\mathsf{Cov}, \beta \times_X U)$ be the functor defined in (3.5.22); it follows that the datum $(\varphi'_1, \rho(\varphi), \alpha)$ comes from a descent datum (φ'_1, ω) in $\mathsf{Desc}(\mathsf{Cov}, \beta)$. By lemma 13.1.2, the latter descends to an object φ' of $\mathsf{Cov}(X)$, and by construction we have $(j, \iota_\bullet)^*\varphi' = \underline{E}$, as required. ◊

Next, we consider assertions (i) and (ii) in case where both X and S are affine. We may find an affine open covering $X = V_0 \cup \cdots \cup V_n$ such that the fibres of $f_{|V_i} : V_i \to fV_i$ are of pure dimension i, for every $i = 0, \dots, n$ ([66, Ch.IV, Prop.17.10.2]). For $i = 0, \dots, n$, let $j_i : V_i \cap U \to V_i$ be the induced open immersion; we have natural equivalences of categories :

$$\mathsf{Cov}(X) \xrightarrow{\sim} \prod_{i=0}^{n} \mathsf{Cov}(V_i) \qquad \mathsf{Cov}(U) \xrightarrow{\sim} \prod_{i=0}^{n} \mathsf{Cov}(V_i \cap U)$$

which induce a natural identification : $j^* = j_0^* \times \cdots \times j_n^*$. It follows j^* is fully faithful if and only if the same holds for every j_i^*, and moreover $\mathscr{D}(S, f, U)$ decomposes as a product of n diagrams $\mathscr{D}(S, f_{|V_i}, U \cap V_i)$. Hence we may replace f by $f_{|V_m}$, for any $m \leq n$, after which we may also assume that all the fibres f have the same pure dimension m. In that case, notice that the assumption on U is equivalent to (13.2.16). Next, say that $X = \operatorname{Spec} A$, and let $I \subset A$ be an ideal such that $V(I) = X \backslash U$; we may write I as the union of the filtered family $(I_\lambda \mid \lambda \in \Lambda)$ of its finitely generated subideals. Set $U_\lambda := X \backslash V(I_\lambda)$ for every $\lambda \in \Lambda$; it follows that $U = \bigcup_{\lambda \in \Lambda} U_\lambda$. For every $\lambda \in \Lambda$, set

$$Z_\lambda := \{s \in S \mid \dim f^{-1}(s) \backslash U_\lambda < m\}.$$

Claim 13.2.17. (i) Z_λ is a constructible subset of S, for every $\lambda \in \Lambda$.

(ii) We have $Z_\lambda \subset Z_\mu$ whenever $\mu \geq \lambda$, and moreover $S = \bigcup_{\lambda \in \Lambda} Z_\lambda$.

Proof of the claim. (i): Let $V_\lambda := \{x \in X \mid \dim_x f^{-1}(f(x)) \setminus U_\lambda = m\}$; according to [65, Ch.IV, Prop.9.9.1], every V_λ is a constructible subset of X, hence $f(V_\lambda)$ is a constructible subset of S ([63, Ch.IV, Th.1.8.4]), so the same holds for $Z_\lambda = S \backslash f(V_\lambda)$.

(ii): Let $\mu, \lambda \in \Lambda$, such that $\mu \geq \lambda$; then it is clear that $f^{-1}(s) \backslash U_\lambda \subset f^{-1}(s) \backslash U_\mu$ for every $s \in S$; using (13.2.16), the claim follows easily. ◊

Claim 13.2.17 and [63, Ch.IV, Cor.1.9.9] imply that $Z_\lambda = S$ for every sufficiently large $\lambda \in \Lambda$. Hence, after replacing Λ by a cofinal subset, we may assume that all the open subsets U_λ are fibrewise dense. We have a natural essentially commutative diagram :

$$\begin{array}{ccc} \mathsf{Cov}(U) & \longrightarrow & 2\text{-}\lim\limits_{\lambda \in \Lambda} \mathsf{Cov}(U_\lambda) \\ \downarrow & & \downarrow \\ \prod_{\eta \in S_{\max}} \mathsf{Cov}(U_\eta) & \longrightarrow & \prod_{\eta \in S_{\max}} 2\text{-}\lim\limits_{\lambda \in \Lambda} \mathsf{Cov}(f^{-1}(\eta) \cap U_\lambda) \end{array}$$

whose horizontal arrows are equivalences (notation of definition 2.5.1(i)); it follows formally that j^* is fully faithful, provided the same holds for all the pull-back functors $\mathsf{Cov}(X) \to \mathsf{Cov}(U_\lambda)$, and likewise, $\mathscr{D}(S, f, U)$ is 2-cartesian, provided the same holds for all the diagrams

$\mathscr{D}(S, f, U_\lambda)$. Hence, we may replace U by U_λ, and assume that U is constructible, and (13.2.16) still holds.

Next, we may write S as the limit of a cofiltered family $(S_\lambda \mid \lambda \in \Lambda)$ of affine schemes of finite type over $\operatorname{Spec}\mathbb{Z}$, and f as the limit of a cofiltered family $f_\bullet := (f_\lambda : X_\lambda \to S_\lambda \in \Lambda)$ of affine finitely presented morphisms, such that :

- The natural morphism $g_\lambda : S \to S_\lambda$ is dominant for every $\lambda \in \Lambda$.
- f_λ is smooth for every $\lambda \in \Lambda$ ([66, Ch.IV, Prop.17.7.8(ii)]), and $f_\mu = f_\lambda \times_{S_\lambda} S_\mu$ whenever $\mu \geq \lambda$.

Furthermore, we may find $\lambda \in \Lambda$ such that $U = U_\lambda \times_{S_\lambda} S$ ([65, Ch.IV, Cor.8.2.11]), so that j is the limit of the cofiltered system of open immersions $(j_\mu : U_\mu := U_\lambda \times_{S_\lambda} S_\mu \to X_\lambda \mid \mu \geq \lambda)$, and after replacing Λ by a cofinal subset, we may assume that j_μ is defined for every $\mu \in \Lambda$. For every $\lambda \in \Lambda$ and $n \in \mathbb{N}$, let $X_{\lambda,n} \subset X_\lambda$ be the open and closed subset consisting of all $x \in X_\lambda$ such that $\dim_x f^{-1}f(x) = n$; clearly $f_\bullet$ restricts to a cofiltered family $f_{\bullet,m} := (f_{\lambda|X_{\lambda,m}} : X_{\lambda,m} \to S_\lambda \mid \lambda \in \Lambda)$, whose limit is again f. Hence we may replace X_λ by $X_{\lambda,m}$, and assume that the fibres of f_λ have pure dimension m, for every $\lambda \in \Lambda$. For every $\lambda \in \Lambda$, let :

$$Z'_\lambda := \{s \in S_\lambda \mid \dim f_\lambda^{-1}(s)\backslash U_\lambda = m\}.$$

and endow Z'_λ with its constructible topology $\mathscr{T}_\lambda$; since Z'_λ is a constructible subset of S_λ ([65, Ch.IV, Prop.9.9.1]), $(Z'_\lambda, \mathscr{T}_\lambda)$ is a compact topological space, and due to (13.2.16), we have :

$$\lim_{\lambda\in\Lambda} Z'_\lambda = \varnothing.$$

Then [41, Ch.I, §9, n.6, Prop.8] implies that $Z'_\lambda = \varnothing$ for every sufficiently large $\lambda \in \Lambda$. Set :

$$\mathsf{Cov}(X_\bullet) := 2\text{-}\underset{\mu\geq\lambda}{\operatorname{colim}}\, \mathsf{Cov}(X_\mu) \qquad \mathsf{Cov}(U_\bullet) := 2\text{-}\underset{\mu\geq\lambda}{\operatorname{colim}}\, \mathsf{Cov}(U_\mu).$$

(See definition 2.5.1(ii).) There follows an essentially commutative diagram of categories:

$$(13.2.18)\qquad \begin{array}{ccc} \mathsf{Cov}(X) & \longrightarrow & \mathsf{Cov}(X_\bullet) \\ {\scriptstyle j^*}\downarrow & & \downarrow{\scriptstyle j^*_\bullet} \\ \mathsf{Cov}(U) & \longrightarrow & \mathsf{Cov}(U_\bullet) \end{array}$$

where $j^*_\bullet$ is the 2-colimit of the system of pull-back functors $j^*_\mu : \mathsf{Cov}(X_\mu) \to \mathsf{Cov}(U_\mu)$. In light of lemma 13.1.6, the horizontal arrows of (13.2.18) are equivalences, so j^* will be fully faithful, provided the same holds for the functors j^*_μ, for every large enough $\mu \in \Lambda$.

Hence, in order to prove assertion (i) when X and S are affine, we may assume that S is of finite type over $\operatorname{Spec}\mathbb{Z}$, the fibres of f have pure dimension m, and (13.2.16) holds, which is the case covered by claim 13.2.15.

Concerning assertion (ii), since the morphism g_μ is dominant, for every $\eta' \in (S_\mu)_{\max}$ we may find $\eta \in S_{\max}$ such that $g_\mu(\eta) = \eta'$. Denote by :

$$h : f^{-1}\eta \to f_\mu^{-1}\eta' \qquad \text{and} \qquad j'_\mu : (U_\mu)_{\eta'} := U_\mu \cap f_\mu^{-1}\eta' \to f_\mu^{-1}\eta'$$

the natural morphisms. With this notation, we have the following :

Claim 13.2.19. The induced essentially commutative diagram :

$$\begin{array}{ccc} \mathsf{Cov}(f_\mu^{-1}\eta') & \xrightarrow{j'^*_\mu} & \mathsf{Cov}((U_\mu)_{\eta'}) \\ {\scriptstyle h^*}\downarrow & & \downarrow{\scriptstyle h^*_U} \\ \mathsf{Cov}(f^{-1}\eta) & \xrightarrow{j^*_\eta} & \mathsf{Cov}(U_\eta) \end{array}$$

is 2-cartesian.

Proof of the claim. The pair (h^*, j'^*_μ) induces a functor $(h, j'_\mu)^*$ from $\mathsf{Cov}(f_\mu^{-1}\eta')$ to the category of data of the form $(\varphi, \varphi', \alpha)$, where φ' (resp φ) is a finite étale covering of $(U_\mu)_{\eta'}$ (resp. of $f^{-1}\eta$) and $\alpha : \varphi \times_{f^{-1}\eta} U_\eta \xrightarrow{\sim} \varphi' \times_{\eta'} \eta$ is an isomorphism in $\mathsf{Cov}(U_\eta)$, and the contention is that $(h, j'_\mu)^*$ is an equivalence. The full faithfulness of the functors j'^*_μ and j^*_η (lemma 13.1.7(iii)) easily implies the full faithfulness of $(h, j'_\mu)^*$. To prove that $(h, j'_\mu)^*$ is essentially surjective, amounts to showing that if $\varphi' : E' \to (U_\mu)_{\eta'}$ is a finite étale morphism and

$$\varphi'' := \varphi' \times_{\eta'} \eta : E'' := E' \times_{\eta'} \eta \to U_\eta$$

extends to a finite étale morphism $\varphi : E \to f^{-1}\eta$, then φ' extends to a finite étale covering of $f_\mu^{-1}\eta'$. Now, let L be the maximal purely inseparable extension of $\kappa(\eta')$ contained in $\kappa(\eta)$. Since the induced morphism $\eta'' := \mathrm{Spec}\, L \to \mathrm{Spec}\, \kappa(\eta')$ is radicial, the base change functors

$$\mathsf{Cov}(f_\mu^{-1}\eta') \to \mathsf{Cov}((f_\mu^{-1}\eta') \times_{\eta'} \eta'') \qquad \mathsf{Cov}((U_\mu)_{\eta'}) \to \mathsf{Cov}((U_\mu)_{\eta'} \times_{\eta'} \eta'')$$

are equivalences (lemma 13.1.7(i)). Thus, we may replace η' by η'', and assume that the field extension $\kappa(\eta') \subset \kappa(\eta)$ is separable, hence the induced morphism $\mathrm{Spec}\, \kappa(\eta) \to \mathrm{Spec}\, \kappa(\eta')$ is regular ([34, Ch.VIII, §7, no.3, Cor.1]), and then the same holds for the morphism h ([64, Ch.IV, Prop.6.8.3(iii)]). Given φ' as above, set $\mathscr{A} := (j'_\mu \circ \varphi')_* \mathscr{O}_{E'}$; then $\mathscr{A}$ is a quasi-coherent $\mathscr{O}_{f_\mu^{-1}\eta'}$-algebra, and we may define the quasi-coherent $\mathscr{O}_{f_\mu^{-1}\eta'}$-algebra $\mathscr{B}$ as the integral closure of $\mathscr{O}_{f_\mu^{-1}\eta'}$ in $\mathscr{A}$. By [64, Ch.IV, Prop.6.14.1], $h^*\mathscr{B}$ is the integral closure of $\mathscr{O}_{f^{-1}\eta}$ in $h^*\mathscr{A} = j_{\eta *} \circ h^*_U(\varphi''_* \mathscr{O}_{E''}) = j_{\eta *}(\varphi_* \mathscr{O}_E)$. By proposition 9.8.3, it then follows that $h^*\mathscr{B} = \varphi^* \mathscr{O}_E$, therefore $\mathscr{B}$ is a finite étale $\mathscr{O}_{f_\mu^{-1}\eta'}$-algebra ([66, Ch.IV, Prop.17.7.3(ii)] and [64, Ch.IV, Prop.2.7.1]). The claim follows. ◊

By the foregoing, we already know that j^* is fully faithful, hence the same holds for $(j, \iota_\bullet)^*$ (claim 13.2.13(i)). To show that $(j, \iota_\bullet)^*$ is essentially surjective, consider any $\underline{E}$ as in (13.2.12); we may find $\mu \in \Lambda$, and a finite étale morphism $\varphi' : E_\mu \to U_\mu$ such that $\varphi = \varphi' \times_{U_\mu} U$, whence objects $\varphi'_{\eta'} := \varphi' \times_{U_\mu} (U_\mu)_{\eta'}$ in $\mathsf{Cov}((U_\mu)_{\eta'})$, for every $\eta' \in (S_\mu)_{\max}$. By construction, we have $\varphi'_{\eta'} \times_{\eta'} \eta \simeq \psi_\eta \times_{f^{-1}\eta} U_\eta$ for every $\eta' \in (S_\mu)_{\max}$ and every $\eta \in S_{\max}$ such that $g_\mu(\eta) = \eta'$. Then claim 13.2.19 shows that, for every $\eta' \in (S_\mu)_{\max}$ there exists an object $\psi'_{\eta'}$ of $\mathsf{Cov}(f_\mu^{-1}\eta')$ with isomorphisms :

$$\psi'_{\eta'} \times_{f_\mu^{-1}\eta'} f^{-1}\eta \simeq \psi_\eta \qquad \alpha_{\eta'} : \psi'_{\eta'} \times_{f_\mu^{-1}\eta'} (U_\mu)_{\eta'} \xrightarrow{\sim} \varphi'_{\eta'}.$$

Therefore, the datum $\underline{E}_\mu := (\varphi', (\psi'_{\eta'}, \alpha'_{\eta'} \mid \eta' \in (S_\mu)_{\max}))$ is an object of the 2-limit of the diagram of categories

$$\mathsf{Cov}(U_\mu) \xleftarrow{j^*_\mu} \mathsf{Cov}(X_\mu) \xrightarrow{\prod_{\eta'} \iota^*_{\eta'}} \prod_{\eta' \in (S_\mu)_{\max}} \mathsf{Cov}(f_\mu^{-1}\eta')$$

(where $\iota_{\eta'} : f_\mu^{-1}\eta' \to X_\mu$ is the natural immersion, for every $\eta' \in (S_\mu)_{\max}$). By claim 13.2.15, the datum $\underline{E}_\mu$ comes from an object φ_μ of $\mathsf{Cov}(X_\mu)$. Let φ'' be the image of φ'_μ in $\mathsf{Cov}(X)$; by construction we have $(j, \iota_\bullet)^*\varphi'' = \underline{E}$, as required.

This conclude the proof of (i) and (ii), in case X and S are affine. To deal with the general case, let $X = \bigcup_{i \in I} V_i$ be a covering consisting of affine open subschemes, and for every $i \in I$, let $fV_i = \bigcup_{\lambda \in \Lambda_i} S_{i\lambda}$ be an affine open covering of the open subscheme $fV_i \subset S$; set also $V_{i\lambda} := V_i \cap f^{-1}S_{i\lambda}$ for every $i \in I$ and $\lambda \in \Lambda_i$. The restrictions $f_{|V_{i\lambda}} : V_{i\lambda} \to S_{i\lambda}$ are smooth morphisms; moreover, the image of the open immersion

$$j_{i\lambda} := j_{|U \cap V_{i\lambda}} : U \cap V_{i\lambda} \to V_{i\lambda}$$

is dense in every fibre of $f_{|V_i}$. The induced morphism

$$\beta : X' := \coprod_{i \in I} \coprod_{\lambda \in \Lambda_i} V_{i\lambda} \to X \qquad (13.2.20)$$

is faithfully flat, hence of universal 2-descent for (13.1.1); moreover, it is easily seen that $X'' := X' \times_X X'$ is separated, and $j'' := j \times_X X''$ is a dense open immersion, hence j''^* is faithful (lemma 13.1.7(ii)). Then, by corollary 3.5.30(ii), j^* is fully faithful, provided the pull-back functor $\mathsf{Cov}(X') \to \mathsf{Cov}(X' \times_X U)$ is fully faithful, *i.e.* provided the same holds for the functors $j^*_{i\lambda} : \mathsf{Cov}(V_{i\lambda}) \to \mathsf{Cov}(V_{i\lambda} \cap U)$. However, each $V_{i\lambda}$ is affine ([59, Ch.I, Prop.5.5.10]), hence assertion (i) is already known for the morphisms $f_{|V_{i\lambda}}$ and the open subsets $U \cap V_{i\lambda}$; this concludes the proof of (i).

To show (ii), we use the criterion of claim 13.2.13(ii) : indeed, assumption (a) is already known, hence we are reduced to showing that assertion (iii) holds. To this aim, we consider again the morphism β of (13.2.20), and denote by $f'' : X'' \to S$ the induced morphism. Clearly f'' is smooth, and j'' is an open immersion, such that $f''^{-1}(s) \times_X U$ is dense in $f''^{-1}(s)$, for every $s \in S$; then assertion (i) implies that j''^* is fully faithful. Moreover it is easily seen that $X''' := X'' \times_X X'$ is separated, and $j \times_X X'''$ is a dense open immersion, so j'''^* is faithful (lemma 13.1.7(ii)), and therefore corollary 3.5.30(ii) reduces to showing that the pull-back functor $\mathsf{Cov}(X') \to \mathsf{Cov}(X' \times_X U)$ is an equivalence, or – what is the same – that this holds for the pull-back functors $j^*_{i\lambda}$, which is already known. □

13.2.21. We consider now the local counterpart of theorem 13.2.11. Namely, suppose that $f : X \to S$ is a smooth morphism, let $\overline{x}$ be any geometric point of X, set $\overline{s} := f(\overline{x})$, and let $s \in S$ be the support of $\overline{s}$. Then f induces the morphism $f_{\overline{x}} : X(\overline{x}) \to S(\overline{s})$, and the latter has geometrically irreducible fibres by proposition 13.1.30(iii). For every open immersion $j : U \to X(\overline{x})$, we may consider the diagram $\mathscr{D}(S(\overline{x}), f_{\overline{x}}, U)$ as in (13.2.10).

Theorem 13.2.22. *In the situation of* (13.2.21)*, suppose that U contains the generic point of $f_{\overline{x}}^{-1}(s)$. Then :*

(i) $j^* : \mathsf{Cov}(X(\overline{x})) \to \mathsf{Cov}(U)$ *is fully faithful.*
(ii) *The diagram $\mathscr{D}(S(\overline{x}), f_{\overline{x}}, U)$ is 2-cartesian.*

Proof. (i): To begin with, since $f_{\overline{x}}$ is generizing ([126, Th.9.5]), and S is local, every fibre of $f_{\overline{x}}$ has a point that specializes to the generic point η_s of $f_{\overline{x}}^{-1}(s)$; since the fibres are irreducible, it follows that the generic point of every fibre specializes to η_s. Therefore U is fibrewise dense in $X(\overline{x})$, and moreover it is connected. Now, the category $\mathsf{Cov}(X)$ is equivalent to the category of finite sets, hence every object in the essential image of j^* is (isomorphic to) a finite disjoint union of copies of U; since U is connected, the morphisms of U-schemes between two such objects E and E' are in natural bijection with the set-theoretic mappings $\pi_0(E) \to \pi_0(E')$ of their sets of connected components, whence the assertion.

(ii): Let us write U as the union of a filtered family $(U_\lambda \mid \lambda \in \Lambda)$ of constructible open subsets of $X(\overline{x})$; up to replacing Λ by a cofinal subset, we may assume that $\eta_s \in U_\lambda$ for every $\lambda \in \Lambda$. Arguing as in the proof of theorem 13.2.11, we see that $\mathscr{D}(S(\overline{x}), f_{\overline{x}}, U)$ is the 2-limit of the system of diagrams $\mathscr{D}(S(\overline{x}), f_{\overline{x}}, U_\lambda)$, hence it suffices to show the assertion with $U = U_\lambda$, for every $\lambda \in \Lambda$, which allows to assume that U is quasi-compact. Next, arguing as in the proof of proposition 13.1.30, we are reduced to the case where $S = S(\overline{s})$. We may write $X(\overline{x})$ as the limit of a cofiltered system $(X_\lambda \mid \lambda \in \Lambda)$ of affine schemes, étale over X, and for $\lambda \in \Lambda$ large enough, we may find an open subset $U_\lambda \subset X_\lambda$ such that $U = U_\lambda \times_{X_\lambda} X(\overline{x})$ ([65, Ch.IV, Cor.8.2.11]). For every $\mu \geq \lambda$, set $U_\mu := U_\lambda \times_{X_\lambda} X_\mu$, and denote by $f_\mu : X_\mu \to S$ the natural morphism. Suppose first that S is irreducible; then, from lemma 13.1.6 it is easily seen that $\mathscr{D}(S, f_{\overline{x}}, U)$ is the 2-colimit of the system of diagrams $\mathscr{D}(S, f_\mu, U_\mu)$, so the assertion follows from theorem 13.2.11(ii) (more generally, this argument works whenever $S_{\max}$ is a finite set, since filtered 2-colimits of categories commute with finite products).

In the general case, let $\varphi : E \to U$ be a finite étale morphism, and suppose that $\varphi_\eta := \varphi \times_{X(\overline{x})} f_{\overline{x}}^{-1}(\eta)$ extends to an object ψ_η of $\mathsf{Cov}(f_{\overline{x}}^{-1}\eta)$, for every $\eta \in S_{\max}$. The assertion boils down to showing that φ extends to an object φ' of $\mathsf{Cov}(X(\overline{x}))$. To this aim, for every $\eta \in S_{\max}$, let $Z_\eta \to S$ be the closed immersion of the topological closure of η in S (which we endow with its reduced scheme structure); set also $Y_\eta := X \times_S Z_\eta$. Then Z_η is a strictly local scheme ([66, Ch.IV, Prop.18.5.6(i)]), and $\overline{x}$ factors through the closed immersion $Y \to X$, which induces an isomorphism of Z-schemes :

$$Y_\eta(\overline{x}) \xrightarrow{\sim} X(\overline{x}) \times_S Z_\eta$$

(lemma 13.1.22(ii)). By the foregoing case, $\varphi \times_S Z_\eta$ extends to an object $\overline{\psi}_\eta$ of $\mathsf{Cov}(Y_\eta(\overline{x}))$. However, Z_η is the limit of the cofiltered system $(Z_{\eta,i} \mid i \in I(\eta))$ consisting of the constructible closed subschemes of S that contain Z_η. By lemma 13.1.6, it follows that we may find $i \in I(\eta)$ and an object $\overline{\psi}_{\eta,i}$ of $\mathsf{Cov}(X(\overline{x}) \times_S Z_{\eta,i})$ whose image in $\mathsf{Cov}(Y_\eta(\overline{x}))$ is isomorphic to $\overline{\psi}_\eta$, and if i is large enough, $\overline{\psi}_{\eta,i} \times_{X(\overline{x})} U$ agrees with $\varphi \times_S Z_{\eta,i}$ in $\mathsf{Cov}(U \times_S Z_{\eta,i})$. For each $\eta, \eta' \in S_{\max}$, choose $i \in I(\eta)$, $i' \in I(\eta')$ with these properties, and to ease notation, set :

$$X'_\eta := X \times_S Z_{\eta,i} \qquad X''_{\eta\eta'} := X'_\eta \times_S Z_{\eta',i'} \qquad \varphi'_\eta := \overline{\psi}_{\eta,i}$$

and denote by $\alpha_\eta : \varphi'_\eta \times_{X(\overline{x})} U \xrightarrow{\sim} \varphi \times_S Z_{\eta,i}$ the given isomorphism. As in the foregoing, we notice that $\overline{x}$ factors through X'_η, and the closed immersion $X'_\eta \to X$ induces an isomorphism $X'_\eta(\overline{x}) \xrightarrow{\sim} X(\overline{x}) \times_S Z_{\eta,i}$ of $Z_{\eta,i}$-schemes. According to [63, Ch.IV, Cor.1.9.9], we may then find a finite subset $T \subset S_{\max}$ such that the induced morphism :

$$\beta : X_1 := \coprod_{\eta \in T} X'_\eta(\overline{x}) \to X(\overline{x})$$

is surjective. Set $X_2 := X_1 \times_{X(\overline{x})} X_1$ and $X_3 := X_2 \times_{X(\overline{x})} X_1$; notice that X_2 is the disjoint union of schemes of the form $X(\overline{x}) \times_S Z_{\eta,i} \times_S Z_{\eta',i'}$, for $\eta, \eta' \in T$, and again, the latter is naturally isomorphic to $X''_{\eta\eta'}(\overline{x})$, for a unique lifting of the geometric point $\overline{x}$ to a geometric point of $X''_{\eta\eta'}$. Similar considerations can be repeated for X_3, and in light of (i), we deduce that the pull-back functors :

$$\mathsf{Cov}(X_i \times_{X(\overline{x})} U) \to \mathsf{Cov}(X_i) \qquad i = 1, 2, 3$$

are fully faithful, in which case corollary 3.5.30(iii) says that the essentially commutative diagram of categories :

$$\begin{array}{ccc} \mathsf{Desc}(\mathsf{Cov}, \beta) & \longrightarrow & \mathsf{Desc}(\mathsf{Cov}, \beta \times_{X(\overline{x})} U) \\ \downarrow & & \downarrow \\ \prod_{\eta \in T} \mathsf{Cov}(X'_\eta(\overline{x})) & \longrightarrow & \prod_{\eta \in T} \mathsf{Cov}(X'_\eta(\overline{x}) \times_{X(\overline{x})} U) \end{array}$$

is 2-cartesian. Let $\rho : \mathsf{Cov}(U) \to \mathsf{Desc}(\mathsf{Cov}, \beta \times_{X(\overline{x})} U)$ be the functor defined in (3.5.22); it follows that the datum $((\varphi'_\eta, \alpha_\eta \mid \eta \in T), \rho(\varphi))$ comes from a descent datum (φ'_1, ω) in $\mathsf{Desc}(\mathsf{Cov}, \beta)$. By lemma 13.1.2, the latter descends to an object φ' of $\mathsf{Cov}(X(\overline{x}))$, and by construction we have $j^*\varphi' = \varphi$, as required. □

13.3. **Étale coverings of log schemes.** We resume the general notation of (12.2.1), especially, we choose implicitly τ to be either the Zariski or étale topology, and we shall omit further mention of this choice, unless the omission might be a source of ambiguities.

13.3.1. Let $\underline{Y} := ((Y, \underline{N}), T, \psi)$ be an object of $\mathscr{K}_{\mathrm{int}}$ (see (12.6.10) : especially $\tau = \mathrm{Zar}$ here), $\varphi : T' \to T$ an integral proper subdivision of the fan T (definition 6.5.22(ii),(iii)), and suppose that both T and T' are locally fine and saturated. Set $((Y', \underline{N}'), T', \psi') := \varphi^*\underline{Y}$ (proposition 12.6.14(iii)), and let $f : Y' \to Y$ be the morphism of schemes underlying the cartesian morphism $\varphi^*\underline{Y} \to \underline{Y}$.

Proposition 13.3.2. *In the situation of* (13.3.1)*, the following holds :*

(i) *For every geometric point ξ of Y, the fibre $f^{-1}(\xi)$ is connected (and hence, non-empty).*
(ii) *The functor $f^* : \mathsf{Cov}(Y) \to \mathsf{Cov}(Y')$ is an equivalence.*

Proof. (i): The assertion is local on Y, hence we may assume that $T = (\mathrm{Spec}\, P)^\sharp$ for a fine, sharp and saturated monoid P. In this case, we may find a subdivision $\varphi' : T'' \to T'$ such that both φ' and $\varphi \circ \varphi'$ are compositions of saturated blow up of ideals generated by at most two elements of P (example 6.6.15(iii)). We are reduced to showing the assertion for the morphisms φ' and $\varphi \circ \varphi'$, after which, we may further assume that φ is the saturated blow up of an ideal generated by two elements of $\Gamma(T, \mathscr{O}_T)$, in which case the assertion follows from the more precise theorem 12.4.51.

(ii): First, we claim that the assertion is local on the Zariski topology of Y. Indeed, let $Y = \bigcup_{i \in I} U_i$ be a Zariski open covering, and set $U_{ij} := U_i \cap U_j$ for every $i, j \in I$; according to corollary 3.5.30(ii) and lemma 13.1.2, it suffices to prove the contention for the objects $(U_i \times_Y (Y, \underline{N}), T, \psi_{|U_i})$ and $(U_{ij} \times_Y (Y, \underline{N}), T, \psi_{|U_{ij}})$, and the morphism φ. Hence, we may again suppose that $T = \mathrm{Spec}\, P$, for a monoid P as in (i).

Arguing as in the proof of (i), we may next reduce to the case where φ is the saturated blow up of an ideal generated by two elements of $\Gamma(T, \mathscr{O}_T)$. Now, the morphism of schemes f induces a morphism of topoi $Y'^{\sim}_{\text{ét}} \to Y^{\sim}_{\text{ét}}$ which we denote again by f; then, assertion (i) and the proper base change theorem [10, Exp.XII, Th.5.1(i)] imply that the unit of adjunction $\mathscr{F} \to f_* f^* \mathscr{F}$ is an isomorphism for every sheaf $\mathscr{F}$ on Y, so f^* is fully faithful (proposition 1.1.20(iii)). Next, if $\varphi : E' \to Y'$ is a finite étale covering, Y' decomposes into a disjoint union of open and closed subsets $Y' = Y'_0 \cup \cdots \cup Y'_k$, such that $(\varphi_* \mathscr{O}_{E'})_{|Y'_r}$ is locally free of rank r, for every $r = 0, \dots, k$. Set $Y_r := f(Y'_r)$ for $r = 0, \dots, k$; since the fibres of f are connected, we see that $Y'_r = f^{-1} Y_r$ for every such r. Moreover, since f is a closed map and the topology of Y is induced from that of Y' via f, we see that Y_r is a closed subset of Y for $r = 0, \dots, k$, so $Y = Y_0 \cup \cdots \cup Y_k$ is a partition of Y by open and closed subsets. After replacing Y by Y_r, we may then assume that $\varphi_* \mathscr{O}_E$ is locally free of rank r, and notice that the isomorphism classes of étale coverings of this type are classified by the pointed set $H^1(Y'_{\text{ét}}, S_{r,Y'})$, where S_r is the symmetric group on r elements. Thus, it suffices to show that the induced map :

$$H^1(Y_{\text{ét}}, S_{r,Y}) \to H^1(Y'_{\text{ét}}, S_{r,Y'}) \tag{13.3.3}$$

is a bijection. However, theorem 4.9.9 yields the exact sequence of pointed sets :

$$\{1\} \to H^1(Y_{\text{ét}}, f_* S_{r,Y'}) \xrightarrow{u} H^1(Y'_{\text{ét}}, S_{r,Y'}) \to H^0(Y_{\text{ét}}, R^1 f_* S_{r,Y'}).$$

On the other hand, assertion (i) and the proper base change theorem [10, Exp.XII, Th.5.1(i)] imply that the unit of adjunction $S_{r,Y} \to f_* f^* S_{r,Y} = f_* S_{r,Y'}$ is an isomorphism, hence u is naturally identified to (13.3.3), and we are reduced to showing that the natural morphism

$$\tau_{f, S_{r,Y'}} : 1_{Y^{\sim}_{\text{ét}}} \to R^1 f_* S_{r,Y'}$$

is an isomorphism (notation of (4.9.3)). The latter can be checked on the stalks, and in view of [10, Exp.XII, Cor.5.2(ii)] we are reduced to showing that $H^1(f^{-1}(\xi)_{\text{ét}}, S_r) = \{1\}$ for every geometric point ξ of Y. However, according to theorem 12.4.51, the reduced geometric fibre $f^{-1}(\xi)_{\text{red}}$ is either isomorphic to $|\xi|$ (in which case the contention is trivial), or else it is isomorphic to the projective line $\mathbb{P}^1_{\kappa(\xi)}$, in which case – in view of lemma 13.1.7(i) – it suffices to show that every finite étale morphism $E \to \mathbb{P}^1_{\kappa(\xi)}$ admits a section, which is well known. $\square$

The class of étale morphisms of log schemes was introduced in section 12.3 : its definition and its main properties parallel those of the corresponding notion for schemes, found in [63, Ch.IV, §17]. In the present section this theme is further advanced : we will consider the logarithmic analogue of the classical notion of *étale covering* of a scheme. To begin with, we make the following :

Definition 13.3.4. (i) Let $\varphi : T \to S$ be a morphism of fans. We say that φ is *of Kummer type*, if the map $(\log \varphi)_t : \mathscr{O}_{S,\varphi(t)} \to \mathscr{O}_{T,t}$ is of Kummer type, for every $t \in T$ (see definition 6.4.58).

(ii) Let $f : (Y, \underline{N}) \to (X, \underline{M})$ be a morphism of log schemes.

(a) We say that f is *of Kummer type*, if for every τ-point ξ of Y, the morphism of monoids $(\log f)_\xi : f^*\underline{M}_\xi \to \underline{N}_\xi$ is of Kummer type.

(b) A *Kummer chart* for f is the datum of charts

$$\omega_P : P_Y \to \underline{N} \qquad \omega_Q : Q_X \to \underline{M}$$

and a morphism of monoids $\vartheta : Q \to P$ such that $(\omega_P, \omega_Q, \vartheta)$ is a chart for f (see definition 12.1.17(iii)), and ϑ is of Kummer type.

Remark 13.3.5. (i) Let $f : P \to Q$ be a morphism of monoids of Kummer type, with P integral and saturated. It follows easily from lemma 6.4.59(iii,v), that the induced morphism of fans $(\mathrm{Spec}\, f)^\sharp : (\mathrm{Spec}\, Q)^\sharp \to (\mathrm{Spec}\, P)^\sharp$ is of Kummer type.

(ii) In the situation of definition 13.3.4(ii), it is easily seen that f is of Kummer type, if and only if the morphism of Y-monoids $f^*\underline{M}^\sharp_\xi \to \underline{N}^\sharp_\xi$ deduced from $\log f$, is of Kummer type for every τ-point ξ of Y.

(iii) In the situation of definition 13.3.4(ii.b), suppose that the chart $(\omega_P, \omega_Q, \vartheta)$ is of Kummer type, and Q is integral and saturated. It then follows easily from (i), (ii) and example 12.6.5(ii), that f is of Kummer type. In the same vein, we have the following :

Lemma 13.3.6. *Let $f : (Y, \underline{N}) \to (X, \underline{M})$ be a morphism of log schemes with coherent log structures, ξ a τ-point of Y, and suppose that :*

(a) *$\underline{M}_{f(\xi)}$ is fine and saturated.*

(b) *The morphism $(\log f)_\xi : \underline{M}_{f(\xi)} \to \underline{N}_\xi$ is of Kummer type.*

Then there exists a (Zariski) open neighborhood U of $|\xi|$ in Y, such that the restriction $f_{|U} : (U, \underline{N}_{|U}) \to (X, \underline{M})$ of f is of Kummer type.

Proof. By corollary 12.1.36(i) and theorem 12.1.37(ii), we may find a neighborhood $U' \to Y$ of ξ in Y_τ, and a finite chart $(\omega_P, \omega_Q, \vartheta)$ for the restriction $f_{|U'}$, with Q fine and saturated. Set

$$S_P := \omega^{-1}_{P,\xi}\underline{N}^\times_\xi \quad S_Q := \omega^{-1}_{Q,f(\xi)}\underline{M}^\times_{f(\xi)} \quad P' := S_P^{-1}P \quad Q' := S_Q^{-1}Q.$$

According to claim 12.1.31(iii) we may find neighborhoods $U'' \to U'$ of ξ in Y_τ, and $V \to X$ of $f(\xi)$ in X_τ, such that the charts $\omega_{P|U''}$ and $\omega_{Q|V}$ extend to charts

$$\omega_{P'} : P'_{U''} \to \underline{N}_{|U''} \qquad \omega_{Q'} : Q'_V \to \underline{M}_{|V}.$$

Clearly ϑ extends as well to a unique morphism $\vartheta' : Q' \to P'$, and after shrinking U'' we may assume that the restriction $f_{|U''} : (U'', \underline{N}_{|U''}) \to (X, \underline{M})$ factors through a morphism $f' : (U'', \underline{N}_{|U''}) \to (V, \underline{M}_{|V})$, in which case it is easily seen that the datum $(\omega_{P'}, \omega_{Q'}, \vartheta')$ is a chart for f'. Notice as well that Q' is still fine and saturated (lemma 6.2.9(i)), and by claim 12.1.31(iv) the maps $\omega_{P'}$ and $\omega_{Q'}$ induce isomorphisms :

$$P'^\sharp \xrightarrow{\sim} \underline{N}^\sharp_\xi \qquad Q'^\sharp \xrightarrow{\sim} \underline{M}^\sharp_{f(\xi)}.$$

Our assumption (b) then implies that the map $Q'^\sharp \to P'^\sharp$ deduced from ϑ' is of Kummer type, and then the morphism of fans $\mathrm{Spec}\, \vartheta' : \mathrm{Spec}\, P' \to \mathrm{Spec}\, Q'$ is of Kummer type as well (remark 13.3.5(i)). However, let

$$\overline{\omega}_{P'} : (U'', \underline{N}^\sharp_{|U''}) \to (\mathrm{Spec}\, P')^\sharp \qquad \overline{\omega}_{Q'} : (V, \underline{M}^\sharp_{|V}) \to (\mathrm{Spec}\, Q')^\sharp$$

be the morphisms of monoidal spaces deduced from $\omega_{P'}$ and $\omega_{Q'}$; we obtain a morphism

$$(f', \mathrm{Spec}\, \vartheta') : (U'', \underline{N}_{|U''}, (\mathrm{Spec}\, P')^\sharp, \overline{\omega}_{P'}) \to (V, \underline{M}_{|V}, (\mathrm{Spec}\, Q')^\sharp, \overline{\omega}_{Q'})$$

in the category $\mathscr{K}$ of (12.6.2), which – in view of remark 13.3.5(ii) – shows that f' is of Kummer type. This already concludes the proof in case $\tau = \mathrm{Zar}$, and for $\tau = \text{ét}$ it suffices to remark that the image of U'' in Y is a Zariski open neighborhood U of ξ, such that the restriction $f_{|U}$ is of Kummer type. □

We shall use the following criterion :

Proposition 13.3.7. *Let k be a field, $f : P \to Q$ an injective morphism of fine monoids, with P sharp. Suppose that the scheme $\operatorname{Spec} k\langle Q/\mathfrak{m}_P Q\rangle$ admits an irreducible component of Krull dimension 0. We have :*

(i) *f is of Kummer type, and $k\langle Q/\mathfrak{m}_P Q\rangle$ is a finite k-algebra.*
(ii) *If moreover, $Q^\times$ is a torsion-free abelian group, then Q is sharp, and $k\langle Q/\mathfrak{m}_P Q\rangle$ is a local k-algebra with k as residue field.*

Proof. Notice that the assumption means especially that $Q/\mathfrak{m}_P Q \neq \{1\}$, so f is a local morphism. Set $I := \mathrm{rad}(\mathfrak{m}_P Q)$ (notation of definition 6.1.8(ii)), and let $\mathfrak{p}_1, \dots, \mathfrak{p}_n \subset Q$ be the minimal prime ideals containing I; then $I = \mathfrak{p}_1 \cap \cdots \cap \mathfrak{p}_n$, by lemma 6.1.16. Clearly the natural closed immersion $\operatorname{Spec} k\langle Q/I\rangle \to \operatorname{Spec} k\langle Q/\mathfrak{m}_P Q\rangle$ is a homeomorphism; on the other hand, say that $\mathfrak{q} \subset k\langle Q\rangle$ is a prime ideal containing I; then $\mathfrak{q} \cap Q$ is a prime ideal of Q containing I, hence $\mathfrak{p}_i \subset \mathfrak{q}$ for some $i \leq n$, *i.e.* $\operatorname{Spec} k\langle Q/I\rangle$ is the union of its closed subsets $\operatorname{Spec} k\langle Q/\mathfrak{p}_i Q\rangle$, for $i = 1, \dots, n$. The Krull dimension of each irreducible component of $\operatorname{Spec} k\langle Q/\mathfrak{p}_i\rangle = \operatorname{Spec} k[Q\backslash\mathfrak{p}_i]$ equals

$$\mathrm{rk}_{\mathbb{Z}}(Q\backslash\mathfrak{p})^\times + \dim Q\backslash\mathfrak{p} = \mathrm{rk}_{\mathbb{Z}} Q^\times + d - \mathrm{ht}(\mathfrak{p}_i) \qquad \text{where } d := \dim Q$$

(claim 11.6.37(ii) and corollary 6.4.12(i,ii)). Our assumption then implies that $Q^\times$ is a finite group, and $\mathrm{ht}(\mathfrak{p}_i) = d$, *i.e.* $\mathfrak{p}_i = \mathfrak{m}_Q$, for at least an index $i \leq n$, and therefore $I = \mathfrak{m}_Q$. Furthermore, since $\mathfrak{m}_Q$ is finitely generated, we have $\mathfrak{m}_Q^n \subset \mathfrak{m}_P Q$ for a sufficiently large integer $n > 0$, and then it follows easily that $k\langle Q/\mathfrak{m}_P Q\rangle$ is a finite k-algebra. If $Q^\times$ is torsion-free, then we also deduce that Q is sharp, and moreover the maximal ideal of $k\langle Q/\mathfrak{m}_P Q\rangle$ generated by $\mathfrak{m}_Q$ is nilpotent, hence the latter k-algebra is local.

Let now $\mathfrak{q} \subset Q$ be any prime ideal, and pick $x \in \mathfrak{m}_Q \backslash \mathfrak{q}$; the foregoing implies that there exists an integer $r > 0$ such that $x^r = f(p_\mathfrak{q})q$ for some $p_\mathfrak{q} \in \mathfrak{m}_P$ and $q \in Q$, hence $f(p_\mathfrak{q}) \notin \mathfrak{q}$, and $f(p_\mathfrak{q})$ is not invertible in Q, since f is local. If now $\mathfrak{q}$ has height $d-1$, it follows that $f(p_\mathfrak{q})$ is a generator of $(Q\backslash\mathfrak{q})_\mathbb{R}$, which is an extremal ray of the polyhedral cone $Q_\mathbb{R}$, and every such extremal ray is of this form (proposition 6.4.9); furthermore, the latter cone is strictly convex, since $Q^\times$ is finite. Hence the set $S := (f(p_\mathfrak{q}) \mid \mathrm{ht}(\mathfrak{q}) = d-1)$ is a system of generators of the polyhedral cone $Q_\mathbb{R}$ (see (6.3.15)). Let $Q' \subset Q$ be the submonoid generated by S; then $S_\mathbb{Q} = S_\mathbb{R} \cap Q_\mathbb{Q} = Q_\mathbb{Q}$ (proposition 6.3.22(iii)), *i.e.* f is of Kummer type. □

13.3.8. Let $f : (Y_{\mathrm{Zar}}, \underline{N}) \to (X_{\mathrm{Zar}}, \underline{M})$ be a morphism of log schemes with Zariski log structures; it follows easily from the isomorphism (12.1.9) and remark 13.3.5(ii) that f is of Kummer type if and only if $\widetilde{u}^* f : (X_{\text{ét}}, \widetilde{u}^*\underline{M}) \to (Y_{\text{ét}}, \widetilde{u}^*\underline{N})$ is a morphism of Kummer type between schemes with étale log structures (notation of (12.2.2)). Suppose now that $\underline{M}$ is an integral and saturated log structure on X_{Zar}, and denote by $\mathbf{s.Kum}(X_{\mathrm{Zar}}, \underline{M})$ (resp. $\mathbf{s.Kum}(X_{\text{ét}}, \widetilde{u}^*\underline{M})$) the full subcategory of $\mathbf{sat.log}/(X_{\mathrm{Zar}}, \underline{M})$ (resp. of $\mathbf{sat.log}/(X_{\text{ét}}, \widetilde{u}^*\underline{M})$ whose objects are all the morphisms of Kummer type. In view of the foregoing (and of lemma 12.1.18(i)), we see that $\widetilde{u}^*$ restricts to a functor :

$$\mathbf{s.Kum}(X_{\mathrm{Zar}}, \underline{M}) \to \mathbf{s.Kum}(X_{\text{ét}}, \widetilde{u}^*\underline{M}). \tag{13.3.9}$$

Lemma 13.3.10. *The functor* (13.3.9) *is an equivalence.*

Proof. By virtue of proposition 12.2.3(ii) we know already that (13.3.9) is fully faithful, hence we only need to show its essential surjectivity. Thus, let $f : (Y_{\text{ét}}, \underline{N}) \to (X_{\text{ét}}, \widetilde{u}^*\underline{M})$ be a morphism of Kummer type. By remark 13.3.5(ii), we know that $\log f$ induces an isomorphism

$$\widetilde{u}^* f^* \underline{M}^\sharp_{\mathbb{Q}} \xrightarrow{\sim} f^* \widetilde{u}^* \underline{M}^\sharp_{\mathbb{Q}} \xrightarrow{\sim} \underline{N}^\sharp_{\mathbb{Q}}$$

(notation of (6.3.20)). Since $\underline{N}$ is integral and saturated, the natural map $\underline{N}^\sharp \to \underline{N}^\sharp_{\mathbb{Q}}$ is a monomorphism, so that the counit of adjunction $\widetilde{u}^*\widetilde{u}_*\underline{N}^\sharp \to \underline{N}^\sharp$ is an isomorphism (lemma 4.9.27(ii)), and then the same holds for the counit of adjunction $\widetilde{u}^*\widetilde{u}_*(Y, \underline{N}) \to (Y, \underline{N})$ (proposition 12.2.3(iii)). □

Proposition 13.3.11. *Let $f : (Y, \underline{N}) \to (X, \underline{M})$ be a morphism of fs log schemes. The following conditions are equivalent:*

(a) *Every geometric point of X admits an étale neighborhood $U \to X$ such that $Y_U := U \times_X Y$ decomposes as a disjoint union $Y_U = \bigcup_{i=1}^n Y_i$ of open and closed subschemes (for some $n \in \mathbb{N}$), and we have :*
   (i) *Each restriction $Y_i \times_Y (Y, \underline{N}) \to U \times_X (X, \underline{M})$ of $f \times_X \mathbf{1}_U$ admits a fine, saturated Kummer chart $(\omega_{P_i}, \omega_{Q_i}, \vartheta_i)$ such that P_i and Q_i are sharp, and the order of $\mathrm{Coker}\,\vartheta_i^{\mathrm{gp}}$ is invertible in $\mathscr{O}_U$.*
   (ii) *The induced morphism of U-schemes $Y_i \to U \times_{\mathrm{Spec}\,\mathbb{Z}[P_i]} \mathrm{Spec}\,\mathbb{Z}[Q_i]$ is an isomorphism, for every $i = 1, \dots, n$.*

(b) *f is étale, and the morphism of schemes underlying f is finite.*

Proof. (a) ⇒ (b): Indeed, it is easily seen that the morphism $\mathrm{Spec}\,\mathbb{Z}[\vartheta_i]$ is finite, hence the same holds for the restriction $Y_i \to U$ of f, in view of (a.ii), and then the same holds for $f \times_X \mathbf{1}_U$, so finally f is finite on the underlying schemes ([64, Ch.IV, Prop.2.7.1]), and it is étale by the criterion of theorem 12.3.37.

(b) ⇒ (a): Arguing as in the proof of theorem 12.3.37, we may reduce to the case where $\tau = \text{ét}$. Suppose first that both X and Y are strictly local. In this case, $\underline{M}$ admits a fine and saturated chart $\omega_P : P_X \to \underline{M}$, sharp at the closed point (corollary 12.1.36(i)). Moreover, f admits a chart $(\omega_P, \omega_Q : Q_Y \to \underline{N}, \vartheta : P \to Q)$, for some fine monoid Q such that $Q^\times$ is torsion-free; also ϑ is injective, the induced morphism of X-schemes

$$g : Y \to X' := X \times_{\mathrm{Spec}\,\mathbb{Z}[P]} \mathrm{Spec}\,\mathbb{Z}[Q]$$

is étale, and the order of $\mathrm{Coker}\,\vartheta^{\mathrm{gp}}$ is invertible in $\mathscr{O}_X$ (corollary 12.3.42). Since f is finite, g is also closed ([60, Ch.II, Prop.6.1.10]), hence its image Z is an open and closed local subscheme, finite over X. Let k be the residue field of the closed point of X; it follows that $X' \times_X \mathrm{Spec}\,k \simeq \mathrm{Spec}\,k\langle Q/\mathfrak{m}_P Q\rangle$ admits an irreducible component of Krull dimension zero (namely, the intersection of Z with the fibre of X' over the closed point of X), in which case the criterion of proposition 13.3.7(ii) ensures that ϑ is of Kummer type and Q is sharp, hence X' is finite over X, and moreover $X' \times_X \mathrm{Spec}\,k$ is a local scheme with k as residue field. Since X is strictly henselian, it follows that X' itself is strictly local, and therefore g is an isomorphism, so the proposition is proved in this case.

Let now X be a general scheme, and ξ a geometric point of X; denote by $X(\xi)$ the strict henselization of X at the point ξ, and set $Y(\xi) := X(\xi) \times_X Y$. Since f is finite, $Y(\xi)$ decomposes as the disjoint union of finitely many open and closed strictly local subschemes $Y_1(\xi), \dots, Y_n(\xi)$. Then we may find an étale neighborhood $U \to X$ of ξ, and open and closed subschemes $Y_1, \dots, Y_n$ of $Y \times_X U$, with isomorphisms of $X(\xi)$-schemes $Y_i(\xi) \xrightarrow{\sim} Y_i \times_U X(\xi)$, for every $i = 1, \dots, n$ ([65, Ch.IV, Cor.8.3.12]). We may then replace X by U, and we reduce to proving the proposition for each of the restrictions $Y_i \to U$ of $f \times_X \mathbf{1}_U$; hence we may assume that $Y(\xi)$ is strictly local. By the foregoing case, we may find a chart

(13.3.12) $$P_{X(\xi)} \to \underline{M}(\xi) \qquad Q_{Y(\xi)} \to \underline{N}(\xi) \qquad \vartheta : P \to Q$$

of $f \times_X \mathbf{1}_{X(\xi)}$, with ϑ of Kummer type, such that P and Q are sharp, the order d of $\mathrm{Coker}\,\vartheta^{\mathrm{gp}}$ is invertible in $\mathscr{O}_{X(\xi)}$, and the induced morphism of $X(\xi)$-schemes $Y(\xi) \to X(\xi) \times_{\mathrm{Spec}\,\mathbb{Z}[P]} \mathrm{Spec}\,\mathbb{Z}[Q]$ is an isomorphism. By corollary 12.2.36 we may find an étale neighborhood $U \to X$ of ξ such that (13.3.12) extends to a chart for $f \times_X \mathbf{1}_U$. After shrinking U, we may assume that d is invertible in $\mathscr{O}_U$. Lastly, after further shrinking of U, we may ensure that the induced morphism of U-schemes $U \times_X Y \to U \times_{\mathrm{Spec}\,\mathbb{Z}[P]} \mathrm{Spec}\,\mathbb{Z}[Q]$ is an isomorphism ([65, Ch.IV, Cor.8.8.2.4]). $\square$

Definition 13.3.13. (i) Let $f : (Y, \underline{N}) \to (X, \underline{M})$ be a morphism of fs log schemes. We say that f is an *étale covering* of $(X, \underline{M})$, if f fulfills the equivalent conditions (a) and (b) of proposition 13.3.11. We denote by

$$\mathsf{Cov}(X, \underline{M})$$

the full subcategory of $\mathbf{log}/(X, \underline{M})$, whose objects are the étale coverings of $(X, \underline{M})$.

(ii) Let K be a field, E a finite separable field extension of K, and w a discrete valuation of E; set $v := w_{|K}$, and denote by Γ_v and $\kappa(v)$ (Γ_w and $\kappa(w)$) the value group of v (resp. of w) and the residue field of the valuation ring K^+ of v (resp. of the valuation ring E^+ of w). We say that the ring extension $K^+ \subset E^+$ *is tamely ramified* if the *ramification index*

$$e(w/v) := (\Gamma_w : \Gamma_v)$$

(which is known to be finite) is invertible in $\kappa(v)$, and the residue field extension $\kappa(v) \to \kappa(w)$ is separable.

Remark 13.3.14. (i) Notice that all morphisms in $\mathsf{Cov}(X, \underline{M})$ are étale coverings, in light of corollary 12.3.25(ii).

(ii) Moreover, $\mathsf{Cov}(X, \underline{M})$ is a Galois category (see [82, Exp.V, Déf.5.1]), and if ξ is any geometric point of $(X, \underline{M})_{\mathrm{tr}}$, we obtain a fibre functor for this category, by the rule : $f \mapsto f^{-1}(\xi)$, for every étale covering f of $(X, \underline{M})$. (Details left to the reader.) We shall denote by

$$\pi_1((X, \underline{M})_{\text{ét}}, \xi)$$

the corresponding fundamental group.

Example 13.3.15. Let $(f, \log f) : (Y, \underline{N}) \to (X, \underline{M})$ be an étale covering of a regular log scheme $(X, \underline{M})$, and suppose that X is strictly local of dimension 1 and Y is connected (hence strictly local as well). Let $x \in X$ (resp. $y \in Y$) be the closed point; it follows that $\mathscr{O}_{X,x}$ is a strictly henselian discrete valuation ring (corollary 12.5.13). The same holds for $\mathscr{O}_{Y,y}$ in view of theorem 12.5.28 and [66, Ch.IV, Prop.18.5.10]. In case $\dim \underline{M}_x = 0$, the log structures $\underline{M}$ and $\underline{N}$ are trivial, so $f : Y \to X$ is an étale morphism of schemes. Otherwise we have $\dim \underline{M}_x = 1 = \dim \underline{N}_y$ (lemma 6.4.59(i)), and then $\underline{M}^\sharp_x \simeq \mathbb{N} \simeq \underline{N}^\sharp_y$ (theorem 6.4.18(ii)); also, the choice of a chart for f as in proposition 13.3.11, induces an isomorphism

$$\mathscr{O}_{X,x} \otimes_{\underline{M}^\sharp_x} \underline{N}^\sharp_y \xrightarrow{\sim} \mathscr{O}_{Y,y}$$

where the map $\underline{M}^\sharp_x \to \underline{N}^\sharp_y$ is the N-Frobenius map of $\mathbb{N}$, where $N > 0$ is an integer invertible in $\mathscr{O}_{X,x}$. Moreover, notice that the image of the maximal ideal of $\underline{M}_x$ generates the maximal ideal of $\mathscr{O}_{X,x}$ (and likewise for the image of $\underline{N}_y$ in $\mathscr{O}_{Y,y}$), so the structure map of $\underline{M}$ induces an isomorphism $\underline{M}^\sharp_x \xrightarrow{\sim} \Gamma_+$, onto the submonoid of the value group $(\Gamma, \leq)$ of $\mathscr{O}_{X,x}$ consisting of all elements ≤ 1 (and likewise for $\underline{N}^\sharp_y$). In other words, $\mathscr{O}_{Y,y}$ is obtained from $\mathscr{O}_{X,x}$ by adding the N-th root of a uniformizer. It then follows that the ring homomorphism $\mathscr{O}_{X,x} \to \mathscr{O}_{Y,y}$ is a finite tamely ramified extension of discrete valuation rings.

Definition 13.3.16. Let X be a normal scheme, and $Z \to X$ a closed immersion such that :

(a) Z is constructible in X.
(b) Z is a union of irreducible closed subsets of codimension one in X.

(c) For every maximal point $z \in Z$, the stalk $\mathscr{O}_{X,z}$ is a discrete valuation ring.

Set $U := X \setminus Z$, let $f : U' \to U$ be an étale covering, and $g : X' \to X$ the normalization of X in U'. Notice that $g^{-1}Z$ is a union of irreducible closed subsets of codimension one in X' (by the going down theorem [126, Th.9.4(ii)]). Notice also that for every $z \in \mathrm{Max}\, Z$, the induced map $A := \mathscr{O}_{X,z} \to B := g_*\mathscr{O}_{X',z}$ is a finite ring homomorphism, since A is a noetherian domain, and since $\mathrm{Frac}(A) \otimes_A B$ is an étale $\mathrm{Frac}(A)$-algebra ([126, §33, Lemma 1]). It follows easily that, for every geometric point ξ of X' localized at a maximal point of $g^{-1}Z$, the induced extension of strictly henselian discrete valuation rings :

$$\mathscr{O}_{X,g(\xi)} \to \mathscr{O}_{X',\xi} \tag{13.3.17}$$

is finite (notation of definition 4.9.17(iii).

(i) We say that f is *tamely ramified along* Z if, for every geometric point ξ of X' localized at a maximal point of $g^{-1}Z$, the corresponding extension (13.3.17) is tamely ramified. Hence, let $\Gamma_{g(\xi)} \to \Gamma_\xi$ be the induced map of value groups; then the *ramification index of* f *at* ξ

$$e_\xi(f) := (\Gamma_\xi : \Gamma_{g(\xi)})$$

is invertible in the residue field $\kappa(\xi)$, and g induces an isomorphism $\kappa(g(\xi)) \xrightarrow{\sim} \kappa(\xi)$.

(ii) Suppose that f is tamely ramified along Z, and that the set of maximal points of Z is finite. Then the *ramification index of* f *along* Z is the least common multiple $e_Z(f)$ of the ramification indices $e_\xi(f)$, where ξ ranges over the set of all geometric points of X' supported at a maximal point of $g^{-1}Z$.

(iii) We denote by $\mathbf{Tame}(X, U)$ the full subcategory of $\mathsf{Cov}(U)$ whose objects are the étale coverings of U that are tamely ramified along Z.

Lemma 13.3.18. *Let K, K', L be subfields of a given field, and $V_{L'}$ a discrete valuation ring of $L' := K'L$; for every subfield $E \subset L'$ set $V_E := E \cap V_{L'}$, and for every pair $E \subset E'$ of such subfields, let $e(E'/E)$ be the ramification index of the extension $V_E \subset V_{E'}$. We have :*

(i) *Suppose moreover that :*

(a) $V_K \neq K$.

(b) *K' is a finite separable extension of K, and the extension $V_K \subset V_{K'}$ is tamely ramified.*

Then the extension $V_L \subset V_{L'}$ is tamely ramified, and $e(L'/L)$ divides $e(K'/K)$.

(ii) *Suppose that :*

(a) *The extension $V_L \subset V_{L'}$ is tamely ramified, and both V_K and V_L are strictly henselian.*

(b) *$[K' : K] = [L' : L] < +\infty$ and $e(L'/K') = 1$.*

Then the extension $V_K \subset V_{K'}$ is tamely ramified, $e(K'/K) = e(L'/L)$, and $e(L/K) = 1$.

Proof. Let κ_K be the residue field of V_K, and define likewise the residue fields $\kappa_{K'}, \kappa_L$ and $\kappa_{L'}$.

(i): To begin with, let us remark :

Claim 13.3.19. In order to show (i), we may assume that V_K and V_L are strictly henselian.

Proof of the claim. Let us fix a separable closure Ω of $\kappa_{L'}$, and let $V_K^{\mathrm{sh}}, V_L^{+\mathrm{sh}}, V_{K'}^{+\mathrm{sh}}, V_{L'}^{+\mathrm{sh}}$ be the strict henselizations of $V_K, V_L, V_{K'}$ and $V_{L'}$ relative to the corresponding maps to Ω. According to [75, Lemma 6.2.5], all these are discrete valuation rings, and we denote by $K^{\mathrm{sh}}, L^{\mathrm{sh}}, K'^{\mathrm{sh}}$ and L'^{sh} the respective fields of fractions; also, the ramification indices $e(K^{\mathrm{sh}}/K)$, $e(L^{\mathrm{sh}}/L)$, $e(K'^{\mathrm{sh}}/K')$ and $e(L'^{\mathrm{sh}}/L')$ of the extensions $V_K \subset V_K^{\mathrm{sh}}$, $V_L \subset V_L^{\mathrm{sh}}$, $V_{K'} \subset V_{K'}^{\mathrm{sh}}$ and $V_{L'} \subset V_{L'}^{\mathrm{sh}}$ all equal one. Moreover, using the explicit construction of strict henselizations of *loc.cit.*, it is easily seen that $K'^{\mathrm{sh}} = K' \cdot K^{\mathrm{sh}}$ and $L'^{\mathrm{sh}} = L' \cdot L^{\mathrm{sh}}$ (details left to the reader), and furthermore the residue field of V_K^{sh} is a separable closure of κ_K, and likewise for the residue fields of $V_L^{\mathrm{sh}}, V_{K'}^{\mathrm{sh}}$ and $V_{L'}^{\mathrm{sh}}$. Then it follows easily that if the extension $V_L^{\mathrm{sh}} \subset V_{L'}^{\mathrm{sh}}$ is tamely ramified, the same holds for the extension $V_L \subset V_{L'}$, and we have both $e(L'^{\mathrm{sh}}/L^{\mathrm{sh}}) = e(L'/L)$ and

$e(K'^{\mathrm{sh}}/K^{\mathrm{sh}}) = e(K'/K)$. Thus, it suffices to prove assertion (i) for the discrete valuation ring $V^{\mathrm{sh}}_{L'}$ and the fields $K^{\mathrm{sh}}, K'^{\mathrm{sh}}, L^{\mathrm{sh}}, L'^{\mathrm{sh}}$. ◊

Henceforth, we thus assume that V_K and V_L are strictly henselian; since K' is separable over K, it is clear that L' is separable over L, and $V_{K'}$ (resp. $V_{L'}$) is strictly henselian as well, and is the integral closure of V_K in K' (resp. of V_L in L'); then $V_{K'}$ is a finite V_K-module ([126, §33, Lemma 1]). Next, let π_K (resp. $\pi_{K'}$, resp. π_L) be a uniformizer for V_K (resp. for $V_{K'}$, resp. for V_L); the assumption means that $\pi_K = \pi^e_{K'} \cdot a$ for some $a \in V^\times_{K'}$, and $e := e(K'/K)$ is invertible in the residue field of V_K. Since $V_{K'}$ is strictly henselian, we have $a = b^e$ for some $b \in V_{K'}$, and after replacing $\pi_{K'}$ by $b \cdot \pi_{K'}$, we may assume that $\pi_K = \pi^e_{K'}$; since $\kappa_K = \kappa_{K'}$, we have :

$$V_{K'} = V_K + \pi_{K'} V_{K'} = V_K + \pi_{K'} V_K + \pi^2_{K'} V_{K'} = \cdots = V_K + \pi_{K'} V_K + \cdots + \pi^{e-1}_{K'} V_K + \pi_K V_{K'}$$

whence $V_{K'} = V_K[\pi_{K'}]$, by Nakayama's lemma; therefore $K' = K(\pi_{K'})$, and K' is the splitting field of $X^e - \pi_K$ over K. It follows that $L' = L(\pi_{K'})$ is the splitting field of the same polynomial over L, and especially, it is a finite Galois extension of L. Moreover, the injective map

$$\mathrm{Gal}(L'/L) \to L^\times \qquad \sigma \mapsto \sigma(\pi_{K'})/\pi_{K'}$$

is a character with values in the e-torsion subgroup of $L^\times$; hence $[L' : L]$ divides e. Recalling that $[L' : L] = e(L'/L) \cdot [\kappa_{L'} : \kappa_L]$ ([34, Ch.VI, §8, no.5, Cor.1]), the assertion follows.

(ii): The assumptions imply that $\kappa_L = \kappa_{L'}$; then, [34, Ch.VI, §8, no.5, Cor.1] yields :

$$\begin{aligned} e(K'/K) \cdot [\kappa_{K'} : \kappa_K] \cdot e(L/K) = [K' : K] \cdot e(L/K) &= [L' : L] \cdot e(L/K) \\ &= e(L' : L) \cdot e(L/K) \\ &= e(L' : K) \\ &= e(L'/K') \cdot e(K'/K) = e(K'/K) \end{aligned}$$

whence $[\kappa_{K'} : \kappa_K] = e(L/K) = 1$ and $e(K'/K) = e(L'/L)$. □

Proposition 13.3.20. *Let $\varphi : X' \to X$ be a maximizing morphism of normal schemes (see definition* 8.1.46(ii)*), $Z \subset X$ a closed subset, and set $Z' := \varphi^{-1}Z$. Suppose that :*

- (a) *The closed immersions $Z \to X$ and $Z' \to X'$ satisfy conditions* (a),(b),(c) *of definition* 13.3.16.
- (b) *φ restricts to a maximizing map $Z' \to Z$.*

Set moreover $U := X \setminus Z$ and $U' := X' \setminus Z'$. We have :

- (i) *$\varphi^* : \mathsf{Cov}(U) \to \mathsf{Cov}(U')$ restricts to a functor*
$$\mathbf{Tame}(X, U) \to \mathbf{Tame}(X', U').$$
- (ii) *Suppose that $\mathrm{Max}\, Z$ and $\mathrm{Max}\, Z'$ are finite sets. Then, for any object $f : V \to U$ of $\mathbf{Tame}(X, U)$, the index $e_{Z'}(\varphi^* f)$ divides $e_Z(f)$.*
- (iii) *Suppose that X is regular and noetherian, and let $j : U \to X$ be the open immersion. Then the essential image of the pull-back functor $j^* : \mathsf{Cov}(X) \to \mathbf{Tame}(X, U)$ consists of the objects $f : V \to U$ such that $e_Z(f) = 1$.*

Proof. (i,ii): Let $V \to U$ be an object of $\mathbf{Tame}(X, U)$, and denote by $g : W \to X$ (resp. $g' : W' \to X'$) the normalization of X in V (resp. of X' in $V \times_U U'$). Let w' be a geometric point of W' localized at a maximal point of $g'^{-1}Z'$, and denote by w (resp. x', resp. x) the image of w' in W (resp. in X', resp. in X); in order to check (i) and (ii), we have to show that the ramification index of g' at the geometric point w' is invertible in $\kappa(w')$, and the residue field extension $\kappa(x') \subset \kappa(w')$ is trivial. To this aim, in view of proposition 9.8.3, we may replace X' by $X'(x')$, X by $X(x)$, W by $W(w)$, and assume from start that X, X' and W are strictly local, say $X = \mathrm{Spec}\, A$, $X' = \mathrm{Spec}\, B$ and $W = \mathrm{Spec}\, C$ for some strictly henselian discrete valuation rings A, B, C. Then, by construction, we have :

$$\mathrm{Frac}\, \mathscr{O}_{W',w'} = \mathrm{Frac}(B) \cdot \mathrm{Frac}(C).$$

hence the assertion follows from lemma 13.3.18.

(iii): Let $f : V \to U$ be an object of $\mathbf{Tame}(X, U)$. By claim 13.1.8, there exists a largest open subset $U_{\max} \subset X$ containing U, and such that f is the restriction of an étale covering $f_{\max} : V' \to U_{\max}$; now, if $e_Z(f) = 1$, every point of codimension one of $X\backslash U$ lies in $U_{\max}$, by claim 13.1.9. Hence $X\backslash U$ has codimension ≥ 2 in X, in which case lemma 13.1.7(iv) implies that $X = U_{\max}$, as required. □

Remark 13.3.21. Let X be a normal scheme, and $Z \to X$ a closed immersion verifying conditions (a),(b),(c) of definition 13.3.16. Then the assumptions (a) and (b) of proposition 13.3.20 are fulfilled, notably, when φ is finite and maximizing, or when φ is flat and X' is locally noetherian ([126, Th.9.4(ii), Th.9.5]).

13.3.22. Let now $\underline{X} := (X_i \mid i \in I)$ be a cofiltered system of quasi-compact and quasi-separated normal schemes, such that, for every morphism $\varphi : i \to j$ in the indexing category I, the corresponding transition morphism $f_\varphi : X_i \to X_j$ is maximizing and affine. Suppose also, that for every $i \in I$, there exists a closed immersion $Z_i \to X_i$, fulfilling conditions (a),(b),(c) of definition 13.3.16, such that $\mathrm{Max}\, Z_i$ is a finite set, and for every morphism $\varphi : i \to j$ of I, we have :

- $Z_i = f_\varphi^{-1} Z_j$.
- The corresponding morphism f_φ restricts to a maximizing map $Z_i \to Z_j$.

Let also X be the limit of $\underline{X}$, and Z the limit of the system $(Z_i \mid i \in I)$, and suppose furthermore that the closed immersion $Z \to X$ fulfills as well conditions (a),(b),(c) of definition 13.3.16.

Proposition 13.3.23. *In the situation of* (13.3.22)*, we have :*

(i) *The induced morphism $\pi_i : Z \to Z_i$ is maximizing for every $i \in I$.*
(ii) *The universal cone $(X \to X_i \mid i \in I)$ induces an equivalence of categories :*

$$2\text{-}\operatorname*{colim}_I \mathbf{Tame}(X_i, X_i\backslash Z_i) \to \mathbf{Tame}(X, X\backslash Z).$$

Proof. (i): More precisely, we shall prove that there is a natural homeomorphism :

$$\mathrm{Max}\, Z \xrightarrow{\sim} \lim_{i \in I} \mathrm{Max}\, Z_i.$$

(Notice the each $\mathrm{Max}\, Z_i$ is a discrete finite set, hence this will show that $\mathrm{Max}\, Z$ is a profinite topological space.) Indeed, suppose that $z := (z_i \mid i \in I)$ is a maximal point of Z. For every $i \in I$, let $T_i \subset \mathrm{Max}\, Z_i$ be the subset of maximal generizations of z_i in Z_i. It is easily seen that $f_\varphi T_i \subset T_j$ for every morphism $\varphi : i \to j$ in I. Clearly T_i is a finite non-empty set for every $i \in I$, hence the limit T of the cofiltered system $(T_i \mid i \in I)$ is non-empty. However, any point of T is a generization of z in Z, hence it must coincide with z. The assertion follows easily.

(ii): To begin with, proposition 13.3.20(i) shows that, for every morphism $\varphi : i \to j$ in I, the transition morphism f_φ induces a pull-back functor $\mathbf{Tame}(X_j, X_j\backslash Z_j) \to \mathbf{Tame}(X_i, X_i\backslash Z_i)$, so the 2-colimit in (ii) is well-defined, and combining (i) with proposition 13.3.20(i) we obtain indeed a well-defined functor from this 2-colimit to $\mathbf{Tame}(X, X\backslash Z)$.

The full faithfulness of the functor of (ii) follows from lemma 13.1.6. Next, let $g : V \to X\backslash Z$ be an object of $\mathbf{Tame}(X, X\backslash Z)$; invoking again lemma 13.1.6, we may descend g to an étale covering $g_j : V_j \to X_j\backslash Z_j$, for some $j \in I$; after replacing I by I/j, we may assume that j is the final object of I and we may define $g_i := f_\varphi^*(g_j)$ for every $\varphi : i \to j$ in I. To conclude the proof, it suffices to show that there exists $i \in I$ such that g_i is tamely ramified along Z_i.

Now, let $\overline{g}_i : \overline{V}_i \to X_i$ be the normalization of X_i in $V_i \times_{X_j} X_i$, for every $i \in I$, and $\overline{g} : \overline{V} \to X$ the normalization of X in V. Given a geometric point $\overline{v}$ localized at a maximal point of $\overline{g}^{-1}Z$, let $\overline{v}_i$ (resp. $\overline{z}_i$) be the image of $\overline{v}$ in $\overline{V}_i$ (resp. in Z_i), and $z_i \in Z_i$ the support of $\overline{z}_i$, for every $i \in I$. Let also $\overline{z}$ be the image of $\overline{v}$ in Z, and $z \in Z$ the support of $\overline{z}$. Then

$$\mathscr{O}_{X,\overline{z}} = \operatorname*{colim}_{i\in I} \mathscr{O}_{X_i,\overline{z}_i} \qquad \mathscr{O}_{\overline{V},\overline{v}} = \operatorname*{colim}_{i\in I} \mathscr{O}_{\overline{V}_i,\overline{v}_i}$$

and $\operatorname{Frac}\mathscr{O}_{\overline{V},\overline{v}} = \operatorname{Frac}(\mathscr{O}_{X,\overline{z}}) \cdot \operatorname{Frac}(\mathscr{O}_{\overline{V}_i,\overline{v}_i})$ for every $i \in I$ ([66, Ch.IV, Prop.18.8.18(ii)]), and it is easily seen that there exists $i \in I$ such that the ramification index of the extension $\mathscr{O}_{\overline{V}_i,\overline{v}_i} \subset \mathscr{O}_{\overline{V},\overline{v}}$ equals 1, and such that $[\operatorname{Frac}\mathscr{O}_{\overline{V}_i,\overline{v}_i} : \operatorname{Frac}\mathscr{O}_{X_i,\overline{z}_i}] = [\operatorname{Frac}\mathscr{O}_{\overline{V},\overline{v}} : \operatorname{Frac}\mathscr{O}_{X,\overline{z}}]$. Moreover, for every sufficiently large i, the induced map $\overline{g}^{-1}(z) \to \overline{g}_i^{-1}(z_i)$ is a bijection. Then, by lemma 13.3.18(ii), for every such index i, the finite extension $\mathscr{O}_{X_i,\overline{z}_i} \to \mathscr{O}_{\overline{V}_i,\overline{v}_i}$ is already tamely ramified, and since I is cofiltered, it follows that there exists $i \in I$ such that the induced morphism $\overline{V}_i \times_{X_i} X_i(\overline{z}_i) \to X_i(\overline{z}_i)$ is already tamely ramified. However, notice that $\pi_i^{-1}(z_i)$ is open in $\operatorname{Max} Z$, for every $i \in I$, and every $z_i \in \operatorname{Max} Z_i$. Therefore, we may find a finite subset $I_0 \subset I$, and for every $i \in I_0$ a subset $T_i \subset \operatorname{Max} Z_i$, such that :

- $\operatorname{Max} Z = \bigcup_{i\in I_0} \pi_i^{-1}(T_i)$.
- For every geometric point $\overline{z}_i$ localized in T_i, the morphism $\overline{V}_i \times_{X_i} X_i(\overline{z}_i) \to X_i(\overline{z}_i)$ is tamely ramified.

Since I is cofiltered, we may find $k \in I$ with morphisms $\varphi_i : k \to i$ for every $i \in I_0$; after replacing T_i by $f_{\varphi_i}^{-1}(T_i)$ for every $i \in I_0$, we may then assume that $I_0 = \{k\}$, so that $\operatorname{Max} Z = \pi_k^{-1}(T_k)$. It follows that $\operatorname{Max} Z_i = f_\varphi^{-1} T_k$ for some $i \in I$ and some $\varphi : i \to k$. Then it is clear that g_i is tamely ramified along Z_i, as required. □

13.3.24. Let X be a scheme, $U \subset X$ a connected open subset, ξ any geometric point of U, and $N > 0$ an integer which is invertible in $\mathscr{O}_U$; then the N-Frobenius map $\boldsymbol{N}$ of $\mathscr{O}_U^\times$ gives a *Kummer exact sequence* of abelian sheaves on $X_{\text{ét}}$:

$$0 \to \boldsymbol{\mu}_{N,U} \to \mathscr{O}_U^\times \xrightarrow{\boldsymbol{N}} \mathscr{O}_U^\times \to 0$$

(where $\boldsymbol{\mu}_{N,U}$ is the N-torsion subsheaf of $\mathscr{O}_{U_{\text{ét}}}^\times$: see [10, Exp.IX, §3.2]). Suppose now that $\boldsymbol{\mu}_{N,U}$ is a constant sheaf on $U_{\text{ét}}$; this means especially that $\boldsymbol{\mu}_N := (\boldsymbol{\mu}_{N,U})_\xi$ is a cyclic group of order N. Indeed, $\boldsymbol{\mu}_N$ certainly contains such a subgroup (since N is invertible in $\mathscr{O}_U$), so denote by ζ one of its generators; then every $u \in \boldsymbol{\mu}_N$ satisfies the identity $0 = u^N - 1 = \prod_{i=1}^N (u - \zeta^i)$, and each factor u_ζ^i of this decomposition vanishes on a closed subset U_i of $U(\xi)$; clearly $U_i \cap U_j = \varnothing$ for $i \neq j$, so we get a decomposition of $U(\xi)$ as a disjoint union of open and closed subsets $U(\xi) = U_1 \cup \cdots \cup U_N$ such that $u = \zeta^i$ on U_i, for every $i \leq N$; since $U(\xi)$ is connected, it follows that $U(\xi) = U_i$ for some i, *i.e.* ζ generates $\boldsymbol{\mu}_N$. There follows a natural map :

$$\partial_N : \Gamma(U_{\text{ét}}, \mathscr{O}_U^\times) \to H^1(U_{\text{ét}}, \boldsymbol{\mu}_{N,U}) \xrightarrow{\sim} \operatorname{Hom}_{\text{cont}}(\pi_1(U_{\text{ét}}, \xi), \boldsymbol{\mu}_N)$$

(lemma 13.1.12). Recall the geometric interpretation of ∂_N : a given $u \in \mathscr{O}_U^\times(U)$ is viewed as a morphism of schemes $u : U \to \mathbb{G}_m$, where $\mathbb{G}_m := \operatorname{Spec}\mathbb{Z}[\mathbb{Z}]$ is the standard multiplicative group scheme; we let U' be the fibre product in the cartesian diagram of schemes :

$$\begin{array}{ccc} U' & \longrightarrow & \mathbb{G}_m \\ {\scriptstyle \varphi_u}\downarrow & & \downarrow{\scriptstyle \operatorname{Spec}\mathbb{Z}[\boldsymbol{N}_\mathbb{Z}]} \\ U & \xrightarrow{u} & \mathbb{G}_m. \end{array} \tag{13.3.25}$$

Then φ_u is a torsor under the $U_{\text{ét}}$-group $\boldsymbol{\mu}_{N,U}$, and to such torsor, lemma 13.1.12 attaches a well defined continuous group homomorphism as required.

If $M > 0$ is any integer dividing N, a simple inspection yields a commutative diagram :

$$\begin{array}{ccc} \Gamma(U_{\text{ét}}, \mathscr{O}_X^\times) & \xrightarrow{\partial_N} & \mathrm{Hom}_{\mathrm{cont}}(\pi_1(U_{\text{ét}}, \xi), \boldsymbol{\mu}_N) \\ & \searrow^{\partial_M} & \downarrow{\scriptstyle \pi_{N,M}} \\ & & \mathrm{Hom}_{\mathrm{cont}}(\pi_1(U_{\text{ét}}, \xi), \boldsymbol{\mu}_M) \end{array} \tag{13.3.26}$$

where $\pi_{N,M}$ is induced by the map $\boldsymbol{\mu}_N \to \boldsymbol{\mu}_M$ given by the rule : $x \mapsto x^{N/M}$ for every $x \in \boldsymbol{\mu}_N$.

13.3.27. Let now X be a strictly local scheme, x the closed point of X, and denote by p the characteristic exponent of the residue field $\kappa(x)$ (so p is either 1 or a positive prime integer). Let also $\beta : \underline{M} \to \mathscr{O}_X$ be a log structure on $X_{\text{ét}}$, take $U := (X, \underline{M})_{\mathrm{tr}}$, suppose that $U \neq \varnothing$, and fix a geometric point ξ of U; for every integer $N > 0$ with $(N, p) = 1$, we get a morphism of monoids :

$$\underline{M}_x \xrightarrow{\beta_x} \Gamma(U_{\text{ét}}, \mathscr{O}_X^\times) \xrightarrow{\partial_N} \mathrm{Hom}_{\mathrm{cont}}(\pi_1(U_{\text{ét}}, \xi), \boldsymbol{\mu}_N) \tag{13.3.28}$$

whose kernel contains $\underline{M}_x^N$, the image of the N-Frobenius endomorphism of $\underline{M}_x$. Notice that the N-Frobenius map of $\mathscr{O}_{X,x}^\times$ is surjective : indeed, since the residue field $\kappa(x)$ is separably closed, and $(N, p) = 1$, all polynomials in $\kappa(x)[T]$ of the form $T^N - u$ (for $u \neq 0$) split as a product of distinct monic polynomials of degree 1; since $\mathscr{O}_{X,x}$ is henselian, the same holds for all polynomials in $\mathscr{O}_{X,x}[T]$ of the form $T^N - u$, with $u \in \mathscr{O}_{X,x}^\times$. It follows that (13.3.28) factors through a natural map:

$$\underline{M}_x^{\sharp\mathrm{gp}} \to \mathrm{Hom}_{\mathrm{cont}}(\pi_1(U_{\text{ét}}, \xi), \boldsymbol{\mu}_N)$$

which is the same as a group homomorphism :

$$\underline{M}_x^{\sharp\mathrm{gp}} \times \pi_1(U_{\text{ét}}, \xi) \to \boldsymbol{\mu}_N. \tag{13.3.29}$$

In view of the commutative diagram (13.3.26), it is easily seen that the pairings (13.3.29), for N ranging over all the positive integers with $(N, p) = 1$, assemble into a single pairing :

$$\underline{M}_x^{\mathrm{gp}} \times \pi_1((X, \underline{M})_{\mathrm{tr},\text{ét}}, \xi) \to \prod_{\ell \neq p} \mathbb{Z}_\ell(1)$$

(where ℓ ranges over the prime numbers different from p, and $\mathbb{Z}_\ell(1) := \lim_{n \in \mathbb{N}} \boldsymbol{\mu}_{\ell^n}$). The latter is the same as a group homomorphism :

$$\pi_1((X, \underline{M})_{\mathrm{tr},\text{ét}}, \xi) \to \underline{M}_x^{\mathrm{gp}\vee} \otimes_{\mathbb{Z}} \prod_{\ell \neq p} \mathbb{Z}_\ell(1). \tag{13.3.30}$$

13.3.31. Let $f : (X, \underline{M}) \to (Y, \underline{N})$ be a morphism of log schemes, such that both X and Y are strictly local, and f maps the closed point x of X to the closed point y of Y. Then f restricts to a morphism of schemes $f_{\mathrm{tr}} : (X, \underline{M})_{\mathrm{tr}} \to (Y, \underline{N})_{\mathrm{tr}}$ (remark 12.2.8(i)). Fix again a geometric point ξ of $(X, \underline{M})_{\mathrm{tr}}$; we get a diagram of group homomorphisms :

$$\begin{array}{ccc} \pi_1((X, \underline{M})_{\mathrm{tr},\text{ét}}, \xi) & \xrightarrow{\pi_1(f_{\mathrm{tr}}, \xi)} & \pi_1((Y, \underline{N})_{\mathrm{tr},\text{ét}}, f(\xi)) \\ \downarrow & & \downarrow \\ \underline{N}_y^{\mathrm{gp}\vee} \otimes_{\mathbb{Z}} \prod_{\ell \neq p} \mathbb{Z}_\ell(1) & \longrightarrow & \underline{M}_x^{\mathrm{gp}\vee} \otimes_{\mathbb{Z}} \prod_{\ell \neq p} \mathbb{Z}_\ell(1) \end{array}$$

whose vertical arrows (resp. bottom horizontal arrow) are the maps (13.3.30) (resp. is induced by $(\log f_x)^{\mathrm{gp}\vee}$), and by inspecting the constructions, it is easily seen that this diagram commutes.

13.3.32. Suppose now that $(X, \underline{M})$ as in (13.3.27) is a fs log scheme, so that $P := \underline{M}^\sharp_x$ is fine and saturated; in this case, we wish to give a second construction of the pairing (13.3.29).

• Namely, for every integer $N > 0$ set $S_P := \operatorname{Spec} \mathbb{Z}[P]$ and consider the finite morphism of schemes $g_N : S_P \to S_P$ induced by the N-Frobenius endomorphism of P. Notice that S_P contains the dense open subset $U_P := \operatorname{Spec} \mathbb{Z}[1/N, P^{\mathrm{gp}}]$, and it is easily seen that the restriction $g_{N|U_P} : U_P \to U_P$ of g_N is an étale morphism. Let $\tau \in U_P$ be any geometric point; then τ corresponds to a ring homomorphism $\mathbb{Z}[1/N, P^{\mathrm{gp}}] \to \kappa := \kappa(\tau)$, which is the same as a character $\chi_\tau : P^{\mathrm{gp}} \to \kappa^\times$. Likewise, any $\tau' \in g_N^{-1}(\tau)$ is determined by a character $\chi_{\tau'} : P^{\mathrm{gp}} \to \kappa^\times$ extending χ_τ, *i.e.* such that $\chi_{\tau'}(x^N) = \chi_\tau(x)$ for every $x \in P^{\mathrm{gp}}$. Notice that every character χ_τ as above admits at least one such extension $\chi_{\tau'}$, since κ is separably closed, and N is invertible in κ. Let C_N be the cokernel of the N-Frobenius endomorphism of P^{gp}; there follows a short exact sequence of finite abelian groups :

$$0 \to \mathrm{Hom}_{\mathbb{Z}}(C_N, \kappa^\times) \to \mathrm{Hom}_{\mathbb{Z}}(P^{\mathrm{gp}}, \kappa^\times) \xrightarrow{N} \mathrm{Hom}_{\mathbb{Z}}(P^{\mathrm{gp}}, \kappa^\times) \to 0.$$

Especially, we see that the fibre $g_N^{-1}(\tau)$ is naturally a torsor under the group $\mathrm{Hom}_{\mathbb{Z}}(C_N, \kappa^\times) = \mathrm{Hom}_{\mathbb{Z}}(P^{\mathrm{gp}}, \boldsymbol{\mu}_N(\kappa))$, where $\boldsymbol{\mu}_N(\kappa) \subset \kappa^\times$ is the N-torsion subgroup. Hence $g_{N|U_P}$ is an étale Galois covering of U_P, whose Galois group is naturally isomorphic to $\mathrm{Hom}_{\mathbb{Z}}(P^{\mathrm{gp}}, \boldsymbol{\mu}_N(\kappa))$; therefore, $g_{N|U_P}$ is classified by a well defined continuous representation :

$$\pi_1(U_{P,\text{ét}}, \tau) \to \mathrm{Hom}_{\mathbb{Z}}(P^{\mathrm{gp}}, \boldsymbol{\mu}_N(\kappa)) \qquad (13.3.33)$$

(lemma 13.1.12). The corresponding action of $\mathrm{Hom}_{\mathbb{Z}}(P^{\mathrm{gp}}, \boldsymbol{\mu}_N(\kappa))$ on U_P can be extracted from the construction : namely, let $\chi : P^{\mathrm{gp}} \to \boldsymbol{\mu}_N(\kappa)$ be a given character; by definition, the action of χ sends the geometric point τ to the geometric point τ' whose character $\chi_{\tau'} : P^{\mathrm{gp}} \to \kappa^\times$ is given by the rule : $x \mapsto \chi(x) \cdot \chi_\tau$ for every $x \in P^{\mathrm{gp}}$. Consider the automorphism ρ_χ of the $\mathbb{Z}$-algebra $\mathbb{Z}[P^{\mathrm{gp}}]$ given by the rule $x \mapsto \chi(x) \cdot x$ for every $x \in P^{\mathrm{gp}}$, and notice that $\rho(\tau) = \tau'$; since the fibre functors are faithful on étale coverings, we conclude that χ acts as $\operatorname{Spec} \rho_\chi$ on U_P.

• Moreover, if $\lambda : Q \to P$ is any morphism of fine and saturated monoids, clearly we have a commutative diagram

$$\begin{array}{ccc} U_P & \xrightarrow{\operatorname{Spec} \mathbb{Z}[\lambda]_{|U_P}} & U_Q \\ {\scriptstyle g_{N|U_P}} \downarrow & & \downarrow {\scriptstyle g_{N|U_Q}} \\ U_P & \xrightarrow{\operatorname{Spec} \mathbb{Z}[\lambda]_{|U_P}} & U_Q \end{array}$$

whence, by remark 13.1.14(iii.a), a well defined group homomorphism

$$\mathrm{Hom}_{\mathbb{Z}}(P^{\mathrm{gp}}, \boldsymbol{\mu}_N) \to \mathrm{Hom}_{\mathbb{Z}}(Q^{\mathrm{gp}}, \boldsymbol{\mu}_N) \qquad (13.3.34)$$

that makes commute the induced diagram :

$$\begin{array}{ccc} \pi_1(U_{P,\text{ét}}, \xi) & \longrightarrow & \pi_1(U_Q, \xi') \\ \downarrow & & \downarrow \\ \mathrm{Hom}_{\mathbb{Z}}(P^{\mathrm{gp}}, \boldsymbol{\mu}_N) & \longrightarrow & \mathrm{Hom}_{\mathbb{Z}}(Q^{\mathrm{gp}}, \boldsymbol{\mu}_N) \end{array}$$

whose vertical arrows are the maps (13.3.33). By inspecting the constructions, it is easily seen that (13.3.34) is just the map $\mathrm{Hom}_{\mathbb{Z}}(\lambda^{\mathrm{gp}}, \boldsymbol{\mu}_N)$.

• Next, by corollary 12.1.36(i) the projection $\underline{M}_x \to P$ admits a splitting

$$\alpha : P \to \underline{M}_x$$

(which defines a sharp chart for $\underline{M}$); if N is invertible in $\mathscr{O}_X$, this splitting induces a morphism of schemes $X \to S_P$, which restricts to a morphism $U \to U_P$. If we let τ be the image of ξ, we deduce a continuous group homomorphism $\pi_1(U_{\text{ét}}, \xi) \to \pi_1(U_{P,\text{ét}}, \tau)$ ([82, Exp.V, §7]), whose composition with (13.3.33) yields a continuous map :

(13.3.35) $$\pi_1(U_{\text{ét}}, \xi) \to \mathrm{Hom}_{\mathbb{Z}}(P^{\mathrm{gp}}, \boldsymbol{\mu}_N(\kappa)).$$

We claim that the pairing $P^{\mathrm{gp}} \times \pi_1(U_{\text{ét}}, \xi) \to \boldsymbol{\mu}_N(\kappa)$ arising from (13.3.35) agrees with (13.3.29), under the natural identification $\boldsymbol{\mu}_N(\kappa) \xrightarrow{\sim} \boldsymbol{\mu}_N$. Indeed, for given $s \in P$, let $j_s : \mathbb{Z} \to P^{\mathrm{gp}}$ be the map such that $j_s(n) := s^n$ for every $n \in \mathbb{Z}$; by composing (13.3.35) with $\mathrm{Hom}_{\mathbb{Z}}(j_s, \boldsymbol{\mu}_N(\kappa))$, we obtain a map $\pi_1(U_{\text{ét}}, \xi) \to \mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}, \boldsymbol{\mu}_N(\kappa)) \xrightarrow{\sim} \boldsymbol{\mu}_N(\kappa)$; in view of the foregoing, it is easily seen that the corresponding $\boldsymbol{\mu}_N(\kappa)$-torsor is precisely $\varphi_{\alpha(s)}$, in the notation of (13.3.25), whence the contention.

Proposition 13.3.36. *In the situation of* (13.3.27)*, suppose that* $(X, \underline{M})$ *is a regular log scheme. Then* (13.3.30) *is a surjection.*

Proof. From the discussion of (13.3.32), we are reduced to showing that the morphism (13.3.35) is surjective, for every $N > 0$ such that $(N, p) = 1$. The latter comes down to showing that the corresponding torsor $g_{N|U_P} \times_{U_P} U : U' \to U$ is connected (remark 13.1.14(i)). However, the map $\alpha : P \to \underline{M}_x$ induces a morphism of log schemes $\psi : (X, \underline{M}) \to \mathrm{Spec}(\mathbb{Z}, P)$ (see (12.2.13)); we remark the following :

Claim 13.3.37. Slightly more generally, for any Kummer morphism $\nu : P \to Q$ of monoids, with Q fine, sharp and saturated, define $(X_\nu, \underline{M}_\nu)$ as the fibre product in the cartesian diagram:

(13.3.38) $$\begin{array}{ccc} (X_\nu, \underline{M}_\nu) & \longrightarrow & \mathrm{Spec}(\mathbb{Z}, Q) \\ {\scriptstyle f_\nu}\downarrow & & \downarrow{\scriptstyle \mathrm{Spec}(\mathbb{Z},\nu)} \\ (X, \underline{M}) & \xrightarrow{\psi} & \mathrm{Spec}(\mathbb{Z}, P) \end{array}$$

Then $(X_\nu, \underline{M}_\nu)$ is regular, and X_ν is strictly local.

Proof of the claim. By lemma 12.5.24, $(X_\nu, \underline{M}_\nu)$ is regular at every point of the closed fibre $X_\nu \times_X \mathrm{Spec}\, \kappa(x)$, and since f_ν is a finite morphism, every point of X_ν specializes to a point of the closed fibre, therefore $(X_\nu, \underline{M}_\nu)$ is regular (theorem 12.5.31). Moreover, X_ν is connected, provided the same holds for the closed fibre; in turn, this follows immediately from proposition 13.3.7(ii). Then X_ν is strictly local, by [66, Ch.IV, Prop.18.5.10]. ♢

From claim 13.3.37 we see that X_ν is normal (corollary 12.5.13) for every such ν, especially this holds for the N-Frobenius endomorphism of P, in which case U' is an open subset of X_ν; since the latter is connected, the same then holds for U'. □

Example 13.3.39. (i) In the situation of example 12.6.20, let $X \to S$ be any morphism of schemes, set $\underline{X} := X \times_S \underline{S}$, denote by $(X, \underline{M})$ the log scheme underlying $\underline{X}$, and define $(X_{(k)}, \underline{M}_{(k)})$ as the fibre product in the cartesian diagram of log schemes :

$$\begin{array}{ccc} (X_{(k)}, \underline{M}_{(k)}) & \xrightarrow{\pi_{(k)}} & \mathrm{Spec}(R, P) \\ {\scriptstyle \boldsymbol{k}_X}\downarrow & & \downarrow{\scriptstyle \mathrm{Spec}(R,\boldsymbol{k}_P)} \\ (X, \underline{M}) & \xrightarrow{\pi} & \mathrm{Spec}(R, P) \end{array}$$

where π is the natural projection. Set as well

$$\underline{X}_{(k)} := ((X_{(k)}, \underline{M}_{(k)}), T_P, \psi_P \circ \pi^\sharp_{(k)})$$

which is an object of $\mathscr{K}_{\mathrm{int}}$; by proposition 12.6.14(iii), diagram (6.5.28) (with $T := T_P$) underlies a commutative diagram in $\mathscr{K}_{\mathrm{int}}$:

$$\begin{array}{ccc} \varphi^*\underline{X}_{(k)} & \longrightarrow & \underline{X}_{(k)} \\ {\scriptstyle \underline{g}_X}\downarrow & & \downarrow{\scriptstyle (\boldsymbol{k}_X,\boldsymbol{k}_{T_P})} \\ \varphi^*\underline{X} & \longrightarrow & \underline{X} \end{array}$$

whose horizontal arrows are cartesian. Clearly this diagram is isomorphic to $X \times_S$ (12.6.21); we deduce that the morphism g_X of log schemes underlying $\underline{g}_X$ is finite, and of Kummer type; by proposition 13.3.11, g_X is even an étale covering, if k is invertible in $\mathscr{O}_X$.

(ii) Suppose furthermore, that $(X, \underline{M})$ is regular; by claim 13.3.37 it follows that $(X_{(k)}, \underline{M}_{(k)})$ is regular as well, and then the same holds for the log schemes $(X_\varphi, \underline{M}_\varphi)$ and $(Y, \underline{N})$ underlying respectively $\varphi^*\underline{X}$ and $\varphi^*\underline{X}_{(k)}$ (proposition 12.6.14(v) and theorem 12.5.28). Let now $y \in Y$ be a point of height one in Y, lying in the closed subset $Y \setminus (Y, \underline{N})_{\mathrm{tr}}$, and set $x := g_X(y)$; arguing as in example 13.3.15, we see that $\underline{N}^\sharp_y$ and $\underline{M}^\sharp_{\varphi,x}$ are both isomorphic to $\mathbb{N}$, and the induced map $\mathscr{O}_{X_\varphi,x} \to \mathscr{O}_{Y,y}$ is an extension of discrete valuation rings, whose corresponding extension of valued fields is finite. Denote by $\Gamma_x \to \Gamma_y$ the associated extension of value groups; in view of (12.6.22) we see that the ramification index $(\Gamma_y : \Gamma_x)$ equals k.

13.3.40. Resume the situation of (13.3.32). Every (finite) discrete quotient map

$$\rho : \underline{M}^{\mathrm{gp}\vee}_x \otimes_{\mathbb{Z}} \prod_{\ell \neq p} \mathbb{Z}_\ell(1) \to G$$

corresponds, via composition with (13.3.30), to a G_U-torsor, which can be explicitly constructed as follows. Set $P := \underline{M}^\sharp_x$, pick a splitting α as in (13.3.32), choose an integer $N > 0$ large enough, so that $(N, p) = 1$, and ρ factors through a group homomorphism

$$\overline{\rho} : \mathrm{Hom}_{\mathbb{Z}}(P^{\mathrm{gp}}, \boldsymbol{\mu}_N(\kappa)) \to G$$

and set $H := \mathrm{Ker}\,\overline{\rho}$. Now, via (13.3.30), the quotient $G' := \mathrm{Hom}_{\mathbb{Z}}(P^{\mathrm{gp}}, \boldsymbol{\mu}_N(\kappa))$ corresponds to the G'_U-torsor on U obtained from $g_N : U_P \to U_P$ via pull-back along the morphism $U \to U_P$ given by the chart α (notation of (13.3.32)). According to remark 13.1.14(ii), the sought G_U is therefore isomorphic to the one obtained from the quotient $\overline{g}_N : U_P/H \to U_P$, via pull-back along the same morphism. To exhibit such quotient, consider the exact sequence:

$$0 \to \mathrm{Hom}_{\mathbb{Z}}(G, \kappa^\times) \to P^{\mathrm{gp}} \otimes_{\mathbb{Z}} \mathbb{Z}/N\mathbb{Z} \to \mathrm{Hom}_{\mathbb{Z}}(H, \kappa^\times) \to 0.$$

Define $Q^{\mathrm{gp}} \subset P^{\mathrm{gp}}$ as the kernel of the induced map $P^{\mathrm{gp}} \to \mathrm{Hom}_{\mathbb{Z}}(H, \kappa^\times)$, and set $Q := Q^{\mathrm{gp}} \cap P$. By construction, the N-Frobenius endomorphism of P factors through an injective map $\nu : P \to Q$ and the inclusion map $j : Q \to P$, so g_N factors as a composition :

$$U_P \to U_Q \xrightarrow{h} U_P.$$

The maps on geometric points $U_P(\kappa) \to U_Q(\kappa) \to U_P(\kappa)$ induced by g_N and h correspond to $j^{\mathrm{gp}*}$ and respectively $\nu^{\mathrm{gp}*}$ in the resulting commutative diagram

$$
\begin{array}{ccccccccc}
 & & & & & & 0 & & \\
 & & & & & & \downarrow & & \\
0 & \to & H & \to & \mathrm{Hom}_{\mathbb{Z}}(P^{\mathrm{gp}}, \boldsymbol{\mu}_N(\kappa)) & \to & G & \to & 0 \\
 & & \| & & \downarrow & & \downarrow & & \\
0 & \to & H & \to & \mathrm{Hom}_{\mathbb{Z}}(P^{\mathrm{gp}}, \kappa^\times) & \xrightarrow{j^{\mathrm{gp}*}} & \mathrm{Hom}_{\mathbb{Z}}(Q^{\mathrm{gp}}, \kappa^\times) & \to & 0 \\
 & & & & & & \downarrow{\scriptstyle \nu^{\mathrm{gp}*}} & & \\
 & & & & & & \mathrm{Hom}_{\mathbb{Z}}(P^{\mathrm{gp}}, \kappa^\times) & & \\
 & & & & & & \downarrow & & \\
 & & & & & & 0 & &
\end{array}
$$

whose rows and column are exact. Hence, let τ and $\chi_\tau : P^{\mathrm{gp}} \to \kappa^\times$ be as in (13.3.32); the fibre $h^{-1}(\tau)$ corresponds to the set of all characters $\chi_{\tau'} : Q^{\mathrm{gp}} \to \kappa^\times$ whose restriction $\chi_{\tau'} \circ \nu^{\mathrm{gp}}$ to P^{gp} agrees with χ_τ. Then, with the notation of (13.3.38), we conclude that the restriction $(f_\nu)_{\mathrm{tr}} : (X_\nu, \underline{M}_\nu)_{\mathrm{tr}} \to U$ is the sought G_U-torsor. Notice as well that f_ν is an étale covering of $(X, \underline{M})$.

• Here is another handier description of the same submonoid Q of P. Notice that ρ is the same as a group homomorphism

$$\rho^\dagger : P^{\mathrm{gp}\vee} \to \mathrm{Hom}_{\mathbb{Z}}(\textstyle\prod_{\ell \neq p} \mathbb{Z}_\ell(1), G)$$

and let $L := \mathrm{Ker}\,\rho^\dagger$. Fix a generator ζ_N of $\boldsymbol{\mu}_N(\kappa)$; by definition

$$
\begin{aligned}
Q^{\mathrm{gp}} &= \{x \in P^{\mathrm{gp}} \mid t(x) \otimes \xi = 0 \text{ for all } t \in P^{\mathrm{gp}\vee} \text{ and } \xi \in \boldsymbol{\mu}_N \text{ such that } \overline{\rho}(t \otimes \xi) = 0\} \\
&= \{x \in P^{\mathrm{gp}} \mid t(x) \otimes \zeta_N = 0 \text{ for all } t \in P^{\mathrm{gp}\vee} \text{ such that } \overline{\rho}(t \otimes \zeta_N) = 0\} \\
&= \{x \in P^{\mathrm{gp}} \mid t(x) \in N\mathbb{Z} \text{ for all } t \in L\}.
\end{aligned}
$$

On the other hand, notice that the N-Frobenius of $P^{\mathrm{gp}\vee}$ factors through a map $\beta : P^{\mathrm{gp}\vee} \to L$ and the inclusion map $i : L \to P^{\mathrm{gp}\vee}$, and $\beta \circ i$ is the N-Frobenius map of L. Let $\omega : P^{\mathrm{gp}} \xrightarrow{\sim} (P^{\mathrm{gp}\vee})^\vee$ be the natural isomorphism. We may then write

$$
\begin{aligned}
Q^{\mathrm{gp}} &= \{x \in P^{\mathrm{gp}} \mid \omega(x)(t) \in N\mathbb{Z} \text{ for all } t \in L\} \\
&= \{x \in P^{\mathrm{gp}} \mid \omega(x) \circ i \in N \cdot L^\vee = i^\vee \circ \beta^\vee(L^\vee)\} \\
&= \omega^{-1}(\mathrm{Im}\,\beta^\vee).
\end{aligned}
$$

In other words, ω induces a natural isomorphism $Q^{\mathrm{gp}} \xrightarrow{\sim} L^\vee$, that identifies $\beta^\vee$ with the map $j^{\mathrm{gp}} : Q^{\mathrm{gp}} \to P^{\mathrm{gp}}$, and then necessarily also the map $i^\vee$ with ν. Now, the image of Q inside $L^\vee$ can be recovered just as $L^\vee \cap P^{\vee\vee}_{\mathbb{Q}}$ (the intersection here takes place in $L^\vee_{\mathbb{Q}}$, which contains $(P^{\mathrm{gp}\vee})^\vee$, via the injective map $i^\vee$: details left to the reader).

13.3.41. Our chief supply of tamely ramified coverings comes from the following source. Let $f : (Y, \underline{N}) \to (X, \underline{M})$ be an étale morphism of log schemes, whose underlying morphism of schemes is finite, and suppose that $(X, \underline{M})$ is regular. Then $(Y, \underline{N})$ is regular, and both X and Y are normal schemes (theorem 12.5.28 and corollary 12.5.13). Moreover, lemma 6.4.59(ii) and proposition 13.3.11 imply that $(Y, \underline{N})_{\mathrm{tr}} = f^{-1}(X, \underline{M})_{\mathrm{tr}}$, hence the restriction of f

$$f_{\mathrm{tr}} : (Y, \underline{N})_{\mathrm{tr}} \to (X, \underline{M})_{\mathrm{tr}}$$

is a finite étale morphism of schemes (corollary 12.3.27(i)). Furthermore, it follows easily from corollary 12.5.20(i) that the closed subset $X\setminus(X,\underline{M})_{\mathrm{tr}}$ is a union of irreducible closed subsets of codimension 1 in X (and the union is locally finite on the Zariski topology of X); the same holds also for $Y\setminus(Y,\underline{N})_{\mathrm{tr}}$, especially Y is the normalization of $(Y,\underline{N})_{\mathrm{tr}}$ over X. Finally, example 13.3.15 implies that f_{tr} is tamely ramified along $X\setminus(X,\underline{M})_{\mathrm{tr}}$. It is then clear that the rule $f\mapsto f_{\mathrm{tr}}$ defines a functor :

$$F_{(X,\underline{M})}:\mathsf{Cov}(X,\underline{M})\to\mathbf{Tame}(X,(X,\underline{M})_{\mathrm{tr}}).$$

It follows easily from remark 12.5.40 that $F_{(X,\underline{M})}$ is fully faithful; therefore, any choice of a geometric point ξ of $(X,\underline{M})_{\mathrm{tr}}$ determines a surjective group homomorphism :

$$\pi_1((X,\underline{M})_{\mathrm{tr,\acute{e}t}},\xi)\to\pi_1((X,\underline{M})_{\mathrm{\acute{e}t}},\xi) \tag{13.3.42}$$

([82, Exp.V, Prop.6.9]).

Proposition 13.3.43. *In the situation of* (13.3.27)*, suppose that* $(X,\underline{M})$ *is a regular log scheme. Then the map* (13.3.30) *factors through* (13.3.42)*, and induces an isomorphism :*

$$\pi_1((X,\underline{M})_{\mathrm{\acute{e}t}},\xi)\xrightarrow{\sim}\underline{M}^{\mathrm{gp}\vee}_{\overline{x}}\otimes_{\mathbb{Z}}\prod_{\ell\neq p}\mathbb{Z}_\ell(1). \tag{13.3.44}$$

Proof. The discussion of (13.3.40) shows that (13.3.30) factors through (13.3.42), and proposition 13.3.36 implies that (13.3.44) is surjective. Next, let $f:(Y,\underline{N})\to(X,\underline{M})$ be an étale covering; according to proposition 13.3.11, f admits a Kummer chart $(\omega_P,\omega_Q,\vartheta)$ with Q fine, sharp and saturated, such that the order k of $\mathrm{Coker}\,\vartheta^{\mathrm{gp}}$ is invertible in $\mathscr{O}_Y$. Moreover, the induced morphism of X-schemes $Y\to X\times_{\mathrm{Spec}\,\mathbb{Z}[P]}\mathrm{Spec}\,\mathbb{Z}[Q]$ is an isomorphism. With this notation, denote by G the cokernel of the induced group homomorphism $\mathrm{Hom}_{\mathbb{Z}}(\vartheta^{\mathrm{gp}},\boldsymbol{k}_{P^{\mathrm{gp}}})$; there follows a map $\rho:P^{\mathrm{gp}}\otimes_{\mathbb{Z}}\prod_{\ell\neq p}\mathbb{Z}_\ell(1)\to G$, and by inspecting the construction, one may check that the corresponding G_U-torsor, constructed as in (13.3.40), is isomorphic to $f\times_X\mathbf{1}_U$ (details left to the reader). This shows the injectivity of (13.3.44), and completes the proof of the proposition. □

The following result is the logarithmic version of the classical Abhyankar's lemma.

Theorem 13.3.45. *The functor* $F_{(X,\underline{M})}$ *is an equivalence.*

Proof. First we show how to reduce to the case where $\tau=\mathrm{\acute{e}t}$.

Claim 13.3.46. Let $(X_{\mathrm{Zar}},\underline{M})$ be a regular log structure on the Zariski site of X, and suppose that the theorem holds for $\widetilde{u}^*(X_{\mathrm{Zar}},\underline{M})$. Then the theorem holds for $(X_{\mathrm{Zar}},\underline{M})$ as well.

Proof of the claim. Let $g:V\to(X_{\mathrm{Zar}},\underline{M})_{\mathrm{tr}}$ be an étale covering whose normalization over X is tamely ramified along $X\setminus(X_{\mathrm{Zar}},\underline{M})_{\mathrm{tr}}$. By assumption, there exists an étale covering $f:(Y_{\mathrm{\acute{e}t}},\underline{N})\to\widetilde{u}^*(X_{\mathrm{Zar}},\underline{M})$ such that $f_{\mathrm{tr}}=g$; by lemma 13.3.10, we may then find a morphism of log schemes of Kummer type $f_{\mathrm{Zar}}:\widetilde{u}_*(Y_{\mathrm{\acute{e}t}},\underline{N})\to(X_{\mathrm{Zar}},\underline{M})$ such that $\widetilde{u}^*f_{\mathrm{Zar}}=f$, therefore f_{Zar} is an étale covering of $(X_{\mathrm{Zar}},\underline{M})$ (corollary 12.3.27(iii)), and clearly $(f_{\mathrm{Zar}})_{\mathrm{tr}}=g$, so the functor $F_{(X_{\mathrm{Zar}},\underline{M})}$ is essentially surjective. Full faithfulness for the same functor is derived formally from the full faithfulness of the functor $F_{\widetilde{u}^*(X_{\mathrm{Zar}},\underline{M})}$, and that of the functor (13.3.9) : details left to the reader. ◊

Henceforth we assume that $\tau=\mathrm{\acute{e}t}$.

Claim 13.3.47. Let $g:V\to(X,\underline{M})_{\mathrm{tr}}$ be an object of $\mathbf{Tame}(X,(X,\underline{M})_{\mathrm{tr}})$. Then g lies in the essential image of $F_{(X,\underline{M})}$ if (and only if) there exists an étale covering family $(U_\lambda\to X\mid\lambda\in\Lambda)$ of X, such that $g\times_X U_\lambda$ lies in the essential image of $F_{(U_\lambda,\underline{M}_{|U_\lambda})}$, for every $\lambda\in\Lambda$.

Proof of the claim. We have to exhibit a finite étale covering $f : (Y, \underline{N}) \to (X, \underline{M})$ such that $f_{\rm tr} = g$. However, given such f, theorem 12.5.28 and corollary 12.5.13 imply that Y is the normalization of V over X, and proposition 12.5.38 says that $\underline{N} = j_*\mathscr{O}_V^\times \cap \mathscr{O}_Y$, where $j : V \to Y$ is the open immersion; then $\log f : f^*\underline{M} \to \underline{N}$ is completely determined by f, hence by g. Thus, we come down to showing that :

(i) $\underline{N} := j_*\mathscr{O}_V^\times \cap \mathscr{O}_Y$ is a regular log structure on the normalization Y of V over X.

(ii) The unique morphism $f : (Y, \underline{N}) \to (X, \underline{M})$ is an étale covering.

However, [126, §33, Lemma 1] implies that Y is finite over X. To show (ii), it then suffices to prove that each restriction $f_\lambda := f \times_X \mathbf{1}_{U_\lambda}$ is étale (proposition 12.3.24(iii)). Likewise, (i) holds, provided the restriction $\underline{N}_{|Y_\lambda}$ is a regular log structure on $Y_\lambda := Y \times_X U_\lambda$, for every $\lambda \in \Lambda$. Let $j_\lambda : V_\lambda := V \times_X U_\lambda \to Y_\lambda$ be the induced open immersion. It is clear that $\underline{N}_{|Y_\lambda} = j_{\lambda *}\mathscr{O}_{V_\lambda}^\times \cap \mathscr{O}_{Y_\lambda}$, and Y_λ is the normalization of V_λ over U_λ (proposition 9.8.3); moreover, $(U_\lambda, \underline{M}_{|U_\lambda})$ is again regular, so our assumption implies that $(Y_\lambda, \underline{N}_{|Y_\lambda})$ is the unique regular log structure on Y_λ whose trivial locus is V_λ, and that f_λ is indeed étale. ◊

Claim 13.3.48. If $F_{(X(\xi), \underline{M}(\xi))}$ is essentially surjective for every geometric point ξ of X, the same holds for $F_{(X,\underline{M})}$.

Proof of the claim. Indeed, let $g : V \to (X, \underline{M})_{\rm tr}$ be an object of $\mathbf{Tame}(X, (X, \underline{M})_{\rm tr})$, and ξ any geometric point of X. By claim 13.3.47 it suffices to find an étale neighborhood $U \to X$ of ξ, such that $g \times_X \mathbf{1}_U$ lies in the essential image of $F_{(U, \underline{M}_{|U})}$. Denote by Y the normalization of X in V, which is a finite X-scheme ([126, §33, Lemma 1]). The scheme $Y(\xi) := Y \times_X X(\xi)$ decomposes as a finite disjoint union of strictly local open and closed subschemes $Y_1(\xi), \dots, Y_n(\xi)$, and we may find an étale neighborhood $U \to X$ of ξ, and a decomposition of $Y \times_X U$ by open and closed subschemes $Y_1, \dots, Y_n$, with isomorphisms of $X(\xi)$-schemes $Y_i(\xi) \xrightarrow{\sim} Y_i \times_X X(\xi)$ for every $i = 1, \dots, n$ ([65, Ch.IV, Cor.8.3.12]). We are then reduced to showing that all the restrictions $Y_i \to U$ lie in the essential image of $F_{(U, \underline{M}_{|U})}$. Thus, we may replace X by U, and Y by any Y_i, after which we may assume that $Y(\xi)$ is strictly local. Proposition 12.5.16 and theorem 12.5.31 imply that $(X(\xi), \underline{M}(\xi))$ is a regular log scheme. Clearly $g_\xi := g \times_X \mathbf{1}_{X(\xi)}$ is an object of $\mathbf{Tame}(X(\xi), (X(\xi), \underline{M}(\xi))_{\rm tr})$, so by assumption there exists a finite étale covering $h : (Z, \underline{N}) \to (X(\xi), \underline{M}(\xi))$ such that $h_{\rm tr} = g_\xi$. By theorem 12.5.28 and corollary 12.5.13 we know that Z is a normal scheme, and we deduce that $Z = Y(\xi)$ ([66, Ch.IV, Prop.17.5.7]).

According to proposition 13.3.11, the morphism h admits a fine and saturated Kummer chart $(\omega_P, \omega_Q, \vartheta : P \to Q)$, such that the order d of $\operatorname{Coker} \vartheta^{\rm gp}$ is invertible in $\mathscr{O}_{X,\xi}$, and such that the induced map $Y(\xi) \to X(\xi) \times_{\operatorname{Spec} P} \operatorname{Spec} Q$ is an isomorphism. By proposition 12.2.30, there exist an étale neighborhood $U \to X$ of ξ, and a coherent log structure $\underline{N}'$ on $Y' := Y \times_X U$ with an isomorphism $Y(\xi) \times_{Y'} (Y', \underline{N}') \xrightarrow{\sim} (Y(\xi), \underline{N})$. Moreover, let $h' : Y' \to U$ be the projection; after shrinking U, the map $\log h$ descends to a morphism of log structures $h'^*\underline{M}_{|U} \to \underline{N}'$, whence a morphism $(h', \log h') : (Y', \underline{N}') \to (U, \underline{M}_{|U})$ of log schemes, such that $h' \times_U \mathbf{1}_{X(\xi)} = h$. After further shrinking U, we may also assume that h' admits a Kummer chart $(\omega'_P, \omega'_Q, \vartheta)$ (corollary 12.2.36), that d is invertible in $\mathscr{O}_U$, and that the induced morphism $Y' \to U \times_{\operatorname{Spec} P} \operatorname{Spec} Q$ is an isomorphism ([65, Ch.IV, Cor.8.8.24]). Then h' is an étale covering, by proposition 13.3.11, and by construction, $F_{(U, \underline{M}_{|U})}(h') = g \times_X \mathbf{1}_U$, as desired. ◊

Claim 13.3.49. Assume that X is strictly local, denote by x the closed point of X, set $U := (X, \underline{M})_{\rm tr}$, and $P := \underline{M}_x^\sharp$. Let $h : V \to U$ be any connected non-empty étale covering, tamely ramified along $X \setminus U$; then h lies in the essential image of $F_{(X,\underline{M})}$, provided there exist a fine, sharp and saturated monoid Q, and a morphism $\nu : P \to Q$ of Kummer type, such that

$$h_\nu := h \times_X X_\nu : V \times_X X_\nu \to U \times_X X_\nu$$

admits a section (notation of (13.3.38)).

Proof of the claim. Suppose first that the order of $\mathrm{Coker}\,\nu^{\mathrm{gp}}$ is invertible in $\mathscr{O}_X$; in this case, f_ν is an étale covering of log schemes (proposition 13.3.11), hence $(f_\nu)_{\mathrm{tr}}$ is an étale covering of the scheme U. Then, by composing a section of h_ν with the projection $V \times_X X_\nu \to V$ we deduce a morphism $U \times_X X_\nu \to V$ of étale coverings of U. Such morphism shall be open and closed, hence surjective, since V is connected; hence the $\pi_1(U,\xi)$-set $h^{-1}(\xi)$ will be a quotient of $f_\nu^{-1}(\xi)$, on which $\pi_1(U,\xi)$ acts through (13.3.30), as required. Next, for a general morphism ν of Kummer type, let $L \subset Q^{\mathrm{gp}}$ be the largest subgroup such that $\nu^{\mathrm{gp}}(P^{\mathrm{gp}}) \subset L$, and $(L : P^{\mathrm{gp}})$ is invertible in $\mathscr{O}_X$. Set $Q' := L \cap Q$, and notice that $Q'^{\mathrm{gp}} = L$. Indeed, every element of L can be written in the form $x = b^{-1}a$, for some $a, b \in Q$; then choose $n > 0$ such that $b^n \in \nu P$, write $x = b^{-n} \cdot (b^{n-1}a)$ and remark that $b^{-n}, b^{n-1}a \in Q'$. The morphism ν factors as the composition of $\nu' : P \to Q'$ and $\psi : Q' \to Q$, and therefore f_ν factors through a morphism $f_\psi : X_\nu \to X_{\nu'}$. In view of the previous case, we are reduced to showing that the morphism $h_{\nu'}$ already admits a section, hence we may replace $(X, \underline{M})$ by $(X_{\nu'}, \underline{M}_{\nu'})$ (which is still regular and strictly local, by claim 13.3.37), h by $h_{\nu'}$, and ν by ψ, after which we may assume that the order of $\mathrm{Coker}\,\nu^{\mathrm{gp}}$ is p^m for some integer $m > 0$, where $p > 0$ is the characteristic of the residue field $\kappa(x)$, and then we need to show that h already admits a section.

Next, using again claim 13.3.37 and an easy induction, we may likewise reduce to the case where $m = 1$. Say that $X = \mathrm{Spec}\,A$, and suppose first that A is a $\mathbb{F}_p$-algebra (where $\mathbb{F}_p$ is the finite field with p elements), so that $X_\nu = \mathrm{Spec}\,A \otimes_{\mathbb{F}_p[P]} \mathbb{F}_p[Q]$; it is easily seen that the ring homomorphism $\mathbb{F}_p[\nu] : \mathbb{F}_p[P] \to \mathbb{F}_p[Q]$ is invertible up to Φ, in the sense of [75, Def.3.5.8(i)]. Especially, $\mathrm{Spec}\,\mathbb{F}_p[\nu]$ is integral, surjective and radicial, hence the same holds for f_ν, and therefore the morphism of sites :

$$f_\nu^* : X_{\text{ét}} \to X_{\nu,\text{ét}}$$

is an equivalence of categories (lemma 13.1.7(i)). It follows that in this case, h admits a section if and only if the same holds for h_ν.

Next, suppose that the field of fractions K of A has characteristic zero; we may write $X_\nu \times_X \mathrm{Spec}\,K = \mathrm{Spec}\,K_\nu$ and $V \times_X \mathrm{Spec}\,K = \mathrm{Spec}\,E$ for two field extensions K_ν and E of K, such that $[K_\nu : K] = p$, and the section of h_ν yields a map $E \to K_\nu$ of K-algebras. Therefore we have either $E = K$ (in which case $V = U$, and then we are done), or else $E = K_\nu$, in which case $V = (X_\nu, \underline{M}_\nu)_{\mathrm{tr}}$, since both these schemes are normal and finite over U.

Hence, let us assume that $V = (X_\nu, \underline{M}_\nu)$, and pick any point $\eta \in X$ of codimension one, whose residue field $\kappa(\eta)$ has characteristic p. Then $X_\nu \times_X X(\eta) = \mathrm{Spec}\,B$, where $B := \mathscr{O}_{X,\eta} \otimes_{\mathbb{Z}[P]} \mathbb{Z}[Q]$, and $\overline{B} := B \otimes_A \kappa(\eta) = \kappa(\eta) \otimes_{\mathbb{F}_p[P]} \mathbb{F}_p[Q]$. Since the map $\mathbb{F}_p[P] \to \mathbb{F}_p[Q]$ is invertible up to Φ, we easily deduce that $\overline{B}$ is local, and its residue field is a purely inseparable extension of $\kappa(\eta)$, say of degree d. Therefore $f_\nu^{-1}\eta$ consists of a single point η', and $\mathscr{O}_{X_\nu,\eta'} \simeq B$ is a normal and finite $\mathscr{O}_{X,\eta}$-algebra, hence it is a discrete valuation ring. Let e denote the ramification index of the extension $\mathscr{O}_{X,\eta} \to \mathscr{O}_{X_\nu,\eta'}$; then $ed = p$ ([34, Ch.VI, §8, n.5, Cor.1]). Suppose that $e = p$; in view of [75, Lemma 6.2.5], the ramification index of the induced extension of strict henselizations $\mathscr{O}^{\mathrm{sh}}_{X,\eta} \to \mathscr{O}^{\mathrm{sh}}_{X_\nu,\eta'}$ is still equal to p, which is impossible, since h is tamely ramified along $X \setminus U$. In case $e = 1$, we must have $d = p$, and since the residue field $\kappa(\eta)^{\mathrm{s}}$ of $\mathscr{O}^{\mathrm{sh}}_{X,\eta}$ is a separable closure of $\kappa(\eta)$, it follows easily that the residue field of $\mathscr{O}^{\mathrm{sh}}_{X_\nu,\eta'}$ must be a purely inseparable extension of $\kappa(\eta)^{\mathrm{s}}$ of degree p, which again contradicts the tameness of h. ◊

Claim 13.3.50. If $(X, \underline{M}) = (X, \underline{M})_2$, then $F_{(X,\underline{M})}$ is essentially surjective (notation of definition 12.2.7(i)).

Proof of the claim. By claim 13.3.48, we may assume that X is strictly henselian. In this case, let U, P and $h : V \to U$ be as in claim 13.3.49. By assumption $d := \dim P \leq 2$, and we have to show that $h \times_X X_\nu$ admits a section, for a suitable Kummer morphism $\nu : P \to Q$ (notation of (13.3.38)). If $d = 0$, then $P = \{1\}$, in which case $U = X$ is strictly local, so its fundamental group is trivial, and there is nothing to prove. In case $d = 1$, then $P \simeq \mathbb{N}$ (theorem 6.4.18(ii)), in which case X is a regular scheme (corollary 12.5.19), and $X \backslash U$ is a regular divisor (remark 12.5.15) and then the assertion follows from the classical Abhyankar's lemma ([82, Exp.XIII, Prop.5.2]). For $d = 2$, we may find $e_1, e_2 \in P$, and an integer $N > 0$ such that

$$\mathbb{N}e_1 \oplus \mathbb{N}e_2 \subset P \subset P' := \mathbb{N}\frac{e_1}{N} \oplus \mathbb{N}\frac{e_2}{N}$$

(see example 6.4.19(i)). Especially, the inclusion $\nu : P \to P'$ is a morphism of Kummer type. Since a composition of morphisms of Kummer type is obviously of Kummer type, claims 13.3.49 and 13.3.37 imply that we may replace $(X, \underline{M})$ by $(X_\nu, \underline{M}_\nu)$ and h by h_ν (notation of (13.3.38)), after which we may assume that P is isomorphic to $\mathbb{N}^{\oplus 2}$. In this case, X is again regular and $X \backslash U$ is a strict normal crossings divisor, so the assertion follows again from [82, Exp.XIII, Prop.5.2]. $\diamondsuit$

Claim 13.3.51. In the situation of (13.3.1), suppose that $(Y, \underline{N})$ is regular. Then the functor $f^*_{\mathrm{tr}} : \mathsf{Cov}(Y, \underline{N})_{\mathrm{tr}} \to \mathsf{Cov}(Y', \underline{N}')_{\mathrm{tr}}$ restricts to an equivalence :

$$\mathbf{Tame}(Y, (Y, \underline{N})_{\mathrm{tr}}) \xrightarrow{\sim} \mathbf{Tame}(Y', (Y', \underline{N}')_{\mathrm{tr}}). \tag{13.3.52}$$

Proof of the claim. Arguing as in the proof of proposition 13.3.2, we may reduce to the case where $\varphi : T' \to T$ is the saturated blow up of an ideal generated by two elements of $\Gamma(T, \mathscr{O}_T)$.

Notice that $(f, \log f)$ is an étale morphism (proposition 12.6.14(v)), and it restricts to an isomorphism $f_{\mathrm{tr}} : (Y', \underline{N}')_{\mathrm{tr}} \xrightarrow{\sim} (Y, \underline{N})_{\mathrm{tr}}$ (remark 12.6.17). Especially, $(Y', \underline{N}')$ is regular, and f^*_{tr} is trivially an equivalence from the étale coverings of $(Y, \underline{N})_{\mathrm{tr}}$ to those of $(Y', \underline{N}')_{\mathrm{tr}}$.

Let $g : V \to (Y, \underline{N})_{\mathrm{tr}}$ be an object of $\mathbf{Tame}(Y, (Y, \underline{N})_{\mathrm{tr}})$. By claim 13.3.50 and lemma 12.5.21, the functor $F_{\widetilde{u}^*(Y,\underline{N})_2}$ is essentially surjective, and then the same holds for $F_{(Y,\underline{N})_2}$, in view of claim 13.3.46; hence we may find an étale covering $(W, \underline{Q}) \to (Y, \underline{N})_2$, and an isomorphism $V \xrightarrow{\sim} (Y, \underline{N})_{\mathrm{tr}} \times_Y W$ of $(Y, \underline{N})_{\mathrm{tr}}$-schemes. On the other hand, example 6.5.56(ii) shows that φ restricts to a morphism $T'_1 \to T_2$ (notation of (6.5.16)), consequently f restricts to a morphism $(Y', \underline{N}')_1 \to (Y, \underline{N})_2$. There follows a well defined étale covering :

$$(Y', \underline{N}')_1 \times_{(Y,\underline{N})_2} (W, \underline{Q}) \to (Y', \underline{N}')_1.$$

whose image under $F_{(Y',\underline{N}')_1}$ is $f^*_{\mathrm{tr}}(g)$. However, $(Y', \underline{N}')_1$ contains all the points of height one of $Y' \backslash (Y', \underline{N}')_{\mathrm{tr}}$ (corollary 12.5.20(i)), hence $f^*_{\mathrm{tr}}(g)$ is tamely ramified along $Y' \backslash (Y', \underline{N}')_{\mathrm{tr}}$ (see (13.3.41)). This shows that (13.3.52) is well defined, and clearly this functor is fully faithful, since the same holds for f^*_{tr}. Lastly, let $y \in Y \setminus (Y, \underline{N})_{\mathrm{tr}}$ be any point of height one; by proposition 12.6.31(ii) and corollary 12.6.29, there exists a point $y' \in Y' \setminus (Y', \underline{N}')_{\mathrm{tr}}$ with $f(y') = y$, and since f restricts to an isomorphism f_{tr}, the corresponding map $\beta : \mathscr{O}_{Y,y} \to \mathscr{O}_{Y',y'}$ is local, injective, and induces an isomorphism on the respective fields of fractions. Since $\mathscr{O}_{Y,y}$ is a discrete valuation ring, it follows easily that β is an isomorphism, and therefore y' is a point of height one in Y'. Consequently, the equivalence $(f^{-1}_{\mathrm{tr}})^* : \mathsf{Cov}(Y', \underline{N}')_{\mathrm{tr}} \xrightarrow{\sim} \mathsf{Cov}(Y, \underline{N})_{\mathrm{tr}}$ induced by the isomorphism of schemes f^{-1}_{tr} restricts to a well defined functor $\mathbf{Tame}(Y', (Y', \underline{N}')_{\mathrm{tr}}) \to \mathbf{Tame}(Y, (Y, \underline{N})_{\mathrm{tr}})$ which yields a quasi-inverse for (13.3.52). $\diamondsuit$

Suppose again that $(X, \underline{M})$ is strictly henselian, define P, U and $h : V \to U$ as in claim 13.3.49, and set $T_P := (\mathrm{Spec}\, P)^\sharp$; it is easily seen that the counit of adjunction

$$\widetilde{u}^* \widetilde{u}_*(X, \underline{M}) \to (X, \underline{M})$$

is an isomorphism (cp. (12.6.48)), hence $\widetilde{u}_*(X, \underline{M})$ is regular (lemma 12.5.21). Let

$$\underline{X} := (\widetilde{u}_*(X, \underline{M}), T_P, \pi_X)$$

be the object of $\mathscr{K}$ arising from $\widetilde{u}_*(X, \underline{M})$, as in (12.6.7); by theorem 12.6.32 (and its proof), we may find an integral proper simplicial subdivision $\varphi : F \to T_P$, such that the morphism of schemes underlying $(f, \varphi) : \varphi^*\underline{X} \to \underline{X}$ is a resolution of singularities for X. For every integer $k \geq 1$ we define $(X_{(k)}, \underline{M}_{(k)})$, $(X_\varphi, \underline{M}_\varphi)$, $(Y, \underline{N})$, g_X and $\boldsymbol{k}_X$ as in example 13.3.39 : this makes sense, since, in the current situation, $\underline{X}$ is isomorphic to $X \times_S \underline{S}$ (where $\underline{S}$ is defined as in example 12.6.5(i)). Moreover, by the same token, the morphism of schemes $Y \to X_{(k)}$ is a resolution of singularities.

Set as well $U_\varphi := (X_\varphi, \underline{M}_\varphi)_{\mathrm{tr}}$ and $U_{(k)} := (X_{(k)}, \underline{M}_{(k)})_{\mathrm{tr}}$; by claim 13.3.51 and proposition 13.3.20(i), we have an essentially commutative diagram of functors :

$$\begin{array}{ccc} \mathbf{Tame}(X, U) & \xrightarrow{f^*_{\mathrm{tr}}} & \mathbf{Tame}(X_\varphi, U_\varphi) \\ {\scriptstyle \boldsymbol{k}^*_X}\downarrow & & \downarrow{\scriptstyle g^*_X} \\ \mathbf{Tame}(X_{(k)}, U_{(k)}) & \longrightarrow & \mathbf{Tame}(Y, (Y, \underline{N})_{\mathrm{tr}}) \end{array}$$

whose horizontal arrows are equivalences. Let k be the ramification index of h_φ along $X_\varphi \backslash U_\varphi$; in light of claim 13.3.49, we are reduced to showing that $\boldsymbol{k}^*_X(h)$ admits a section. Set $V_\varphi := V \times_U U_\varphi$ and $h_\varphi := f^*_{\mathrm{tr}}(h) : V_\varphi \to U_\varphi$; then it suffices to show that $g^*_X(h_\varphi)$ has a section.

Let $\overline{V}_\varphi \to X_\varphi$ be the normalization of h_φ over X_φ, and $\overline{W} \to Y$ the normalization of $\overline{V}_\varphi \times_{X_\varphi} Y$ in $V_\varphi \times_{X_\varphi} Y$. Choose a geometric point w of $\overline{W}$ whose support has height one; denote by y (resp. v, resp. x) the image of w in Y (resp. in $\overline{V}_\varphi$, resp. in X_φ), and suppose that the support of x lies in $X_\varphi \setminus U_\varphi$. Denote by $K(x)$ the field of fractions of the strictly henselian local ring $\mathscr{O}_{X,x}$, and define likewise $K(w)$, $K(y)$ and $K(v)$. There follows a commutative diagram of inclusions of valued fields :

$$\begin{array}{ccc} K(x) & \longrightarrow & K(y) \\ \downarrow & & \downarrow \\ K(v) & \longrightarrow & K(w) \end{array}$$

such that $K(w)$ is the compositum of $K(y)$ and $K(v)$: cp. the proof of proposition 13.3.20(i).

Example 13.3.39(ii) shows that the ramification index of $\mathscr{O}_{Y,y}$ over $\mathscr{O}_{X_\varphi,x}$ is k, which is a multiple of the ramification index of $\mathscr{O}_{\overline{V}_\varphi,v}$ over $\mathscr{O}_{X_\varphi,x}$. It then follows (*e.g.* from [75, Claim 6.2.15]) that $K(v) \subset K(y)$, and therefore $K(w) = K(y)$; this shows that the ramification index of $g^*_X(h_\varphi)$ along $Y \backslash (Y, \underline{N})_{\mathrm{tr}}$ equals 1, therefore $g^*_X(h_\varphi)$ is the restriction of an étale covering $\overline{h}$ of Y (proposition 13.3.20(iii)). By proposition 13.3.2(ii), $\overline{h}$ is the pull-back of an étale covering of $X_{(k)}$. Since $X_{(k)}$ is strictly local (claim 13.3.37), it follows that $\overline{h}$ admits a section, hence the same holds for $g^*_X(h_\varphi)$, as required. □

Remark 13.3.53. A proof of theorem 13.3.45 similar to the one given here can be found in [130, §2.3].

13.3.54. As an application of theorem 13.3.45, we shall determine the fundamental group of the "punctured" scheme obtained by removing the closed point from a strictly local regular log scheme $(X, \underline{M})$ (with non-trivial log structure) of dimension ≥ 2. Indeed, let $x \in X$ be the closed point, and set $r := \dim \underline{M}_x$. Also, let $\overline{y}$ be any geometric point of X, localized at a point $y \in U := X \setminus \{x\}$, and ξ a geometric point of X localized at the maximal point. Let p (resp. p') denote the characteristic exponent of $\kappa(x)$ (resp. of $\kappa(y)$). Pick any lifting of ξ to a geometric point ξ_y of $X(\overline{y})$; since $(X(\overline{y}), \underline{M}(\overline{y}))$ is regular (theorem 12.5.31), according to proposition 13.3.43, the vertical arrows of the commutative diagram in (13.3.31) factor through the surjections (13.3.42), and we get a commutative diagram of group homomorphisms :

$$\begin{array}{ccc} \pi_1((X(\overline{y}),\underline{M}(\overline{y}))_{\text{ét}},\xi_y) & \xrightarrow{\varphi_y} & \pi_1((X,\underline{M})_{\text{ét}},\xi) \\ \downarrow & & \downarrow \\ \underline{M}^{\text{gp}\vee}_{\overline{y}} \otimes_{\mathbb{Z}} \prod_{\ell\neq p'} \mathbb{Z}_\ell(1) & \longrightarrow & \underline{M}^{\text{gp}\vee}_x \otimes_{\mathbb{Z}} \prod_{\ell\neq p} \mathbb{Z}_\ell(1) \end{array}$$

whose vertical arrows are the isomorphisms (13.3.44), and whose top (resp. bottom) horizontal arrow is induced by the natural morphism $X(\overline{y}) \to X$ (resp. by the specialization map $\underline{M}_x \to \underline{M}_{\overline{y}}$). Now, by corollary 12.5.13, the scheme U is connected and normal, hence the restriction functor $\mathsf{Cov}(U) \to \mathbf{Tame}(X,(X,\underline{M})_{\text{tr}})$ is fully faithful (lemma 13.1.7(iii)); by [82, Exp.V, Prop.6.9] and theorem 13.3.45, it follows that the induced group homomorphism

(13.3.55) $$\pi_1((X,\underline{M})_{\text{ét}},\xi) \to \pi_1(U_{\text{ét}},\xi)$$

is surjective (see (13.3.41)). Clearly, the image of φ_y lies in the kernel of (13.3.55). Especially:

$$(U,\underline{M}_{|U})_r \neq \varnothing \Rightarrow \pi_1(U_{\text{ét}},\xi) = \{1\}$$

since, for any geometric point $\overline{y}$ of $(X,\underline{M})_r$, the specialization map $\underline{M}_x \to \underline{M}_{\overline{y}}$ is an isomorphism (notation of definition 12.2.7(i)). Thus, suppose that $(X,\underline{M})_r = \{x\}$, set $P := \underline{M}^\sharp_x$, and denote by $\psi : X \to \operatorname{Spec} P$ the natural continuous map; we have $\underline{M}^\sharp_{\overline{y}} = P_{\psi(y)}$, and if we let $F_y := P \setminus \psi(y)$, we get a short exact sequence of free abelian groups of finite rank :

(13.3.56) $$0 \to F^{\text{gp}}_y \to \underline{M}^{\sharp\text{gp}}_x \to \underline{M}^{\sharp\text{gp}}_{\overline{y}} \to 0.$$

It is easily seen that ψ is surjective; hence, for any $\mathfrak{p} \in \operatorname{Spec} P$ of height $r-1$, pick $y \in \psi^{-1}(\mathfrak{p})$. With this choice, we have $F^{\text{gp}}_y = \mathbb{Z}$; considering $(13.3.56)^\vee$, we deduce that $\pi_1(U_{\text{ét}},\xi)$ is a quotient of $\widehat{\mathbb{Z}}'(1) := \prod_{\ell\neq p} \mathbb{Z}_\ell(1)$. More precisely, let $(\operatorname{Spec} P)_{r-1}$ be the set of prime ideals of P of height $r-1$; then we have :

Theorem 13.3.57. *If $(X,\underline{M})_r = \{x\}$, we have a natural identification :*

(13.3.58) $$\frac{P^\vee}{\sum_{\mathfrak{p}\in(\operatorname{Spec} P)_{r-1}} P^\vee_{\mathfrak{p}}} \otimes_{\mathbb{Z}} \widehat{\mathbb{Z}}'(1) \xrightarrow{\sim} \pi_1(U_{\text{ét}},\xi)$$

and these two abelian groups are cyclic of finite order prime to p.

Proof. The foregoing discussion already yields a natural surjective map as stated; it remains only to check the injectivity, and to verify that the source is a cyclic finite group.

However, since $d \geq 2$, and $(X,\underline{M})_r = \{x\}$, corollary 12.5.20(i) implies that $r \geq 2$, in which case $(\operatorname{Spec} P)_{r-1}$ must contain at least two distinct elements, say $\mathfrak{p}$ and $\mathfrak{q}$. Let $F := P \setminus \mathfrak{p}$; the image H of $(P_{\mathfrak{q}})^{\sharp\text{gp}\vee}$ in $F^{\text{gp}\vee}$ is clearly a non-trivial subgroup, hence $F^{\text{gp}\vee}/H$ is a cyclic finite group, and then the same holds for the source of (13.3.58).

Next, it follows easily from lemma 13.1.7(iii) that (13.3.55) identifies $\pi_1(U_{\text{ét}},\xi)$ with the quotient of $\pi_1((X,\underline{M})_{\text{ét}},\xi)$ by the sum of the images of the maps φ_y, for y ranging over all the points of U. However, it is clear that the same sum is already spanned by the sum of the images of the φ_y such that $y \in (X,\underline{M})_{r-1}$; whence the theorem. ☐

Example 13.3.59. Let $P \subset \mathbb{N}^{\oplus 2}$ be the submonoid of all pairs (a,b) such that $a+b \in 2\mathbb{N}$. Clearly P is fine and saturated of dimension 2. Let K be any field; the K-scheme $X := \operatorname{Spec} K[P]$ is the singular quadric in $\mathbb{A}^3_K$ cut by the equation $XY - Z^2 = 0$. It is easily seen that $\operatorname{Spec}(K,P)_2$ consists of a single point x (the vertex of the cone); let $\overline{x}$ be a geometric point of X localized at x, and $U \subset X(\overline{x})$ the complement of the closed point. Then U is a normal K-scheme of dimension 1, and we have a natural isomorphism

$$\pi_1(U,\xi) \xrightarrow{\sim} \mathbb{Z}/2\mathbb{Z}.$$

Indeed, a simple inspection shows that P admits exactly two prime ideals of height one, namely $\mathfrak{p} := P \setminus (2\mathbb{N} \oplus \{0\})$ and $\mathfrak{q} := P \setminus (\{0\} \oplus 2\mathbb{N})$. Then, $P_\mathfrak{p} = \{(a,b) \in \mathbb{Z} \oplus \mathbb{N} \mid a+b \in 2\mathbb{N}\}$, and similarly $P_\mathfrak{q}$ is a submonoid of $\mathbb{N} \oplus \mathbb{Z}$. The quotients $P^\sharp_\mathfrak{p}$ and $P^\sharp_\mathfrak{q}$ are both isomorphic to $\mathbb{N}$, and are both generated by the class of $(1,1)$. Let $\varphi : P^\sharp_\mathfrak{p} \to \mathbb{Z}$ be a map of monoids; then the image of φ in $P^{\mathrm{gp}\vee}$ is the unique map of monoids $P \to \mathbb{Z}$ given by the rule : $(2,0) \mapsto 0$, $(1,1) \mapsto \varphi(1,1)$, $(0,2) \mapsto 2\varphi(1,1)$. Likewise, a map $\psi : P^\sharp_\mathfrak{q} \to \mathbb{Z}$ gets sent to the morphism $P \to \mathbb{Z}$ such that $(2,0) \mapsto 2\psi(1,1)$, $(1,1) \mapsto \psi(1,1)$, and $(0,2) \mapsto 0$. We see therefore that $(P_\mathfrak{p})^{\sharp\mathrm{gp}\vee} + (P_\mathfrak{q})^{\sharp\mathrm{gp}\vee}$ is a subgroup of index two in $P^{\mathrm{gp}\vee}$, and the contention follows from theorem 13.3.57.

13.4. **Local acyclicity of smooth morphisms of log schemes.** In this section we consider a smooth and saturated morphism $f : (X, \underline{M}) \to (Y, \underline{N})$ of fine log schemes. We fix a geometric point $\overline{x}$ of X, localized at a point x, and let $\overline{y} := f(\overline{x})$. We shall suppose as well that Y is strictly local and normal, that $(Y, \underline{N})_{\mathrm{tr}}$ is a dense open subset of Y, and that $\overline{y}$ is localized at the closed point y of Y. Let $\overline{\eta}$ be a strict geometric point of Y, localized at the generic point η; to ease notation, set :

$$U := f^{-1}_{\overline{x}}(\eta) \qquad U_{\mathrm{tr}} := (X(\overline{x}), \underline{M}(\overline{x}))_{\mathrm{tr}} \cap U \qquad \overline{U} := U \times_{|\eta|} |\overline{\eta}| \qquad \overline{U}_{\mathrm{tr}} := U_{\mathrm{tr}} \times_{|\eta|} |\overline{\eta}|$$

and notice that U_{tr} is a dense open subset of U, by virtue of proposition 12.7.17(ii,iv). Choose a geometric point ξ of $\overline{U}_{\mathrm{tr}}$, and let ξ' be the image of ξ in U_{tr}. There follows a short exact sequence of topological groups :

$$1 \to \pi_1(\overline{U}_{\mathrm{tr,ét}}, \xi) \to \pi_1(U_{\mathrm{tr,ét}}, \xi') \xrightarrow{\alpha} \pi_1(|\eta|_{\mathrm{ét}}, \overline{\eta}) \to 1.$$

On the other hand, let p be the characteristic exponent of $\kappa := \kappa(\overline{y})$; for every integer e such that $(e,p) = 1$, the discussion of (13.3.27) yields a commutative diagram :

(13.4.1)
$$\begin{array}{ccccc}
\underline{N}_{\overline{y}} & \longrightarrow & \kappa(\eta)^\times & \longrightarrow & \mathrm{Hom}_{\mathrm{cont}}(\pi_1(|\eta|_{\mathrm{ét}}, \overline{\eta}), \boldsymbol{\mu}_e(\kappa)) \\
{\scriptstyle \log f_{\overline{x}}}\downarrow & & \downarrow & & \downarrow{\scriptstyle \mathrm{Hom}_{\mathrm{cont}}(\alpha, \boldsymbol{\mu}_e(\kappa))} \\
\underline{M}_{\overline{x}} & \longrightarrow & \Gamma(U_{\mathrm{tr}}, \mathscr{O}^\times_U) & \longrightarrow & \mathrm{Hom}_{\mathrm{cont}}(\pi_1(U_{\mathrm{tr,ét}}, \xi'), \boldsymbol{\mu}_e(\kappa))
\end{array}$$

such that the composition of the two top (rep. bottom) horizontal arrows factors through $\underline{N}^\sharp_{\overline{y}}$ (resp. $\underline{M}^\sharp_{\overline{x}}$). There follows a system of natural group homomorphisms :

(13.4.2)
$$\mathrm{Coker}\,(\log f)^{\mathrm{gp}}_{\overline{x}} \to \mathrm{Hom}_{\mathrm{cont}}(\pi_1(\overline{U}_{\mathrm{tr,ét}}, \xi), \boldsymbol{\mu}_e(\kappa)) \qquad \text{where } (e,p) = 1$$

which assemble into a group homomorphism :

(13.4.3)
$$\pi_1(\overline{U}_{\mathrm{tr,ét}}, \xi) \to \mathrm{Coker}\,(\log f^{\mathrm{gp}}_{\overline{x}})^\vee \otimes_\mathbb{Z} \prod_{\ell \neq p} \mathbb{Z}_\ell(1).$$

13.4.4. We wish to give a second description of the map (13.4.3), analogous to the discussion in (13.3.32). To this aim, let R be a ring; for any monoid P, and any integer $e > 0$, denote by $\boldsymbol{e}_P : P \to P$ the e-Frobenius map of P. Let $\lambda : P \to Q$ be a local morphism of finitely generated monoids. For any integer $e > 0$, we get a commutative diagram of monoids :

(13.4.5)
$$\begin{array}{ccccc}
P & \xrightarrow{\boldsymbol{e}_P} & P & & \\
{\scriptstyle\lambda}\downarrow & & \downarrow{\scriptstyle\lambda_e} & \searrow^{\lambda} & \\
Q & \xrightarrow{\mu'} & Q' & \xrightarrow{\boldsymbol{e}_{Q|P}} & Q
\end{array}$$

whose square subdiagram is cocartesian, and such that $\boldsymbol{e}_{Q|P} \circ \mu' = \boldsymbol{e}_Q$. The latter induces a commutative diagram of log schemes :

$$\begin{array}{ccccc} \mathrm{Spec}(R,Q) & \xrightarrow{g_{Q|P}} & \mathrm{Spec}(R,Q') & \xrightarrow{g'} & \mathrm{Spec}(R,Q) \\ & \searrow^{g} & \downarrow{\scriptstyle g_e} & & \downarrow{\scriptstyle g} \\ & & \mathrm{Spec}(R,P) & \xrightarrow{g_P} & \mathrm{Spec}(R,P) \end{array}$$

whose square subdiagram is cartesian, and such that $g_Q := g' \circ g_{Q|P}$ is the morphism induced by $\boldsymbol{e}_Q$. Also, by example 12.6.5, we have a commutative diagram of monoidal spaces :

$$\begin{array}{ccccc} \mathrm{Spec}(R,Q) & \xrightarrow{g_{Q|P}} & \mathrm{Spec}(R,Q') & \xrightarrow{g_e} & \mathrm{Spec}(R,P) \\ \downarrow{\scriptstyle \psi_Q} & & \downarrow{\scriptstyle \psi_{Q'}} & & \downarrow{\scriptstyle \psi_P} \\ T_Q & \xrightarrow{\varphi} & T_{Q'} & \longrightarrow & T_P \end{array}$$

(where $\varphi := (\mathrm{Spec}\, \boldsymbol{e}_{Q|P})^\sharp$) which determines morphisms in the category $\mathscr{K}$:

$$(\mathrm{Spec}(R,Q), T_Q, \psi_Q) \to (\mathrm{Spec}(R,Q'), T_{Q'}, \psi_{Q'}) \to (\mathrm{Spec}(R,P), T_P, \psi_P).$$

13.4.6. Now, suppose that the closed point $\mathfrak{m}_Q$ of T_Q lies in the strict locus of $(\mathrm{Spec}\, \lambda)^\sharp$ (which just means that $\lambda^\sharp$ is an isomorphism). Notice that the functor $M \mapsto M^\sharp$ commutes with colimits (since it is a left adjoint); taking into account lemma 6.1.13, we deduce that the square subdiagram of $(13.4.5)^\sharp$ is still cocartesian, and therefore $\boldsymbol{e}^\sharp_{Q|P}$ is an isomorphism, so the same holds for φ.

More generally, let $\mathfrak{q} \in \mathrm{Spec}\, Q$ be any prime ideal in the strict locus of $(\mathrm{Spec}\, \lambda)^\sharp$; set $\mathfrak{p} := \lambda^{-1}\mathfrak{q}$, $\mathfrak{r} := \varphi(\mathfrak{q})$, and recall that $T_{Q_\mathfrak{q}} := \mathrm{Spec}\, Q_\mathfrak{q}$ is naturally an open subset of T_Q (see (6.5.16)). A simple inspection shows that the restriction $T_{Q_\mathfrak{q}} \to T_{Q'_\mathfrak{r}}$ of φ is naturally identified with the morphism of affine fans $(\mathrm{Spec}\, \boldsymbol{e}_{Q_\mathfrak{q}|P_\mathfrak{p}})^\sharp$. Since $\mathfrak{q}$ is the closed point of $T_{Q_\mathfrak{q}}$, the foregoing shows that $T_{Q_\mathfrak{q}}$ lies in the strict locus of φ; in other words, $\mathrm{Str}(\varphi)$ is an open subset of T_Q, and we have

$$\mathrm{Str}((\mathrm{Spec}\, \lambda)^\sharp) \subset \mathrm{Str}(\varphi). \tag{13.4.7}$$

Moreover, recall that $\mathrm{Spec}\, \boldsymbol{e}_Q : T_Q \to T_Q$ is the identity on the underlying topological space (see example 6.5.10(i)), and by construction it factors through φ, so the latter is injective on the underlying topological spaces. Especially, $\mathrm{Str}(\varphi) = \varphi^{-1}\varphi(\mathrm{Str}(\varphi))$, and therefore

$$\mathrm{Str}(g_{Q|P}) = \psi_Q^{-1}(\mathrm{Str}(\varphi)) = g^{-1}_{Q|P}(\psi^{-1}_{Q'}\varphi(\mathrm{Str}(\varphi))). \tag{13.4.8}$$

Hence, set $g := \mathrm{Spec}(R, \lambda)$; from (13.4.7) and (12.6.3) we obtain :

$$\mathrm{Str}(g) \subset \mathrm{Str}(g_{Q|P})$$

and together with (13.4.8) we deduce that :

- $\mathrm{Str}(g_{Q|P})$ is an open subset of $\mathrm{Spec}\, R[Q]$.
- $\psi^{-1}_{Q'}\varphi(\mathrm{Str}(\varphi))$ is a locally closed subscheme of $\mathrm{Spec}\, R[Q']$.
- The restriction $\mathrm{Str}(g) \to \psi^{-1}_{Q'}\varphi(\mathrm{Str}(\varphi))$ of $g_{Q|P}$ is a finite morphism.

Lastly, suppose that e is invertible in R; in this case, the morphisms g_P and g_Q are étale (proposition 12.3.34), so the same holds for $g_{Q|P}$ (corollary 12.3.25(iii)). From corollary 12.3.27(i) we deduce that the restriction $\mathrm{Str}(g) \to \psi^{-1}_{Q'}\varphi(\mathrm{Str}(\varphi))$ of $g_{Q|P}$ is a (finite) étale covering.

13.4.9. In the situation of (13.4.4), suppose additionally, that R is a $\mathbb{Z}[1/e, \boldsymbol{\mu}_e]$-algebra (where $\boldsymbol{\mu}_e$ is the e-torsion subgroup of $\mathbb{C}^\times$), P and Q are fine monoids, and λ is integral, so that Q' is also fine. Set

$$G_P := \mathrm{Hom}_{\mathbb{Z}}(P^{\mathrm{gp}}, \boldsymbol{\mu}_e) \qquad G_Q := \mathrm{Hom}_{\mathbb{Z}}(Q^{\mathrm{gp}}, \boldsymbol{\mu}_e) \qquad G_{Q|P} := \mathrm{Hom}_{\mathbb{Z}}(\mathrm{Coker}\, \lambda^{\mathrm{gp}}, \boldsymbol{\mu}_e).$$

Notice that the trivial locus $\mathrm{Spec}(R, P)_{\mathrm{tr}}$ is the open subset $\mathrm{Spec}\, R[P^{\mathrm{gp}}]$, and likewise for $\mathrm{Spec}(R, Q)_{\mathrm{tr}}$ and $\mathrm{Spec}(R, Q')_{\mathrm{tr}}$; therefore, (13.4.5)$^{\mathrm{gp}}$ induces a cartesian diagram of schemes

$$\begin{array}{ccc} \mathrm{Spec}(R, Q')_{\mathrm{tr}} & \xrightarrow{g'_{\mathrm{tr}}} & \mathrm{Spec}(R, Q)_{\mathrm{tr}} \\ {\scriptstyle g_{e,\mathrm{tr}}}\downarrow & & \downarrow{\scriptstyle g_{\mathrm{tr}}} \\ \mathrm{Spec}(R, P)_{\mathrm{tr}} & \xrightarrow{g_{P,\mathrm{tr}}} & \mathrm{Spec}(R, P)_{\mathrm{tr}}. \end{array}$$

Fix a geometric point τ'_Q of $\mathrm{Spec}(R, Q')_{\mathrm{tr}}$, and let $\tau_Q := g'(\tau'_Q)$, $\tau_P := g(\tau_Q)$, $\tau'_P := g_e(\tau'_Q)$. It was shown in (13.3.32) that $g_P^{-1}(\tau_P)$ is a G_P-torsor, so $g_{P,\mathrm{tr}}$ is a Galois étale covering, corresponding to a continuous representation (13.3.33) into G_P. Hence $g'^{-1}(\tau_Q)$ is a G_P-torsor, and g'_{tr} is a Galois étale covering, whose corresponding representation of $\pi_1(\mathrm{Spec}(R, Q)_{\mathrm{tr,ét}}, \tau_Q)$ is obtained by composing (13.3.33) with the natural continuous group homomorphism

$$\pi_1(g_{\mathrm{tr}}, \tau_Q) : \pi_1(\mathrm{Spec}(R, Q)_{\mathrm{tr,ét}}, \tau_Q) \to \pi_1(\mathrm{Spec}(R, P)_{\mathrm{tr,ét}}, \tau_P).$$

By the same token, $g_Q^{-1}(\tau_Q)$ is a G_Q-torsor, so also $g_{Q,\mathrm{tr}}$ is a Galois étale covering, and a simple inspection shows that the surjection

$$g_Q^{-1}(\tau_Q) \to g'^{-1}(\tau_Q)$$

induced by $g_{Q|P}$ is G_Q-equivariant, for the G_Q-action on the target obtained from the map

$$\mathrm{Hom}_{\mathbb{Z}}(\lambda^{\mathrm{gp}}, \boldsymbol{\mu}_e) : G_Q \to G_P.$$

The situation is summarized by the commutative diagram of continuous group homomorphisms

$$\begin{array}{ccccc} \pi_1(\mathrm{Spec}(R, Q')_{\mathrm{tr,ét}}, \tau'_Q) & \longrightarrow & \pi_1(\mathrm{Spec}(R, Q)_{\mathrm{tr,ét}}, \tau_Q) & \longrightarrow & G_Q \\ {\scriptstyle \pi_1(g_{e,\mathrm{tr}}, \tau'_Q)}\downarrow & & {\scriptstyle \pi_1(g_{\mathrm{tr}}, \tau_Q)}\downarrow & & \downarrow{\scriptstyle \mathrm{Hom}_{\mathbb{Z}}(\lambda^{\mathrm{gp}}, \boldsymbol{\mu}_e)} \\ \pi_1(\mathrm{Spec}(R, P)_{\mathrm{tr,ét}}, \tau'_P) & \longrightarrow & \pi_1(\mathrm{Spec}(R, P)_{\mathrm{tr,ét}}, \tau_P) & \longrightarrow & G_P \end{array}$$

whose horizontal right-most arrows are the maps (13.3.33). Consequently, $g_{Q|P}^{-1}(\tau'_Q)$ is a $G_{Q|P}$-torsor, and $g_{Q|P,\mathrm{tr}}$ is a Galois étale covering, classified by a continuous group homomorphism

$$\mathrm{Ker}\, \pi_1(g_{e,\mathrm{tr}}, \tau'_Q) \to \mathrm{Ker}\, \pi_1(g_{\mathrm{tr}}, \tau_Q) \to G_{Q|P}. \tag{13.4.10}$$

13.4.11. Let us return to the situation of (13.4), and assume additionally, that both $(X, \underline{M})$ and $(Y, \underline{N})$ are fs log schemes. Take $R := \mathscr{O}_{Y,\overline{y}}$ in (13.4.4); by corollary 12.3.42 and theorem 12.1.37(iii), we may assume that there exist

- a local and saturated morphism $\lambda : P \to Q$ of fine and saturated monoids, such that P is sharp, $Q^\times$ is a free abelian group of finite type, say of rank r, and $\mathrm{Ass}_{\mathbb{Z}}\, \mathrm{Coker}\, \lambda^{\mathrm{gp}}$ does not contain the characteristic exponent of $\kappa(\overline{y})$;
- a morphism of schemes $\pi : Y \to \mathrm{Spec}\, R[P]$, which is a section of the projection $\mathrm{Spec}\, R[P] \to Y$, such that

  $$(Y, \underline{N}) = Y \times_{\mathrm{Spec}\, R[P]} \mathrm{Spec}(R, P) \qquad (X, \underline{M}) = Y \times_{\mathrm{Spec}\, R[P]} \mathrm{Spec}(R, Q)$$

  and f is obtained by base change from the morphism $g := \mathrm{Spec}(R, \lambda)$. Moreover, the induced chart $Q_X \to \underline{M}$ shall be local at the geometric point $\overline{x}$.

By claim 12.1.39, we may further assume that the projection $Q \to Q^\sharp$ admits a section $\sigma : Q^\sharp \to Q$, such that $\lambda(P)$ lies in the image of σ. In this case, g factors through the morphism $\mathrm{Spec}(R,P) \to \mathrm{Spec}(R,Q^\sharp)$ induced by $\lambda^\sharp$, and σ induces an isomorphism of log schemes :

$$\mathrm{Spec}(R,Q) = \mathbb{G}_{m,Y}^{\oplus r} \times_Y \mathrm{Spec}(R,Q^\sharp)$$

(where $\mathbb{G}_{m,Y}^{\oplus r}$ denotes the standard torus of rank r over Y). In this situation, X is smooth over $Y \times_{\mathrm{Spec}\,R[P]} \mathrm{Spec}\,R[Q^\sharp]$, and more precisely

$$(X,\underline{M}) = \mathbb{G}_{m,Y}^{\oplus r} \times_{\mathrm{Spec}\,R[P]} \mathrm{Spec}(R,Q^\sharp). \tag{13.4.12}$$

Summing up, after replacing Q by $Q^\sharp$, we may assume that Q is also sharp, and (13.4.12) holds with $\mathrm{Spec}(R,Q)$ instead of $\mathrm{Spec}(R,Q^\sharp)$. Moreover, the image of x in T_Q is the closed point $\mathfrak{m}_Q$.

Let $e > 0$ be an integer which is invertible in R; by inspecting the definition, it is easily seen that there exists a finite separable extension K_e of $\kappa(\eta) = \mathrm{Frac}(R)$, such that the normalization Y_e of Y in $\mathrm{Spec}\,K_e$ fits into a commutative diagram of schemes :

$$\begin{array}{ccc} Y_e & \longrightarrow & Y \\ {\scriptstyle\pi_e}\big\downarrow & & \big\downarrow{\scriptstyle\pi} \\ \mathrm{Spec}\,R[P] & \xrightarrow{g_P} & \mathrm{Spec}\,R[P] \end{array}$$

(whose top horizontal arrow is the obvious morphism); namely, π is defined by some morphism of monoids $\beta : P \to R$, and one takes for K_e any subfield of $\kappa(\overline{\eta})$ containing $\kappa(\eta)$ and the e-th roots of the elements of $\beta(P)$. Set $(Y_e,\underline{N}_e) := Y_e \times_{\mathrm{Spec}\,R[P]} \mathrm{Spec}(R,P)$, and define log schemes $(X_e,\underline{M}_e)$, $(X'_e,\underline{M}'_e)$ so that the two square subdiagrams of the diagram of log schemes

$$\begin{array}{ccccc} (X'_e,\underline{M}'_e) & \xrightarrow{h_e} & (X_e,\underline{M}_e) & \longrightarrow & \mathbb{G}_{m,Y}^{\oplus r} \times_Y (Y_e,\underline{N}_e) \\ \big\downarrow & & \big\downarrow & & \big\downarrow{\scriptstyle\pi'_e} \\ \mathrm{Spec}(R,Q) & \xrightarrow{g_{Q|P}} & \mathrm{Spec}(R,Q') & \xrightarrow{g_e} & \mathrm{Spec}(R,P) \end{array}$$

are cartesian (here π'_e is the composition of π_e and the projection $\mathbb{G}_{m,Y}^{\oplus r} \times_Y Y_e \to Y_e$), whence a commutative diagram :

$$\begin{array}{ccc} (X'_e,\underline{M}'_e) & \xrightarrow{h_e} & (X_e,\underline{M}_e) \\ & {\scriptstyle f'_e}\searrow & \big\downarrow{\scriptstyle f_e} \\ & & (Y_e,\underline{N}_e). \end{array} \tag{13.4.13}$$

Notice that both f_e and f'_e are smooth and saturated morphisms of fine log schemes. Also, by construction Y_e is strictly local, and $(Y_e,\underline{N}_e)_{\mathrm{tr}}$ is a dense subset of Y_e. In other words, f_e and f'_e are still of the type considered in (13.4). Moreover, h_e is étale, since the same holds for $g_{Q|P}$, and the discussion in (13.4.6) shows that the restriction

$$\mathrm{Str}(f'_e) \to X_e$$

is an étale morphism of schemes. Furthermore, the discussion in (13.4.9) shows that

$$h_{e,\mathrm{tr}} : (X'_e,\underline{M}'_e)_{\mathrm{tr}} \to (X_e,\underline{M}_e)_{\mathrm{tr}}$$

is a Galois étale covering.

13.4.14. More precisely, notice that $\lambda^\sharp = \log f^\sharp_{\overline{x}}$; combining with (13.4.10), we deduce a continuous group homomorphism :

$$\mathrm{Ker}\, \pi_1(f_{e,\mathrm{tr}}, \xi'_e) \to \mathrm{Hom}_{\mathbb{Z}}(\mathrm{Coker}\,(\log f)^{\mathrm{gp}}_{\overline{x}}, \boldsymbol{\mu}_e(\kappa)) \qquad (13.4.15)$$

where ξ'_e is the image in X_e of the geometric point ξ. The geometric point $\overline{y}$ lifts uniquely to a geometric point $\overline{y}_e$ of Y_e, localized at the closed point y_e, and the pair $(\overline{x}, \overline{y}_e)$ determines a unique geometric point $\overline{x}_e$ such that $f_e(\overline{x}_e) = \overline{y}_e$. Also, since the field extension $\kappa(y) \to \kappa(y_e)$ is purely inseparable, it is easily seen that the induced map $f_e^{-1}(y_e) \to f^{-1}(y)$ is a homeomorphism; there follows an isomorphism of $X(\overline{x})$-schemes ([66, Ch.IV, Prop.18.8.10]) :

$$X_e(\overline{x}_e) \stackrel{\sim}{\to} X(\overline{x}) \times_Y Y_e.$$

Let η_e be the generic point of Y_e; by construction, $\overline{\eta}$ lifts to a geometric point $\overline{\eta}_e$ of Y_e, localized at η_e, and we have continuous group homomorphisms :

$$\pi_1(\overline{U}_{\mathrm{tr}}, \xi) \stackrel{\sim}{\to} \mathrm{Ker}\,(\pi_1(U_{e,\mathrm{tr}}, \xi'_e) \to \pi_1(\eta_e, |\overline{\eta}_e|)) \to \mathrm{Ker}\, \pi_1(f_{e,\mathrm{tr}}, \xi'_e). \qquad (13.4.16)$$

The composition of (13.4.15) and (13.4.16) is a continuous group homomorphism

$$\pi_1(\overline{U}_{\mathrm{tr}}, \xi) \to \mathrm{Hom}_{\mathbb{Z}}(\mathrm{Coker}\,(\log f)^{\mathrm{gp}}_{\overline{x}}, \boldsymbol{\mu}_e(\kappa)) \qquad (13.4.17)$$

whence, finally, a pairing

$$\mathrm{Coker}\,(\log f)^{\mathrm{gp}}_{\overline{x}} \times \pi_1(\overline{U}_{\mathrm{tr,ét}}, \xi) \to \boldsymbol{\mu}_e(\kappa).$$

We claim that this pairing agrees with the one deduced from (13.4.2). Indeed, by tracing back through the constructions, we see that (13.4.17) is the homomorphism arising from the Galois covering of $\overline{U}_{\mathrm{tr}}$, which is obtained from $g_{Q|P}$, after base change along the composition

$$\overline{U}_{\mathrm{tr}} \to X_e \to \mathrm{Spec}\, R[Q'].$$

On the other hand, the discussion of (13.3.32) shows that the homomorphism $\pi_1(U_{\mathrm{tr,ét}}, \xi') \to G_Q$ arising from the bottom row of (13.4.1), classifies the Galois covering $C \to \overline{U}_{\mathrm{tr}}$ obtained from g_Q, by base change along the same map. By the same token, the top row of (13.4.1) corresponds to the G_P-Galois covering $C' \to |\eta|$ obtained by base change of g_P along the composition $|\eta| \to Y \to S_P$. The map $\log f_{\overline{x}}$ induces a morphism of schemes $C \to C' \times_{|\eta|} U_{\mathrm{tr}}$, and (13.4.2) corresponds to the $G_{Q|P}$-torsor obtained from a fibre of this morphism. Evidently, this torsor is isomorphic to $g^{-1}_{Q|P}(\tau'_Q)$, whence the contention.

13.4.18. In the situation of (13.4), recall that there is a natural bijection between the set of maximal points of $f^{-1}_{\overline{x}}(\overline{y})$, and the set Σ of maximal points of the closed fibre of the induced map

$$\mathrm{Spec}\, \underline{M}_{\overline{x}} \to \mathrm{Spec}\, \underline{N}_{\overline{y}} \qquad (13.4.19)$$

(proposition 12.7.14). For every $\mathfrak{q} \in \Sigma$, denote by $\eta_{\mathfrak{q}}$ the corresponding maximal point of $f^{-1}_{\overline{x}}(\overline{y})$, choose a geometric point $\overline{\eta}_{\mathfrak{q}}$ localized at $\eta_{\mathfrak{q}}$, and let $X(\overline{\eta}_{\mathfrak{q}})$ be the strict henselization of $X(\overline{x})$ at $\overline{\eta}_{\mathfrak{q}}$. Also, set

$$U_{\mathfrak{q}} := U \times_{X(\overline{x})} X(\overline{\eta}_{\mathfrak{q}}) \qquad \overline{U}_{\mathfrak{q}} := U_{\mathfrak{q}} \times_{|\eta|} |\overline{\eta}|$$

and notice that $\overline{U}_{\mathfrak{q}}$ is an irreducible normal scheme. Notice as well that f induces a strict morphism $(X(\overline{\eta}_{\mathfrak{q}}), \underline{M}(\overline{\eta}_{\mathfrak{q}})) \to (Y, \underline{N})$ (theorem 12.7.8(iii.a)), and therefore the log structure of $U_{\mathfrak{q}} \times_{X(\overline{\eta}_{\mathfrak{q}})} (X(\overline{\eta}_{\mathfrak{q}}), \underline{M}(\overline{\eta}_{\mathfrak{q}}))$ is trivial.

Recall that $Z := \overline{U} \setminus \overline{U}_{\mathrm{tr}}$ is a finite union of irreducible closed subsets of codimension one in $\overline{U}$, and $\mathscr{O}_{\overline{U},z}$ is a discrete valuation ring, for each maximal point $z \in Z$ (proposition

12.7.17(iv,v)); especially, the category $\mathbf{Tame}(\overline{U}, \overline{U}_{\mathrm{tr}})$ is well defined (definition 13.3.16(iii)). We denote

$$\mathbf{Tame}(f, \overline{x})$$

the full subcategory of $\mathbf{Tame}(\overline{U}, \overline{U}_{\mathrm{tr}})$ consisting of all the coverings $C \to \overline{U}_{\mathrm{tr}}$ such that, for every $\mathfrak{q} \in \Sigma$, the induced covering

$$C \times_{\overline{U}_{\mathrm{tr}}} \overline{U}_{\mathfrak{q}} \to \overline{U}_{\mathfrak{q}}$$

is trivial (*i.e.* $C \times_{\overline{U}_{\mathrm{tr}}} \overline{U}_{\mathfrak{q}}$ is a disjoint union of copies of $\overline{U}_{\mathfrak{q}}$). It is easily seen that $\mathbf{Tame}(f, \overline{x})$ is a Galois category (see [82, Exp.V, Déf.5.1]), and we obtain a fibre functor for this category, by restriction of the usual fibre functor $\varphi \mapsto \varphi^{-1}(\xi)$ defined on all étale coverings φ of $\overline{U}_{\mathrm{tr}}$; we denote by $\pi_1(\overline{U}_{\mathrm{tr}}/Y_{\mathrm{\acute{e}t}}, \xi)$ the corresponding fundamental group. According to [82, Exp.V, Prop.6.9], the fully faithful inclusion $\mathbf{Tame}(f, \overline{x}) \to \mathsf{Cov}(\overline{U}_{\mathrm{tr}})$ induces a continuous surjective group homomorphism

$$\pi_1(\overline{U}_{\mathrm{tr,\acute{e}t}}, \xi) \to \pi_1(\overline{U}_{\mathrm{tr}}/Y_{\mathrm{\acute{e}t}}, \xi). \tag{13.4.20}$$

Proposition 13.4.21. *The map* (13.4.3) *factors through* (13.4.20)*, and the induced group homomorphism :*

$$\pi_1(\overline{U}_{\mathrm{tr}}/Y_{\mathrm{\acute{e}t}}, \xi) \to \mathrm{Coker}\,(\log f^{\mathrm{gp}}_{\overline{x}})^\vee \otimes_{\mathbb{Z}} \prod_{\ell \neq p} \mathbb{Z}_\ell(1). \tag{13.4.22}$$

is surjective.

Proof. Let $\sigma_Y : Y \to Y^{\mathrm{qfs}}$ be the natural morphism of schemes exhibited in remark 12.2.38(iv), and set

$$(Y, \underline{N}') := Y \times_{Y^{\mathrm{qfs}}} (Y, \underline{N})^{\mathrm{qfs}} \qquad (X, \underline{M}') := (Y, \underline{N}') \times_{(Y, \underline{N})} (X, \underline{M}).$$

Since f is saturated, both $(X, \underline{M}')$ and $(Y, \underline{N}')$ are fs log schemes (see remark 12.2.38(i)); also, the morphism of schemes underlying the induced morphism of log schemes $f' : (X, \underline{M}') \to (Y, \underline{N}')$, agrees with that underlying f. Moreover, by construction we have $\underline{N}'^{\sharp}_{\overline{z}} = (\underline{N}^{\sharp}_{\overline{z}})^{\mathrm{sat}}$ for every geometric point $\overline{z}$ of Y, especially $(Y, \underline{N}')_{\mathrm{tr}} = (Y, \underline{N})_{\mathrm{tr}}$. Likewise, $\underline{M}'^{\sharp}_{\overline{z}} = (\underline{M}^{\sharp}_{\overline{z}})^{\mathrm{sat}}$ (lemma 6.2.12(iii,iv)), therefore $\mathrm{Str}(f') = \mathrm{Str}(f)$, and especially, $(X, \underline{M}')_{\mathrm{tr}} = (X, \underline{M})_{\mathrm{tr}}$. Furthermore, notice that the the natural map

$$\mathrm{Coker}\,(\log f)^{\mathrm{gp}}_{\overline{x}} \to \mathrm{Coker}\,(\log f')^{\mathrm{gp}}_{\overline{x}} \tag{13.4.23}$$

is surjective, and its kernel is a quotient of $(\underline{M}^{\mathrm{sat}}_{\overline{x}})^\times / \underline{M}^\times_{\overline{x}}$, especially it is a torsion subgroup. However, the cokernel of $(\log f)^{\mathrm{gp}}_{\overline{x}}$ equals the cokernel of $(\log f^\sharp_{\overline{x}})^{\mathrm{gp}}$, hence it is torsion-free (corollary 6.2.32(ii)), so (13.4.23) is an isomorphism. Thus, we may replace $\underline{N}$ (resp. $\underline{M}$) by $\underline{N}'$ (resp. $\underline{M}'$), and assume from start that f is a smooth, saturated morphism of fs log schemes.

In this case, in light of the discussion of (13.4.14), it suffices to prove that (13.4.17) is a surjection, and that it factors through $\pi_1(\overline{U}_{\mathrm{tr}}/Y_{\mathrm{\acute{e}t}}, \xi)$. To prove the surjectivity comes down to showing that $\overline{U}_{\mathrm{tr}} \times_{X_e} X'_e$ is a connected scheme. However, let x_e be the support of $\overline{x}_e$, and notice that $\psi_P \circ \pi_e(y_e) = \mathfrak{m}_P$, the closed point of T_P. Since x maps to the closed point of T_Q, we deduce easily that the image of x_e in $T_{Q'}$ is the closed point $\mathfrak{m}_{Q'}$, *i.e.* x_e lies in the closed subscheme $X_e \times_{S'_Q} \mathrm{Spec}\,\kappa\langle Q'/\mathfrak{m}_{Q'}\rangle$. Notice as well that $\boldsymbol{e}_{Q|P}$ is of Kummer type (see definition 6.4.58); by proposition 13.3.7(ii), it follows that there exists a unique geometric point $\overline{x}'_e$ of X'_e lying over $\overline{x}_e$, whence an isomorphism of $X_e(\overline{x}_e)$-schemes ([66, Ch.IV, Prop.18.8.10])

$$X'_e(\overline{x}'_e) \xrightarrow{\sim} X'_e \times_{X_e} X_e(\overline{x}_e).$$

Hence $\overline{U}_{\mathrm{tr}} \times_{X_e} X'_e$ is an open subset of $|\overline{\eta}_e| \times_{Y_e} X'_e(\overline{x}_e)$, and the latter is an irreducible scheme, by proposition 12.7.17(ii). We also deduce that the induced morphism

$$h_{e,\overline{x}} : (X'_e(\overline{x}'_e), \underline{M}'_e(\overline{x}'_e)) \to (X_e(\overline{x}_e), \underline{M}_e(\overline{x}_e))$$

is a finite étale covering of log schemes. From the discussion in (13.4.11), we see that the restriction of $h_{e,\overline{x}}$

$$\mathrm{Str}(h_{e,\overline{x}}) \to X_e(\overline{x}_e)$$

is an étale morphism, and $\mathrm{Str}(h_{e,\overline{x}})$ contains the strict locus of the induced morphism

$$f'_{e,\overline{x}} : (X'_e(\overline{x}'_e), \underline{M}'_e(\overline{x}'_e)) \to (Y_e, \underline{N}_e).$$

Since the field extension $\kappa(\overline{y}) \to \kappa(\overline{y}_e)$ is purely inseparable, $\overline{\eta}_{\mathfrak{q}}$ lifts uniquely to a geometric point $\eta_{e,\mathfrak{q}} \in X_e(\overline{x}_e)$, and as usual we deduce that the strict henselization $X_e(\overline{\eta}_{\mathfrak{q}})$ of $X_e(\overline{x}_e)$ at $\overline{\eta}_{e,\mathfrak{q}}$ is isomorphic, as an $X_e(\overline{x}_e)$-scheme, to $X_e(\overline{x}_e) \times_{X(\overline{x})} X(\overline{\eta}_{\mathfrak{q}})$. Moreover, if $\eta_{e,\mathfrak{q}}$ is the support of $\overline{\eta}_{e,\mathfrak{q}}$, a simple inspection shows that the fibre $h^{-1}_{e,\overline{x}}(\eta_{e,\mathfrak{q}})$ consists of maximal points of $f'^{-1}_{e,\overline{x}}(y_e)$. By theorem 12.7.8(iii.a), every point of $h^{-1}_{e,\overline{x}}(\eta_{e,\mathfrak{q}})$ lies in $\mathrm{Str}(f'_{e,\overline{x}})$, therefore the induced morphism $X'_e \times_{X_e} X_e(\overline{\eta}_{\mathfrak{q}}) \to X_e(\overline{\eta}_{\mathfrak{q}})$ is finite and étale. Taking into account (13.3.41), we conclude that the étale covering $X'_e \times_{X_e} \overline{U}_{\mathrm{tr}} \to \overline{U}_{\mathrm{tr}}$ is an object of $\mathbf{Tame}(f, \overline{x})$, whence the proposition. □

13.4.24. Say that $Y = \mathrm{Spec}\, R$; for every algebraic field extension K of $\kappa(\eta) = \mathrm{Frac}(R)$, let R_K be the normalization of R in K, set $|\eta_K| := \mathrm{Spec}\, K$ and

$$Y_K := \mathrm{Spec}\, R_K \quad (Y_K, \underline{N}_K) := Y_K \times_Y (Y, \underline{N}) \quad (X_K, \underline{M}_K) := Y_K \times_Y (X, \underline{M}).$$

Moreover, let $f_K : (X_K, \underline{M}_K) \to (Y_K, \underline{N}_K)$ be the induced morphism, and $\overline{y}_K$ any geometric point localized at the closed point y_K of the strictly local scheme Y_K; since the extension $\kappa(\overline{y}) \to \kappa(\overline{y}_K)$ is purely inseparable, there exists a unique geometric point $\overline{x}_K$ of X_K lifting $\overline{x}$, and we have an isomorphism of $(X(\overline{x}), \underline{M}(\overline{x}))$-schemes :

$$(X_K(\overline{x}_K), \underline{M}_K(\overline{x}_K)) \xrightarrow{\sim} X_K \times_X (X(\overline{x}), \underline{M}(\overline{x})) = Y_K \times_Y (X(\overline{x}), \underline{M}(\overline{x})).$$

Clearly the morphism f_K is again of the type considered in (13.4.18); especially, the maximal points of $f^{-1}_{K,\overline{x}_K}(\overline{y}_K)$ are in natural bijection with the elements of Σ, and it is natural to denote

$$U_K := U \times_Y |\eta_K| \qquad U_{K,\mathrm{tr}} := U_{\mathrm{tr}} \times_Y |\eta_K| \qquad U_{K,\mathfrak{q}} := U_{K,\mathrm{tr}} \times_{X(\overline{x})} X(\overline{\eta}_{\mathfrak{q}})$$

for every $\mathfrak{q} \in \Sigma$. Then, let $\overline{\eta}_{K,\mathfrak{q}}$ be the unique geometric point of $f^{-1}_{K,\overline{x}_K}(\overline{y}_K)$ lying over $\overline{\eta}_{\mathfrak{q}}$, and $\eta_{K,\mathfrak{q}}$ the support of $\overline{\eta}_{K,\mathfrak{q}}$; as usual, we have

$$X_K(\overline{\eta}_{K,\mathfrak{q}}) = X(\overline{\eta}_{\mathfrak{q}}) \times_Y Y_K \tag{13.4.25}$$

hence the above notation is consistent with the one introduced for the original morphism f. Furthermore, if z is any maximal point of $\overline{U} \backslash \overline{U}_{\mathrm{tr}}$, the image z_K of z in U_K is a maximal point of $U_K \backslash U_{K,\mathrm{tr}}$, and since the induced map $\mathscr{O}_{U_K, z_K} \to \mathscr{O}_{\overline{U}, z}$ is faithfully flat, proposition 12.7.17(iv,v) easily implies that $\mathscr{O}_{U_K, z_K}$ is a discrete valuation ring. We may then denote

$$\mathbf{Tame}(f, \overline{x}, K)$$

the full subcategory of $\mathbf{Tame}(U_K, U_{K,\mathrm{tr}})$, consisting of those objects $C \to U_{K,\mathrm{tr}}$, such that the induced covering $C \times_{U_{K,\mathrm{tr}}} U_{K,\mathfrak{q}} \to U_{K,\mathfrak{q}}$ is trivial, for every $\mathfrak{q} \in \Sigma$. We have a natural functor

$$2\text{-}\operatorname*{colim}_{K} \mathbf{Tame}(f, \overline{x}, K) \to \mathbf{Tame}(f, \overline{x}) \tag{13.4.26}$$

where the 2-colimit ranges over the filtered family of all finite separable extensions K of $\kappa(\eta)$.

Lemma 13.4.27. *The functor* (13.4.26) *is an equivalence.*

Proof. Let $\overline{h} : \overline{C} \to \overline{U}_{\mathrm{tr}}$ be an object of the category $\mathbf{Tame}(f, \overline{x})$. According to [66, Ch.IV, Prop.17.7.8(ii)] and [65, Ch.IV, Prop.8.10.5], we may find a finite extension K of $\kappa(\eta)$, such that $\overline{h}$ descends to a finite étale morphism

$$h_K : C_K \to U_{K,\mathrm{tr}}.$$

Let C'_K (resp. $\overline{C}'$) denote the normalization of C_K (resp. of $\overline{C}$) over U_K (resp. over $\overline{U}$). Since the morphism $|\overline{\eta}| \to |\eta_K|$ is pro-étale, we have $\overline{C}' = C'_K \times_{|\eta_K|} |\overline{\eta}|$ (proposition 9.8.3), and it follows easily that C_K is tamely ramified along the divisor $U_K \setminus U_{K,\mathrm{tr}}$. From (13.4.25) we get a natural isomorphism :

$$\overline{U}_{\mathfrak{q}} \stackrel{\sim}{\to} U_{K,\mathfrak{q}} \times_{|\eta_K|} |\overline{\eta}|.$$

Thus, after replacing K by a larger finite separable extension of $\kappa(\eta)$, we may assume that the induced morphism $C_K \times_{U_{K,\mathrm{tr}}} U_{K,\mathfrak{q}} \to U_{K,\mathfrak{q}}$ is a trivial étale covering, for every $\mathfrak{q} \in \Sigma$.

This shows that (13.4.26) is essentially surjective; likewise one shows the full faithfulness : the details shall be left to the reader. □

13.4.28. In the situation of (13.4.24), let K be an algebraic extension of $\kappa(\eta)$, and

$$h : C \to U_{K,\mathrm{tr}}$$

any object of $\mathbf{Tame}(U_K, U_{K,\mathrm{tr}})$; denote by C' the normalization of $X_K(\overline{x}_K)$ in C, and let $h' : C' \to X_K(\overline{x}_K)$ be the induced morphism of schemes. We claim that there exists a largest non-empty open subset

$$E(h) \subset X_K(\overline{x}_K)$$

such that the restriction $h'^{-1}E(h) \to E(h)$ of h' is étale. Indeed, in any case, h' restricts to an étale morphism on a dense open subset containing $U_{K,\mathrm{tr}}$, and there exists a largest open subset $E' \subset C'$ such that $h'_{|E'}$ is étale (claim 13.1.8 and lemma 13.1.7(iii)). Then it is easily seen that $E(h) := X_K(\overline{x}_K) \setminus h'(C' \setminus E')$ will do.

Lemma 13.4.29. *With the notation of* (13.4.28)*, the category* $\mathbf{Tame}(f, \overline{x}, K)$ *is the full subcategory of* $\mathbf{Tame}(U_K, U_{K,\mathrm{tr}})$ *consisting of those objects* $h : C \to U_{K,\mathrm{tr}}$ *such that* $E(h)$ *contains the maximal points of* $X_K(\overline{x}_K) \times_{Y_K} |y_K|$.

Proof. In view of claim 13.1.9, this characterization is a rephrasing of the definition of the category $\mathbf{Tame}(f, \overline{x}, K)$. □

13.4.30. Keep the notation of (13.4.28), and suppose that h is an object of $\mathbf{Tame}(f, \overline{x}, K)$. Fix $\mathfrak{q} \in \Sigma$; then lemma 13.4.29 says that $\eta_{K,\mathfrak{q}} \in E(h)$. Thus, we obtain a functor

$$\mathbf{Tame}(f, \overline{x}, K) \to \mathsf{Cov}(|\eta_{K,\mathfrak{q}}|) \qquad : \qquad C \mapsto C' \times_{X_K(\overline{x}_K)} |\eta_{K,\mathfrak{q}}|.$$

However, the natural morphism $|\eta_{K,\mathfrak{q}}| \to |\eta_{\mathfrak{q}}|$ is radicial, hence it induces an equivalence

$$\mathsf{Cov}(|\eta_{\mathfrak{q}}|) \stackrel{\sim}{\to} \mathsf{Cov}(|\eta_{K,\mathfrak{q}}|)$$

(lemma 13.1.7(i)). Combining these two functors in the special special case where $K := \kappa(\overline{\eta})$, we get a functor

$$\mathbf{Tame}(f, \overline{x}) \to \mathsf{Cov}(|\eta_{\mathfrak{q}}|) \quad : \quad (C \to \overline{U}_{\mathrm{tr}}) \mapsto (C_{|\eta_{\mathfrak{q}}} \to |\eta_{\mathfrak{q}}|). \tag{13.4.31}$$

Now, the rule $\varphi \mapsto \varphi^{-1}(\overline{\eta}_{\mathfrak{q}})$ yields a fibre functor for the Galois category $\mathsf{Cov}(|\eta_{\mathfrak{q}}|)$; by composition with (13.4.31), we deduce a fibre functor for $\mathbf{Tame}(f, \overline{x})$, whose group of automorphisms we denote $\pi_1(\overline{U}_{\mathrm{tr}}/Y_{\mathrm{\acute{e}t}}, \overline{\eta}_{\mathfrak{q}})$. Also, set $F(\mathfrak{q}) := \underline{M}_{\overline{x}} \setminus \mathfrak{q}$, and notice that the structure map $\underline{M}_{\overline{x}} \to \mathscr{O}_{X(\overline{x}),\overline{x}}$ induces a group homomorphism

$$F(\mathfrak{q})^{\mathrm{gp}} \to \kappa(\eta_{\mathfrak{q}})^{\times}. \tag{13.4.32}$$

Lemma 13.4.33. *With the notation of* (13.4.30)*, we have :*

(i) *The natural map* $\mathrm{Coker}\,(\log f_{\overline{x}}) \to F(\mathfrak{q})$ *induces a commutative diagram of groups*

$$\begin{array}{ccccc}
\pi_1(|\eta_{\mathfrak{q}}|_{\text{ét}}, \overline{\eta}_{\mathfrak{q}}) & \longrightarrow & \pi_1(\overline{U}_{\mathrm{tr}}/Y_{\text{ét}}, \overline{\eta}_{\mathfrak{q}}) & \longrightarrow & \pi_1(\overline{U}_{\mathrm{tr}}/Y_{\text{ét}}, \xi) \\
\downarrow{\scriptstyle\alpha} & & & & \downarrow{\scriptstyle\beta} \\
F(\mathfrak{q})^{\mathrm{gp}\vee} \otimes_{\mathbb{Z}} \prod_{\ell\neq p} \mathbb{Z}_\ell(1) & & \xrightarrow{\quad\gamma\quad} & & \mathrm{Coker}\,(\log f^{\mathrm{gp}}_{\overline{x}})^\vee \otimes_{\mathbb{Z}} \prod_{\ell\neq p} \mathbb{Z}_\ell(1)
\end{array}$$

where β *is* (13.4.22)*, and* α *is deduced from* (13.4.32)*, as in the discussion of* (13.3.27).

(ii) α *is surjective, and* γ *is an isomorphism.*

Proof. (i): The proof amounts to unwinding the definitions, and shall be left as an exercice for the reader. Notice that the second arrow on the top row is only well-defined up to inner automorphisms, but since the groups on the bottom row are abelian, the ambiguity does not affect the statement.

(ii): Notice that $\log f_{\overline{x}}$ restricts to a map of monoids $\mathscr{O}^\times_{Y,\overline{y}} \to F(\mathfrak{q})$, which induces an isomorphism $\mathrm{Coker}(\log f)^\sharp \stackrel{\sim}{\to} F(\mathfrak{q})^\sharp$; we deduce that γ is an isomorphism. Next, let Z be the topological closure of $\eta_{\mathfrak{q}}$ in $X(\overline{x})$, and endow Z with its reduced subscheme structure; set also $(Z, \underline{M}(Z)) := Z \times_{X(\overline{x})} (X, \underline{M})$. The map α factors as a composition

$$\pi_1(|\eta_{\mathfrak{q}}|_{\text{ét}}, \overline{\eta}_{\mathfrak{q}}) \to \pi_1((Z, \underline{M}(Z))_{\mathrm{tr,ét}}, \overline{\eta}_{\mathfrak{q}}) \to F(\mathfrak{q})^{\mathrm{gp}\vee} \otimes_{\mathbb{Z}} \prod_{\ell\neq p} \mathbb{Z}_\ell(1)$$

where the first map is surjective, by lemma 13.1.7(ii). Lastly, notice that $\underline{M}(Z)_{\mathrm{red},\overline{x}} = F(\mathfrak{q})_\circ$; by propositions 13.3.43 and 12.7.14(ii), it follows that the second map is surjective as well, so the proof of (ii) is complete. □

13.4.34. In the situation of (12.3.44), suppose that Y_i is a strictly local normal scheme for every $i \in I$, and the transition morphisms $Y_j \to Y_i$ are local and dominant, for every morphism $i \to j$ in I. Let $\overline{x}$ be a geometric point of X, and denote by $\overline{x}_i$ the image of $\overline{x}$ in X_i, for every $i \in I$. Suppose that the image $\overline{y}$ of $\overline{x}$ in Y is localized at the closed point. Also, let $\overline{\eta}$ be a strict geometric point of Y, localized at the generic point η_i, and denote by $\overline{\eta}_i$ (resp. $\overline{y}_i$) the strict image of $\overline{\eta}$ (resp. $\overline{y}$) in Y_i (see definition 4.9.17(v)).

Lemma 13.4.35. *In the situation of* (13.4.34)*, suppose that* $(g, \log g) : (X, \underline{M}) \to (Y, \underline{N})$ *is a smooth and saturated morphism of fine log schemes. Then there exist* $i \in I$*, and a smooth and saturated morphism* $(g_i, \log g_i) : (X_i, \underline{M}_i) \to (Y_i, \underline{N}_i)$ *of fine log schemes, such that* $\log g = \pi_i^* \log g_i$.

Proof. By corollary 12.3.45, we can descend $(g, \log g)$ to a smooth morphism $(g_i, \log g_i)$ of fine log schemes, and after replacing I by I/i, we may assume that $i = 0$. Then the contention follows from corollary 12.2.36(ii). □

13.4.36. Keep the situation of (13.4.34), and suppose that $(g_0, \log g_0) : (X_0, \underline{M}_0) \to (Y_0, \underline{N}_0)$ is a smooth and saturated morphism of fine log schemes; set

$$(X_i, \underline{M}_i) := X_i \times_{X_0} (X_0, \underline{M}_0) \qquad (Y_i, \underline{N}_i) := Y_i \times_{Y_0} (Y_0, \underline{Y}_0)$$

and denote $(g_i, \log g_i) : (X_i, \underline{M}_i) \to (Y_i, \underline{N}_i)$ the induced morphism of log schemes, for every $i \in I$. Also, let $(g, \log g) : (X, \underline{M}) \to (Y, \underline{N})$ be the limit of the system of morphisms $((g_i, \log g_i) \mid i \in I)$. These are morphisms of the type considered in (13.4), so we may define $U_i := g^{-1}_{i,\overline{x}_i}(\eta_i)$, and introduce likewise the schemes $U_{i,\mathrm{tr}}$, $\overline{U}_i$ and $\overline{U}_{i,\mathrm{tr}}$ as in (13.4). Moreover, set $Z_i := \overline{U}_i \backslash \overline{U}_{i,\mathrm{tr}}$ for every $i \in I$; clearly $Z_i = Z_j \times_{X_j(\overline{x}_j)} X_i(\overline{x}_i)$ for every morphism $i \to j$ in I. Also, each Z_i is a finite union of irreducible subsets of codimension one, and for every $i \to j$ in I, the transition morphisms $X_i \to X_j$ restrict to maps

$$\mathrm{Max}\, Z_i \to \mathrm{Max}\, Z_j \qquad \mathrm{Max}\, X_i(\overline{x}_i) \times_{Y_i} |\overline{y}_i| \to \mathrm{Max}\, X_j(\overline{x}_j) \times_{Y_j} |\overline{y}_j|$$

Combining proposition 13.3.23(ii) and lemma 13.4.29, we deduce a fully faithful functor

$$(13.4.37) \qquad 2\text{-}\underset{i\in I}{\mathrm{colim}}\,\mathbf{Tame}(g_i,\overline{x}_i) \to \mathbf{Tame}(g,\overline{x}).$$

Lemma 13.4.38. *The functor* (13.4.37) *is an equivalence.*

Proof. It remains only to show the essential surjectivity. Hence, let h be a given object of $\mathbf{Tame}(g,\overline{x})$; by proposition 13.3.23(ii), we know that there exists $j \in I$ such that h descends to an étale covering $h_j : V_j \to \overline{U}_{j,\mathrm{tr}}$, tamely ramified along Z_j, and after replacing I by I/i, we may assume that j is the final object of I, and define $h_i := \overline{U}_{i,\mathrm{tr}} \times_{\overline{U}_{j,\mathrm{tr}}} h_j$ for every $i \to j$ in I. Now, let $E' \subset E(h)$ be a constructible open subset containing the maximal points of $X(\overline{x}) \times_Y |\overline{y}|$. For every $i \in I$, let $\overline{Y}_i$ be the normalization of Y_i in $\mathrm{Spec}\,\kappa(\overline{\eta}_i)$, and set $\overline{X}_i := X_i(\overline{x}_i) \times_{Y_i} \overline{Y}_i$; according to [65, Ch.IV, Th.8.3.11], there exists $i \in I$ such that E' descends to a constructible open subset $E'_i \subset \overline{X}_i$, and then necessarily E'_i contains all the maximal points of $X_i(\overline{x}_i) \times_{Y_i} |\overline{y}_i|$. As usual, we may assume that i is the final object, so E'_i is defined for every $i \in I$. Lastly, since h extends to an étale covering on E', we see that h_i extends to an étale covering of E'_k, for some $k \in I$ ([66, Ch.IV, Prop.17.7.8(i)]). In view of lemma 13.4.29, the contention follows. □

Theorem 13.4.39. *The map* (13.4.22) *is an isomorphism.*

Proof. Arguing as in the proof of proposition 13.4.21, we may assume that both $(X,\underline{M})$ and $(Y,\underline{N})$ are fs log schemes, and in view of proposition 13.4.21, we need only show that (13.4.22) is injective. This comes down to the following assertion. For every object $\overline{h} : \overline{C} \to \overline{U}_{\mathrm{tr}}$ of the category $\mathbf{Tame}(f,\overline{x})$, the induced action of $\pi_1(\overline{U}_{\mathrm{tr}},\xi)$ on $\overline{h}^{-1}(\xi)$ factors through the quotient $\mathrm{Coker}\,(\log f^{\mathrm{gp}}_{\overline{x}})^\vee \otimes_{\mathbb{Z}} \prod_{\ell\neq p}\mathbb{Z}_\ell(1)$.

• By lemma 13.4.27, there exist a finite separable extension K of $\kappa(\eta)$, and an object $h : C_K \to U_{K,\mathrm{tr}}$ of $\mathbf{Tame}(f,\overline{x},K)$, with an isomorphism $C_K \times_{U_{K,\mathrm{tr}}} \overline{U}_{\mathrm{tr}} \xrightarrow{\sim} \overline{C}$ of $\overline{U}_{\mathrm{tr}}$-schemes. Since $\log f_{\overline{x}} = \log f_{K,\overline{x}_K}$, the theorem will hold for the morphism f and the point $\overline{x}$, if and only if it holds for f_K and the point $\overline{x}_K$.

Claim 13.4.40. The theorem holds if Y is noetherian of dimension one.

Proof of the claim. In this case, Y is the spectrum of a strictly henselian discrete valuation ring R, and the same then holds for Y_K. Hence, we may replace throughout f by f_K, and assume from start that there exists an object $h : C \to U_{\mathrm{tr}}$ of $\mathbf{Tame}(f,\overline{x},\kappa(\eta))$, with an isomorphism $\overline{C} \xrightarrow{\sim} C \times_{U_{\mathrm{tr}}} \overline{U}_{\mathrm{tr}}$ of $\overline{U}_{\mathrm{tr}}$-schemes. Endow Y with the fine log structure $\underline{N}'$ such that $\Gamma(Y,\underline{N}') = R\setminus\{0\}$; since $(Y,\underline{N})_{\mathrm{tr}}$ is dense in Y, we have a well defined morphism of log schemes $\pi : (Y,\underline{N}') \to (Y,\underline{N})$, which is the identity on the underlying schemes. Set $(X,\underline{M}') := (Y,\underline{N}') \times_{(Y,\underline{N})} (X,\underline{M})$. Then $(Y,\underline{N}')$ is a regular log scheme, and consequently the same holds for $(X,\underline{M}')$, by theorem 12.5.28.

Furthermore, π trivially restricts to a strict morphism on the open subset $|\eta|$, hence the induced morphism $(X,\underline{M}') \times_Y |\eta| \to (X,\underline{M}) \times_Y |\eta|$ is an isomorphism, especially U_{tr} is the trivial locus of $(X(\overline{x}),\underline{M}'(\overline{x})) \times_Y |\eta|$. However, it is easily seen that $(X(\overline{x}),\underline{M}'(\overline{x}))_{\mathrm{tr}}$ does not intersect the closed fibre $f^{-1}_{\overline{x}}(\overline{y})$, so finally $U_{\mathrm{tr}} = (X(\overline{x}),\underline{M}'(\overline{x}))_{\mathrm{tr}}$.

From theorem 13.3.45, we deduce that h extends to an étale covering of $(X(\overline{x}),\underline{M}'(\overline{x}))$. Then, arguing as in (13.4) we get a commutative diagram of groups :

$$\begin{array}{ccc} \pi_1(\overline{U}_{\mathrm{tr,\acute{e}t}},\xi) & \longrightarrow & \mathrm{Coker}\,(\log f^{\mathrm{gp}}_{\overline{x}})^\vee \otimes_{\mathbb{Z}} \prod_{\ell\neq p}\mathbb{Z}_\ell(1) \\ \downarrow & & \downarrow \\ \pi_1(U_{\mathrm{tr,\acute{e}t}},\xi') & \xrightarrow{\ \alpha\ } & \underline{M}^{\mathrm{gp}\vee}_{\overline{x}} \otimes_{\mathbb{Z}} \prod_{\ell\neq p}\mathbb{Z}_\ell(1) \end{array}$$

whose top horizontal arrow is (13.4.3), and whose right vertical arrow is deduced from the projection $\underline{M}^{\mathrm{gp}}_{\overline{x}} \to \mathrm{Coker}\,(\log f^{\mathrm{gp}}_{\overline{x}})$. Lastly, proposition 13.3.43 shows that the natural action of $\pi_1(U_{\mathrm{tr,\acute{e}t}}, \xi')$ on $h^{-1}(\xi')$ factors through α, so the claim follows. $\diamondsuit$

• Next, suppose that Y is an arbitrary normal, strictly local scheme. The discussion in (13.4.14) implies that, in order to prove the theorem, it suffices to find an integer $e > 0$, a $(X, \underline{M})$-scheme $(X'_e, \underline{M}'_e)$ as in (13.4.11), and a geometric point $\overline{x}'_e$ of X'_e lying over $\overline{x}$, such that $h \times_{X(\overline{x})} X'_e(\overline{x}'_e)$ is a trivial covering. To this aim, we write Y as the limit of a cofiltered system $(Y_i \mid i \in I)$ of strictly local excellent and normal schemes (lemma 13.1.29), and we denote by η_i the generic point of Y_i, for every $i \in I$. By lemma 13.4.35, we may then descend $(f, \log f)$ to a smooth and saturated morphism $(f_i, \log f_i) : (X_i, \underline{M}_i) \to (Y_i, \underline{N}_i)$, for some $i \in I$, and as usual, we may assume that i is the final object of I. Let $\overline{x}_i$ be the image of $\overline{x}$ in X_i; by lemmata 13.4.38 and 13.4.27, the object h of $\mathbf{Tame}(f, \overline{x}, \kappa(\eta))$ descends to an object h_i of $\mathbf{Tame}(f_i, \overline{x}_i, K)$, for some $i \in I$, and some finite separable extension K of $\kappa(\eta_i)$. It suffices therefore to find $e > 0$, a $(X_i, \underline{M}_i)$-scheme $(X'_{i,e}, \underline{M}'_{i,e})$, and a geometric point $\overline{x}'_{i,e}$ of $X'_{i,e}$ lying over $\overline{x}_i$, such that $h_i \times_{X_i(\overline{x}_i)} X'_{i,e}(\overline{x}'_{i,e})$ is a trivial covering. In other words, we may replace throughout Y by $Y_{i,K}$, and assume from start that Y is excellent, and $\overline{h}$ descends to an object $h : C \to U_{\mathrm{tr}}$ of $\mathbf{Tame}(f, \overline{x}, \kappa(\eta))$.

• By [60, Ch.II, Prop.7.1.7] (see also remark 12.5.34) we may find a discrete valuation ring V and a local injective morphism $R \to \mathsf{V}$ inducing an isomorphism on the respective fields of fractions. Let V^{sh} be the strict henselization of V (at a geometric point whose support is the closed point), and set

$$\mathsf{Y} := \mathrm{Spec}\,\mathsf{V}^{\mathrm{sh}} \quad (\mathsf{Y}, \underline{\mathsf{N}}) := \mathsf{Y} \times_Y (Y, \underline{N}) \quad (\mathsf{X}, \underline{\mathsf{M}}) := \mathsf{Y} \times_Y (X, \underline{M}).$$

Also, let $\mathsf{f} : (\mathsf{X}, \underline{\mathsf{M}}) \to (\mathsf{Y}, \underline{\mathsf{N}})$ be the induced morphism. Denote by $\overline{\mathsf{y}}$ a geometric point localized at the closed point y of Y; also, pick any geometric point $\overline{\mathsf{x}}$ of X, whose image in X is $\overline{x}$; the induced morphism

(13.4.41) $$(\mathsf{X}(\overline{\mathsf{x}}), \underline{\mathsf{M}}(\overline{\mathsf{x}})) \to (X(\overline{x}), \underline{M}(\overline{x}))$$

restricts to a flat morphism $\mathsf{f}^{-1}_{\overline{\mathsf{x}}}(\overline{\mathsf{y}}) \to f^{-1}_{\overline{x}}(\overline{y})$ and from proposition 12.7.14, we see that the latter induces a bijection between the sets of maximal points of the two fibres. On the other hand, let $\overline{\eta}_{\mathsf{V}}$ denote a geometric point localized at the generic point η_{V} of Y; then (13.4.41) restricts to an ind-étale morphism $\mathsf{f}^{-1}_{\overline{\mathsf{x}}}(\eta_{\mathsf{V}}) \to f^{-1}_{\overline{x}}(\eta)$. Hence, set

$$\mathsf{U}_{\mathrm{tr}} := (\mathsf{X}(\overline{\mathsf{x}}), \underline{\mathsf{M}}(\overline{\mathsf{x}}))_{\mathrm{tr}} \times_{\mathsf{Y}} |\eta_{\mathsf{V}}|.$$

From lemma 13.4.29, it follows easily that the covering $C \times_{U_{\mathrm{tr}}} \mathsf{U}_{\mathrm{tr}} \to \mathsf{U}_{\mathrm{tr}}$ is an object of $\mathbf{Tame}(\mathsf{f}, \overline{\mathsf{x}}, \kappa(\eta_{\mathsf{V}}))$.

For any integer $e > 0$ invertible in R, pick a $(Y, \underline{N})$-scheme $(Y_e, \underline{N}_e)$ as in (13.4.11), so that we may define the étale morphism $(X'_e, \underline{M}'_e) \to (X_e, \underline{M}_e)$ of $(Y_e, \underline{N}_e)$-schemes as in (13.4.13). Notice that the morphism $(X'_e, \underline{M}'_e) \to (Y_e, \underline{N}_e)$ is again of the type considered in (13.4), and there exists, up to isomorphism, a unique geometric point $\overline{x}'_e$ of X'_e lifting $\overline{x}$; moreover, for any geometric point $\overline{y}_e$ supported at y_e, the induced map

$$\mathrm{Spec}\,\underline{M}'_{e,\overline{x}'_e} \to \mathrm{Spec}\,\underline{N}'_{e,\overline{y}_e}$$

is naturally identified with (13.4.19). Likewise, pick a $(\mathsf{Y}, \underline{\mathsf{N}})$-scheme $(\mathsf{Y}_e, \underline{\mathsf{N}}_e)$ in the same fashion, and denote by η_e (resp. $\eta_{\mathsf{V},e}$) the generic point of Y_e (resp. of Y_e), and by $\mathsf{y}_e \in \mathsf{Y}_e$ (resp. $y_e \in Y_e$) the closed point. We may choose Y_e so that $\kappa(\eta_{\mathsf{V},e})$ contains $\kappa(\eta_e)$, in which case we have a strict morphism

$$(\mathsf{Y}_e, \underline{\mathsf{N}}_e) \to (Y_e, \underline{N}_e)$$

of log schemes, and we may set $(\mathsf{X}'_e, \underline{\mathsf{M}}'_e) := \mathsf{Y}_e \times_{Y_e} (X'_e, \underline{M}'_e)$. Again, there exists, up to isomorphism, a unique geometric point $\overline{\mathsf{x}}'_e$ of X'_e lifting $\overline{\mathsf{x}}$, and by claim 13.4.40, we may assume that both e and $\kappa(\eta_{\mathsf{V},e})$ have been chosen large enough, so that the base change

$$h \times_{X(\overline{x})} \mathsf{X}'_e(\overline{\mathsf{x}}'_e)$$

shall be a trivial étale covering. Hence, we may replace Y by Y_e, Y by Y_e, X by X'_e, and h by $h \times_{X(\overline{x})} X'_e(\overline{x}'_e)$, and assume from start that $C \times_{U_{\mathrm{tr}}} \mathsf{U}_{\mathrm{tr}}$ is a trivial covering of U_{tr}. The theorem will follow, once we show that – in this case – h is a trivial étale covering.

Let C' (resp. C') be the normalization of $X(\overline{x})$ in C (resp. of $\mathsf{X}(\overline{\mathsf{x}})$ in $C \times_{U_{\mathrm{tr}}} \mathsf{U}_{\mathrm{tr}}$), and define $E(h)$ as in (13.4.28). Then C' is a trivial étale covering of $\mathsf{X}(\overline{\mathsf{x}})$, and since $X(\overline{x})$ is excellent, the induced morphism $h' : C' \to X(\overline{x})$ is finite.

Claim 13.4.42. For every maximal point η_{q} of $f_{\overline{x}}^{-1}(\overline{y})$, the induced covering $C_{|\eta_{\mathsf{q}}} \to |\eta_{\mathsf{q}}|$ is trivial (notation of (13.4.31)).

Proof of the claim. Let Z_{q} denote the topological closure of $\{\eta_{\mathsf{q}}\}$ in $X(\overline{x})$, and endow Z_{q} with its reduced subscheme structure; then $E_{\mathsf{q}} := E(h) \cap Z_{\mathsf{q}}$ is non-empty (lemma 13.4.29), and geometrically normal (proposition 12.7.14(ii) and corollary 12.5.13). Also, (13.4.41) induces an isomorphism of $\kappa(\mathsf{y})$-schemes

$$E_{\mathsf{q}} \times_{X(\overline{x})} \mathsf{X}(\overline{x}) \xrightarrow{\sim} E_{\mathsf{q}} \times_{\kappa(y)} \kappa(\mathsf{y}).$$

Moreover, Z_{q} is strictly local, and $Z_{\mathsf{q}} \times_{X(\overline{x})} \mathsf{X}(\overline{\mathsf{x}})$ is the strict henselization of $Z_{\mathsf{q}} \times_{\kappa(y)} \kappa(\mathsf{y})$ at the point x. Furthermore, the morphism $h'' := h' \times_{X(\overline{x})} E_{\mathsf{q}}$ is an étale covering of E_{q}, and $h'' \times_{\kappa(y)} \kappa(\mathsf{y})$ is naturally identified with the restriction of C' to the subscheme $E_{\mathsf{q}} \times_{X(\overline{x})} \mathsf{X}(\overline{\mathsf{x}})$ ([66, Ch.IV, Prop.17.5.7]), hence it is a trivial covering. By example 13.2.6, it follows that h'' is trivial as well. Since $C_{|\eta_{\mathsf{q}}}$ is the restriction of h'' to $|\eta_{\mathsf{q}}|$, the claim follows. ◊

Clearly (13.4.41) maps each stratum U_{q} of the logarithmic stratification of $\mathsf{X}(\overline{\mathsf{x}})$, to the corresponding stratum U_{q} of the logarithmic stratification of $X(\overline{x})$ (see (12.5.35)). More precisely, since (13.4.41) $\times_Y |\eta|$ is ind-étale, proposition 12.7.17(iii) implies that the generic point of $\mathsf{U}_{\mathsf{q}} \times_{\mathsf{Y}} |\eta_{\mathsf{V}}|$ gets mapped to the generic point of $U_{\mathsf{q}} \times_Y |\eta|$. We conclude that $E(h)$ contains the generic point of every stratum $U_{\mathsf{q}} \times_Y |\eta|$.

Claim 13.4.43. $X(\overline{x}) \times_Y |\eta| \subset E(h)$.

Proof of the claim. Notice first that $(X, \underline{M}) \times_Y |\eta|$ is a regular log scheme (corollary 12.5.29).

For any geometric point ξ of $X(\overline{x})$, denote by $(X(\xi), \underline{M}(\xi))$ the strict henselization of $(X(\overline{x}), \underline{M}(\overline{x}))$ at ξ, and set $C'(\xi) := C' \times_{X(\overline{x})} X(\xi)$. Now, suppose that the support of ξ lies in the stratum $U_{\mathsf{q}} \times_Y |\eta|$, and let ξ_{q} be a geometric point localized at the generic point of U_{q}. By assumption, $C'(\xi)$ is a finite $X(\xi)$-scheme, tamely ramified along the non-trivial locus of $(X(\xi), \underline{M}(\xi))$. Likewise, $C'(\xi_{\mathsf{q}})$ is tamely ramified along the non-trivial locus of $(X(\xi_{\mathsf{q}}), \underline{M}(\xi_{\mathsf{q}}))$. Pick any strict specialization map $(X(\xi_{\mathsf{q}}), \underline{M}(\xi_{\mathsf{q}})) \to (X(\xi), \underline{M}(\xi))$ (see (12.7.11)); it induces a functor

$$\mathsf{Cov}(X(\xi), \underline{M}(\xi)) \to \mathsf{Cov}(X(\xi_{\mathsf{q}}), \underline{M}(\xi_{\mathsf{q}})) \tag{13.4.44}$$

and theorem 13.3.45 implies that $C'(\xi)$ is an object of the source of (13.4.44), which is mapped, under this functor, to the object $C'(\xi_{\mathsf{q}})$. By proposition 13.3.43, for any geometric point ξ of $X(\overline{x}) \times_Y |\eta|$, the category $\mathsf{Cov}(X(\xi), \underline{M}(\xi))$ is equivalent to the category of finite sets with a continuous action of $(\underline{M}_\xi)^{\mathrm{gp}\vee} \otimes_{\mathbb{Z}} \prod_{\ell \neq p} \mathbb{Z}_\ell(1)$. On the other hand, clearly $\underline{M}(\overline{x})^\sharp$ restricts to a constant sheaf of monoids on $(U_{\mathsf{q}})_\tau$. In view of (13.3.54), we deduce that (13.4.44) is an equivalence; lastly, we have seen that the induced morphism $C'(\xi_{\mathsf{q}}) \to X(\xi_{\mathsf{q}})$ is étale, *i.e.* is a trivial covering, therefore the same holds for the morphism $C'(\xi) \to X(\xi)$, and consequently the support of ξ lies in $E(h)$ (claim 13.1.9). Since ξ is arbitrary, the assertion follows. ◊

Claim 13.4.45. There exists a non-empty open subset $U_Y \subset Y$ such that $X(\overline{x}) \times_Y U_Y \subset E(h)$.

Proof of the claim. Since $X(\overline{x})$ is a noetherian scheme, $E(h)$ is a constructible open subset, hence $Z := X(\overline{x}) \setminus E(h)$ is a constructible closed subset of $X(\overline{x})$. The subset $f_{\overline{x}}(Z)$ is pro-constructible ([63, Ch.IV, Prop.1.9.5(vii)]) and does not contain η (by claim 13.4.43), hence neither does its topological closure W ([63, Ch.IV, Th.1.10.1]). It is easily seen that $U_Y := Y \setminus W$ will do. ◊

Claim 13.4.46. Let U_Y be as in claim 13.4.45. We have :

(i) There exists an irreducible closed subset Z of Y of dimension one, such that $Z \cap (Y, \underline{N})_{\mathrm{tr}} \cap U_Y \neq \varnothing$.

(ii) For any Z as in (i), the induced functor $\mathsf{Cov}(E(h)) \to \mathsf{Cov}(Z \times_Y E(h))$ is fully faithful.

Proof of the claim. (i): More generally, let $(A, \mathfrak{m})$ be any local noetherian domain of Krull dimension $d \geq 1$, and $W \subset \mathrm{Spec}\, A$ a proper closed subset; we show that there exists an irreducible closed subset $Z \subset \mathrm{Spec}\, A$ of dimension one, not contained in W. To this aim, we may assume that $W = \mathrm{Spec}\, A/fA$ for some $f \in \mathfrak{m} \setminus \{0\}$; let $\mathfrak{n}$ be any maximal ideal of $A[f^{-1}]$, and $\mathfrak{p} := A \cap \mathfrak{n}$. Since $A/\mathfrak{p}[f^{-1}]$ is a field, [63, Ch.0, Cor.16.3.3] implies that $Z := \mathrm{Spec}\, A/\mathfrak{p}$ will do.

(ii): It suffices to check that conditions (i)–(iii) of proposition 13.1.37 hold for Z and the open subset $E(h)$. However, condition (i) is immediate, since the generic point η_Z of Z lies in U_Y. Likewise, condition (ii) holds trivially for the fibre over the point η_Z, so it suffices to consider the fibre over the closed point y of Z, in which case the assertion is just lemma 13.4.29. Lastly, condition (iii) follows directly from theorem 12.7.8(iii.b) and [66, Ch.IV, Prop.18.8.10, 18.8.12(i)]. ◊

Let Z be as in claim 13.4.46(i), and endow Z with its reduced subscheme structure. Let also Z' be the normalization of Z; then both Z and Z' are strictly local, and the morphism $Z' \to Z$ is radicial and surjective, hence the induced functor

$$\mathsf{Cov}(Z \times_Y E(h)) \to \mathsf{Cov}(Z' \times_Y E(h))$$

is an equivalence (lemma 13.1.7(i)). Taking into account claim 13.4.46, we are thus reduced to showing that the morphism

$$(Z' \times_Y E(h)) \times_{X(\overline{x})} C' \to Z' \times_Y E(h)$$

is a trivial étale covering. However, let $\eta_{Z'}$ be the generic point of Z', and set

$$(Z', \underline{N}') := Z' \times_Y (Y, \underline{N}) \qquad (X', \underline{M}') := Z' \times_Y (X, \underline{M}).$$

The open subset $(Z', \underline{N}')_{\mathrm{tr}}$ is dense in Z', by virtue of claim 13.4.46(i), so the induced morphism $f' : (X', \underline{M}') \to (Z', \underline{N}')$ is still of the type considered in (13.4), the geometric point $\overline{x}$ lifts uniquely (up to isomorphism) to a geometric point $\overline{x}'$ of X', and $h \times_Y Z'$ is an object of $\mathbf{Tame}(f', \overline{x}', \kappa(\eta_{Z'}))$ (proposition 13.3.20(i)). Hence, we may replace from start $(X, \underline{M})$ by $(X', \underline{M}')$, $(Y, \underline{N})$ by $(Z', \underline{N}')$, h by $h \times_Y Z'$, after which, we may assume that Y is noetherian and of dimension one. Moreover, taking into account claim 13.4.42, we may assume that the induced covering $C_{|\eta_\mathfrak{q}} \to |\eta_\mathfrak{q}|$ is trivial, for every maximal point $\eta_\mathfrak{q}$ of $f_{\overline{x}}^{-1}(\overline{y})$, and it remains to show that h is trivial under these assumptions.

To this aim, we look at the corresponding commutative diagram of groups, provided by lemma 13.4.33(i) : with the notation of *loc.cit.*, we see that in the current situation, β is an isomorphism as well, by claim 13.4.40, therefore lemma 13.4.33(ii) says that the group homomorphism $\pi_1(|\eta_\mathfrak{q}|_{\acute{e}t}, \overline{\eta}_\mathfrak{q}) \to \pi_1(\overline{U}_{\mathrm{tr}}/Y_{\acute{e}t}, \xi)$ is surjective, for any maximal point $\eta_\mathfrak{q}$ of $f_{\overline{x}}^{-1}(\overline{y})$. From this, we deduce that $\overline{h}$ is a trivial covering, and therefore there exists an étale covering $C_Y \to |\eta|$ with an isomorphism $C \overset{\sim}{\to} C_Y \times_{|\eta|} U_{\mathrm{tr}}$ ([82, Exp.IX, Th.6.1]). Denote by C_Y^ν the normalization of Y in C_Y. Also, set $E' := E(h) \subset \mathrm{Str}(f_{\overline{x}})$. In light of theorem 12.7.8(iii.a) and lemma 13.4.29, it is easily seen that the restriction $E' \to Y$ of $f_{\overline{x}}$ is surjective; the latter is also a smooth morphism of schemes (corollary 12.3.27(i)). It follows that $C^{\nu}_Y \times_Y E'$ is the normalization of E' in C ([66, Ch.IV, Prop.17.5.7]), especially, it is an étale covering of E'. We then deduce that C^{ν}_Y is already a (trivial) étale covering of Y ([66, Ch.IV, Prop.17.7.1(ii)]), and then clearly h must be a trivial covering as well. □

Remark 13.4.47. Theorem 13.4.39 is the local acyclicity result that gives the name to this section. However, the title is admittedly not self-explanatory, and its full justification would require the introduction of a more advanced theory of the *log-étale site*, that lies beyond the bounds of this treatise. In rough terms, we can try to describe the situation as follows. In lieu of the standard strict henselization, one should consider a suitable notion of strict *log henselization* for points of the *log-étale topoi* associated with log schemes. Then, for $f : X \to Y$ as in (13.4) with saturated log structures on both X and Y, and log-étale points $\widetilde{x}$ of X with image $\widetilde{y}$ in Y, one should look, not at our $f_{\overline{x}}$, but rather at the induced morphism $f_{\widetilde{x}}$ of strict log henselizations (of X at $\widetilde{x}$ and of Y at $\widetilde{y}$). The (suitably defined) *log geometric fibres* of $f_{\widetilde{x}}$ will be the *log Milnor fibres* of f at the log-étale point $\widetilde{x}$, and one can state for such fibres an acyclicity result : namely, the prime-to-p quotients of their (again, suitably defined) *log fundamental groups* vanish. The proof proceeds by reduction to our theorem 13.4.39, which, with hindsight, is seen to supply the essential geometric information encoded in the more sophisticated log-étale language.

14. THE ALMOST PURITY TOOLBOX

The sections of this rather heterogeneous chapter are each devoted to a different subject, and are linked to each other only very loosely, if they are at all. They have been lumped here together, because they each contribute a distinct self-contained little theory, that will find application in one step or other of the proof of the almost purity theorem or of its applications in chapter 17. The exception is section 14.8 : it studies a class of rings more general than the measurable algebras introduced in section 14.5; the results of section 14.8 will not be used elsewhere in this treatise, but they might be interesting for other purposes.

Section 14.4 develops the yoga of almost pure pairs (see definition 14.4.1(i)); the relevance to the almost purity theorem is clear, since the latter establishes the almost purity of certain pairs (X, Z) consisting of a scheme X and a closed subscheme $Z \subset X$. This section provides the means to perform various kinds of reductions in the proof of the almost purity theorem, allowing to replace the given pair (X, Z) by more tractable ones.

Section 14.5 introduces measurable (and more generally, ind-measurable) K^+-algebras, for K^+ a fixed valuation ring of rank one : see definitions 14.5.3(ii) and 14.5.64. For modules over a measurable algebra, one can define a well-behaved real-valued normalized length. This length function is non-negative, and additive for short exact sequences of modules. Moreover, the length of an almost zero module vanishes (for the standard almost structure associated with K^+). Conversely, under some suitable assumptions, a module of normalized length zero will be almost zero.

Lastly, section 14.6 studies some questions concerning the formation of quotients of affine almost schemes under a finite group action.

14.1. **Non-flat almost structures.**

This section contains some material that complements the generalities of [75, §2.4, §2.5] : indeed, whereas many of the preliminaries in *loc.cit.* make no assumptions on the basic setup $(V, \mathfrak{m})$ that underlies the whole discussion, for the more advanced results it is usually required that $\widetilde{\mathfrak{m}} := \mathfrak{m} \otimes_V \mathfrak{m}$ is a flat V-module. We shall show how, with more work, one can remove this condition (or at least, weaken it significantly) and still recover most of the useful almost ring theory of [75]. This extension shall be applied in a later section, in order to state and prove the most general case of almost purity.

14.1.1. We begin with a simple observation, that completes the discussion of [75, §2.1.6].

Proposition 14.1.2. *Let V be a reduced ring, and consider ideals $\mathfrak{m}, J_1, \dots, J_k \subset V$ such that:*

(a) $\mathfrak{m}$ *is a filtered union of principal ideals.*

(b) $J_1 \otimes_V \cdots \otimes_V J_k$ *is a flat V-module.*

Then the following holds :

(i) *The natural map $\mathfrak{m} \otimes_V \mathfrak{m} \to \mathfrak{m}^2$ is an isomorphism.*

(ii) *If the set $\mathrm{Min}\, V$ of minimal prime ideals of V is a quasi-compact subset of $\mathrm{Spec}\, V$, then the natural map $J_1 \otimes_V \cdots \otimes_V J_k \to J_1 \cdots J_k$ is an isomorphism.*

Proof. (i): We are easily reduced to checking the following. For every $x \in V$, the natural map $\mu : Vx \otimes_V Vx \to Vx^2$ is an isomorphism. Now, $I_n := \mathrm{Ann}_V(x^n)$ for $n = 1, 2$, and notice that $I_1 \subset I_2$; the map μ is naturally identified with the map

$$V/I_1 \otimes_V V/I_1 \to V/I_2 \qquad \overline{a} \otimes \overline{b} \mapsto \overline{ab}.$$

The latter is the composition of the natural isomorphism $V/I_1 \otimes_V V/I_1 \stackrel{\sim}{\to} V/I_1$ and the projection $V/I_1 \to V/I_2$, so we are reduced to checking that $I_1 = I_2$. But if $x^2 y = 0$ for some $y \in V$, then $(xy)^2 = 0$, hence $xy = 0$, since V is reduced, and so $y \in I_1$, whence the contention.

(ii): Set $L := J_1 \otimes_V \cdots \otimes_V J_k$ and $J := J_1 \cdots J_k$; the natural map $\varphi : L \to J$ is surjective, so it remains to check that it is injective, under the assumptions of (ii). However, notice that, for every $\mathfrak{p} \in Y := \mathrm{Min}\, V$, the localization $V_\mathfrak{p}$ is a field, since V is reduced; it follows easily that $\varphi_\mathfrak{p} : L_\mathfrak{p} \to J_\mathfrak{p}$ is an isomorphism for every such $\mathfrak{p}$. We are then reduced to checking that the natural map $\psi_L : L \to \prod_{\mathfrak{p} \in \mathrm{Min}\, V} L_\mathfrak{p}$ is injective. However, endow Y with the topology induced by $X := \mathrm{Spec}\, V$ via the inclusion map $i : Y \to X$, and denote by $L^\sim$ the quasi-coherent $\mathscr{O}_X$-module arising from L. Then ψ_L is a composition of maps

$$L \xrightarrow{\psi'_L} \Gamma(Y, i^* L^\sim) \xrightarrow{\psi''_L} \prod_{\mathfrak{p} \in Y} L^\sim_\mathfrak{p} = \prod_{\mathfrak{p} \in Y} L_\mathfrak{p}$$

and ψ''_L is obviously injective. Thus, it remains to show that ψ'_L is injective. But, by Lazard's theorem [120, Ch.I,Th.1.2], L is the colimit of a filtered system $(F_\lambda \mid \lambda \in \Lambda)$ of free V-modules of finite rank, so $L^\sim$ is the colimit of the induced filtered system $(F^\sim_\lambda \mid \lambda \in \Lambda)$ of quasi-coherent $\mathscr{O}_X$-modules. By lemma 10.1.7(i), we are then reduced to checking that the natural map $F_\lambda \to \Gamma(Y, i^* F^\sim_\lambda)$ is injective for every $\lambda \in \Lambda$. For the latter, it suffices to check that the natural map $\psi_V : V \to \Gamma(Y, i^* \mathscr{O}_X)$ is injective; but the composition of ψ_V with the natural map $\Gamma(Y, i^* \mathscr{O}_X) \to \prod_{\mathfrak{p} \in Y} \mathscr{O}_{X,\mathfrak{p}} = \prod_{\mathfrak{p} \in Y} V_\mathfrak{p}$ is injective, since V is reduced, whence the claim. □

Remark 14.1.3. As a corollary, we see that if $(V, \mathfrak{m})$ is a basic setup (in the sense of [75, §2.1.1]), such that V is a reduced ring, then the natural map $\widetilde{\mathfrak{m}} \to \mathfrak{m}$ is an isomorphism, provided that either (a) $\mathfrak{m}$ is a filtered union of principal ideal, or else (b) $\widetilde{\mathfrak{m}}$ is a flat V-module, and $\mathrm{Min}\, V$ is a quasi-compact subset of $\mathrm{Spec}\, V$.

14.1.4. Let now $(V, \mathfrak{m})$ be any *basic setup* in the sense of [75, §2.1.1], and R any V-algebra. For every interval $I \subset \mathbb{N}$, we have a localization functor

$$\mathsf{C}^I(R\text{-}\mathbf{Mod}) \to \mathsf{C}^I(R^a\text{-}\mathbf{Mod}) \qquad K^\bullet \mapsto K^{\bullet a} \tag{14.1.5}$$

from complexes of R-modules, to complexes of R^a-modules, which is obviously exact, hence it induces a derived localization functor :

$$\mathsf{D}^I(R\text{-}\mathbf{Mod}) \to \mathsf{D}^I(R^a\text{-}\mathbf{Mod}). \tag{14.1.6}$$

The functor (14.1.5) admits a left (resp. right) adjoint

$$\mathsf{C}^I(R^a\text{-}\mathbf{Mod}) \to \mathsf{C}^I(R\text{-}\mathbf{Mod}) \qquad K^\bullet \mapsto K^\bullet_! \qquad (\text{ resp. } K^\bullet \mapsto K^\bullet_*) \tag{14.1.7}$$

defined by applying termwise to $K^\bullet$ the functor $M \mapsto M_!$ (resp. $M \mapsto M_*$) for R^a-modules given by [75, §2.2.10, §2.2.21]. However, if $\widetilde{\mathfrak{m}}$ is not flat, the functor $M \mapsto M_!$ is obviously not exact, and the localization functor $R\text{-}\mathbf{Mod} \to R^a\text{-}\mathbf{Mod}$ does not send injectives to injectives (cp. [75, Cor.2.2.24]). This makes it trickier to deal with constructions in the derived category; for instance, if $\widetilde{\mathfrak{m}}$ is flat, we get a left adjoint to (14.1.6), simply by deriving trivially the exact functor $M \mapsto M_!$. This fails in the general case, but we shall see later that a suitable derived version of the construction of $M_!$ is still available.

14.1.8. For any interval $I \subset \mathbb{N}$, let Σ_I be the multiplicative set of morphisms φ in $\mathsf{D}^I(R\text{-}\mathbf{Mod})$ such that φ^a is an isomorphism in $\mathsf{D}^I(R^a\text{-}\mathbf{Mod})$; arguing as in the proof of [163, Prop.10.4.4], one sees that Σ_I is right locally small, hence the localized category $\Sigma_I^{-1}\mathsf{D}^I(R\text{-}\mathbf{Mod})$ has small Hom-sets (proposition 1.6.16(ii)) which are independent (up to natural isomorphism) of the choice of universe. Obviously the derived localization functor factors through a natural functor

$$\Sigma_I^{-1}\mathsf{D}^I(R\text{-}\mathbf{Mod}) \to \mathsf{D}^I(R^a\text{-}\mathbf{Mod}). \tag{14.1.9}$$

Lemma 14.1.10. (i) *For every interval I, the functor* (14.1.9) *is an equivalence.*

(ii) *For every $K^\bullet, L^\bullet \in \mathrm{Ob}(\mathsf{D}^I(R\text{-}\mathbf{Mod}))$ the induced R^a-linear morphism*

$$\mathrm{Hom}_{\mathsf{D}^I(R\text{-}\mathbf{Mod})}(K^\bullet, L^\bullet)^a \to \mathrm{Hom}_{\mathsf{D}^I(R^a\text{-}\mathbf{Mod})}(K^{\bullet a}, L^{\bullet a})^a$$

is an isomorphism.

Proof. (i): A proof is sketched in [75, §2.4.9], in case $\widetilde{\mathfrak{m}}$ is flat, but in fact this assumption is superfluous. Indeed, since the unit of adjunction $M \to M_!^a$ is an isomorphism ([75, Prop.2.2.23(ii)]), it is clear that the functor $K^\bullet \mapsto K_!^\bullet$ of (14.1.7) descends to a functor

$$\mathsf{D}^I(R^a\text{-}\mathbf{Mod}) \to \Sigma_I^{-1}\mathsf{D}^I(R\text{-}\mathbf{Mod}) \tag{14.1.11}$$

such that the composition (14.1.9) ∘ (14.1.11) is naturally isomorphic to the identity automorphism of $\mathsf{D}^I(R^a\text{-}\mathbf{Mod})$. Likewise, a simple inspection shows that (14.1.11) ∘ (14.1.9) is naturally isomorphic to the identity of $\Sigma_I^{-1}\mathsf{D}^I(R\text{-}\mathbf{Mod})$, whence the contention.

(ii): The R-module $\mathrm{Hom}_{\Sigma_I^{-1}\mathsf{D}^I(R\text{-}\mathbf{Mod})}(K^\bullet, L^\bullet)$ is calculated as the colimit of the system of R-modules $(\mathrm{Hom}_{\mathsf{D}^I(R\text{-}\mathbf{Mod})}(K'^\bullet, L^\bullet) \mid \varphi^\bullet : K'^\bullet \to K^\bullet)$, where $\varphi^\bullet$ ranges over the elements of Σ_I with target $K^\bullet$. For such a morphism $\varphi^\bullet$, we have $\mathfrak{m} \cdot H^i(\mathrm{Cone}\,\varphi^\bullet) = 0$ for every $i \in \mathbb{Z}$.

Claim 14.1.12. Let $C^\bullet$ be any object of $\mathsf{D}^I(R\text{-}\mathbf{Mod})$ such that $(H^iC^\bullet)^a = 0$ for every $i \in \mathbb{Z}$. Then $\mathrm{Hom}_{\mathsf{D}^I(R\text{-}\mathbf{Mod})}(C^\bullet, L^\bullet)^a = 0$ for every $L^\bullet \in \mathrm{Ob}(\mathsf{D}^I(R\text{-}\mathbf{Mod}))$.

Proof of the claim. Set $H_{n,k} := \mathrm{Hom}_{\mathsf{D}^I(R\text{-}\mathbf{Mod})}(C^\bullet, (\tau^{\geq -n}L^\bullet)[k])$ for every $n, k \in \mathbb{N}$; the natural morphism $L^\bullet \to \lim_{n\in\mathbb{N}} \tau^{\geq -n}L^\bullet$ is an isomorphism in $\mathsf{C}(R\text{-}\mathbf{Mod})$, so we have a short exact sequence

$$0 \to \lim_{n\in\mathbb{N}}{}^1 H_{n,-1} \to \mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(C^\bullet, L^\bullet) \to \lim_{n\in\mathbb{N}} H_{n,0} \to 0$$

(proposition 7.3.45(ii)). Hence, it suffices to check that $H_{n,0}^a = H_{n,-1}^a = 0$ for every $n \in \mathbb{N}$, and we are reduced to the case where $L^\bullet$ is bounded below.

Likewise, set $H'_n := \mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(\tau^{\leq n}C^\bullet, L^\bullet)$ for every $n, k \in \mathbb{Z}$; since the natural morphism $\mathrm{colim}_{n\in\mathbb{N}}\, \tau^{\leq n}C^\bullet \to C^\bullet$ is an isomorphism in $\mathsf{C}(R\text{-}\mathbf{Mod})$, we have an isomorphism

$$\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(C^\bullet, L^\bullet) \xrightarrow{\sim} \lim_{n\in\mathbb{N}} H'_n$$

(proposition 7.3.45(i)), so we may assume that $C^\bullet$ is a bounded above complex. In this situation, say that $L^\bullet \in \mathrm{Ob}(\mathsf{D}^{\geq a}(R\text{-}\mathbf{Mod}))$ and $C^\bullet \in \mathrm{Ob}(\mathsf{D}^{\leq b}(R\text{-}\mathbf{Mod}))$ for some $a, b \in \mathbb{Z}$; we may assume that $a \leq b$, and we show, by induction on n, that $(H'_n)^a = 0$ for every $n \geq a - 1$. The claim will follow for $n = b$. Indeed, notice that

$$H'_r = \mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(\tau^{\leq r}C^\bullet, \tau^{\leq r}L^\bullet) \qquad \text{for every } r \in \mathbb{Z}$$

by virtue of remark 7.3.14(iv), so the assertion is clear for $n = a - 1$. Next, suppose that the assertion is already known for every integer $< n$; from the short exact of complexes $0 \to \tau^{\leq n-1}C^\bullet \to \tau^{\leq n}C^\bullet \to (H^n C^\bullet)[-n] \to 0$ we deduce the exact sequence

$$\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}((H^n C^\bullet)[-n], L^\bullet) \to H'_n \to H'_{n-1}$$

(remark 7.3.35). But since $\mathfrak{m} \cdot H^n C^\bullet = 0$, the first term in this exact sequence is annihilated by $\mathfrak{m}$, and the same holds for the third term, by inductive assumption; then it holds for the middle term as well, as required. ◊

By claim 14.1.12, we have $\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(\mathrm{Cone}\,\varphi^\bullet, L^\bullet)^a = 0$; by considering the long exact $\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(-, L^\bullet)$-sequence associated with the distinguished triangle $K'^\bullet \to K^\bullet \to \mathrm{Cone}\,\varphi$, we deduce an R^a-linear isomorphism

$$\mathrm{Hom}_{\mathsf{D}^I(R\text{-}\mathbf{Mod})}(\varphi^\bullet, L^\bullet)^a : \mathrm{Hom}_{\mathsf{D}^I(R\text{-}\mathbf{Mod})}(K'^\bullet, L^\bullet)^a \xrightarrow{\sim} \mathrm{Hom}_{\mathsf{D}^I(R\text{-}\mathbf{Mod})}(K^\bullet, L^\bullet)^a$$

(see remark 7.3.35). In light of (i), the assertion follows straightforwardly. □

14.1.13. We sketch a few generalities on derived tensor products, that will be applied to construct useful objects in various derived categories. Recall first that the tensor product $-\otimes_R -$ on R-modules descends to a bifunctor $-\otimes_{R^a} -$ ([75, §2.2.6, §2.2.12]), and if M is a flat R-module, then M^a is a flat R^a-module ([75, Lemma 2.4.7]). It follows that the category R^a-$\mathbf{Mod}$ has enough flat objects, so every bounded above complex of R^a-modules admits a bounded above flat resolution. Now, given bounded above complexes $K^\bullet, L^\bullet$ of R^a-modules, set

$$K^\bullet \overset{\mathbf{L}}{\otimes}_{R^a} L^\bullet := (K^\bullet_! \overset{\mathbf{L}}{\otimes}_R L^\bullet_!)^a$$

which is a well defined object of $\mathsf{D}(R^a\text{-}\mathbf{Mod})$.

- We claim that this rule yields a well defined functor

$$- \overset{\mathbf{L}}{\otimes}_{R^a} - : \mathsf{D}^-(R^a\text{-}\mathbf{Mod}) \times \mathsf{D}^-(R^a\text{-}\mathbf{Mod}) \to \mathsf{D}^-(R^a\text{-}\mathbf{Mod}).$$

Indeed, suppose $\varphi^\bullet : K^\bullet_1 \to K^\bullet_2$ is a morphism in $\mathsf{C}(R^a\text{-}\mathbf{Mod})$, inducing an isomorphism in $\mathsf{D}(R^a\text{-}\mathbf{Mod})$, and set $C^\bullet := \mathrm{Cone}\,(\varphi^\bullet_!)$; clearly, $C^{\bullet a} = 0$ in $\mathsf{D}(R^a\text{-}\mathbf{Mod})$. Now, pick any flat bounded above resolution $P^\bullet \to L^\bullet_!$, so that $K^\bullet_{i!} \otimes_R P^\bullet$ computes $K^\bullet_{i!} \overset{\mathbf{L}}{\otimes}_R L^\bullet_!$, for $i = 1, 2$. We get natural isomorphism :

$$\mathrm{Cone}(\varphi^\bullet \overset{\mathbf{L}}{\otimes}_{R^a} L^\bullet) \xrightarrow{\sim} (C^\bullet \otimes_R P^\bullet)^a \xrightarrow{\sim} C^{\bullet a} \otimes_{R^a} P^{\bullet a} = 0.$$

so the derived tensor product depends only on the image of $K^\bullet$ in $\mathsf{D}^-(R^a\text{-}\mathbf{Mod})$; likewise for the argument $L^\bullet$, whence the contention.

- Next, suppose that $P^\bullet \to K^\bullet$ is a bounded above resolution, with $P^\bullet$ a complex of flat R^a-modules; we claim that there is a natural isomorphism in $\mathsf{D}(R^a\text{-}\mathbf{Mod})$

$$K^\bullet \overset{\mathbf{L}}{\otimes}_{R^a} L^\bullet \xrightarrow{\sim} P^\bullet \otimes_{R^a} L^\bullet.$$

Indeed, pick any bounded above flat resolution $Q^\bullet \to L^\bullet_!$; we have natural isomorphisms

$$K^\bullet \overset{\mathbf{L}}{\otimes}_{R^a} L^\bullet \xrightarrow{\sim} (K^\bullet_! \otimes_R Q^\bullet)^a \xrightarrow{\sim} K^\bullet \otimes_{R^a} Q^{\bullet a} \xrightarrow{\sim} P^\bullet \otimes_{R^a} Q^{\bullet a}$$

in $\mathsf{D}(R^a\text{-}\mathbf{Mod})$, where the last holds, since $Q^{\bullet a}$ is a complex of flat R^a-modules. Finally, the induced map

$$P^\bullet \otimes_{R^a} Q^{\bullet a} \to P^\bullet \otimes_{R^a} L^\bullet$$

is also an isomorphism in $\mathsf{D}(R^a\text{-}\mathbf{Mod})$, since $P^\bullet$ is a complex of flat R^a-modules, so the claim follows.

• Notice that, for any $K^\bullet \in \mathrm{Ob}(\mathsf{D}^-(R\text{-}\mathbf{Mod}))$ and any flat resolution $P^\bullet \to K^\bullet$, the induced morphism $P^{\bullet a} \to K^{\bullet a}$ is a flat resolution; it follows that, for any $L^\bullet \in \mathrm{Ob}(\mathsf{D}(R\text{-}\mathbf{Mod}))$ we get a natural isomorphism

$$(K^\bullet \overset{\mathbf{L}}{\otimes}_R L^\bullet)^a \xrightarrow{\sim} K^{\bullet a} \overset{\mathbf{L}}{\otimes}_{R^a} L^{\bullet a} \qquad \text{in } \mathsf{D}(R^a\text{-}\mathbf{Mod}). \tag{14.1.14}$$

Remark 14.1.15. Clearly, for the derived tensor products of R^a-modules, one has the same commutativity and associativity isomorphisms as the ones detailed in remark 7.3.39(i) for usual modules, as well as the vanishing properties of lemma 7.3.42(ii).

We are now ready to return to the question of the existence of adjoints to derived localization. The key point is the following :

Lemma 14.1.16. *In the situation of* (14.1.4)*, let $K^\bullet$ be any complex of R-modules, $i \in \mathbb{Z}$ any integer and suppose that :*
   (a) $K^\bullet \in \mathrm{Ob}(\mathsf{D}^{\leq i}(R\text{-}\mathbf{Mod}))$
   (b) $K^{\bullet a} \in \mathrm{Ob}(\mathsf{D}^{\leq i-1}(R^a\text{-}\mathbf{Mod}))$.

Then $\mathfrak{m} \overset{\mathbf{L}}{\otimes}_V K^\bullet \in \mathrm{Ob}(\mathsf{D}^{\leq i-1}(R\text{-}\mathbf{Mod}))$.

Proof. We apply the standard spectral sequence

$$E^2_{pq} := \mathrm{Tor}^V_p(\mathfrak{m}, H^q K^\bullet) \Rightarrow H^{q-p}(\mathfrak{m} \overset{\mathbf{L}}{\otimes}_V K^\bullet).$$

Indeed, (a) says that $H^q K^\bullet = 0$ for every $q > i$, and (b) says that $(H^i K^\bullet)^a = 0$, and therefore $\mathfrak{m}_V \otimes_V H^i K^\bullet = 0$ ([75, Rem.2.1.4(i)]). In either case, we conclude that $E^2_{pq} = 0$ whenever $q - p \geq i$, whence the lemma. □

14.1.17. Now, let us define inductively :

$$\mathfrak{M}^\bullet_0 := V[0] \quad \text{and} \quad \mathfrak{M}^\bullet_{i+1} := \mathfrak{m} \overset{\mathbf{L}}{\otimes}_V \mathfrak{M}^\bullet_i \quad \text{for every } i \in \mathbb{N}.$$

A simple induction shows that $\mathfrak{M}^\bullet_i \in \mathsf{D}^{\leq 0}(V\text{-}\mathbf{Mod})$ for every $i \in \mathbb{N}$, so all these derived tensor product are well defined in $\mathsf{D}^{\leq 0}(V\text{-}\mathbf{Mod})$. Moreover, from the short exact sequence of V-modules

$$\Sigma \quad : \quad 0 \to \mathfrak{m} \to V \to V/\mathfrak{m} \to 0$$

we obtain a distiguished triangle

$$\mathfrak{M}^\bullet_i \overset{\mathbf{L}}{\otimes}_V \Sigma \quad : \quad \mathfrak{M}^\bullet_{i+1} \to \mathfrak{M}^\bullet_i \to \mathfrak{M}^\bullet_i \overset{\mathbf{L}}{\otimes}_V (V/\mathfrak{m}) \to \mathfrak{M}^\bullet_{i+1}[1] \qquad \text{for every } i \in \mathbb{N}.$$

Especially, we get an inverse system of morphisms in $\mathsf{D}^{\leq 0}(V\text{-}\mathbf{Mod})$:

$$\cdots \to \mathfrak{M}^\bullet_{i+1} \xrightarrow{\pi^\bullet_i} \mathfrak{M}^\bullet_i \xrightarrow{\pi^\bullet_{i-1}} \mathfrak{M}^\bullet_{i-1} \to \cdots \to \mathfrak{M}^\bullet_0 := V[0].$$

Also, from (14.1.14) we deduce natural isomorphisms in $\mathsf{D}^{\leq 0}(V^a\text{-}\mathbf{Mod})$:

$$\mathfrak{M}^{\bullet a}_i \xrightarrow{\sim} V^a[0] \qquad \text{for every } i \in \mathbb{N} \tag{14.1.18}$$

and under these identifications, the morphism $\pi^{\bullet a}_i$ corresponds to the identity automorphism of $V^a[0]$ (details left to the reader). Furthermore, we deduce the following derived version of [75, Rem.2.1.4(i)] :

Proposition 14.1.19. *Let $a, b \in \mathbb{Z}$ be any integers with $a \leq b$. We have :*
   (i) *For every $K^\bullet \in \mathrm{Ob}(\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod}))$, the following conditions are equivalent :*
      (a) $K^{\bullet a} \simeq 0$ *in* $\mathsf{D}^{[a,b]}(R^a\text{-}\mathbf{Mod})$.
      (b) $\tau^{\geq a}(\mathfrak{M}^\bullet_{b-a+1} \overset{\mathbf{L}}{\otimes}_V K^\bullet) \simeq 0$ *in* $\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod})$.

(ii) *For every morphism* $\varphi^\bullet : K^\bullet \to L^\bullet$ *in* $\mathsf{D}^{\leq b}(R\text{-}\mathbf{Mod})$*, the following conditions are equivalent :*

(a) $\varphi^{\bullet a}$ *is an isomorphism in* $\mathsf{D}^{[a,b]}(R^a\text{-}\mathbf{Mod})$.

(b) $\tau^{\geq a}(\mathfrak{M}^\bullet_{b-a+2} \overset{\mathbf{L}}{\otimes}_V \varphi^\bullet)$ *is an isomorphism in* $\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod})$.

Proof. (i): From (14.1.18), it is easily seen that (b)⇒(a). The other direction follows straightforwardly from lemma 14.1.16, via an easy descending induction on b.

(ii): Again, the direction (b)⇒(a) is immediate from (14.1.18). For the other direction, denote by $C^\bullet$ the cone of $\varphi^\bullet$; then $C^\bullet \in \mathrm{Ob}(\mathsf{D}^{[a-1,b]}(R\text{-}\mathbf{Mod}))$, and $C^{\bullet a} \simeq 0$ in $\mathsf{D}^{[a-1,b]}(R^a\text{-}\mathbf{Mod})$. From (i) we deduce that $\tau^{\geq a-1}(\mathfrak{M}^\bullet_{b-a+2} \overset{\mathbf{L}}{\otimes}_V C^\bullet) \simeq 0$ in $\mathsf{D}^{[a-1,b]}(R\text{-}\mathbf{Mod})$. Since the derived tensor product is a triangulated functor, the assertion follows easily : details left to the reader. □

Corollary 14.1.20. *With the notation of* (14.1.17)*, the morphism*

$$\tau^{\geq 2-i}\pi^\bullet_i : \tau^{\geq 2-i}\mathfrak{M}^\bullet_{i+1} \to \tau^{\geq 2-i}\mathfrak{M}^\bullet_i$$

is an isomorphism in $\mathsf{D}^{[2-i,0]}(V\text{-}\mathbf{Mod})$ *for every integer* $i \geq 2$.

Proof. By construction, we have a natural isomorphism :

$$\mathrm{Cone}(\tau^{\geq 2-i}\pi^\bullet_i) \xrightarrow{\sim} \tau^{\geq 1-i}(\mathfrak{M}^\bullet_i \overset{\mathbf{L}}{\otimes}_V (V/\mathfrak{m})) \qquad \text{in } \mathsf{D}^{[1-i,0]}(V\text{-}\mathbf{Mod})$$

in light of which, the assertion is an immediate consequence of proposition 14.1.19(i). □

Proposition 14.1.21. *In the situation of* (14.1.4)*, we have :*

(i) *The localization functor* $\mathsf{D}^+(R\text{-}\mathbf{Mod}) \to \mathsf{D}^+(R^a\text{-}\mathbf{Mod})$ *admits the right adjoint :*

$$\mathsf{D}^+(R^a\text{-}\mathbf{Mod}) \to \mathsf{D}^+(R\text{-}\mathbf{Mod}) \quad : \quad K^\bullet \mapsto K^\bullet_{[*]} := R\mathrm{Hom}^\bullet_{R^a}(R^a[0], K^\bullet). \tag{14.1.22}$$

(ii) *Let* $a, b, i \in \mathbb{Z}$ *be any three integers with* $b \geq a$ *and* $i \geq b - a + 2$*. The localization functor* $\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod}) \to \mathsf{D}^{[a,b]}(R^a\text{-}\mathbf{Mod})$ *admits the left adjoint :*

$$\mathsf{D}^{[a,b]}(R^a\text{-}\mathbf{Mod}) \to \mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod}) \quad : \quad K^\bullet \mapsto K^\bullet_{[!]} := \tau^{\geq a}(\mathfrak{M}^\bullet_i \overset{\mathbf{L}}{\otimes}_V K^\bullet_{[*]}).$$

and the right adjoint

$$\mathsf{D}^{[a,b]}(R^a\text{-}\mathbf{Mod}) \to \mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod}) \quad : \quad K^\bullet \mapsto \tau^{\leq b}K^\bullet_{[*]}.$$

(iii) *For every* $K^\bullet \in \mathrm{Ob}(\mathsf{D}^+(R^a\text{-}\mathbf{Mod}))$ *(resp.* $L^\bullet \in \mathrm{Ob}(\mathsf{D}^{[a,b]}(R^a\text{-}\mathbf{Mod}))$*) the counit of adjunction is an isomorphism*

$$(K^\bullet_{[*]})^a \xrightarrow{\sim} K^\bullet \qquad (\textit{ resp. } (\tau^{\leq b}L^\bullet_{[*]})^a \xrightarrow{\sim} L^\bullet \ ).$$

(iv) *For every* $L^\bullet \in \mathrm{Ob}(\mathsf{D}^{[a,b]}(R^a\text{-}\mathbf{Mod}))$*, the unit of adjunction is an isomorphism*

$$L^\bullet \to (L^\bullet_{[!]})^a.$$

Proof. (i): This is analogous to lemma 10.1.16(iii). Recall the construction : we know that the category R^a-$\mathbf{Mod}$ admits enough injectives ([75, 2.2.18]), hence (14.1.22) can be represented by $I^\bullet_*$, where $K^\bullet \xrightarrow{\sim} I^\bullet$ is any injective resolution of $K^\bullet$, and $I^\bullet_*$ is obtained by applying termwise to $I^\bullet$ the functor $M \mapsto M_*$ of [75, §2.2.10]. Indeed, taking into account [75, Cor.2.2.19] we get natural isomorphisms :

$$\begin{aligned}
\mathrm{Hom}_{\mathsf{D}^+(R\text{-}\mathbf{Mod})}(L^\bullet, I^\bullet_*) &\xrightarrow{\sim} H^0\mathrm{Hom}^\bullet_R(L^\bullet, I^\bullet_*) \\
&\xrightarrow{\sim} H^0\mathrm{Hom}^\bullet_{R^a}(L^{\bullet a}, I^\bullet) \\
&\xrightarrow{\sim} \mathrm{Hom}_{\mathsf{D}(R^a\text{-}\mathbf{Mod})}(L^{\bullet a}, I^\bullet) \\
&\xrightarrow{\sim} \mathrm{Hom}_{\mathsf{D}(R^a\text{-}\mathbf{Mod})}(L^{\bullet a}, K^\bullet)
\end{aligned}$$

for every bounded below complex $L^\bullet$ of R-modules.

(iii) follows by direct inspection of the definitions, taking into account that, for every R^a-module M, the counit of adjunction $(M_*)^a \to M$ is an isomorphism ([75, Prop.2.2.14(iii)]) : details left to the reader.

(ii): We consider first the assertion concerning the right adjoint : let $K^\bullet \in \mathsf{D}^{[a,b]}(R^a\text{-}\mathbf{Mod})$; we may find an injective resolution $K^\bullet \stackrel{\sim}{\to} I^\bullet$ such that $I^j = 0$ for every $j < a$, in which case $I^\bullet_* \in \mathsf{D}^{\geq a}(R\text{-}\mathbf{Mod})$, and $\tau^{\leq b} I^\bullet_*$ represents $\tau^{\leq b} K^\bullet_{[*]}$ in $\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod})$. Then, in view of (i), the assertion is reduced to remark 7.3.14(iv). For the left adjoint, let us set

$$\omega L^\bullet := \tau^{\geq a}(\mathfrak{M}^\bullet_i \overset{\mathbf{L}}{\otimes}_V L^\bullet) \qquad \text{for every } L^\bullet \in \mathrm{Ob}(\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod})).$$

Then $\omega L^\bullet$ is naturally an object of $\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod})$, as explained in remark 7.3.39(ii), and likewise for $K^\bullet_{[!]}$, if $K^\bullet$ is any object of $\mathsf{D}^{[a,b]}(R^a\text{-}\mathbf{Mod})$. We begin with the following :

Claim 14.1.23. Let $K^\bullet, L^\bullet \in \mathrm{Ob}(\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod}))$ be any two objects. Then the natural map

$$\mathrm{Hom}_{\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod})}(\omega K^\bullet, L^\bullet) \to \mathrm{Hom}_{\mathsf{D}^{[a,b]}(R^a\text{-}\mathbf{Mod})}(K^{\bullet a}, L^{\bullet a})$$

is an isomorphism.

Proof of the claim. Arguing as in [75, §2.2.2], and taking into account lemma 14.1.10(i), we reduce to showing that for any $K^\bullet \in \mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod})$, the natural morphism

$$\varphi_{K^\bullet} : \omega K^\bullet \to K^\bullet$$

is initial in the full subcategory of $\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod})/K^\bullet$ whose objects are the morphisms $\psi : L^\bullet \to K^\bullet$ that lie in $\Sigma_{[a,b]}$. However, for any such ψ, we have a commutative diagram in $\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod})$:

$$\begin{array}{ccc} \omega L^\bullet & \xrightarrow{\varphi_{L^\bullet}} & L^\bullet \\ \downarrow & & \downarrow \psi \\ \omega K^\bullet & \xrightarrow{\varphi_{K^\bullet}} & K^\bullet \end{array}$$

whose left vertical arrow is an isomorphism, by proposition 14.1.19(ii). There follows a morphism $\varphi_{K^\bullet} \to \psi$, and we have to check that this is the unique morphism from $\varphi_{K^\bullet}$ to ψ. However, say that $\alpha, \beta : \varphi_{K^\bullet} \to \psi$ are two such morphisms; then their difference is a morphism $\gamma := \alpha - \beta : \omega K^\bullet \to L^\bullet$ such that $\psi \circ \gamma = 0$, so γ factors through a morphism $\overline{\gamma} : \omega K^\bullet \to \mathrm{Cone}\,\psi[-1]$. Set $C^\bullet := \tau^{\leq b}\mathrm{Cone}\,\psi[-1]$; then $C^\bullet \in \mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod})$, and according to remark 7.3.14(iv), $\overline{\gamma}$ lifts uniquely to a morphism $\omega K^\bullet \to C^\bullet$ that we denote again $\overline{\gamma}$. We deduce a commutative diagram

$$\begin{array}{ccc} \omega \circ \omega K^\bullet & \longrightarrow & \omega C^\bullet \\ {\scriptstyle \varphi_{\omega_{K^\bullet}}} \downarrow & & \downarrow {\scriptstyle \varphi_{C^\bullet}} \\ \omega K^\bullet & \xrightarrow{\overline{\gamma}} & C^\bullet. \end{array}$$

Now, by construction $C^{\bullet a} = 0$, therefore $\omega C^\bullet = 0$ (proposition 14.1.19(i)); on the other hand, $\varphi_{\omega_{K^\bullet}}$ is an isomorphism, by proposition 14.1.19(ii). We conclude that $\overline{\gamma} = 0$, whence $\alpha = \beta$, as sought. ◊

Assertion (ii.a) is an immediate consequence of (iii) and claim 14.1.23; from this, also (iv) is immediate : details left to the reader. □

Remark 14.1.24. Let $a, b, i \in \mathbb{Z}$ be any three integers such that $a \leq b$ and $i \geq b - a + 2$. From propositions 14.1.21(ii.a,iii) and 14.1.19(ii) we deduce a natural isomorphism

$$\tau^{\geq a}(\mathfrak{M}^\bullet_i \overset{\mathbf{L}}{\otimes}_V K^\bullet) \stackrel{\sim}{\to} (K^{\bullet a})_{[!]} \qquad \text{for every } K^\bullet \in \mathrm{Ob}(\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod}))$$

(details left to the reader), which allows to compute $(K^{\bullet a})_{[!]}$ purely in terms of $K^\bullet$ and operations within $\mathsf{D}(R\text{-}\mathbf{Mod})$. It turns out that an analogous isomorphism is available also for $K^\bullet_{[*]}$: this is contained in the following

Lemma 14.1.25. *Let $a, b, i \in \mathbb{N}$ be any integers such that $a \leq b$ and $i \geq b - a + 2$. For every $K^\bullet \in \mathrm{Ob}(\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod}))$, we have a natural isomorphism :*

$$\tau^{\leq b} R\mathrm{Hom}^\bullet_V(\mathfrak{M}^\bullet_i, K^\bullet) \xrightarrow{\sim} \tau^{\leq b} K^{\bullet a}_{[*]}.$$

Proof. Theorem 10.1.18(ii) yields a natural isomorphism

$$R\mathrm{Hom}^\bullet_V(\mathfrak{M}^\bullet_i, K^\bullet) \xrightarrow{\sim} R\mathrm{Hom}^\bullet_R(\mathfrak{M}^\bullet_i \overset{\mathbf{L}}{\otimes}_V R[0], K^\bullet).$$

To compute the right-hand side, we may fix an injective resolution $K^\bullet \xrightarrow{\sim} I^\bullet$; the complex $I^{\bullet a}$ is not necessarily injective, but we can find an injective resolution $\varphi : I^{\bullet a} \xrightarrow{\sim} J^\bullet$ (in the category of bounded below complexes of R^a-modules). In view of (14.1.14) and (14.1.18), the morphism φ induces a natural transformation

$$\psi : R\mathrm{Hom}^\bullet_R(\mathfrak{M}^\bullet_i \overset{\mathbf{L}}{\otimes}_V R[0], K^\bullet) \to R\mathrm{Hom}^\bullet_{R^a}(R^a[0], K^{\bullet a}) = (K^{\bullet a})_{[*]}$$

and it suffices to show that, for every $j \leq b$, the map

$$H^j\psi : \mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(\mathfrak{M}^\bullet_i \overset{\mathbf{L}}{\otimes}_V R[0], K^\bullet[j]) \to \mathrm{Hom}_{\mathsf{D}(R^a\text{-}\mathbf{Mod})}(R^a[0], K^{\bullet a}[j])$$

is an isomorphism. However, by remark 7.3.14(iv), the latter is the same as a map

$$\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(\mathfrak{M}^\bullet_i \overset{\mathbf{L}}{\otimes}_V R[0], \tau^{\leq 0}K^\bullet[j]) \to \mathrm{Hom}_{\mathsf{D}(R^a\text{-}\mathbf{Mod})}(R^a[0], \tau^{\leq 0}K^{\bullet a}[j]) \tag{14.1.26}$$

and a direct inspection shows that (14.1.26) agrees with the map arising in claim 14.1.23, for every $j \leq b$. Especially, for every such j, the map (14.1.26) is an isomorphism, as sought. □

Proposition 14.1.27. *Let $a, b, c \in \mathbb{Z}$ be any three integers such that $a \leq b$, and $K^\bullet, L^\bullet$ any two objects of $\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod})$). Suppose that*

(a) $\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(K^\bullet, X[-j]) = 0$ *for all $j \in [c, b]$ and all R-modules X with $X^a = 0$.*
(b) $\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(Y[-j], L^\bullet) = 0$ *for all $j \in [a, c]$ and all R-modules Y with $Y^a = 0$.*

Then the natural map

$$\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(K^\bullet, L^\bullet) \to \mathrm{Hom}_{\mathsf{D}(R^a\text{-}\mathbf{Mod})}(K^{\bullet a}, L^{\bullet a}) \tag{14.1.28}$$

is an isomorphism.

Proof. We start out with the following observation :

Claim 14.1.29. Consider the following conditions :

(a') $\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(K^\bullet, X^\bullet) = 0$ for every $X^\bullet \in \mathrm{Ob}(\mathsf{D}^{[c,b]}(R\text{-}\mathbf{Mod}))$ such that $X^{\bullet a} = 0$.
(b') $\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(Y^\bullet, L^\bullet) = 0$ for every $Y^\bullet \in \mathrm{Ob}(\mathsf{D}^{[a,c]}(R\text{-}\mathbf{Mod}))$ such that $Y^{\bullet a} = 0$.

Then (a)⇔(a') and (b)⇔(b').

Proof of the claim. Obviously (a')⇒(a). For the converse, one argues by decreasing induction on $c \leq b$. Indeed, the case $c = b$ is immediate. Then, suppose that the sought equivalence has already been established for some $d \leq b$; if $X^\bullet \in \mathsf{D}^{[d-1,b]}$ and $X^{\bullet a} = 0$, and if we know that (a) holds with $c := d - 1$, we set $H^\bullet := H^cX^\bullet[-c]$, and consider the distinguished triangle

$$H^\bullet \to X^\bullet \to \tau^{\geq d}X^\bullet \to H^\bullet[1].$$

By inductive assumption, we have $\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(K^\bullet, \tau^{\geq d}X^\bullet) = 0$, and (a) says that

$$\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(K^\bullet, H^\bullet) = 0.$$

It then follows that $\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(K^\bullet, X^\bullet) = 0$, which shows that the equivalence holds for c.

The proof of the equivalence (b)⇔(b') is wholly analogous. ◊

Fix an integer $i \geq b - a + 2$, and set

$$C^\bullet := \mathrm{Cone}(\pi_0^\bullet \circ \cdots \circ \pi_i^\bullet : \mathfrak{M}_i^\bullet \to V[0])$$

(notation of (14.1.17)); notice that $C^\bullet \in \mathsf{D}^{\leq 1}(R\text{-}\mathbf{Mod})$, and $C^{\bullet a} = 0$. By virtue of condition (b), claim 14.1.29 and remark 7.3.14(iv), it follows that :

$$R^j\mathrm{Hom}^\bullet_R(C^\bullet, L^\bullet) = \mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(\tau^{\geq a}(C^\bullet[-j]), L^\bullet) = 0 \qquad \text{for every } j < c$$

In other words, $D^\bullet := R\mathrm{Hom}^\bullet_R(C^\bullet, L^\bullet) \in \mathsf{D}^{\geq c}(R\text{-}\mathbf{Mod})$, and clearly $D^{\bullet a} = 0$; also notice the induced distinguished triangle

$$\Sigma \quad : \quad D^\bullet \to L^\bullet \to R\mathrm{Hom}^\bullet_R(\mathfrak{M}_i^\bullet, L^\bullet) \to D^\bullet[-1].$$

Now, condition (a), claim 14.1.29 and remark 7.3.14(iv) imply that

$$\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(K^\bullet, D^\bullet[j]) = \mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(K^\bullet, \tau^{\leq b}D^\bullet[j]) = 0 \qquad \text{for every } j \leq 0$$

whence, by considering the distinguished triangle $R\mathrm{Hom}^\bullet_R(K^\bullet, \Sigma)$, natural isomorphisms

$$\begin{aligned}
\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(K^\bullet, L^\bullet) &\xrightarrow{\sim} \mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(K^\bullet, R\mathrm{Hom}^\bullet_R(\mathfrak{M}_i^\bullet, L)) \\
&\xrightarrow{\sim} \mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(\mathfrak{M}_i^\bullet \overset{\mathbf{L}}{\otimes}_V K^\bullet, L^\bullet) && \text{(by [163, Th.10.8.7])} \\
&\xrightarrow{\sim} \mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(\tau^{\geq a}\mathfrak{M}_i^\bullet \overset{\mathbf{L}}{\otimes}_V K^\bullet, L^\bullet) && \text{(by remark 7.3.14(iv))} \\
&\xrightarrow{\sim} \mathrm{Hom}_{\mathsf{D}(R^a\text{-}\mathbf{Mod})}(K^{\bullet a}, L^{\bullet a}) && \text{(by claim 14.1.23)}
\end{aligned}$$

whose composition, after a simple inspection, is seen to agree with the map (14.1.28). □

Remark 14.1.30. (i) For every interval $I \subset \mathbb{N}$, denote by

$$\Phi_I : \mathsf{D}^I(R/\mathfrak{m}R\text{-}\mathbf{Mod}) \to \mathsf{D}^I(R\text{-}\mathbf{Mod})$$

the forgetful functor. It follows easily from lemma 10.1.16(iii) and remark 7.3.14(iv), that, for every interval $[a, b]$, the functor $\Phi_{[a,b]}$ admits the right adjoint

$$\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod}) \to \mathsf{D}^{[a,b]}(R/\mathfrak{m}R\text{-}\mathbf{Mod}) \qquad K^\bullet \mapsto \Psi^r_{[a,b]}K^\bullet := \tau^{\leq b}R\mathrm{Hom}^\bullet_R(R/\mathfrak{m}R[0], K^\bullet).$$

(ii) Likewise, theorem 10.1.18 and remark 7.3.14(iv) imply that $\Phi_{[a,b]}$ admits the left adjoint

$$\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod}) \to \mathsf{D}^{[a,b]}(R/\mathfrak{m}R\text{-}\mathbf{Mod}) \qquad K^\bullet \mapsto \Psi^l_{[a,b]}K^\bullet := \tau^{\geq a}(K^\bullet \otimes_R R/\mathfrak{m}R[0]).$$

(iii) Consider as well the following two conditions :

(a”) $\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(K^\bullet, \Phi_{[c,b]}X^\bullet) = 0$ for every $X^\bullet \in \mathrm{Ob}(\mathsf{D}^{[c,b]}(R/\mathfrak{m}R\text{-}\mathbf{Mod}))$.

(b”) $\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(\Phi_{[a,c]}Y^\bullet, L^\bullet) = 0$ for every $Y^\bullet \in \mathrm{Ob}(\mathsf{D}^{[a,c]}(R/\mathfrak{m}R\text{-}\mathbf{Mod}))$.

Then, arguing as in the proof of claim 14.1.29 it is easily seen that condition (a) of proposition 14.1.27 is equivalent to (a”), and condition (b) is equivalent to (b”).

Proposition 14.1.31. *Let $a, b \in \mathbb{Z}$ be any two integers such that $a \leq b$. For every object $K^\bullet$ of $\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod})$, the following conditions are equivalent :*

(a) *$K^\bullet$ lies in the essential image of the left adjoint functor $X^\bullet \mapsto X^\bullet_{[!]}$.*

(b) $K^\bullet \overset{\mathbf{L}}{\otimes}_R R/\mathfrak{m}R[0] \in \mathrm{Ob}(\mathsf{D}^{<a-1}(R/\mathfrak{m}R\text{-}\mathbf{Mod}))$.

Proof. We start out with the following :

Claim 14.1.32. We may assume that $V = R$.

Proof of the claim. Clearly condition (b) does not depend on the underlying ring V. It suffices then to remark that condition (a) depends only on the basic setup $(R, \mathfrak{m}R)$ (as opposed to the original basic setup $(V, \mathfrak{m})$). Indeed, notice that there is a natural equivalence

$$\Omega : R^a\text{-}\mathbf{Mod} \xrightarrow{\sim} (R, \mathfrak{m}R)^a\text{-}\mathbf{Mod}$$

(where R^a denotes, as in the foregoing, the image of R in the category of $(V, \mathfrak{m})$-algebras), and the induced equivalence of the respective derived categories fits into an essentially commutative diagram

$$\begin{array}{ccc} & \mathsf{D}(R\text{-}\mathbf{Mod}) & \\ \swarrow & & \searrow \\ \mathsf{D}(R^a\text{-}\mathbf{Mod}) & \xrightarrow{\mathsf{D}(\Omega)} & \mathsf{D}((R, \mathfrak{m}R)^a\text{-}\mathbf{Mod}) \end{array}$$

whose downward arrows are the forgetful functors. Especially, the left (resp. right) adjoints of these two forgetful functors share the same essential images. ◊

Henceforth, we assume that $V = R$ (and therefore, $\mathfrak{m} = \mathfrak{m}R$). Fix an integer $i \geq b - a + 2$, set $L^\bullet := \tau^{\geq a-1}(\mathfrak{M}_i^\bullet \overset{\mathbf{L}}{\otimes}_V K^\bullet)$, and notice first that, taking into account proposition 14.1.21(iv) and remark 14.1.24, condition (a) is equivalent to :

(c) The morphism $\pi_0^\bullet \circ \cdots \circ \pi_{i-1}^\bullet : \mathfrak{M}_i \to V[0]$ induces an isomorphism $\tau^{\geq a} L^\bullet \to K^\bullet$.

(c)⇒(b): Indeed, set $H := H^{a-1} L^\bullet$; if (c) holds, we have a distinguished triangle

$$H[a-1] \to L^\bullet \to K^\bullet \to H[a]$$

whence a distinguished triangle in $\mathsf{D}(V/\mathfrak{m}\text{-}\mathbf{Mod})$

$$H[a-1] \overset{\mathbf{L}}{\otimes}_V V/\mathfrak{m}[0] \to L^\bullet \overset{\mathbf{L}}{\otimes}_V V/\mathfrak{m}[0] \to K^\bullet \overset{\mathbf{L}}{\otimes}_V V/\mathfrak{m}[0] \to H[a] \overset{\mathbf{L}}{\otimes}_V V/\mathfrak{m}[0]. \tag{14.1.33}$$

However, we have natural isomorphisms

$$\begin{aligned} \tau^{\geq a-1}(L^\bullet \overset{\mathbf{L}}{\otimes}_V V/\mathfrak{m}[0]) &\xrightarrow{\sim} \tau^{\geq a-1}((\mathfrak{M}_i^\bullet \overset{\mathbf{L}}{\otimes}_V K^\bullet) \overset{\mathbf{L}}{\otimes}_V V/\mathfrak{m}[0]) && \text{(by lemma 7.3.42(ii))} \\ &\xrightarrow{\sim} \tau^{\geq a-1}(\mathfrak{M}_i^\bullet \overset{\mathbf{L}}{\otimes}_V (K^\bullet \overset{\mathbf{L}}{\otimes}_V V/\mathfrak{m}[0])) && \text{(by remark 7.3.39(i))} \\ &\xrightarrow{\sim} \tau^{\geq a-1}(\mathfrak{M}_i^\bullet \overset{\mathbf{L}}{\otimes}_V \tau^{\geq a-1}(K^\bullet \overset{\mathbf{L}}{\otimes}_V V/\mathfrak{m}[0])) && \text{(by lemma 7.3.42(ii))} \\ &\xrightarrow{\sim} 0 && \text{(by proposition 14.1.19(i))} \end{aligned}$$

whence (b), after considering the distinguished triangle $\tau^{\geq a-1}$(14.1.33).

(b)⇒(a): We remark

Claim 14.1.34. Condition (b) is equivalent to condition (a”) of remark 14.1.30(iii), with $c := a - 1$.

Proof of the claim. Indeed, (b) holds if and only if $\Psi^l_{[a-1,b]} K^\bullet = 0$ in $\mathsf{D}^{[a-1,b]}(R/\mathfrak{m}R\text{-}\mathbf{Mod})$ (notation of remark 14.1.30(ii)). If the latter condition holds, then clearly (a”) holds with $c := a - 1$. Conversely, if (a”) holds for this value of c, then $\mathrm{Hom}_{\mathsf{D}(R/\mathfrak{m}R\text{-}\mathbf{Mod})}(\Psi^l_{[a-1,b]} K^\bullet, X^\bullet) = 0$ for every $X^\bullet \in \mathsf{D}^{[a-1,b]}(R/\mathfrak{m}R\text{-}\mathbf{Mod})$; especially, the identity automorphism of $\Psi^l_{[a-1,b]} K^\bullet$ factors through 0, so $\Psi^l_{[a-1,b]} K^\bullet$ vanishes. ◊

From claim 14.1.34 and remark 14.1.30(iii) we deduce that if (b) holds, condition (a) of proposition 14.1.27 holds for $c := a - 1$, and condition (b) of the same proposition holds trivially for this value of c, for every $L^\bullet \in \mathsf{D}^{[a;b]}(R\text{-}\mathbf{Mod})$. We conclude that the natural map

$$\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(K^\bullet, L^\bullet) \to \mathrm{Hom}_{\mathsf{D}(R^a\text{-}\mathbf{Mod})}(K^{\bullet a}, L^{\bullet a}) \xrightarrow{\sim} \mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(K^{\bullet a}_{[!]}, L^\bullet)$$

is an isomorphism, for every $L^\bullet \in \mathsf{D}^{[a;b]}(R\text{-}\mathbf{Mod})$, whence (a). □

Proposition 14.1.35. *Let $a, b \in \mathbb{Z}$ be any two integers such that $a \leq b$. For every $L^\bullet \in \mathrm{Ob}(\mathsf{D}^{[a,b]}(R\text{-}\mathbf{Mod}))$, the following conditions are equivalent :*

(a) *$L^\bullet$ lies in the essential image of the right adjoint functor $X^\bullet \mapsto \tau^{\leq b} X^\bullet_{[*]}$.*

(b) $R\mathrm{Hom}^\bullet_R(R/\mathfrak{m}R[0], L^\bullet) \in \mathrm{Ob}(\mathsf{D}^{>b+1}(R/\mathfrak{m}R\text{-}\mathbf{Mod}))$.

Proof. By the same argument as in the proof of claim 14.1.32, we reduce to the case where $V = R$. Next, fix $i \in \mathbb{N}$ such that $i \geq b - a + 2$, define

$$K^\bullet := R\mathrm{Hom}^\bullet_V(\mathfrak{M}^\bullet_i, L^\bullet) \qquad \mathfrak{P}_i := \mathfrak{M}_i \overset{\mathbf{L}}{\otimes}_V V/\mathfrak{m}[0]$$

and notice that

$$\tau^{\geq a-b-1}\mathfrak{P}_i = 0 \qquad \text{in } \mathsf{D}^{[a-b-1,0]}(V/\mathfrak{m}\text{-}\mathbf{Mod}) \tag{14.1.36}$$

due to proposition 14.1.19(i). Moreover, in view of proposition 14.1.21(iii) and lemma 14.1.25, condition (a) is equivalent to :

(c) The morphism $\pi^\bullet_0 \circ \cdots \circ \pi^\bullet_{i-1} : \mathfrak{M}_i \to V[0]$ induces an isomorphism $L^\bullet \xrightarrow{\sim} \tau^{\leq b} K^\bullet$.

(c)⇒(b): We argue as in the proof of proposition 14.1.31; namely, set $H := H^{b+1}K^\bullet$; if (c) holds, we obtain a distinguished triangle

$$H[-b-2] \to L^\bullet \to \tau^{\leq b+1} K^\bullet \to H[-b-1] \tag{14.1.37}$$

and by considering the induced distinguished triangle $\tau^{\leq b+1} R\mathrm{Hom}^\bullet_V(V/\mathfrak{m}[0], (14.1.37))$, we reduce to observing that

$$\begin{aligned}
\tau^{\leq b+1} R\mathrm{Hom}^\bullet_V(V/\mathfrak{m}[0], \tau^{\leq b+1} K^\bullet) &\xrightarrow{\sim} \tau^{\leq b+1} R\mathrm{Hom}^\bullet_V(V/\mathfrak{m}[0], K^\bullet) && \text{(by lemma 7.3.42)} \\
&\xrightarrow{\sim} \tau^{\leq b+1} R\mathrm{Hom}^\bullet_V(\mathfrak{P}^\bullet_i, L^\bullet) && \text{(by [163, Th.10.8.7])} \\
&\xrightarrow{\sim} \tau^{\leq b+1} R\mathrm{Hom}^\bullet_V(\tau^{\geq a-b-1}\mathfrak{P}^\bullet_i, L^\bullet) && \text{(by lemma 7.3.42)} \\
&\xrightarrow{\sim} 0 && \text{(by (14.1.36)).}
\end{aligned}$$

(b)⇒(a): Again, we proceed as in the proof of the corresponding assertion in proposition 14.1.31; namely, arguing as in the proof of claim 14.1.34, we see that condition (b) is equivalent to condition (b”) of remark 14.1.30(iii), with $c := b + 1$. Hence, if (b) holds, condition (b) of proposition 14.1.27 holds for $c := b + 1$, and notice that condition (a) of *loc.cit.* holds trivially for this value of c, for every $K^\bullet \in \mathsf{D}^{[a;b]}(R\text{-}\mathbf{Mod})$. We conclude that the natural map

$$\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(K^\bullet, L^\bullet) \to \mathrm{Hom}_{\mathsf{D}(R^a\text{-}\mathbf{Mod})}(K^{\bullet a}, L^{\bullet a}) \xrightarrow{\sim} \mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(K^\bullet, \tau^{\leq b} L^{\bullet a}_{[*]})$$

is an isomorphism, for every $K^\bullet \in \mathsf{D}^{[a;b]}(R\text{-}\mathbf{Mod})$, whence (a). □

14.1.38. Let A be any V^a-algebra; recall that the localization functor V-Alg $\to V^a$-Alg admits a left adjoint $R \mapsto R_{!!}$, whose restriction to the subcategory of $A_{!!}$-algebras yields a left adjoint for the localization functor $A_{!!}$-Alg $\to A$-Alg ([75, Prop.2.2.29]). In [75], we have studied the deformation theory of A-algebras by means of this left adjoint, under the assumption that $\widetilde{\mathfrak{m}}$ is V-flat; here we wish to show that the same can be repeated in the current setting, if one appeals instead to the results of the foregoing paragraphs. To begin with, we remark :

Proposition 14.1.39. *Let $A \to B$ be a morphism of V^a-algebras, N a $B_{!!}$-module. We have:*

(i) *If the unit of adjunction $N \to N^a_*$ is injective, the natural map*

$$\mathrm{Exal}_{A_{!!}}(B_{!!}, N) \to \mathrm{Exal}_A(B, N^a) \tag{14.1.40}$$

is a bijection (notation of [75, §2.5.7]*).*

(ii) *If $N^a = 0$, then* $\mathrm{Exal}_{A_{!!}}(B_{!!}, N) = 0$.

Proof. (i): Consider any square-zero extension of A-algebras

$$\Sigma \quad : \quad 0 \to N^a \to E \xrightarrow{\varphi} B \to 0.$$

There follows a square-zero extension of $A_{!!}$-algebras

$$\Sigma_{!!} \quad : \quad 0 \to N_!^a/\mathrm{Ker}\,\varphi_{!!} \to E_{!!} \to B_{!!} \to 0$$

Under the stated assumption, the counit of adjunction $N_!^a \to N$ factors uniquely through a B-linear map $g_\varphi : N_!^a/\mathrm{Ker}\,\varphi_{!!} \to N$; then $g_\varphi * \Sigma_{!!}$ (defined as in [75, §2.5.5]) yields an element of $\mathrm{Exal}_{A_{!!}}(B_{!!}, N)$ whose image under (14.1.40) equals the class of Σ. Conversely, if

$$\Omega \quad : \quad 0 \to N \to F \xrightarrow{\psi} B_{!!} \to 0$$

is a square-zero extension of $A_{!!}$-algebras, then by adjunction we get a natural map

$$\Omega^a_{!!} \to \Omega$$

which in turns, by simple inspection, induces an isomorphism $g_{\psi^a} * \Omega^a_{!!} \xrightarrow{\sim} \Omega$ in the category of square-zero $A_{!!}$-algebra extensions of $B_{!!}$ (details left to the reader). The assertion follows.

(ii): Suppose $N^a = 0$, and let Ω be as in the foregoing; it follows that $\psi^a : F^a \to B$ is an isomorphism of A-algebras. By adjunction, the morphism $(\psi^a)^{-1}$ corresponds to a map of $A_{!!}$-algebras $\varphi : B_{!!} \to E$, and it is easily seen that $\psi \circ \varphi$ is the identity automorphism of $B_{!!}$, whence the assertion. □

Definition 14.1.41. Let $f : A \to B$ be a morphism of V^a-algebras. We set

$$\mathbb{L}^a_{B/A} := (\mathbb{L}_{B_{!!}/A_{!!}})^a$$

which is a simplicial complex of B-modules that we call the *almost cotangent complex* of f.

Remark 14.1.42. (i) In case $\widetilde{\mathfrak{m}}$ is a flat V-module, we have introduced in [75, Def.2.5.20] a simplicial $B_{!!}$-module $\mathbb{L}_{B/A}$. Notice that the notation of *loc.cit.* agrees with the current one: indeed, [75, Prop.8.1.7(ii)] shows that complex $(\mathbb{L}_{B/A})^a$ obtained by applying the derived localization functor to $\mathbb{L}_{B/A}$ is naturally isomorphic (in $\mathsf{D}(s.B\text{-}\mathbf{Mod})$) to the complex of definition 14.1.41.

(ii) Depending on the context, we will want to regard $\mathbb{L}_{B/A}$ either as a simplicial object, or as a cochain complex, via the Dold-Kan isomorphism ([163, Th.8.4.1]). The resulting slight notational ambiguity should not be a source of confusion.

Theorem 14.1.43. *In the situation of definition* 14.1.41*, let N be any B-module. Then there are natural isomorphisms*

$$\mathrm{Der}_A(B, N) \xrightarrow{\sim} \mathrm{Ext}^0_B(\mathbb{L}^a_{B/A}, N)$$
$$\mathrm{Exal}_A(B, N) \xrightarrow{\sim} \mathrm{Ext}^1_B(\mathbb{L}^a_{B/A}, N).$$

(Notation of [75, Def.2.5.22(i)]*; so, here we view $\mathbb{L}^a_{B/A}$ as an object of $\mathsf{D}^{\leq 0}(B\text{-}\mathbf{Mod})$.)*

Proof. The first isomorphism follows easily from [103, II.1.2.4.2] and the natural isomorphism

$$\Omega_{B_{!!}/A_{!!}} \xrightarrow{\sim} (\Omega_{B/A})_! \qquad (14.1.44)$$

proved in [75, Lemma 2.5.29] (the proof in *loc.cit.* does not use the assumption that $\widetilde{\mathfrak{m}}$ is V-flat). Clearly we have

(14.1.45) $\quad \mathrm{Hom}_{\mathsf{D}(B_{!!}\text{-}\mathbf{Mod})}(Y[0], N_*[0]) = 0 \qquad$ for every $B_{!!}$-module Y such that $Y^a = 0$.

On the other hand, we have :

Claim 14.1.46. $\mathrm{Hom}_{\mathsf{D}(B_{!!}\text{-}\mathbf{Mod})}(\mathbb{L}_{B_{!!}/A_{!!}}, X^\bullet) = 0$ for every $X^\bullet \in \mathrm{Ob}(\mathsf{D}^{[0,1]}(B_{!!}\text{-}\mathbf{Mod}))$ such that $X^{\bullet a} = 0$.

Proof of the claim. For every $X^\bullet \in \mathrm{Ob}(\mathsf{D}^{[0,1]}(B_{!!}\text{-}\mathbf{Mod}))$ we have a distinguished triangle

$$H^0X^\bullet[0] \to X^\bullet \to H^1X^\bullet[-1] \to (H^0X^\bullet)[1]$$

which reduces to considering the cases where $X^\bullet = M[j]$ for some almost zero $B_{!!}$-module M, and $j = 0, -1$. The case where $j = -1$ follows from [103, III.1.2.3] and proposition 14.1.39(ii). The case where $j = 0$ follows easily from [103, II.1.2.4.2] and (14.1.44) : details left to the reader. ♢

Now, (14.1.45) says that $L^\bullet := N_*[0]$ fulfills condition (b) of proposition 14.1.27, and claim 14.1.46 says that $K^\bullet := \mathbb{L}_{B_{!!}/A_{!!}}$ fulfills condition (a), so the natural map

$$\mathrm{Ext}^1_{B_{!!}}(\mathbb{L}_{B_{!!}/A_{!!}}, N_*) \to \mathrm{Ext}^1_B(\mathbb{L}^a_{B/A}, N)$$

is an isomorphism. Taking into account proposition 14.1.39(i) and [103, III.1.2.3], the theorem follows. □

14.1.47. For the further study the almost cotangent complex, we shall need some preliminaries concerning the derived functors of certain non-additive functors. This material generalizes the results of [75, §8.1], that were obtained under the assumption that $\widetilde{\mathfrak{m}}$ is V-flat.

Lemma 14.1.48. *Let $(V, \mathfrak{m})$ be any basic setup, R a simplicial V-algebra, $n \in \mathbb{N}$ an integer, M and N two R-modules such that $H_iM = H_iN = 0$ for every $i \geq n$. The following holds :*

(i) *If $M^a = 0$ in $\mathsf{D}(R^a\text{-}\mathbf{Mod})$, then $a \cdot \mathbf{1}_M = 0$ in $\mathsf{D}(R\text{-}\mathbf{Mod})$, for every $a \in \mathfrak{m}$.*

(ii) *If $\varphi : M \to N$ is a morphism of R-modules such that φ^a in an isomorphism in $\mathsf{D}(R^a\text{-}\mathbf{Mod})$, then for every $a \in \mathfrak{m}$ we may find a morphism $\psi : N \to M$ in $\mathsf{D}(R\text{-}\mathbf{Mod})$, such that $\psi \circ \varphi = a \cdot \mathbf{1}_M$ and $\varphi \circ \psi = a \cdot \mathbf{1}_N$ in $\mathsf{D}(R\text{-}\mathbf{Mod})$.*

Proof. (i): For every R-module X, set (notation of remark 7.10.31(iii))

$$\tau^{\leq -1}X := \sigma \circ \omega X$$

According to [103, I.3.2.1.9(ii)], there exists a natural sequence of morphisms

$$(14.1.49) \qquad \tau^{\leq -1}X \to X \to s.H_0(X) \to \sigma(\tau^{\leq -1}X) \qquad \text{in } \mathsf{D}(R\text{-}\mathbf{Mod})$$

whose induced sequence of normalized complexes is a distinguished triangle in $\mathsf{D}(V\text{-}\mathbf{Mod})$ (*i.e.* a distinguished triangle of $\mathsf{D}(R\text{-}\mathbf{Mod})$, in the terminology of [103, I.3.2.2.4], and in view of [103, I.3.2.2.5]). Let now n and M be as in the lemma; we argue by induction on n. The case where $n = 0$ is trivial, so suppose that $n > 0$, and that the assertion has already been proven for all almost zero R-modules N such that $H_iN = 0$ for every $i \geq n-1$. Especially, for $N := \tau^{\leq 1}X$ and $P := s.H_0(M)$ we have $a \cdot \mathbf{1}_{\omega N} = 0$ and $a \cdot \mathbf{1}_P = 0$ in $\mathsf{D}(R\text{-}\mathbf{Mod})$, for every $a \in \mathfrak{m}$. Since the adjunction $\sigma \circ \omega N \to N$ is an isomorphism in $\mathsf{D}(R\text{-}\mathbf{Mod})$ ([103, I.3.2.1.10]), we deduce that

$$\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(M, N)^a = 0 = \mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(M, P)^a$$

whence $\mathrm{End}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(M)^a = 0$, by virtue of (14.1.49) (with $X := M$) and [103, I.3.2.2.10]. The assertion follows.

(ii): Set $C := \mathrm{Cone}\,\varphi$; according to [103, I.3.2.2], we have a distinguished triangle

$$(14.1.50) \qquad M \xrightarrow{\varphi} N \to C \to \sigma M \qquad \text{in } \mathsf{D}(R\text{-}\mathbf{Mod})$$

whence – by [103, I.3.2.2.10] – an exact sequence of V-modules

$$\mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(N, M) \xrightarrow{\alpha} \mathrm{End}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(N) \xrightarrow{\beta} \mathrm{Hom}_{\mathsf{D}(R\text{-}\mathbf{Mod})}(N, C).$$

Now, let us write $a = \sum_{i=1}^n a_ib_i$ for some $a_1, b_1, \dots, a_n, b_n \in \mathfrak{m}$; the assumption on φ implies that $C^a = 0$ in $\mathsf{D}(R^a\text{-}\mathbf{Mod})$, therefore (i) yields $\beta(a_i \cdot \mathbf{1}_N) = a_i \cdot \beta(\mathbf{1}_N) = 0$, so there exists a morphism $\psi_i : N \to M$ in $\mathsf{D}(R\text{-}\mathbf{Mod})$ such that $\alpha(\psi_i) = a_i \cdot \mathbf{1}_N$, *i.e.* $\varphi \circ \psi_i = a_i \cdot \mathbf{1}_N$ for every $i = 1, \dots, n$. Likewise, by considering the long exact sequence $\mathbb{E}\mathsf{xt}^\bullet_R((14.1.50), M)$

provided by [103, I.3.2.2.10] we find, for every $i = 1, \dots, n$, a morphism $\psi'_i : N \to M$ such that $\psi'_i \circ \varphi = b_i \cdot \mathbf{1}_M$. Thus,

$$a_i \cdot \psi'_i = \psi'_i \circ \varphi \circ \psi_i = b_i \cdot \psi_i \qquad \text{for every } i = 1, \dots, n$$

and a simple computation shows that $\psi := \sum_{i=1}^n b_i \cdot \psi_i$ will do. □

Remark 14.1.51. Before considering non-additive functors, let us see how to define derived tensor products in $\mathsf{D}(R^a\text{-}\mathbf{Mod})$, for any simplicial V-algebra R. We proceed as in (14.1.13) : for given R^a-modules M, N, set

$$M \overset{\ell}{\otimes}_{R^a} N := (M_! \overset{\ell}{\otimes}_R N_!)^a.$$

(i) We claim that this rule yields a well defined functor

$$- \overset{\ell}{\otimes}_{R^a} - : \mathsf{D}(R^a\text{-}\mathbf{Mod}) \times \mathsf{D}(R^a\text{-}\mathbf{Mod}) \to \mathsf{D}(R^a\text{-}\mathbf{Mod}).$$

Indeed, say that $\varphi : M \to M'$ is a quasi-isomorphism of R^a-modules, and set $C := \mathrm{Cone}(\varphi_!)$. We need to check that $(\varphi_! \overset{\ell}{\otimes}_R N)^a$ is a quasi-isomorphism, for any R-module N; in light of remark 7.10.31(iv), it then suffices to show that $(C \overset{\ell}{\otimes}_R N)^a = 0$; but the latter R^a-module may be computed as

$$(C \otimes_R \perp^R_\bullet N)^a = C^a \otimes_{R^a} (\perp^R_\bullet N)^a$$

whence the claim, since $C^a = 0$ in $R^a\text{-}\mathbf{Mod}$.

(ii) Next, suppose that M is a flat R^a-module; then we claim that the natural morphism of R^a-modules

$$M \overset{\ell}{\otimes}_{R^a} N \to M \otimes_{R^a} N$$

is a quasi-isomorphism, for every R^a-module N. Indeed, by Eilenberg-Zilber's theorem 7.4.50, the assertion comes down to checking that the augmented simplicial R^a-module

$$(M_! \otimes_R \perp^R_\bullet N_!)^a \to M \otimes_{R^a} N$$

is aspherical. But for every $k \in \mathbb{N}$, the k-th column of the latter is isomorphic to the augmented R^a-module

$$M[k] \otimes_{R^a[k]} (\perp^{R[k]}_\bullet N_![k])^a \to M[k] \otimes_{R^a[k]} N[k]$$

which is aspherical, since $M[k]$ is a flat $R^a[k]$-module, whence the assertion.

(iii) Just as in (14.1.13), the foregoing immediately implies yields a natural isomorphism

$$(M \overset{\ell}{\otimes}_R N)^a \xrightarrow{\sim} M^a \overset{\ell}{\otimes}_{R^a} N^a \qquad \text{in } \mathsf{D}(R^a\text{-}\mathbf{Mod})$$

for any two R-modules M and N (details left to the reader).

(iv) Furthermore, we get suspension and loop functors σ and ω for R^a-modules, by the rule :

$$\sigma M := (\sigma M_!)^a \quad \text{and} \quad \omega M := (\omega M_*)^a \qquad \text{for every } R^a\text{-module } M$$

from which it follows that σ is left adjoint to ω. Then, it is clear that the assertions of remark 7.10.31(iii) hold as well for these functors.

(v) Likewise, we define the cone of a morphism $\varphi : M \to N$ of R^a-modules, by the rule

$$\mathrm{Cone}\,\varphi := (\mathrm{Cone}\,\varphi_!)^a$$

and then the assertion of remark 7.10.31(iv) holds also for morphisms of R^a-modules.

(vi) In view of (iv) and (v), it is then easy to check that also lemma 7.10.32 holds *verbatim* for $A := V$, and any two R^a-modules X, Y.

Remark 14.1.52. (i) In the same vein, we may define derived tensor products of R^a-algebras, for any simplicial V-algebra R. Namely, if S and S'' are any two R^a-algebras, we set

$$S \overset{\ell}{\otimes}_{R^a} S' := (S_{!!} \overset{\ell}{\otimes}_R S'_{!!})^a$$

(see (14.1.38)), where $\overset{\ell}{\otimes}_R$ denotes the derived tensor product for R-algebras, defined in example 7.10.25. In view of remarks 7.10.31(ii) and 14.1.51(i), it is easily seen that this rule defines a functor

$$- \overset{\ell}{\otimes}_{R^a} - : \mathsf{D}(R^a\text{-}\mathsf{Alg}) \times \mathsf{D}(R^a\text{-}\mathsf{Alg}) \to \mathsf{D}(R^a\text{-}\mathsf{Alg})$$

and moreover, the formation of these tensor products commutes with the forgetful functor $\mathsf{D}(R^a\text{-}\mathsf{Alg}) \to \mathsf{D}(R^a\text{-}\mathbf{Mod})$.

(ii) Moreover, they are computed by arbitrary flat resolutions : if S (or S') is a flat R^a-algebras, then the natural morphism

$$S \overset{\ell}{\otimes}_{R^a} S' \to S \otimes_{R^a} S'$$

is an isomorphism in $\mathsf{D}(R^a\text{-}\mathsf{Alg})$.

(iii) Furthermore, if $R^a \to S$ is a given morphism of simplicial V^a-algebras, we obtain a well defined functor

$$\mathsf{D}(R^a\text{-}\mathsf{Alg}) \to \mathsf{D}(S\text{-}\mathsf{Alg}) \qquad S' \mapsto S \overset{\ell}{\otimes}_{R^a} S'.$$

Namely, given an R^a-algebra S', we pick a resolution $P \to S'$ with P a flat R^a-algebra, and endow $S \otimes_{R^a} P$ with its natural S-algebra structure, which is independent, up to natural isomorphism, of the choice of P. All the verifications are exercises for the reader.

Definition 14.1.53. Let V be a ring, A a V-algebra, $d \in \mathbb{N}$ and $T : A\text{-}\mathbf{Mod} \to A\text{-}\mathbf{Mod}$ a functor. We say that T is *V-homogeneous of degree d* if we have

$$T(a \cdot \mathbf{1}_M) = a^d \cdot \mathbf{1}_{TM} \qquad \text{for every } A\text{-module } M \text{ and every } a \in V.$$

Remark 14.1.54. Let $(V, \mathfrak{m})$ be a basic setup, A a V-algebra, $d \in \mathbb{N}$, and $T : A\text{-}\mathbf{Mod} \to A\text{-}\mathbf{Mod}$ a V-homogeneous functor of degree d. Suppose that either $d \leq 1$ or else $\mathfrak{m}$ fulfills condition $(\mathbf{B})$ of [75, §2.1.6].

(i) Let also $\varphi : M \to N$ be a homomorphism of A-modules such that $\varphi^a : M^a \to N^a$ is an isomorphism (for the almost structure given by $(V, \mathfrak{m})$); arguing as in the proof of lemma 14.1.48(ii), it is easily seen that, for every $a \in \mathfrak{m}$ there exists a B-linear map $\psi : N \to M$ such that $\varphi \circ \psi = a \cdot \mathbf{1}_N$ and $\psi \circ \varphi = a \cdot \mathbf{1}_M$. Then, the V-homogeneity property of T implies that $(T\varphi)^a$ is an isomorphism as well (details left to the reader).

(ii) Hence, T induces a well defined functor

$$T^a : A^a\text{-}\mathbf{Mod} \to A^a\text{-}\mathbf{Mod} \qquad M^a \mapsto (TM)^a \qquad (\varphi^a : M^a \to N^a) \mapsto (T\varphi)^a.$$

For every cardinality c, let $\mathscr{M}_c(A^a)$ be the set of isomorphism classes of A^a-modules which admit a set of generators of cardinality $\leq c$. We endow $\mathscr{M}_c(A^a)$ with the uniform structure as in [75, Def.2.3.1(i)]. Let ω be an infinite cardinality, such that $\mathfrak{m}$ is generated by at most ω elements; then there exists a cardinality $\omega' \geq \omega$ such that the isomorphism class of $T^a M$ lies in $\mathscr{M}_{\omega'}(A^a)$, for every A^a-module M whose isomorphism class lies in $\mathscr{M}_\omega(A^a)$; thus, T^a induces a map

$$\mathscr{M}_{\omega,\omega'}(T^a) : \mathscr{M}_\omega(A^a) \to \mathscr{M}_{\omega'}(A^a) \qquad N \mapsto T^a N.$$

Lemma 14.1.55. *Let $(V, \mathfrak{m})$ be a basic setup, A a V-algebra, $I, J \subset A$ two ideals, and $\varphi : M' \to M$ a morphism of A^a-modules with $I \cdot \mathrm{Ker}\,\varphi = J \cdot \mathrm{Coker}\,\varphi = 0$. Then there exists an A^a-linear morphism $\lambda : I \otimes_A J \otimes_A M \to M'$ with*

$$\varphi \circ \lambda = \mu_{I,J} \otimes_A \mathbf{1}_M \qquad \textit{and} \qquad \lambda \circ (I \otimes_A J \otimes_A \varphi) = \mu_{I,J} \otimes_A \mathbf{1}_{M'}$$

where $\mu_{I,J} : I \otimes_A J \to A$ is the multiplication law : $a \otimes b \mapsto ab$ for every $a \in I$ and $b \in J$.

Proof. Let $M' \xrightarrow{\overline{\varphi}} M_0 := \mathrm{Im}\,\varphi \xrightarrow{i} M$ be the natural factorization of φ; then for every $a \in I$ and $b \in J$ we have A^a-linear morphisms

$$\psi_a : M_0 \to M' \quad \text{and} \quad \mu_b : M \to M_0 \qquad \text{such that} \qquad \psi_a \circ \overline{\varphi} = a \cdot \mathbf{1}_{M'} \quad \text{and} \quad i \circ \mu_b = b \cdot \mathbf{1}_M.$$

Let us check that $\overline{\varphi} \circ \psi_a = a \cdot \mathbf{1}_{M_0}$; since $\overline{\varphi}$ is an epimorphism, it suffices to show that $\overline{\varphi} \circ \psi_a \circ \overline{\varphi} = (a \cdot \mathbf{1}_{M_0}) \circ \overline{\varphi}$, which is clear. Likewise, let us check that $\mu_b \circ i = b \cdot \mathbf{1}_{M_0}$; since i is a monomorphism, it suffices to show that $i \circ \mu_b \circ i = i \circ b \cdot \mathbf{1}_{M_0}$, which is clear. For every $a \in I$ and $b \in J$ set $\lambda_{a,b} := \psi_a \circ \mu_b : M \to M'$; we deduce that

$$\varphi \circ \lambda_{a,b} = i \circ \overline{\varphi} \circ \psi_a \circ \mu_b = i \circ (a \cdot \mathbf{1}_{M_0}) \circ \mu_b = i \circ \mu_b \circ (a \cdot \mathbf{1}_M) = ab \cdot \mathbf{1}_M$$

and a similar computation yields : $\lambda_{a,b} \circ \varphi = ab \cdot \mathbf{1}_{M'}$. Thus, we obtain a map

$$I \times J \times M \to M' \qquad (a, b, x) \mapsto \lambda_{a,b}(x).$$

A simple inspection shows that this map is A-trilinear, hence it factors uniquely through an A-linear map $\lambda : I \otimes_A J \otimes_A M \to M'$, and the foregoing easily implies that λ fulfills the required identities. □

Proposition 14.1.56. *In the situation of remark* 14.1.54 *the following holds :*

(i) *If T commutes with filtered colimits, and for every free A-module L of finite rank, $(TL)^a$ is a flat A^a-module (resp. is the zero A^a-module), then for every flat A^a-module M, the A^a-module $T^a M$ is flat (resp. is the zero A^a-module).*

(ii) *If for every free A-module L of finite rank (resp. for every free A-module L), $(TL)^a$ is an almost projective A^a-module, then for every almost projective and almost finitely generated A^a-module M (resp. for every almost projective A^a-module M), the A^a-module $T^a M$ is almost projective.*

(iii) *The map $\mathscr{M}_{\omega,\omega'}(T^a)$ of remark* 14.1.54(ii) *is uniformly continuous.*

Proof. (i): Say that $M = N^a$ for an A-module N, and let $\mathscr{F}$ be the category whose objects are the pairs (C, φ), where C is a finitely presented A-module and $\varphi : C \to N$ is an A-linear map; the morphisms $\psi : (C, \varphi) \to (C', \varphi')$ in $\mathscr{F}$ are the A-linear maps $\psi : C \to C'$ such that $\varphi' \circ \psi = \varphi$, with the obvious composition law. We have a functor

$$F : \mathscr{F} \to A\text{-}\mathbf{Mod} \qquad (C, \varphi) \mapsto C \qquad ((C, \varphi) \xrightarrow{\psi} (C', \varphi')) \mapsto (C \xrightarrow{\psi} C')$$

as well as a natural co-cone $\beta : F \Rightarrow c_N$ given by the rule : $(C, \varphi) \mapsto \varphi$. It is easily seen that $\mathscr{F}$ is filtered, and β is a universal co-cone : the details are left to the reader. Since T commutes with filtered colimits, TN is isomorphic to the colimit of the functor $T \circ F : \mathscr{F} \to A\text{-}\mathbf{Mod}$, and $T * \beta : T \circ F \Rightarrow c_{TN}$ is again a universal co-cone. We need to show that $\mathfrak{m}\mathrm{Tor}_1^A(TN, X) = 0$ for every A-module X (resp. that $\mathfrak{m}TN = 0$), and by the foregoing it then suffices to check that for every $(C, \varphi) \in \mathrm{Ob}(\mathscr{F})$, the induced map

$$\lambda := \mathrm{Tor}_1^A(T\varphi, X) : \mathrm{Tor}_1^A(TC, X) \to \mathrm{Tor}_1^A(TN, X)$$

is almost zero (resp. that $T\varphi$ is almost zero). However, since N^a is a flat A^a-module, [75, Lemma 2.4.17] implies that for every $a \in \mathfrak{m}$ there exists a free A-module L of finite rank and A-linear maps $\varphi' : C \to L$, $\varphi'' : L \to M$ with $a \cdot \varphi = \varphi'' \circ \varphi'$. Hence $a^d \cdot T\varphi = T(\varphi'') \circ T(\varphi'')$, and therefore $a^d \cdot \lambda^a = 0$, since by assumption $(TL)^a$ is a flat A^a-module (resp. and therefore $a^d \cdot (T\varphi)^a = 0$, since $(TL)^a = 0$); the contention follows, since we have either $d \leq 1$, or else $\mathfrak{m}$ fulfills condition $(\mathbf{B})$.

(ii): Suppose first that for every free A-module L of finite rank, $(TL)^a$ is almost projective, and let M be an almost projective and almost finitely generated A-module. According to [75, 2.4.15], for every $a \in \mathfrak{m}$ there exists a free A-module L of finite rank and A^a-linear morphisms $\varphi' : M \to L^a$, $\varphi'' : L^a \to M$ such that $a \cdot \mathbf{1}_M = \varphi'' \circ \varphi'$. We deduce that

$$a^d \cdot \mathrm{Ext}^1_A(\mathbf{1}_{TM}, X)^a = \mathrm{Ext}^1_A(T\varphi', X)^a \circ \mathrm{Ext}^1_A(T\varphi'', X)^a = 0$$

for every A-module X, since $\mathrm{Ext}^1_A(TL, X)^a = 0$ by assumption (and by [75, Rem.2.4.12(i)]). The contention follows, again because either $d \leq 1$ or else $\mathfrak{m}$ fulfills condition $(\mathbf{B})$. One argues similarly in case M is almost projective and $(TL)^a$ is almost projective for every free A-module L : the details shall be left to the reader.

(iii): Let $\mathfrak{m}_0 \subset \mathfrak{m}$ be a subideal of finite type, and $\varphi : M' \to M$ a morphism of A^a-module with $\mathfrak{m}_0 \mathrm{Ker}\,\varphi = \mathfrak{m}_0 \mathrm{Coker}\,\varphi = 0$. Denote by $\mathfrak{m}_0^{(2d)} \subset \mathfrak{m}_0$ the subideal generated by the system $(a^d \mid a \in \mathfrak{m}_0^2)$. By lemma 14.1.55, for every $a \in \mathfrak{m}_0^2$ there exists a morphism $\lambda : M \to M'$ of A^a-modules with $\varphi \circ \lambda = a \cdot \mathbf{1}_M$ and $\lambda \circ \varphi = a \cdot \mathbf{1}_{M'}$; therefore

$$T^a(\varphi) \circ T^a(\lambda) = a^d \cdot \mathbf{1}_{T^aM} \qquad \text{and} \qquad T^a(\lambda_a) \circ T^a(\varphi) = a^d \cdot \mathbf{1}_{T^aM'}$$

which implies that $\mathfrak{m}_0^{(2d)} \cdot \mathrm{Ker}\,T^a(\varphi) = \mathfrak{m}_0^{(2d)} \cdot \mathrm{Coker}\,T^a(\varphi) = 0$, whence the assertion, since we either have $d \leq 1$ or $\mathfrak{m}$ fulfills condition $(\mathbf{B})$. ☐

Example 14.1.57. Let $(V, \mathfrak{m})$ be a basic setup such that $\mathfrak{m}$ satisfies condition $(\mathbf{B})$; let A be a V-algebra, and P any A-module. According to [37, §9, n.3], for every integer $n > 0$ we have a complex of A-modules

$$\Sigma^\bullet_A(P) \qquad : \qquad 0 \to \Lambda^n_A P \to \cdots \to (\Lambda^j_A P) \otimes_A (\mathrm{Sym}^{n-j}_A P) \to \cdots \to \mathrm{Sym}^n_A P \to 0$$

which is functorial for morphisms of A-modules, and is acyclic if P is a flat A-module ([37, §9, n.3, Prop.3]). Clearly, for every $j \in \mathbb{N}$ the functor

$$T^j : A\text{-}\mathbf{Mod} \to A\text{-}\mathbf{Mod} \qquad P \mapsto H^j(\Sigma^\bullet_A(P))$$

fulfills the conditions of (14.1.58) (with $d := n$) and $T^jP = 0$ if P is a flat A-module. By proposition 14.1.56(i), we deduce that the induced complex of A^a-modules $\Sigma^\bullet_A(P)^a$ is acyclic, if P^a is a flat A^a-module. With this observation, all the results of [75, §4.3, §4.4] extend now *verbatim* to the case where $\mathfrak{m}$ fulfills condition $(\mathbf{B})$ (whereas the proofs in *loc.cit.* used the stronger condition that $\mathfrak{m}$ is a flat V-module : the details shall be left to the reader).

14.1.58. Let $\pi : V\text{-}\mathsf{Alg.Mod} \to V\text{-}\mathsf{Alg}$ be the functor such that $\pi(A, M) := A$ and $\pi(f, \varphi) := f$ for every object (A, M) and every morphism (f, φ) of V-$\mathsf{Alg.Mod}$. We consider a functor

$$T : V\text{-}\mathsf{Alg.Mod} \to V\text{-}\mathsf{Alg.Mod} \qquad \text{such that } \pi \circ T = \pi.$$

Let also be R a simplicial V-algebra, $d \in \mathbb{N}$ and suppose that :

- T is *V-homogeneous of degree d, i.e.* for every V-algebra A, the restriction of T

$$T_A : A\text{-}\mathbf{Mod} \to A\text{-}\mathbf{Mod}$$

  is V-homogeneous of degree d.
- T_A commutes with filtered colimits (cp. (7.10.26)) for every V-algebra A.
- Either $d \leq 1$ or else the ideal $\mathfrak{m} \cdot H_0(R)$ of $H_0(R)$ satisfies condition $(\mathbf{B})$ of [75, §2.1.6].

Remark 14.1.59. (i) As detailed in (7.10.26), the functor T induces a functor

$$T_R : R\text{-}\mathbf{Mod} \to R\text{-}\mathbf{Mod} \qquad (M[n] \mid n \in \mathbb{N}) \mapsto (T_{R[n]}M[n] \mid n \in \mathbb{N}).$$

(ii) Let T and T' be two functors as in (14.1.58), V-homogeneous of degrees respectively d and d'; then we get the functor V-homogeneous of degree $d + d'$

$$T \otimes T' : V\text{-}\mathsf{Alg.Mod} \to V\text{-}\mathsf{Alg.Mod} \qquad (A, M) \mapsto (A, T_AM \otimes_A T'_AM)$$

and it is easily seen that $(T \otimes T')_A$ commutes with filtered colimits, for every V-algebra A.

(iii) Likewise, if $f : T \to T'$ is a natural transformation of functors fulfilling the conditions of (14.1.58), for the same degree d; then the same holds for the functors $\mathrm{Ker}\, f$ and $\mathrm{Coker}\, f$.

(iv) In the situation of (14.1.58), let $f : H_0(R) \to B$ be any morphism of V-algebras. If condition $(\mathbf{B})$ holds for $\mathfrak{m} \cdot H_0(R)$, it holds also also for $\mathfrak{m}B$; then remark 14.1.54(ii) implies that T_B induces a functor $T_{B^a} := T_B^a : B^a\text{-}\mathbf{Mod} \to B^a\text{-}\mathbf{Mod}$. Especially, the above holds with $B := R[p]$, for any $p \in \mathbb{N}$, and f the natural map given by the degeneracies of the simplicial V-algebra R. It is then clear that T_R induces a well defined functor

$$T_{R^a} : R^a\text{-}\mathbf{Mod} \to R^a\text{-}\mathbf{Mod}.$$

The following result shows that, in this situation, the construction of left derived functors descends likewise to R^a-modules.

Theorem 14.1.60. *In the situation of* (14.1.58)*, the following holds :*

(i) *Let $\varphi : M \to N$ be a morphism of R-modules, and $n \in \mathbb{N}$ an integer such that $H_i(\varphi)^a : (H_iM)^a \to (H_iN)^a$ is an isomorphism of V^a-modules, for every $i \leq n$. Then*

$$H_i(LT\varphi)^a : H_i(LTM)^a \to H_i(LTN)^a$$

is an isomorphism of V^a-modules, for every $i \leq n$.

(ii) *Especially, the functor T_R induces a well defined left derived functor*

$$LT_{R^a} : \mathsf{D}(R^a\text{-}\mathbf{Mod}) \to \mathsf{D}(R^a\text{-}\mathbf{Mod}).$$

Proof. Clearly (ii) follows from (i).

(i): In light of corollary 7.10.34(i), we may replace M and N by respectively $\mathrm{cosk}_n M$ and $\mathrm{cosk}_n N$, after which, we may assume that $H_iM = H_iN = 0$ for every $i > n$, so φ^a is an isomorphism in $\mathsf{D}(R^a\text{-}\mathbf{Mod})$. Next, by proposition 7.10.28, we may replace M and N by their respective standard free resolutions, in which case we are reduced to checking that the induced map $(T_R\varphi)^a$ is an isomorphism in $\mathsf{D}(R^a\text{-}\mathbf{Mod})$. Since T is homogeneous and $(\mathbf{B})$ holds for $\mathfrak{m} \cdot H_0(R)$, the latter assertion follows straightforwardly from lemma 14.1.48(ii). ☐

14.1.61. Next, we wish to decide how much of the foregoing theory can be salvaged, when we drop condition $(\mathbf{B})$. We will concentrate on the functors that are relevant to the later study of the cotangent complex. Thus, henceforth, for every integer $d \in \mathbb{N}$, we shall denote by T^d one of the three standard functors

$$\mathrm{Sym}^d, \Lambda^d, \Gamma^d : V\text{-}\mathsf{Alg.Mod} \to V\text{-}\mathsf{Alg.Mod}$$

(namely, the symmetric and exterior d-th power functors, and the d-th divided power functor). Notice that the functor T^d fulfills the conditions of (14.1.58), for every $d \in \mathbb{N}$. Moreover, in all three cases we have natural identifications :

$$T^1 \xrightarrow{\sim} \mathbf{1}_{V\text{-}\mathsf{Alg.Mod}}. \tag{14.1.62}$$

In general, we can no longer expect that T^d descends to almost modules; indeed, consider the following :

Example 14.1.63. Let $(V, \mathfrak{m})$ be as in (14.1.61), and $p \in \mathbb{N}$ any prime integer. The Frobenius map $\Phi_R : R/pR \to R/pR$ for V-algebras R, can be seen as a homogeneous polynomial law of degree p on the V-module V/pV. Denote by $\mathfrak{m}^{(p)} \subset V$ the ideal generated by $(x^p \mid x \in \mathfrak{m})$. Clearly Φ descends to a polynomial law

$$\overline{\Phi} : V/(pV + \mathfrak{m}) \to W_p := V/(pV + \mathfrak{m}^{(p)})$$

which is still homogeneous of degree p, so it factors through a unique V-linear map

$$\Gamma^p_A(V/(pV + \mathfrak{m})) \to W_p.$$

The latter is surjective, since its image contains the class of the unit element of V. Now, the proof of [75, Prop.2.1.7(ii)] shows that – if $(\mathbf{B})$ does not hold for $\mathfrak{m}$ – there exists some prime p such that $pV + \mathfrak{m}^{(p)}$ does not contain $\mathfrak{m}$, therefore $W_p^a \neq 0$. This shows that the functor

$$V\text{-}\mathbf{Mod} \to V^a\text{-}\mathbf{Mod} \qquad M \mapsto (\Gamma_A^p M)^a$$

does not factor through V^a-$\mathbf{Mod}$.

However, we will see that example 14.1.63 is, in a sense, the worst that can happen.

Lemma 14.1.64. *In the situation of* (14.1.61)*, we have :*

(i) *There are natural transformations*

$$T^{i+j} \to T^i \otimes T^j \to T^{i+j} \qquad \textit{for every } i, j \in \mathbb{N}$$

whose composition equals $\binom{i+j}{i} \cdot \mathbf{1}_{T^{i+j}}$. *(Notation of remark* 14.1.59(ii).*)*

(ii) *For every simplicial V-algebra R, the maps of* (i) *induce natural transformations*

$$LT_R^{i+j} \to LT_R^i \overset{\ell}{\otimes}_R LT_R^j \to LT_R^{i+j} \qquad \textit{for every } i, j \in \mathbb{N}$$

whose composition equals $\binom{i+j}{i} \cdot \mathbf{1}_{LT_R^{i+j}}$.

Proof. (i): For $T = \Lambda$, the sought morphism $\Lambda^{i+j} \to \Lambda^i \otimes \Lambda^j$ is the one denoted $\Delta_{i,j}$ in [75, §4.3.20], and the morphism $\Lambda^i \otimes \Lambda^j \to \Lambda^{i+j}$ is given by the rule : $x \otimes y \mapsto x \wedge y$, for every $(A, M) \in \mathrm{Ob}(V\text{-}\mathsf{Alg.Mod})$, every $x \in \Lambda_A^i M$ and every $y \in \Lambda_A^j M$. The sought identity follows easily from the explicit formula given in [75, (4.3.21)] : details left to the reader.

For $T = \mathrm{Sym}$, the natural transformation $\mathrm{Sym}^{i+j} \to \mathrm{Sym}^i \otimes \mathrm{Sym}^j$ is given by a similar formula; namely, for every object (A, M) of V-$\mathsf{Alg.Mod}$, every sequence of elements $x_1, \dots, x_{i+j} \in M$, and every subset $I \subset \{1, \dots, i+j\}$, set $x_I := \prod_{k \in I} x_k \in \mathrm{Sym}_A^k M$ (where the multiplication is formed in the graded ring $\mathrm{Sym}_A^\bullet M$); one checks easily that the rule

$$x_1 \cdots x_{i+j} \mapsto \sum_{I,J} x_I \otimes x_J$$

defines a well defined A-linear map on $\mathrm{Sym}_A^{i+j} M$ (where the sum ranges over all the partitions (I, J) of $\{1, \dots, i+j\}$ such that the cardinality of I equals i). Then one defines a map $\mathrm{Sym}_A^i M \otimes_A \mathrm{Sym}_A^j M \to \mathrm{Sym}_A^{i+j} M$ by the rule : $u \otimes v \mapsto u \cdot v$ for every $u \in \mathrm{Sym}_A^i M$ and $v \in \mathrm{Sym}_A^j M$. Again, the sought identity is verified by direct computation.

If $T = \Gamma$, then for every object (A, M) of V-$\mathsf{Alg.Mod}$ we define a homogeneous polynomial law $M \rightsquigarrow \Gamma_A^i M \otimes_A \Gamma_A^j M$ of degree $i + j$, by the rule : $x \mapsto x^{[i]} \otimes x^{[j]}$ for every A-algebra B, and every $x \in B \otimes_A M$. This law yields a transformation $\Gamma^{i+j} \to \Gamma^i \otimes \Gamma^j$ as sought. Next, the multiplication of the graded ring functor $\Gamma^\bullet$ gives a transformation $\Gamma^i \otimes \Gamma^j \to \Gamma^{i+j}$. The composition of these two transformations is characterized as the unique transformation ψ of Γ^{i+j} such that $\psi_{(A,M)}(x^{[i+j]}) = x^{[i]} \cdot x^{[j]}$ for every object (A, M) of V-$\mathsf{Alg.Mod}$, and every $x \in M$. Then, by corollary 9.5.56 we must have $\psi_{(A,M)} = \binom{i+j}{i} \mathbf{1}_M$, as required.

(ii): Recall that the three functors Λ, Γ and Sym transform free A-modules into free A-modules, for every V-algebra A. Therefore, the sought natural transformation is none else than the map

$$T_R^{i+j}(\perp_\bullet^R M) \to T_R^i(\perp_\bullet^R M) \otimes_R T_R^j(\perp_\bullet^R M) \to T_R^{i+j}(\perp_\bullet^R M)$$

given by (i), for any R-module M. □

Proposition 14.1.65. *In the situation of* (14.1.61)*, let $p \in \mathbb{N}$ be a prime integer, R a simplicial $V \otimes_{\mathbb{Z}} \mathbb{Z}_{(p)}$-algebra, M an R-module such that $M^a = 0$ in* $\mathsf{D}(R^a\text{-}\mathbf{Mod})$. *Then*

$$(LT_R^d M)^a = 0 \qquad \textit{in } \mathsf{D}(R^a\text{-}\mathbf{Mod}), \textit{for every } d \in \mathbb{N} \textit{ such that } (p, d) = 1.$$

Proof. In light of corollary 7.10.34(i), we may replace M by $\mathrm{cosk}_i M$, in which case lemma 14.1.48(i) implies that $a \cdot \mathbf{1}_M = 0$ for every $a \in \mathfrak{m}$. Now, we apply lemma 14.1.64(ii) with $i = 1$ and $j = d-1$ (notice that $j \geq 0$, since $d > 0$); in view of (14.1.62), there result natural transformations

$$LT^d_R M \to M \otimes_R LT^{d-1}_R M \to LT^d_R M$$

whose composition is $d \cdot \mathbf{1}_{LT^d_R M}$. Since the image of d is invertible in R, it follows easily that $a \cdot \mathbf{1}_{LT^d_R M} = 0$ for every $a \in \mathfrak{m}$, whence the assertion. □

Theorem 14.1.66. *Let $d, n, p \in \mathbb{N}$ be any three integers, with $d > 0$ and p a prime. Let also R be a simplicial $V \otimes_{\mathbb{Z}} \mathbb{Z}_{(p)}$-algebra, M an R-module, and suppose that*

(a) $H_i M = 0$ *for every $i < n$.*
(b) $M^a = 0$ *in* $\mathsf{D}(R^a\text{-}\mathbf{Mod})$.

Then we have :

(i) $H_i(L\Gamma^d_R M)^a = 0$ *for every $i < n$.*
(ii) $H_i(L\Lambda^d_R M)^a = 0$ *for every $i < n + p - 1$.*
(iii) $H_i(L\mathrm{Sym}^d_R M)^a = 0$ *for every $i < n + 2(p-1)$.*

Proof. (i) is just a special case of corollary 7.10.34(ii), and for $d < p$, assertions (ii) and (iii) follow from the more general proposition 14.1.65, hence we may assume that $d \geq p$. For every $j = 0, \dots, d$, set

$$F^j := \Gamma^j \otimes \Lambda^{d-j} \qquad G^j := \Lambda^j \otimes \mathrm{Sym}^{d-j}.$$

By remark 14.1.59(ii), these functors are homogeneous of degree d, and fulfill the conditions of (14.1.58). Moreover, since Γ, Λ and Sym transform free modules into free modules, we have natural isomorphisms of functors :

$$(14.1.67) \quad LF^j_R \xrightarrow{\sim} L\Gamma^j_R \overset{\ell}{\otimes}_R L\Lambda^{d-j}_R \quad LG^j_R \xrightarrow{\sim} L\Lambda^j_R \overset{\ell}{\otimes}_R L\mathrm{Sym}^{d-j}_R \qquad \text{for every } j = 0, \dots, d$$

(details left to the reader).

(ii): According to [103, I.4.3.1.7], there is a natural complex of functors :

$$(14.1.68) \qquad 0 \to F^d_R \xrightarrow{\partial_{d-1}} F^{d-1}_R \to \cdots \to F^1_R \xrightarrow{\partial_0} F^0_R \to 0$$

which is exact on flat R-modules. Set $Z_p := \mathrm{Ker}\,\partial_{p-1}$; due to remark 14.1.59(iii) we may consider the derived functor LZ_p, and from corollary 7.10.34(ii) and assumption (a), we get

$$(14.1.69) \qquad H_i(LZ_p M) = 0 \qquad \text{for every } i < n.$$

The evaluation of (14.1.68) on $(\perp^R_\bullet M)^\Delta$ gives an exact sequence of R-modules :

$$0 \to LZ_p M \to LF^{p-1}_R M \to \cdots \to LF^1_R M \to LF^0_R M \to 0.$$

Notice as well, that

$$(14.1.70) \qquad (LF^j_R M)^a = 0 \qquad \text{in } \mathsf{D}(R^a\text{-}\mathbf{Mod}) \text{ for } j = 1, \dots, p-1$$

in view of (14.1.67), remark 14.1.51(iii), and proposition 14.1.65. The assertion now follows from (14.1.69) and claim 7.10.50.

(iii): According to [103, I.4.3.1.7], there is a natural complex of functors :

$$\Sigma \quad : \quad 0 \to G^d_R \xrightarrow{\partial_{d-1}} G^{d-1}_R \to \cdots \to G^1_R \xrightarrow{\partial_0} G^0_R \to 0.$$

Set $Z'_p := \mathrm{Ker}\,\partial_{p-1}$; due to remark 14.1.59(iii) we may consider the derived functor LZ'_p, and since Σ is exact on flat R-modules, we obtain two exact sequences of R-modules :

$$\Sigma' \quad : \quad 0 \to LG^d_R M \to LG^{d-1}_R M \to \cdots \to LG^p_R M \to LZ'_p M \to 0$$
$$\Sigma'' \quad : \quad 0 \to LZ'_p M \to LG^{p-1}_R M \to \cdots \to LG^1_R M \to LG^0_R M \to 0.$$

On the one hand, in light of (ii), remark 14.1.51(iii,vi) and (14.1.67), we see that

$$\mathrm{cosk}_{n+p-1}(LG^j_R M)^a = 0 \qquad \text{in } \mathsf{D}(R^a\text{-}\mathbf{Mod}) \text{ for every } j = 1, \dots, d.$$

By applying claim 7.10.50 to the exact sequence $\mathrm{cosk}_{n+p-1}\Sigma'^a$, we deduce that $H_i(LZ'_p M)^a = 0$ for every $i < n+p-1$. On the other hand, (14.1.67) and proposition 14.1.65 imply that

$$(LG^j_R M)^a = 0 \qquad \text{in } \mathsf{D}(R^a\text{-}\mathbf{Mod}) \text{ for } j = 1, \dots, p-1$$

so the assertion follows, after applying claim 7.10.50 to the exact sequence Σ''. □

14.1.71. Let now $\varphi : R \to S$ be any morphism of simplicial V^a-algebras; pick any resolution $\rho : P \to S$ with P a flat R-algebra, and consider the composition

$$S \otimes_R P \xrightarrow{S \otimes_R \rho} S \otimes_R S \xrightarrow{\mu_S} S \tag{14.1.72}$$

where μ_S is the multiplication law of S. Then (14.1.72) represents a morphism

$$\Delta(\varphi) : S \overset{\ell}{\otimes}_R S \to S \qquad \text{in } \mathsf{D}(R\text{-}\mathsf{Alg})$$

which is independent (up to unique isomorphism) of the choice of P. Notice that if φ is an isomorphism in $\mathsf{D}(s.V^a\text{-}\mathsf{Alg})$, then the same holds for $\varphi \overset{\ell}{\otimes}_R \varphi : R \to S \overset{\ell}{\otimes}_R S$; also, we have

$$\varphi = \Delta(\varphi) \circ (\varphi \overset{\ell}{\otimes}_R \varphi) \qquad \text{in } \mathsf{D}(s.V^a\text{-}\mathsf{Alg}).$$

More generally, set $C := \mathrm{Cone}\,\varphi$; then, by considering the section $S \overset{\ell}{\otimes}_R \varphi$ of $\Delta(\varphi)$, we get a natural decomposition

$$S \overset{\ell}{\otimes}_R S \xrightarrow{\sim} S \oplus (S \overset{\ell}{\otimes}_R C) \qquad \text{in } \mathsf{D}(R\text{-}\mathbf{Mod})$$

which identifies $\Delta(\varphi)$ with the natural projection, whence a natural isomorphism

$$\mathrm{Cone}\,\Delta(\varphi) \xrightarrow{\sim} \sigma S \overset{\ell}{\otimes}_R C. \tag{14.1.73}$$

Thus, say that $C = \sigma^k C'$ in $\mathsf{D}(R\text{-}\mathbf{Mod})$, for some R-module C' with $H_0 C' \neq 0$; there follows a distinguished triangle in $\mathsf{D}(R\text{-}\mathbf{Mod})$

$$\sigma^k C' \to \sigma^k S \overset{\ell}{\otimes}_R C' \to \sigma^{2k} C' \overset{\ell}{\otimes}_R C' \to \sigma^{k+1} C'.$$

Especially, if $k \geq 2$, then $H_k C = H_k(S \overset{\ell}{\otimes}_R C)$, and we see that, in this case, $\mathrm{Cone}\,\Delta(\varphi) = \sigma^{k+1} C''$ in $\mathsf{D}(R\text{-}\mathbf{Mod})$, for some C'' such that $H_0 C'' \neq 0$. However, it is clear from (14.1.73) that $\mathrm{Cone}\,\Delta^2(\varphi) = \sigma^2 C''$ for some object C'' of $\mathsf{D}(R\text{-}\mathbf{Mod})$. We conclude that if $\Delta^n(\varphi)$ is an isomorphism in $\mathsf{D}(R\text{-}\mathbf{Mod})$ for some $n \geq 2$, then the same holds already for $\Delta^2(\varphi)$.

Definition 14.1.74. In the situation of (14.1.71), we say that φ is a *weakly étale morphism*, if $\Delta^2(\varphi)$ is an isomorphism in $\mathsf{D}(R\text{-}\mathsf{Alg})$.

14.1.75. Let $\varphi : R' \to R$ be any morphism of simplicial V^a-algebras, and S, T two R-algebras. Since the standard resolution $F_R(S) := F_{R_{!!}}(S_{!!})^a$ of example 7.10.25 is clearly functorial in both R and S, we have a natural map

$$F_{R'}(S)^\Delta \to F_R(S)^\Delta$$

of simplicial R'-algebras, whence a natural morphism

$$S \overset{\ell}{\otimes}_{R'} T \to F_R(S)^\Delta \otimes_{R'} T \to S \overset{\ell}{\otimes}_R T. \tag{14.1.76}$$

Lemma 14.1.77. *In the situation of* (14.1.75)*, suppose that φ is a quasi-isomorphism. Then the same holds for* (14.1.76)*.*

Proof. Let $\psi : F_{R'}(S)^\Delta \otimes_{R'} R \to F_R(S)^\Delta$ be the natural morphism; by construction, (14.1.76) factors as the composition of $\psi \otimes_R \mathbf{1}_T$ and the natural isomorphism

$$F_{R'}(S)^\Delta \otimes_{R'} T \xrightarrow{\sim} (F_{R'}(S)^\Delta \otimes_{R'} R) \otimes_R T.$$

Since both $F_{R'}(S)^\Delta \otimes_{R'} R$ and $F_R(S)^\Delta$ are flat R-algebras, remark 14.1.52(ii) then reduces to checking that ψ is a quasi-isomorphism. Since the natural maps $\beta : F_R(S)^\Delta \to S$ and $\alpha : F_{R'}(S)^\Delta \to F_{R'}(\Delta) \otimes_{R'} R$ are quasi-isomorphisms, it suffices to show that the composition $\beta \circ \psi \circ \alpha$ is a quasi-isomorphism. But the latter is none else than the standard resolution $F_{R'}(S) \to S$, whence the lemma. □

Proposition 14.1.78. *Let $\varphi : R \to S$ and $\varphi' : R' \to S'$ be two morphisms of simplicial V-algebras, and suppose we have a commutative diagram in $\mathsf{D}(R\text{-}\mathsf{Alg})$*

(14.1.79)
$$\begin{array}{ccc} R & \xrightarrow{\varphi} & S \\ {\scriptstyle\psi}\downarrow & & \downarrow{\scriptstyle\psi'} \\ R' & \xrightarrow{\varphi'} & S' \end{array}$$

where ψ and ψ' are isomorphisms (in $\mathsf{D}(R\text{-}\mathsf{Alg})$). Then φ^a is weakly étale if and only if the same holds for φ'^a.

Proof. Denote by $\mathsf{Hot}(V\text{-}\mathsf{Alg})$ the homotopy category of simplicial V-algebras, and recall that the multiplicative system of quasi-isomorphisms in $\mathsf{Hot}(V\text{-}\mathsf{Alg})$ admits a right calculus of fractions ([103, I.3.1.8(ii)]). We begin with the following special case :

Claim 14.1.80. Suppose that ψ and ψ' are also morphisms of simplicial V-algebras, and that (14.1.79) commutes in the category $\mathsf{Hot}(V\text{-}\mathsf{Alg})$. Then the proposition holds.

Proof of the claim. Indeed, in this situation it follows easily from lemma 14.1.77 that φ^a (resp. φ'^a) is weakly étale if and only if the same holds for $\psi'^a \circ \varphi^a$ (resp. for $\varphi'^a \circ \psi^a$), so we are reduced to the case where $R = R'$, $S = S'$, and $\varphi, \varphi' : R \to S$ are two homotopic morphisms of simplicial V-algebras. In this case, there exist morphisms of simplicial V-algebras $\varphi'' : R \to S''$ and $d_0, d_1 : S'' \to S$, such that d_0 and d_1 are quasi-isomorphisms, and $\varphi = d_0 \circ \varphi''$, $\varphi' = d_1 \circ \varphi''$ (see [103, I.2.3.2]). Then the claim follows by applying repeatedly lemma 14.1.77. ◊

Next, there exist a simplicial V-algebra S'' and morphisms $\beta : S'' \to S$ and $\gamma : S'' \to S'$ of simplicial V-algebras, such that both β and γ are quasi-isomorphisms, and $\psi' = \gamma \circ \beta^{-1}$ in $\mathsf{D}(s.V\text{-}\mathsf{Alg})$. Moreover, there exist morphisms $\varphi'' : R'' \to S''$ and $\psi'' : R'' \to R$ such that ψ'' is a quasi-isomorphism, and the resulting diagram

$$\begin{array}{ccc} R'' & \xrightarrow{\varphi''} & S'' \\ {\scriptstyle\psi''}\downarrow & & \downarrow{\scriptstyle\beta} \\ R & \xrightarrow{\varphi} & S \end{array}$$

commutes in $\mathsf{Hot}(V\text{-}\mathsf{Alg})$. By claim 14.1.80, we may then replace φ by φ'' and ψ' by β, after which we may assume that ψ' is a morphism of simplicial V-algebras.

Likewise, we may find morphisms $\beta' : R'' \to R$ and $\gamma' : R'' \to R'$ of simplicial V-algebras that are quasi-isomorphisms, and such that $\psi = \gamma' \circ \beta'^{-1}$ in $\mathsf{D}(s.V\text{-}\mathsf{Alg})$; again by lemma 14.1.77, we see that φ^a is weakly étale if and only if the same holds for $\varphi^a \circ \beta^a$, so we may replace φ by $\varphi \circ \beta$, ψ by $\psi \circ \gamma$, and assume from start that also ψ is a map of simplicial V-algebras.

In this situation, by applying once again lemma 14.1.77 we see that φ^a (resp. φ'^a) is weakly étale if and only if the same holds for $\psi'^a \circ \varphi^a$ (resp. for $\varphi'^a \circ \psi^a$). Therefore, we may assume from start that $R = R'$, $S = S'$, and $\varphi, \varphi' : R \to S$ are two maps of simplicial V-algebras that represent the same morphism in $\mathsf{D}(s.V\text{-}\mathsf{Alg})$. In this case, we may find a morphism $\vartheta : R''' \to R$ of simplicial V-algebras, such that ϑ is a quasi-isomorphism, and $\varphi \circ \vartheta, \varphi' \circ \vartheta : R''' \to S$ are homotopic maps; then the assertion follows from claim 14.1.80 (and again, from lemma 14.1.77: details left to the reader). □

Corollary 14.1.81. *Let $\varphi : R \to S$ and $\psi : S \to T$ be any two morphisms of simplicial V^a-algebras. We have :*

(i) *If φ and ψ are weakly étale, the same holds for $\psi \circ \varphi$.*
(ii) *If φ and $\psi \circ \varphi$ are weakly étale, the same holds for ψ.*
(iii) *If φ is weakly étale, and $R \to R'$ is any morphism of simplicial V^a-algebras, then $\varphi' := R' \overset{\ell}{\otimes}_R \varphi$ is weakly étale.*
(iv) *φ is weakly étale if and only if the same holds for $\Delta(\varphi)$.*

Proof. (iv) is immediate from the discussion of (14.1.71).

(iii): Endow $S' := R' \overset{\ell}{\otimes}_R S$ with the R'-algebra structure deduced from its left tensor factor; then the assertion is an immediate consequence of the following more general

Claim 14.1.82. There exists a commutative diagram in $\mathsf{D}(R'\text{-}\mathsf{Alg})$

$$\begin{array}{ccc} S' \overset{\ell}{\otimes}_{R'} S' & \xrightarrow{\qquad\qquad} & R' \overset{\ell}{\otimes}_R (S \overset{\ell}{\otimes}_R S) \\ & {\scriptstyle \Delta(\varphi')} \searrow \quad \swarrow {\scriptstyle R' \overset{\ell}{\otimes}_R \Delta(\varphi)} & \\ & S' & \end{array}$$

whose horizontal arrow is an isomorphism.

Proof of the claim. Pick any resolution $\rho : P \to S$ with P a flat R-algebra; then $R' \otimes_R P$ represents $R' \overset{\ell}{\otimes}_R S$, and we have a natural isomorphism of R'-algebras

$$(R' \otimes_R P) \otimes_{R'} (R' \otimes_R P) \xrightarrow{\sim} R' \otimes_R (P \otimes_R P).$$

In view of remark 7.10.31(i), the source of this map represents $S' \overset{\ell}{\otimes}_{R'} S'$, and the target represents $R' \overset{\ell}{\otimes}_R (S \overset{\ell}{\otimes}_R S)$. Under these identifications, the morphism $R' \overset{\ell}{\otimes}_R \Delta(\varphi)$ becomes the map $\mathbf{1}_{R'} \otimes_R (\mu_S \circ (\rho \otimes_R \rho))$ (notation of (14.1.71)), whereas $\Delta(\varphi')$ is represented by the multiplication map $\mu_{R' \otimes_R P} = \mathbf{1}_{R'} \otimes_R \mu_P$ of $R' \otimes_R P$. The claim follows straightforwardly. ◊

(i): Pick a resolution $P \to S_{!!}$ with P a flat $R_{!!}$-algebra, and a resolution $Q \to T_{!!}$ with Q a flat P-algebra; in light of proposition 14.1.78 it suffices to show that the resulting morphism $R \to Q^a$ is weakly étale, so we may replace S by P^a and T by Q^a, and assume from start that both φ and ψ are flat morphisms. Due to (iv), it then suffices to check that $\Delta(\psi \circ \varphi) : T \otimes_R T \to T$ is weakly étale; however, the latter can be factored as the composition

$$T \otimes_R T \xrightarrow{\sim} T \otimes_S (S \otimes_R S) \otimes_S T \xrightarrow{T \otimes_S \Delta(\varphi) \otimes_S T} T \otimes_S T \xrightarrow{\Delta(\psi)} T \qquad (14.1.83)$$

and by (iv) the maps $\Delta(\psi)$ and $\Delta(\varphi)$ are weakly étale, so the same holds for $T \otimes_S \Delta(\varphi) \otimes_S T$, in view of (iii). We may therefore replace ψ by $\Delta(\psi)$ and φ by $T \otimes_S \Delta(\varphi) \otimes_S T$, after which, we may assume that $\Delta(\psi)$ is an isomorphism in $\mathsf{D}(s.A\text{-}\mathsf{Alg})$. In this case, the factorization (14.1.83) makes it clear that $\Delta(\psi \circ \varphi)$ is weakly étale, as stated.

(ii): Set $S' := S \overset{\ell}{\otimes}_R S$ and $T' := S \overset{\ell}{\otimes}_R T$; we may factor ψ as the composition

$$S \xrightarrow{S \overset{\ell}{\otimes}_R (\psi \circ \varphi)} T' \xrightarrow{T' \overset{\ell}{\otimes}_{S'} \Delta(\varphi)} T$$

so the assertion follows from (i), (iii) and (iv). □

Theorem 14.1.84. *Let $\varphi : R \to S$ be a morphism of simplicial V-algebras, $c, p \in \mathbb{N}$ two integers, with p a prime, and suppose that φ^a is weakly étale. We have :*

(i) *If the ideal $\mathfrak{m} \cdot H_0(S)$ of $H_0(S)$ satisfies condition $(\mathbf{B})$ of* [75, §2.1.6]*, then*

$$\mathbb{L}^a_{S/R} = 0 \qquad \textit{in } \mathsf{D}(S^a\text{-}\mathbf{Mod}).$$

(ii) *If S is a $\mathbb{Z}_{(p)}$-algebra and $H_i\mathbb{L}_{S/R} = 0$ for every $i < c$, then*

$$H_i\mathbb{L}^a_{S/R} = 0 \qquad \textit{for every } i < c + 2p - 1.$$

Proof. We begin with the following :

Claim 14.1.85. We may assume that both $\Delta(\varphi^a)$ and $H_0(\varphi)$ are isomorphisms.

Proof of the claim. To ease notation, set $S' := S \overset{\ell}{\otimes}_R S$, and consider the sequence of morphisms

$$S \xrightarrow{\mathbf{1}_S \overset{\ell}{\otimes}_R \varphi} S' \xrightarrow{\mu_B} S \tag{14.1.86}$$

where μ_S is the composition of the multiplication map $S \otimes_R S \to S$ and the natural map $S' \to S \otimes_R S$; the transitivity triangle ([103, III.2.1.2]) relative to (14.1.86) yields a natural isomorphism

$$\mathbb{L}_{S'/S} \xrightarrow{\sim} \sigma S \otimes_{S'} \mathbb{L}_{S'/S} \xrightarrow{\sim} \sigma S \otimes_{S'} (S' \otimes_S \mathbb{L}_{S/R}) \qquad \text{in } \mathsf{D}(S\text{-}\mathbf{Mod})$$

where the last isomorphism follows from the base change theorem of [103, III.2.2.1]. Thus, $\mathbb{L}_{S'/S} \simeq \sigma\mathbb{L}_{S/R}$ in $\mathsf{D}(S\text{-}\mathbf{Mod})$, so assertion (i) (resp. (ii)) holds for φ, provided it holds for $\Delta(\varphi)$, and then the claim follows from corollary 14.1.81(iv). ◊

Henceforth, we assume that both $\Delta(\varphi^a)$ and $H_0(\varphi)$ are isomorphisms. Let $P \to S$ be a resolution, with P an R-algebra, such that $P[n]$ is a free $R[n]$-algebra for every $n \in \mathbb{N}$; set $P' := S \otimes_R P$, and recall that there are natural isomorphisms

$$\mathbb{L}_{S/R} \xrightarrow{\sim} S \otimes_P \Omega^1_{P/R} \xrightarrow{\sim} S \otimes_{P'} \Omega^1_{P'/S}$$

where $\Omega^1_{P/R}$ denotes the flat simplicial P-module such that $\Omega^1_{P/R}[n] := \Omega_{P[n]/R[n]}$ (and likewise for $\Omega^1_{P'/S}$), with faces and degeneracies deduced from those of P and R (resp. those of P' and S), in the obvious way. In other words, set

$$J := \mathrm{Ker}(\mu_S : P' \to S)$$

(with μ_S as in the proof of claim 14.1.85); then $\mathbb{L}_{S/R} \simeq J/J^2$ in $\mathsf{D}(S\text{-}\mathbf{Mod})$, and notice that

$$J^a = 0 \qquad \text{in } \mathsf{D}(S^a\text{-}\mathbf{Mod}) \tag{14.1.87}$$

since $\Delta(\varphi^a)$ is an isomorphism.

Claim 14.1.88. J is a quasi-regular ideal, and $H_0 J = 0$.

Proof of the claim. Since $H_0(\varphi)$ is an isomorphism, it is clear that $H_0 J = 0$. Next, for every $n \in \mathbb{N}$, the $S[n]$-algebra $P'[n]$ is free, hence we reduce to showing the following. Let B be any ring, $C := B[X_i \mid i \in I]$ any free B-algebra (for any set I), and $f : C \to B$ any morphism of B-algebras; then $\mathrm{Ker}\, f$ is a quasi-regular ideal of C. However, for every $i \in I$, set $b_i := f(X_i)$, and let $g : C \xrightarrow{\sim} C$ be the isomorphism of B-algebras such that $g(X_i) = X_i - a_i$ for every $i \in I$; clearly $\mathrm{Ker}\, f$ is a quasi-regular ideal if and only if the same holds for $g^{-1}\mathrm{Ker}\, f$. But the latter is the ideal $(X_i \mid i \in I)$, so the assertion follows from remark 7.10.44(iii). ◊

(i): We need to show that $H_n(J/J^2)^a = 0$ for every $n \in \mathbb{N}$, and we shall argue by induction on n. The assertion for $n = 0$ is clear from (14.1.87), in view of the exact sequence

$$H_n J \to H_n(J/J^2) \to H_{n-1} J^2 \qquad \text{for every } n \in \mathbb{N}.$$

Hence, suppose that $n > 0$, and the assertion is already known for every degree $< n$. The same exact sequence reduces to checking that $H_{n-1}(J^2)^a = 0$. Now, from claim 14.1.88 and theorem 7.10.48, we know that $H_{n-1}J^n = 0$. Therefore, by an easy induction, we are further reduced to showing that $H_{n-1}(J^i/J^{i+1})^a = 0$ for every $i = 2, \dots, n-1$. However, on the one hand, proposition 7.10.45(ii.a) says that the natural map

$$L\mathrm{Sym}^i_S(J/J^2) \to J^i/J^{i+1}$$

is an isomorphism in $\mathsf{D}(S\text{-}\mathbf{Mod})$, for every $i \in \mathbb{N}$; on the other hand, the inductive assumption and theorem 14.1.60(i) imply that $H_j(L\mathrm{Sym}^i J/J^2)^a = 0$ for every $j \leq n$, whence the contention.

(ii): We show, by induction on n, that $H_n(J/J^2)^a = 0$ for every $n < c + 2p - 1$. Arguing as in the foregoing, we may assume that $c + 2p - 1 > n > 0$, and the sought vanishing is already known in degrees $< n$, in which case we reduce to checking that $H_{n-1}(L\mathrm{Sym}^i_S J/J^2)^a = 0$ for every $i = 2, \dots, n-1$. Set $M := \mathrm{cosk}_n(s.\mathrm{trunc}_n J/J^2)$; then $H_j M = 0$ for every $j < c$, and the inductive assumption implies that $M^a = 0$ in $\mathsf{D}(S^a\text{-}\mathbf{Mod})$, so $H_{n-1}(L\mathrm{Sym}^i_S M)^a = 0$, by theorem 14.1.66(iii). Lastly, by corollary 7.10.34(i), we see that

$$H_{n-1}(L\mathrm{Sym}^i_S M) = H_{n-1}(L\mathrm{Sym}^i_S J/J^2) \qquad \text{for every } i \in \mathbb{N}$$

whence the contention. □

Remark 14.1.89. Let $A \to B$ be any morphism of simplicial rings such that the multiplication map $\mu_B : B \otimes_A B \to B$ induces an isomorphism $H_0(\mu_B) : H_0(B) \otimes_{H_0(A)} H_0(B) \xrightarrow{\sim} H_0(B)$. Pick a resolution $\varphi : P \to B$ such that $P[n]$ is a free $A[n]$-algebra for every $n \in \mathbb{N}$, and set $P' := B \otimes_A P$, $J := \mathrm{Ker}\,(\mu_B \circ (B \otimes_A \varphi) : P' \to B)$. The assumption on B implies that $H_0 J = 0$. On the other hand, arguing as in the proof of claim 14.1.88 we see that J is a quasi-regular ideal. Taking into account proposition 7.10.45(ii) the spectral sequence associated with the J-adic filtration of P' can be written as

$$E^2_{pq} := H_{p+q}(L\mathrm{Sym}^q_B(\mathbb{L}_{B/A})) \Rightarrow \mathrm{Tor}^A_{p+q}(B, B).$$

Though the J-adic filtration is not finite, using proposition 7.2.18(i) and theorem 7.10.48 one sees that this spectral sequence is convergent, and the filtration on its abutment is finite. We will not use this result.

Corollary 14.1.90. *Let $\varphi : A \to B$ be a morphism of V^a-algebras, $p \in \mathbb{N}$ a prime integer, and suppose that*

(a) *V is a $\mathbb{Z}_{(p)}$-algebra*
(b) *the induced morphism $s.\varphi : s.A \to s.B$ of simplicial V^a-algebras is weakly étale.*

Then $H_i \mathbb{L}^a_{B/A} = 0$ for every $i \leq 2p$.

Proof. Notice that condition (a) implies that $B_{!!}$ is a $\mathbb{Z}_{(p)}$-algebra; letting $c := 0$ in theorem 14.1.84(ii), we deduce that $H_i \mathbb{L}^a_{B/A} = 0$ for $i = 0, 1$. But in view of claim 14.1.46, the latter implies that $H_i \mathbb{L}_{B_{!!}/A_{!!}} = 0$ for $i = 0, 1$. So, actually the morphism φ fulfills the conditions of theorem 14.1.84(ii), with $c = 2$, whence the assertion. □

Remark 14.1.91. As an application we can now generalize the deformation theory for almost rings in [75, §3.2] to the case of an arbitrary basic setup $(V, \mathfrak{m})$. Indeed, [75, Lemmata 3.2.1 and 3.26, Prop.3.2.9 and Cor.3.2.11] hold *verbatim* for any such basic setup, with the same proof : the only difference is that instead of invoking [75, 3.2.1] we must appeal to our theorem 14.1.43 in the explanation of [75, §3.2.7]. Next, let $A \to B$ be any weakly étale morphism of V^a-algebras; for every prime integer p, let $V_{(p)} := \mathbb{Z}_{(p)} \otimes_{\mathbb{Z}} V$, and denote

$$j_p : (V, \mathfrak{m})^a\text{-}\mathsf{Alg} \to (V_{(p)}, \mathfrak{m}V_{(p)})^a\text{-}\mathsf{Alg} \qquad C \mapsto \mathbb{Z}_{(p)} \otimes_{\mathbb{Z}} C$$

the natural functor; with this notation, it is easily seen that

$$\mathbb{Z}_{(p)} \otimes_{\mathbb{Z}} B_{!!} = (j_p B)_{!!}$$

(details left to the reader), and in view of [103, II,2.2.1] we deduce a natural isomorphism

$$\mathbb{Z}_{(p)} \otimes_{\mathbb{Z}} \mathbb{L}_{B_{!!}/A_{!!}} \xrightarrow{\sim} \mathbb{L}_{(j_p B)_{!!}/(j_p A)_{!!}}.$$

Corollary 14.1.90 then easily implies that $H_i \mathbb{L}^a_{B/A} = 0$ for every $i \leq 4$. Combining with the results just quoted from [75], we see that the whole of [75, Th.3.2.18] still holds under the current assumptions. In the same vein, we may complement as follows the descent results of [75, §3.4] :

Corollary 14.1.92. *Consider a cartesian diagram of V^a-algebras*

$$\mathscr{D} \quad : \quad \begin{array}{ccc} A_0 & \longrightarrow & A_1 \\ \downarrow & & \downarrow \\ A_2 & \longrightarrow & A_3 \end{array}$$

such that the morphism $A_1 \to A_3$ is an epimorphism on the underlying V^a-modules. Then the resulting morphism $A_0 \to A_1 \times A_2$ is of universal effective descent for the fibred categories $\mathbf{w}.\mathbf{\acute{E}t}$ *of weakly étale morphisms and* $\mathbf{\acute{E}t}$ *of étale morphisms.*

Proof. Arguing as in the proof of [75, Prop.3.4.33], and using [75, Cor.3.4.22], we see that the morphism $A_0 \to A_1 \times A_2$ is of effective descent for the fibred categories $\mathbf{w}.\mathbf{\acute{E}t}$ and $\mathbf{\acute{E}t}$. Next, consider any morphism $A_0 \to B_0$ of V^a-algebras, and set $B_i := B_0 \otimes_{A_0} A_i$ for $i = 1, 2, 3$. The resulting diagram $B_0 \otimes_{A_0} \mathscr{D}$ is not necessarily cartesian; however, we notice :

Claim 14.1.93. The induced morphism $f : B_0 \to B'_0 := B_1 \times_{B_3} B_2$ is an epimorphism on the underlying V^a-modules, with nilpotent kernel.

Proof of the claim. Indeed, we have a short exact sequence of A_0-modules

$$0 \to A_0 \to A_1 \times A_2 \to A_3 \to 0$$

inducing a right exact sequence $B_0 \to B_1 \times B_2 \to B_3 \to 0$, which shows that f is an epimorphism. Newt, for any B-module M we show more generally that

$$\mathrm{Ann}_B(M \otimes_{A_0} A_1) \cdot \mathrm{Ann}_B(M \otimes_{A_0} A_2) \subset \mathrm{Ann}_B(M).$$

Letting $M := B$, it will then follow easily that $(\mathrm{Ker}\, f)^2 = 0$. Now, let $x, y \in B_*$ be two almost elements such that $x \cdot (M \otimes_{A_0} A_1) = 0$ and $y \cdot (M \otimes_{A_0} A_2) = 0$, and let also $I := \mathrm{Ker}\,(A_1 \to A_3) = \mathrm{Ker}\,(A_0 \to A_2)$; since $M \otimes_{A_0} A_2 = M/IM$, we deduce that $yM \subset IM$, and on the other hand the natural morphism of A_0-modules $M \otimes_{A_0} A_1 \otimes_{A_1} I \xrightarrow{\sim} M \otimes_{A_0} I \to IM$ is an epimorphism, so that $x \cdot IM = 0$, and the assertion follows. ◊

Now, by the foregoing we known already that the induced morphism $B'_0 \to B_1 \times B_2$ is of effective descent for $\mathbf{w}.\mathbf{\acute{E}t}$ and $\mathbf{\acute{E}t}$. But claim 14.1.93 together with remark 14.1.91 implies that the base change functors

$$B_0\text{-}\mathbf{w}.\mathbf{\acute{E}t} \to B'_0\text{-}\mathbf{w}.\mathbf{\acute{E}t} \qquad \text{and} \qquad B_0\text{-}\mathbf{\acute{E}t} \to B'_0\text{-}\mathbf{\acute{E}t}$$

are equivalences of categories; thus, also the induced morphism $B_0 \to B_1 \times B_2$ is of effective descent, as required. □

14.1.94. We conclude this section with a few words on the cohomology of sheaves of almost modules. Namely, let $(V, \mathfrak{m})$ again be an arbitrary basic setup, which we view as a basic setup relative to the one-point topos $\{\mathrm{pt}\}$, in the sense of [75, §3.3]. Let $(X, \mathscr{O}_X)$ be a ringed topos, $\mathfrak{m}_X \subset \mathscr{O}_X$ an ideal, such that $(\mathscr{O}_X, \mathfrak{m}_X)$ is a basic setup relative to the topos X, and suppose also that we are given a morphism of ringed topoi :

$$\pi : (X, \mathscr{O}_X) \to (\{\mathrm{pt}\}, V) \quad \text{such that} \quad (\pi^*\mathfrak{m}) \cdot \mathscr{O}_X \subset \mathfrak{m}_X.$$

We deduce a natural morphism :

$$R\pi_* : \mathsf{D}^+((\mathscr{O}_X, \mathfrak{m}_X)^a\text{-}\mathbf{Mod}) \to \mathsf{D}^+((V, \mathfrak{m})^a\text{-}\mathbf{Mod})$$

which can be constructed as usual, by taking injective resolutions. In case $\widetilde{\mathfrak{m}}$ is a flat V-module, this is the same as setting

$$R\pi_*(K^\bullet) := (R\pi_* K^\bullet_!)^a.$$

Using [75, Cor.2.2.24] one may verify that the two definitions coincide : the details shall be left to the reader. In many cases, both statements and proofs of results concerning the cohomology of $\mathscr{O}_X$-modules carry over *verbatim* to $\mathscr{O}_X^a$-modules. One sets, as customary :

$$H^\bullet(X, K^\bullet) := H^\bullet R\pi_* K^\bullet \qquad \text{for every object } K^\bullet \text{ of } \mathsf{D}^+((\mathscr{O}_X, \mathfrak{m}_X)^a\text{-}\mathbf{Mod}).$$

14.1.95. As an illustration, we consider the following situation. Suppose that :

- $f : A \to A'$ is a map of V-algebras, and set :
$$\varphi := \mathrm{Spec}\, f : X' := \mathrm{Spec}\, A' \to X := \mathrm{Spec}\, A.$$
- $t \in A$ is an element which is regular both in A and in A', and such that the induced map $A/tA \to A'/tA'$ is an isomorphism.
- $U \subset X$ is any open subset containing $D(t) := \{\mathfrak{p} \in X \mid t \notin \mathfrak{p}\}$, and set $U' := \varphi^{-1}U$.
- $\mathscr{F}$ is a quasi-coherent $\mathscr{O}_U^a$-module, and set $\mathscr{F}' := \varphi^*_{|U'}\mathscr{F}$, which is a quasi-coherent $\mathscr{O}_{U'}^a$-module.

Then we have natural morphisms of A^a-modules :

$$H^q(U, \mathscr{F}) \to H^q(U', \mathscr{F}') \qquad \text{for every } q \in \mathbb{N}. \tag{14.1.96}$$

Lemma 14.1.97. *In the situation of* (14.1.95)*, suppose moreover that t is $\mathscr{F}$-regular. Then* (14.1.96) *is an isomorphism for every $q > 0$, and induces an isomorphism of A'^a-modules :*

$$H^0(U, \mathscr{F}) \otimes_A A' \xrightarrow{\sim} H^0(U', \mathscr{F}').$$

Proof. To ease notation, we shall write φ instead of $\varphi_{|U'}$. To start out, we remark :

Claim 14.1.98. (i) $\mathscr{T}\!or_1^{\mathscr{O}_U^a}(\mathscr{F}, \mathscr{O}_U^a/t\mathscr{O}_U^a) = 0$ and $\mathrm{Tor}_1^{A^a}(H^0(U, \mathscr{F}), A/tA) = 0$.

(ii) The $\mathscr{O}_U^a$-module $\varphi_*\mathscr{F}' = \mathscr{F} \otimes_{\mathscr{O}_U^a} \varphi_*\mathscr{O}_{U'}^a$ (resp. the A'^a-module $H^0(U, \mathscr{F}) \otimes_{A^a} A'^a$) is t-torsion-free.

Proof of the claim. (i): Since t is regular on $\mathscr{O}_U$, we have a short exact sequence : $\mathscr{E} := (0 \to \mathscr{O}_U^a \to \mathscr{O}_U^a \to \mathscr{O}_U^a/t\mathscr{O}_U^a \to 0)$, and since t is regular on $\mathscr{F}$, the sequence $\mathscr{E} \otimes_{\mathscr{O}_U^a} \mathscr{F}$ is still exact; the vanishing of $\mathscr{T}\!or_1^{\mathscr{O}_U^a}(\mathscr{F}, \mathscr{O}_U^a/t\mathscr{O}_U^a)$ is an easy consequence. For the second stated vanishing one argues similarly, using the exact sequence $0 \to A \to A \to A/tA \to 0$.

(ii): Under the current assumptions, the natural map $\mathscr{O}_U/t\mathscr{O}_U \to \varphi_*(\mathscr{O}_{U'}/t\mathscr{O}_{U'})$ is an isomorphism, whence a short exact sequence : $\mathscr{E}' := (0 \to \varphi_*\mathscr{O}_{U'}^a \to \varphi_*\mathscr{O}_{U'}^a \to \mathscr{O}_U^a/t\mathscr{O}_U^a \to 0)$. In view of (i), the sequence $\mathscr{E}' \otimes_{\mathscr{O}_U^a} \mathscr{F}$ is still exact, so $\mathscr{F} \otimes_{\mathscr{O}_U^a} \varphi_*\mathscr{O}_{U'}^a$ is t-torsion-free. An analogous argument works as well for $H^0(U, \mathscr{F}) \otimes_{A^a} A'^a$. ◊

Claim 14.1.99. For every $n > 0$, the map $A/t^nA \to A'/t^nA'$ induced by f is an isomorphism.

Proof of the claim. Indeed, since t is regular on both A and A', and $A/tA \xrightarrow{\sim} A'/tA'$, the map of graded rings $\oplus_{n\in\mathbb{N}} t^n A/t^{n+1}A \to \oplus_{n\in\mathbb{N}} t^n A'/t^{n+1}A'$ is bijective. Then the claim follows from [34, Ch.III, §2, n.8, Cor.3]. $\Diamond$

Let $j : D(t) \to U$ be the natural open immersion, and set :

$$\mathscr{F}[t^{-1}] := j_* j^* \mathscr{F} \simeq \mathscr{F} \otimes_{\mathscr{O}^a_U} j_* \mathscr{O}^a_{D(t)}.$$

Notice the natural isomorphisms :

$$j_* j^* \varphi_* \mathscr{F}' \simeq (\mathscr{F} \otimes_{\mathscr{O}^a_U} \varphi_* \mathscr{O}^a_{U'}) \otimes_{\mathscr{O}^a_U} j_* \mathscr{O}^a_{D(t)} \simeq \mathscr{F}[t^{-1}] \otimes_{\mathscr{O}^a_U} \varphi_* \mathscr{O}^a_{U'}. \tag{14.1.100}$$

Since t is $\mathscr{F}$-regular, the natural map $\mathscr{F} \to \mathscr{F}[t^{-1}]$ is a monomorphism, and the same holds for the corresponding map $\varphi_* \mathscr{F}' \to j_* j^* \varphi_* \mathscr{F}'$, in view of claim 14.1.98(ii). Moreover, $\mathscr{G} := \mathscr{F}[t^{-1}]/\mathscr{F}$ can be written as the increasing union of its subsheaves $\mathrm{Ann}_{\mathscr{G}}(t^n)$ (for all $n \in \mathbb{N}$); hence claim 14.1.99 implies that the natural map $\mathscr{G} \to \mathscr{G} \otimes_{\mathscr{O}^a_U} \varphi_* \mathscr{O}^a_{U'}$ is an isomorphism. There follows a ladder of short exact sequences :

$$\begin{array}{ccccccccc} 0 & \to & \mathscr{F} & \to & \mathscr{F}[t^{-1}] & \to & \mathscr{G} & \to & 0 \\ & & \downarrow & & \downarrow & & \| & & \\ 0 & \to & \varphi_* \mathscr{F}' & \to & \mathscr{F}[t^{-1}] \otimes_{\mathscr{O}^a_U} \varphi_* \mathscr{O}^a_{U'} & \to & \mathscr{G} & \to & 0. \end{array} \tag{14.1.101}$$

On the other hand, since j is an affine morphism, we may compute :

$$H^q(U, \mathscr{F}[t^{-1}]) \simeq H^q(U, Rj_* j^* \mathscr{F}) \simeq H^q(D(t), j^* \mathscr{F}) \simeq 0 \qquad \text{for every } q > 0.$$

Likewise, from (14.1.100) we get :

$$H^q(U, \mathscr{F}[t^{-1}] \otimes_{\mathscr{O}^a_U} \varphi_* \mathscr{O}^a_{U'}) \simeq 0 \qquad \text{for every } q > 0.$$

Thus, in the commutative diagram :

$$\begin{array}{ccc} H^{q-1}(U, \mathscr{G}) & \xrightarrow{\partial} & H^q(U, \mathscr{F}) \\ {\scriptstyle \partial'} \downarrow & & \downarrow \\ H^q(U, \varphi_* \mathscr{F}) & \xrightarrow{\sim} & H^q(U', \mathscr{F}') \end{array}$$

the boundary maps ∂ and ∂' are isomorphisms whenever $q > 1$, and the right vertical arrow is (14.1.96), so the assertion follows already for every $q > 1$. To deal with the remaining cases with $q = 0$ or 1, we look at the ladder of exact cohomology sequences:

$$\begin{array}{ccccccccccc} 0 & \to & H^0(U, \mathscr{F}) & \xrightarrow{\alpha} & H^0(D(t), \mathscr{F}) & \xrightarrow{\beta} & H^0(U, \mathscr{G}) & \to & H^1(U, \mathscr{F}) & \to & 0 \\ & & \downarrow & & \downarrow & & \| & & \downarrow & & \\ 0 & \to & H^0(U', \mathscr{F}') & \to & H^0(D(t), \mathscr{F}) \otimes_{A^a} A'^a & \xrightarrow{\beta'} & H^0(U, \mathscr{G}) & \to & H^1(U', \mathscr{F}') & \to & 0 \end{array}$$

deduced from (14.1.101). On the one hand, we remark that the natural inclusion $\mathrm{Im}\,\beta \subset \mathrm{Im}\,\beta'$ factors as a composition

$$\mathrm{Im}\,\beta \xrightarrow{\iota} M := A'^a \otimes_{A^a} \mathrm{Im}\,\beta \xrightarrow{\pi} \mathrm{Im}\,\beta'$$

where ι is given by the rule : $x \mapsto 1 \otimes x$, for all $x \in A^a_*$, and π is an epimorphism.

On the other hand, the image of β is isomorphic to $N := \mathrm{Coker}\,\alpha$, and the latter is the increasing union of its submodules $\mathrm{Ann}_N(t^n)$ (for all $n \in \mathbb{N}$). Again from claim 14.1.99 we deduce that $M = \mathrm{Im}\,\beta$, hence $\mathrm{Im}\,\beta' = \mathrm{Im}\,\beta$, which shows that (14.1.96) is an isomorphism also for $q = 1$. By the same token, $\mathrm{Ker}(\alpha \otimes_{A^a} \mathbf{1}_{A'^a})$ is the increasing union of its t^n-torsion submodules (for all $n \in \mathbb{N}$), since it is a quotient of $\mathrm{Tor}_1^{A^a}(\mathrm{Im}\,\beta, A'^a)$; hence $\mathrm{Ker}(\alpha \otimes_{A^a} \mathbf{1}_{A'^a}) = 0$, in view of claim 14.1.98(ii). This easily implies the last assertion for $q = 0$. $\square$

14.2. **Inverse systems of almost modules.** The considerations of this section expand upon [75, §2.3.14, §2.4.1, Lemmata 2.3.15, 2.4.2 and 2.4.13].

14.2.1. Let V be a ring, $(\mathfrak{m}_\lambda \mid \lambda \in \Lambda)$ a filtered system of ideals of V such that $\mathfrak{m}_\lambda^2 = \mathfrak{m}_\lambda$ for every λ, and set $\mathfrak{m} := \bigcup_{\lambda\in\Lambda} \mathfrak{m}_\lambda$. Then $(V, \mathfrak{m})$ and $(V, \mathfrak{m}_\lambda)$ for every $\lambda \in \Lambda$ are basic setups, and we have an obvious compatible system of localization functors :

$$\begin{array}{ccc} (V,\mathfrak{m})^a\text{-}\mathbf{Mod} & \xrightarrow{\pi_\lambda} & (V,\mathfrak{m}_\lambda)^a\text{-}\mathbf{Mod} \\ & \searrow^{\pi_\mu} & \downarrow{\scriptstyle \pi_{\lambda\mu}} \\ & & (V,\mathfrak{m}_\mu)^a\text{-}\mathbf{Mod} \end{array} \qquad \text{for every } \lambda \geq \mu \text{ in } \Lambda. \tag{14.2.2}$$

Proposition 14.2.3. *(i) The compatible system* (14.2.2) *induces an equivalence of categories*

$$\omega : (V, \mathfrak{m})^a\text{-}\mathbf{Mod} \xrightarrow{\sim} 2\text{-}\lim_{\lambda\in\Lambda} (V, \mathfrak{m}_\lambda)^a\text{-}\mathbf{Mod}.$$

(ii) If $\mathfrak{m}_\lambda$ fulfills condition $(\mathbf{B})$ *of* [75, §2.1.6] *for every $\lambda \in \Lambda$, then the same holds for $\mathfrak{m}$.*

Proof. (ii) is obvious. To show (i), we construct a quasi-inverse τ for ω as follows. Recall that an object of the above 2-limit is a datum $(M_\bullet, f_{\bullet\bullet}) := ((M_\lambda \mid \lambda \in \Lambda), (f_{\lambda\mu} : \pi_{\lambda\mu}(M_\lambda) \xrightarrow{\sim} M_\mu \mid \lambda \geq \mu))$ consisting of $(V, \mathfrak{m}_\lambda)^a$-modules M_λ for every $\lambda \in \Lambda$, and isomorphisms $f_{\lambda\mu}$ of $(V, \mathfrak{m}_\mu)^a$-modules, for every $\lambda \geq \mu$ in Λ. Such a datum is required moreover to satisfy the compatibility condition :

$$f_{\mu\nu} \circ a_{\mu\nu}(f_{\lambda\mu}) = f_{\lambda\nu} \qquad \text{whenever } \lambda \geq \mu \geq \nu.$$

However, the discussion of [75, §2.2.2] allows to describe such a datum more concretely as follows. Choose, for every $\lambda \in \Lambda$ a V-module M'_λ whose image in $(V, \mathfrak{m}_\lambda)^a$-$\mathbf{Mod}$ represents M_λ; the isomorphism $f_{\lambda\mu}$ corresponds then to a unique V-linear isomorphism

$$f'_{\lambda\mu} : \widetilde{\mathfrak{m}}_\mu \otimes_V M'_\lambda \xrightarrow{\sim} \widetilde{\mathfrak{m}}_\mu \otimes_V M'_\mu \qquad \text{whenever } \lambda \geq \mu$$

(with $\widetilde{\mathfrak{m}}_\lambda := \mathfrak{m}_\lambda \otimes_V \mathfrak{m}_\lambda$ for every $\lambda \in \Lambda$) such that

$$f'_{\mu\nu} \circ (\widetilde{\mathfrak{m}}_\nu \otimes_V f'_{\lambda\mu}) = \widetilde{\mathfrak{m}}_\nu \otimes_V f'_{\lambda\nu} \qquad \text{whenever } \lambda \geq \mu \geq \nu. \tag{14.2.4}$$

Set $M_{\lambda!} := \widetilde{\mathfrak{m}}_\lambda \otimes_V M'_\lambda$; by composing the inverse of $f'_{\lambda\mu}$ with the natural map $\widetilde{\mathfrak{m}}_\mu \otimes_V M'_\lambda \to M_{\lambda!}$, we obtain a well defined V-linear map

$$f''_{\lambda\mu} : M_{\mu!} \to M_{\lambda!} \qquad \text{whenever } \lambda \geq \mu$$

and in light of (14.2.4) we deduce easily that $f''_{\lambda\nu} = f''_{\mu\nu} \circ f''_{\lambda\mu}$ whenever $\lambda \geq \mu \geq \nu$ (details left to the reader). We now let

$$\tau(M_\bullet, f_{\bullet\bullet}) := \big(\operatorname*{colim}_{\lambda\in\Lambda} M_{\lambda!}\big)^a \in \mathrm{Ob}((V, \mathfrak{m})^a\text{-}\mathbf{Mod}).$$

If $(N_\bullet, g_{\bullet\bullet})$ is another object of the above 2-limit of categories, a morphism $(M_\bullet, f_{\bullet\bullet}) \to (N_\bullet, g_{\bullet\bullet})$ is the datum of a system of morphisms $h_\lambda : M_\lambda \to N_\lambda$ fulfilling obvious compatibility conditions with respect ot the isomorphisms $f_{\bullet\bullet}$ and $g_{\bullet\bullet}$; after choosing representative V-modules N'_λ for each N_λ, the morphism h_λ corresponds to a unique V-linear map $h'_\lambda : M_! \to N_! := \widetilde{\mathfrak{m}}_\lambda \otimes_V N'_\lambda$, for every $\lambda \in \Lambda$. It is then clear that the resulting system $h'_\bullet$ yields a natural transformation $M_{\bullet!} \to N_{\bullet!}$ of direct systems indexed by Λ, whence a well defined morphism of $(V, \mathfrak{m})^a$-modules

$$\tau(h_\bullet) := \big(\operatorname*{colim}_{\lambda\in\Lambda} h'_\lambda\big)^a : \tau(M_\bullet, f_{\bullet\bullet}) \to \tau(N_\bullet, g_{\bullet\bullet}).$$

This completes the construction of our functor τ. It is easily seen that the definition of τ is independent of all choices, up to a canonical isomorphism of functors. Especially, if $(M_\bullet, f_{\bullet\bullet}) = \omega(M^a)$ for some V-module M, we may assume that M'_λ has been chosen equal to M, and

$f'_{\lambda\mu} = \widetilde{\mathfrak{m}}_\lambda \otimes_V \mathbf{1}_M$ for every $\lambda, \mu \in \Lambda$ with $\lambda \geq \mu$. With these choices, we get a natural isomorphism $\tau \circ \omega(M^a) \stackrel{\sim}{\to} M^a$ for every $(V, \mathfrak{m})^a$-module M^a. Next, for any given datum $(M_\bullet, f_{\bullet\bullet})$ as in the foregoing, set $(P_\bullet, t_{\bullet\bullet}) := \omega \circ \tau(M_\bullet, f_{\bullet\bullet})$; for every $\mu \in \Lambda$, the subset $\Lambda(\mu) := \{\lambda \in \Lambda \mid \lambda \geq \mu\}$ is cofinal in Λ, hence P_μ is naturally isomorphic to

$$\big(\operatorname*{colim}_{\lambda \in \Lambda(\mu)} M_{\lambda !}\big)^a \stackrel{\sim}{\to} \operatorname*{colim}_{\lambda \in \Lambda(\mu)} (M_{\lambda !})^a \stackrel{\sim}{\to} \operatorname*{colim}_{\lambda \in \Lambda(\mu)} \pi_{\lambda\mu}(M_\lambda)$$

where the transition morphisms in the latter colimit are given by the isomorphisms $f_{\lambda\mu}$; *i.e.* is naturally isomorphic to M_μ. Lastly, under this identification, it is easily seen that the morphism $t_{\lambda\mu}$ corresponds to $f_{\lambda\mu}$ whenever $\lambda \geq \mu$ in Λ (details left to the reader); summing up, we have obtained a natural isomorphism $\omega \circ \tau(M_\bullet, f_{\bullet\bullet}) \stackrel{\sim}{\to} (M_\bullet, f_{\bullet\bullet})$, and the proof is concluded. □

Corollary 14.2.5. *With the notation of* (14.2.1)*, for every $(V, \mathfrak{m})^a$-module M and every $\lambda \in \Lambda$, denote by M_λ the image of M in $(V, \mathfrak{m}_\lambda)^a$-**Mod**. Let A be a $(V, \mathfrak{m})^a$-algebra, M an A-module, B an A-algebra, and $r \in \mathbb{N}$. Then the following holds :*

(i) *We have natural isomorphisms of V-modules :*

$$\operatorname*{colim}_{\lambda \in \Lambda} M_{\lambda !} \stackrel{\sim}{\to} M_! \qquad M_* \stackrel{\sim}{\to} \lim_{\lambda \in \Lambda} M_{\lambda *}.$$

(ii) *The system of localization functors A-$\mathsf{Alg} \to A_\lambda$-$\mathsf{Alg}$ induces a natural equivalence*

$$A\text{-}\mathsf{Alg} \stackrel{\sim}{\to} 2\text{-}\lim_{\lambda \in \Lambda} A_\lambda\text{-}\mathsf{Alg}.$$

(iii) *The A-module M is flat (resp. faithfully flat, resp. almost projective, resp. almost finitely generated, resp. almost finitely presented) if and only if the same holds for the A_λ-module M_λ, for every $\lambda \in \Lambda$.*

(iv) *Suppose that $\mathfrak{m}_\lambda$ fulfills condition* $(\mathbf{B})$ *for every $\lambda \in \Lambda$. Then the A-module M is almost projective of almost finite rank (resp. of finite rank $\leq r$) if and only if the same holds for the A_λ-module M_λ, for every $\lambda \in \Lambda$.*

(v) *The A-algebra B is flat (resp. faithfully flat, resp. weakly unramified, resp. weakly étale, resp. unramified, resp. étale) if and only if the same holds for the A_λ-algebra B_λ, for every $\lambda \in \Lambda$.*

Proof. (i): The assertion for $M_!$ is clear. For the assertion concerning M_*, it suffices to notice that for any two $(V, \mathfrak{m})^a$-modules M and N, proposition 14.2.3(i) implies that the natural map

$$\mathrm{Hom}_{(V,\mathfrak{m})^a\text{-}\mathbf{Mod}}(M, N) \to \lim_{\lambda \in \Lambda} \mathrm{Hom}_{(V,\mathfrak{m}_\lambda)^a\text{-}\mathbf{Mod}}(M_\lambda, N_\lambda) \qquad (14.2.6)$$

is an isomorphism of V-modules.

(ii),(iii): Clearly the functors π_λ and $\pi_{\lambda\mu}$ of (14.2.1) are all compatible with tensor products and with the alHom functors; moreover, for every $\lambda \in \Lambda$, every short exact sequence of $(V, \mathfrak{m}_\lambda)^a$-modules is isomorphic to Σ^a, for some short exact sequence Σ of V-modules (and likewise for short exact sequences of $(V, \mathfrak{m})^a$-modules : details left to the reader). In view of proposition 14.2.3(i), assertion (ii) follows straightforwardly, and taking into account the isomorphism (14.2.6), we also deduce that the A-module M is flat (resp. almost projective) if and only if the same holds for the A_λ-module M_λ, for every $\lambda \in \Lambda$.

Next, if every M_λ is a faithfully flat A_λ-module, and X is an A-module with $M \otimes_A X = 0$, it follows that $M_\lambda \otimes_{A_\lambda} X_\lambda = 0$ for every $\lambda \in \Lambda$, whence $X_\lambda = 0$ for every such λ, and hence $X = 0$, by proposition 14.2.3(i). Conversely, if M is faithfully flat and $\lambda \in \Lambda$, consider any A-module X such that $M_\lambda \otimes_{A_\lambda} X_\lambda = 0$; then $(M \otimes_A X)_\lambda = 0$, *i.e.* $\widetilde{\mathfrak{m}}_\lambda \otimes (M_* \otimes_{A_*} X_*) = 0$, so that $M \otimes_A (\widetilde{\mathfrak{m}}_\lambda \otimes_V X) = 0$. By assumption, this implies that $\widetilde{\mathfrak{m}}_\lambda \otimes_V X = 0$, and therefore $X_\lambda = 0$; this shows that M_λ is faithfully flat.

Next, say that $A = R^a$ and $M = N^a$ for some V-algebra R and some R-module N; suppose that each M_λ is almost finitely generated (resp. almost finitely presented), and let $\mathfrak{m}_0 \subset \mathfrak{m}$

be any finitely generated subideal. We then find $\lambda \in \Lambda$ such that $\mathfrak{m}_0 \subset \mathfrak{m}_\lambda$, and by applying [75, Cor.2.3.13] to the A_λ-module M_λ we find a finitely generated (resp. finitely presented) R-module N' and an R-linear map $N' \to N$ whose kernel and cokernel are annihilated by $\mathfrak{m}_0$. Then, by applying [75, Cor.2.3.13] to the A-module M, we deduce the assertion.

(iv): If every M_λ is almost projective of almost finite rank, we already know that M is almost projective, and it remains only to check that M is of almost finite rank. To this aim, let $\varepsilon \in \mathfrak{m}$ be any element, choose $\lambda \in \Lambda$ such that $\varepsilon \in \mathfrak{m}_\lambda^2$, and write $\varepsilon = \sum_{i=1}^n \varepsilon_i\varepsilon'_i$ for some $n \in \mathbb{N}$ and $\varepsilon_1, \varepsilon'_1, \dots, \varepsilon_n, \varepsilon'_n \in \mathfrak{m}_\lambda$; if M_λ is of almost finite rank, we may then find $j \in \mathbb{N}$ such that $\varepsilon_i \cdot \Lambda^j_{A_\lambda} M_\lambda = 0$ for $i = 1, \dots, n$, in which case it follows easily that $\varepsilon_i\varepsilon'_i \cdot \Lambda^j_A M = 0$ for every $i = 1, \dots, n$ (details left to the reader), whence the assertion. One argues likewise in case each M_λ has rank $\leq r$: the details shall be left to the reader.

(v) follows immediately from (i), (ii) and (iii). □

Remark 14.2.7. (i) Let V be a ring, $\mathfrak{m}, \mathfrak{m}' \subset V$ two ideals such that $(V, \mathfrak{m})$ and $(V, \mathfrak{m}')$ are both basic setups, and let $\mathfrak{m}'' := \mathfrak{m} \cdot \mathfrak{m}'$; set as usual $\widetilde{\mathfrak{m}} := \mathfrak{m} \otimes_V \mathfrak{m}$, and define likewise the V-modules $\widetilde{\mathfrak{m}}'$ and $\widetilde{\mathfrak{m}}''$. It is easily seen that $(V, \mathfrak{m}'')$ is a basic setup as well. Moreover, we claim that there exists a natural isomorphism of V-modules :

$$\widetilde{\mathfrak{m}} \otimes_V \widetilde{\mathfrak{m}}' \xrightarrow{\sim} \widetilde{\mathfrak{m}}'' \qquad x \otimes y \otimes x' \otimes y' \mapsto xx' \otimes yy'. \tag{14.2.8}$$

Indeed, let $\mu : \mathfrak{m} \otimes_V \mathfrak{m}' \to \mathfrak{m}''$ be the multiplication map; we know already that $\operatorname{Ker} \mu$ is annihilated by both $\mathfrak{m}$ and $\mathfrak{m}'$, hence $\mathfrak{m}'' \otimes_V \mu : \mathfrak{m}'' \otimes_V \mathfrak{m} \otimes_V \mathfrak{m}' \to \widetilde{\mathfrak{m}}''$ is an isomorphism, and likewise for $\mu \otimes_V \mathfrak{m} \otimes_V \mathfrak{m}' : \widetilde{\mathfrak{m}} \otimes_V \widetilde{\mathfrak{m}}' \to \mathfrak{m}'' \otimes_V \mathfrak{m} \otimes_V \mathfrak{m}'$, so the same holds for their composition, which is (14.2.8).

(ii) Let M be any V-module; denote by $(M, \mathfrak{m})^a \in \operatorname{Ob}((V, \mathfrak{m})^a\text{-}\mathbf{Mod})$ the image of M, and define likewise $(M, \mathfrak{m}')^a \in \operatorname{Ob}((V, \mathfrak{m}')^a\text{-}\mathbf{Mod})$ and $(M, \mathfrak{m}'')^a \in \operatorname{Ob}((V, \mathfrak{m}'')^a\text{-}\mathbf{Mod})$. We deduce from (i) natural V-linear identifications

$$(M, \mathfrak{m}'')^a_* \xrightarrow{\sim} ((M, \mathfrak{m})^a_*, \mathfrak{m}')^a_* \xrightarrow{\sim} ((M, \mathfrak{m}')^a_*, \mathfrak{m})^a_*$$
$$(M, \mathfrak{m}'')^a_! \xrightarrow{\sim} ((M, \mathfrak{m})^a_!, \mathfrak{m}')^a_! \xrightarrow{\sim} ((M, \mathfrak{m}')^a_!, \mathfrak{m})^a_!.$$

14.2.9. Let V be any ring; a *V-linear abelian category* is the datum of an abelian category $\mathscr{A}$ together with a V-module structure on $\operatorname{Hom}_{\mathscr{A}}(A, B)$ for every $A, B \in \operatorname{Ob}(\mathscr{A})$, such that the composition law of $\mathscr{A}$ is a V-bilinear map

$$\operatorname{Hom}_{\mathscr{A}}(A, B) \times \operatorname{Hom}_{\mathscr{A}}(B, C) \to \operatorname{Hom}_{\mathscr{A}}(A, C) \qquad \text{for every } A, B, C \in \operatorname{Ob}(\mathscr{A}).$$

We say that a functor $F : \mathscr{A} \to \mathscr{A}'$ between V-linear abelian categories is *V-linear* if the map

$$\operatorname{Hom}_{\mathscr{A}}(A, B) \to \operatorname{Hom}_{\mathscr{A}'}(FA, FB) \qquad f \mapsto Ff$$

is V-linear, for every $A, B \in \operatorname{Ob}(\mathscr{A})$.

Remark 14.2.10. Let V be a ring, and $\mathscr{A}, \mathscr{A}'$ two V-linear abelian categories.

(i) For every $x \in V$ and $A \in \operatorname{Ob}(\mathscr{A})$ we define the suboobject $xA := \operatorname{Im} x \cdot \mathbf{1}_A \subset A$. Moreover, if $J \subset V$ is an ideal generated by a finite system $x_1, \dots, x_n \in V$, we let $JA := \sum_{i=1}^n x_i A \subset A$. Let us check that the subobject JA does not depend on the choice of a finite system of generators for J : it suffices to show that for every $a \in J$ we have $aA \subset JA$; to this aim, say that $a = \sum_{i=1}^n a_i x_i$ for certain $a_1, \dots, a_n \in V$, and for every $i = 1, \dots, n$ denote by $A \xrightarrow{e_i} A^{\oplus n} \xrightarrow{p_i} A$ the inclusion into the i-the direct summand and the projection onto the i-th direct factor of $A^{\oplus n}$. Set $\varphi := \sum_{i=1}^n x_i \cdot p_i$ and $\psi := \sum_{i=1}^n a_i \cdot e_i$; it is easily seen that $\operatorname{Im} \varphi = JA$ and the V-bilinearity of the composition law implies that $\varphi \circ \psi = a \cdot \mathbf{1}_A$. Since $\operatorname{Im} \varphi \circ \psi \subset \operatorname{Im} \varphi$, the assertion follows.

(ii) Recall that the opposite $\mathscr{A}^o$ of the abelian category $\mathscr{A}$ is abelian; moreover, $\mathscr{A}^o$ inherits from $\mathscr{A}$ an obvious V-linear structure : the reader may spell out the details. Likewise, if $F : \mathscr{A} \to \mathscr{A}'$ any V-linear functor, then $F^o : \mathscr{A}^o \to \mathscr{A}'^o$ is again V-linear.

(iii) Obviously, for every V-algebra A, the category A-$\mathbf{Mod}$ is naturally a V-linear abelian category. If $(V, \mathfrak{m})$ is any basic setup, and A any $(V, \mathfrak{m})^a$-algebra, then also A-$\mathbf{Mod}$ is a V-linear abelian category.

(iv) Let $J \subset V$ be any ideal, and $A \in \mathrm{Ob}(\mathscr{A})$ any object. We say that $JA = 0$ if $xA = 0$ for every $x \in J$; notice that if J is finitely generated, this notation agrees with that of (i). We say that $\mathscr{A}$ is *J-torsion-free* if there are no non-zero objects A of $\mathscr{A}$ with $JA = 0$. For instance, if $(V, \mathfrak{m})$ is any basic setup, and A any $(V, \mathfrak{m})^a$-algebra, then A-$\mathbf{Mod}$ is $\mathfrak{m}$-torsion-free. Clearly, if $\mathscr{A}$ is J-torsion-free, the same holds for $\mathscr{A}^o$, for its natural V-linear structure.

(v) Let $f : A \to B$ be any morphism of $\mathscr{A}$, and $J, J' \subset V$ two ideals such that $J \cdot \mathrm{Ker}\, f = J' \cdot \mathrm{Coker}\, f = 0$ (notation of (iv)). Then for every $a \in J$ and $b \in J'$ there exists a morphism

$$g : B \to A \qquad \text{such that} \qquad f \circ g = ab \cdot \mathbf{1}_B \quad \text{and} \quad g \circ f = ab \cdot \mathbf{1}_A.$$

Indeed, write $f = e \circ p$, where $A \xrightarrow{p} \mathrm{Im}\, f \xrightarrow{e} B$ are the natural morphisms. Since $J \cdot \mathrm{Ker}\, p = J \cdot \mathrm{Ker}\, f = 0$, the endomorphism $a \cdot \mathbf{1}_A$ factors through p and a morphism $g_1 : \mathrm{Im}\, f \to A$. Likewise, since $J' \cdot \mathrm{Coker}\, e = J' \cdot \mathrm{Coker}\, f = 0$, the endomorphism $b \cdot \mathbf{1}_B$ factors through e and a morphism $g_2 : B \to \mathrm{Im}\, f$. Then $g := g_1 \circ g_2$ fulfills the stated conditions.

(vi) In the situation of (v), let $F : \mathscr{A} \to \mathscr{A}'$ be a V-linear functor; we get $Ff \circ Fg = ab \cdot \mathbf{1}_{FB}$ and $Fg \circ Ff = ab \cdot \mathbf{1}_{FA}$. It follows easily that $JJ' \cdot \mathrm{Ker}\, Ff = JJ' \cdot \mathrm{Coker}\, Ff = 0$.

Definition 14.2.11. Let $(V, \mathfrak{m})$ be a basic setup, $\mathscr{A}$ a V-linear abelian category, I a small category, and consider a functor

$$M_\bullet : I \to \mathscr{A} \qquad i \mapsto M_i \qquad (j \xrightarrow{\varphi} i) \mapsto (M_j \xrightarrow{M_\varphi} M_i).$$

(i) We say that $M_\bullet$ is *essentially zero*, if for every $i \in \mathrm{Ob}(I)$ there exists a morphism $\varphi : j \to i$ in I with $M_\varphi = 0$.

(ii) We say that $M_\bullet$ is *almost essentially zero*, if for every $i \in \mathrm{Ob}(I)$ and every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type there exists a morphism $\varphi : j \to i$ in I with $\mathfrak{m}_0 \cdot M_\varphi = 0$. We denote

$$\mathsf{Fun}(I, \mathscr{A})_{\mathrm{a.ess.0}}$$

the full subcategory of $\mathsf{Fun}(I, \mathscr{A})$ whose objects are the almost essentially zero functors.

(iii) We say that $M_\bullet$ is *almost essentially constant*, if there exist $L \in \mathrm{Ob}(\mathscr{A})$ and a cone $\pi_\bullet : c_L \Rightarrow M_\bullet$ inducing almost essentially zero functors

$$\mathrm{Ker}\, \pi_\bullet : I \to A\text{-}\mathbf{Mod} \qquad \text{and} \qquad \mathrm{Coker}\, \pi_\bullet : I \to A\text{-}\mathbf{Mod}.$$

(iv) We say that $M_\bullet$ has the *almost Mittag-Leffler property* if for every $i \in \mathrm{Ob}(I)$ and every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type there exists a morphism $j \xrightarrow{\varphi} i$ in I with :

$$\mathfrak{m}_0 \cdot \mathrm{Im}\, M_\varphi \subset \mathrm{Im}\, M_{\varphi \circ \psi} \qquad \text{for every morphism } \psi : k \to j \text{ in } I.$$

(v) We say that $M_\bullet$ is a *Cauchy functor*, if for every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type there exists $i \in \mathrm{Ob}(I)$ with $\mathfrak{m}_0 \cdot \mathrm{Ker}\, M_\varphi = \mathfrak{m}_0 \cdot \mathrm{Coker}\, M_\varphi = 0$ for every morphism $\varphi : j \to i$ of I.

We say that $M_\bullet$ is *null*, if it is both a Cauchy functor and almost essentially zero.

(vi) Let $\mathbf{P}(M_\bullet)$ be either one of the conditions : "$M_\bullet$ is essentially zero", "$M_\bullet$ is almost essentially zero", "$M_\bullet$ is almost essentially constant", "$M_\bullet$ has the almost Mittag-Leffler property", "$M_\bullet$ is a Cauchy functor" or "$M_\bullet$ is null". We say that $M_\bullet$ *has the dual* $\mathbf{P}$ *property* if $\mathbf{P}(M_\bullet^o)$ holds, for the opposite functor $M_\bullet^o : I^o \to \mathscr{A}^o$ (see remark 14.2.10(ii)).

Remark 14.2.12. (i) In the situation of definition 14.2.11, for every $M \in \mathrm{Ob}(\mathscr{A})$ and every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type, set $M[\mathfrak{m}_0] := \bigcap_{x \in \mathfrak{m}_0} \mathrm{Ker}\, x \cdot \mathbf{1}_M$. Notice that $M_\bullet$ is almost essentially zero if and only if the following holds. For every such $\mathfrak{m}_0$, the induced functor

$$M_\bullet / M_\bullet[\mathfrak{m}_0] : I \to \mathscr{A} \qquad i \mapsto M_i / M_i[\mathfrak{m}_0]$$

is essentially zero.

(ii) Suppose that I is cofiltered and $\mathscr{A}$ is complete, and let us set :

$$M_i^\triangle := \bigcap_{\varphi:j\to i} \mathrm{Im}\, M_\varphi \qquad \text{for every } i \in \mathrm{Ob}(I).$$

We claim that M_ψ restricts to a morphism in $\mathscr{A}$

$$M_\psi^\triangle : M_{i'}^\triangle \to M_i^\triangle \qquad \text{for every morphism } \psi : i' \to i \text{ in } I.$$

Indeed, it suffices to check that $M_\psi(M_{i'}^\triangle) \subset \mathrm{Im}\, M_\varphi$ for every morphism $\varphi : j \to i$ in I. However, since I is cofiltered, for every such φ there exist $k \in \mathrm{Ob}(I)$ and morphisms $\varphi' : k \to i'$ and $\psi' : k \to j$ such that $\varphi\circ\psi' = \psi\circ\varphi'$. It follows that $M_\psi(M_{i'}^\triangle) \subset M_\psi(\mathrm{Im}\,\varphi') = M_\varphi(\mathrm{Im}\,\psi')$ whence the contention. Next, let $\tau_\bullet : c_L \Rightarrow M_\bullet$ be any cone; notice that

$$\mathrm{Im}\,\tau_i \subset M_i^\triangle \qquad \text{for every } i \in \mathrm{Ob}(I). \tag{14.2.13}$$

On the other hand, a direct inspection of the definitions shows that

$$(M_\bullet/M_\bullet^\triangle)_i^\triangle = 0 \qquad \text{for every } i \in \mathrm{Ob}(I).$$

Hence, (14.2.13) implies that every cone $c_{L'} \Rightarrow M_\bullet/M_\bullet^\triangle$ is the zero morphism, so we must have $\lim_I M_\bullet/M_\bullet^\triangle = 0$, and since $\lim_I$ is a left exact functor (because it is a right adjoint : see (1.3)) we conclude that the inclusion $M_\bullet^\triangle \to M_\bullet$ induces an isomorphism :

$$\lim_I M_\bullet^\triangle \xrightarrow{\sim} \lim_I M_\bullet.$$

(iii) In the situation of (ii), let A be any $(V,\mathfrak{m})^a$-algebra, and take $\mathscr{A} := A\text{-}\mathbf{Mod}$ (see remark 14.2.10(iii)); notice then that $M_\bullet$ has the almost Mittag-Leffler property if and only if the following holds. For every $i \in \mathrm{Ob}(I)$, the induced system $M_{\bullet/i} := (\mathrm{Im}\, M_\varphi \mid \varphi : j \to i)$ of submodules of M_i is a Cauchy net of the uniform space $\mathscr{I}_A(M_i)$ defined as in [75, Def.2.3.1]. In this case, by [75, Lemma 2.3.5], the Cauchy sequence $M_{\bullet/i}$ admits a unique limit in $\mathscr{I}_A(M_i)$, and by direct inspection we see that this limit is $M_i^\triangle$, since for every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type there exists a morphism $\varphi : j \to i$ in I such that $\mathfrak{m}_0 \cdot \mathrm{Im}\, M_\varphi \subset M_i^\triangle$.

(iv) Notice that $M_\bullet : I \to \mathscr{A}$ is a Cauchy functor if and only if the following holds. For every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type there exists $i \in \mathrm{Ob}(I)$ such that for every pair of morphisms $k \xrightarrow{\psi} j \xrightarrow{\varphi} i$ of I, we have $\mathfrak{m}_0 \cdot \mathrm{Ker}\, M_\psi = \mathfrak{m}_0 \cdot \mathrm{Coker}\, M_\psi = 0$. Indeed, the latter condition clearly implies that $M_\bullet$ is a Cauchy functor; conversely, suppose that $M_\bullet$ is a Cauchy functor, and let $\mathfrak{m}_0 \subset \mathfrak{m}_1 \subset \mathfrak{m}$ be subideals of finite type with $\mathfrak{m}_0 \subset \mathfrak{m}_1^2$; by assumption, we may find $i \in \mathrm{Ob}(I)$ such that, for every φ and ψ as in the foregoing, $\mathfrak{m}_1$ annihilates all but the first and the fourth terms in the induced exact sequence :

$$0 \to \mathrm{Ker}\, M_\psi \to \mathrm{Ker}\, M_{\varphi\circ\psi} \to \mathrm{Ker}\, M_\varphi \to \mathrm{Coker}\, M_\psi \to \mathrm{Coker}\, M_{\varphi\circ\psi} \to \mathrm{Coker}\, M_\varphi \to 0.$$

It follows easily that $\mathfrak{m}_1 \cdot \mathrm{Ker}\, M_\psi = \mathfrak{m}_0 \cdot \mathrm{Coker}\, M_\psi$, as required. Notice also that every Cauchy functor has the almost Mittag-Leffler property : the details shall be left to the reader.

(v) Suppose again that I is cofiltered. In view of (iv), we deduce that a functor $M_\bullet : I \to \mathscr{A}$ is null if and only if the following holds. For every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type there exists $i \in \mathrm{Ob}(I)$ such that $\mathfrak{m}_0 M_j = 0$ for every morphism $\varphi : j \to i$: the details shall be left to the reader. It follows easily that the full subcategory of $\mathsf{Fun}(I, \mathscr{A})$ whose objects are the null functors, is a Serre subcategory : again, we leave the details to the reader.

Lemma 14.2.14. *In the situation of definition* 14.2.11*, the following holds :*

(i) *The category* $\mathsf{Fun}(I, \mathscr{A})_{\text{a.ess.0}}$ *is a Serre subcategory of* $\mathsf{Fun}(I, \mathscr{A})$*. Hence*

$$\mathscr{L}(I, \mathscr{A}) := \mathsf{Fun}(I, \mathscr{A})/\mathsf{Fun}(I, \mathscr{A})_{\text{a.ess.0}}.$$

is an abelian category whose objects are the functors $I \to \mathscr{A}$.

(ii) *If $\mathscr{A}$ is $\mathfrak{m}$-torsion-free (see remark* 14.2.10(iv)*), then for every almost essentially zero functor $M_\bullet : I \to A$-$\mathbf{Mod}$, we have* $\lim_I M_\bullet = 0$.

(iii) *Suppose that I is cofiltered, and $\mathscr{A}$ is complete and $\mathfrak{m}$-torsion-free. Then the functor*

$$\operatorname*{Lim}_I : \mathsf{Fun}(I, \mathscr{A}) \to \mathscr{A}$$

(see (1.3)*) factors through the localization* $\mathsf{Fun}(I, \mathscr{A}) \to \mathscr{L}(I, \mathscr{A})$ *and a functor*

$$\mathscr{L}(I, \mathscr{A}) \to \mathscr{A} \qquad M_\bullet \mapsto \lim_I M_\bullet.$$

Proof. (i): Consider a short exact sequence of functors from I to A-$\mathbf{Mod}$:

$$(14.2.15) \qquad 0 \to M'_\bullet \xrightarrow{f_\bullet} M_\bullet \xrightarrow{g_\bullet} M''_\bullet \to 0.$$

It is easily seen that if $M_\bullet$ is almost essentially zero, the same holds for $M'_\bullet$ and $M''_\bullet$. Conversely, suppose that $M'_\bullet$ and $M''_\bullet$ are almost essentially zero, and let $i \in \mathrm{Ob}(I)$, and $\mathfrak{m}_0 \subset \mathfrak{m}$ a finitely generated subideal. By assumption there exists a morphism $\varphi : j \to i$ in I such that $\mathfrak{m}_0 \cdot \operatorname{Im} M'_\varphi = 0$, and also a morphism $\psi : k \to j$ such that $\mathfrak{m}_0 \cdot \operatorname{Im} M''_\psi = 0$. It follows that there exists a morphism $h : \mathfrak{m}_0 M_k \to M'_j$ such that $f_j \circ h : \mathfrak{m}_0 M_k \to M_j$ is the restriction of M_ψ. Then $M_{\varphi\circ\psi}(\mathfrak{m}_0^2 M_k) = \mathfrak{m}_0 \cdot \operatorname{Im}(M_\varphi \circ f_j \circ h) = \mathfrak{m}_0 \cdot \operatorname{Im}(f_i \circ M'_\varphi \circ h) = 0$, which shows that $M_\bullet$ is almost essentially zero.

(ii): Suppose first that $M_\bullet$ is essentially zero. Let $X \in \mathrm{Ob}(\mathscr{A})$ be any object, and $\tau_\bullet : c_X \Rightarrow M_\bullet$ any cone; by assumption, for evey $i \in \mathrm{Ob}(I)$ there exists a morphism $\varphi : j \to i$ in I with $M_\varphi = 0$. Then $\tau_i = M_\varphi \circ \tau_j = 0$ for every such i, so that $\tau_\bullet = 0$, whence the contention.

For a general almost essentially zero functor $M_\bullet$, and every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type, we have a short exact sequence of functors

$$0 \to M_\bullet[\mathfrak{m}_0] \to M_\bullet \to M_\bullet/M_\bullet[\mathfrak{m}_0] \to 0$$

whose right-most term is essentially zero, by remark 14.2.12(i)), so that $\lim_I M_\bullet/M_\bullet[\mathfrak{m}_0] = 0$ by the previous case. On the other hand, clearly $\mathfrak{m}_0$ annihilates $\lim_I M_\bullet[\mathfrak{m}_0]$. The functor Lim_I is left exact (since it admits a left adjoint : see (1.3)); it then follows that $\mathfrak{m}_0$ annihilates as well $\lim_I M_\bullet$, and since $\mathfrak{m}_0$ is arbitrary and $\mathscr{A}$ is $\mathfrak{m}$-torsion-free, the claim follows.

(iii): As Lim_I is left exact, in the situation of (14.2.15) we see easily from (ii) that if $M''_\bullet$ is almost essentially zero, then $f_\bullet$ induces an isomorphism $\lim_I M'_\bullet \xrightarrow{\sim} \lim_I M_\bullet$. Thus, it remains only to check that if $M'_\bullet$ is almost essentially zero, then $g_\bullet$ induces an isomorphism $g : \lim_I M_\bullet \xrightarrow{\sim} \lim_I M''_\bullet$. To this aim, we suppose first that $M_\bullet$ is the constant functor of value M, and that for every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type there exists $i \in \mathrm{Ob}(I)$ such that $\mathfrak{m}_0 \cdot M'_i = 0$. Then, for every morphism $\varphi : j \to i$ in I we have as well $\mathfrak{m}_0 \cdot M'_j = 0$. Hence, for such $\mathfrak{m}_0$ and i, and for every $b \in \mathfrak{m}_0$ and every $\varphi : j \to i$, the endomorphism $b \cdot \mathbf{1}_M : M \to M$ is the composition of $g_j : M \to M''_j$ and a unique morphism $h_j : M''_j \to M$ of $\mathscr{A}$, and it is easily seen that $g_j \circ h_j = b \cdot \mathbf{1}_{M''_j}$. Moreover, the system of morphisms $(g_j \mid \varphi : j \to i)$ amounts to a natural cocone $h_\bullet : M''_\bullet \circ \mathsf{s}_i \Rightarrow M_\bullet \circ \mathsf{s}_i$, where $\mathsf{s}_i : I/i \to I$ denotes the source functor. Since s_i is coinitial (example 1.5.9(i)), we deduce a morphism of $\mathscr{A}$

$$h : L'' := \lim_I M''_\bullet \to M = \lim_I M_\bullet.$$

By construction, we have $g \circ h = b \cdot \mathbf{1}_{L''}$ and $h \circ g = b \cdot \mathbf{1}_M$. Especially, b annihilates $\operatorname{Ker} g$ and $\operatorname{Coker} g$, and since $\mathfrak{m}_0$ and b are arbitrary, the assertion follows in this case.

Lastly, let $M'_\bullet$ be an arbitrary almost essentially zero functor, and notice that

$$N_\varphi := f_i(\operatorname{Im} M'_\varphi) = M_\varphi(\operatorname{Ker} g_j) \qquad \text{for every morphism } \varphi : j \to i \text{ in } I.$$

Hence, for every such φ, the morphism M''_φ is the composition of unique morphisms of $\mathscr{A}$

$$h_\varphi : M''_j \xrightarrow{h_\varphi} Q_\varphi := M_i/N_\varphi \xrightarrow{\overline{g}_\varphi} M''_i \qquad \text{such that} \qquad h_\varphi \circ g_j = \pi_\varphi \circ M_\varphi \quad \text{and} \quad \overline{g}_\varphi \circ \pi_\varphi = g_i$$

where $\pi_\varphi : M_i \to Q_i$ is the projection. For any fixed $i \in \mathrm{Ob}(I)$, let $c_{M_i} : I/i \to \mathscr{A}$ be the constant functor of value M_i; we get a short exact sequence of functors

$$0 \to N_\bullet \to c_{M_i} \xrightarrow{\pi_\bullet} Q_\bullet \to 0$$

where $N_\bullet, Q_\bullet : I/i \to \mathscr{A}$ are given by the rules : $\varphi \mapsto N_\varphi$ and respectively $\varphi \mapsto Q_\varphi$ for every morphism $\varphi : j \to i$ in I. By construction, for every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type there exists $\varphi \in \mathrm{Ob}(I/i)$ such that $\mathfrak{m}_0 \cdot N_\varphi = 0$; by the foregoing case, it follows that $\pi_\bullet$ induces an isomorphism

$$\pi_i : M_i \xrightarrow{\sim} Q := \lim_{I/i} Q_\bullet.$$

On the other hand, the system $(h_\varphi \mid \varphi \in \mathrm{Ob}(I/i))$ amounts to a natural transformation $h_\bullet : M''_\bullet \circ \mathsf{s}_i \Rightarrow Q_\bullet$ (the details are left to the reader), whence an induced morphism of $\mathscr{A}$

$$h_i : L'' := \lim_I M''_\bullet \xrightarrow{\sim} \lim_{I/i} M''_\bullet \circ \mathsf{s}_i \to Q.$$

In turn, the system $(\pi_i^{-1} \circ h_i \mid i \in \mathrm{Ob}(I))$ amounts to a cone $c_{L''} \Rightarrow M_\bullet$, whence an induced morphism of $\mathscr{A}$

$$h : L'' \to L := \lim_I M_\bullet.$$

Claim 14.2.16. $g \circ h = \mathbf{1}_{L''}$.

Proof of the claim. Indeed, let also $\tau_\bullet : c_L \Rightarrow M_\bullet$ and $\tau''_\bullet : c_{L''} \Rightarrow M''_\bullet$ be the universal cones; it suffices to show that $\tau''_i \circ g \circ h = \tau''_i$ for every $i \in \mathrm{Ob}(I)$. But we have

$$\tau''_i \circ g \circ h = \tau''_i = g_i \circ \tau_i \circ h = g_i \circ \pi_i^{-1} \circ h_i = \overline{g}_\varphi \circ \pi_\varphi \circ \pi_i^{-1} \circ h_i$$

for every morphism $\varphi : j \to i$ in I, and on the other hand $\tau''_i = M''_\varphi \circ \tau''_j = \overline{g}_\varphi \circ h_\varphi \circ \tau''_j$ so we are reduced to checking that

$$\pi_\varphi \circ \pi_i^{-1} \circ h_i = h_\varphi \circ \tau''_j \qquad \text{for every morphism } \varphi : j \to i \text{ in } I.$$

Now, let $\tau^Q_\bullet : c_Q \Rightarrow Q_\bullet$ be the universal cone; then $\pi_\varphi \circ \pi_i^{-1} = \tau^Q_\varphi$ for every such φ, and finally, $\tau^Q_\varphi \circ h_i = h_\varphi \circ \tau''_j$, as required. ◊

From claim 14.2.16 we see that g is an epimorphism; but it is also a monomorphism, since $\lim_I M'_\bullet = 0$, and since the functor $\lim_I$ is left exact. Hence g is an isomorphism, as stated. □

Remark 14.2.17. Keep the situation of definition 14.2.11, and suppose that I is cofiltered.

(i) Consider a short exact sequence (14.2.15) of functors $I \to \mathscr{A}$, such that $M'_\bullet$ and $M''_\bullet$ are Cauchy functors. Then $M_\bullet$ is also a Cauchy functor. Indeed, let $\mathfrak{m}_0 \subset \mathfrak{m}_1 \subset \mathfrak{m}$ be two subideals of finite type with $\mathfrak{m}_0 \subset \mathfrak{m}_1^2$. Since I is cofiltered, taking into account remark 14.2.12(iv), we find $i \in \mathrm{Ob}(I)$ such that $\mathfrak{m}_1$ annihilates the kernel and cokernel of both M'_φ and M''_φ, for every morphism $\varphi : j \to i$; by the snake lemma, it follows easily that $\mathfrak{m}_0 \cdot \mathrm{Ker}\, M_\varphi = \mathfrak{m}_0 \cdot \mathrm{Coker}\, M_\varphi = 0$ for every such φ, whence the contention.

(ii) Moreover, if $X_\bullet, Y_\bullet : I \to \mathscr{A}$ are Cauchy functors, and $f_\bullet : X_\bullet \to Y_\bullet$ is any morphism of functors, then $\mathrm{Ker}\, f_\bullet$, $\mathrm{Coker}\, f_\bullet$ and $\mathrm{Im}\, f_\bullet$ are Cauchy functors. Indeed, let us check first the assertion for $Z_\bullet := \mathrm{Im}\, f_\bullet$: since the latter is a subfunctor of $Y_\bullet$, for every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type we find $i \in \mathrm{Ob}(I)$ such that for every pair of morphisms $k \xrightarrow{\psi} j \xrightarrow{\varphi} i$ we have $\mathfrak{m}_0 \cdot \mathrm{Ker}\, Z_\psi = 0$ (remark 14.2.12(iv)). Likewise, since $Z_\bullet$ is a quotient of $X_\bullet$, for every such $\mathfrak{m}_0$ there exists $i' \in \mathrm{Ob}(I)$ such that for every pair of morphisms $k' \xrightarrow{\psi'} j' \xrightarrow{\varphi'} i'$ we have $\mathfrak{m}_0 \cdot \mathrm{Coker}\, Z_{\psi'} = 0$. Since I is cofiltered, we find $i'' \in \mathrm{Ob}(I)$ with morphisms $i \leftarrow i'' \to i'$, and then $\mathfrak{m}_0$ annihilates the kernel of cokernel of Z_λ, for every morphism $\lambda : j'' \to i''$ of I.

Lastly, by considering the short exact sequences of functors :

$$0 \to \mathrm{Ker}\, f_\bullet \to X_\bullet \to Z_\bullet \to 0 \qquad 0 \to Z_\bullet \to Y_\bullet \to \mathrm{Coker}\, f_\bullet \to 0$$

and combining with (i), we deduce the assertions for $\mathrm{Ker}\, f_\bullet$ and $\mathrm{Coker}\, f_\bullet$.

Proposition 14.2.18. *With the notation of definition* 14.2.11 *and of remark* 14.2.12(ii)*, assume that I is cofiltered, and $\mathscr{A}$ is complete and $\mathfrak{m}$-torsion-free. Then we have :*

(i) *If $M_\bullet : I \to \mathscr{A}$ has the almost Mittag-Leffler property, the following holds :*

(a) *$M^\triangle_\varphi : M^\triangle_j \to M^\triangle_i$ is an epimorphism in $\mathscr{A}$, for every morphism $\varphi : j \to i$ of I.*

(b) *The inclusions $(M^\triangle_i \to M_i \mid i \in \mathrm{Ob}(I))$ define an isomorphism $M^\triangle_\bullet \xrightarrow{\sim} M_\bullet$ in $\mathscr{L}(I, \mathscr{A})$.*

(ii) *For every functor $M_\bullet : I \to \mathscr{A}$ the following conditions are equivalent :*

(a) *$M_\bullet$ is almost essentially constant.*

(b) *$M_\bullet$ is isomorphic to a constant functor, in the category $\mathscr{L}(I, \mathscr{A})$ of lemma* 14.2.14(i).

(c) *Every universal cone $c_L \Rightarrow M_\bullet$ is an isomorphism in the category $\mathscr{L}(I, \mathscr{A})$.*

(d) *$M_\bullet$ has the almost Mittag-Leffler property, and $M^\triangle_\bullet$ is a Cauchy functor.*

(iii) *Every Cauchy functor $M_\bullet : I \to \mathscr{A}$ is almost essentially constant.*

Proof. (i.a): Pick a morphism $k \xrightarrow{\psi} j$ such that $\mathfrak{m}_0 \cdot \mathrm{Im}\, M_\psi \subset M^\triangle_j$ (remark 14.2.12(iii)). Then

$$\mathfrak{m}_0 M^\triangle_i \subset \mathfrak{m}_0 \cdot \mathrm{Im}\, M_{\varphi\circ\psi} = M_\varphi(\mathfrak{m}_0 \cdot \mathrm{Im}\, M_\psi) \subset M^\triangle_\varphi(M^\triangle_j).$$

Since $\mathfrak{m}_0$ is arbitrary, the assertion follows.

(i.b): For every $i \in \mathrm{Ob}(I)$, let $\beta_i : M^\triangle_i \to M_i$ be the inclusion; we need to check that the resulting functor $\mathrm{Coker}\, \beta_\bullet : I \to \mathscr{A}$ is almost essentially zero. Indeed, let $i \in \mathrm{Ob}(I)$ and $\mathfrak{m}_0 \subset \mathfrak{m}$ any subideal of finite type; since $M_\bullet$ has the almost Mittag-Leffler property, there exists a morphism $\varphi : j \to i$ in I such that $\mathfrak{m}_0 \cdot \mathrm{Im}\, M_\varphi \subset M^\triangle_i$. Hence, $\mathfrak{m}_0$ annihilates the image of the induced morphism $\mathrm{Coker}\, \beta_j \to \mathrm{Coker}\, \beta_i$, whence the assertion.

(ii.a)⇒(ii.d): Let $L \in \mathrm{Ob}(\mathscr{A})$ with a cone $\tau_\bullet : c_L \Rightarrow M_\bullet$ such that the functors $\mathrm{Ker}\, \tau_\bullet$ and $\mathrm{Coker}\, \tau_\bullet$ are almost essentially zero. This means that for every $i \in \mathrm{Ob}(I)$ and every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type, there exists a morphism $\varphi : j \to i$ such that $\mathfrak{m}_0 \cdot \mathrm{Im}\, M_\varphi \subset \mathrm{Im}\, \tau_i$. But clearly $\mathrm{Im}\, \tau_i \subset M^\triangle_i$, so we see that $M_\bullet$ has the almost Mittag-Leffler property. By the same token, since $\mathfrak{m}_0 M^\triangle_i \subset \mathfrak{m}_0 \cdot \mathrm{Im}\, M_\varphi$, we get $\mathfrak{m}_0 M^\triangle_i \subset \mathrm{Im}\, \tau_i$, and since $\mathfrak{m}_0$ is arbitrary, we conclude that $M^\triangle_i = \mathrm{Im}\, \tau_i$ for every $i \in \mathrm{Ob}(I)$. Next, by assumption, for every $i \in \mathrm{Ob}(I)$ and every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type there exists a morphism $\varphi : j \to i$ of I such that $\mathfrak{m}_0$ annihilates the image of the induced morphism $\mathrm{Ker}\, \tau_j \to \mathrm{Ker}\, \tau_i$; but obviously the latter is a monomorphism, so the condition means that for every such $\mathfrak{m}_0$ there exists $j \in \mathrm{Ob}(I)$ such that $\mathfrak{m}_0 \cdot \mathrm{Ker}\, \tau_j = 0$. Now, let $\psi : k \to j$ be any morphism of I, and set $K := \tau_k^{-1}(\mathrm{Ker}\, M^\triangle_\psi)$; it is easily seen that $K \subset \mathrm{Ker}\, \tau_j$, hence $\mathfrak{m}_0 K = 0$, and finally $\mathfrak{m}_0 \cdot \mathrm{Ker}\, M^\triangle_\psi = 0$, since we have already established that $\tau_k : L \to M^\triangle_k$ is an epimorphism.

(ii.d)⇒(ii.b): In light of (i.b), we are reduced to checking that the functor $M^\triangle_\bullet$ is almost essentially constant. Thus, let $M^\triangle$ be the limit of the functor $M^\triangle_\bullet$, and $\tau_\bullet : c_{M^\triangle} \Rightarrow M^\triangle_\bullet$ the universal cone; let also $\mathfrak{m}_0 \subset \mathfrak{m}$ be any subideal of finite type, and pick $i \in \mathrm{Ob}(I)$ such that $\mathfrak{m}_0 \cdot \mathrm{Ker}\, M^\triangle_\varphi = 0$ for every morphism $\varphi : j \to i$ of I. Recall that the source functor $\mathsf{s}_i : I/i \to I$ is cofinal, so that $M^\triangle$ represents also the limit of $M^\triangle_\bullet \circ \mathsf{s}_i : I/i \to \mathscr{A}$. It follows easily that $\mathrm{Ker}(\tau_i : M^\triangle \to M^\triangle_i)$ represents the limit of the induced functor

$$(0 \times_{M^\triangle_i} M^\triangle_\bullet) \circ \mathsf{s}_i : I \to \mathscr{A} \qquad (j \xrightarrow{\varphi} i) \mapsto \mathrm{Ker}\, M^\triangle_\varphi = 0 \times_{M^\triangle_i} M^\triangle_j.$$

But then it is clear that $\mathfrak{m}_0 \cdot \mathrm{Ker}\, \tau_i = 0$. Especially, the functor $\mathrm{Ker}\, \tau_\bullet : I \to \mathscr{A}$ is trivially almost essentially zero. To conclude, we show that τ_i is an epimorphism for every $i \in \mathrm{Ob}(I)$. To this aim, let $\mathfrak{m}_0 \subset \mathfrak{m}$ be any subideal of finite type; in view of (i.a), we may assume that $\mathfrak{m}_0 \cdot \mathrm{Ker}\, M^\triangle_\varphi = 0$ for every morphism $\varphi : j \to i$. Hence, for every $b \in \mathfrak{m}_0$ we have a unique morphism in $\mathscr{A}$

$$f_{\varphi,b} : M_i^\triangle \to M_j^\triangle \qquad \text{such that} \qquad M_\varphi^\triangle \circ f_{\varphi,b} = b \cdot \mathbf{1}_{M_i^\triangle}.$$

By inspecting the construction, it is easily seen that $M_\psi^\triangle \circ f_{\varphi\circ\psi,b} = f_{\varphi,b}$ for every morphism $\psi : k \to j$ in I, hence the rule $\varphi \mapsto f_{\varphi,b}$ defines a cone $c_{M_i^\triangle} \Rightarrow M_\bullet^\triangle \circ \mathsf{s}_i$, whence a unique morphism of A-modules

$$h : M_i^\triangle \to M^\triangle \qquad \text{such that } f_{\varphi,b} = \tau_j \circ h \text{ for every } \varphi : j \to i.$$

Especially, $\tau_i \circ h = M_\varphi^\triangle \circ \tau_j \circ h = M_\varphi^\triangle \circ f_{\varphi,b} = b \cdot \mathbf{1}_{M_i^\triangle}$, and since $b \in \mathfrak{m}_0$ is arbitrary, the assertion follows.

(ii.b)⇒(ii.a): It suffices to prove :

Claim 14.2.19. Let $M_\bullet, M'_\bullet : I \to \mathscr{A}$ be two functors, $f_\bullet : M_\bullet \Rightarrow M'_\bullet$ a natural transformation, and suppose that $f_\bullet$ is an isomorphism in $\mathscr{L}(I, \mathscr{A})$. Then $M_\bullet$ is almost essentially constant if and only if the same holds for $M'_\bullet$.

Proof of the claim. Let L and L' be the limits of $M_\bullet$ and respectively $M'_\bullet$; denote by $\tau_\bullet : c_L \Rightarrow M_\bullet$ and $\tau'_\bullet : c_{L'} \Rightarrow M'_\bullet$ the respective universal cones. There exists a unique morphism $f : L \to L'$ in $\mathscr{A}$ that makes commute the diagram :

$$\begin{array}{ccc} c_L & \xrightarrow{c_f} & c_{L'} \\ {\scriptstyle\tau_\bullet}\downarrow & & \downarrow{\scriptstyle\tau'_\bullet} \\ M_\bullet & \xrightarrow{f_\bullet} & M'_\bullet. \end{array}$$

But lemma 14.2.14(iii) implies that f is an isomorphism; as $f_\bullet$ is an isomorphism in $\mathscr{L}(I, \mathscr{A})$, it follows that $\tau_\bullet$ is an isomorphism in $\mathscr{L}(I, \mathscr{A})$ if and only if the same holds for $\tau'_\bullet$. ◊

Lastly, clearly (c)⇒(a). Suppose then that (a) holds, and let $\tau_\bullet : c_L \Rightarrow M_\bullet$ be a universal cone; let also $\mu_\bullet : c_X \Rightarrow M_\bullet$ be another cone that is an isomorphism in $\mathscr{L}(I, \mathscr{A})$. Then there exists a unique morphism $f : X \to L$ in $\mathscr{A}$ such that $\tau_\bullet \odot c_f = \mu_\bullet$. Set $\mu := \lim_I \mu_\bullet$ and $\tau := \lim_I \tau_\bullet$, so that $\tau \circ f = \mu$. Now, τ is an isomorphism, and the same holds for $\mu_\bullet$, by lemma 14.2.14(iii); hence f is an isomorphism, so the cone $\mu_\bullet$ is universal, whence (c).

(iii): We know already that $M_\bullet$ has the almost Mittag-Leffler property (remark 14.2.12(iv)); moreover, $\operatorname{Ker} M_\varphi^\triangle \subset \operatorname{Ker} M_\varphi$ for every morphism φ of I, hence $M_\bullet$ fulfills condition (ii.c), whence the contention. □

Proposition 14.2.20. *Let $\mathscr{A}$ and $\mathscr{A}'$ be V-linear abelian categories, I a small category, $F : \mathscr{A} \to \mathscr{A}'$ a V-linear functor, and $M_\bullet, M'_\bullet : I \to \mathscr{A}$ two functors. The following holds :*

(i) *Let $f_\bullet : M_\bullet \Rightarrow M'_\bullet$ be a natural transformation. If* $\operatorname{Ker} f_\bullet$ *and* $\operatorname{Coker} f_\bullet$ *are almost essentially zero (resp. null, resp. dual almost essentially zero, resp. dual null), then the same holds for the kernel and cokernel of $Ff_\bullet : FM_\bullet \Rightarrow FM'_\bullet$.*

(ii) *If $M_\bullet$ is a Cauchy functor, the same holds for $FM_\bullet$.*

(iii) *If $M_\bullet$ is almost essentially constant (resp. dual almost essentially constant), so is $FM_\bullet$.*

(iv) *Suppose that F is right exact (resp. left exact). If $M_\bullet$ has the almost Mittag-Leffler property (resp. the dual almost Mittag-Leffler property), then the same holds for $FM_\bullet$.*

Proof. (ii): The assertion follows immediately from remark 14.2.10(vi).

(i): We can write $f_\bullet = e_\bullet \circ p_\bullet$, where $e_\bullet : I \to \mathscr{A}$ is a monomorphism of functors, and $p_\bullet : I \to \mathscr{A}$ is an epimorphism of functors, and then clearly it suffices to check the stated assertions for $e_\bullet$ and $p_\bullet$. Moreover, if the stated assertions are known for all monomorphisms of functors and all V-linear categories $\mathscr{A}$, they follow for every epimorphism as well, by considering the opposite transformation $f_\bullet^o : M'^o_\bullet \Rightarrow M^o_\bullet$ and invoking remark 14.2.10(ii).

Thus, let $f_\bullet$ be a monomorphism, $\varphi : j \to i$ any morphism in I, and $a \in V$ that annihilates the morphism $\mathrm{Coker}\, f_j \to \mathrm{Coker}\, f_i$ induced by M'_φ. The latter means that $\mathrm{Im}(aM'_\varphi) \subset \mathrm{Im}\, f_i$; it follows that there exists a morphism $g : M'_j \to M_i$ in $\mathscr{A}$ such that $f_i \circ g = aM'_\varphi$, and therefore

$$f_i \circ g \circ f_j = aM'_\varphi \circ f_j = af_i \circ M_\varphi = f_i \circ (aM_\varphi)$$

whence $g \circ f_j = aM_\varphi$, since f_i is a monomorphism. The induced identities $Ff_i \circ Fg = aFM'_\varphi$ and $Fg \circ Ff_j = aFM_\varphi$ imply that $\mathrm{Im}(aFM'_\varphi) \subset \mathrm{Im}\, Ff_i$ and $aM_\varphi(\mathrm{Ker}\, Ff_j) = 0$. Hence, if $\mathrm{Ker}\, f_\bullet$ and $\mathrm{Coker}\, f_\bullet$ are almost essentially zero (resp. dual almost essentially zero) then the same holds for $\mathrm{Ker}\, Ff_\bullet$ and $\mathrm{Coker}\, Ff_\bullet$. Combining with (ii), we deduce that if $\mathrm{Ker}\, f_\bullet$ and $\mathrm{Coker}\, f_\bullet$ are null (resp. dual null), the same follows for $\mathrm{Ker}\, Ff_\bullet$ and $\mathrm{Coker}\, Ff_\bullet$.

(iii) is an immediate consequence of (i).

(iv): As usual, the assertion in case F is left exact will follow from the assertion for the case F is right exact, by considering $M^o_\bullet$ and F^o. Hence, suppose that F is right exact and $M_\bullet$ has the almost Mittag-Leffler property. For a given subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type and $i \in \mathrm{Ob}(I)$, choose a morphism $\varphi : j \to i$ in I such that for every morphism $\psi : k \to j$ of I we have $\mathfrak{m}_0 \cdot \mathrm{Im}\, M_\varphi \subset \mathrm{Im}\, M_{\varphi\circ\psi}$. Let C be the cokernel of the morphism $\overline{M}_{\varphi\circ\psi} : M_k \to \mathrm{Im}\, M_\varphi$ of $\mathscr{A}$ induced by $M_{\varphi\circ\psi}$; the assumption means that $\mathfrak{m}_0 C = 0$. Since F is right exact, FC is the cokernel of $F\overline{M}_{\varphi\circ\psi} : FM_k \to F(\mathrm{Im}\, M_\varphi)$, and obviously $\mathfrak{m}_0 FC = 0$. By the same token, $M_\varphi : M_j \to M_i$ factors through epimorphisms $FM_j \to F(\mathrm{Im}\, M_\varphi) \to \mathrm{Im}\, FM_\varphi$; we conclude that the cokernel of the morphism $FM_k \to \mathrm{Im}\, FM_\varphi$ induced by $FM_{\varphi\circ\psi}$ is a quotient of FC, and especially is annihilated by $\mathfrak{m}_0$. The assertion follows. □

Remark 14.2.21. Keep the notation of definition 14.2.11, and let $M_\bullet : I \to \mathscr{A}$ be any functor.

(i) By unwinding the definitions, we find that $M_\bullet$ has the dual almost Mittag-Leffler property if and only if the following holds. For every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type, and every $i \in \mathrm{Ob}(I)$ there exists a morphism $\varphi : i \to j$ in I such that

$$\mathfrak{m}_0 \cdot \mathrm{Ker}\, M_{\psi\circ\varphi} \subset \mathrm{Ker}\, M_\varphi \qquad \text{for every morphism } \psi : j \to k \text{ in } I.$$

(ii) The natural isomorphism $\mathsf{Fun}(I, \mathscr{A}) \xrightarrow{\sim} \mathsf{Fun}(I^o, \mathscr{A}^o)^o$ of remark 1.1.19(i) identifies $(\mathsf{Fun}(I^o, \mathscr{A}^o)_{\text{a.ess.0}})^o$ with the full subcategory of $\mathsf{Fun}(I, \mathscr{A})$ whose objects are the dual almost essentially zero functors. Since the opposite of a Serre subcategory is a Serre subcategory, lemma 14.2.14(i) implies that the quotient

$$\mathscr{C}(I, \mathscr{A}) := \mathsf{Fun}(I, \mathscr{A})/(\mathsf{Fun}(I^o, \mathscr{A}^o)_{\text{a.ess.0}})^o$$

is again an abelian category, whose objects are the functors $I \to \mathscr{A}$.

(iii) The rest of lemma 14.2.14 dualizes as well : first, part (ii) of the lemma implies that if $\mathscr{A}$ is $\mathfrak{m}$-torsion-free and $M_\bullet$ is dual almost essentially zero, then $\mathrm{colim}_I\, M_\bullet = 0$. Next, if I is filtered, and $\mathscr{A}$ is cocomplete and $\mathfrak{m}$-torsion-free, the functor Colim_I of remark 1.3.3(ii) factors through the localization $\mathsf{Fun}(I, \mathscr{A}) \to \mathscr{C}(I, \mathscr{A})$ and a functor

$$\mathscr{C}(I, \mathscr{A}) \to \mathscr{A} \qquad M_\bullet \mapsto \operatorname*{colim}_I M_\bullet.$$

(iv) Also remark 14.2.12(ii,iii) admits a valid dual : namely, suppose that I is filtered and $\mathscr{A}$ is cocomplete. We set

$$M_i^\triangledown := \bigcup_{\varphi:i\to j} \mathrm{Ker}\, M_\varphi \subset M_i \qquad \text{for every } i \in \mathrm{Ob}(I).$$

Then, arguing as in 14.2.12(ii) one easily checks that M_φ restricts to a morphism

$$M_\psi^\triangledown : M_i^\triangledown \to M_{i'}^\triangledown \qquad \text{for every morphism } \psi : i \to i' \text{ in } I$$

whence an induced functor $M_\bullet^\triangledown : I \to \mathscr{A}$, and a direct inspection of the definitions shows that

$$(M_\bullet^\triangledown)_\bullet^\triangledown = M_\bullet^\triangledown. \qquad (14.2.22)$$

Notice moreover that every cocone $\tau : M_\bullet \Rightarrow c_L$ factors (uniquely) through the projection $\pi_\bullet : M_\bullet \to M_\bullet/M_\bullet^\triangledown$. Combining with (14.2.22) we deduce that

$$\operatorname*{colim}_I M_\bullet^\triangledown = 0$$

and furthermore, $\pi_\bullet$ induces an isomorphism in $\mathscr{A}$:

$$\operatorname*{colim}_I M_\bullet \xrightarrow{\sim} \operatorname*{colim}_I M_\bullet/M_\bullet^\triangledown.$$

(v) Under the assumptions of (iv), we deduce that $M_\bullet$ has the dual almost Mittag-Leffler property if and only if for every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type and every $i \in \mathrm{Ob}(I)$ there exists a morphism $\varphi : i \to j$ such that $\mathfrak{m}_0 \cdot M_i^\triangledown \subset \operatorname{Ker} M_\varphi$. In the case where $\mathscr{A} = A$-$\mathbf{Mod}$ for a given $(V, \mathfrak{m})^a$-algebra A, it follows that for every $i \in \mathrm{Ob}(I)$ the system $(\operatorname{Ker} M_\varphi \mid \varphi : i \to j)$ is a Cauchy net in the uniform space $\mathscr{I}_A(M_i)$, and its unique limit is the A-submodule $M_i^\triangledown$.

(vi) Suppose that I is filtered, and is $\mathscr{A}$ is cocomplete and $\mathfrak{m}$-torsion-free. Then :

- By dualizing proposition 14.2.18(ii), we see that the following conditions are equivalent :
  - (a) $M_\bullet$ is dual almost essentially constant.
  - (b) $M_\bullet$ is isomorphic to a constant functor, in the category $\mathscr{C}(I, \mathscr{A})$ of remark 14.2.21(ii).
  - (c) $M_\bullet$ has the dual almost Mittag-Leffler property, and for every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type, there exists $i \in \mathrm{Ob}(I)$ such that $\mathfrak{m}_0$ annihilates the cokernel of the morphism

$$M_i/M_i^\triangledown \to M_j/M_j^\triangledown \qquad (14.2.23)$$

induced by M_φ, for every morphism $\varphi : i \to j$ in I (notation of remark 14.2.21(iv)).

- Moreover, the dual of proposition 14.2.18(i) states that if $M_\bullet$ has the dual almost Mittag-Leffler property, then (14.2.23) is a monomorphism for every morphism $\varphi : i \to j$ in I, and the projections $(M_i \to M_i/M_i^\triangledown \mid i \in \mathrm{Ob}(I))$ define an isomorphism $M_\bullet \xrightarrow{\sim} M_\bullet/M_\bullet^\triangledown$ in $\mathscr{C}(I, \mathscr{A})$.

Lemma 14.2.24. *In the situation of definition* 14.2.11*, let A be any $(V, \mathfrak{m})^a$-algebra, $M_\bullet$: $\mathbb{N}^o \to A$-$\mathbf{Mod}$ a functor whose transition morphisms $M_{m,n} : M_m \to M_n$ are epimorphisms for every $m, n \in \mathbb{N}$, and set $L := \lim_{n\in\mathbb{N}} M_n$. Then we have :*

(i) *The universal cone $\tau_\bullet : c_L \Rightarrow M_\bullet$ is an epimorphism of functors.*

(ii) $\lim^1_{n\in\mathbb{N}} M_n = 0$.

(iii) *For every almost finitely generated (resp. almost finite projective) A-module N, the cone $N \otimes_A \tau_\bullet$ induces an epimorphism (resp. an isomorphism)*

$$\varphi_N : N \otimes_A L \to \lim_{n\in\mathbb{N}} N \otimes_A M_n.$$

(iv) *More generally, if N is an A-module and $a \in A_*$ such that $a \cdot \mathbf{1}_N$ factors as a composition of A-linear morphisms $N \xrightarrow{\alpha} N_0 \xrightarrow{\beta} N$ with N_0 almost finitely generated (resp. almost finite projective), then $a \cdot \operatorname{Coker} \varphi_N = 0$ (resp. $a \cdot \operatorname{Ker} \varphi_N = 0$).*

Proof. (i): Let $M_{\bullet!} : \mathbb{N}^o \to A_*$-$\mathbf{Mod}$ be the composition of $M_\bullet$ with the left adjoint $(-)_! :$ A-$\mathbf{Mod} \to A_*$-$\mathbf{Mod}$ of the localization $(-)^a$. Set $T := \lim_{n\in\mathbb{N}} M_{n!}$, and let $\mu_\bullet : c_T \Rightarrow M_{\bullet!}$ be the universal cone; then $L = T^a$ and the natural isomorphism $M_\bullet \xrightarrow{\sim} (M_{\bullet!})^a$ identifies $\tau_\bullet$ with $\mu_\bullet^a$. Thus, it suffices to check that $\mu_\bullet$ is an epimorphism of functors. However, the transition morphisms $(M_{m,n})_! : M_{m!} \to M_{n!}$ are surjective, so the assertion is clear.

(ii): Recall that for every functor $M_\bullet : \mathbb{N}^o \to A$-$\mathbf{Mod}$ (resp. $N_\bullet : \mathbb{N}^o \to A_*$-$\mathbf{Mod}$) the right derived functor $R\lim_{\mathbb{N}^o} M_\bullet$ (resp. $R\lim_{\mathbb{N}^o} N_\bullet$) is computed by a natural two-term complex $\Pi(M_\bullet)$ (resp. $\Pi(N_\bullet)$) : see [163, §3.5]. With this notation, we have $\Pi(M_\bullet) = \Pi(M_{\bullet!})^a$, since the localization $(-)^a$ commutes with all products. However, $\lim^1_{n\in\mathbb{N}} M_{n!} = 0$, since the transition morphisms $(M_{m,n})_!$ are surjective ([163, Lemma 3.5.3]). The assertion follows.

(iii): Suppose first that N is finitely generated; hence there exists $r \in \mathbb{N}$ and a short exact sequence $0 \to K \to A^{\oplus r} \to N \to 0$ of A-modules. For every $n \in \mathbb{N}$, let $C_n \subset A^{\oplus r} \otimes_A M_n$ be the image of $K \otimes_A M_n$; we get an inverse system $(C_n \mid n \in \mathbb{N})$ whose transition morphisms are also epimorphisms (details left to the reader). By virtue of (ii), there follows an epimorphism of A-modules

$$\lim_{n\in\mathbb{N}} A^{\oplus r} \otimes_A M_n = A^{\oplus r} \otimes_A L \xrightarrow{\psi} \lim_{n\in\mathbb{N}} N \otimes_A M_n.$$

Lastly, it is easily seen that ψ factors through φ_N and the induced morphism $A^{\oplus r} \otimes_A L \to N \otimes_A L$, whence the contention in this case. Next, consider the functor

$$T : A_*\text{-}\mathbf{Mod} \to A_*\text{-}\mathbf{Mod} \qquad X \mapsto (\mathrm{Coker}\,\varphi_{X^a})_*$$

that assigns to every A-linear morphism $f : N \to N'$ the induced map $(\mathrm{Coker}\,\varphi_{N^a})_* \to (\mathrm{Coker}\,\varphi_{N'^a})_*$ of A_*-modules. It is easily seen that T is V-homogeneous of degree 1 (see definition 14.1.53), and the associated functor $T^a : A\text{-}\mathbf{Mod} \to A\text{-}\mathbf{Mod}$ is given by the rule: $N \mapsto \mathrm{Coker}\,\varphi_N$ for every A-module N (notation of remark 14.1.54(ii)). By the foregoing, $T^a N = 0$ whenever N is finitely generated; however, on the one hand, for every suitable pair of infinite cardinalities ω, ω' the associated map $\mathscr{M}_{\omega,\omega'}(T^a) : \mathscr{M}_\omega(A) \to \mathscr{M}_{\omega'}(A)$ is uniformly continuous (proposition 14.1.56(iii)), and on the other hand, it is easily seen that the subset $\{0\}$ is closed in the topology of the uniform space $\mathscr{M}(A)$. Hence, $T^a N = 0$ for every almost finitely generated A-module, as stated.

Next, suppose that N is almost finite projective; then for every $a \in \mathfrak{m}$ there exists $r \in \mathbb{N}$ and A-linear morphisms $N \xrightarrow{\alpha} A^{\oplus r} \xrightarrow{\beta} N$ whose composition is $a \cdot \mathbf{1}_N$ ([75, Lemma 2.4.15]). There follows a commutative diagram :

$$\begin{array}{ccccc} N \otimes_A L & \xrightarrow{\alpha\otimes_A L} & A^{\oplus r} \otimes_A L & \xrightarrow{\beta\otimes_A L} & N \otimes_A L \\ \downarrow{\scriptstyle \varphi_N} & & \downarrow & & \downarrow{\scriptstyle \varphi_N} \\ \lim_{n\in\mathbb{N}} N \otimes_A M_n & \longrightarrow & \lim_{n\in\mathbb{N}} A^{\oplus r} \otimes_A M_n & \longrightarrow & \lim_{n\in\mathbb{N}} N \otimes_A M_n \end{array}$$

whose central arrow is an isomorphism, and we already know that φ_N is an epimorphism. By a simple diagram chase we deduce that $a \cdot \mathrm{Ker}\,\varphi_N = 0$, and since a is arbitrary, we conclude that φ_N is an isomorphism in this case, as stated.

(iv): In light of (iii) we have : $a \cdot \mathbf{1}_{TN} = T\beta \circ T\alpha = 0$, *i.e.* $a \cdot \mathrm{Coker}\,\varphi_N = 0$. If N_0 is almost finite projective, consider the functor $T' : A^a\text{-}\mathbf{Mod} \to A^a\text{-}\mathbf{Mod}$ such that $T'X := \mathrm{Ker}\,\varphi_X$ for every A^a-module X : by (iii) we have $T'N_0 = 0$, whence $a \cdot \mathbf{1}_{T'N} = 0$. ☐

Proposition 14.2.25. *In the situation of definition* 14.2.11*, let A be any $(V,\mathfrak{m})^a$-algebra, $M_\bullet : I \to A\text{-}\mathbf{Mod}$ any functor, and $\tau_\bullet : c_L \Rightarrow M_\bullet$ and $\tau'_\bullet : M_\bullet \Rightarrow c_{L'}$ be respectively a universal cone and a universal cocone. We have :*

(i) *Suppose that I is cofiltered and consider the following conditions :*

(a) *The functor* $\mathrm{Coker}\,\tau_\bullet$ *is almost essentially zero.*

(b) *$M_\bullet$ has the almost Mittag-Leffler property.*

Then (a)⇒(b)*, and if there exists a coinitial functor* $\mathbb{N}^o \to I$*, then* (b)⇒(a)*.*

(ii) *Suppose that is I filtered. Then $M_\bullet$ has the dual almost Mittag-Leffler property if and only if the functor* $\mathrm{Ker}\,\tau'_\bullet$ *is dual almost essentially zero.*

(iii) *Suppose that $I = \mathbb{N}^o$, where $\mathbb{N}$ is endowed with its standard total ordering. If $M_\bullet$ has the almost Mittag-Leffler property, then* $\lim^1_{n\in\mathbb{N}} M_n = 0$.

Proof. (iii): Suppose first that $M_\bullet$ is almost essentially zero, and consider, for every finitely generated subideal $\mathfrak{m}_0 \subset \mathfrak{m}$, the short exact sequence of functors

$$\Sigma_\bullet \quad : \quad 0 \to M_\bullet[\mathfrak{m}_0] \to M_\bullet \to M_\bullet/M_\bullet[\mathfrak{m}_0] \to 0$$

whose right-most term is an essentially zero inverse system, by remark 14.2.12(i)), and therefore

$$\lim_{n\in\mathbb{N}} M_n/M_n[\mathfrak{m}_0] = \lim_{n\in\mathbb{N}}{}^1 M_n/M_n[\mathfrak{m}_0] = 0.$$

On the other hand, clearly $\mathfrak{m}_0$ annihilates $\lim^1_{n\in\mathbb{N}} M_n[\mathfrak{m}_0]$. From the long exact cohomology sequence associated with $\Sigma_\bullet$ it follows that $\mathfrak{m}_0$ annihilates as well $\lim^1_{n\in\mathbb{N}} M_n$. Since $\mathfrak{m}_0$ is arbitrary, the claim follows in this case.

Next, let $M_\bullet$ be an arbitrary functor with the almost Mittag-Leffler property; for every $m, n \in \mathbb{N}$ with $m > n$, we let $M_{m,n} : M_m \to M_n$ be the transition morphism. By proposition 14.2.18(i.a), the restriction $M^\triangle_{p,n} : M^\triangle_m \to M^\triangle_n$ of $M_{m,n}$ is an epimorphism for every such n and p. Let us then consider the short exact sequence of inverse systems

$$\Sigma'_\bullet \quad : \quad 0 \to M^\triangle_\bullet \to M_\bullet \to M_\bullet/M^\triangle_\bullet \to 0.$$

Proposition 14.2.18(i.b) implies that $M_\bullet/M^\triangle_\bullet$ is almost essentially zero, so $\lim^1_{n\in\mathbb{N}} M_n/M^\triangle_n = 0$, by the previous case; also, $\lim^1_{n\in\mathbb{N}} M^\triangle_n = 0$, by lemma 14.2.24(ii). The assertion follows then, by considering the long exact $R\lim$ sequence associated with $\Sigma'_\bullet$.

(i.a)⇒(i.b): By assumption, for every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type and every $i \in \mathrm{Ob}(I)$ there exists a morphism $\varphi : j \to i$ in I such that $\mathfrak{m}_0$ annihilates the image of the induced morphism $\mathrm{Coker}\,\tau_j \to \mathrm{Coker}\,\tau_i$. The latter means that $\mathfrak{m}_0 \cdot \mathrm{Im}\,M_\varphi \subset \mathrm{Im}\,\tau_i$; but clearly $\mathrm{Im}\,\tau_i \subset \mathrm{Im}\,M_{\varphi\circ\psi}$ for every morphism $\psi : k \to j$ in I, whence the contention.

Next, suppose that there exists a coinitial functor $\lambda : \mathbb{N}^o \to I$, and that $M_\bullet$ has the almost Mittag-Leffler property; notice that τ_i factors through a morphism $\mu_i : L \to M^\triangle_i$ and the inclusion $M^\triangle_i \to M_i$, for every $i \in \mathrm{Ob}(I)$. There follows a short exact sequence of functors :

$$\mathrm{Coker}\,\mu_\bullet \to \mathrm{Coker}\,\tau_\bullet \to M_\bullet/M^\triangle_\bullet \to 0.$$

By proposition 14.2.18(i.b), $M_\bullet/M^\triangle_\bullet$ is almost essentially zero, hence L also represents the limit of $M^\triangle_\bullet$, and $\mu_\bullet$ is a universal cone; by lemma 14.2.14(i) it then suffices to show that $\mathrm{Coker}\,\mu_\bullet = 0$. Now, $\mu_\bullet * \lambda : c_L \Rightarrow M^\triangle_\bullet \circ \lambda$ is still a universal cone (remark 1.5.5(ii,iii)). Since we also know that $M^\triangle_\varphi$ is an epimorphism for every morphism φ of I (proposition 14.2.18(i.a)), we are then reduced to checking that $\mu_{\lambda(n)} : L \to M^\triangle_{\lambda(n)}$ is an epimorphism for every $n \in \mathbb{N}$. The latter follows from lemma 14.2.24(i).

(ii): Suppose that $\mathrm{Ker}\,\tau'_\bullet$ is dual almost essentially zero; this means that for every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type, and every $i \in \mathrm{Ob}(I)$ there exists a morphism $\varphi : i \to j$ in I such that $M_\varphi(\mathfrak{m}_0 \cdot \mathrm{Ker}\,\tau'_i) = 0$. But we have $\mathrm{Ker}\,M_{\psi\circ\varphi} \subset \mathrm{Ker}\,\tau'_i$ for every morphism $\psi : j \to k$ in I; whence $\mathfrak{m}_0 \cdot \mathrm{Ker}\,M_{\psi\circ\varphi} \subset \mathrm{Ker}\,M_\varphi$ for every such ψ. Hence $M_\bullet$ has the dual Mittag-Leffler property, by remark 14.2.21(i). Conversely, suppose that $M_\bullet$ has the dual Mittag-Leffler property; we know that the functor $M^\triangledown_\bullet$ is almost essentially zero (remark 14.2.21(vi)) hence it suffices to check that $M^\triangledown_i = \mathrm{Ker}\,\tau'_i$ for every $i \in \mathrm{Ob}(I)$. After replacing I by i/I, we may assume that i is an initial object of I, whence an induced cone $\mu_\bullet : c_{M_i} \Rightarrow M_\bullet$, and notice that $M^\triangledown_i = \mathrm{colim}_I\,\mathrm{Ker}\,\mu_\bullet$. On the other hand, $\mathrm{colim}_I\,\mu_\bullet = \tau'_i$; since filtered colimits in A-**Mod** are exact, the assertion follows. □

14.2.26. *Pontryagin duality.* Recall that for every ring R and every R-module N, we have a natural R-module structure on

$$N^\vee := \mathrm{Hom}_\mathbb{Z}(N, \mathbb{Q}/\mathbb{Z}).$$

Namely, for every $a \in R$ and every $\mathbb{Z}$-linear map $\varphi : N \to \mathbb{Q}/\mathbb{Z}$ we set $a \cdot \varphi := \varphi \circ (a\mathbf{1}_N)$. Especially, $R^\vee$ is naturally an R-module, and there follows a natural R-linear isomorphism :

$$\mathrm{Hom}_R(N, R^\vee) \xrightarrow{\sim} N^\vee$$

assigning to every R-linear map $\varphi : N \to R^\vee$ the $\mathbb{Z}$-linear map $\varphi' : N \to \mathbb{Q}/\mathbb{Z}$ such that $\varphi'(n) := \varphi(n)(1)$ for every $n \in N$. Its inverse assigns to every $\mathbb{Z}$-linear map $\psi : N \to \mathbb{Q}/\mathbb{Z}$ the homomorphism of R-modules $\psi' : N \to R^\vee$ that sends every $n \in N$ to the $\mathbb{Z}$-linear map $\psi'(n) : R \to \mathbb{Q}/\mathbb{Z}$ such that $\psi'(n)(a) := \psi(an)$ for every $a \in R$. Since $\mathbb{Q}/\mathbb{Z}$ is an injective $\mathbb{Z}$-module, there results an exact functor

$$R\text{-}\mathbf{Mod} \to R\text{-}\mathbf{Mod}^o \qquad N \mapsto N^\vee.$$

Moreover, it is easily seen that the natural *biduality R-linear map* is an injection :

$$N \to N^{\vee\vee} \qquad \text{for every } R\text{-module } N.$$

Let now $(V, \mathfrak{m})$ be a basic setup, and A a $(V, \mathfrak{m})^a$-algebra; we consider the associated A-module

$$J_A := ((A_*)^\vee)^a$$

and from the foregoing it is easily seen that the *Pontryagin duality* functor

$$(-)^\vee : A\text{-}\mathbf{Mod} \to A\text{-}\mathbf{Mod}^o \qquad M \mapsto M^\vee := \mathrm{alHom}_A(M, J_A)$$

is again exact and V-linear, where $\mathrm{alHom}_A(-,-)$ denotes the bifunctor of *almost homomomorphisms* defined as in [75, §2.2.11]; indeed, we have a natural isomorphism of A-modules

$$M^\vee \xrightarrow{\sim} ((M_*)^\vee)^a \qquad \text{for every } A\text{-module } M$$

(details left to the reader). Moreover, it follows that the biduality morphism $M \to M^{\vee\vee}$ is a monomorphism of A-modules; especially, $(-)^\vee$ is a conservative functor.

Remark 14.2.27. (i) For every small category I, we get a natural extension of Pontryagin duality to functors $I \to A\text{-}\mathbf{Mod}$. Namely, we have a conservative exact functor :

$$\mathsf{Fun}(I, A\text{-}\mathbf{Mod})^o \to \mathsf{Fun}(I^o, A\text{-}\mathbf{Mod}) \qquad M_\bullet \mapsto M_\bullet^\vee := (-)^\vee \circ M_\bullet.$$

(ii) For every A-module M, and every A-submodule $N \subset M$, let $i_N : N \to M$ the inclusion; it is easily seen that the induced map

$$\mathscr{I}_A(M) \to \mathscr{I}_A(M^\vee) \qquad N \mapsto \mathrm{Ker}(i_N^\vee : M^\vee \to N^\vee)$$

is uniformly continuous, for the uniform structures defined as in [75, Def.2.3.1(i)].

(iii) Then, if I is cofiltered, and $M_\bullet : I \to A\text{-}\mathbf{Mod}$ is any functor with the almost Mittag-Leffler property, combining with remarks 14.2.12(iii) and 14.2.21(v) we deduce that the A-linear epimorphism $i^\vee_{M_i^\triangle} : M_i^\vee \to (M_i^\triangle)^\vee$ factors through an isomorphism of A-modules

$$M_i^\vee/(M_\bullet^\vee)_i^\triangledown \xrightarrow{\sim} (M_i^\triangle)^\vee \qquad \text{for every } i \in \mathrm{Ob}(I).$$

Lemma 14.2.28. *With the notation of remark* 14.2.27*, for every functor* $M_\bullet : I \to A\text{-}\mathbf{Mod}$ *the following holds :*

(i) *$M_\bullet$ is essentially zero (resp. almost essentially zero) if and only if $M_\bullet^\vee$ is dual essentially zero (resp. dual almost essentially zero).*

(ii) *Suppose that I is cofiltered. Then $M_\bullet$ is almost essentially constant (resp. has the almost Mittag-Leffler property) if and only if $M_\bullet^\vee$ is dual almost essentially constant (resp. has the dual almost Mittag-Leffler property).*

Proof. (i): By direct inspection we see that if $M_\bullet$ is essentially zero (resp. almost essentially zero), then $M^\vee$ is dual essentially zero (resp. dual almost essentially zero). Likewise, if $M_\bullet$ is dual essentially zero (resp. dual almost essentially zero), then $M^\vee$ is essentially zero (resp. almost essentially zero). From this, the converse assertions follow easily, since the biduality morphism $M_\bullet \to M_\bullet^{\vee\vee}$ is a monomorphism.

(ii): For a given pair of morphisms $k \xrightarrow{\psi} j \xrightarrow{\varphi} i$ of I, set $N := \mathrm{Im} M_\varphi / \mathrm{Im}\, M_{\varphi\circ\psi}$. Since Pontryagin duality is exact and conservative, for every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ we have :

$$\mathfrak{m}_0 N = 0 \Leftrightarrow \mathfrak{m}_0 N^\vee = 0 \Leftrightarrow \mathfrak{m}_0 \cdot \mathrm{Ker}(\mathrm{Im}\, M^\vee_{\varphi\circ\psi} \to M^\vee_\varphi) = 0 \Leftrightarrow \mathfrak{m}_0 \mathrm{Ker}\, M^\vee_{\varphi\circ\psi} \subset \mathrm{Ker} M^\vee_\varphi.$$

Taking into account remark 14.2.21(i), we deduce that $M_\bullet$ has the almost Mittag-Leffler property if and only if $M^\vee_\bullet$ has the dual almost Mittag-Leffler property.

Next, proposition 14.2.20(ii) implies that if $M_\bullet$ is almost essentially constant, then $M^\vee_\bullet$ is dual almost essentially constant. Conversely, if $M^\vee_\bullet$ is dual almost essentially constant, then $M^\vee_\bullet$ has the dual almost Mittag-Leffler property, and for every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type there exists $i \in \mathrm{Ob}(I)$ with

$$\mathfrak{m}_0 \cdot \mathrm{Coker}(M^\vee_i / (M^\vee_\bullet)^\nabla_i \to M^\vee_j / (M^\vee_\bullet)^\nabla_j) = 0 \qquad \text{for every morphism } i \xrightarrow{\varphi} j \tag{14.2.29}$$

(remark 14.2.21(vi)). By the foregoing, we deduce already that $M_\bullet$ has the almost Mittag-Leffler property. Moreover, by remark 14.2.27(iii), condition (14.2.29) is equivalent to :

$$\mathfrak{m}_0 \cdot \mathrm{Coker}((M^\triangle_i)^\vee \to (M^\triangle_j)^\vee) = 0 \qquad \text{for every morphism } i \xrightarrow{\varphi} j.$$

But $\mathrm{Coker}((M^\triangle_i)^\vee \to (M^\triangle_j)^\vee) = (\mathrm{Ker}\, M^\triangle_\varphi)^\vee$, and in light of proposition 14.2.18(ii), we deduce that $M_\bullet$ is almost essentially constant. □

Proposition 14.2.30. *Let I be a small cofiltered category, and*

$$0 \to M'_\bullet \to M_\bullet \to M''_\bullet \to 0$$

a short exact sequence of functors $I \to A$-$\mathbf{Mod}$. We have:

(i) *If $M'_\bullet$ and $M''_\bullet$ are almost essentially constant (resp. have the almost Mittag-Leffler property), then the same holds for $M_\bullet$.*

(ii) *If $M_\bullet$ has the almost Mittag-Leffler property, the same holds for $M''_\bullet$.*

(iii) *If $M_\bullet$ has the almost Mittag-Leffler property and $M''_\bullet$ is almost essentially constant, then $M'_\bullet$ has the almost Mittag-Leffler property.*

(iv) *If $f_\bullet : X_\bullet \to Y_\bullet$ is a natural transformation between almost essentially constant functors, then* Ker $f_\bullet$ *and* Coker $f_\bullet$ *are almost essentially constant.*

Proof. (ii) is clear from the definitions.

(iv): By proposition 14.2.18(ii), the universal cones $\tau^X_\bullet : c_X \Rightarrow X_\bullet$ and $\tau^Y_\bullet : c_X \Rightarrow Y_\bullet$ are isomorphisms in $\mathscr{L}(I, A\text{-}\mathbf{Mod})$. Thus, there exists a unique morphism $f : X \to Y$ of A-modules that makes commute the diagram

$$\begin{array}{ccc} c_X & \xrightarrow{c_f} & c_Y \\ {\scriptstyle \tau^X_\bullet}\downarrow & & \downarrow{\scriptstyle \tau^Y_\bullet} \\ X_\bullet & \xrightarrow{f_\bullet} & Y_\bullet \end{array}$$

whose vertical arrows are isomorphism in $\mathscr{L}(I, A\text{-}\mathbf{Mod})$. Set $K := \mathrm{Ker}\, f$ and $C := \mathrm{Coker}\, f$; there follow induced isomorphisms $c_K \xrightarrow{\sim} \mathrm{Ker}\, f_\bullet$ and $c_C \xrightarrow{\sim} \mathrm{Coker}\, f_\bullet$ in $\mathscr{L}(I, A\text{-}\mathbf{Mod})$, whence the contention, in light of proposition 14.2.18(ii).

(i): Let L, L' and L'' be the colimits of the functors $M^\vee_\bullet, M'^\vee_\bullet$ and respectively $M''^\vee_\bullet$; since filtered colimits are exact in the category A-$\mathbf{Mod}$, we get a commutative diagram of functors with exact rows :

$$\begin{array}{ccccccccc} 0 & \to & M''^\vee_\bullet & \to & M^\vee_\bullet & \to & M'^\vee_\bullet & \to & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \to & c_{L''} & \to & c_L & \to & c_{L'} & \to & 0 \end{array}$$

whose vertical arrows are the universal cocones. Consider first the case where $M'_\bullet$ and $M''_\bullet$ are almost essentially constant; then $M'^\vee_\bullet$ and $M''^\vee_\bullet$ are dual almost essentially constant (lemma 14.2.28(ii)), and arguing as in the proof of (iv) we deduce that the first and third vertical arrows are isomorphisms in the quotient category $\mathscr{C}(I, A\text{-}\mathbf{Mod})$, hence the same holds for the middle one, by the 5-lemma. Then $M^\bullet_\bullet$ is dual almost essentially constant, by remark 14.2.21(vi), hence $M_\bullet$ is almost essentially constant, again by lemma 14.2.28(ii).

Next, if $M'_\bullet$ and $M''_\bullet$ have the almost Mittag-Leffler property, then $M'^\vee_\bullet$ and $M''^\vee_\bullet$ have the dual almost Mittag-Leffler property (lemma 14.2.28(ii)), hence the kernels of the first and third vertical arrows are dual almost essentially zero (proposition 14.2.25(ii)). Then the same holds for the kernel of the middle vertical arrow, so $M^\vee_\bullet$ has the dual almost Mittag-Leffler property, again by proposition 14.2.25(ii); finally, $M_\bullet$ has the almost Mittag-Leffler property, by lemma 14.2.28(ii).

(iii): We consider again the induced commutative ladder with exact rows. Arguing as in the proof of (ii), we see that the kernel of the middle vertical arrow and the cokernel of the left-most vertical arrow are both dual almost essentially zero, hence the same holds for the kernel of the right-most vertical arrow, by the snake lemma. Then $M'^\vee_\bullet$ has the dual almost Mittag-Leffler property, by proposition 14.2.25(ii), and finally, $M'_\bullet$ has the almost Mittag-Leffler property, by lemma 14.2.28(ii). □

14.2.31. Let us now consider a basic setup $(V, \mathfrak{m})$, a (small) cofiltered category I, and a functor

$$I \to (V, \mathfrak{m})^a\text{-}\mathsf{Alg.Mod} \qquad i \mapsto (A_i, M_i)$$

where $(V, \mathfrak{m})^a$-$\mathsf{Alg.Mod}$ is defined as in [75, Def.2.5.22(ii)]. Hence, for every $i \in \mathrm{Ob}(I)$, the pair (A_i, M_i) consists of a $(V, \mathfrak{m})^a$-algebra A_i, and an A_i-module M_i. To each morphism $\varphi : j \to i$ of I, the functor assigns a pair $(A_\varphi, g_\varphi) : (A_j, M_j) \to (A_i, M_i)$, where $A_\varphi : A_j \to A_i$ is a morphism of $(V, \mathfrak{m})^a$-algebras, and $g_\varphi : A_i \otimes_{A_j} M_j \to M_i$ is an A_i-linear morphism. We get two obvious induced functors

$$A_\bullet : I \to (V, \mathfrak{m})^a\text{-}\mathsf{Alg} \qquad M_\bullet : I \to (V, \mathfrak{m})^a\text{-}\mathbf{Mod}.$$

Namely, for every morphism φ as in the foregoing we let $M_\varphi : M_j \to M_i$ be the composition of g_φ with the natural A_j-linear morphism $M_j \to A_i \otimes_{A_j} M_j$. Set also

$$A := \lim_I A_\bullet \qquad \text{and} \qquad M := \lim_I M_\bullet.$$

Notice that $A_\bullet$ (resp. $M_\bullet$) can also be viewed as a functor with values in A-Alg (resp. A-$\mathbf{Mod}$).

Proposition 14.2.32. *With the notation of* (14.2.31)*, the following holds :*

(i) *If $A_\bullet : I \to A\text{-}\mathbf{Mod}$ has the almost Mittag-Leffler property, and g_φ is an epimorphism for every morphism φ of I, then $M_\bullet : I \to A\text{-}\mathbf{Mod}$ has the almost Mittag-Leffler property.*

(ii) *Suppose that g_φ is an isomorphism for every morphism φ of I. Then, if $A_\bullet : I \to A\text{-}\mathbf{Mod}$ is almost essentially constant (resp. is a Cauchy functor), the same holds for $M_\bullet$.*

(iii) *Moreover, under the assumptions of* (i) *(resp.* (ii)*), the natural morphism*

$$\alpha_i : A_i \otimes_A M_i^\triangle \to M_i \qquad (\textit{resp. } \beta_i : A_i \otimes_A M \to M_i\ )$$

is an epimorphism (resp. an isomorphism) for every $i \in \mathrm{Ob}(I)$.

(iv) *Lastly, under the assumptions of* (i)*, if there exists a coinitial functor $\mathbb{N}^o \to I$, then β_i is an epimorphism for every $i \in \mathrm{Ob}(I)$.*

Proof. We fix universal cones $\tau^A_\bullet : c_A \Rightarrow A_\bullet$ and $\tau^M_\bullet : c_M \Rightarrow M_\bullet$.

Claim 14.2.33. Assertions (ii) and (iii) hold if $A_\bullet$ is a Cauchy functor and g_φ is an isomorphism for every morphism φ of I.

Proof of the claim. Indeed, in this case for every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type we find $i \in \mathrm{Ob}(I)$ such that for every morphism $\varphi : j \to i$ we have $\mathfrak{m}_0 \cdot \mathrm{Ker}\, A_\varphi = \mathfrak{m}_0 \cdot \mathrm{Coker}\, A_\varphi = 0$. By virtue of remark 14.2.10(vi), it follows that $\mathfrak{m}_0^2$ annihilates the kernel and cokernel of $A_\varphi \otimes_{A_j} M_j$, for every such φ. Since g_φ is an isomorphism, it follows that $\mathfrak{m}_0^2 \cdot \mathrm{Ker}\, M_\varphi = \mathfrak{m}_0^2 \cdot \mathrm{Coker}\, M_\varphi = 0$, for every such φ. This shows that $M_\bullet$ is a Cauchy functor.

Next, notice that $\mathrm{Ker}\, \tau^A_\bullet$ and $\mathrm{Coker}\, \tau^A_\bullet$ are also Cauchy functors (remark 14.2.17(ii)), and moreover they are almost essentially zero, since $A_\bullet$ is almost essentially constant (proposition 14.2.18(ii,iii)). Hence, $\mathrm{Ker}\, \tau^A_\bullet$ and $\mathrm{Coker}\, \tau^A_\bullet$ are null. The same argument shows that $\mathrm{Ker}\, \tau^M_\bullet$ and $\mathrm{Coker}\, \tau^M_\bullet$ are null, since $M_\bullet$ is a Cauchy functor. Moreover, the kernel and cokernel of $\tau^A_\bullet \otimes_A M$ are null as well, since the functor $- \otimes_A M : A\text{-}\mathbf{Mod} \to A\text{-}\mathbf{Mod}$ is V-linear (proposition 14.2.20(i)). Since we have :

$$\beta_i \circ (\tau^A_i \otimes_A M) = \tau^M_i \qquad \text{for every } i \in \mathrm{Ob}(I)$$

and as the null functors form a full Serre subcategory of $\mathsf{Fun}(I, A\text{-}\mathbf{Mod})$ (remark 14.2.12(v)), it follows that also $\mathrm{Ker}\, \beta_\bullet$ and $\mathrm{Coker}\, \beta_\bullet$ are null functors. Now, let $\mathfrak{m}_0 \subset \mathfrak{m}$ be a subideal of finite type, and $i \in \mathrm{Ob}(I)$; since I is cofiltered, we deduce that there exists a morphism $\varphi : j \to i$ such that $\mathfrak{m}_0 \cdot \mathrm{Ker}\, \beta_j = \mathfrak{m}_0 \cdot \mathrm{Coker}\, \beta_j = 0$. Since the functor $A_i \otimes_{A_j} - : A_j\text{-}\mathbf{Mod} \to A_i\text{-}\mathbf{Mod}$ is V-linear, it follows that $\mathfrak{m}_0^2$ annihilates the kernel and cokernel of $A_i \otimes_{A_j} \beta_j : A_i \otimes_A M \to A_i \otimes_{A_j} M_j$ (remark 14.2.10(vi)). But notice that

$$g_\varphi \circ (A_i \otimes_{A_j} \beta_j) = \beta_i.$$

So finally $\mathfrak{m}_0^2 \cdot \mathrm{Ker}\, \beta_i = \mathfrak{m}_0^2 \cdot \mathrm{Coker}\, \beta_i = 0$. Since $\mathfrak{m}_0$ is arbitrary, we conclude that β_i is an isomorphism, as stated. $\Diamond$

We can now complete the proof of (ii) and (iii), for the case where $A_\bullet$ is almost essentially constant, and g_φ is still an isomorphism for every morphism φ of I. To this aim, set

$$\overline{A}_\varphi := \mathrm{Im}\, A_\varphi \quad \text{and} \quad \overline{M}_\varphi := \overline{A}_\varphi \otimes_{A_j} M_j \qquad \text{for every morphism } \varphi : j \to i \text{ of } I.$$

Let $j \xrightarrow{\varphi} i$ and $j' \xrightarrow{\varphi'} i'$ be two object of $\mathsf{Morph}(I)$, and $(\psi, \psi') : \varphi' \to \varphi$ a morphism of $\mathsf{Morph}(I)$; by definition, $\psi : j' \to j$ and $\psi' : i' \to i$ are morphisms in I such that $\psi' \circ \varphi' = \varphi \circ \psi$, and then it is clear that $A_{\psi'}$ restricts to a morphism of $(V, \mathfrak{m})^a$-algebras

$$\overline{A}_{(\psi,\psi')} : \overline{A}_{\varphi'} \to \overline{A}_\varphi.$$

Then, $M_\psi : M_{j'} \to M_j$ induces a $\overline{A}_\varphi$-linear morphism

$$\overline{g}_{(\psi,\psi')} : \overline{A}_\varphi \otimes_{\overline{A}_{\varphi'}} \overline{M}_{\varphi'} \xrightarrow{\sim} \overline{A}_\varphi \otimes_{A_{j'}} M_{j'} \to \overline{M}_\varphi$$

and it is easily seen that the rules :

$$\varphi \mapsto (\overline{A}_\varphi, \overline{M}_\varphi) \qquad \text{and} \qquad (\varphi' \xrightarrow{(\psi,\psi')} \varphi) \mapsto (\overline{A}_{(\psi,\psi')}, \overline{g}_{(\psi,\psi')})$$

for every $\varphi \in \mathrm{Ob}(\mathsf{Morph}(I))$ and every morphism (ψ, ψ') of $\mathsf{Morph}(I)$, define a functor

$$\mathsf{Morph}(I) \to (V, \mathfrak{m})^a\text{-}\mathsf{Alg.Mod}$$

whence, as in (14.2.31), two functors

$$\overline{A}_\bullet : \mathsf{Morph}(I) \to A\text{-}\mathsf{Alg} \qquad \overline{M}_\bullet : \mathsf{Morph}(I) \to A\text{-}\mathbf{Mod}$$

and notice also that :

(14.2.34) $$\overline{A}^\triangle_\varphi = A^\triangle_i \qquad \text{for every morphism } \varphi : j \to i \text{ in } I.$$

Next, let $\mathscr{I}$ be the category whose objects are the pairs $(j \xrightarrow{\varphi} i, \mathfrak{m}_0)$ where φ is a morphism of I and $\mathfrak{m}_0 \subset \mathfrak{m}$ is a subideal of finite type such that :

$$\mathfrak{m}_0 \overline{A}_\varphi \subset \overline{A}^\triangle_\varphi$$

(notation of remark 14.2.12(ii)). For every $(\varphi,\mathfrak{m}_0),(\varphi',\mathfrak{m}'_0)\in\mathrm{Ob}(\mathscr{I})$, the set of morphisms $(\varphi',\mathfrak{m}'_0)\to(\varphi,\mathfrak{m}_0)$ in $\mathscr{I}$ is empty if $\mathfrak{m}_0\not\subset\mathfrak{m}'_0$, and otherwise consists of the morphisms $\varphi'\to\varphi$ in $\mathsf{Morph}(I)$. The composition law is then the same as that of $\mathsf{Morph}(I)$, so that the projection $(\varphi,\mathfrak{m}_0)\mapsto\varphi$ and the rule : $i\mapsto\mathbf{1}_i$ for every $i\in\mathrm{Ob}(I)$ define functors

$$\mathscr{I}\xrightarrow{\pi}\mathsf{Morph}(I)\xleftarrow{\delta}I.$$

Claim 14.2.35. The functors π and δ are coinitial.

Proof of the claim. It is easily seen that both $\mathscr{I}$ and $\mathsf{Morph}(I)$ are cofiltered, so we can apply the (dual of the) criterion of lemma 1.5.7(i). Condition (a) of the lemma is trivially verified by π. To check condition (b) for π, consider any object $\varphi:j\to i$ of $\mathsf{Morph}(I)$, any object $(\varphi':j'\to i',\mathfrak{m}_0)$ of $\mathscr{I}$, and a pair of morphisms $(\psi,\psi'),(\mu,\mu'):\varphi'\to\varphi$. Since I is cofiltered, we find morphisms $\nu:j''\to j'$ and $\nu':i''\to i'$ in I such that $\psi\circ\nu=\mu\circ\nu$ and $\psi'\circ\nu'=\mu'\circ\nu'$. Then we also find $k\in\mathrm{Ob}(I)$ with morphisms $\lambda:k\to j''$ and $\lambda':k\to i''$ such that $\nu'\circ\lambda'=\varphi'\circ\nu\circ\lambda$. Set $\varphi'':=\nu'\circ\lambda'$; we deduce a morphism $(\nu\circ\lambda,\mathbf{1}_{i'}):\varphi''\to\varphi'$ in $\mathsf{Morph}(I)$ with $(\psi,\psi')\circ(\nu\circ\lambda,\mathbf{1}_{i'})=(\mu,\mu')\circ(\nu\circ\lambda,\mathbf{1}_{i'})$. From (14.2.34) we get $\overline{A}{}^{\triangle}_{\varphi''}=\overline{A}{}^{\triangle}_{\varphi'}$. By assumption we have $\mathfrak{m}_0\cdot\overline{A}_{\varphi'}\subset\overline{A}{}^{\triangle}_{\varphi'}$, and clearly $\overline{A}_{\varphi''}\subset\overline{A}_{\varphi'}$. Hence $\mathfrak{m}_0\cdot\overline{A}_{\varphi''}\subset\overline{A}{}^{\triangle}_{\varphi''}$, so $(\varphi'',\mathfrak{m}_0)\in\mathrm{Ob}(\mathscr{I})$, and $(\nu\circ\lambda,\mathbf{1}_{i'})$ is a morphism $(\varphi'',\mathfrak{m}_0)\to(\varphi',\mathfrak{m}_0)$ in $\mathscr{I}$ such that $(\psi,\psi')\circ\pi(\nu\circ\lambda,\mathbf{1}_{i'})=(\mu,\mu')\circ\pi(\nu\circ\lambda,\mathbf{1}_{i'})$, as required. The verification of conditions (a) and (b) for the functor δ is easy, and shall be left to the reader. ◊

We consider then the induced functor :

$$\overline{A}_\bullet\circ\pi:\mathscr{I}\to A\text{-}\mathbf{Mod}\qquad(j\xrightarrow{\varphi}i,\mathfrak{m}_0)\mapsto\overline{A}_\varphi.$$

Notice that $\mathrm{Im}\,\tau^A_i\subset\overline{A}_\varphi$ for every morphism $\varphi:j\to i$ of I; we deduce a cone

$$\overline{\tau}{}^A_\bullet:c_A\Rightarrow\overline{A}_\bullet\qquad(j\xrightarrow{\varphi}i)\mapsto(\tau^A_i:A\to\overline{A}_\varphi)$$

such that $\overline{\tau}{}^A_\bullet*\delta=\tau^A_\bullet$. In light of claim 14.2.35, it follows that $\overline{\tau}{}^A_\bullet$ is a universal cone, and by the same token, the same holds for the cone $\overline{\tau}{}^A_\bullet*\pi:c_A\Rightarrow\overline{A}_\bullet\circ\pi$.

Claim 14.2.36. $\overline{A}_\bullet\circ\pi$ is a Cauchy functor.

Proof of the claim. By proposition 14.2.18, the functor $A^{\triangle}_\bullet:I\to A\text{-}\mathbf{Mod}$ is Cauchy and $A_\bullet$ has the almost Mittag-Leffler property, so $A^{\triangle}_\varphi:A^{\triangle}_j\to A^{\triangle}_i$ is an epimorphism for every morphism $\varphi:j\to i$ in I. Hence, for every subideal $\mathfrak{m}_0\subset\mathfrak{m}$ of finite type there exists $i\in\mathrm{Ob}(I)$ with $\mathfrak{m}_0\cdot\mathrm{Ker}\,A^{\triangle}_\varphi=0$ for every such φ, and moreover there exists $\varphi:j\to i$ with $\mathfrak{m}_0\overline{A}_\varphi\subset A^{\triangle}_i$. For such φ, we have $(\varphi,\mathfrak{m}_0)\in\mathrm{Ob}(\mathscr{I})$; now, let $(\psi,\psi'):(\varphi':j'\to i',\mathfrak{m}'_0)\to(\varphi,\mathfrak{m}_0)$ be any morphism in $\mathscr{I}$; this means that $\mathfrak{m}_0\subset\mathfrak{m}'_0$ and $\mathfrak{m}'_0\overline{A}_{\varphi'}\subset\overline{A}{}^{\triangle}_{\varphi'}=A^{\triangle}_{i'}$. Also, $\overline{A}_{(\psi,\psi')}:\overline{A}_{\varphi'}\to\overline{A}_\varphi$ is the restriction of $A_{\psi'}:A_{i'}\to A_i$. Therefore

$$\mathfrak{m}_0\cdot\mathrm{Ker}\,\overline{A}_{(\psi,\psi')}\subset A^{\triangle}_{i'}\cap\mathrm{Ker}\,A_{\psi'}\subset\mathrm{Ker}\,A^{\triangle}_{\psi'}$$

whence $\mathfrak{m}_0^2\cdot\mathrm{Ker}\,\overline{A}_{(\psi,\psi')}=0$. Lastly, $\mathrm{Coker}\,\overline{A}_{(\psi,\psi')}$ is a quotient of $\overline{A}_\varphi/A_{\psi'}(A^{\triangle}_{i'})=\overline{A}_\varphi/A^{\triangle}_i$, which is annihilated by $\mathfrak{m}_0$, so $\mathfrak{m}_0\cdot\mathrm{Coker}\,\overline{A}_{(\psi,\psi')}=0$. ◊

Since the morphisms g_φ are isomorphisms for every morphism φ of I, a simple inspection shows that $\overline{g}_{(\psi,\psi')}$ is an isomorphism for every morphism (ψ,ψ') of $\mathsf{Morph}(I)$. Together with claims 14.2.36, and 14.2.33, we deduce that assertion (iii) holds for the functors $\overline{A}_\bullet\circ\pi$ and $\overline{M}_\bullet\circ\pi$, and moreover $\overline{M}_\bullet\circ\pi$ is a Cauchy functor.

However, let $\lambda:I\to\mathscr{I}$ be the functor given by the rules : $i\mapsto(\mathbf{1}_i,0)$ and $\varphi\mapsto(\varphi,\varphi)$ for every $i\in\mathrm{Ob}(I)$ and every morphism φ of I. It is easily seen that $\overline{A}_\bullet\circ\pi\circ\lambda=A_\bullet$ and $\overline{M}_\bullet\circ\pi\circ\lambda=M_\bullet$. Then assertion (iii) for $A_\bullet$ and $M_\bullet$ follows straightforwardly. Especially, the functor $M_\bullet$ is isomorphic to the functor $A_\bullet\otimes_A M$. Since the functor $-\otimes_A M:A\text{-}\mathbf{Mod}\to$

A-$\mathbf{Mod}$ is V-linear, proposition 14.2.20(iii) implies then that $M_\bullet$ is almost essentially constant, and the proof of (iii) is completed, under the assumptions of (ii).

Lastly, suppose that the assumptions of (i) hold; hence g_φ is an epimorphism for every morphism $\varphi : j \to i$ in I, and it follows easily that the induced morphism $A_i \otimes_{A_j} \mathrm{Im}\, M_\varphi \to M_i$ is an epimorphism as well, for every such φ. On the other hand, by assumption for every $i \in \mathrm{Ob}(I)$ and every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ of finite type there exists $\varphi : j \to i$ such that $\mathfrak{m}_0 \mathrm{Im}\, M_\varphi \subset M_i^\triangle$. Hence, $\mathfrak{m}_0 M_i \subset \mathrm{Im}\, \alpha_i$. Since $\mathfrak{m}_0$ is arbitrary, we conclude that α_i is an epimorphism.

(i): By assumption, for every $i \in \mathrm{Ob}(I)$ and every subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ there exists a morphism $\varphi : j \to i$ in I such that for every morphism $\psi : k \to j$ in I we have $\mathfrak{m}_0 \cdot \mathrm{Im}\, A_{\varphi\circ\psi} \subset \mathrm{Im}\, A_\varphi$. It then follows that for every such $\mathfrak{m}_0$, φ and ψ we have

$$\mathfrak{m}_0 \cdot \mathrm{Im}(A_\varphi \otimes_{A_k} M_k) \subset \mathrm{Im}(A_{\varphi\circ\psi} \otimes_{A_k} M_k).$$

Since g_ψ is an epimorphism and $g_{\varphi\circ\psi} \circ (A_{\varphi\circ\psi} \otimes_{A_k} M_k) = M_{\varphi\circ\psi}$, we deduce :

$$\mathfrak{m}_0 \cdot \mathrm{Im}\, M_\varphi = \mathfrak{m}_0 \cdot \mathrm{Im}(M_\varphi \circ g_\psi) = \mathfrak{m}_0 \cdot \mathrm{Im}(g_{\varphi\circ\psi} \circ (A_\varphi \otimes_{A_k} M_k)) \subset \mathrm{Im}\, M_{\varphi\circ\psi}$$

which shows that $M_\bullet$ has the almost Mittag-Leffler property, as stated.

(iv): Notice that $\tau_i^M : M \to M_i$ factors through a morphism $\mu_i : M \to M_i^\triangle$ and the inclusion $M_i^\triangle \to M_i$, for every $i \in \mathrm{Ob}(I)$. Since $M_\bullet / M_\bullet^\triangle$ is almost essentially zero (proposition 14.2.18(i.b)), it follows that $\mu_\bullet : c_M \Rightarrow M_\bullet^\triangle$ is a universal cone. If $\lambda : \mathbb{N}^o \to I$ is a coinitial functor, the cone $\mu_\bullet * \lambda$ is still universal (remark 1.5.5(ii,iii)), and then $\mu_{\lambda(n)} : M \to M_{\lambda(n)}^\triangle$ is an epimorphism for every $n \in \mathbb{N}$ (lemma 14.2.24(i)). Since $M_\varphi^\triangle$ is an epimorphism for every $i \in \mathrm{Ob}(I)$ (proposition 14.2.18(i.a)), we conclude that $\mu_i : M \to M_i^\triangle$ is an epimorphism for every $i \in \mathrm{Ob}(I)$. Since we already know that α_i is an epimorphism, it follows that the same holds for β_i, for every such i. □

14.2.37. Keep the notation of (14.2.31), and consider a second functor

$$I \to (V, \mathfrak{m})^a\text{-}\mathsf{Alg.Mod} \qquad i \mapsto (A'_i, N_i).$$

as well as the corresponding induced functors

$$A'_\bullet : I \to (V, \mathfrak{m})^a\text{-}\mathsf{Alg} \qquad N_\bullet : I \to (V, \mathfrak{m})^a\text{-}\mathbf{Mod}$$

and suppose that $A_\bullet = A'_\bullet$. Let also N be the limit of $N_\bullet$. Then we get an induced functor

$$I \to (V, \mathfrak{m})^a\text{-}\mathsf{Alg.Mod} \qquad i \mapsto (A_i, M_i \otimes_{A_i} N_i)$$

and the corresponding induced functor

$$M_\bullet \otimes_{A_\bullet} N_\bullet : I \to (V, \mathfrak{m})^a\text{-}\mathbf{Mod} \qquad i \mapsto M_i \otimes_{A_i} N_i.$$

Proposition 14.2.38. *In the situation of* (14.2.37)*, suppose that $A_\bullet$, $M_\bullet$ and $N_\bullet$ are almost essentially constant functors with values in A-$\mathbf{Mod}$. Then the same holds for $M_\bullet \otimes_{A_\bullet} N_\bullet$, and $M \otimes_A N$ represents the limit of $M_\bullet \otimes_{A_\bullet} N_\bullet$.*

Proof. For every $i \in \mathrm{Ob}(I)$, the V^a-linear map

$$\varphi_i : M_i \otimes_{V^a} A_i \otimes_{V^a} N_i \to M_i \otimes_{V^a} N_i \qquad x \otimes a \otimes y \mapsto ax \otimes y - x \otimes ay$$

yields a natural identification : $\mathrm{Coker}\, \varphi_i \xrightarrow{\sim} M_i \otimes_{A_i} N_i$. In view of proposition 14.2.30(iv), we are then easily reduced to showing that the two functors :

$$I \to (V, \mathfrak{m})^a\text{-}\mathbf{Mod} \qquad i \mapsto M_i \otimes_{V^a} A_i \otimes_{V^a} N_i \qquad i \mapsto M_i \otimes_{V^a} N_i$$

are both almost essentially constant, and their limits are represented by $M \otimes_{V^a} A \otimes_{V^a} N$ and respectively $M \otimes_{V^a} N$. Moreover, if both $P_\bullet := M_\bullet \otimes_{V^a} A_\bullet$ and $P_\bullet \otimes_{V^a} N_\bullet$ are almost essentially constant with limits $P := M \otimes_{V^a} A$ and respectively $P \otimes_{V^a} N$, then $M_\bullet \otimes_{V^a} A_\bullet \otimes_{V^a} N_\bullet$ will be almost essentially constant with the sought limit. Hence, we are further reduced to showing the proposition in case $A_\bullet$ is the constant functor with $A_i = V^a$ for every $i \in \mathrm{Ob}(I)$. Now, let $\tau_\bullet : c_M \Rightarrow M_\bullet$ be the universal cone. We have right exact sequences :

$$K_i := (\mathrm{Ker}\,\tau_i) \otimes_{V^a} N_i \to \mathrm{Ker}(\tau_i \otimes_{V^a} N_i) \to T_i \to 0 \qquad \text{for every } i \in \mathrm{Ob}(I)$$

where T_i is the cokernel of the natural morphism $\mathrm{Tor}_1^{V^a}(M_i, N_i) \to \mathrm{Tor}_1^{V^a}(\mathrm{Coker}\,\tau_i, N_i)$. Since, by assumption, both $\mathrm{Ker}\,\tau_\bullet$ and $\mathrm{Coker}\,\tau_\bullet$ are almost essentially zero, it is easily seen that the same holds for the induced functors $K_\bullet$ and $T_\bullet$, and then the same follows for the functor $\mathrm{Ker}(\tau_\bullet \otimes_{V^a} N_\bullet)$, by lemma 14.2.14(i). Likewise, $\mathrm{Coker}(\tau_\bullet \otimes_{V^a} N_\bullet)$ is the functor $(\mathrm{Coker}\,\tau_\bullet) \otimes_{V^a} N_\bullet$, which is again almost essentially zero. Thus, $M_\bullet \otimes_{V^a} N_\bullet$ is isomorphic to $M \otimes_{V^a} N_\bullet$ in the category $\mathscr{L}(I, (V, \mathfrak{m})^a\text{-}\mathbf{Mod})$. Lastly, let $F : (V, \mathfrak{m})^a\text{-}\mathbf{Mod} \to (V, \mathfrak{m})^a\text{-}\mathbf{Mod}$ be the functor such that $FX := M \otimes_{V^a} X$ for every V^a-module X; since $N_\bullet$ is almost essentially constant, the same holds for $FN_\bullet = M \otimes_{V^a} N_\bullet$, and its limit is $M \otimes_{V^a} N$, by proposition 14.2.20(i,iii), whence the assertion. □

Theorem 14.2.39. *Let $(V, \mathfrak{m})$ be a basic setup, I a small cofiltered category, and consider an almost essentially constant functor $A_\bullet : I \to (V, \mathfrak{m})^a$-$\mathsf{Alg}$. Denote by A the limit of $A_\bullet$, and let $\tau_\bullet^A : c_A \Rightarrow A_\bullet$ be a universal cone; let also M be an A-module, B an A-algebra, $r \in \mathbb{N}$ and*

$$A_\bullet\text{-}\mathbf{Mod} : I \to \mathbf{Cat} \quad i \mapsto A_i\text{-}\mathbf{Mod} \qquad \textit{and} \qquad A_\bullet\text{-}\mathsf{Alg} : I \to \mathbf{Cat} \quad i \mapsto A_i\text{-}\mathsf{Alg}$$

the pseudo-functors naturally induced by $A_\bullet$. The following holds :

(i) *The cone $\tau_\bullet^A$ induces equivalences of categories*

$$A\text{-}\mathsf{Alg} \xrightarrow{\sim} 2\text{-}\lim_I A_\bullet\text{-}\mathsf{Alg} \qquad A\text{-}\mathbf{Mod} \xrightarrow{\sim} 2\text{-}\lim_I A_\bullet\text{-}\mathbf{Mod}.$$

(ii) *The A-module M is almost finitely generated (resp. almost finitely presented, resp. flat, resp. faithfully flat resp. almost projective) if and only if the same holds for the A_i-module $A_i \otimes_A M$, for every $i \in \mathrm{Ob}(I)$.*

(iii) *Suppose that $(V, \mathfrak{m})$ fulfills condition* $(\mathbf{B})$ *of* [75, §2.1.6]. *Then M is almost projective of almost finite rank (resp. of finite rank $\leq r$) if and only if the same holds for the A_i-module $A_i \otimes_A M$, for every $i \in \mathrm{Ob}(I)$.*

(iv) *The A-algebra B is weakly unramified (resp. unramified, resp. weakly étale, resp. étale) if and only if the same holds for the A_i-algebra $A_i \otimes_A B$, for every $i \in \mathrm{Ob}(I)$.*

Proof. (i): Let $\pi : (V, \mathfrak{m})^a$-$\mathsf{Alg.Mod} \to (V, \mathfrak{m})^a$-$\mathsf{Alg}$ be the natural projection functor. Then $2\text{-}\lim_I A_\bullet\text{-}\mathbf{Mod}$ is the subcategory of $\mathsf{Fun}(I, (V, \mathfrak{m})^a\text{-}\mathsf{Alg.Mod})$ whose objects are the functors

$$(A_\bullet, M_\bullet) : I \to (V, \mathfrak{m})^a\text{-}\mathsf{Alg.Mod} \qquad i \mapsto (A_i, M_i)$$

with $\pi \circ (A_\bullet, M_\bullet) = A_\bullet$, and such that, with the notation of (14.2.31), the morphism $g_\varphi : A_i \otimes_{A_j} M_j \to M_i$ is an isomorphim of A_i-modules, for every morphism $\varphi : j \to i$ in I. The morphisms $\beta_\bullet : (A_\bullet, M_\bullet) \to (A_\bullet, M'_\bullet)$ are the natural transformations such that $\pi * \beta_\bullet = \mathbf{1}_{A_\bullet}$.

Under this identification, the functor $(A_\bullet, A_\bullet \otimes_A -) : A\text{-}\mathbf{Mod} \to 2\text{-}\lim_I A_\bullet\text{-}\mathbf{Mod}$ of (i) assigns to every A-module M the functor

$$(A_\bullet, A_\bullet \otimes_A M) : I \to (V, \mathfrak{m})^a\text{-}\mathsf{Alg.Mod} \qquad i \mapsto (A_i, A_i \otimes_A M).$$

Conversely, following (14.2.31), with every functor $(A_\bullet, M_\bullet)$ as in the foregoing, we associate a functor $M_\bullet : I \to A\text{-}\mathbf{Mod}$, and let M be the limit of $M_\bullet$. From proposition 14.2.32(iii) we obtain a natural isomorphism

$$(A_\bullet, A_\bullet \otimes_A M) \xrightarrow{\sim} (A_\bullet, M_\bullet).$$

This shows that $(A_\bullet, A_\bullet \otimes_A -)$ is essentially surjective. Next, let M, N be two A-modules; according to proposition 14.2.20(i), the kernel and cokernel of $\tau_\bullet^A \otimes_A N : c_N \Rightarrow A_\bullet \otimes_A N$

are almost essentially zero, and therefore $\tau_\bullet^A \otimes_A N$ is a universal cone. There follow natural isomorphisms

$$\mathrm{Hom}_A(M,N) \stackrel{\sim}{\to} \lim_I \mathrm{Hom}_A(M, A_\bullet \otimes_A N) \stackrel{\sim}{\to} \lim_I \mathrm{Hom}_{A_i}(A_\bullet \otimes_A M, A_\bullet \otimes_A N)$$

and notice that the latter limit is naturally identified with the set of morphisms $(A_\bullet, A_\bullet \otimes_A M) \to (A_\bullet, A_\bullet \otimes_A N)$ in 2-$\lim_I A_\bullet$-**Mod**. Thus $(A_\bullet, A_\bullet \otimes_A -)$ is an equivalence.

(ii): Suppose first that $M_i := A_i \otimes_A M$ is almost finitely generated for every $i \in \mathrm{Ob}(I)$. Let $N_\bullet : \Lambda \to A$-**Mod** be any functor from a small filtered category Λ; denote by N the colimit of $N_\bullet$, and let $\tau_\bullet^N : N_\bullet \Rightarrow c_N$ be a universal cocone. We have two V-linear functors

$$F : A\text{-}\mathbf{Mod} \to A\text{-}\mathbf{Mod} \qquad P \mapsto \operatorname*{colim}_\Lambda \mathrm{alHom}_A(M, P \otimes_A N_\bullet)$$
$$G : A\text{-}\mathbf{Mod} \to A\text{-}\mathbf{Mod} \qquad P \mapsto \mathrm{alHom}_A(M, P \otimes_A N)$$

and $\tau_\bullet^N$ induces a natural transformation

$$\beta_\bullet : F \Rightarrow G \qquad P \mapsto \operatorname*{colim}_\Lambda \mathrm{alHom}_A(M, P \otimes_A \tau_\bullet^N) : FP \to GP$$

and according to [75, Prop.2.3.16(i)], it suffices to check that β_A is a monomorphism. However, we have a commutative diagram of functors :

$$\begin{array}{ccc} c_{FA} & \xrightarrow{c_{\beta_A}} & c_{GA} \\ {\scriptstyle F*\tau_\bullet^A}\downarrow & & \downarrow{\scriptstyle G*\tau_\bullet^A} \\ F \circ A_\bullet & \xrightarrow{\beta_\bullet * A_\bullet} & G \circ A_\bullet \end{array}$$

and by propositions 14.2.18(ii) and 14.2.20(i), the vertical arrows of the diagram are both isomorphisms in the category $\mathscr{L}(I, A\text{-}\mathbf{Mod})$. We claim that $\beta_{A_i} : FA_i \to GA_i$ is a monomorphism for every $i \in \mathrm{Ob}(I)$. Indeed :

$$FA_i = \operatorname*{colim}_\Lambda \mathrm{alHom}_{A_i}(M_i, A_i \otimes_A N_\bullet) \qquad \text{and} \qquad GA_i = \mathrm{alHom}_{A_i}(M_i, A_i \otimes_A N)$$

and since by assumption the A_i-module M_i is almost finitely generated, the assertion follows from [75, Prop.2.3.16(i)]. We deduce that c_{β_A} is also a monomorphism in $\mathscr{L}(I, A\text{-}\mathbf{Mod})$, *i.e.* β_A is a monomorphism, as required.

One argues likewise, in case M_i is almost finitely presented for every $i \in \mathrm{Ob}(I)$, invoking [75, Prop.2.3.16(ii)] to see that in this case β_{A_i} is an isomorphism for every such i, whence β_A is an isomorphism, so that M is almost finitely presented, again by [75, Prop.2.3.16(ii)].

Next, suppose that M_i is an almost projective A_i-module for every $i \in \mathrm{Ob}(I)$, and let $f : N' \to N$ be an epimorphism of A-modules. We attach to the pair (M, N) the V-linear functor

$$H_{M,N} : A\text{-}\mathbf{Mod} \to A\text{-}\mathbf{Mod} \qquad P \mapsto \mathrm{alHom}_A(P \otimes_A M, P \otimes_A N)$$

and define likewise $H_{M,N'} : A\text{-}\mathbf{Mod} \to A\text{-}\mathbf{Mod}$. The morphism f induces a natural transformation $H_{M,f} : H_{M,N} \Rrightarrow H_{M,N'}$, whence a commutative diagram of functors :

$$\begin{array}{ccc} c_{H_{M,N}(A)} & \xrightarrow{c_{H_{M,f}(A)}} & c_{H_{M,N'}(A)} \\ {\scriptstyle H_{M,N}*\tau_\bullet^A}\downarrow & & \downarrow{\scriptstyle H_{M,N'}*\tau_\bullet^A} \\ H_{M,N} \circ A_\bullet & \xrightarrow{H_{M,f}*A_\bullet} & H_{M,N'} \circ A_\bullet \end{array}$$

whose vertical arrows are isomorphisms in $\mathscr{L}(I, A\text{-}\mathbf{Mod})$, by virtue of propositions 14.2.18(ii) and 14.2.20(i); moreover, $H_{M,N'} * \tau_i^A$ is an epimorphism for every $i \in \mathrm{Ob}(I)$, since M_i is an almost projective A_i-module. As in the previous case, we deduce that $H_{M,f}(A)$ is an epimorphism of A-modules, so M is almost projective.

Suppose next that M_i is flat for every $i \in \mathrm{Ob}(I)$, and let $f : N \to N'$ be a monomorphism of A-modules. Set $N_i := A_i \otimes_A N$ and $N'_i := A_i \otimes_A N'$ for every $i \in \mathrm{Ob}(I)$, and let $\overline{N}_i := \mathrm{Im}(A_i \otimes_A f) \subset N'_i$. Clearly the rule : $i \mapsto \overline{N}_i$ defines a subfunctor $\overline{N}_\bullet$ of $A_\bullet \otimes_A N'$. By proposition 14.2.20(i), the kernel of $A_\bullet \otimes_A f : A_\bullet \otimes_A N \Rightarrow A_\bullet \otimes_A N'$ is almost essentially zero, hence the induced natural transformation $\pi_\bullet : A_\bullet \otimes_A N \to \overline{N}_\bullet$ is an isomorphism in $\mathscr{L}(I, A\text{-}\mathbf{Mod})$. By the same token, the same holds for the natural transformation $\tau^A_\bullet \otimes_A N : c_N \Rightarrow A_\bullet \otimes_A N$, and therefore also for the composition $\mu_\bullet := \pi_\bullet \odot (\tau^A_\bullet \otimes_A N) : c_N \Rightarrow \overline{N}_\bullet$. We obtain therefore a commutative diagram of functors :

$$\begin{array}{ccc} c_{M\otimes_A N} & \xrightarrow{c_{M\otimes_A f}} & c_{M\otimes_A N'} \\ {\scriptstyle M\otimes_A \mu_\bullet}\downarrow & & \downarrow{\scriptstyle M\otimes_A \tau^A_\bullet \otimes_A N} \\ M \otimes_A \overline{N}_\bullet & \longrightarrow & M \otimes_A A_i \otimes_A N' \end{array}$$

whose vertical arrows are, as usual, isomorphisms in $\mathscr{L}(I, A\text{-}\mathbf{Mod})$. Let $j_i : \overline{N}_i \to N'_i$ be the inclusion; we have natural isomorphisms $M \otimes_A \overline{N}_i \xrightarrow{\sim} M_i \otimes_{A_i} \overline{N}_i$ and $M \otimes_A A_i \otimes_A N' \xrightarrow{\sim} M_i \otimes_{A_i} N'_i$ for every $i \in \mathrm{Ob}(I)$, that identify the bottom horizontal arrow with the morphism $M \otimes_{A_i} j_i$. The latter is a monomorphism for every $i \in \mathrm{Ob}(I)$, since M_i is a flat A_i-module; as usual it follows that $M \otimes_A f$ is a monomorphism as well, so M is flat.

Lastly, suppose that M_i is a faithfully flat A_i-module for every $i \in \mathrm{Ob}(I)$; by the foregoing, we know already that M is a flat A-module. Then, let X be any A-module such that $M \otimes_A X = 0$; it follows that $M_i \otimes_{A_i} (A_i \otimes_A X) = 0$ for every $i \in \mathrm{Ob}(I)$, whence $A_i \otimes_A X = 0$ for every such i. But by the foregoing, X is the limit of the functor $A_\bullet \otimes_A X$, whence $X = 0$; this shows that M is faithfully flat.

(iii): Suppose that M_i is an almost projective A_i-module of almost finite rank, for every $i \in \mathrm{Ob}(I)$. By the foregoing, we know already that M is an almost projective A-module, and it remains to check that it is of almost finite rank. To this aim, define the category $\mathscr{I}$ and the functors $\pi : \mathscr{I} \to \mathsf{Morph}(I)$ and $\overline{A}_\bullet : \mathsf{Morph}(I) \to A\text{-}\mathsf{Alg}$ as in the proof of proposition 14.2.32; recall that π is coinitial, and $\overline{A}_\bullet \circ \pi$ is a Cauchy functor (claims 14.2.35 and 14.2.36). Moreover, the cone $\overline{\tau}^A_\bullet : c_A \Rightarrow \overline{A}_\bullet$ deduced from $\tau^A_\bullet$, is universal, so the same holds for $\overline{\tau}^A_\bullet * \pi$. It follows that $\mathrm{Ker}\,(\overline{\tau}^A_\bullet * \pi)$ and $\mathrm{Coker}\,(\overline{\tau}^A_\bullet * \pi)$ are null functors (remark 14.2.17(ii)). Now, let $\mathfrak{m}_0 \subset \mathfrak{m}$ be a subideal of finite type; by the foregoing there exists $(\varphi : j \to i, \mathfrak{m}_1) \in \mathrm{Ob}(\mathscr{I})$ such that the kernel and cokernel of $\overline{\tau}^A_\varphi : A \to \overline{A}_\varphi := \mathrm{Im}\, A_\varphi$ are both annihilated by $\mathfrak{m}_0$. On the other hand, since M_j has almost finite rank, there exists $n \in \mathbb{N}$ such that $\mathfrak{m}_0 \cdot \Lambda^n_{A_j} M_j = 0$, and then we have as well $\mathfrak{m}_0 \cdot (\overline{A}_\varphi \otimes_{A_j} \Lambda^n_{A_j} M_j) = 0$. But by remark 14.2.10(vi), the kernel of

$$\overline{\tau}^A_\varphi \otimes_A \Lambda^n_A M : \Lambda^n_A M \to \overline{A}_\varphi \otimes_A \Lambda^n_A M \xrightarrow{\sim} \overline{A}_\varphi \otimes_{A_j} \Lambda^n_{A_j} M_j$$

is annihilated by $\mathfrak{m}_0^2$. We conclude that $\mathfrak{m}_0^3 \cdot \Lambda^n_A M = 0$, whence the contention. Lastly, if M_i has rank $\leq r$ for every $i \in \mathrm{Ob}(I)$, the same argument shows that $\mathfrak{m} \cdot \mathfrak{m}_0^2 \cdot \Lambda^r_A M = 0$ for every such $\mathfrak{m}_0$, *i.e.* $\Lambda^r_A M = 0$, so M has rank $\leq r$.

(iv): Set $C := B \otimes_A B$, and let $\mu : C \to B$ be the multiplication law of the A-algebra B; the functor $C_\bullet := C \otimes_A A_\bullet : I \to (V, \mathfrak{m})^a\text{-}\mathsf{Alg}$ is still almost essentially constant, and $C \otimes_A \tau^A_\bullet : c_C \Rightarrow C_\bullet$ is an isomorphism in $\mathscr{L}(I, A\text{-}\mathbf{Mod})$ (proposition 14.2.20(i,iii)). Suppose now that $B_i := B \otimes_A A_i$ is a weakly unramified A_i-algebra, *i.e.* that the morphism $\mu \otimes_A A_i : C_i \to B_i$ is flat for every $i \in \mathrm{Ob}(I)$. By (ii), it follows that μ is flat, *i.e.* B is a weakly unramified A-algebra. One argues likewise in case B_i is an unramified (resp. weakly étale, resp. étale) A_i-algebra for every $i \in \mathrm{Ob}(I)$. □

The following notion of *flatness for almost modules, relative to a given base ring* will find application in section 17.5.

Definition 14.2.40. Let $(V, \mathfrak{m})$ be a basic setup, $f : A \to V$ a ring homomorphism, and M any V-module; we say that M^a is *flat over* A (resp. *faithfully flat over* A) if the functor

$$A\text{-}\mathbf{Mod} \to (V, \mathfrak{m})^a\text{-}\mathbf{Mod} \qquad N \mapsto M^a \otimes_A N := (M \otimes_A N)^a$$

is exact (resp. is exact and faithful).

Lemma 14.2.41. *In the situation of definition* 14.2.40*, let* $g : V \to B$ *be a ring homomorphism, and* N *a* B*-module. The following holds :*

(i) *If the* V^a*-module* B^a *is faithfully flat over* A*, the map* $g \circ f : A \to B$ *is injective.*
(ii) M^a *is faithfully flat over* A *if and only if it is flat over* A *and* $(M/\mathfrak{n}M)^a \neq 0$ *for every maximal ideal* $\mathfrak{n} \subset A$*.*
(iii) *If the* V^a*-module* B^a *is flat (resp. faithfully flat) over* A*, and* N^a *is a flat (resp. faithfully flat)* B^a*-module, then* N^a *is flat (resp. faithfully flat) over* A*.*

Proof. (i): Set $I := \mathrm{Ker}\,(g \circ f)$; by assumption, the inclusion map $I \to A$ induces a monomorphism $(I \otimes_A B)^a \to B^a$ of V^a-modules, *i.e.* the natural morphism $(I \otimes_A B)^a \to (IB)^a = 0$ is an isomorphism of V^a-modules. By assumption, the latter implies that $I = 0$.

Assertions (ii) and (iii) shall be left to the reader. □

14.2.42. In the situation of definition 14.2.40, suppose that A is *noetherian*, let $I \subset A$ be a given ideal, and set $A_n := A/I^n$, $V_n := V/I^nV$, for every $n \in \mathbb{N}$. Consider an inverse system $M_\bullet := (M_n, \varphi_n \mid n \in \mathbb{N})$, where M_n is a V_n-module such that M_n^a is flat over A_n, and $\varphi_n : M_{n+1} \to M_n$ is a V-linear map, such that the induced inverse system of V^a-modules $M_\bullet^a := (M_n^a, \varphi_n^a \mid n \in \mathbb{N})$ has the almost Mittag-Leffler property (see definition 14.2.11(iv)). Let also M be the limit of $M_\bullet$ (in the category V-$\mathbf{Mod}$). The following result refines [107, Tag 0912].

Proposition 14.2.43. *With the notation of* (14.2.42)*, the following holds :*

(i) M^a *is flat over* A*.*
(ii) *Every* A*-module* N *of finite type induces an isomorphism of* V^a*-modules*

$$(N \otimes_A M)^a \xrightarrow{\sim} \lim_{n\in\mathbb{N}} (N \otimes_A M_n)^a.$$

Proof. (ii): Let $(F_\bullet, d_\bullet) \to N$ be a resolution of N by free A-modules of finite rank (hence the differential $d_i : F_i \to F_{-1}$ is an A-linear map, for every $i > 0$, and $d_0 : F_0 \to N$ is an A-linear surjection). There follows, for every $n \in \mathbb{N}$, exact sequences of A-modules :

$$0 \to \mathrm{Tor}_1^A(N, M_n) \to \mathrm{Coker}(d_2) \otimes_A M_n \xrightarrow{d_{1,n}} F_0 \otimes_A M_n \to N \otimes_A M_n \to 0$$
$$0 \to \mathrm{Im}(d_2 \otimes_A M_n) \to F_1 \otimes_A M_n \to \mathrm{Coker}(d_2) \otimes_A M_n \to 0$$

where $d_{1,n}$ is induced by $d_1 \otimes_A M_n$, for every such n. Since M_n^a is flat over A_n, we have a natural isomorphism of V^a-modules :

$$\mathrm{Tor}_1^A(N, M_n)^a \xrightarrow{\sim} (\mathrm{Tor}_1^A(N, A_n) \otimes_A M_n)^a \qquad \text{for every } n \in \mathbb{N}.$$

Claim 14.2.44. (i) The inverse system $(\mathrm{Tor}_1^A(N, A_n) \mid n \in \mathbb{N})$ is essentially zero.

(ii) Consider an exact sequence of inverse systems of V^a-modules :

$$K_{\bullet\bullet} \quad : \quad (K_{3,n} \mid n \in \mathbb{N}) \xrightarrow{\varphi_{3,\bullet}} (K_{2,n} \mid n \in \mathbb{N}) \xrightarrow{\varphi_{2,\bullet}} (K_{1,n} \mid n \in \mathbb{N}) \xrightarrow{\varphi_{1,\bullet}} (K_{0,n} \mid n \in \mathbb{N}) \to 0$$

such that $K_{3,\bullet}$ is almost essentially zero, and $K_{2,\bullet}$ has the almost Mittag-Leffler property. Then $K_{\bullet\bullet}$ induces a short exact sequence of V^a-modules :

$$0 \to \lim_{n\in\mathbb{N}} K_{2,n} \to \lim_{n\in\mathbb{N}} K_{1,n} \to \lim_{n\in\mathbb{N}} K_{0,n} \to 0.$$

Proof of the claim. (i): Let $K := \mathrm{Ker}(d_0 : F_0 \to N)$; we have a natural identification :

$$\mathrm{Tor}_1^A(N, A_n) \xrightarrow{\sim} (K \cap I^n F)/(I^n K) \qquad \text{for every } n \in \mathbb{N}$$

and by the Artin-Rees lemma there exists $c \in \mathbb{N}$ such that $K \cap I^{n+c}F_0 \subset I^n K$ for every $n \in \mathbb{N}$, whence the assertion.

(ii): Set $J_n := \mathrm{Im}\,\varphi_{2,n}$ for every $n \in \mathbb{N}$; we get induced exact sequences of inverse systems :

$$K_{3,\bullet} \to K_{2,\bullet} \to J_\bullet \to 0 \qquad 0 \to J_\bullet \to K_{2,\bullet} \to K_{1,\bullet} \to 0$$

whence, by lemma 14.2.14(iii), an isomorphism of V^a-modules :

$$\lim_{n\in\mathbb{N}} K_{2,n} \xrightarrow{\sim} \lim_{n\in\mathbb{N}} J_n$$

and notice that $J_\bullet$ has the almost Mittag-Leffler property, as the same holds for $K_{2,\bullet}$ (proposition 14.2.30(ii)); then, proposition 14.2.25(iii) yields a short exact sequence of V^a-modules :

$$0 \to \lim_{n\in\mathbb{N}} J_n \to \lim_{n\in\mathbb{N}} K_{1,n} \to \lim_{n\in\mathbb{N}} K_{0,n} \to 0$$

whence the assertion. $\diamondsuit$

From claim 14.2.44(i) we deduce easily that the inverse system $(\mathrm{Tor}_1^A(N, M_n)^a \mid n \in \mathbb{N})$ is also essentially zero. On the other hand, since $M_\bullet^a$ has the almost Mittag-Leffler property, the same holds for the inverse system of V^a-modules $(\mathrm{Coker}\, d_2 \otimes_A M_n)^a$; Likewise, with proposition 14.2.30(ii)) one checks that the inverse system $(\mathrm{Im}(d_2 \otimes_A M_n)^a \mid n \in \mathbb{N})$ has the almost Mittag-Leffler property; then, claim 14.2.44(ii) yields short exact sequences of V^a-modules :

$$0 \to \lim_{n\in\mathbb{N}} (\mathrm{Coker}\, d_2 \otimes_A M_n)^a \to \lim_{n\in\mathbb{N}} (F_0 \otimes_A M_n)^a \to \lim_{n\in\mathbb{N}} (N \otimes_A M_n)^a \to 0$$

$$0 \to \lim_{n\in\mathbb{N}} \mathrm{Im}(d_2 \otimes_A M_n)^a \to \lim_{n\in\mathbb{N}} (F_1 \otimes_A M_n)^a \to \lim_{n\in\mathbb{N}} (\mathrm{Coker}\, d_2 \otimes_A M_n)^a \to 0.$$

Lastly, since F_i is a free A-module of finite type, clearly we have a natural identification

$$\lim_{n\in\mathbb{N}} (F_i \otimes_A M_n)^a \xrightarrow{\sim} (F_i \otimes_A M)^a \qquad \text{for every } i \in \mathbb{N}.$$

Summing up, we get a right exact sequence of V^a-modules

$$(F_1 \otimes_A M)^a \xrightarrow{(d_1 \otimes_A M)^a} (F_0 \otimes_A M)^a \to \lim_{n\in\mathbb{N}} (N \otimes_A M_n)^a \to 0$$

whence the contention.

(i): We need to check that every A-linear injection $f : N \to N'$ of A-modules of finite type induces a monomorphism $(f \otimes_A M)^a$. However, for every $n \in \mathbb{N}$ we have an exact sequence :

$$\mathrm{Tor}_1^A(\mathrm{Coker}\, f, M_n) \to N \otimes_A M_n \xrightarrow{f \otimes_A M_n} N' \otimes_A M_n \to \mathrm{Coker}\, f_n \otimes_A M_n \to 0$$

and arguing as in the proof of (i) we see that the inverse system $(\mathrm{Tor}_1^A(\mathrm{Coker}\, f, M_n)^a \mid n \in \mathbb{N})$ is essentially zero, and the inverse system $(N \otimes_A M_n \mid n \in \mathbb{N})$ has the almost Mittag-Leffler property, therefore claim 14.2.44(ii) implies that the inverse system $((f \otimes_A M_n)^a \mid n \in \mathbb{N})$ induces a monomorphism $\lim_{n\in\mathbb{N}}(N \otimes_A M_n)^a \to \lim_{n\in\mathbb{N}}(N' \otimes_A M_n)^a$. By (i), the latter is naturally identified with $(f \otimes_A M)^a$, whence the asssertion. $\square$

For future reference, let us also point out the following almost analogue of proposition 8.2.13(i,v) :

Lemma 14.2.45. *Let $(V, \mathfrak{m})$ be a basic setup, $f : M' \to M$ a morphism of V^a-modules, and $\mathscr{T}$ a linear topology on M. Endow M' (resp. $M'' := \mathrm{Coker}\, f$) with the linear topology $\mathscr{T}'$ (resp. $\mathscr{T}''$) induced by $\mathscr{T}$ via f (resp. via the projection $\pi : M \to M''$). We have :*

(i) *f induces a short exact sequence of the respective separated completions :*

$$0 \to (M', \mathscr{T}')^\wedge \xrightarrow{f^\wedge} (M, \mathscr{T})^\wedge \xrightarrow{\pi^\wedge} (M'', \mathscr{T}'')^\wedge.$$

(ii) *If $\mathscr{T}$ has a countable fundamental system of open submodules, $\pi^\wedge$ is an epimorphism.*

Proof. (i): See [75, §5.3] for generalities concerning linear topologies on V^a-modules. By definition, $\mathscr{T}$ is determined by a cofiltered family $(M_\lambda \mid \lambda \in \Lambda)$ of V^a-submodules of M, and $\mathscr{T}'$ and $\mathscr{T}''$ are likewise given by the families $(M'_\lambda := f^{-1}M_\lambda \mid \lambda \in \Lambda)$ and $(M''_\lambda := \pi(M_\lambda)) \mid \lambda \in \Lambda)$. We need to check that f induces an exact sequence of V^a-modules :

$$0 \to \lim_{\lambda\in\Lambda} M'/M'_\lambda \to \lim_{\lambda\in\Lambda} M/M_\lambda \to \lim_{\lambda\in\Lambda} M''/M''_\lambda.$$

To this aim, it suffices to show that the induced sequence of V-modules :

$$0 \to \lim_{\lambda\in\Lambda}(M'/M'_\lambda)_* \to \lim_{\lambda\in\Lambda}(M/M_\lambda)_* \to \lim_{\lambda\in\Lambda}(M''/M''_\lambda)_*$$

is exact. However, f induces a short exact sequence of V^a-modules

$$0 \to M'/M'_\lambda \to M/M_\lambda \to M''/M''_\lambda \to 0 \qquad \text{for every } \lambda \in \Lambda$$

whence a corresponding short exact sequence of V-modules

$$0 \to (M'/M'_\lambda)_* \to (M/M_\lambda)_* \to (M''/M''_\lambda)_* \qquad \text{for every } \lambda \in \Lambda.$$

The assertion follows immediately.

(ii): Under the stated assumptions, we may suppose that $\Lambda = \mathbb{N}^o$; then the assertion follows from proposition 14.2.25(iii). □

We conclude with two homological applications to usual rings : the techiques developed in this section are employed in the proof of the following propositions, but only trivial almost structures intervene.

Proposition 14.2.46. *Let $g : A \to B$ be a ring homomorphism, $I \subset A$ an ideal generated by a sequence $\mathbf{f} := (f_1, \dots, f_r)$, and $g(\mathbf{f}) := (g(f_1), \dots, g(f_r))$. Endow A and B with their I-adic topologies, and suppose that g is adically flat, and that B is complete and separated. We have :*

(i) *If A satisfies condition $(\mathrm{c})_{\mathbf{f}}$, the ring B satisfies $(\mathrm{c})_{g(\mathbf{f})}$ (notation of (7.8.21)).*

(ii) *Suppose additionally that also A is complete and separated, that g is adically faithfully flat, and that B satisfies $(\mathrm{c})_{g(\mathbf{f})}$; then A satisfies $(\mathrm{c})_{\mathbf{f}}$.*

Proof. (i): By assumption, the inverse system $(H_i(\mathbf{f}, I^n) \mid n \in \mathbb{N})$ is essentially zero for every $i > 0$, and we need to check that the same holds for the inverse system $(H_i(g(\mathbf{f}), I^nB) \mid n \in \mathbb{N})$. To this aim, we notice :

Claim 14.2.47. Let R be a ring, $J \subset R$ an ideal generated by a finite sequence $\mathbf{g}$, and consider the following conditions :

(a) R satisfies condition $(\mathrm{c})_{\mathbf{g}}$ of (7.8.21).

(b) For every $i, n \in \mathbb{N}$ there exists an integer $n' \geq n$ such that for every integer $m \geq n$ the natural map
$$H_i(\mathbf{g}, J^{n'}/J^{m'}) \to H_i(\mathbf{g}, J^n/J^m)$$
vanishes for some integer $m' \geq \max(m, n')$.

(c) For every $i, n \in \mathbb{N}$ there exists an integer $n' \geq n$ such that the natural map
$$H_i(\mathbf{g}, J^{n'}) \to H_i(\mathbf{g}, J^n/J^m)$$
vanishes for every integer $m \geq n$.

Then (a)⇒(b)⇒(c), and if R is J-adically complete and separated, we have also (c)⇒(a).

Proof of the claim. (a)⇒(b): By assumption, for every $i \in \mathbb{N}$ there exists a map $\varphi_i : \mathbb{N} \to \mathbb{N}$ with $\varphi_i(n) \geq n$, and such that the induced map $H_i(\mathbf{g}, J^{\varphi_i(n)}) \to H_i(\mathbf{g}, J^n)$ vanishes, for every $n \in \mathbb{N}$. Clearly, we may assume that $\varphi_i(n) \geq \varphi_i(m)$ whenever $n \geq m$ Set also $\varphi_{-1}(n) := n$

for every $n \in \mathbb{N}$, and define $\psi_i := \varphi_{i-1} \circ \psi_i$ for every $i \in \mathbb{N}$. For every $i, n, m \in \mathbb{N}$ with $m \geq n$ we get a commutative diagram with exact horizontal rows :

$$\begin{array}{ccccccc}
H_i(\mathbf{g}, J^{\psi_i(m)}) & \longrightarrow & H_i(\mathbf{g}, J^{\psi_i(n)}) & \longrightarrow & H_i(\mathbf{g}, J^{\psi_i(n)}/J^{\varphi_i(m)}) & \longrightarrow & H_{i-1}(\mathbf{g}, J^{\psi_i(m)}) \\
\downarrow{\scriptstyle \alpha_0} & & \downarrow{\scriptstyle \alpha_1} & & \downarrow{\scriptstyle \alpha_2} & & \downarrow{\scriptstyle \alpha_3} \\
H_i(\mathbf{g}, J^{\varphi_i(m)}) & \longrightarrow & H_i(\mathbf{g}, J^{\varphi_i(n)}) & \longrightarrow & H_i(\mathbf{g}, J^{\varphi_i(n)}/J^{\varphi_i(m)}) & \longrightarrow & H_{i-1}(\mathbf{g}, J^{\varphi_i(m)}) \\
\downarrow{\scriptstyle \beta_0} & & \downarrow{\scriptstyle \beta_1} & & \downarrow{\scriptstyle \beta_2} & & \downarrow{\scriptstyle \beta_3} \\
H_i(\mathbf{g}, J^m) & \longrightarrow & H_i(\mathbf{g}, J^n) & \longrightarrow & H_i(\mathbf{g}, J^n/J^m) & \longrightarrow & H_{i-1}(\mathbf{g}, J^m)
\end{array}$$

and by construction, the composition $\beta_k \circ \alpha_k$ vanishes for $k = 0, 1, 3$. By the snake lemma, it follows that $\beta_2 \circ \alpha_2 = 0$ as well; then $n' := \psi_i(n)$ and $m' := \psi_i(m)$ will do.

(b)⇒(c) is trivial.

(c)⇒(a): Recall that for every $n \in \mathbb{N}$, the natural map $J^n \to \lim_{k \in \mathbb{N}} J^n/J^{n+k}$ is an isomorphism (remark 8.3.3(iii,iv)); then, according to [163, Th.3.5.8], we have a short exact sequence

$$L_{i,n} := \lim_{k \in \mathbb{N}}{}^1 H_{i+1}(\mathbf{g}, J^n/J^{n+k}) \to H_i(\mathbf{g}, J^n B) \xrightarrow{\tau_{i,n}} L'_{i,n} := \lim_{k \in \mathbb{N}} H_i(\mathbf{f}, J^n/J^{n+k}) \to 0$$

for every $i, n \in \mathbb{N}$. On the other hand, for every $i, n, k \in \mathbb{N}$ we have an exact sequence :

$$H_{i+1}(\mathbf{g}, J^n) \xrightarrow{\alpha_{i,n,k}} H_{i+1}(\mathbf{g}, J^n/J^{n+k}) \xrightarrow{\beta_{i,n,k}} H_i(\mathbf{g}, J^{n+k}) \xrightarrow{\gamma_{i,n,k}} H_i(\mathbf{g}, J^n).$$

But notice that (c) implies that the inverse system $H_i(\mathbf{f}, I^{n+k} \mid k \in \mathbb{N})$ has the Mittag-Leffler property, for every $i, n \in \mathbb{N}$; then, the inverse system $(\mathrm{Im}\, \gamma_{i,n,k} \mid k \in \mathbb{N})$ is essentially constant, and consequently $(\mathrm{Ker}\, \gamma_{i,n,k} \mid k \in \mathbb{N})$ has the Mittag-Leffler property (proposition 14.2.30(iii)). The same holds for $(\mathrm{Im}\, \alpha_{i,n,k} \mid k \in \mathbb{N})$ (proposition 14.2.30(ii)), and finally we conclude that $(H_{i+1}(\mathbf{g}, J^n/J^{n+k}) \mid k \in \mathbb{N})$ has the Mittag-Leffler property, for every $i, n \in \mathbb{N}$ (proposition 14.2.30(i)). Hence, $L_{i,n} = 0$ for every $i, n \in \mathbb{N}$ (proposition 14.2.25(iii)), and $\tau_{i,n}$ is an isomorphism. Lastly, (c) implies that for every $i, n \in \mathbb{N}$ there exists an integer $n' \geq n$ such that the induced map $H_i(\mathbf{g}, J^{n'}) \to L'_{i,n}$ vanishes, so the same holds for the natural map $H_i(\mathbf{g}, J^{n'}) \to H_i(\mathbf{g}, J^n)$, whence (a). ◊

We are then reduced to checking that condition (b) of claim 14.2.47 holds for $R := B$, $\mathbf{g} := g(\mathbf{f})$, and $J := IB$. But since g is adically flat for the I-adic topologies, we have a natural identification

$$B \otimes_A H_i(\mathbf{f}, I^n/I^{n+k}) \xrightarrow{\sim} H_i(g(\mathbf{f}), I^n B/I^{n+k} B) \qquad \text{for every } i, n, k \in \mathbb{N}. \tag{14.2.48}$$

On the other hand, by assumption condition (a) of claim 14.2.47 holds for $R := A$, $\mathbf{g} := \mathbf{f}$, and $J := I$, so condition (b) of the claim holds as well for $A, \mathbf{f}$ and I, whence the assertion.

(ii): Again, we have the isomorphisms (14.2.48), and by assumption, condition (b) of claim 14.2.47 holds for $R := B$, $\mathbf{g} := g(\mathbf{f})$, and $J := IB$. Under the current assumptions, it then follows that condition (b) of claim 14.2.47 also holds for $R := A$, $\mathbf{g} := \mathbf{f}$ and $J := I$. Since A is I-adically complete, the assertion follows. □

Proposition 14.2.49. *Let $g : A \to B$ be a ring homomorphism, $\mathbf{f} := (f_1, \dots, f_r)$ a finite sequence of elements of A that generates an ideal $I \subset A$, $n \in \mathbb{N} \setminus \{0\}$, and $\mathbf{f}'$ the image of $\mathbf{f}$ in B. Suppose that B/IB is a flat A/I-algebra, and consider the following conditions :*

- (a) *The natural map $\varphi_i : B \otimes_A H_i(\mathbf{f}, A) \to H_i(\mathbf{f}', B)$ is bijective for $i = 0, \dots, n-1$ and surjective for $i = n$.*
- (b) $\mathrm{Tor}_i^A(B, M) = 0$ *for $i = 1, \dots, n$, every $k \in \mathbb{N} \setminus \{0\}$, and every A/I^k-module M.*
- (c) $\mathrm{Tor}_i^A(B, A/I) = 0$ *for $i = 1, \dots, n$.*
- (d) $\mathrm{Tor}_1^A(B, A/I) = 0$.

(e) *g is adically flat for the I-adic topologies of A and B.*

Then we have :

(i) (a)⇔(b)⇔(c) ⇒(d)⇒(e).

(ii) *If* (a) *holds for all $n \geq 0$, and A verifies $(\mathrm{c})_{\mathbf{f}}$ of* (7.8.21)*, then B verifies $(\mathrm{c})_{\mathbf{f}'}$.*

(iii) *If* (e) *holds and A satisfies $(\mathrm{c})_{\mathbf{f}}$, and B satisfies $(\mathrm{c})_{\mathbf{f}'}$, then* (a) *holds for all $n \geq 0$.*

Proof. (d)⇒(e) holds by by [126, Th.22.3], and trivially (b)⇒(c)⇒(d).

(c)⇒(b): The short exact sequence $0 \to IM \to M \to M/IM \to 0$ induces an exact sequence

$$\mathrm{Tor}_i^A(B, IM) \to \mathrm{Tor}_i^A(B, M) \to \mathrm{Tor}_i^A(B, M/IM) \qquad \text{for every } i \in \mathbb{N}.$$

Clearly IM is annihilated by I^{k-1}, and M/IM is annhilated by I; by a simple induction, we are then reduced to the case where $k = 1$. In this case, we find a set S and an A-linear surjection $h : (A/I)^{(S)} \to M$, whence an exact sequence :

$$T_i := \mathrm{Tor}_i^A(B, (A/I)^{(S)}) \to \mathrm{Tor}_i^A(B, M) \to \mathrm{Tor}_{i-1}^A(B, \mathrm{Ker}\, h) \qquad \text{for every } i > 0$$

and since the functor $\mathrm{Tor}_i^A(B, -)$ commutes with direct limits and finite sums, we have $T_i = 0$ for $i = 1, \dots, n$, due to (a). Hence, we are further reduced to checking that $\mathrm{Tor}_1^A(B, M) = 0$ for every A/I-module M, and we reduced easily first to the case where M is of finite type, say generated by k elements (since $\mathrm{Tor}_1^A(B, -)$ commutes with direct limits), and then to the case where $k = 1$, arguing by induction on k : the details are left to the reader. So, we may assume that $M = A/J$ for some ideal $J \subset A$ with $I \subset J$. In this case, notice that the short exact sequence $0 \to J/I \to A/I \to A/J \to 0$ is still exact after tensoring by B, since B/IB is a flat A/I-algebra; so the induced map $\mathrm{Tor}_1^A(B, A/I) \to \mathrm{Tor}_1^A(B, A/J)$ is surjective, whence the assertion.

(b)⇒(a): We consider the Künneth spectral sequence (see [163, Th.5.6.4])

$$E^2_{pq} := \mathrm{Tor}_p^A(B, H_q(\mathbf{f}, A)) \Rightarrow H_{p+q}(\mathbf{f}', B)$$

and recall that $H_q(\mathbf{f}, A)$ is an A/I-module for every $q \in \mathbb{N}$ (lemma 7.8.2(i)); thus, $E^2_{pq} = 0$ for every $p = 1, \dots, n$, due to (b). It follows easily that $E^\infty_{p,i-p} = 0$ for $p = 1, \dots, i$, and $E^\infty_{0,i} = E^2_{0,i}$, if $i < n$. Hence, φ_i is bijective for $i < n$. Lastly, for $i = n$ we get an exact sequence

$$E^2_{n+1,0} \xrightarrow{\partial^{n+1}_{n+1,0}} E^2_{0,n} = B \otimes_A H_n(\mathbf{f}, A) \to H_n(\mathbf{f}', B) \to 0$$

which shows that φ_n is surjective.

(a)⇒(c): We argue by induction on $n \in \mathbb{N} \setminus \{0\}$. If $n = 1$, notice that $E^\infty_{1,0} = E^2_{1,0} = \mathrm{Tor}_1^A(B, A/I)$, and we have a short exact sequence :

$$E^2_{0,1} = B \otimes_A H_1(\mathbf{f}, A) \to H_1(\mathbf{f}', B) \to E^\infty_{1,0} \to 0.$$

But (a) implies that $E^\infty_{1,0} = 0$, whence (c). Next, let $n > 1$, and suppose that it is already known that $\mathrm{Tor}_i^A(B, A/I) = 0$ for $i = 1, \dots, n-1$. By the foregoing, it follows that $\mathrm{Tor}_i^A(B, M) = 0$ for $i = 1, \dots, n-1$ and every A/I-module M. Hence, $E^2_{pq} = 0$ whenever $p = 1, \dots, n-1$, and therefore $E^\infty_{pq} = 0$ for every such p. In particular, $E^\infty_{0,n-1} = H_{n-1}(\mathbf{f}', B)$, and on the other hand, (a) implies that $H_{n-1}(\mathbf{f}', B) = E^2_{0,n-1}$. It follows that $E^r_{0,n-1} = E^2_{0,n-1}$ for every $r \geq 2$, and especially, the differential $\partial^r_{r,n-r} : E^r_{r,n-r} \to E^2_{0,n-1}$ is the zero map for every such r. But notice that $E^\infty_{n,0} = \mathrm{Ker}(\partial^n_{n,0} : E^2_{n,0} \to E^2_{0,n-1})$, so finally $E^\infty_{n,0} = E^2_{n,0}$. The subquotients of the filtration on the abutment $H_n(\mathbf{f}', B)$ vanish, except possibly for $E^\infty_{0,n}$ and $E^\infty_{n,0}$, so we arrive at the short exact sequence :

$$0 \to E^\infty_{0,n} \to H_n(\mathbf{f}', B) \to E^2_{n,0} \to 0.$$

where $E^\infty_{0,n}$ is a quotient of $E^2_{0,n} = B \otimes_A H_n(\mathbf{f}, A)$. Since φ_n is surjective by assumption, we deduce that $E^2_{n,0} = 0$, *i.e.* $\mathrm{Tor}^A_n(B, A/I) = 0$, as required.

(ii): To ease notation, set $H_i(A) := H_i(\mathbf{f}, A)$ and $H_{i,n}(A) := H_i(\mathbf{f}, A/I^n)$ for every $i, n \in \mathbb{N}$, and define likewise $H_i(B)$ and $H_{i,n}(B)$. The short exact sequences $0 \to I^n \to A \to A/I^n \to 0$ and $0 \to I^nB \to B \to B/I^nB \to 0$ yield a commutative ladder :

$$\begin{array}{ccccccccc} B\otimes_A H_{i+1}(A) & \xrightarrow{\psi_{i+1,n}} & B\otimes_A H_{i+1,n}(A) & \longrightarrow & B\otimes_A H_i(\mathbf{f}, I^n) & \longrightarrow & B\otimes_A H_i(A) & \xrightarrow{\psi_{i,n}} & B\otimes_A H_{i,n}(A) \\ {\scriptstyle\varphi_{i+1}}\downarrow & & {\scriptstyle\beta_{i+1,n}}\downarrow & & \downarrow{\scriptstyle\gamma_{i,n}} & & \downarrow{\scriptstyle\varphi_i} & & \downarrow{\scriptstyle\beta_{i,n}} \\ H_{i+1}(B) & \xrightarrow{\psi'_{i+1,n}} & H_{i+1,n}(B) & \longrightarrow & H_i(\mathbf{f}', I^nB) & \longrightarrow & H_i(B) & \xrightarrow{\psi'_{i,n}} & H_{i,n}(B) \end{array}$$

whose bottom horizontal row is exact, and the same holds for its top horizontal row, since we know already that (a) implies (e), and since $H_i(\mathbf{f}, M)$ is an A/I-module for every A-module M (lemma 7.8.2(ii)). By the same token, $\beta_{i,n}$ is bijective for every $i, n \in \mathbb{N}$, so the same holds for $\gamma_{i,n}$, by the five lemma, whence the assertion.

(iii): Under the assumptions of (iii), the horizontal rows of the commutative ladder in the proof of (ii) are still exact, and both $(B \otimes_A H_i(\mathbf{f}, I^n) \mid n \in \mathbb{N})$ and $(H_i(\mathbf{f}', I^nB) \mid n \in \mathbb{N})$ are essentially zero inverse systems, for every $i > 0$. The same also holds trivially for $i = 0$. In light of lemma 14.2.14(iii), it follows that the systems $(\psi_{i,n} \mid n \in \mathbb{N})$ and $(\psi'_{i,n} \mid n \in \mathbb{N})$ induce isomorphisms :

$$B \otimes_A H_i(A) \xrightarrow{\sim} \lim_{n\in\mathbb{N}} B \otimes_A H_{i,n}(A) \qquad H_i(B) \xrightarrow{\sim} \lim_{n\in\mathbb{N}} H_{i,n}(B).$$

Moreover, $\beta_{i,n}$ is still an isomorphism for every $n \in \mathbb{N}$, whence (a). ☐

Corollary 14.2.50. *Let $(A, \mathfrak{m})$ be a local noetherian ring, $\mathbf{f}$ a system of parameters for A, and $g : B \to B'$ a homomorphism of A-algebras. Endow B and B' with their $\mathfrak{m}$-adic topologies, and let $\mathbf{g}$ (resp. $\mathbf{g}'$) be the image of $\mathbf{f}$ in B (resp. in B'). Suppose that g is adically flat; then :*

(i) *If B satisfies condition $(\mathrm{c})_{\mathbf{g}}$ and B' satisfies condition $(\mathrm{c})_{\mathbf{g}'}$ of* (7.8.21)*, we have :*

$$\mathrm{depth}_A B' \geq \mathrm{depth}_A B.$$

(ii) *If B' is complete and separated, and if* $\mathrm{depth}_A B \geq \dim A$*, then* $\mathrm{depth}_A B' \geq \dim A$.

(iii) *If B and B' are complete and separated, g is adically faithfully flat, and* $\mathrm{depth}_A B' \geq \dim A$*, then* $\mathrm{depth}_A B \geq \dim A$.

Proof. (i) follows directly from propositions 14.2.49(iii) and 10.4.32(i), and lemma 7.8.2(v).

(ii): The assumptions trivially imply that B satisfies condition $(\mathrm{d})_{\mathbf{f}}$ of (7.8.21), so it also satisfies condition $(\mathrm{c})_{\mathbf{f}}$ (proposition 7.8.25(i)). Then B' satisfies condition $(\mathrm{c})_{\mathbf{f}}$, by proposition 14.2.46(i), and we apply (i) to conclude.

(iii): The assumptions trivially imply that B' satisfies condition $(\mathrm{d})_{\mathbf{f}}$ of (7.8.21), so it also satisfies condition $(\mathrm{c})_{\mathbf{f}}$ (proposition 7.8.25(i)). Then B satisfies condition $(\mathrm{c})_{\mathbf{f}}$, by proposition 14.2.46(i). Then, by proposition 14.2.49(iii), we have $B' \otimes_B H_i(\mathbf{g}, B) = 0$ for every $i > 0$; but since g is adically faithfully flat, and since $H_i(\mathbf{f}, B)$ is an A/I-module, we get $H_i(\mathbf{g}, B) = 0$ for every $i > 0$. Then the assertion follows from proposition 10.4.32(i), and lemma 7.8.2(v). ☐

14.3. **Quasi-coherent sheaves of almost modules and almost rings.** Throughout this section, we fix a basic setup $(V, \mathfrak{m})$ (see [75, §2.1.1]) and we set $S := \mathrm{Spec}\, V$; for every S-scheme X we may consider the sheaf $\mathscr{O}^a_X$ of almost algebras on X, and we refer to [75, §5.5] for the definition of quasi-coherent $\mathscr{O}^a_X$-modules and algebras. However, whereas in [75] it was assumed that $\widetilde{\mathfrak{m}} := \mathfrak{m} \otimes_V \mathfrak{m}$ is a flat V-module, in this section the basic setup can be arbitrary, except where it is explicitly said otherwise. This of course requires some care when quoting from [75]; however, it turns out that – thanks to the work done in section 14.1 – most of the results in [75] do extend *verbatim* to the case of a general setup. The main exception is the theory of the finite and almost finite rank of almost projective modules, that relies on the existence of a well behaved exterior power functor, which is available only if the basic setup satisfies some minimal conditions (see (14.1.61)). In any case, whenever we need to import some theorem from [75], we shall comment on its range of validity.

Definition 14.3.1. Let X be an S-scheme, $\mathscr{A}$ a quasi-coherent $\mathscr{O}_X^a$-algebra, and $\mathscr{F}$ an $\mathscr{A}$-module which is quasi-coherent as an $\mathscr{O}_X^a$-module.

(i) $\mathscr{F}$ is said to be an $\mathscr{A}$-module *of almost finite type* (resp. *of almost finite presentation*, resp *flat*, resp. *faithfully flat*) if, for every affine open subset $U \subset X$, the $\mathscr{A}(U)$-module $\mathscr{F}(U)$ is almost finitely generated (resp. almost finitely presented, resp. flat, resp. faithfully flat).

(ii) $\mathscr{F}$ is said to be an *almost coherent* $\mathscr{A}$-module if it is an $\mathscr{A}$-module of almost finite type, and for every open subset $U \subset X$, every quasi-coherent $\mathscr{A}_{|U}$-submodule of $\mathscr{F}_{|U}$ of almost finite type, is almost finitely presented.

(iii) We say that $\mathscr{F}$ is a *torsion-free* $\mathscr{O}_X^a$-module if we have $\operatorname{Ker} b \cdot \mathbf{1}_{\mathscr{F}(U)} = 0$, for every affine open subset $U \subset X$ and every regular element $b \in \mathscr{O}_X(U)$.

(iv) Suppose that $\mathfrak{m}$ satisfies condition $(\mathbf{B})$ of [75, §2.1.6]. Then we say that $\mathscr{F}$ is an $\mathscr{A}$-module *of almost finite rank* (resp. *of finite rank*) if, for every affine open subset $U \subset X$, the $\mathscr{A}(U)$-module $\mathscr{F}(U)$ is almost finitely generated projective of almost finite (resp. finite) rank.

Remark 14.3.2. In the situation of definition 14.3.1 :

(i) We denote by

$$\mathscr{E}nd_{\mathscr{A}}(\mathscr{F})$$

the $\mathscr{O}_X$-module of *$\mathscr{A}$-linear endomorphisms of $\mathscr{F}$*, defined by the rule : $U \mapsto \operatorname{End}_{\mathscr{A}(U)}(\mathscr{F}(U))$ for every open subset $U \subset X$. It is easily seen that $\mathscr{E}nd_{\mathscr{A}}(\mathscr{F})^a$ is an $\mathscr{A}$-module.

(ii) Suppose that $\mathscr{F}$ is a flat and almost finitely presented $\mathscr{A}$-module. Then there exists a *trace morphism*

$$\operatorname{tr}_{\mathscr{F}/\mathscr{A}} : \mathscr{E}nd_{\mathscr{A}}(\mathscr{F}) \to \mathscr{A}$$

that, on every affine open subset $U \subset X$, induces the trace morphism $\operatorname{tr}_{\mathscr{F}(U)\mathscr{A}(U)}$ of the almost finitely generated projective $\mathscr{A}(U)$-module $\mathscr{F}(U)$ (details left to the reader : see [75, §4.1], which does not depend on any assumption on the basic setup).

14.3.3. Let $f : Y \to X$ be any morphism of V-schemes. The usual functor f^* for quasi-coherent $\mathscr{O}_X$-module admits a variant for quasi-coherent $\mathscr{O}_X^a$-modules; namely, we define

$$f^* : \mathscr{O}_X^a\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \to \mathscr{O}_Y^a\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \qquad \mathscr{F} \mapsto (f^*\mathscr{F}_!)^a.$$

If f is also quasi-compact and quasi-separated, we have as well a direct image functor

$$f_* : \mathscr{O}_Y^a\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \to \mathscr{O}_X^a\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \qquad \mathscr{G} \mapsto (f_*\mathscr{G}_!)^a$$

([59, Ch.I, Prop.9.2.1]). Moreover, if $\mathscr{F}$ (resp. $\mathscr{G}$) is any quasi-coherent $\mathscr{O}_X$-module (resp. $\mathscr{O}_Y$-module), it is easily seen that the natural morphism

$$f^*(\mathscr{F}^a) \to (f^*\mathscr{F})^a \qquad \text{resp. } f_*(\mathscr{G}^a) \to (f_*\mathscr{G})^a$$

is an isomorphism. It follows that, if $Z \subset X$ is any constructible closed subset, there is a well defined functor of sections with support in Z :

$$\underline{\Gamma}_Z : \mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \to \mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}} \qquad \mathscr{F} \mapsto (\underline{\Gamma}_Z\mathscr{F}_!)^a$$

(see (10.4.16)) and again, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, the natural map

$$\underline{\Gamma}_Z(\mathscr{F}^a) \to (\underline{\Gamma}_Z\mathscr{F})^a$$

is an isomorphism (details left to the reader).

Lemma 14.3.4. *Suppose that* $\mathfrak{m}$ *fulfills condition* $(\mathbf{B})$*, and let* X *be a reduced* S*-scheme,* $\mathscr{F}$ *a flat quasi-coherent* $\mathscr{O}_X^a$*-module of almost finite type. We have :*

(i) *If X is reduced and $\mathscr{F}$ is an $\mathscr{O}_X^a$-module of almost finite presentation, then $\mathscr{F}$ is an $\mathscr{O}_X^a$-module of almost finite rank.*
(ii) *If X is integral, then $\mathscr{F}$ is an $\mathscr{O}_X^a$-module of finite rank.*

Proof. (i): We may assume that X is affine, say $X = \operatorname{Spec} R$ for a reduced V-algebra R, and $\mathscr{F} = P^\sim$ for a flat and almost finitely presented R^a-module P. Then P is almost projective ([75, Prop.2.4.18(ii)]), and we need to check that it has almost finite rank. Thus, let $\varepsilon \in \mathfrak{m}$ be any element and set $R' := R[\varepsilon^{-1}]$; then $P' := R' \otimes_{R^a} P$ is a projective R'-module of finite rank, so there exists $n \in \mathbb{N}$ such that $R' \otimes_R \Lambda^n_R P = \Lambda^n_{R'} P' = 0$. Since $\Lambda^n_R P$ is also almost finitely presented (see [75, §4.3.1]), we deduce easily that there exists $N \in \mathbb{N}$ such that $\varepsilon^N \cdot \Lambda^n_R P = 0$, and since moreover $\Lambda^n_R P$ is a flat R^a-module and R is reduced, we have

$$\operatorname{Ann}_{\Lambda^n_R P}(\varepsilon^N) = \operatorname{Ann}_R(\varepsilon^N) \cdot \Lambda^n_R P = \operatorname{Ann}_R(\varepsilon) \cdot \Lambda^n_R P$$

i.e. $\varepsilon \cdot \Lambda^n_R P = 0$, whence the contention.

(ii): Let η be the generic point of X; if $\kappa(\eta)^a = 0$, we have $\mathscr{O}_X^a = 0$ as well, and there is nothing to show. If $\kappa(\eta)^a \neq 0$, the almost structure on $\kappa(\eta)$ is the trivial one (the "classical limit" case of [75, Ex.2.1.2(ii)]); in this case, clearly $\mathscr{F}_\eta$ is a free $\kappa(\eta)^a$-module of finite rank, and let r be this rank. From [75, Prop.2.4.19], it follows easily that $\mathscr{F}$ is almost finitely presented. Moreover, the exterior powers of $\mathscr{F}$ are still flat $\mathscr{O}_X^a$-modules; then the r-th exterior power vanishes, since it vanishes at the generic point of X. □

Lemma 14.3.5. *Let $f : Y \to X$ a faithfully flat and quasi-compact morphism of S-schemes, $\mathscr{A}$ a quasi-coherent $\mathscr{O}_X^a$-algebra, $\mathscr{F}$ a quasi-coherent $\mathscr{A}$-module, and $r \in \mathbb{N}$. Then :*

(i) *The $\mathscr{A}$-module $\mathscr{F}$ is of almost finite type (resp. of almost finite presentation, resp. flat, resp. faithfully flat) if and only if the same holds for the $f^*\mathscr{A}$-module $f^*\mathscr{F}$.*
(ii) *Suppose that $\mathfrak{m}$ fulfills condition $(\mathbf{B})$. Then the $\mathscr{A}$-module $\mathscr{F}$ is of almost finite rank (resp. of finite rank $\leq r$) if and only if the same holds for the $f^*\mathscr{A}$-module $f^*\mathscr{F}$.*
(iii) *If the $f^*\mathscr{A}$-module $f^*\mathscr{F}$ is almost coherent, then the same holds for the $\mathscr{A}$-module $\mathscr{F}$.*

Proof. The assertions are local on X, so we may assume that X is affine; then Y admits a finite covering $(U_i \mid i \in I)$ consisting of affine open subsets, and we may further reduce to the case where Y is the disjoint union of the schemes U_i, so Y is affine as well.

(i): For the conditions "almost finite type", "almost finite presentation", and "flat", the assertion follows from [75, Rem.3.2.26(ii)], which holds for any basic setup. It remains to check that if $A \to B$ is a faithfully flat map of V-algebras, and M is any A-module, such that $(B \otimes_A M)^a$ is a faithfully flat B^a-module, then M^a is a faithfully flat A^a-module. To this aim, let X be any A-module such that $(M \otimes_A X)^a = 0$; then $(B \otimes_A X)^a \otimes_{B^a} (B \otimes_A X)^a = 0$, and therefore $(B \otimes_A X)^a = 0$, *i.e.* $\widetilde{\mathfrak{m}} \otimes_V B \otimes_A X = 0$, whence $\widetilde{\mathfrak{m}} \otimes_V X = 0$, *i.e.* $X^a = 0$. Since we know already that M^a is a flat A^a-module, the contention follows.

(ii): It suffices to apply [75, Rem.3.2.26(iii)], and recall that exterior powers commute with any base changes : the details shall be left to the reader.

(iii) follows easily from (i). □

Lemma 14.3.6. *Let X be any S-scheme.*

(i) *The full subcategory $\mathscr{O}_X^a$-$\mathbf{Mod}_{\mathrm{acoh}}$ of $\mathscr{O}_X^a$-$\mathbf{Mod}_{\mathrm{qcoh}}$ consisting of all almost coherent modules is abelian and closed under extensions. (More precisely, the embedding $\mathscr{O}_X^a$-$\mathbf{Mod}_{\mathrm{acoh}} \to \mathscr{O}_X^a$-$\mathbf{Mod}_{\mathrm{qcoh}}$ is an exact functor.)*
(ii) *If X is a coherent scheme, then every quasi-coherent $\mathscr{O}_X^a$-module of almost finite presentation is almost coherent.*

Proof. Both assertions are local on X, hence we may assume that X is affine, say $X = \operatorname{Spec} R$.

(i): Let $f : M \to N$ be a morphism of almost coherent R^a-modules. It is clear that $\operatorname{Coker} f$ is again almost coherent. Moreover, $f(M) \subset N$ is almost finitely generated, hence almost finitely presented; then by [75, Lemma 2.3.18], $\mathrm{Ker}\, f$ is almost finitely generated, and so it is almost coherent as well. Similarly, using [75, Lemma 2.3.18] one sees that $\mathscr{O}^a_X\text{-}\mathbf{Mod}_{\mathrm{acoh}}$ is closed under extensions.

(ii): Let M be an almost finitely presented R^a-module; according to [75, Cor.2.3.13], for every finitely generated ideal $\mathfrak{m}_0 \subset \mathfrak{m}$ there exist a finitely presented R-module N and an R-linear map $\varphi : N \to M_*$ whose kernel and cokernel are annihilated by $\mathfrak{m}_0$. Likewise, if $M' \subset M$ is an almost finitely generated R^a-submodule, we may find finitely many almost elements $x_1, \dots, x_n \in M'_*$ that generate an R-module containing $\mathfrak{m}_0 M'_*$. Let $a_1, \dots, a_k$ be a finite system of generators for $\mathfrak{m}_0$; for each $i \leq k$ and $j \leq n$ we may find $y_{ij} \in N$ such that $\varphi(y_{ij}) = a_i x_j$. Denote by N' the R-submodule of N generated by $(y_{ij} \mid i \leq k,\ j \leq n)$. Then φ restricts to an R-linear map $N' \to M'_*$ whose kernel is annihilated by $\mathfrak{m}_0$ and whose cokernel is annihilated by $\mathfrak{m}_0^2$. Since R is coherent, N' is finitely presented, and since $\mathfrak{m}_0$ is arbitrary, we conclude that M' is almost finitely presented, as stated. □

Lemma 14.3.7. *Let X be an S-scheme, $\varphi : \mathscr{A} \to \mathscr{B}$ a morphism of quasi-coherent $\mathscr{O}^a_X$-algebras, and $\mathscr{B}_\bullet := (\mathscr{B}_\lambda \mid \lambda \in \Lambda)$ a filtered system of quasi-coherent and faithfully flat $\mathscr{A}$-algebras. We have :*

(i) *φ is faithfully flat if and only if φ is injective and* $\mathrm{Coker}\,\varphi$ *is a flat $\mathscr{A}$-module.*

(ii) *The colimit of $\mathscr{B}_\bullet$ is a faithfully flat $\mathscr{A}$-algebra.*

Proof. It is easily seen that (i)⇒(ii). In order to show (i), we may assume that X is affine, in which case φ is the morphism of quasi-coherent $\mathscr{O}^a_X$-algebras arising from a morphism $f : A \to B$ of $\mathscr{O}_X(X)^a$-algebras. Now, let M be any A-module; if f is injective, the short exact sequence of A-modules $0 \to A \to B \to \mathrm{Coker}\, f \to 0$ induces a long exact sequence

$$0 \to \mathrm{Tor}_1^A(B, M) \to \mathrm{Tor}_1^A(\mathrm{Coker}\, f, M) \to M \xrightarrow{f \otimes_A M} B \otimes_A M \to \mathrm{Coker}\, f \otimes_A M \to 0.$$

Then, if $\mathrm{Coker}\, f$ is a flat A-module, we deduce that $f \otimes_A M$ is injective and $\mathrm{Tor}_1^A(B, M) = 0$ for every A-module M, so B is a faithfully flat A-algebra. Conversely, if the latter holds, then f and $f \otimes_M A$ are both injective, hence the foregoing short exact sequence shows that $\mathrm{Tor}_1^A(\mathrm{Coker}\, f, M) = 0$ for every A-module M, so that $\mathrm{Coker}\, f$ is a flat A-module. □

Definition 14.3.8. Let X be an S-scheme, and $\mathscr{A}$ a quasi-coherent $\mathscr{O}^a_X$-algebra.

(i) We say that a quasi-coherent $\mathscr{A}$-algebra $\mathscr{B}$ is *almost finite* (resp. *weakly unramified*, resp. *weakly étale*, resp. *unramified*, resp. *étale*) if, for every affine open subset $U \subset X$, the $\mathscr{A}(U)$-algebra $\mathscr{B}(U)$ is almost finite (resp. weakly unramified, resp. weakly étale, resp. unramified, resp. étale) .

(ii) We define the $\mathscr{O}_X$-algebra $\mathscr{A}_{!!}$ by the short exact sequence :

$$\widetilde{\mathfrak{m}} \otimes_V \mathscr{O}_X \to \mathscr{O}_X \oplus \mathscr{A}_! \to \mathscr{A}_{!!} \to 0$$

analogous to [75, §2.2.25]. This agrees with the definition of [75, §3.3.2], corresponding to the basic setup $(\mathscr{O}_X, \mathfrak{m}\mathscr{O}_X)$ relative to the Zariski topos of X; in general, this is *not* the same as forming the algebra $\mathscr{A}_{!!}$ relative to the basic setup $(V, \mathfrak{m})$. The reason why we prefer the foregoing version of $\mathscr{A}_{!!}$, is explained by the following lemma 14.3.9.

Lemma 14.3.9. *Let X be an S-scheme, $\mathscr{A}$ a quasi-coherent $\mathscr{O}^a_X$-algebra. Then $\mathscr{A}_{!!}$ is a quasi-coherent $\mathscr{O}_X$-algebra, and if $\mathscr{A}$ is almost finite, then $\mathscr{A}_{!!}$ is an integral $\mathscr{O}_X$-algebra.*

Proof. First, $\mathscr{A}_!$ is a quasi-coherent $\mathscr{O}_X$-module ([75, §5.5.4]), hence the same holds for $\mathscr{A}_{!!}$. It remains to show that if $\mathscr{A}$ is almost finite, then $\mathscr{A}_{!!}(U) = \mathscr{A}(U)_{!!}$ is an integral $\mathscr{O}_X(U)$-algebra for every affine open subset $U \subset X$. Since $\mathscr{A}(U)_{!!} = \mathscr{O}_X(U) + \mathfrak{m}\mathscr{A}(U)_{!!}$, we need only show that every element of $\mathfrak{m}\mathscr{A}(U)_{!!}$ is integral over $\mathscr{O}_X(U)$. However, by adjunction we get a map :

$$\mathscr{A}(U)_{!!} \to A_U := \mathscr{O}^a_X(U)_* + \mathfrak{m}\mathscr{A}(U)_*$$

whose kernel is annihilated by $\mathfrak{m}$, and according to [75, Lemma 5.1.13(i)], A_U is integral over $\mathscr{O}_X^a(U)_*$. Let $a \in \mathfrak{m}\mathscr{A}(U)_{!!}$ be any element, and $\overline{a}$ its image in $\mathfrak{m}\mathscr{A}(U)_*$; we can then find $b_0, \dots, b_n \in \mathscr{O}_X(U)_*$ such that $\overline{a}^{n+1} + \sum_{i=0}^n b_i \overline{a}^i = 0$ in A_U. It follows that $(\varepsilon a)^{n+1} + \sum_{i=0}^n \varepsilon^{n+1-i} b_i (\varepsilon a)^i = 0$ in $\mathscr{A}(U)_{!!}$, for every $\varepsilon \in \mathfrak{m}$. Since $\varepsilon^{n+1-i} b_i$ lies in the image of $\mathscr{O}_X(U)$ for every $i \leq n$, the claim follows easily. □

Remark 14.3.10. With the notation of definition 14.3.8 we have :

(i) $\mathscr{B}$ is an unramified $\mathscr{A}$-algebra if and only if, for every affine open subset $U \subset X$, there exists an idempotent element $e_{\mathscr{B}(U)/\mathscr{A}(U)} \in (\mathscr{B} \otimes_{\mathscr{A}} \mathscr{B})(U)_*$, uniquely characterized by the following conditions :

(a) $\mu_{\mathscr{B}/\mathscr{A}}(e_{\mathscr{B}(U)/\mathscr{A}(U)}) = 1$, where $\mu_{\mathscr{B}/\mathscr{A}} : \mathscr{B} \otimes_{\mathscr{A}} \mathscr{B} \to \mathscr{B}$ is the multiplication morphism of the $\mathscr{A}$-algebra $\mathscr{B}$.

(b) $e_{\mathscr{B}(U)/\mathscr{A}(U)} \cdot \operatorname{Ker} \mu_{\mathscr{B}/\mathscr{A}}(U) = 0$

([75, Lemma 3.1.4]). It is easily seen that, on $U' \subset U$, the element $e_{\mathscr{B}(U)/\mathscr{A}(U)}$ restricts to $e_{\mathscr{B}(U')/\mathscr{A}(U')}$; hence, the system $(e_{\mathscr{B}(U)/\mathscr{A}(U)} \mid U \subset X)$, for U ranging over all the affine open subsets of X, determines a global section

$$e_{\mathscr{B}/\mathscr{A}} \in \Gamma(X, \mathscr{B} \otimes_{\mathscr{A}} \mathscr{B})_*$$

which we call the *diagonal idempotent* of the $\mathscr{A}$-algebra $\mathscr{B}$ (see [75, §5.5.4]).

(ii) In the situation of (i), let $\mathscr{A} \to \mathscr{A}'$ be any morphism of quasi-coherent $\mathscr{O}_X^a$-algebras, and set $\mathscr{B}' := \mathscr{A}' \otimes_{\mathscr{A}} \mathscr{B}$. Then the induced morphism $\mathscr{A}' \to \mathscr{B}'$ is unramified, and in view of the characterization provided by (i), it is easily seen that $e_{\mathscr{B}'/\mathscr{A}'}$ is the image in $\mathscr{B}' \otimes_{\mathscr{A}'} \mathscr{B}'$ of $e_{\mathscr{B}/\mathscr{A}}$.

(iii) If $\mathscr{B}$ is a flat and almost finitely presented $\mathscr{A}$-algebra, there exists a *trace form*

$$t_{\mathscr{B}/\mathscr{A}} : \mathscr{B} \otimes_{\mathscr{A}} \mathscr{B} \to \mathscr{A}$$

that, on each open affine subset $U \subset X$, induces the trace form $t_{\mathscr{B}(U)/\mathscr{A}(U)}$ of [75, §4.1.12] (details left to the reader).

(iv) Suppose that $\mathscr{B}$ is a flat, unramified and almost finitely presented $\mathscr{A}$-algebra. Then the diagonal idempotent and the trace form of $\mathscr{B}$ are related by the identity

$$t_{\mathscr{B}/\mathscr{A}}(e_{\mathscr{B}/\mathscr{A}} \cdot (1 \otimes b)) = b = t_{\mathscr{B}/\mathscr{A}}(e_{\mathscr{B}/\mathscr{A}} \cdot (b \otimes 1))$$

for every affine open subset $U \subset X$ and every $b \in \mathscr{B}(U)_*$ ([75, Rem.4.1.17]).

Definition 14.3.11. (i) Let X be an S-scheme. For a monomorphism $\mathscr{R} \subset \mathscr{S}$ of quasi-coherent $\mathscr{O}_X$-algebras, the integral closure $\mathrm{i.c.}(\mathscr{R}, \mathscr{S})$ of $\mathscr{R}$ in $\mathscr{S}$ is a quasi-coherent $\mathscr{O}_X$-algebra. For a monomorphism $\mathscr{A} \to \mathscr{B}$ of $\mathscr{O}_X^a$-algebras, the *integral closure of $\mathscr{A}$ in $\mathscr{B}$* is

$$\mathrm{i.c.}(\mathscr{A}, \mathscr{B}) := \mathrm{i.c.}(\mathscr{A}_{!!}, \mathscr{B}_{!!})^a$$

(see also [75, Lemma 8.2.28]). In view of lemma 14.3.9, this is a well defined quasi-coherent $\mathscr{O}_X^a$-algebra. It is characterized as the unique $\mathscr{A}$-subalgebra of $\mathscr{B}$ such that :

$$\mathrm{i.c.}(\mathscr{A}, \mathscr{B})(U) = \mathrm{i.c.}(\mathscr{A}(U), \mathscr{B}(U))$$

for every affine open subset $U \subset X$ (notation of [75, Def.8.2.27]). We say that $\mathscr{A}$ is *integrally closed in $\mathscr{B}$*, if $\mathscr{A} = \mathrm{i.c.}(\mathscr{A}, \mathscr{B})$. We say that $\mathscr{B}$ is an *integral $\mathscr{A}$-algebra* if $\mathrm{i.c.}(\mathscr{A}, \mathscr{B}) = \mathscr{B}$.

(ii) Likewise, the weak normalization $\mathscr{C}$ and the p-integral closure $\mathscr{D}$ of the image of $\mathscr{A}_{!!}$ in $\mathscr{B}_{!!}$ are quasi-coherent $\mathscr{O}_X$-algebras (see (9.8.27)); then we define the *weak normalization* (resp. the *p-integral closure*) of $\mathscr{A}$ in $\mathscr{B}$ as the quasi-coherent $\mathscr{O}_X^a$-algebra $\mathscr{C}^a$ (resp. $\mathscr{D}^a$).

Remark 14.3.12. (i) In the notation of definition 14.3.11, if $\mathscr{R}'$ is the integral closure of $\mathscr{R}$ in $\mathscr{S}$, then $\mathscr{R}'^a$ is the integral closure of $\mathscr{R}^a$ in $\mathscr{S}^a$. Indeed, we may assume that X is affine, in which case the assertion follows from [75, Lemma 8.2.28].

(ii) It follows that $\mathscr{B}$ is an integral $\mathscr{A}$-algebra if and only if $\mathscr{B}_{!!}$ is an integral $\mathscr{A}_{!!}$-algebra. Indeed, suppose that $\mathscr{B}$ is an integral $\mathscr{A}$-algebra, so that $\mathscr{B} = \mathrm{i.c.}(\mathscr{A}_{!!}, \mathscr{B}_{!!})^a$, whence by adjunction, a morphism of $\mathscr{A}_{!!}$-algebras $\mathscr{B}_{!!} \to \mathrm{i.c.}(\mathscr{A}_{!!}, \mathscr{B}_{!!})$, which must be the identity map.

(iii) Also, if $\mathscr{R}''$ is the weak normalization of $\mathscr{R}$ in $\mathscr{S}$, then it follows easily from proposition 9.8.29(i,ii) that $\mathscr{R}''^a$ is the weak normalization of $\mathscr{R}^a$ in $\mathscr{S}^a$: the details are left to the reader.

Proposition 14.3.13. *Suppose that the ideal* $\mathfrak{m}$ *fulfills condition* $(\mathbf{B})$ *of* [75, §2.1.6]. *Let X be a quasi-compact S-scheme, $\mathscr{A}$ a quasi-coherent $\mathscr{O}_X^a$-algebra, and $\mathscr{B}$ a flat $\mathscr{A}$-algebra that is almost finitely presented as an $\mathscr{A}$-module. Then $\mathscr{B}(X)$ is an integral $\mathscr{A}(X)$-algebra.*

Proof. For every $b \in \mathscr{B}(X)_*$ and every $i \in \mathbb{N}$, set :

$$c_i(b) := \mathrm{tr}_{\Lambda^i_{\mathscr{A}}\mathscr{B}/\mathscr{A}}(\Lambda^i_{\mathscr{A}}(b\mathbf{1}_{\mathscr{B}})) \in \mathscr{A}(X)$$

(see remark 14.3.2(ii)). In view of [75, Lemma 8.2.28], it suffices to show

Claim 14.3.14. For every $b \in \mathscr{B}(X)_*$ and $a \in \mathfrak{m}$, there exists $n \in \mathbb{N}$ such that :

(i) $c_i(ab) = 0$ for every $i > n$.
(ii) $\sum_{i=0}^n (-ab)^{i+1} \cdot c_{n-i}(ab) = 0$.

Proof of the claim. Since X admits a finite affine covering, and since the trace morphism commutes with arbitrary base changes, we are easily reduced to the case where X is affine. In this case, set $A := \mathscr{A}(X)$ and $B := \mathscr{B}(X)$; then B is an almost finitely generated projective A-algebra, and there exists $n \in \mathbb{N}$ such that $a\mathbf{1}_B$ factors through A-linear maps $u : B \to A^{\oplus n}$ and $v : A^{\oplus n} \to B$ ([75, Lemma 2.4.15]). Thus, $ab\mathbf{1}_B = v \circ (u \circ b\mathbf{1}_B)$, and we get :

$$c_i(ab) = \mathrm{tr}_{\Lambda^i_A A^{\oplus n}/A}(\Lambda^i_A(u \circ b\mathbf{1}_B \circ v)) \qquad \text{for every } i \in \mathbb{N}$$

([75, Lemma 4.1.2(i)]), from which (i) already follows. By the same token, we also obtain :

$$\chi := \sum_{i=0}^n (-u \circ b\mathbf{1}_B \circ v)^i \cdot c_{n-i}(ab) = 0$$

([75, Prop.4.4.30]). However, the left-hand side of the identity of (ii) is none else than $(-1) \cdot v \circ \chi \circ (u \circ b\mathbf{1}_B)$; whence the claim. ☐

The following lemma generalizes [75, Cor. 4.4.31].

Lemma 14.3.15. *Let A be a V^a-algebra, $B \subset A$ a V^a-subalgebra, P an almost finitely generated projective A-module, and φ an A-linear endomorphism of P. Suppose that :*

(a) *B is integrally closed in A.*
(b) *φ is integral over B_*.*

Then we have :

(i) $\mathrm{tr}_{P/A}(\varphi) \in B_*$.
(ii) *If* $\mathfrak{m}$ *fulfills condition* $(\mathbf{B})$ *of* [75, §2.1.6], *then* $\det(\mathbf{1}_P + T\varphi) \in B_*[[T]]$.

Proof. For the meaning of assumption (b), see the proof of [75, Cor. 4.4.31].

(i): For every $\varepsilon \in \mathfrak{m}$ we may find a free A-module L of finite rank, and A-linear morphisms $u : P \to L$, $v : L \to P$ such that $v \circ u = \varepsilon\mathbf{1}_P$ ([75, Lemma 2.4.15]). It follows that

$$\mathrm{tr}_{L/A}(u \circ \varphi \circ v) = \mathrm{tr}_{P/A}(\varphi \circ v \circ u) = \varepsilon \cdot \mathrm{tr}_{P/A}(\varphi)$$

([75, Lemma 4.1.2]). On the other hand, say that the polynomial $T^n + \sum_{j=0}^{n-1} b_j T^j \in B_*[T]$ annihilates φ; it is easily seen that $T^n + \sum_{j=0}^{n-1} b_j \varepsilon^{n-j} T^j$ annihilates $u \circ \varphi \circ v$, so the latter is integral over B_* as well, and therefore its trace lies in B_* ([75, Cor.4.4.31 and Rem.8.2.30(i)]). Summing up, we have shown that $\varepsilon \cdot \mathrm{tr}_{P/A}(\varphi) \in B_*$ for every $\varepsilon \in \mathfrak{m}$, whence the contention.

(ii): Recall that $\det(\mathbf{1}_P + T\varphi)$ is the power series in the variable T, whose coefficient in degree i is the trace of $\Lambda^i_A\varphi$ on $\Lambda^i_A P$: see [75, §4.3.1, §4.3.3].

Claim 14.3.16. Let Q be another almost finitely generated projective A-module, ψ be an endomorphism of P that is also integral over B_*. Then the endomorphism $\varphi \otimes_A \psi$ of $P \otimes_A Q$ is integral over B_*.

Proof of the claim. The tensor product defines a map of unital associative B_*-algebras

$$\mathrm{End}_A(P) \otimes_{B_*} \mathrm{End}_A(Q) \to \mathrm{End}_A(P \otimes_A Q).$$

By assumption, the subalgebra $B_*[\varphi] \subset \mathrm{End}_A(P)$ is finite over B_*, and similarly for $B_*[\psi] \subset \mathrm{End}_A(Q)$. Hence, the same holds for the image of $B_*[\varphi] \otimes_{B_*} B_*[\psi]$ in $\mathrm{End}_A(P \otimes_A Q)$, whence the claim. ♢

It follows easily from claim 14.3.16, that the endomorphism $\Lambda^i_A \varphi$ of $\Lambda^i_A P$ is integral over B_*. Hence, we may replace P by $\Lambda^i_A P$, and reduce to showing that the trace of φ lies in B_*, which is known, by (i). □

Lemma 14.3.17. *Let A be a V^a-algebra, $I \subset \mathrm{rad}(A)$ a tight ideal (see* [75, Def.5.1.5]*), and P a flat and almost finitely generated A-module. Let also $r \in \mathbb{N}$. We have :*

(i) *If P/IP is a faithfully flat A-module, then P is a faithfully flat A-module.*
(ii) *If $\mathfrak{m}$ fulfills condition* $(\mathbf{B})$*, and P is an almost projective A-module such that P/IP is an A/I-module of almost finite rank (resp. of finite rank $\leq r$), then P is an A-module of almost finite rank (resp. of finite rank $\leq r$).*

Proof. (i): It suffices to show that for every almost finitely generated A-module $M \neq 0$, we have $M \otimes_A P \neq 0$. To this aim, it suffices to check that $M \otimes_A P/IP \neq 0$; since $M \otimes_A P/IP = (M \otimes_A A/I) \otimes_{A/I} P/IP$, and since by assumption P/IP is a faithfully flat A/I-module, we are further reduced to showing that $M \otimes_A A/I \neq 0$; the latter follows from [75, Lemma 5.1.7].

(ii): Suppose first that P/IP is of finite rank $\leq r$, so that $\Lambda^r_{A/I}(P/IP) = 0$. Hence $(\Lambda^r_A P) \otimes_A P/IP = 0$, and then [75, Lemma 5.1.7] yields $\Lambda^r_A P = 0$, as sought. In the more general case where P/IP has almost finite rank, pick $n \in \mathbb{N}$ and a finitely generated subideal $\mathfrak{m}_0 \subset \mathfrak{m}$, such that $I^n \subset \mathfrak{m}_0$. Let also $\mathfrak{m}_1 \subset \mathfrak{m}$ be any finitely generated subideal such that $\mathfrak{m}_0 \subset \mathfrak{m}_1^{n+1}$; by assumption, there exists $i \in \mathbb{N}$ such that $\mathfrak{m}_1 \Lambda^i_{A/I}(P/IP) = 0$, *i.e.* $\mathfrak{m}_1 \Lambda^i_A P \subset I \Lambda^i_A P$. Therefore

$$\mathfrak{m}_0 \Lambda^i_A P \subset \mathfrak{m}_1^{n+1} \Lambda^i_A P \subset I^{n+1} \Lambda^i_A P \subset \mathfrak{m}_0 I \Lambda^i_A P$$

whence $\mathfrak{m}_0 \Lambda^i_A P = 0$, by [75, Lemma 5.1.7]. Since $\mathfrak{m}_0$ is arbitrary, we deduce that P has almost finite rank, as claimed. □

Lemma 14.3.18. *Let $A \to B$ be a morphism of V^a-algebras which is a monomorphism on the underlying V^a-modules, P an almost finitely generated and almost projective A-module, and $r \in \mathbb{N}$. Suppose as well that $\mathfrak{m}$ fulfills condition* $(\mathbf{B})$*; the following holds :*

(i) *P is an A-module of almost finite rank (resp. of finite rank $\leq r$) if and only if the same holds for the B-module $B \otimes_A P$.*
(ii) *Suppose that P has almost finite rank. Then P is a faithfully flat A-module if and only if the same holds for the B-module $B \otimes_A P$.*

Proof. (i): According to proposition 14.1.56(i), the A-module $\Lambda^i_A P$ is flat for every $i \in \mathbb{N}$; hence the natural A-linear morphism

$$\Lambda^i_A P \to B \otimes_A \Lambda^i_A P \stackrel{\sim}{\to} \Lambda^i_B(B \otimes_A P)$$

is a monomorphism for every $i \in \mathbb{N}$; the assertion follows straightforwardly.

(ii): According to [75, Th.4.3.28] (which holds whenever $\mathfrak{m}$ fulfills condition $(\mathbf{B})$) we have V^a-algebras A_0, A' and an isomorphism of V^a-algebras $A \stackrel{\sim}{\to} A_0 \times A'$ such that $A_0 \otimes_A P = 0$ and $A' \otimes_A P$ is a faithfully flat A'-module. Suppose now that $B \otimes_A P$ is a faithfully flat B-module; since $(B \otimes_A A_0) \otimes_B (B \otimes_A P) \simeq B \otimes_A A_0 \otimes_A P = 0$, it follows that $B \otimes_A A_0 = 0$.

On the other hand, the induced A-linear morphism $A_0 \to B \otimes_A A_0$ is a monomorphism, since A_0 is a flat A-module; thus, $A_0 = 0$, and consequently $P = A' \otimes_A P$ is faithfully flat. $\square$

Lemma 14.3.19. *Let $j : U \to X$ be an open quasi-compact immersion of S-schemes, $\mathscr{B}$ a quasi-coherent $\mathscr{O}_U^a$-algebra, $\mathscr{A}$ a quasi-coherent $\mathscr{O}_X^a$-algebra, and $j^*\mathscr{A} \to \mathscr{B}$ an étale morphism. Then the induced morphism*

$$\mathscr{A} \to j_*j^*\mathscr{A} \to j_*\mathscr{B}$$

is flat if and only if it is étale.

Proof. We may assume that $j_*\mathscr{B}$ is a flat $\mathscr{A}$-algebra, and it suffices to show that $j_*\mathscr{B}$ admits a diagonal idempotent as in remark 14.3.10(i). To this aim, let us remark more generally :

Claim 14.3.20. Let $f : Y \to X$ be a quasi-compact and quasi-separated morphism, $\mathscr{F}$ a flat quasi-coherent $\mathscr{A}$-module, and $\mathscr{G}$ an $f^*\mathscr{A}$-module, quasi-coherent as an $\mathscr{O}_Y^a$-module. Then the natural map

$$\mathscr{F} \otimes_{\mathscr{A}} f_*\mathscr{G} \to f_*(f^*\mathscr{F} \otimes_{f^*\mathscr{A}} \mathscr{G})$$

is an isomorphism.

Proof of the claim. This is proved just as for $\mathscr{O}_X$-modules. Namely, one reduces easily to the case where X is affine, and one needs to check that the natural map

$$\mathscr{F}(X) \otimes_{\mathscr{A}(X)} \mathscr{G}(Y) \to (f^*\mathscr{F} \otimes_{f^*\mathscr{A}} \mathscr{G})(Y)$$

is an isomorphism. However, by assumption Y can be covered by finitely many affine open subsets $U_1, \dots, U_n$, and the intersection $U_{ij} := U_i \cap U_j$ can be covered by finitely many affine open subsets $U_{ij1}, \dots, U_{ijn}$, for every $i, j = 1, \dots, n$. Since $f^*\mathscr{F}$, $\mathscr{G}$ and $f^*\mathscr{A}$ are quasi-coherent $\mathscr{O}_Y^a$-modules, the natural maps

$$\mathscr{F}(X) \otimes_{\mathscr{A}(X)} \mathscr{G}(U_i) \to (f^*\mathscr{F} \otimes_{f^*\mathscr{A}} \mathscr{G})(U_i)$$
$$\mathscr{F}(X) \otimes_{\mathscr{A}(X)} \mathscr{G}(U_{ijk}) \to (f^*\mathscr{F} \otimes_{f^*\mathscr{A}} \mathscr{G})(U_{ijk})$$

are isomorphisms, for every $i, j, k = 1, \dots, n$. Then we get :

$$(f^*\mathscr{F} \otimes_{\mathscr{A}} \mathscr{G})(Y) = \operatorname{Ker}(\prod_{i=1}^n \mathscr{F}(X) \otimes_{\mathscr{A}(X)} \mathscr{G}(U_i) \rightrightarrows \prod_{i,j,k=1}^n \mathscr{F}(X) \otimes_{\mathscr{A}(X)} \mathscr{G}(U_{ijk}))$$
$$= \mathscr{F}(X) \otimes_{\mathscr{A}(X)} \operatorname{Ker}(\prod_{i=1}^n \mathscr{G}(U_i) \rightrightarrows \prod_{i,j,k=1}^n \mathscr{G}(U_{ijk}))$$

(since $\mathscr{F}(X)$ is a flat $\mathscr{A}(X)$-module) whence the claim. $\Diamond$

Now, set $\mathscr{R} := \mathscr{B} \otimes_{j^*\mathscr{A}} \mathscr{B}$; since j is quasi-compact and $j_*\mathscr{B}$ is a flat $\mathscr{A}$-algebra, claim 14.3.20 implies that the natural morphism :

$$j_*\mathscr{B} \otimes_{\mathscr{A}} j_*\mathscr{B} \to j_*\mathscr{R}$$

is an isomorphism. Especially, the diagonal idempotent of $\mathscr{B}$ extends to a global section of $j_*\mathscr{B} \otimes_{\mathscr{A}} j_*\mathscr{B}$, and the assertion follows. $\square$

The criterion of lemma 14.3.19 has limited usefulness, since it is not usually known a priori that $j_*\mathscr{B}$ is a flat $\mathscr{A}$-algebra. In several situations, one can however apply the following variant.

Proposition 14.3.21. *Let X be an S-scheme, $j : U \to X$ a quasi-compact open immersion, $\mathscr{A} \to \mathscr{B}$ a morphism of quasi-coherent $\mathscr{O}_X^a$-algebras, and suppose that :*

(a) *The units of adjunction $\mathscr{A} \to j_*j^*\mathscr{A}$ and $\mathscr{B} \to j_*j^*\mathscr{B}$ are monomorphisms.*
(b) *$\mathscr{A}$ is integrally closed in $j_*j^*\mathscr{A}$, and $\mathscr{B}$ is an integral $\mathscr{A}$-algebra.*
(c) *$j^*\mathscr{B}$ is an étale $j^*\mathscr{A}$-algebra and an almost finitely presented $j^*\mathscr{A}$-module.*
(d) *The diagonal idempotent $e_{j^*\mathscr{B}/j^*\mathscr{A}}$ is a global section of the subalgebra*

$$\operatorname{Im}(\mathscr{B} \otimes_{\mathscr{A}} \mathscr{B} \to j_*j^*(\mathscr{B} \otimes_{\mathscr{A}} \mathscr{B})).$$

Then $\mathscr{B}$ is an étale $\mathscr{A}$-algebra and an almost finitely presented $\mathscr{A}$-module.

Proof. We may assume that X is affine. Under our assumptions, the restriction map $\mathscr{A}(X)_* \to \mathscr{A}(U)_*$ is injective, and its image is integrally closed in $\mathscr{A}(U)_*$ ([75, Rem.8.2.30]); moreover, $\mathscr{B}(X)_{!!}$ is an integral $\mathscr{A}(X)_{!!}$-algebra (remark 14.3.12(ii)). In view of lemma 14.3.15(i), we deduce a commutative diagram

$$(14.3.22)\qquad \begin{array}{ccc} \mathscr{B} \otimes_{\mathscr{A}} \mathscr{B} & \xrightarrow{\quad t \quad} & \mathscr{A} \\ \downarrow & & \downarrow \\ j_*j^*(\mathscr{B} \otimes_{\mathscr{A}} \mathscr{B}) & \xrightarrow{j_*(t_{j^*\mathscr{B}/j^*\mathscr{A}})} & j_*j^*\mathscr{A} \end{array}$$

whose vertical arrows are the units of adjunctions, and where t is a uniquely determined $\mathscr{A}$-bilinear form. Then we are reduced to showing :

Claim 14.3.23. Let $j : U \to X$ be as in the proposition, and $\mathscr{A} \to \mathscr{B}$ a morphism of quasi-coherent $\mathscr{O}_X^a$-algebras fulfilling conditions (a), (c), (d) of the proposition, and such that there exists a bilinear form t making commute diagram 14.3.22. Then $\mathscr{B}$ is an étale $\mathscr{A}$-algebra and an almost finitely presented $\mathscr{A}$-module.

Proof of the claim. The proof proceeds by a familiar argument (see *e.g.* the proof of [75, Claim 3.5.33]). Namely, for a given $\varepsilon \in \mathfrak{m}$, we can write

$$\varepsilon \cdot e_{j^*\mathscr{B}/j^*\mathscr{A}} = \sum_{j=1}^{m} a_j \otimes b_j \qquad \text{where } a_j, b_j \in \mathscr{B}(X)_* \text{ for every } j = 1, \dots, m.$$

In light of remark 14.3.10(iv), we deduce

$$\varepsilon \cdot a = \sum_{j=1}^{m} t(a \otimes a_j) \cdot b_j \qquad \text{for every } a \in \mathscr{B}(X)_*.$$

Indeed, the identity holds after restriction to U, and assumption (a) implies that the restriction map $\mathscr{B}(X)_* \to \mathscr{B}(U)_*$ is injective. We may then define $\mathscr{A}$-linear maps : $\mathscr{B} \xrightarrow{\varphi} \mathscr{A}^{\oplus m} \xrightarrow{\psi} \mathscr{B}$ by the rules :

$$\varphi(a) := (t(a \otimes a_1), \dots, t(a \otimes a_m)) \qquad \psi(s_1, \dots, s_m) := \sum_{j=1}^{m} s_j b_j$$

for every open subset $U \subset X$, every $a \in \mathscr{B}(U)_*$, and every $s_1, \dots, s_m \in \mathscr{A}(U)_*$. Thus we have $\psi \circ \varphi = \varepsilon \mathbf{1}_{\mathscr{B}}$, and since ε is arbitrary, this already proves that $\mathscr{B}$ is an $\mathscr{A}$-module of almost finite type, so we may apply [75, Lemma 2.4.15 and Prop.2.4.18(i)] to deduce that $\mathscr{B}$ is a flat and almost finitely presented $\mathscr{A}$-module. Now, assumption (a) and claim 14.3.20 imply that the horizontal arrows of the induced diagram

$$\begin{array}{ccc} \mathscr{B} \otimes_{\mathscr{A}} \mathscr{B} & \longrightarrow & j_*j^*(\mathscr{B} \otimes_{\mathscr{A}} \mathscr{B}) \\ {\scriptstyle \mu_{\mathscr{B}/\mathscr{A}}} \downarrow & & \downarrow {\scriptstyle j_*j^*\mu_{\mathscr{B}/\mathscr{A}}} \\ \mathscr{B} & \longrightarrow & j_*j^*\mathscr{B} \end{array}$$

are monomorphisms. From the characterization of remark 14.3.10(i), it follows easily that the section $e_{j^*\mathscr{B}/j^*\mathscr{A}}$ is the diagonal idempotent for the morphism $\mathscr{A} \to \mathscr{B}$, so $\mathscr{B}$ is an unramified $\mathscr{A}$-algebra, and the proof is concluded. $\square$

Corollary 14.3.24. *Let X be an S-scheme, $j : U \to X$ a quasi-compact open immersion, $\mathscr{A} \to \mathscr{B}$ a morphism of quasi-coherent $\mathscr{O}_U^a$-algebras, and suppose that :*

(a) *$\mathscr{B}$ is an étale $\mathscr{A}$-algebra and an almost finitely presented $\mathscr{A}$-module.*

(b) *The diagonal idempotent* $e_{\mathscr{B}/\mathscr{A}}$ *is a global section of the subalgebra*

$$\mathrm{Im}((j_*\mathscr{B}) \otimes_{j_*\mathscr{A}} (j_*\mathscr{B}) \to j_*(\mathscr{B} \otimes_{\mathscr{A}} \mathscr{B})).$$

Then $j_*\mathscr{B}$ *is an étale* $j_*\mathscr{A}$*-algebra and an almost finitely presented* $j_*\mathscr{A}$*-module.*

Proof. Indeed, the induced morphism $j_*\mathscr{A} \to j_*\mathscr{B}$ fulfills conditions (a), (c) and (d) of proposition 14.3.21, and diagram 14.3.22 trivially commutes with $t := j_*(t_{\mathscr{B}/\mathscr{A}})$, so the corollary follow from claim 14.3.23. □

Using lemma 14.3.15 we can also relax one assumption in [75, Prop.8.2.31(i)]; namely, we have the following :

Proposition 14.3.25. *Let* $A \subset B$ *be a pair of* V^a*-algebras, such that* $A = \mathrm{i.c.}(A, B)$*. Then, for every étale almost finite projective* A*-algebra* A_1 *we have* $A_1 = \mathrm{i.c.}(A_1, A_1 \otimes_A B)$*.*

Proof. Set $B_1 := A_1 \otimes_A B$, and suppose that $x \in B_{1*}$ is integral over A_{1*}. Let $e \in (A_1 \otimes_A A_1)_*$ be the diagonal idempotent of the unramified A-algebra A_1; for given $\varepsilon_1, \varepsilon_2, \varepsilon_3 \in \mathfrak{m}$ we write $\varepsilon_1 \cdot e = \sum_{j=1}^k c_i \otimes d_i$ for some $c_i, d_i \in A_{1*}$. According to remark 14.3.10(iv) and [75, Prop.4.1.8(ii)], we have $\sum_{j=1}^k c_i \cdot \mathrm{Tr}_{B_1/B}(xd_i) = \varepsilon \cdot x$. On the other hand, $\varepsilon_2 \cdot x$ and $\varepsilon_3 \cdot d_i$ are integral over A_* (by [75, Lemma 5.1.13(i)], which holds for arbitrary basic setups); then lemma 14.3.15(i) implies that $\mathrm{Tr}_{B_1/B}(\varepsilon_2\varepsilon_3 \cdot xd_i) \in A_*$ for every $i = 1, \dots, k$. Hence $\varepsilon_1\varepsilon_2\varepsilon_3 \cdot x \in A_{1*}$, and since $\varepsilon_1, \varepsilon_2, \varepsilon_3$ are arbitrary, the assertion follows. □

Lemma 14.3.26. *Let* X *be an* S*-scheme,* $\mathscr{A}$ *a quasi-coherent* $\mathscr{O}_X^a$*-algebra. We have :*

(i) *Let* $f : Y \to X$ *a faithfully flat and quasi-compact morphism. Then* $\mathscr{A}$ *is an étale (resp. weakly étale, resp. weakly unramified)* $\mathscr{O}_X^a$*-algebra if and only if* $f^*\mathscr{A}$ *is an étale (resp. weakly étale, resp. weakly unramified)* $\mathscr{O}_Y^a$*-algebra.*

(ii) *Suppose that* X *is integral and* $\mathscr{A}$ *is a weakly étale* $\mathscr{O}_X^a$*-algebra. Let* $\eta \in X$ *be the generic point; then* $\mathscr{A}$ *is an étale* $\mathscr{O}_X^a$*-algebra if and only if* $\mathscr{A}_\eta$ *is an étale* $\mathscr{O}_{X,\eta}^a$*-algebra.*

(iii) *Suppose that* X *is normal and irreducible, and* $\mathscr{A}$ *is integral, torsion-free and unramified over* $\mathscr{O}_X^a$*. Then* $\mathscr{A}$ *is étale over* $\mathscr{O}_X^a$*, and almost finitely presented as an* $\mathscr{O}_X^a$*-module.*

(iv) *Let* $j : X \to Y$ *be an open quasi-compact immersion of* S*-schemes, with* Y *normal and irreducible, and such that* $j_*\mathscr{O}_X = \mathscr{O}_Y$*, and suppose that* $\mathscr{A}$ *is integral and torsion-free over* $\mathscr{O}_X^a$*. Then* $j_*\mathscr{A}$ *is an integral* $\mathscr{O}_Y^a$*-algebra.*

Proof. (i): Arguing as in the proof of lemma 14.3.5, one reduces easily to the case where X and Y are affine, in which case the assertion follows from [75, §3.4.1].

(ii): Let $U \subset X$ be any affine open subset; by assumption $\mathscr{A}(U)$ is flat over the almost ring $B := \mathscr{A}(U) \otimes_{\mathscr{O}_X^a(U)} \mathscr{A}(U)$, and $\mathscr{A}(U) \otimes_{\mathscr{O}_X^a(U)} \kappa(\eta)^a$ is almost projective over $B \otimes_{\mathscr{O}_X^a(U)} \kappa(\eta)^a$. Then the assertion follows from [75, Prop.2.4.19].

(iii): Let $\eta \in X$ be the generic point. We begin with the following :

Claim 14.3.27. Suppose that $V = \mathfrak{m}$ (the "classical limit" case of [75, Ex.2.1.2(ii)]), and let $f : A \to B$ be a local homomorphism of local rings. Then :

(i) f^a is weakly étale if and only if f extends to an isomorphism of strict henselizations $A^{\mathrm{sh}} \to B^{\mathrm{sh}}$.

(ii) Especially, if A is a field and f^a is weakly étale, then B is a separable algebraic extension of A.

Proof of the claim. (i): In the classical limit case, a weakly étale morphism is the same as an "absolutely flat" map as defined in [137]; then the assertion is none else than [137, Th.5.2].

(ii): If A is a field, A^{sh} is a separable closure of A; hence (i) implies that B is a subring of A^{sh}, hence it is a subfield of A^{sh}. ◊

Claim 14.3.28. Suppose that $V = \mathfrak{m}$. Let A be a field and $f : A \to B$ a ring homomorphism such that f^a is weakly étale. Then :

(i) Every finitely generated A-subalgebra of B is finite étale over A (that is, in the usual sense of [66, Ch.IV, §17]).
(ii) f^a is étale if and only if f is étale (in the usual sense of [66]).

Proof of the claim. (i): From claim 14.3.27(ii) we see that B is reduced of Krull dimension ≤ 0, and all its residue fields are separable algebraic extensions of A. We consider first the case of a monogenic extension $C := A[b] \subset B$. For every prime ideal $\mathfrak{p} \subset B$, let $b_\mathfrak{p}$ be the image of b in $B_\mathfrak{p}$; then for every such $\mathfrak{p}$ we may find an irreducible separable monic polynomial $P_\mathfrak{p}(T) \in A[T]$ with $P_\mathfrak{p}(b_\mathfrak{p}) = 0$. This identity persists in an open neighborhood $U_\mathfrak{p} \subset \operatorname{Spec} B$ of $\mathfrak{p}$, and finitely many such $U_\mathfrak{p}$ suffice to cover $\operatorname{Spec} B$. Thus, we find finitely many $P_{\mathfrak{p}_1}(T), \dots, P_{\mathfrak{p}_k}(T)$ such that $\prod_{i=1}^k P_{\mathfrak{p}_i}(b) = 0$ holds in B, and after omitting repetitions, we may assume that all these polynomials are distinct. Since C is a quotient of the separable A-algebra $A[T]/(\prod_{i=1}^k P_{\mathfrak{p}_i}(T))$, the claim follows in this case. In the general case, we may write $C = A[b_1, \dots, b_n]$ for certain $b_1, \dots, b_n \in B$. Then $\operatorname{Spec} C$ is a reduced closed subscheme of $\operatorname{Spec} A[b_1] \times_{\operatorname{Spec} A} \cdots \times_{\operatorname{Spec} A} \operatorname{Spec} A[b_n]$; by the foregoing, the latter is étale over $\operatorname{Spec} A$, hence the same holds for $\operatorname{Spec} C$.

(ii): We may assume that f^a is étale, and we have to show that f is étale, *i.e.* that B is a finitely generated A-module. Hence, let $e_{B/A} \in B \otimes_A B$ be the diagonal idempotent (see remark 14.3.10(i)); we choose a finitely generated A-subalgebra $C \subset B$ such that $e_{B/A}$ is the image of an element $e' \in C \otimes_A C$. Notice that $1 - e'$ lies in the kernel of the multiplication map $\mu_{C/A} : C \otimes_A C \to C$. By (i), the morphism $A \to C$ is étale, hence it admits as well a diagonal idempotent $e_{C/A} \in C \otimes_A C$; on the other hand, [75, Lemma 3.1.2(v)] says that B^a is étale over C^a, especially B is a flat C-algebra, hence the natural map $C \otimes_A C \to B \otimes_A B$ is injective. Since $1 - e_{C/A}$ lies in the kernel of the multiplication map $\mu_{B/A} : B \otimes_A B \to B$, we have :

$$e_{B/A}(1 - e_{C/A}) = 0 = e_{C/A}(1 - e') = e_{C/A}(1 - e_{B/A})$$

from which it follows easily that $e_{B/A} = e_{C/A}$. Moreover, the induced morphism $\operatorname{Spec} B \to \operatorname{Spec} C$ has dense image, so it must be surjective, since $\operatorname{Spec} C$ is a discrete finite set; therefore B is even a faithfully flat C-algebra. Let $J := \operatorname{Ker}(B \otimes_A B \to B \otimes_C B)$; then J is the ideal generated by all elements of the form $1 \otimes c - c \otimes 1$, where $c \in C$; clearly this is the same as the extension of the ideal $I_{C/A} := \operatorname{Ker} \mu_{C/A}$. However, $I_{C/A}$ is generated by the idempotent $1 - e_{C/A}$ ([75, Cor.3.1.9]), consequently J is generated by $1 - e_{B/A}$, *i.e.* $J = \operatorname{Ker} \mu_{B/A}$. So finally, the multiplication map $\mu_{B/C} : B \otimes_C B \to B$ is an isomorphism, whose inverse is the map $B \to B \otimes_C B : b \mapsto b \otimes 1$. The latter is of the form $j \otimes_C \mathbf{1}_B$, where $j : C \to B$ is the natural inclusion map. By faithfully flat descent we conclude that $C = B$, whence the claim. ◊

Next, we remark that $\mathscr{A}_\eta$ is a finitely presented $\mathscr{O}^a_{X,\eta}$-module. Indeed, since $K := \mathscr{O}_{X,\eta}$ is a field, we have either $\mathfrak{m}K = 0$, in which case the category of K^a-modules is trivial and there is nothing to show, or else $\mathfrak{m}K = K$. So we may assume that we are in the "classical limit" case, and then the assertion follows from claim 14.3.28(ii).

Now, set $\mathscr{B} := \mathscr{A} \otimes_{\mathscr{O}^a_X} \mathscr{A}$, and let $j : X(\eta) \to X$ be the natural morphism; since X is normal and $\mathscr{A}$ is torsion-free, the units of adjunction $\mathscr{O}^a_X \to j_*j^*\mathscr{O}_{X(\eta)}$ and $\mathscr{A} \to j_*j^*\mathscr{A}$ are monomorphisms. Since $\mathscr{A}$ is unramified over $\mathscr{O}^a_X$, the diagonal idempotent of $j^*\mathscr{A}$ lies in the image of the restriction map $\mathscr{B}(X)_* \to \mathscr{B}_{\eta *}$. In view of these observations, an easy inspection shows that the proof of proposition 14.3.21 carries over *verbatim* to the current situation, and yields assertion (iii).

(iv): Let $\mathscr{T} \subset \mathscr{A}_{!!}$ be the maximal torsion $\mathscr{O}_X$-subsheaf, and set $\mathscr{B} := \mathscr{A}_{!!}/\mathscr{T}$. Then $\mathscr{B}$ is an integral, torsion-free $\mathscr{O}_X$-algebra, by remark 14.3.12(ii), and $\mathscr{B}^a \simeq \mathscr{A}$, hence $(j_*\mathscr{B})^a \simeq j_*\mathscr{A}$. Let $\eta \in Y$ be the generic point; in light of remark 14.3.12(ii), it then suffices to show :

Claim 14.3.29. Under the assumptions of (v), let $\mathscr{R}$ be an integral quasi-coherent and torsion-free $\mathscr{O}_X$-algebra. Then $j_*\mathscr{R}$ is an integral $\mathscr{O}_Y$-algebra.

Proof of the claim. Let us write $\mathscr{R}_\eta$ as the filtered union of the family $(R_\lambda \mid \lambda \in \Lambda)$ of its finite $\mathscr{O}_{Y,\eta}$-subalgebras, and for every $\lambda \in \Lambda$, let $\mathscr{R}_\lambda \subset \mathscr{R}$ be the quasi-coherent $\mathscr{O}_X$-subalgebra such that $\mathscr{R}_\lambda(V) = R_\lambda \cap \mathscr{R}(V)$ for every non-empty open subset $V \subset X$. Then $\mathscr{R}$ is the filtered colimit of the family $(\mathscr{R}_\lambda \mid \lambda \in \Lambda)$, and clearly it suffices to show the claim for every $\mathscr{R}_\lambda$. We may thus assume from start that $\mathscr{R}_\eta$ is a finite $\mathscr{O}_{Y,\eta}$-algebra. Let $\mathscr{R}^\nu$ be the integral closure of $\mathscr{R}$, *i.e.* the quasi-coherent $\mathscr{O}_X$-algebra such that $\mathscr{R}^\nu(V)$ is the integral closure of $\mathscr{R}(V)$ in $\mathscr{R}_\eta$, for every non empty affine open subset $V \subset X$. Clearly it suffices to show that $j_*\mathscr{R}^\nu$ is integral, hence we may replace $\mathscr{R}$ by $\mathscr{R}^\nu$ and assume from start that $\mathscr{R}$ is integrally closed. In this case, for every non-empty open subset $V \subset X$ the restriction map $\mathscr{R}(V) \to \mathscr{R}_\eta$ induces a bijection between the idempotents of $\mathscr{R}(V)$ and those of $\mathscr{R}_\eta$. Especially, $\mathscr{R}(X)$ admits finitely many idempotents, and moreover we have a natural decomposition $\mathscr{R} = \mathscr{R}_1 \times \cdots \times \mathscr{R}_k$, as a product of $\mathscr{O}_X$-algebras, such that $\mathscr{R}_{i,\eta}$ is a field for every $i \leq k$. It then suffices to show the claim for every $j_*\mathscr{R}_i$, and then we may assume throughout that $\mathscr{R}_\eta$ is a field. Up to replacing $\mathscr{R}$ by its normalization in a finite extension of $\mathscr{R}_\eta$, we may even assume that $\mathscr{R}_\eta$ is a finite normal extension of $\mathscr{O}_{Y,\eta}$. Hence, let $V \subset Y$ be any non-empty affine open subset, and $a \in \mathscr{R}(X \cap V)$ any element. Let $P(T)$ be the minimal polynomial of a over the field $\mathscr{O}_{Y,\eta}$; we have to show that the coefficients of $P(T)$ lie in $\mathscr{O}_Y(V) = \mathscr{O}_X(X \cap V)$, and since Y is normal, it suffices to prove that these coefficients are integral over $\mathscr{O}_X(W)$, for every non-empty affine open subset $W \subset X \cap V$. However, since $\mathscr{R}_\eta$ is normal over $\mathscr{O}_{Y,\eta}$, such coefficients can be written as some elementary symmetric polynomials of the conjugates of a in $\mathscr{R}_\eta$. Hence, we come down to showing that the conjugates of a are still integral over $\mathscr{O}_X(W)$. The latter assertion is clear: indeed, if $Q(T) \in \mathscr{O}_X(W)[T]$ is a monic polynomial with $Q(a) = 0$, then we have also $Q(a') = 0$ for every conjugate a' of a. □

Proposition 14.3.30. *Let X be a quasi-compact and quasi-separated S-scheme, $j : U \to X$ a quasi-compact open immersion, and $\mathscr{A}$ a quasi-coherent $\mathscr{O}_U^a$-algebra, almost finitely presented as an $\mathscr{O}_U^a$-module. Then for every finitely generated subideal $\mathfrak{m}_0 \subset \mathfrak{m}$, there exist a quasi-coherent $\mathscr{O}_X$-algebra $\mathscr{B}$, finitely presented as an $\mathscr{O}_X$-module, and a morphism $\mathscr{B}^a_{|U} \to \mathscr{A}$ of $\mathscr{O}_U^a$-algebras, whose kernel and cokernel are annihilated by $\mathfrak{m}_0$.*

Proof. Set $\mathscr{C} := \mathrm{i.c.}(\mathscr{O}_X^a, j_*\mathscr{A})$; then $\mathscr{C}$ is a quasi-coherent $\mathscr{O}_X^a$-algebra, and $\mathscr{C}_{|U} = \mathscr{A}$, by lemma 14.3.9. According to proposition 10.3.31, we may write $\mathscr{C}_{!!}$ as the colimit of a filtered family $(\mathscr{F}_i \mid i \in I)$ of finitely presented quasi-coherent $\mathscr{O}_X$-modules. Pick a finitely generated subideal $\mathfrak{m}_1 \subset \mathfrak{m}$ such that $\mathfrak{m}_0 \subset \mathfrak{m}_1^2$; for every affine open subset $U' \subset U$, we may find $i \in I$ such that $\mathfrak{m}_1 \cdot \mathscr{A}_{!!}(U') \subset \mathrm{Im}(\mathscr{F}_i(U') \to \mathscr{A}_{!!}(U'))$, and since U is quasi-compact, finitely many such open subsets cover U; hence, we may find $i \in I$ such that $\mathfrak{m}_1 \cdot \mathscr{A}_{!!} \subset \mathrm{Im}(\mathscr{F}_{i|U} \to \mathscr{A}_{!!})$; we set $\mathscr{F} := \mathscr{F}_i$, and let $\varphi : \mathscr{G} := \mathrm{Sym}^\bullet_{\mathscr{O}_X}\mathscr{F} \to \mathscr{C}_{!!}$ be the induced morphism of quasi-coherent $\mathscr{O}_X$-algebras. Notice that $\mathscr{G}$ is finitely presented as an $\mathscr{O}_X$-algebra. Using again proposition 10.3.31 (or [59, Ch.I, Cor.9.4.9]) we may write $\mathrm{Ker}\,\varphi$ as the colimit of a filtered family $(\mathscr{K}_\lambda \mid \lambda \in \Lambda)$ of quasi-coherent $\mathscr{O}_X$-submodules of finite type. Fix a finite covering $(U'_i \mid i \in I)$ of X consisting of affine open subsets, and for every $i \in I$, let $f_{i,1}, \dots, f_{i,n(i)}$ be a finite set of generators of $\mathscr{F}(U'_i)$; we may find monic polynomials $P_{i,1}(T), \dots, P_{i,n(i)}(T)$ with coefficients in $\mathscr{O}_X(U'_i)$ such that $P_{i,j}(\varphi(f_{i,j})) = 0$ in $\mathscr{C}(U'_i)_{!!}$, for every $i \in I$ and every $j \leq n(i)$. Let $\lambda \in \Lambda$ be chosen large enough, so that $P_{i,j}(f_{i,j}) \in \mathscr{K}_\lambda(U'_i)$ for every $i \in I$ and every $j \leq n(i)$. Let also $\mathscr{K}'_\lambda \subset \mathscr{G}$ be the ideal generated by $\mathscr{K}_\lambda$; then $\mathscr{G}' := \mathscr{G}/\mathscr{K}'_\lambda$ is an integral $\mathscr{O}_X$-algebra of finite presentation, hence it is finitely presented as an $\mathscr{O}_X$-module, in view of claim 9.1.35. Clearly $\varphi_{|U}$ descends to a map $\varphi' : \mathscr{G}'_{|U} \to \mathscr{A}_{!!}$, whose cokernel is annihilated by $\mathfrak{m}_1$, and by [75, Claim 2.3.12 and the proof of Cor.2.3.13] we may find, for every affine open subset $U' \subset U$, a finitely generated submodule $K_{U'} \subset \mathrm{Ker}\,(\varphi'_{U'} : \mathscr{G}'(U') \to \mathscr{A}(U')_{!!})$ such that $\mathfrak{m}_1^2 \cdot \mathrm{Ker}\,\varphi'_{U'} \subset K_{U'}$. Another invocation of proposition 10.3.31 ensures the existence of a quasi-coherent $\mathscr{O}_X$-submodule of finite type $\mathscr{J} \subset \mathrm{Ker}\,\varphi$ such that $K_{U'} \subset \mathscr{J}(U')$ for all the U' of a finite covering of U; the $\mathscr{O}_X$-algebra $\mathscr{B} := \mathscr{G}'/\mathscr{J} \cdot \mathscr{G}'$ fulfills the required conditions. □

14.3.31. Let $(X_i \mid i \in I)$ be a cofiltered system of quasi-compact and quasi-separated S-schemes, with affine transition morphisms $h_\varphi : X_j \to X_i$, for every morphism $\varphi : j \to i$ in I. Let also $U_i \subset X_i$ be a quasi-compact open subset, for every $i \in I$, such that $U_j = h_\varphi^{-1} U_i$ for every $\varphi : j \to i$ in I. Set

$$X := \lim_{i \in I} X_i \qquad U := \lim_{i \in I} U_i.$$

and denote by $h_i : U \to X_i$ the natural morphism, for every $i \in I$.

Corollary 14.3.32. *In the situation of* (14.3.31)*, let $\mathscr{A}$ be any flat almost finitely presented $\mathscr{O}_U^a$-algebra. Then, for every finitely generated subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ there exist $i \in I$, a quasi-coherent $\mathscr{O}_{X_i}$-algebra $\mathscr{R}$, finitely presented as an $\mathscr{O}_{X_i}$-module, and a map of $\mathscr{O}_U^a$-algebras $f : h_i^* \mathscr{R}^a \to \mathscr{A}$ such that :*

(a) $\mathrm{Ker}\, f$ *and* $\mathrm{Coker}\, f$ *are annihilated by* $\mathfrak{m}_0$.
(b) *For every $x \in U_i$ and every $b \in \mathfrak{m}_0$, the map $b \cdot \mathbf{1}_{\mathscr{R},x} : \mathscr{R}_x \to \mathscr{R}_x$ factors through a free $\mathscr{O}_{U_i,x}$-module.*

Proof. From [65, Ch.IV, Th.8.3.11] it is easily seen that X is a quasi-compact and quasi-separated S-scheme, and U is a quasi-compact open subset of X. Pick a finitely generated subideal $\mathfrak{m}_1$ such that $\mathfrak{m}_0 \in \mathfrak{m}_1^2$; according to proposition 14.3.30, we may find a quasi-coherent $\mathscr{O}_X$-algebra $\mathscr{B}$, finitely presented as an $\mathscr{O}_X$-module, and a morphism $g : \mathscr{B}^a_{|U} \to \mathscr{A}$ of $\mathscr{O}_U^a$-algebras whose kernel and cokernel are annihilated by $\mathfrak{m}_1$. By standard arguments we deduce

$$\mathfrak{m}_1^2 \cdot \mathrm{Tor}^1_{\mathscr{O}_X(U')}(M, \mathscr{B}(U')) = 0 \qquad (14.3.33)$$

for every affine open subset $U' \subset U$ and every $\mathscr{O}_X(U')$-module M. Now, let us remark, quite generally :

Claim 14.3.34. Let A be any ring, M and N any two A-modules, $\varphi : M \to N$ any A-linear map, and $M^\vee := \mathrm{Hom}_A(M, A)$. Then φ factors through a free A-module of finite rank if and only if it lies in the image of the natural map

$$M^\vee \otimes_A N \to \mathrm{Hom}_A(M, N). \qquad (14.3.35)$$

Proof of the claim. Suppose first that φ factors as the composition of A-linear maps $\psi : M \to A^{\oplus n}$ and $\psi' : A^{\oplus n} \to N$, for some $n \in \mathbb{N}$. For every $i = 1, \dots, n$, let $p_i : A^{\oplus n} \to A$ (resp. $e_i : A \to A^{\oplus n}$) be the natural epimorphism (resp. monomorphism), and set $\psi_i := p_i \circ \psi$, $\psi'_i := \psi' \circ e_i$. Then $\varphi = \sum_{i=1}^n \psi'_i \circ \psi_i$ and each summand $\psi'_i \circ \psi_i$ lies in the image of (14.3.35). Conversely, if φ lies in the image of (14.3.35), we have $\varphi = \sum_{i=1}^n \psi'_i \circ \psi_i$, for some $\psi_1, \dots, \psi_n \in M^\vee$ and $\psi'_1, \dots, \psi'_n \in \mathrm{Hom}_A(A, N) = N$, and we may define $\psi := \sum_{i=1}^n e_i \circ \psi_i$, $\psi'_i := \sum_{i=1}^n \psi'_i \circ p_i$. Then $\varphi = \psi' \circ \psi$. ◊

Now, pick a finite covering $(U'_{i,\lambda} \mid \lambda \in \Lambda)$ of U_i, consisting of affine open subsets, and a finite system $b_1, \dots, b_k$ of generators of $\mathfrak{m}_1^2$, and set $U'_\lambda := h_i^{-1} U'_{i,\lambda}$ for every $\lambda \in \Lambda$; from claim 14.3.34, (14.3.33) and [75, Lemma 2.4.17] we deduce that for every $\lambda \in \Lambda$ and every $j = 1, \dots, k$ there exists $n(\lambda, j) \in \mathbb{N}$ such that $b_j \cdot (\mathbf{1}_{\mathscr{B}})_{|U'_\lambda}$ factors through $\mathscr{O}_{U'_\lambda}^{\oplus n(\lambda,j)}$. Next, by virtue of [65, Ch.IV, Th.8.5.2] we may assume that $\mathscr{B}$ descends to a $\mathscr{O}_{X_i}$-algebra $\mathscr{R}$, finitely presented as an $\mathscr{O}_{X_i}$-module, and such that $b_j \cdot (\mathbf{1}_{\mathscr{R}})_{|U'_{i,\lambda}}$ factors through $\mathscr{O}_{U'_{i,\lambda}}^{\oplus n(\lambda,j)}$ for every $j = 1, \dots, k$ and every $\lambda \in \Lambda$. It follows easily that

$$\mathfrak{m}_1^2 \cdot \mathrm{Tor}^1_{\mathscr{O}_{X_i}(U'_{i,\lambda})}(M, \mathscr{R}(U'_{i,\lambda})) = 0$$

for every $\lambda \in \Lambda$ and every $\mathscr{O}_{X_i}(U'_{i,\lambda})$-module M. Then, again [75, Lemma 2.4.17] and claim 14.3.34 imply that condition (b) holds for $\mathscr{R}$, and by construction we also get condition (a). □

14.4. **Almost pure pairs.** Throughout this section, we keep the notation of (14.3), and *we assume that* $\mathfrak{m}$ *fulfills condition* $(\mathbf{B})$.

Definition 14.4.1. Let X be an S-scheme, $Z \subset X$ a closed subscheme such that $U := X\setminus Z$ is a dense subset of X, and denote by $j : U \to X$ the open immersion.

(i) We say that the pair (X, Z) is *almost pure relative to* $(V, \mathfrak{m})$ (or just *almost pure*, when the underlying basic setup is clear from the context) if the restriction functor

$$\mathscr{O}^a_X\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} \to \mathscr{O}^a_U\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} \quad : \quad \mathscr{A} \mapsto \mathscr{A}_{|U} \tag{14.4.2}$$

from the category of étale $\mathscr{O}^a_X$-algebras of almost finite rank, to the category of étale $\mathscr{O}^a_U$-algebras of almost finite rank, is an equivalence.

(ii) We say that the pair (X, Z) is *normal* if Z is a constructible subset of X, and the natural map $\mathscr{O}^a_X \to j_*\mathscr{O}^a_U$ is a monomorphism, whose image is integrally closed in $j_*\mathscr{O}^a_U$.

Remark 14.4.3. Let (X, Z) be a pair as in definition 14.4.1, where Z is a constructible subset of X, and set $U := X\setminus Z$.

(i) Consider the following conditions:

(a) $\mathscr{O}_{X,z}$ is a normal domain, for every $z \in Z$.

(b) the natural map $\mathscr{O}_X \to j_*\mathscr{O}_U$ is a monomorphism, and $\mathscr{O}_X = \mathrm{i.c.}(\mathscr{O}_X, j_*\mathscr{O}_U)$.

(c) The pair (X, Z) is normal.

Then (a)⇒(b), since $(j_*\mathscr{O}_U)_z = \mathscr{O}_{X(z)}(U \cap X(z))$ for every $z \in Z$. Also, (b)⇒(c), by virtue of [75, Lemma 8.2.28].

(ii) Let $\mathscr{A}$ be a quasi-coherent $\mathscr{O}^a_U$-algebra. Then $j_*\mathscr{A}_{!!}$ is a quasi-coherent $\mathscr{O}_X$-algebra ([59, Ch.I, Prop.9.4.2(i)] and lemma 14.3.9), hence the integral closure $\mathscr{A}^\nu$ of the image of $\mathscr{O}^a_X$ in $j_*\mathscr{A}$ is a well defined quasi-coherent $\mathscr{O}^a_X$-algebra (see definition 14.3.11). We call $\mathscr{A}^\nu$ the *normalization* of $\mathscr{A}$ over X.

(iii) Let (X, Z) be any normal pair, and $U \subset X$ any open subset. Directly from the definition, we see that $(U, Z \cap U)$ is still a normal pair.

Lemma 14.4.4. *Let* (X, Z) *be a normal pair as in definition* 14.4.1(ii)*, and set* $U := X\setminus Z$*. Let* $\mathscr{A}$ *be an étale* $\mathscr{O}^a_U$*-algebra whose underlying* $\mathscr{O}^a_U$*-module is almost finitely presented (resp. is of finite rank). The following conditions are equivalent :*

(a) *The normalization* $\mathscr{A}^\nu$ *of* $\mathscr{A}$ *over* X *(see remark* 14.4.3(ii)*) is a weakly unramified* $\mathscr{O}^a_X$*-algebra.*

(b) $\mathscr{A}^\nu$ *is an étale* $\mathscr{O}^a_X$*-algebra, and an almost finitely presented* $\mathscr{O}^a_X$*-module (resp. and an* $\mathscr{O}^a_X$*-module of finite rank).*

Proof. Obviously (b)⇒(a), hence suppose that (a) holds, and let $\mathscr{B} := \mathscr{A}^\nu \otimes_{\mathscr{O}^a_X} \mathscr{A}^\nu$. We may assume that X is affine, and we set

$$A := \mathscr{A}^\nu(X) \qquad B := \mathscr{B}(X).$$

By assumption, the multiplication morphism $\mu : \mathscr{B} \to \mathscr{A}^\nu$ is flat, especially A is a flat B-module. Let also B' be the image of B in $\mathscr{B}(U)$; clearly $\mu(X) : B \to A$ factors through an epimorphism $\mu' : B' \to A$, therefore $A = A \otimes_B B'$, so A is also a flat B'-module. Pick a finite covering $U = U_1 \cup \cdots \cup U_k$ consisting of affine open subsets of U. The induced morphism

$$B' \to \mathscr{B}(U_1) \times \cdots \times \mathscr{B}(U_k)$$

is a monomorphism. On the other hand, notice that $A \otimes_{B'} \mathscr{B}(U_i) = \mathscr{A}(U_i)$ is an almost finitely presented $\mathscr{B}(U_i)$-module. It follows that A is an almost finitely generated projective B'-module

([75, Prop. 2.4.18 and 2.4.19]), and therefore the kernel of μ' is generated by an idempotent $e \in B'_*$ ([75, Rem. 3.1.8]). A simple inspection shows that e is necessarily the diagonal idempotent of the unramified $\mathscr{O}_U^a$-algebra $\mathscr{A}$. Then all the assumptions of proposition 14.3.21 are fulfilled, so $\mathscr{A}^\nu$ is an étale $\mathscr{O}_X^a$-algebra, and an almost finitely presented $\mathscr{O}_X^a$-module.

Lastly, suppose that $\mathscr{A}$ is an $\mathscr{O}_U^a$-module of finite rank, and pick $r \in \mathbb{N}$ such that, for every $i = 1, \dots, k$, the r-th exterior power of the $\mathscr{O}_U^a(U_i)$-module $\mathscr{A}(U) = A \otimes_{\mathscr{O}_X^a(X)} \mathscr{O}_U^a(U_i)$ vanishes. Since the induced morphism $\mathscr{O}_X^a \to \mathscr{O}_U^a(U_1) \times \cdots \times \mathscr{O}_U^a(U_1)$ is a monomorphism, and A is a flat $\mathscr{O}_X^a$-module, we deduce that the r-th exterior power of A vanishes as well. Especially, $\mathscr{A}^\nu$ is an $\mathscr{O}_X^a$-module of finite rank. □

Lemma 14.4.5. *Let (X, Z) be a normal pair, $j : X \setminus Z \to X$ the open immersion, $\mathscr{B}$ any étale almost finitely presented $\mathscr{O}_X^a$-algebra, and $Z' \subset Z$ any constructible closed subset. We have :*

(i) *The natural map $\mathscr{B} \to j_* j^* \mathscr{B}$ factors through an isomorphism $\mathscr{B} \xrightarrow{\sim} (j^*\mathscr{B})^\nu$.*
(ii) *The restriction functor* (14.4.2) *is fully faithful.*
(iii) *The pair (X, Z') is normal.*
(iv) *If the pair (X, Z) is almost pure, the same holds for (X, Z').*

Proof. (i): Set $U := X \setminus Z$ and $\mathscr{A} := \mathscr{B}_{|U}$; the natural map $\mathscr{B} \to j_*\mathscr{A}$ factors through a morphism $\varphi : \mathscr{B} \to \mathscr{A}^\nu$ of $\mathscr{O}_X^a$-algebras (lemma 14.3.9 and remark 14.3.12(ii)). Fix $z \in Z$, and set $R := \mathscr{O}_{X,z}^a$, $R' := (j_*\mathscr{O}_X^a)_z$. It follows that the stalk $\mathscr{B}_z$ is an étale R-algebra. Notice that $(j_*\mathscr{A})_z = R' \otimes_R \mathscr{B}_z$, therefore φ is a monomorphism. Moreover, since $\mathscr{B}$ is also an almost finitely presented $\mathscr{O}_X^a$-module, we have

$$\mathscr{B}_z = \text{i.c.}(\mathscr{B}_z, R' \otimes_R \mathscr{B}_z) \qquad \mathscr{A}_z^\nu = \text{i.c.}(R, R' \otimes_R \mathscr{B}_z)$$

(proposition 14.3.25). On the other hand, $\mathscr{B}_z$ is an integral R-algebra, therefore $\mathscr{B}_z = \mathscr{A}_z^\nu$, and since z is arbitrary, we conclude that φ is an isomorphism, as asserted.

(ii): Let $\mathscr{B}_1$ and $\mathscr{B}_2$ be two étale almost finitely presented $\mathscr{O}_X^a$-algebra, set $\mathscr{A}_i := \mathscr{B}_{i|U}$ for $i = 1, 2$, and let $\psi : \mathscr{A}_1 \to \mathscr{A}_2$ be any morphism of $\mathscr{O}_U^a$-algebras; by (i), ψ extends uniquely to a morphism $\psi^\nu : \mathscr{B}_1 = \mathscr{A}_1^\nu \to \mathscr{A}_2^\nu = \mathscr{B}_2$ of $\mathscr{O}_X^a$-algebras, whence the contention.

(iii): Set $U' := X \setminus Z'$ and let $j' : U' \to X$ be the open immersion; the natural morphism $\mathscr{O}_X^a \to j_*\mathscr{O}_U$ factors through the morphism $\mathscr{O}_X^a \to j'_*\mathscr{O}_{U'}$, so the latter is a monomorphism. In order to show that (X, Z') is normal, it then suffices to check that the image of $\mathscr{O}_X^a$ is integrally closed in $j'_*\mathscr{O}_{U'}^a$, and since $\mathscr{O}_X^a$ is integrally closed in $j_*\mathscr{O}_U^a$, we are reduced to proving that the natural morphism $j'_*\mathscr{O}_{U'}^a \to j_*\mathscr{O}_U^a$ is a monomorphism. However, let $V \subset X$ be any affine open subset, and write $U' \cap V = V_1 \cap \cdots \cap V_n$ for certain affine open subsets $V_1, \dots, V_n$ of X; by assumption, the restriction map $\mathscr{O}_X^a(V_i) \to \mathscr{O}_X^a(U \cap V_i)$ is a monomorphism for every $i = 1, \dots, n$, so the same holds for the restriction map $\mathscr{O}_X^a(U' \cap V) \to \mathscr{O}_X^a(U \cap V)$, whence the assertion.

(iv): Suppose that (X, Z) is almost pure; in view of (ii), in order to check that (X, Z') is almost pure, it suffices to show that every étale $\mathscr{O}_{U'}^a$-algebra $\mathscr{A}$ of finite rank extends to an étale $\mathscr{O}_X^a$-algebra of finite rank. However, the assumption implies that $\mathscr{A}_{|U}$ extends to an $\mathscr{O}_X^a$-algebra $\mathscr{B}$ as sought, and since $(X \setminus Z', Z \setminus Z')$ is normal (remark 14.4.3(iii)), (ii) says that the isomorphism $\mathscr{B}_{|U} \xrightarrow{\sim} \mathscr{A}$ extends to an isomorphism $\mathscr{B}_{|U'} \xrightarrow{\sim} \mathscr{A}$, *i.e.* $\mathscr{B}$ is an extension of $\mathscr{A}$, as required. □

Lemma 14.4.6. *Let $(A_i \mid i \in \mathbb{N})$ be a system of V^a-algebras, and set $A := \prod_{i \in \mathbb{N}} A_i$. Let also P be an A-module, B an A-algebra, and suppose that*

(a) $\lim_{i \to \infty} \mathrm{Ann}_{V^a}(A_i) = V^a$ *for the uniform structure of* [75, Def.2.3.1].
(b) *For every $i \in \mathbb{N}$, the A_i-modules $P_i := P \otimes_A A_i$, $B_i := B \otimes_A A_i$ are almost projective of finite constant rank equal to i, and B_i is an étale A_i-algebra.*

Then P is an almost projective A-module of almost finite rank, and B is an étale A-algebra.

Proof. For every $j \in \mathbb{N}$, the finite product $P_{\leq j} := \prod_{i=1}^{j} P_i$ is an almost projective A-module of finite rank, and clearly the induced morphism $\pi_j : P \to P_{\leq j}$ is an epimorphism. On the other hand, the $(j+1)$-th exterior power of P equals the $(j+1)$-th exterior power of $\mathrm{Ker}\,\pi_j$, and from condition (i) we see that $\lim_{j\to\infty} \mathrm{Ann}_{V^a}(\mathrm{Ker}\,\pi_j) = 0$, whence the assertion for P.

It follows already that B is an almost projective A-module. It remains to show that B is an unramified A-algebra, to which aim, we may apply the criterion of [75, Prop.3.1.4].

Claim 14.4.7. Under the assumptions of the lemma, the natural morphism

$$\varphi : B \otimes_A B \to C := \prod_{i \in \mathbb{N}} B_i \otimes_{A_i} B_i$$

is an isomorphism of A-algebras.

Proof of the claim. For every $j \in \mathbb{N}$, let $\pi_j : C \to \prod_{i \leq j} B_i \otimes_A B_i$ be the natural morphism. Then

$$\lim_{j\to\infty} \mathrm{Ann}_{V^a}\mathrm{Ker}(\pi_j \circ \varphi) = V^a = \lim_{j\to\infty} \mathrm{Ann}_{V^a}\mathrm{Ker}\,\pi_j.$$

The first identity implies that φ is a monomorphism. Next, since $\pi_j \circ \varphi$ is an epimorphism, the natural morphism $\mathrm{Ker}\,\pi_j \to \mathrm{Coker}\,\varphi$ is an epimorphism; then the second identity implies that φ is also an epimorphism. ◊

Now, by [75, Prop.3.1.4], for every $i \in \mathbb{N}$ there exists an idempotent $e_i \in (B_i \otimes_{A_i} B_i)_*$ uniquely characterized by the conditions (i)–(iii) of *loc.cit.* In view of claim 14.4.7, the sequence $(e_i \mid i \in \mathbb{N})$ defines an idempotent in $(B \otimes_A B)_*$, which clearly fulfills the same conditions, whence the contention, again by [75, Prop.3.1.4]. □

Proposition 14.4.8. *Let (X, Z) be a normal pair, and set $U := X \setminus Z$. Then the following conditions are equivalent :*

(a) *The pair (X, Z) is almost pure.*

(b) *The restriction functor*

$$\mathscr{O}_X^a\text{-}\mathbf{\acute{E}t}_{\mathrm{fr}} \to \mathscr{O}_U^a\text{-}\mathbf{\acute{E}t}_{\mathrm{fr}} \quad : \quad \mathscr{A} \mapsto \mathscr{A}_{|U}$$

from the category of étale $\mathscr{O}_X^a$-algebras of finite rank, to the category of étale $\mathscr{O}_U^a$-algebras of finite rank, is an equivalence.

(c) *For every étale $\mathscr{O}_U^a$-algebra $\mathscr{A}$ of finite rank, the normalization $\mathscr{A}^\nu$ of $\mathscr{A}$ over X is an étale $\mathscr{O}_X^a$-algebra of finite rank (see remark* 14.4.3(ii)*).*

(d) *For every étale $\mathscr{O}_U^a$-algebra $\mathscr{A}$ of finite rank, $\mathscr{A}^\nu$ is a weakly unramified $\mathscr{O}_X^a$-algebra.*

(e) *Every étale $\mathscr{O}_U^a$-algebra $\mathscr{A}$ of finite rank extends to an étale almost finite $\mathscr{O}_X^a$-algebra.*

Proof. The equivalence (b)⇔(c) is already clear from lemma 14.4.5(i,ii).

Next, clearly (c)⇒(d). Conversely, suppose that (d) holds, and let $\mathscr{A}$ be any étale $\mathscr{O}_U^a$-algebra of finite rank, so $\mathscr{A}^\nu$ is a weakly unramified $\mathscr{O}_X^a$-algebra. Then $\mathscr{A}^\nu$ is actually an étale $\mathscr{O}_X^a$-algebra, and an almost finitely presented $\mathscr{O}_X^a$-module (lemma 14.4.4). Fix any affine open subset $V \subset X$, and pick a finite covering of $U \cap V$ consisting of affine open subsets $V_1, \dots, V_k$ of U. Let $r \in \mathbb{N}$ be an integer such that the r-th exterior power of the $\mathscr{O}_X^a(V_i)$-modules $\mathscr{A}(V_i)$ vanish. The induced map

$$B := \mathscr{O}_X^a(V) \to B' := \mathscr{O}_X^a(V_1) \times \cdots \times \mathscr{O}_X^a(V_k)$$

is a monomorphism, since (X, Z) is a normal pair. Moreover, the r-th exterior power of the B'-module $\mathscr{A}^\nu(V) \otimes_B B'$ vanishes; since $\mathscr{A}^\nu(V)$ is a flat B-module, we conclude that the r-th exterior power of $\mathscr{A}^\nu(V)$ vanishes as well. Especially, $\mathscr{A}^\nu$ is of finite rank, so (c) holds.

Since (c)⇒(e), we suppose that (e) holds, and deduce that (d) holds as well. Indeed, let $\mathscr{B}$ be an almost finite étale $\mathscr{O}_X^a$-algebra extending $\mathscr{A}$. In the foregoing, we have already remarked that $\mathscr{B} \subset \mathscr{A}^\nu$; especially, the diagonal idempotent of $\mathscr{A}$ lies in the image of the restriction map

$\mathscr{A}^\nu \otimes_{\mathscr{O}_X^a} \mathscr{A}^\nu(X)_* \to \mathscr{A} \otimes_{\mathscr{O}_X^a} \mathscr{A}(U)_*$. Then proposition 14.3.21 implies that $\mathscr{A}^\nu$ is an étale almost finite $\mathscr{O}_X^a$-algebra, as sought.

Obviously, (a)⇒(e); to conclude, it suffices then to check that (c)⇒(a). Thus, let $\mathscr{A}$ be an étale $\mathscr{O}_U^a$-algebra of almost finite rank, $V \subset U$ an affine open subset, and set $A := \mathscr{O}_X^a(V)$, $B := \mathscr{A}(V)$. According to [75, Th.4.3.28], there exists a decomposition of A as an infinite product of a system of V^a-algebras $(A_i \mid i \in \mathbb{N})$ fulfilling condition (a) of lemma 14.4.6. Such a decomposition determines a system of idempotent elements $e_{V,i} \in A_*$, for every $i \in \mathbb{N}$, such that $e_{V,i} \cdot e_{V,j} = 0$ whenever $i \neq j$, and characterized by the identities $e_{V,i}A = A_i$ for every $i \in \mathbb{N}$. Since $\mathscr{O}_{X*}$ is a sheaf ([75, §5.5.4]), condition (ii) ensures that, for any fixed $i \in \mathbb{N}$, and V ranging over the affine open subsets of U, the idempotents $e_{V,i}$ glue to a global section $e_i \in \mathscr{O}_X^a(U)_*$, which will still be an idempotent; moreover, the direct factor $\mathscr{A}_i := e_i\mathscr{A}$ of $\mathscr{A}$ is an étale $\mathscr{O}_U^a$-algebra of finite rank, and the projection $\mathscr{A} \to \mathscr{A}_i$ is a morphism of $\mathscr{O}_U^a$-algebras. Especially, A and B fulfill as well condition (b) of lemma 14.4.6. By (c), we deduce that the normalization $\mathscr{A}_i^\nu$ of $\mathscr{A}_i$ over X is an étale $\mathscr{O}_X^a$-algebra of finite rank, for every $i \in \mathbb{N}$. On the other hand, notice that the natural morphism

$$\mathscr{O}_{X*}^a \to j_*(\mathscr{O}_{U*}^a) = (j_*\mathscr{O}_U^a)_*$$

is a monomorphism, and its image is integrally closed in $j_*\mathscr{O}_{U*}^a$ ([75, Rem.8.2.30(i)]). It follows easily that $e_i \in \mathscr{O}_{X*}^a(X)$; hence

$$e_i\mathscr{A}_i^\nu = \mathscr{A}_i^\nu \qquad \text{for every } i \in \mathbb{N}$$

and the latter is the integral closure of $e_i\mathscr{O}_X^a$ in $j_*(\mathscr{A}_i)$. Consequently, $\mathscr{A}^\nu = \prod_{i\in\mathbb{N}} \mathscr{A}^\nu$ ([75, Rem.8.2.30(ii)]). By lemma 14.4.6, it follows that $\mathscr{A}^\nu$ is an étale $\mathscr{O}_X^a$-algebra of almost finite rank. This shows that the functor (14.4.2) is essentially surjective; combining with lemma 14.4.5(ii), we get (a). □

Corollary 14.4.9. *Let (X, Z) be a normal pair, and suppose that :*

(a) *The scheme $Z(z)$ is finite dimensional, for every $z \in Z$.*
(b) *The pair $(X(z), \{z\})$ is almost pure, for every $z \in Z$.*

Then the pair (X, Z) is almost pure.

Proof. Let $\mathscr{A}$ be any étale $\mathscr{O}_U^a$-algebra of finite rank, and $\mathscr{A}^\nu$ the normalization of $\mathscr{A}$ over X. In light of proposition 14.4.8, it suffices to show that $\mathscr{A}_z^\nu$ is a weakly unramified $\mathscr{O}_{X,z}^a$-algebra, for every $z \in Z$. Suppose, by way of contradiction, that the latter assertion fails; in view of condition (a), we may then find a point $z \in Z$, such that $\mathscr{A}_z^\nu$ is not weakly unramified over $\mathscr{O}_{X,z}^a$, but for every proper generization $w \in Z$ of z, the $\mathscr{O}_{X,w}^a$-algebra $\mathscr{A}_w^\nu$ is weakly unramified.

Now, set $U(z) := U \cap X(z)$, $V(z) := X(z)\setminus\{z\}$, and let $j : V(z) \to U$ be the induced morphism. Notice that $(V(z), Z(z))$ is a normal pair, and our assumption implies that $j^*\mathscr{A}^\nu$ is a weakly unramified $\mathscr{O}_{V(z)}^a$-algebra. By lemma 14.4.4, it follows that $j^*\mathscr{A}^\nu$ is actually an étale $\mathscr{O}_{V(z)}^a$-algebra of finite rank. Since by assumption, $(X(z), \{z\})$ is almost pure, proposition 14.4.8 says that $\mathscr{A}_z^\nu$ is an étale $\mathscr{O}_{X,z}^a$-module of finite rank, a contradiction. □

Proposition 14.4.10. *Let (X, Z) be a normal pair, and $f : X' \to X$ a morphism of S-schemes; set $Z' := f^{-1}Z$, and suppose that :*

(a) *$f(Z') = Z$ and f is pro-smooth at every point of Z' (see definition* 9.8.5*).*
(b) *The pair (X', Z') is almost pure.*

Then the pair (X, Z) is almost pure.

Proof. Set $U := X\setminus Z$, $U' := X'\setminus Z'$, and let $f_{|U} : U' \to U$ be the restriction of f. Notice that the open immersion $j' : U' \to X'$ is quasi-compact ([59, Ch.I, Prop.6.6.4]), and since f is flat at every point of Z' (corollary 9.8.6(i)), U' is dense in X'. Moreover :

Claim 14.4.11. (i) The pair (X', Z') is normal.

(ii) More generally, let $\mathscr{A}$ be any quasi-coherent $\mathscr{O}_U^a$-algebra. Then the natural morphism

$$f^*(\mathscr{A}^\nu) \to (f^*_{|U}\mathscr{A})^\nu$$

is an isomorphism (notation of remark 14.4.3(ii)).

Proof of the claim. Since f is flat at every point of Z', and the unit of adjunction $\mathscr{O}_X^a \to j_*\mathscr{O}_U^a$ is a monomorphism, the induced morphism $\mathscr{O}_{X'}^a \to f^*j_*\mathscr{O}_U^a = j'_*\mathscr{O}_{U'}^a$ is a monomorphism as well (corollary 10.3.8). Also, $(\mathscr{O}_U^a)^\nu = \mathscr{O}_X^a$, since (X, Z) is a normal pair; hence, (ii) implies (i).

(ii): Denote $\mathscr{A}_{!!}^\nu$ the integral closure in $j_*(\mathscr{A}_{!!})$ of the image of of $\mathscr{O}_X$; by corollary 10.3.8, the natural map

$$f^*j_*(\mathscr{A}_{!!}) \to j'_*f^*_{|U}(\mathscr{A}_{!!})$$

is an isomorphism of $\mathscr{O}_{X'}$-algebras. On the other hand, corollary 9.8.6(ii) implies that the integral closure of the image of $\mathscr{O}_{X'}$ in $f^*j_*(\mathscr{A}_{!!})$ equals $f^*(\mathscr{A}_{!!}^\nu)$. The assertion follows. ◊

Suppose now that $\mathscr{A}$ is an étale $\mathscr{O}_U^a$-algebra of finite rank. Since, by assumption, (X', Z') is almost pure, proposition 14.4.8 says that $(f^*_{|U}\mathscr{A})^\nu$ is an étale $\mathscr{O}_{X'}^a$-algebra of finite rank. By claim 14.4.11 and lemma 14.3.26(i) and corollary 9.8.6(ii), we deduce that $\mathscr{A}^\nu$ is a weakly étale $\mathscr{O}_X^a$-algebra. To conclude the proof, it suffices now to invoke proposition 14.4.8. □

Lemma 14.4.12. *Let (A, I) be a tight henselian pair (see* [75, Def.5.1.9]*). Then we have :*

(i) *The base change functor*

$$\mathsf{Cov}(\operatorname{Spec} A) \to \mathsf{Cov}(\operatorname{Spec} A/I)$$

is an equivalence (notation of [75, §8.2.22]*).*

(ii) *More generally, the base change functor A-$\mathbf{\acute{E}t} \to A/I$-$\mathbf{\acute{E}t}$ restricts to an equivalence*

$$A\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} \xrightarrow{\sim} A/I\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}}$$

on the respective full subcategories of étale algebras of almost finite rank.

Proof. In view of [75, Th.5.5.7(iii)], the assertions follow from lemma 14.3.17(ii). □

14.4.13. Let R be a V-algebra, $I \subset R$ a principal ideal generated by a regular element, $R^\wedge$ the I-adic completion of R. Set

$$X := \operatorname{Spec} R \qquad X^\wedge := \operatorname{Spec} R^\wedge \qquad Z := \operatorname{Spec} R/I \qquad Z^\wedge := \operatorname{Spec} R^\wedge/IR^\wedge.$$

Proposition 14.4.14. *In the situation of* (14.4.13)*, suppose furthermore that :*

(i) *There exist $n \in \mathbb{N}$ and a finitely generated subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ such that $I^n \subset \mathfrak{m}_0 R$.*

(ii) *The pair (R, I) is henselian.*

Then the pair (X, Z) is almost pure if and only if the same holds for the pair $(X^\wedge, Z^\wedge)$.

Proof. Under the current assumptions, the pair (R^a, I^a) is tight henselian ([75, §5.1.12]). Hence the assertion is a straightforward consequence of [75, Prop.5.4.53] and lemma 14.4.12(i) (details left to the reader). □

14.4.15. Let $p \in \mathbb{Z}$ be a prime integer with $pV \subset \mathfrak{m}$, and such that p is a regular element of V, and suppose that V contains an element, denoted $p^{1/p}$, whose p-th power generates the ideal pV. Let A and B be two flat V-algebras, and for every $n \in \mathbb{N}$ set $V_n := V/p^{n+1}V$, $A_n := A/p^{n+1}A$, $B_n := B/p^{n+1}B$. Let also

$$A_0 \xrightarrow{\sim} B_0 \qquad (14.4.16)$$

be a given isomorphism of V_0-algebras, and suppose that the Frobenius endomorphisms of V_0 and A_0 induce isomorphisms

$$V/p^{1/p}V \xrightarrow{\sim} V_0 \qquad A/p^{1/p}A \xrightarrow{\sim} A_0. \qquad (14.4.17)$$

Set $X := \mathrm{Spec}\, A$, $X_0 := \mathrm{Spec}\, A_0$, $Y := \mathrm{Spec}\, B$ and $Y_0 := \mathrm{Spec}\, B_0$.

Corollary 14.4.18. *In the situation of* (14.4.15)*, suppose moreover that the pairs* (A, pA) *and* (B, pB) *are henselian. Then the pair* (X, X_0) *is almost pure if and only if the same holds for the pair* (Y, Y_0).

Proof. In view of proposition 14.4.14, it suffices to show that (14.4.16) lifts to an isomorphism $A^\wedge \stackrel{\sim}{\to} B^\wedge$ between the p-adic completions of A and B. In turns, this reduces to exhibiting a system of isomorphisms $(\varphi_n : A_n \stackrel{\sim}{\to} B_n \mid n \in \mathbb{N})$ such that $\varphi_n \otimes_{V_n} V_{n_1} = \varphi_{n-1}$ for every $n > 0$. To this aim, it suffices to show that

$$\mathbb{L}_{A_n/V_n} = 0 \qquad \text{in } \mathsf{D}(s.A\text{-}\mathbf{Mod}) \text{ for every } n \in \mathbb{N}$$

([75, Prop.3.2.16]). However, in view of [75, Th.2.5.36], for every $n \in \mathbb{N}$, the short exact sequence $0 \to p^{n+1}V/p^{n+2}V \to V_{n+1} \to V_n \to 0$ induces a distinguished triangle in $\mathsf{D}(s.A\text{-}\mathbf{Mod})$

$$\mathbb{L}_{A_0/V_0} \to \mathbb{L}_{A_{n+1}/V_{n+1}} \to \mathbb{L}_{A_n/V_n} \to \sigma\mathbb{L}_{A_0/V_0}.$$

Hence, an easy induction further reduces to checking that $\mathbb{L}_{A_0/V_0} = 0$ in $\mathsf{D}(s.A\text{-}\mathbf{Mod})$. According to [75, Lemma 6.5.13], this will follow, once we have shown that the natural map

$$V_{0,(\Phi)} \overset{\mathbf{L}}{\otimes}_{V_0} A_0 \to A_{0,(\Phi)}$$

is an isomorphism in $\mathsf{D}(V_0\text{-}\mathbf{Mod})$ (notation of *loc.cit.*). Taking into account the isomorphisms (14.4.17), this holds if and only if the natural map

$$V/p^{1/p}V \overset{\mathbf{L}}{\otimes}_{V_0} A_0 \to A/p^{1/p}A$$

is an isomorphism in $\mathsf{D}(V_0\text{-}\mathbf{Mod})$. The latter assertion is clear, since A is a flat V-algebra. □

14.5. **Normalized lengths.** Let $(V, |\cdot|)$ be any valuation ring, with value group Γ_V; according to our general conventions, the composition law of Γ_V is denoted multiplicatively; however, sometimes it is convenient to switch to an additive notation. Hence, we adopt the notation :

$$(\log \Gamma_V, \leq)$$

to denote the ordered group Γ_V with additive composition law and whose ordering is the reverse of the original ordering of Γ_V. The unit of $\log \Gamma_V$ shall be naturally denoted by 0, and we shall extend the ordering of $\log \Gamma_V$ by adding a largest element $+\infty$, as customary. Also, we set : $\log \Gamma_V^+ := \{\gamma \in \log \Gamma_V \mid \gamma \geq 0\}$ and $\log |0| := +\infty$.

14.5.1. In this section, $(K, |\cdot|)$ denotes a valued field of rank one, with value group Γ. We let κ be the residue field of K^+. As usual, we set $S := \mathrm{Spec}\, K^+$, and denote by s (resp. η) the closed (resp. generic) point of S. Let $\mathfrak{m}_K \subset K^+$ be the maximal ideal, and set $\mathfrak{m} := \mathfrak{m}_K$ in case Γ is not discrete, or else $\mathfrak{m} := K^+$, in case $\Gamma \simeq \mathbb{Z}$; in the following, whenever we refer to almost rings or almost modules, we shall assume – unless otherwise stated – that the underlying almost ring theory is the one defined by the standard setup $(K^+, \mathfrak{m})$ (see [75, §6.1.15]).

Let A be any K^{+a}-algebra, and c a cardinal number; following [75, §2.3], we denote by $\mathscr{M}_c(A)$ the set of isomorphism classes of K^{+a}-modules which admit a set of generators of cardinality $\leq c$. The set $\mathscr{M}_c(A)$ carries a natural uniform structure (see [75, Def.2.3.1]), which admits the fundamental system of entourages

$$(E_\gamma \mid \gamma \in \log \Gamma^+ \setminus \{0\})$$

defined as follows. For any $b \in \mathfrak{m} \setminus \{0\}$, we let $E_{|b|}$ be the set of all pairs (M, M') of elements of $\mathscr{M}_c(A)$ such that there exist a third A-module N and A-linear morphisms $N \to M$, $N \to M'$ whose kernel and cokernel are annihilated by b.

14.5.2. The aim of this section is to define and study a well-behaved notion of *normalized length* for torsion modules M over K^+-algebras of a fairly general type. This shall be achieved in several steps. Let us first introduce the categories of algebras with which we will be working.

Definition 14.5.3. Let V be any valuation ring, with maximal ideal $\mathfrak{m}_V$.

(i) We let $V\text{-}\mathbf{m}.\mathbf{Alg}_0$ be the subcategory of V-Alg whose objects are the local and essentially finitely presented V-algebras A whose maximal ideal $\mathfrak{m}_A$ contains $\mathfrak{m}_V A$. The morphisms $\varphi : A \to B$ in $K^+\text{-}\mathbf{m}.\mathbf{Alg}_0$ are the local maps. Notice that every morphism in $V\text{-}\mathbf{m}.\mathbf{Alg}_0$ is an essentially finitely presented ring homomorphism ([63, Ch.IV, Prop.1.4.3(v)]).

Recall as well, that every object of $V\text{-}\mathbf{m}.\mathbf{Alg}_0$ is a coherent ring (see (11.4)). More generally, if $\underline{A} := (A_i \mid i \in I)$ is any filtered system of essentially finitely presented V-algebras with flat transition morphisms, then the colimit of $\underline{A}$ is still a coherent ring (lemma 11.3.7(ii.a)).

(ii) We say that a local V-algebra A is *measurable* if it admits an ind-étale local map of V-algebras $A_0 \to A$, from some object A_0 of $V\text{-}\mathbf{m}.\mathbf{Alg}_0$. The measurable V-algebras form a category $V\text{-}\mathbf{m}.\mathbf{Alg}$, whose morphisms are the local maps of V-algebras. As noted above, every measurable V-algebra is a coherent ring.

Lemma 14.5.4. *In the situation of definition* 14.5.3*, let* $(A, \mathfrak{m}_A)$ *be any measurable* V*-algebra. Then the following holds :*

(i) $A/\mathfrak{m}_V A$ *is a noetherian ring.*

(ii) *If the valuation of* V *has finite rank, every* $\mathfrak{m}_A$*-primary ideal of* A *contains a finitely generated* $\mathfrak{m}_A$*-primary subideal.*

(iii) *For every* A*-module* M *of finite type supported at the closed point of* $\operatorname{Spec} A$*, the* A*-module* $M/\mathfrak{m}_V M$ *has finite length.*

(iv) *For every finitely generated ideal* $I \subset A$*, the* V*-algebra* A/I *is measurable.*

Proof. (i): Let A^{sh} be the strict henselization of A at a geometric point localized at the closed point; then $A^{\mathrm{sh}}/\mathfrak{m}_V A^{\mathrm{sh}}$ is a strict henselization of $A/\mathfrak{m}_V A$ ([66, Ch.IV, Prop.18.8.10]), and it is therefore also a strict henselization of a $V/\mathfrak{m}_V$-algebra of finite type. Hence $A^{\mathrm{sh}}/\mathfrak{m}_V A^{\mathrm{sh}}$ is noetherian, and then the same holds for $A/\mathfrak{m}_V A$ ([66, Ch.IV, Prop.18.8.8(iv)]).

(iii) follows easily from (i) : the details shall be left to the reader.

(ii): If the valuation of V has finite rank, there exists an element $t_0 \in \mathfrak{m}_V$ that generates a $\mathfrak{m}_V$-primary ideal. Let $I \subset A$ be a $\mathfrak{m}_A$-primary ideal; then $t_0^N \in I$, for some integer $N > 0$; moreover, the image $\overline{I}$ of I in $A/\mathfrak{m}_V A$ is finitely generated, by (i). Pick elements $t_1, \dots, t_n \in I$ whose images in $A/\mathfrak{m}_V A$ form a system of generators of $\overline{I}$; it follows that $t_0^N, t_1, \dots, t_n$ form a $\mathfrak{m}_A$-primary ideal contained in I.

(iv): We may find an ind-étale local morphism $A_0 \to A$ from an object A_0 of $V\text{-}\mathbf{m}.\mathbf{Alg}_0$, and a finitely generated ideal $I_0 \subset A_0$ such that $I = I_0 A$. Then A/I_0 is an object of $V\text{-}\mathbf{m}.\mathbf{Alg}_0$ as well, and the induced map $A_0/I_0 \to A/I$ is ind-étale. □

14.5.5. Now, suppose that V is both a valuation ring and a flat, measurable K^+-algebra, and denote $\mathfrak{m}_V$ (resp. $\kappa(V)$, resp. $|\cdot|_V$) the maximal ideal (resp. the residue field, resp. the valuation) of V. We claim that V has rank one, and the ramification index $(\Gamma_V : \Gamma)$ is finite. Indeed, let us write V as the colimit of a filtered system $(V_i \mid i \in I)$ of objects of $K^+\text{-}\mathbf{m}.\mathbf{Alg}_0$ with essentially étale transition maps; it follows that each V_i is a valuation ring of rank one (claim 9.1.36). Also, the transition maps induce isomorphisms on the value groups : indeed, this is clear if K^+ is a discrete valuation ring, since in that case the same holds for the V_i, and the transition maps are unramified by assumption; in the case where Γ is not discrete, the assertion follows from corollary 11.4.42. Therefore, we are reduced to the case where V is an object of $K^+\text{-}\mathbf{m}.\mathbf{Alg}_0$, to which corollary 11.4.42 applies.

Suppose first that M is a finitely generated torsion V-module; in this case the Fitting ideal $F_0(M) \subset V$ is well defined, and it is shown in [75, Lemma 6.3.1 and Rem.6.3.5] that the map

$M \mapsto F_0(M)$ is additive on the set of isomorphism classes of finitely generated V-modules, *i.e.* for every short exact sequence $0 \to M_1 \to M_2 \to M_3 \to 0$ of such modules, one has :

(14.5.6) $$F_0(M_2) = F_0(M_1) \cdot F_0(M_3).$$

Next, the almost module $F_0(M)^a$ is an element of the group of fractional ideals $\mathrm{Div}(V^a)$ defined in [75, §6.1.16], and there is a natural isomorphism

(14.5.7) $$\mathrm{Div}(V^a) \simeq \log \Gamma_V^\wedge \qquad I \mapsto |I|$$

where $\Gamma_V^\wedge$ is the completion of Γ_V for the uniform structure deduced from the ordering : see [75, Lemma 6.1.19]. Hence we may define :

$$\lambda_V(M) := (\Gamma_V : \Gamma) \cdot |F_0(M)^a| \in \log \Gamma_V^\wedge.$$

In view of (14.5.6), we see that :

(14.5.8) $$\lambda_V(M') \leq \lambda_V(M) \qquad \text{whenever } M' \subset M \text{ are finitely generated.}$$

More generally, if M is any torsion V-module, we let :

(14.5.9) $$\lambda_V(M) := \sup \{\lambda_V(M') \mid M' \subset M,\ M' \text{ finitely generated}\} \in \log \Gamma_V^\wedge \cup \{+\infty\}$$

which, in view of (14.5.8), agrees with the previous definition, in case M is finitely generated.

14.5.10. Suppose now that the V^a-module M^a is uniformly almost finitely generated. Then according to [75, Prop.2.3.23] one has a well defined Fitting ideal $F_0(M^a) \subset V^a$, which agrees with $F_0(M)^a$ in case M is finitely generated.

Lemma 14.5.11. *In the situation of* (14.5.10)*, we have :*

(i) $\lambda_V(M) = (\Gamma_V : \Gamma) \cdot |F_0(M^a)|$.

(ii) *If* $0 \to N_1 \to N_2 \to N_3 \to 0$ *is any short exact sequence of uniformly almost finitely generated* V^a*-modules, then*

$$|F_0(N_2)| = |F_0(N_1)| + |F_0(N_3)|.$$

Proof. (ii): It is a translation of [75, Lemma 6.3.1 and Rem.6.3.5(ii)].

(i): Let k be a uniform bound for M^a, and denote by $\mathscr{I}_k(M)$ the set of all submodules of M generated by at most k elements. Set $e := (\Gamma_V : \Gamma)$; if $N \in \mathscr{I}_k(M)$, then $\lambda_V(N) \leq e \cdot |F_0(M^a)|$, due to (ii). By inspecting the definitions, it then follows that

$$e \cdot |F_0(M^a)| = \sup \{\lambda_V(N) \mid N \in \mathscr{I}_k(M)\} \leq \lambda_V(M).$$

Now, suppose $M' \subset M$ is any submodule generated by, say r elements; for every $\varepsilon \in \mathfrak{m}$ we can find $N \in \mathscr{I}_k(M)$ such that $\varepsilon M \subset N$, hence $\varepsilon M' \subset N$, therefore $\lambda_V(\varepsilon M') \leq \lambda_V(N) \leq e \cdot |F_0(M^a)|$. However, $\lambda_V(M') - \lambda_V(\varepsilon M') = \lambda_V(M'/\varepsilon M') \leq \lambda_V(K^{+\oplus r}/\varepsilon K^{+\oplus r}) = r \cdot \lambda_V(K^+/\varepsilon K^+)$. We deduce easily that $\lambda_V(M') \leq e \cdot |F_0(M^a)|$, whence the claim. □

Proposition 14.5.12. (i) *Let* $0 \to M_1 \to M_2 \to M_3 \to 0$ *be a short exact sequence of torsion* V*-modules. Then :*

$$\lambda_V(M_2) = \lambda_V(M_1) + \lambda_V(M_3).$$

(ii) $\lambda_V(M) = 0$ *if and only if* $M^a = 0$.

(iii) *Let* M *be any torsion* V*-module. Then :*

(a) *If* M *is finitely presented,* $\lambda_V(N) > 0$ *for every non-zero submodule* $N \subset M$.

(b) *If* $(M_i \mid i \in I)$ *is a filtered system of submodules of* M*, then :*

$$\lambda_V(\operatorname*{colim}_{i \in I} M_i) = \lim_{i \in I} \lambda_V(M_i).$$

Proof. (ii): By lemma 14.5.11(i) it is clear that $\lambda_V(M) = 0$ whenever $M^a = 0$. Conversely, suppose that $\lambda_V(M) = 0$, and let $m \in M$ be any element; then necessarily $\lambda_V(Vm) = 0$, and then it follows easily that $\mathfrak{m} \subset \mathrm{Ann}_V(m)$, so $M^a = 0$.

(iii.a): It suffices to show that M does not contain non-zero elements that are annihilated by $\mathfrak{m}$, which follows straightforwardly from [75, Lemma 6.1.14].

(iii.b): Set $M := \mathrm{colim}_{i\in I} M_i$. By inspecting the definitions we see easily that $\lambda_V(M) \geq \sup\{\lambda_V(M_i) \mid i \in I\}$. To show the converse inequality, let $N \subset M$ be any finitely generated submodule; we may find $i \in I$ such that $N \subset M_i$, hence $\lambda_V(N) \leq \lambda_V(M_i)$, and the assertion follows.

(i): Set $e := (\Gamma_V : \Gamma)$. We shall use the following :

Claim 14.5.13. Every submodule of a uniformly almost finitely generated V^a-module is uniformly almost finitely generated.

Proof of the claim. Let $N' \subset N$, with N uniformly almost finitely generated, and let k be a uniform bound for N; for every $\varepsilon \in \mathfrak{m}$ we can find $N'' \subset N$ such that N'' is generated by at most k almost elements and $\varepsilon N \subset N''$. Clearly, it suffices to show that $N' \cap N''$ is uniformly almost finitely generated and admits k as a uniform bound, so we may replace N by N'' and N' by $N' \cap N''$, and assume from start that N is finitely generated. Let us pick an epimorphism $\varphi : (V^a)^{\oplus k} \to N$; it suffices to show that $\varphi^{-1}(N')$ is uniformly almost finitely generated with k as a uniform bound, so we are further reduced to the case where N is free of rank k. Then we can write $N' = L^a$ for some submodule $L \subset V^{\oplus k}$; notice that $(V^{\oplus k}/L)^a$ is almost finitely presented, since it is finitely generated ([75, Prop.6.3.6(i)]), hence N' is almost finitely generated ([75, Lemma 2.3.18(iii)]). Furthermore, L is the colimit of the family $(L_i \mid i \in I)$ of its finitely generated submodules, and each L_i is a free V-module ([34, Ch.VI, §3, n.6, Lemma 1]). Necessarily the rank of L_i is $\leq k$ for every $i \in I$, hence $\Lambda^{k+1}_V L \simeq \mathrm{colim}_{i\in I} \Lambda^{k+1}_V L_i = 0$, and then the claim follows from [75, Prop.6.3.6(ii)]. ◊

Now, let $N \subset M_2$ be any finitely generated submodule, $\overline{N} \subset M_3$ the image of N; by claim 14.5.13, $M_1 \cap N$ is uniformly almost finitely generated, hence lemma 14.5.11(i,ii) shows that :

$$\lambda_V(N) = e \cdot |F_0(N^a)| = e \cdot |F_0(M_1^a \cap N^a)| + e \cdot |F_0(\overline{N}^a)| = \lambda_V(M_1 \cap N) + \lambda_V(\overline{N}).$$

Taking the supremum over the family $(N_i \mid i \in I)$ of all finitely generated submodules of M_2 yields the identity :

$$\lambda_V(M_2) = \lambda_V(M_3) + \sup\{\lambda_V(M_1 \cap N_i) \mid i \in I\}.$$

By definition, $\lambda_V(M_1 \cap N_i) \leq \lambda_V(M_1)$ for every $i \in I$; conversely, every finitely generated submodule of M_1 is of the form N_i for some $i \in I$, whence the contention. □

Remark 14.5.14. Suppose that $\Gamma \simeq \mathbb{Z}$, and let $\gamma_0 \in \log \Gamma^+$ be the positive generator. Then by a direct inspection of the definition one finds the identity :

$$\lambda(M) = (\Gamma_V : \Gamma) \cdot \mathrm{length}_V(M) \cdot \gamma_0$$

for every torsion V-module M. The verification shall be left to the reader.

14.5.15. Let M be a torsion V-module, such that M^a is almost finitely generated; we wish now to explain that $\lambda_V(M)$ can also be computed in terms of a suitable sequence of elementary divisors for M^a. Indeed, suppose first that M is a finitely presented torsion V-module; then we have a decomposition

$$M = (V/a_0V) \oplus \cdots \oplus (V/a_nV) \qquad \text{where } n := \dim_{\kappa(V)} M/\mathfrak{m}_V M - 1 \tag{14.5.16}$$

for certain $a_0, \dots, a_n \in \mathfrak{m}_V$ ([75, Lemma 6.1.14]). Clearly $\gamma_i := \log |a_i|_V > 0$ for every $i = 0, \dots, n$, and after reordering we may assume that $\gamma_0 \geq \cdots \geq \gamma_n$; then we may set

$\gamma_i := 0$ for every $i > n$, and the resulting sequence $(\gamma_i \mid i \in \mathbb{N})$ of *elementary divisors* of M is independent of the chosen decomposition (14.5.16), since we have more precisely :

$$a_i V = \mathrm{Ann}_V(\Lambda_V^{i+1} M) \qquad \text{for every } i \in \mathbb{N}. \tag{14.5.17}$$

Indeed, from a decomposition (14.5.16) with $a_j V \subset a_{j+1} V$ for every $j < n$, we get a V-linear surjection $M \to (V/a_i V)^{\oplus i+1}$, whence a surjection

$$N_i := \Lambda_V^{i+1} M \to \Lambda_V^{i+1} (V/a_i V)^{\oplus i+1} \stackrel{\sim}{\to} V/a_i V$$

which shows that $J_i := \mathrm{Ann}_V N_i \subset a_i V$. For the converse inclusion, notice that N_i is generated by the system of all elements of the form $\omega := x_0 \wedge \cdots \wedge x_i$, where $x_0 \in M_{j(0)}, \dots, x_i \in M_{j(i)}$ for some strictly increasing map $j : \{0, \dots, i\} \to \{0, \dots, n\}$; especially, $j(i) \geq i$, whence $a_i \omega = 0$, and the assertion follows. Moreover, a simple inspection yields the identity

$$\lambda_V(M) = (\Gamma_V : \Gamma) \cdot (\gamma_0 + \cdots + \gamma_n). \tag{14.5.18}$$

We regard the sequence $(\gamma_i \mid i \in \mathbb{N})$ as an element of the $\log \Gamma_V^\wedge$-normed space $\ell^\infty(\Gamma_V^+)$ of *bounded* sequences of elements of $\log \Gamma_V^{\wedge +}$, *i.e.* the set of all sequences $\underline{\delta} := (\delta_i \mid i \in \mathbb{N})$ with

$$\|\underline{\delta}\| := \sup(\delta_i \mid i \in \mathbb{N}) < +\infty.$$

Lemma 14.5.19. *Let $\varphi : N \to N'$ be a map of finitely presented torsion V-modules, and denote by $(\gamma_i \mid i \in \mathbb{N})$ (resp. $(\gamma'_i \mid i \in \mathbb{N})$) the sequence of elementary divisors of N (resp. N'). Then :*

(i) *If φ is injective, we have $\gamma_i \leq \gamma'_i$ for every $i \in \mathbb{N}$.*
(ii) *If φ is surjective, we have $\gamma_i \geq \gamma'_i$ for every $i \in \mathbb{N}$.*

Proof. Denote by K_V the field of fractions of V, and set $P^\dagger := \mathrm{Hom}_V(P, K_V/V)$ for every V-module P. We have a natural bilinear pairing $P \otimes_V P^\dagger \to K_V/V$, whence a V-linear map

$$\omega_P : P \to (P^\dagger)^\dagger.$$

Claim 14.5.20. (i) If φ is injective, $\varphi^\dagger := \mathrm{Hom}_V(\varphi, K_V/V)$ is surjective.

(ii) For every finitely presented V-module P, we have :
  (a) The map ω_P is an isomorphism.
  (b) P and $P^\dagger$ are isomorphic V-modules.

Proof of the claim. (ii) is left to the reader. (i) follows immediately from lemma 11.5.9(i). ◇

By virtue of claim 14.5.20(ii.b), the V-modules N and $N^\dagger$ have the same sequences of elementary divisors. Taking into account claim 14.5.20(i), we deduce that (ii)⇒(i), so it remains only to show that (ii) holds. However, if φ is surjective, the same holds for $\Lambda_V^{i+1}\varphi$, and then the assertion follows immediately from (14.5.17). □

Proposition 14.5.21. *Let $0 \to M' \to M \to M'' \to 0$ be a short exact sequence of finitely presented torsion V-modules. Then for every $i, j, t \in \mathbb{N}$ we have :*

$$\sum_{k=i+j}^{i+j+t} \gamma_k(M) \leq \sum_{k=i}^{i+t} \gamma_k(M') + \sum_{k=j}^{j+t} \gamma_k(M'').$$

Proof. Let us choose a decomposition for M as in (14.5.16), with $a_0 V \subset a_1 V \subset \cdots \subset a_n V$, and set $\overline{M} := (V/b_0 V) \oplus \cdots \oplus (V/b_{i+j+t} V)$, where $b_i = a_{i+j}$ for $i = 0, \dots, i+j$ and $b_i = a_i$ for $i = i+j+1, \dots, i+j+t$. We have an obvious V-linear surjection $M \to \overline{M}$, and we let as well $\overline{M}'$ be the image of M' in $\overline{M}$, and $\overline{M}'' := \overline{M}/\overline{M}'$. By construction, we have $\sum_{k=i+j}^{i+j+t} \gamma_k(M) = \sum_{k=i+j}^{i+j+t} \gamma_k(\overline{M})$, and taking into account lemma 14.5.19(ii), we are easily reduced to checking the stated inequality for the resulting short exact sequence $0 \to \overline{M}' \to \overline{M} \to \overline{M}'' \to 0$. Next, for $k = 0, \dots, i+j+t$ we consider the V-linear map $\varphi_k : V \to V/a_{i+j}V$ that maps 1 to the class of a_{i+j}/b_k; clearly φ_k factors through a V-linear injection $\overline{\varphi}_k : V/b_k V \to V/a_{i+j}V$, and the direct sum of the latter maps is a V-linear injection $\overline{\varphi} : \overline{M} \to N := (V/a_{i+j}V)^{\oplus i+j+t+1}$. Let $N' \subset N$ be the image of $\overline{M}'$, and set $N'' := N/N'$; we notice that

$$\sum_{k=i+j}^{i+j+t} (\gamma_k(N) - \gamma_k(\overline{M})) = |F_0(N)| - |F_0(\overline{M})| = C := \sum_{k=1}^{t} (\log |a_{i+j}|_V - \log |a_{i+j+k}|_V).$$

Taking into account proposition 14.5.12(i), we deduce that

$$\sum_{k=j}^{j+t} (\gamma_k(N'') - \gamma_k(\overline{M}'')) \leq |F_0(N'')| - |F_0(\overline{M}'')| = C.$$

Summing up, we are further reduced to checking the sought inequality for the short exact sequence $0 \to N' \to N \xrightarrow{\pi} N'' \to 0$. Let us remark, quite generally :

Claim 14.5.22. Let A be a local ring, M a finitely generated A-module, F, F' two free A-modules of the same rank $r \in \mathbb{N}$, and $\pi : F \to M$, $\pi' : F' \to M$ two A-linear surjections. Then there exists an A-linear isomorphism $\omega : F \stackrel{\sim}{\to} F'$ such that $\pi' \circ \omega = \pi$.

Proof of the claim. Let κ be the residue field of A, and set $m := \dim_\kappa(M \otimes_A \kappa)$; by Nakayama's lemma, M admits a minimal system of generators $x_1, \dots, x_m$, and we choose $f_1, \dots, f_m \in F$ with $\pi(f_i) = x_i$ for $i = 1, \dots, m$. Next, notice that $G := \mathrm{Ker}\,(\pi \otimes_A \kappa)$ is a κ-vector space of dimension $r - m$, and pick a system of elements $f_{m+1}, \dots, f_r \in F$ whose image in G is a basis; applying again Nakayama's lemma, it is easily seen that the system $f_1, \dots, f_r$ generates the A-module F, and it is therefore a basis of the latter. Likewise, we may find a basis $f'_1, \dots, f'_r$ of F' such that $\pi'(f_i) = x_i$ for $i = 1, \dots, m$ and $\pi'(f_i) = 0$ for $i = m+1, \dots, r$; then the unique A-linear map $\omega : F \to F'$ such that $\omega(f_i) = f'_i$ for $i = 1, \dots, r$ will do. ◊

Now, say that $N'' = (V/c_0V) \oplus \cdots \oplus (V/c_pV)$ is a minimal decomposition with $c_0V \subset \cdots \subset c_pV$; clearly we must have $p \leq i + j + t$ and $a_{i+j} \in c_0V$. Set $c_{p+1} = \cdots = c_{i+j+t} = 1$, and let $\pi'_k : V/a_{i+j+t} \to V/c_kV$ be the natural projection, for $k = 0, \dots, i + j + t$; the direct sum of the maps π'_k is a V-linear surjection $\pi' : N \to N''$, and by virtue of claim 14.5.22 there exists a V-linear automorphism ω of N such that $\pi' \circ \omega = \pi$. Thus, it suffices to show the stated inequality for the short exact sequence $0 \to Q := \omega(N') \to N \xrightarrow{\pi'} N'' \to 0$. But notice that $Q = \bigoplus_{k=0}^{i+j+t} \ker \pi'_k$, and therefore

$$\gamma_k(Q) = \log |a_{i+j}|_V - \log |c_{i+j+t-k}|_V \qquad \text{for } k = 0, \dots, i + j + t.$$

On the other hand $\gamma_k(N) = \log |a_{i+j}|_V$ and $\gamma_k(N'') = \log |c_k|_V$ for $k = 0, \dots, i + j + t$; summing up, we conclude the the sought inequality holds, and indeed it is an equality for this last short exact sequence. □

14.5.23. We fix now a large cardinal number ω, and write just $\mathscr{M}(V^a)$ instead of $\mathscr{M}_\omega(V^a)$. Also, for any $\gamma \in \log \Gamma_V^+$, set $[-\gamma, \gamma] := \{\delta \in \log \Gamma_V \mid -\gamma \leq \delta \leq \gamma\}$. Suppose that N and N' are two finitely presented V-modules such that $(N^a, N'^a) \in E_\delta$ for some $\delta \in \log \Gamma_V^+ \setminus \{0\}$. Say that $\delta = \log |b|_V$ for some $b \in \mathfrak{m}_V$; by standard arguments, we obtain maps $\varphi : N \to N'$ and $\varphi' : N' \to N$ such that $\varphi' \circ \varphi = b^4 \cdot \mathbf{1}_N$ and $\varphi' \circ \varphi = b^4 \cdot \mathbf{1}_{N'}$. Let now $(\gamma_i \mid i \in \mathbb{N})$ (resp. $(\gamma'_i \mid i \in \mathbb{N})$) be the sequence of elementary divisors for N (resp. for N'). Then the sequence of elementary divisors for b^4N is $(\max(0, \gamma_i - 4\delta) \mid i \in \mathbb{N})$, and likewise for b^4N'. In view of lemma 14.5.19, we deduce easily that

$$\gamma_i - \gamma'_i \in [-4\delta, 4\delta] \qquad \text{for every } i \in \mathbb{N}.$$

Consider a torsion almost finitely generated V^a-module M, and recall that M is almost finitely presented ([75, Prop.6.3.6(i)]); we then may attach to M a net of elements of $\ell^\infty(\log \Gamma_V^+)$, as follows. For every $\delta \in \log \Gamma_V^+ \setminus \{0\}$, pick a finitely presented V-module N_δ such that

$(M, N_\delta^a) \in E_\delta$, and denote by $\underline{\gamma}_\delta$ the sequence of elementary divisors of N_δ. The foregoing easily implies that the system $(\underline{\gamma}_\delta \mid \delta \in \log\Gamma_V^+ \setminus \{0\})$ is a net for the uniform structure of $\ell^\infty(\log\Gamma_V^+)$ induced by the norm $\|\cdot\|$. However, $(\ell^\infty(\log\Gamma_V^+), \|\cdot\|)$ is a complete normed space, hence this net converges to a well defined sequence $\underline{\gamma}_M := (\gamma_i \mid i \in \mathbb{N}) \in \ell^\infty(\log\Gamma_V^+)$. It is easily seen that $\underline{\gamma}_M$ is independent of the chosen net, and defines an invariant which we call the *sequence of elementary divisors* of M. A simple inspection of the construction shows that the sequence $\underline{\gamma}_M$ is monotonically decreasing, and

$$\lim_{i \to +\infty} \gamma_i = 0.$$

14.5.24. Denote again by K_V the field of fractions of V; as in the proof of lemma 14.5.19, we consider the functor

$$V^a\text{-}\mathbf{Mod} \to V^a\text{-}\mathbf{Mod} \quad : \quad M \mapsto M^\dagger := \mathrm{alHom}_{V^a}(M, K_V^a/V^a).$$

For every V^a-module M we have a natural V^a-bilinear pairing

$$M \otimes_{V^a} M^\dagger \to K_V^a/V^a$$

which in turns yields a natural transformation

$$M \to (M^\dagger)^\dagger. \tag{14.5.25}$$

Together with the constructions of (14.5.23), we may now extend lemma 14.5.19 *verbatim* to arbitrary almost finitely generated V^a-modules.

Proposition 14.5.26. *Let $\varphi : M \to M'$ be a morphism of almost finitely generated torsion V^a-modules, and denote by $(\gamma_i \mid i \in \mathbb{N})$ (resp. $(\gamma'_i \mid i \in \mathbb{N})$) the sequence of elementary divisors of M (resp. M'). Then :*

(i) *$M^\dagger$ is an almost finitely generated torsion V^a-module, the morphism* (14.5.25) *is an isomorphism, and the sequences of elementary divisors of M and $M^\dagger$ coincide.*
(ii) *If φ is a monomorphism, we have $\gamma_i \leq \gamma'_i$ for every $i \in \mathbb{N}$.*
(iii) *If φ is an epimorphism, we have $\gamma_i \geq \gamma'_i$ for every $i \in \mathbb{N}$.*

Proof. (i): Since M is almost finitely presented ([75, Prop.6.3.6(i)]), the assertion follows immediately from [75, Lemma 2.3.7(iii)] and claim 14.5.20(ii).

(iii): To begin with, we remark more generally :

Claim 14.5.27. Let P, Q be two torsion almost finitely generated V^a-modules, and $\delta \in \log\Gamma_V^+$ any element such that $(P, Q) \in E_\delta$. Denote by $(\gamma_i^P \mid i \in \mathbb{N})$ (resp. $(\gamma_i^Q \mid i \in \mathbb{N})$) the sequence of elementary divisors of P (resp. of Q). Then

$$\gamma_i^P - \gamma_i^Q \in [-4\delta, 4\delta] \qquad \text{for every } i \in \mathbb{N}.$$

Proof of the claim. For any $\varepsilon \in \log\Gamma_V^+$ pick a torsion finitely presented V-module N such that $(P, N^a) \in E_\varepsilon$, and let $(\gamma_i^N \mid i \in \mathbb{N})$ be the sequence of elementary divisors of N. It follows that $(Q, N^a) \in E_{\delta+\varepsilon}$, and from the construction of (14.5.23) we see that

$$\gamma_i^N - \gamma_i^P \in [-4\varepsilon, 4\varepsilon] \qquad \gamma_i^N - \gamma_i^Q \in [-4(\varepsilon+\delta), 4(\varepsilon+\delta)] \qquad \text{for every } i \in \mathbb{N}$$

so $\gamma_i^P - \gamma_i^Q \in [-8\varepsilon - 4\delta, 8\varepsilon + 4\delta]$ for every $i \in \mathbb{N}$. Since ε is arbitrary, the claim follows. ◊

Fix $\delta \in \log\Gamma_V^+ \setminus \{0\}$, pick finitely presented V-modules N, N' such that

$$(N^a, M), (N'^a, M') \in E_\delta$$

and denote by $(\beta_i \mid i \in \mathbb{N})$ (resp. $(\beta'_i \mid i \in \mathbb{N})$) the sequence of elementary divisors of N (resp. of N'). According to claim 14.5.27 we have :

$$\gamma_i - \beta_i, \gamma'_i - \beta'_i \in [-4\delta, 4\delta] \qquad \text{for every } i \in \mathbb{N}. \tag{14.5.28}$$

On the other hand, by the usual arguments we may find V-linear maps $f : N \to M_*$ and $g : M'_* \to N'$ such that $b^2 \cdot \mathrm{Coker}\, f = b^2 \cdot \mathrm{Coker}\, g = 0$ for every $b \in V$ with $\log |b|_V = \delta$. Set $h := g \circ \psi_* \circ f$; it follows easily that $b^5 \cdot \mathrm{Coker}\, h = 0$. The sequence of elementary divisors of $b^5 N'$ is $(\max(0, \beta'_i - 5\delta) \mid i \in \mathbb{N})$, and since $N'' := \mathrm{Im}\, h$ is a finitely presented V-module, the sequence $(\beta''_i \mid i \in \mathbb{N})$ of its elementary divisors satisfies the inequalities

$$\beta_i \geq \beta''_i \geq \beta'_i - 5\delta \qquad \text{for every } i \in \mathbb{N}$$

by lemma 14.5.19(i,ii). Combining with (14.5.28), we deduce that

$$\gamma_i \geq \gamma'_i - 13\delta \qquad \text{for every } i \in \mathbb{N}$$

and since δ is arbitrary, the assertion follows.

(ii): in light of [75, Lemma 2.3.7(iii)] and claim 14.5.20(i), it is easily seen that $\varphi^\dagger$ is an epimorphism, so the assertion follows formally from (i) and (iii), as in the proof of lemma 14.5.19(i). □

One may ask, to which extent the sequence of elementary divisors of a V^a-module M determines the isomorphism class of M. To address this question, we make the following :

Definition 14.5.29. Let $(V, \mathfrak{m})$ be an arbitrary basic setup, A any V^a-algebra, M an A-module and ω a (very large) cardinal number, such that $\mathscr{M}_\omega(A)$ contains the isomorphism class of M. The topological space underlying the uniform space $\mathscr{M}_\omega(A)$ is not necessarily separated, but it admits a maximal separated quotient space $\mathscr{M}^{\mathrm{sep}}_\omega(A)$. The *$\omega$-type of* M is the image in $\mathscr{M}^{\mathrm{sep}}_\omega(A)$ of the isomorphism class of M. If ω' is any cardinal larger than ω, clearly the ω-type of M maps to the ω'-type of M, under the natural map $\mathscr{M}^{\mathrm{sep}}_\omega(A) \to \mathscr{M}^{\mathrm{sep}}_{\omega'}(A)$. For this reason, we shall usually omit explicit mention of ω, and shall call the *type of* M any one of these invariants.

Lemma 14.5.30. *In the situation of definition* 14.5.29*, suppose that M and M' are two A-modules of the same type. Then we have :*

(i) *M is almost finitely presented (resp. almost finitely generated) if and only if the same holds for M'.*
(ii) *M is a flat (resp. almost projective) A-module if and only if the same holds for M'.*

Proof. (i) follows directly from the definitions.

(ii) follows easily from [75, Lemma 2.3.7(iii,iv)] : details left to the reader. □

We may now answer as follows to the foregoing question :

Proposition 14.5.31. *Let $(V, \mathfrak{m}_V)$ be as in* (14.5.5)*, and M, M' any two almost finitely generated torsion V^a-modules. The following conditions are equivalent :*

(a) *M and M' have the same type.*
(b) *The sequences of elementary divisors of M and M' coincide.*

Proof. (a)⇒(b): Condition (a) means that $(M, M') \in E_\delta$ for every $\delta \in \log \Gamma^+_V \setminus \{0\}$, so the assertion is immediate from the construction of the sequences of elementary divisors.

(b)⇒(a): Let $(\gamma_i \mid i \in \mathbb{N})$ be the common sequence of elementary divisors for M and M'. Fix δ as in the foregoing, pick finitely presented V-modules N, N' such that

$$(M, N), (M', N') \in E_\delta$$

and let $(\beta_i \mid i \in \mathbb{N})$, respectively $(\beta'_i \mid i \in \mathbb{N})$ be the sequences of elementary divisors of N and N'. From claim 14.5.27 we deduce

$$\beta_i - \gamma, \beta'_i - \gamma_i \in [-4\delta, 4\delta] \qquad \text{for every } i \in \mathbb{N}.$$

Thus, $\beta_i - \beta'_i \in [-8\delta, 8\delta]$ for every $i \in \mathbb{N}$. Say that $8\delta = \log |a|_V$ for some $a \in V$.

Claim 14.5.32. There exists a V-linear map $f : N \to N'$ whose kernel and cokernel is annihilated by a.

Proof of the claim. By [75, Lemma 6.1.14] we reduce easily to the case where N and N' are cyclic V-modules, so $N = V/bV$ and $N' = V/b'V$, for $b, b' \in V \setminus \{0\}$ such that $\log |b/b'|_V \in [-2\delta, 2\delta]$. Now, if $b \in b'V$, we let f be the natural projection $V/bV \to V/b'V$. If $b' \in bV$, we notice that $b'b^{-1}\mathbf{1}_N$ factors through a map $N \to N'$ with the sought properties (details left to the reader). ♢

Clearly claim 14.5.32 implies that $(N, N') \in E_{8\delta}$, and therefore $(M, M') \in E_{10\delta}$. Since δ is arbitrary, the assertion follows. □

Corollary 14.5.33. *Let $b \in \mathfrak{m}_V$ be any non-zero element, M an almost finitely generated V^a/bV^a-module, and $(\gamma_i \mid i \in \mathbb{N})$ the sequence of elementary divisors of M. The following conditions are equivalent :*

(a) *M is a flat V^a/bV^a-module.*
(b) *There exists $n \in \mathbb{N}$ such that $\gamma_i = \log |b|_V$ for every $i \leq n$, and $\gamma_i = 0$ for every $i > n$.*

Proof. For every $i \in \mathbb{N}$, pick $a_i \in V$ with $\log |a_i|_V = \gamma_i$. According to proposition 14.5.31, the type of M coincides with that of $M' := \bigoplus_{i\in\mathbb{N}} V^a/a_iV^a$, and by lemma 14.5.30(ii), we may then assume that $M = M'$, in which case clearly (b)⇒(a). For the converse, notice that a standard computation gives

$$\mathrm{Tor}_1^{V/bV}(V/aV, V/aV) \simeq V/(aV + a^{-1}bV) \qquad \text{for every } a \in V \text{ such that } \log |a|_V \leq \log |b|_V$$

from which the assertion follows easily (details left to the reader). □

Proposition 14.5.34. *Let $(V, \mathfrak{m}_V)$ be as in* (14.5.5)*, and M a torsion V-module such that M^a is almost finitely generated. Let $(\gamma_i \mid i \in \mathbb{N})$ be the sequence of elementary divisors of M^a. Then*

$$\lambda_V(M) = (\Gamma_V : \Gamma) \cdot \sum_{i\in\mathbb{N}} \gamma_i.$$

Especially, $\lambda_V(M)$ depends only on the type of M^a.

Proof. Fix a sequence $(a_k \mid k \in \mathbb{N})$ of elements of $\mathfrak{m}_V \setminus \{0\}$ with $\lim_{k\to+\infty} \log |a_k|_V = 0$. For every $k \in \mathbb{N}$, let $M_k \subset M$ be a finitely generated submodule such that $a_kM \subset M_k$ ([75, Prop. 2.3.10(i)]), and denote also by $(\gamma_i^k \mid i \in \mathbb{N})$ the sequence of elementary divisors of M_k^a. After replacing each M_k by $\sum_{j=0}^k M_j$, we may also assume that $M_k \subset M_{k+1}$ for every $k \in \mathbb{N}$.

Claim 14.5.35. For every $i, k \in \mathbb{N}$ we have

$$4\delta_k \geq \gamma_i - \gamma_i^k \geq 0 \qquad \gamma_i^{k+1} \geq \gamma_i^k \qquad \text{where } \delta_k := \log |a_k|.$$

Proof of the claim. The inequalities $\gamma_i \geq \gamma_i^{k+1} \geq \gamma_i^k$ follow from proposition 14.5.26(ii). Next, clearly we have $(M_k^a, M^a) \in E_{\delta_k}$ for every $k \in \mathbb{N}$, so the upper bound for $\gamma_i - \gamma_i^k$ follows from claim 14.5.27. ♢

Set $L^k := \sum_{i\in\mathbb{N}} \gamma_i^k$ and $L := \sum_{i\in\mathbb{N}} \gamma_i$. It follows easily from claim 14.5.35 that

$$\lim_{k\to+\infty} L^k = \sum_{i\in\mathbb{N}} \lim_{k\to+\infty} \gamma_i^k = L.$$

In light of proposition 14.5.12(iii.b), it then suffices to check the proposition with M replaced by M_k, for every $k \in \mathbb{N}$. We may therefore assume from start that M is finitely generated, and let g be the cardinality of a finite system of generators for M. We may then find a surjective V-linear map $f : F := V^{\oplus g} \to M$, and $N := \mathrm{Ker}\, f^a$ is almost finitely generated (claim 14.5.13). Thus, for every $k \in \mathbb{N}$ we may find a finitely generated V-submodule $N_k \subset N$ with $a_kN \subset N_k$, so that $(F^a/N_k^a, M) \in E_{\delta_k}$. After replacing each N_k by $\sum_{j=0}^k N_j$, we may also assume that

$N_k \subset N_{k+1}$ for every $k \in \mathbb{N}$. Denote by $(\beta_i^k \mid i \in \mathbb{N})$ the sequence of elementary divisors of F/N_k, and notice that $\beta_i^k = 0$ for every $i \geq g$. Taking into account (14.5.18), claim 14.5.27 and proposition 14.5.26(iii) we get

$$\lambda_V(F/N_k) = \sum_{i\in\mathbb{N}} \beta_i^k \qquad 4\delta_k \geq \beta_i^k - \gamma_i \geq 0 \qquad \text{for every } i,k \in \mathbb{N}.$$

Therefore $\lim_{k\to+\infty} \lambda_V(F/N_k) = L$, and in view of proposition 14.5.12(i), it remains only to check that $\lim_{k\to+\infty} \lambda_V(N/N_k) = 0$, or equivalently, that $\lim_{k\to+\infty} \lambda_V(N_k) = \lambda_V(N)$ (proposition 14.5.12(i)). However, set $N' := \bigcup_{k\in\mathbb{N}} N_k$; by proposition 14.5.12(iii.b), the latter identity holds if and only $\lambda_V(N') = \lambda_V(N)$, and since $(N/N')^a = 0$, this follows from proposition 14.5.12(i,ii). □

14.5.36. In order to deal with general measurable K^+-algebras, we introduce hereafter some further notation which shall be standing throughout this section.

• To begin with, any ring homomorphism $\varphi : A \to B$ induces functors

$$\text{(14.5.37)} \qquad \varphi_* : B\text{-}\mathbf{Mod} \to A\text{-}\mathbf{Mod} \qquad \text{and} \qquad \varphi^* : A\text{-}\mathbf{Mod} \to B\text{-}\mathbf{Mod}.$$

Namely, φ_* assigns to any B-module M the A-module φ_*M obtained by restriction of scalars, and $\varphi^*(M) := B \otimes_A M$.

• For any local ring $(A, \mathfrak{m}_A)$, we let $\kappa(A) := A/\mathfrak{m}_A$, and we denote by $s(A)$ the closed point of $\operatorname{Spec} A$. If A is also a coherent ring, we denote by $A\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$ the full subcategory of $A\text{-}\mathbf{Mod}$ consisting of all the finitely presented A-modules M such that $\operatorname{Supp} M \subset \{s(A)\}$. Notice that the coherence of A implies that $A\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$ is an abelian category.

• Lastly, let $\mathscr{A}$ be any small abelian category; recall that $K_0(\mathscr{A})$ is the abelian group defined by generators and relations as follows. The generators are the isomorphism classes $[T]$ of objects T of $\mathscr{A}$, and the relations are generated by the elements of the form $[T_1] - [T_2] + [T_3]$, for every short exact sequence $0 \to T_1 \to T_2 \to T_3 \to 0$ of objects of $\mathscr{A}$. One denotes by $K_0^+(\mathscr{A}) \subset K_0(\mathscr{A})$ the submonoid generated by the classes $[T]$ of all objects of $\mathscr{A}$. We shall use the following well known *dévissage* lemma :

Lemma 14.5.38. *Let $\iota : \mathscr{B} \subset \mathscr{A}$ be an additive exact and fully faithful inclusion of abelian categories, and suppose that :*

(a) *If $T \in \mathrm{Ob}(\mathscr{B})$ and T' is a subquotient of $\iota(T)$, then T' is in the essential image of ι.*
(b) *Every object T of $\mathscr{A}$ admits a finite filtration $\mathrm{Fil}^\bullet T$ such that the associated graded object $\mathrm{gr}^\bullet T$ is in the essential image of ι.*

Then ι induces an isomorphism :

$$K_0(\mathscr{B}) \xrightarrow{\sim} K_0(\mathscr{A}).$$

Proof. Left to the reader. □

Proposition 14.5.39. *Let $\varphi : A \to B$ be a morphism of measurable K^+-algebras. We have :*

(i) *If φ induces a finite field extension $\kappa(A) \to \kappa(B)$, then the functor φ_* of* (14.5.37) *restricts to a functor*

$$\varphi_* : B\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}} \to A\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$$

which induces a group homomorphism of the respective K_0-groups :

$$\varphi_* : K_0(B\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}) \to K_0(A\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}).$$

(ii) *If φ induces an integral morphism $\kappa(A) \to B/\mathfrak{m}_A B$, then $\mathrm{length}_B(B/\mathfrak{m}_A B)$ is finite, and the functor φ^* of* (14.5.37) *restricts to a functor*

$$\varphi^* : A\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}} \to B\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$$

and if φ is also a flat morphism, φ^* induces a group homomorphism :

$$\varphi^* : K_0(A\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}) \to K_0(B\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}).$$

Proof. Write A (resp. B) as the colimit of a filtered system $\underline{A} := (A_i \mid i \in I)$ (resp. $\underline{B} := (B_j \mid j \in J)$) of objects of $K^+\text{-}\mathbf{m}.\mathbf{Alg}_0$, with local and essentially étale transition maps. After replacing J (resp. I) by a cofinal subsets, we may assume that the indexing set admits an initial element $0 \in J$ (resp. $0 \in I$). Furthermore, we may assume that the induced map $A_0 \to B$ factors through a morphism $A_0 \to B_0$ in $K^+\text{-}\mathbf{m}.\mathbf{Alg}_0$.

(i): Let M be any object of $B\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$. We need to show that $\varphi_* M$ is finitely presented. We may find $j \in J$ and a finitely presented B_j-module M_j, with an isomorphism $M \xrightarrow{\sim} M_j \otimes_{B_j} B$ of B-modules. After replacing J by J/j, we may assume that $j = 0$ is the initial index. Since the natural map $B_0 \to B$ is local and ind-étale, it is easily seen that M_0 is an object of $B_0\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$. Especially, there exists a finitely generated $\mathfrak{m}_{B_0}$-primary ideal $I \subset \mathrm{Ann}_{B_0} M_0$. We may then replace the system $\underline{B}$ by $(B_j/IB_j \mid j \in J)$ and assume that each B_j has Krull dimension zero.

Claim 14.5.40. Let $\varphi : A \to B$ be a morphism of measurable K^+-algebras inducing a finite residue field extension $\kappa(A) \to \kappa(B)$, and such that B has dimension zero. Let also M be any finitely presented B-module. Then we may find :

(a) a cocartesian diagram of local maps of K^+-algebras

$$\begin{array}{ccc} A_l & \xrightarrow{\varphi_l} & C_l \\ \downarrow & & \downarrow \\ A & \xrightarrow{\varphi} & B \end{array}$$

whose vertical arrows are ind-étale, and where φ_l is a morphism in $K^+\text{-}\mathbf{m}.\mathbf{Alg}_0$

(b) and an object M_l of $C_l\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$, with an isomorphism $M_l \otimes_{C_l} B \xrightarrow{\sim} M$.

Proof of the claim. Define $\underline{A}$ and $\underline{B}$ as in the foregoing. Notice that – under the current assumptions – B_j is a henselian ring, for every $j \in J$. Moreover, we may find $j \in J$ such that $\kappa(B)$ is generated by the image of $\kappa(A) \otimes_{\kappa(B_0)} \kappa(B_j)$; after replacing again J by J/j, we may then also assume that $\kappa(B) = \kappa(A) \cdot \kappa(B_0)$.

For every $i \in I$, set $B'_i := A_i \otimes_{A_0} B_0$; the natural map $B_0 \to B$ factors through a map $B'_i \to B$, and we let $\mathfrak{p}_i \subset B'_i$ be the preimage of $\mathfrak{m}_B$. Set also $C_i := B'_{i,\mathfrak{p}_i}$, so we deduce a filtered system of local maps $(C_i \to B \mid i \in I)$, whose limit is a local map $\psi : C \to B$ of local ind-étale B_0-algebras, which – by construction – induces an isomorphism $\kappa(C) \xrightarrow{\sim} \kappa(B)$ on residue fields. It follows easily that ψ is itself ind-étale, so say that ψ is the colimit of a filtered system $(\psi_\lambda : C \to D_\lambda \mid \lambda \in \Lambda)$ of étale C-algebras. Notice that C is a henselian local ring; in light of [66, Ch.IV, Th.18.5.11] we may then assume that D_λ is a local ring and ψ_λ is a finite étale map, for every $\lambda \in \Lambda$. Clearly the induced residue field extension $\kappa(C) \to \kappa(D_\lambda)$ is an isomorphism; in view of [66, Ch.IV, Prop.18.5.15] it follows that ψ_λ is an isomorphism, for every $\lambda \in \Lambda$, so the same holds for ψ.

Notice that the sequence of residue degrees $d_i := [\kappa(C_i) : \kappa(A_i)]$ is non-increasing, hence there exists $l \in I$ such that $d_i = d := d_l$ for every index $i \geq l$. Notice as well that, for $i \geq l$, the local algebra C_i is also a localization of $C'_i := A_i \otimes_{A_l} C_l$, and the latter is an essentially finitely presented K^+-algebras of Krull dimension zero, hence its spectrum is finite and discrete (lemma 9.1.29). Moreover, since the image of the map $\mathrm{Spec}\, C_l \to \mathrm{Spec}\, A_l$ is the closed point, it is clear that the same holds for the image of the induced map $\mathrm{Spec}\, C'_i \to \mathrm{Spec}\, A_i$. Since the extension $\kappa(A_l) \to \kappa(A_i)$ is finite and separable, we conclude that

$$\kappa(A_i) \otimes_{\kappa(A_l)} \kappa(C_l) = \prod_{\mathfrak{p}\in\mathrm{Spec}\, C'_i} \kappa(C'_{i,\mathfrak{p}}). \tag{14.5.41}$$

However, clearly the left-hand side of (14.5.41) is a $\kappa(A_i)$-algebra of degree d, whereas one of factors of the right-hand side – namely $\kappa(C_i)$ – is already of degree d over $\kappa(A_i)$. Hence $\mathrm{Spec}\, C'_i$ contains a single element, *i.e.* $C'_i = C_i$ is a local ring, and $C = A \otimes_{A_l} C_l$. Summing up, we have obtained the sought cocartesian diagram, and the claim holds with $M_l := M_0 \otimes_{B_0} C_l$. ◊

Let M_l and φ_l be as in claim 14.5.40; then $\varphi_* M$ is isomorphic to $A \otimes_{A_l} \varphi_{l*} M_l$, so may replace from start φ by φ_l, and assume that φ is a morphism in $K^+\text{-}\mathbf{m}.\mathbf{Alg}_0$, with B of Krull dimension zero. In such situation, one sees easily that φ is integral, hence B/I is a finitely presented A-module, by proposition 9.1.34(i), therefore $\varphi_* M$ is a finitely presented A-module, as required. Lastly, since the functor φ_* is exact, it is clear that it induces a map on K_0-groups as stated.

(ii): Under the current assumptions, the induced map $\kappa(A_0) \to B_0/\mathfrak{m}_{A_0} B_0$ is integral and essentially finitely presented, hence it is finite, so $B_0/\mathfrak{m}_{A_0} B_0$ is a B_0-module of finite length; but this is also the length of the B-module $B/\mathfrak{m}_A B$, whence the first assertion. Next, let M be an object of $A\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$; then $\varphi^* M$ is a finitely presented B-module; moreover, we may find a $\mathfrak{m}_A$-primary ideal $I \subset A$ such that M is a A/I-module, hence $\varphi^* M$ is a B/IB-module. Notice that the induced map $\mathrm{Spec}\, B/\mathfrak{m}_A B \to \mathrm{Spec}\, B/IB$ is bijective, and its target is a local scheme of dimension zero (since $B/\mathfrak{m}_A B$ is integral over a field). It follows easily that IB is a $\mathfrak{m}_B$-primary ideal, so $\varphi^* M$ is an object of $B\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$. The last assertion is then a trivial consequence of the exactness of the functor φ^*, when φ is flat. □

Lemma 14.5.42. *Let A be any measurable K^+-algebra. Then there exists a morphism*

$$V \xrightarrow{\varphi} A/I$$

of measurable K^+-algebras, where :

(a) *$I \subset A$ is a finitely generated $\mathfrak{m}_A$-primary ideal.*
(b) *V is a valuation ring, φ is a finitely presented surjection and the natural map $K^+ \to V$ induces an isomorphism of value groups $\Gamma \xrightarrow{\sim} \Gamma_V$.*

Proof. Suppose first that A is an object of $K^+\text{-}\mathbf{m}.\mathbf{Alg}_0$. In this case, choose an affine finitely presented S-scheme X and a point $x \in X$ such that $A = \mathscr{O}_{X,x}$; next, take a finitely presented closed immersion $h : X \to Y := \mathbb{A}^n_{K^+}$ of S-schemes; set $\overline{Y} := \mathbb{A}^n_\kappa \subset Y$, pick elements $f_1, \dots, f_d \in B := \mathscr{O}_{Y,h(x)}$ whose images in the regular local ring $\mathscr{O}_{\overline{Y},h(x)}$ form a regular system of parameters (*i.e.* a regular sequence that generates the maximal ideal), and let $J \subset B$ be the ideal generated by the f_i, $i = 1, \dots, d$. Let $I \subset A$ be any finitely generated $\mathfrak{m}_A$-primary ideal containing the image of J. We deduce a surjection $\varphi : V := B/J \to A/I$, and by construction $V/\mathfrak{m}_K V$ is a field; moreover, the induced map $K^+ \to V$ is flat by virtue of [65, Ch.IV, Th.11.3.8]. It follows that V is a valuation ring with the sought properties, by proposition 9.1.34(ii). Also, φ is finitely presented, by proposition 9.1.34(i).

Next, let A be a general measurable K^+-algebra, and write A as the colimit of a filtered system $(A_j \mid j \in J)$ of objects of $K^+\text{-}\mathbf{m}.\mathbf{Alg}_0$. We may assume that $0 \in J$ is an initial index, and the foregoing case yields an $\mathfrak{m}_{A_0}$-primary ideal $I_0 \subset A_0$, and a surjective finitely presented morphism $\varphi_0 : V_0 \to A_0/I_0$ in $K^+\text{-}\mathbf{m}.\mathbf{Alg}_0$ from a valuation ring V_0, such that $\Gamma_V = \Gamma$. Notice that A/I_0 is a henselian ring, hence φ_0 extends to a ring homomorphism $\varphi_0^{\mathrm{h}} : V_0^{\mathrm{h}} \to A_0/I_0$ from the henselization V_0^{h} of V_0; more precisely, φ_0 induces an isomorphism of V_0^{h}-algebras :

$$V_0^{\mathrm{h}} \otimes_{V_0} (A_0/I_0) \xrightarrow{\sim} A_0/I_0$$

so $\varphi_0^{\rm h}$ is still finitely presented. On the one hand, $\varphi_0^{\rm h}$ induces an identification

$$\kappa(V_0^{\rm h}) = \kappa(A_0).$$

On the other hand, we have the filtered system of separable field extensions $(\kappa(A_j) \mid j \in J)$, whose colimit is $\kappa(A)$. There follows a corresponding filtered system $(V_j^{\rm h} \mid j \in J)$ of finite étale $V_0^{\rm h}$-algebras, whose colimit we denote V ([66, Ch.IV, Prop.18.5.15]). Then V is a valuation ring, and the map $V_0^{\rm h} \to V$ induces an isomorphism on value groups. Moreover, the induced isomorphisms $\kappa(V_j^{\rm h}) \stackrel{\sim}{\to} \kappa(A_j)$ lift uniquely to morphisms of A_0-algebras $\varphi_j^{\rm h} : V_j^{\rm h} \to A_j/I_0A_j$, for every $j \in J$ ([66, Ch.IV, Cor.18.5.12]). Due to the uniqueness of $\varphi_j^{\rm h}$, we see that the resulting system $(\varphi_j^{\rm h} \mid j \in J)$ is filtered, and its colimit is a morphism $\varphi : V \to A/I_0A$. Moreover, $\varphi_j^{\rm h}$ induces an isomorphism $V_j^{\rm h} \otimes_{V_0^{\rm h}} A_0/IA_0 \stackrel{\sim}{\to} A_j/I_0A_j$, especially $\varphi_j^{\rm h}$ is surjective for every $j \in J$, so the same holds for φ. More precisely, $\varphi_0^{\rm h}$ induces an isomorphism $V \otimes_{V_0^{\rm h}} (A_0/I_0) \stackrel{\sim}{\to} A/I_0A$, hence φ is still finitely presented. □

Theorem 14.5.43. *With the notation of* (14.5.36)*, the following holds :*

(i) *For every measurable K^+-algebra A there is a natural group isomorphism :*

$$\boldsymbol{\lambda}_A : K_0(A\text{-}\mathbf{Mod}_{\rm coh,\{s\}}) \stackrel{\sim}{\to} \log \Gamma$$

which induces an isomorphism $K_0^+(A\text{-}\mathbf{Mod}_{\rm coh,\{s\}}) \stackrel{\sim}{\to} \log \Gamma^+$.

(ii) *The family of isomorphisms $\boldsymbol{\lambda}_A$ (for A ranging over the measurable K^+-algebras) is characterized uniquely by the following two properties.*

(a) *If V is a valuation ring and a flat measurable K^+-algebra, then*

$$\boldsymbol{\lambda}_V([M]) = \lambda_V(M) \qquad \textit{for every object } M \textit{ of } V\text{-}\mathbf{Mod}_{\rm coh,\{s\}}$$

where $\lambda_V(M)$ is defined as in (14.5.2)*.*

(b) *Let $\psi : A \to B$ be a morphism of measurable K^+-algebras inducing a finite residue field extension $\kappa(A) \to \kappa(B)$. Then*

$$\boldsymbol{\lambda}_A(\psi_*[M]) = [\kappa(B) : \kappa(A)] \cdot \boldsymbol{\lambda}_B([M]) \qquad \textit{for every } [M] \in K_0(B\text{-}\mathbf{Mod}_{\rm coh,\{s\}}).$$

(iii) *For every $a \in K^+ \setminus \{0\}$ and any object M of A-$\mathbf{Mod}_{\rm coh,\{s\}}$ we have :*

(a) *$[M] = 0$ in $K_0(A\text{-}\mathbf{Mod}_{\rm coh,\{s\}})$ if and only if $M = 0$.*

(b) *If M is flat over K^+/aK^+, then :*

$$\boldsymbol{\lambda}_A([M]) = |a| \cdot {\rm length}_A(M \otimes_{K^+} \kappa). \qquad (14.5.44)$$

(iv) *Let $\psi : A \to B$ be a flat morphism of measurable K^+-algebras inducing an integral map $\kappa(A) \to B/\mathfrak{m}_AB$. Then :*

$$\boldsymbol{\lambda}_B(\psi^*[M]) = {\rm length}_B(B/\mathfrak{m}_AB) \cdot \boldsymbol{\lambda}_A([M]) \qquad \textit{for every } [M] \in K_0(A\text{-}\mathbf{Mod}_{\rm coh,\{s\}}).$$

Proof. We start out with the following :

Claim 14.5.45. Let $(K, |\cdot|) \to (E, |\cdot|)$ be an extension of valued fields of rank one inducing an isomorphism of value groups, $a \in K^+ \setminus \{0\}$ any element, M an E^+/aE^+ module. Then :

(i) M is a flat E^+/aE^+-module if and only if it is a flat K^+/aK^+-module.

(ii) $M \otimes_{K^+} \kappa = M \otimes_{E^+} \kappa(E)$.

Proof of the claim. According to [126, Th.7.8], in order to show (i) it suffices to prove that

$${\rm Tor}_1^{E^+/aE^+}(E^+/bE^+, M) = {\rm Tor}_1^{K^+/aK^+}(K^+/bK^+, M)$$

for every $b \in K^+$ such that $|b| \geq |a|$. The latter assertion is an easy consequence of the faithful flatness of the extension $K^+ \to E^+$. (ii) follows from the identity : $\mathfrak{m}_E = \mathfrak{m}_K E^+$, which holds since $\Gamma_E = \Gamma$. ◊

Claim 14.5.46. Let $f : K^+ \to V$ be a morphism of measurable K^+-algebras, where V is a valuation ring and f induces an isomorphism on value groups. Then $\boldsymbol{\lambda}_V$ (defined by (ii.a)) is an isomorphism and assertion (iii) holds for $A = V$.

Proof of the claim. According to (ii.a), $\boldsymbol{\lambda}_V([M]) = \lambda_V(M)$ for every finitely presented torsion V-module. However, every such module M admits a decomposition of the form $M \simeq (V/a_1V) \oplus \cdots \oplus (V/a_kV)$, with $a_1, \dots, a_k \in \mathfrak{m}_K$ ([75, Lemma 6.1.14]). Then by claim 14.5.45(i), M is flat over K^+/aK^+ if and only if M is flat over V/aV, if and only if $|a| = |a_i|$ for every $i \leq k$. In this case, an explicit calculation shows that $\lambda_V(M) = |a| \cdot \mathrm{length}(M \otimes_V \kappa(V))$, which is equivalent to (14.5.44), in view of claim 14.5.45(ii). Next, we consider the map :

$$\boldsymbol{\mu} : \log \Gamma^+ \to K_0(V\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}) \quad : \quad |a| \mapsto [V/aV] \quad \text{for every } a \in K^+ \setminus \{0\}.$$

We leave to the reader the verification that $\boldsymbol{\mu}$ extends to a group homomorphism well-defined on the whole of Γ, that provides an inverse to $\boldsymbol{\lambda}_V$. Finally, it is clear that $\lambda_V(M) = 0$ if and only if $M = 0$, so also (iii.a) holds. ♢

Claim 14.5.47. Let A be any measurable K^+-algebra. For every object N of $A\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$ there exist a finite filtration $0 = N_0 \subset \cdots \subset N_k = N$ by finitely presented A-submodules, and elements $a_1, \dots, a_k \in \mathfrak{m}$ such that N_i/N_{i-1} is a flat K^+/a_iK^+-module for every $1 \leq i \leq k$.

Proof of the claim. Let us find $I \subset A$ and $\varphi : V \to A/I$ as in lemma 14.5.42. It suffices to show the claim for the finitely presented A-modules $I^nN/I^{n+1}N$ (for every $n \in \mathbb{N}$), hence we may assume that N is an A/I-module. Then φ_*N is a finitely presented V-module, hence of the form $(V/a_1V) \oplus \cdots \oplus (V/a_kV)$ for some $a_i \in \mathfrak{m}$; we may order the summands so that $|a_i| \geq |a_{i+1}|$ for all $i < k$. We argue by induction on $d(N) := \dim_\kappa(N \otimes_V \kappa(V))$. If $d(N) = 0$, then $N = 0$ by Nakayama's lemma. Suppose $d > 0$; we remark that N/a_1N is a flat V/a_1V-module, hence a flat K^+/a_1K^+-module (claim 14.5.45), and $d(a_1N) < d(N)$; the claim follows. ♢

Claim 14.5.48. Let A be any measurable K^+-algebra, $I \subset A$ a finitely generated $\mathfrak{m}_A$-primary ideal, and $\pi_I : A \to A/I$ the natural projection. Then the map :

$$\pi_{I*} : K_0(A/I\text{-}\mathbf{Mod}_{\mathrm{coh}}) \to K_0(A\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}})$$

is an isomorphism.

Proof of the claim. On the one hand we have :

$$A\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}} = \bigcup_{n \in \mathbb{N}} A/I^n\text{-}\mathbf{Mod}_{\mathrm{coh}}$$

and on the other hand, in view of lemma 14.5.38, we see that the projections $A/I^{n+1} \to A/I^n$ induce isomorphisms $K_0(A/I^n\text{-}\mathbf{Mod}_{\mathrm{coh}}) \to K_0(A/I^{n+1}\text{-}\mathbf{Mod}_{\mathrm{coh}})$ for every $n > 0$, whence the claim. ♢

Let A, I and $\varphi : V \to A/I$ be as in lemma 14.5.42, and $\pi_I : A \to A/I$ the natural surjection; taking into account claim 14.5.48, we may let :

$$\boldsymbol{\lambda}_A := \boldsymbol{\lambda}_V \circ \varphi_* \circ \pi_{I*}^{-1} \tag{14.5.49}$$

where $\boldsymbol{\lambda}_V$ is given by the rule of (ii.a). In view of claim 14.5.46 we see that $\boldsymbol{\lambda}_A([M]) = 0$ if and only if $M = 0$, so (iii.a) follows already.

Claim 14.5.50. The isomorphism $\boldsymbol{\lambda}_A$ is independent of the choice of I, V and φ.

Proof of the claim. Indeed, suppose that $J \subset A$ is another ideal and $\psi : W \to A/J$ is another surjection from a valuation ring W, fulfilling the foregoing conditions. We consider the commutative diagram

$$\begin{array}{ccccc} & & A/I & \xleftarrow{\ \varphi\ } & V \\ & \nearrow^{\pi_I} & & \searrow^{\overline{\pi}_J} & \downarrow{\scriptstyle \varphi'} \\ A & & \xrightarrow{\ \pi_{I+J}\ } & & A/(I+J) \\ & \searrow_{\pi_J} & & \nearrow_{\overline{\pi}_I} & \uparrow{\scriptstyle \psi'} \\ & & A/J & \xleftarrow[\ \psi\ ]{} & W. \end{array}$$

We compute : $\varphi_* \circ \pi_{I*}^{-1} = \varphi_* \circ \pi_{J*} \circ \overline{\pi}_{J*}^{-1} \circ \overline{\pi}_{I*}^{-1} = \varphi'_* \circ \pi_{I+J,*}^{-1}$, and a similar calculation shows that $\psi_* \circ \pi_{J*}^{-1} = \psi'_* \circ \pi_{I+J,*}^{-1}$. We are thus reduced to showing that $\boldsymbol{\lambda}_V \circ \varphi'_*([N]) = \boldsymbol{\lambda}_W \circ \psi'_*([N])$ for every $A/(I+J)$-module N. In view of claim 14.5.47 we may assume that N is flat over K^+/aK^+, for some $a \in \mathfrak{m}$, in which case the assertion follows from claim 14.5.46. ◇

Claims 14.5.46 and 14.5.50 show already that (i) holds. Next, let $\psi : A \to B$ be as in (ii.b). Choose an ideal $I \subset A$ and a surjection $\varphi : V \to A/I$ as in lemma 14.5.42. Let also $J \subset B$ be a finitely generated $\mathfrak{m}_B$-primary ideal containing $\psi(I)$, and $\overline{\psi} : A/I \to B/J$ the induced map.

By inspecting the definitions we see that (ii.b) amounts to the identity : $\boldsymbol{\lambda}_V((\overline{\psi} \circ \varphi)_*[M]) = [\kappa(B) : \kappa(A)] \cdot \boldsymbol{\lambda}_{B/J}([M])$ for every finitely presented B/J-module M. Furthermore, up to enlarging J, we may assume that there is a finitely presented surjection $\xi : W \to B/J$ of K^+-algebras, where W is a valuation ring with value group Γ, and then we come down to showing:

$$\boldsymbol{\lambda}_V((\overline{\psi} \circ \varphi)_*[M]) = [\kappa(B) : \kappa(A)] \cdot \boldsymbol{\lambda}_W(\xi_*[M]).$$

In view of claim 14.5.47 we may also assume that M is a flat K^+/aK^+-module for some $a \in \mathfrak{m}$, in which case the identity becomes :

$$|a| \cdot \mathrm{length}_V(M \otimes_{K^+} \kappa) = [\kappa(B) : \kappa(A)] \cdot |a| \cdot \mathrm{length}_W(M \otimes_{K^+} \kappa)$$

thanks to claim 14.5.46. However, the latter is an easy consequence of the identities : $\kappa(A) = \kappa(V)$ and $\kappa(B) = \kappa(W)$. Next, we show that (iii.b) holds for a general measurable K^+-algebra A. Indeed, let M be any object of $A\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$; as usual, we may find a local ind-étale map $A_0 \to A$ from some object A_0 of $K^+\text{-}\mathbf{m}.\mathbf{Alg}_0$, and an object M_0 of $A_0\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$ with an isomorphism of A-modules $A \otimes_{A_0} M_0 \xrightarrow{\sim} M$ (cp. the proof of proposition 14.5.39(i)). Since (ii.b) is already proved, we have

$$\boldsymbol{\lambda}_A([M]) = \boldsymbol{\lambda}_{A_0}([M_0]) \quad \text{and} \quad \mathrm{length}_A(M \otimes_{K^+} \kappa) = \mathrm{length}_{A_0}(M \otimes_{K^+} \kappa).$$

Therefore, we may replace A by A_0, and assume that A is an object of $K^+\text{-}\mathbf{m}.\mathbf{Alg}_0$. In this case, by lemma 9.1.32 we may find morphisms $f : K^+ \to V$ and $g : V \to A$ in $K^+\text{-}\mathbf{m}.\mathbf{Alg}_0$ such that V is a valuation ring with value group Γ and g induces a finite extension of residue fields $\kappa(V) \to \kappa(A)$. Let N be an A-module supported at $s(A)$ and flat over K^+/aK^+; we may find a finitely generated $\mathfrak{m}_A$-primary ideal $I \subset A$ such that $I \subset \mathrm{Ann}_A(N)$, and since (ii.b) is already known in general, we reduce to showing that (iii.b) holds for the A/I-module N. However, the induced map $\overline{g} : V \to A/I$ is finite and finitely presented (proposition 9.1.34(i)), so another application of (ii.b) reduces to showing that (14.5.44) holds for $A := V$ and $M := \overline{g}_* N$, in which case the assertion is already known by claim 14.5.46.

(ii.a): Suppose that A is a valuation ring, and let M be any object of $A\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$. The sought assertion is obvious when $\Gamma_A = \Gamma$, since in that case we can choose $A = V$ and $\varphi = \pi_I$ in (14.5.49). However, we know already that the rank of A equals one, and $e := (\Gamma_A : \Gamma)$ is finite (see (14.5.5)); we can then assume that $e > 1$, in which case corollary 11.4.42(ii) implies that $\Gamma \simeq \mathbb{Z}$. Then it suffices to check (ii.a) for $M = \kappa(A)$, which is a (flat) κ-module, so that – by assertion (iii) – one has $\boldsymbol{\lambda}_A([M]) = e \cdot \gamma_0$, where $\gamma_0 \in \log \Gamma_A^+$ is the positive generator. In view of remark 14.5.14, we see that this value agrees with $\lambda_V(M)$, as stated.

(iv): In view of claim 14.5.47, we may assume that M is a flat K^+/aK^+-module, for some $a \in \mathfrak{m}$, and then the same holds for $\psi^* M$, since ψ is flat. In view of (iii.b), it then suffices to show that :

$$\mathrm{length}_B(B \otimes_A M) = \mathrm{length}_A(M) \cdot \mathrm{length}_B(B/\mathfrak{m}_A B)$$

for any A-module M of finite length. In turn, this is easily reduced to the case where $M = \kappa(A)$, for which the identity is obvious. □

14.5.51. Let A be a measurable K^+-algebra. The next step consists in extending the definition of $\boldsymbol{\lambda}_A$ to the category $A\text{-}\mathbf{Mod}_{\{s\}}$ of arbitrary A-modules M supported at $s(A)$. First of all, suppose that M is finitely generated. Let $\mathscr{C}_M$ be the set of isomorphism classes of objects M' of $A\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$ that admit a surjection $M' \to M$. Then we set :

$$\lambda_A^*(M) := \inf \{\boldsymbol{\lambda}_A([M']) \mid M' \in \mathscr{C}_M\} \in \log \Gamma^\wedge.$$

Notice that – by the positivity property of theorem 14.5.43(i) – we have $\lambda_A^*(M) = \boldsymbol{\lambda}_A([M])$ whenever M is finitely presented. Next, for a general object of $A\text{-}\mathbf{Mod}_{\{s\}}$ we let :
(14.5.52)

$$\lambda_A(M) := \sup \{\lambda_A^*(M') \mid M' \subset M \text{ and } M' \text{ is finitely generated}\} \in \log \Gamma^\wedge \cup \{+\infty\}.$$

Lemma 14.5.53. *If M is finitely generated, then $\lambda_A^*(M) = \lambda_A(M)$.*

Proof. Let $M' \subset M$ be a finitely generated submodule; we have to show that $\lambda^*(M') \leq \lambda^*(M)$. To this aim, let $f : N \to M$ and $g : N' \to M'$ be two surjections of A-modules with $N \in \mathscr{C}_M$ and $N' \in \mathscr{C}_{M'}$; by filtering the kernel of f by the system of its finitely generated submodules, we obtain a filtered system $(N_i \mid i \in I)$ of finitely presented quotients of N, with surjective transition maps, such that $\mathrm{colim}_{i\in I} N_i = M$. By [75, Prop.2.3.16(ii)] the induced map $N' \to M$ lifts to a map $h : N' \to N_i$ for some $i \in I$. Since A is coherent, $h(N')$ is a finitely presented A-module with a surjection $h(N') \to M'$, hence $\lambda_A^*(M') \leq \boldsymbol{\lambda}_A([h(N')]) \leq \boldsymbol{\lambda}_A([N_i]) \leq \boldsymbol{\lambda}_A(N)$. Since N is arbitrary, the claim follows. □

Proposition 14.5.54. (i) *If A is a valuation ring,* (14.5.52) *agrees with* (14.5.9).

(ii) *If $(M_i \mid i \in I)$ is a filtered system of objects of $A\text{-}\mathbf{Mod}_{\{s\}}$ with injective (resp. surjective) transition maps, then :*

$$\lambda_A(\mathop{\mathrm{colim}}_{i\in I} M_i) = \lim_{i\in I} \lambda_A(M_i)$$

(resp. provided there exists $i \in I$ such that $\lambda_A(M_i) < +\infty$).

(iii) *If $\psi : A \to B$ is a morphism of measurable K^+-algebras inducing a finite extension $\kappa(A) \to \kappa(B)$ of residue fields, then :*

$$\lambda_B(M) = \frac{\lambda_A(\psi_* M)}{[\kappa(B) : \kappa(A)]} \qquad \textit{for every object } M \textit{ of } B\text{-}\mathbf{Mod}_{\{s\}}.$$

(iv) *Let $0 \to M_1 \to M_2 \to M_3 \to 0$ be a short exact sequence in $A\text{-}\mathbf{Mod}_{\{s\}}$. Then :*

$$\lambda_A(M_2) = \lambda_A(M_1) + \lambda_A(M_3).$$

(v) *Let ψ be a flat morphism of measurable K^+-algebras inducing an integral map $\kappa(A) \to B/\mathfrak{m}_A B$. Then :*

$$\lambda_B(\psi^* M) = \mathrm{length}_B(B/\mathfrak{m}_A B) \cdot \lambda_A(M) \qquad \textit{for every object } M \textit{ of } A\text{-}\mathbf{Mod}_{\{s\}}.$$

Proof. (i): Set $e := (\Gamma_V : \Gamma)$. It suffices to check the assertion for a finitely generated A-module M, in which case one has to show the identity :

$$e \cdot |F_0(M)^a| = \lambda^*_A(M).$$

By proposition 14.5.12(i) we have $|F_0(M')^a| \geq |F_0(M)^a|$ for every $M' \in \mathscr{C}_M$, hence $\lambda^*_A(M) \geq e \cdot |F_0(M)^a|$. On the other hand, let us fix a surjection $V^{\oplus n} \to M$, and let us write its kernel in the form $K = \bigcup_{i\in I} K_i$, for a filtered system $(K_i \mid i \in I)$ of a finitely generated V-submodules; it follows that :

$$F_0(M) = \bigcup_{i\in I} F_0(V^{\oplus n}/K_i).$$

In view of proposition 14.5.12(iii.b) we deduce : $e \cdot |F_0(M)^a| = \lim_{i\in I} e \cdot |F_0(V^{\oplus n}/K_i)^a| \geq \lambda^*_A(M)$.

The proof of (ii) in the case where the transition maps are injective, is the same as that of proposition 14.5.12(iii.b).

(iii): Let us write $M = \bigcup_{i\in I} M_i$ for a filtered family $(M_i \mid i \in I)$ of finitely generated B-submodules. By the case already known of (ii) we have : $\lambda_B(M) = \lim_{i\in I} \lambda_B(M_i)$, and likewise for $\lambda_A(\psi_*M)$, hence we may assume from start that M is a finitely generated B-module, in which case the annihilator of M contains a finitely generated $\mathfrak{m}_B$-primary ideal $J' \subset B$. Choose a finitely generated $\mathfrak{m}_A$-primary ideal $J \subset A$ contained in the kernel of the induced map $A \to B/J'$.

Claim 14.5.55. $\lambda_B(M) = \lambda_{B/J'}(M)$ and $\lambda_A(\psi_*M) = \lambda_{A/J}(\overline{\psi}_*M)$.

Proof of the claim. Directly on the definition (and by applying theorem 14.5.43(ii.b) to the surjection $B \to B/J'$) we see that $\lambda_B(M) \leq \lambda_{B/J'}(M)$. On the other hand, any surjection of B-modules $M' \to M$ with M' finitely presented, factors through the natural map $M' \to M'/J'M'$, and by theorem 14.5.43(i,ii.b) we have $\lambda_B(M') - \lambda_{B/J'}(M'/J'M') = \lambda_B(J'M') \geq 0$, whence the first stated identity. The proof of the second identity is analogous. ◊

In view of claim 14.5.55 we are reduced to proving the assertion for the morphism $\overline{\psi}$ and the B/J'-module M, hence we may replace ψ by $\overline{\psi}$, and assume from start that A and B have Krull dimension zero.

Claim 14.5.56. Let A be a measurable K^+-algebra of Krull dimension zero. Then there exists a morphism $\varphi : V \to A$ of measurable K^+-algebras, with V a valuation ring flat over K^+, such that the residue field extension $\kappa(V) \to \kappa(A)$ is finite, and the induced map of value groups $\Gamma \to \Gamma_V$ is an isomorphism.

Proof of the claim. Let $A_0 \to A$ be a local ind-étale map, from an object A_0 of $K^+\text{-}\mathbf{m}.\mathbf{Alg}_0$. By lemma 9.1.32 we may find a K^+-flat valuation ring V_0 in $K^+\text{-}\mathbf{m}.\mathbf{Alg}_0$ and a local map $\varphi_0 : V \to A_0$, inducing a finite residue field extension $\kappa(V_0) \to \kappa(A_0)$ and an isomorphism on value groups $\Gamma \xrightarrow{\sim} \Gamma_V$. Then A_0 has also Krull dimension zero; especially, it is henselian, hence φ_0 factors through a morphism $\varphi_0^{\mathrm{h}} : V_0^{\mathrm{h}} \to A_0$, from the henselization V_0^{h} of V_0. Let $E \subset \kappa(A)$ be the largest separable subextension of $\kappa(V_0) = \kappa(V_0^{\mathrm{h}})$ contained in $\kappa(A)$; there exists a unique (up to unique isomorphism) finite étale morphism $V_0^{\mathrm{h}} \to V'$ with an isomorphism $\kappa(V') \xrightarrow{\sim} E$ of $\kappa(V_0)$-algebras, and φ_0^{h} factors through a morphism $V' \to A_0$. Notice that V' is still a henselian valuation ring and a measurable K^+-algebra, hence we may replace V_0 by V', and assume that V_0 is henselian, and the residue field extension $\overline{\varphi}_0 : \kappa(V_0) \to \kappa(A_0)$ is purely inseparable. Since A_0 is henselian, we may write A as the colimit of a filtered system $(A_i \mid i \in I)$ of finite étale A_0-algebras. Now, on the one hand, $\overline{\varphi}_0$ induces an equivalence from the category of finite étale $\kappa(V_0)$-algebras, to the category of finite étale $\kappa(A_0)$-algebras (lemma 13.1.7(i)). On the other hand, the category of finite étale V_0-algebras is equivalent to the category of finite étale $\kappa(V_0)$-algebras, and likewise for A_0. Therefore, for every $i \in I$ we may find a finite étale morphism

$V_0 \to V_i$, unique up to unique isomorphism, inducing an isomorphism of $\kappa(A_0)$-algebras :

$$\kappa(V_i) \otimes_{\kappa(V_0)} \kappa(A_0) \xrightarrow{\sim} \kappa(A_i) \tag{14.5.57}$$

and the transition maps of residue fields $\kappa(A_i) \to \kappa(A_j)$ induce unique maps $V_i \to V_j$ of V_0-algebras, compatible with the isomorphisms (14.5.57). Hence, the resulting system $(V_i \mid i \in I)$ is filtered, and its colimit is a valuation ring V, which is still a measurable K^+-algebra. Moreover, the field extensions $\kappa(V_i) \to \kappa(A_i)$ deduced from (14.5.57) lift uniquely to maps of V_0-algebras $V_i \to A_i$ ([66, Ch.IV, Cor.18.5.12]); taking colimits, we get finally a map $V \to A$ as sought. $\diamondsuit$

Let φ be as in claim 14.5.56; clearly it suffices to prove the sought identity for the two morphisms $\psi \circ \varphi$ and φ, so we may replace A by V, and assume from start that A is a valuation ring. Let us set $d := [\kappa(B) : \kappa(A)]$; we deduce :

$$\lambda_B(M) = \inf \{d^{-1} \cdot \lambda_A(\psi_* M') \mid M' \in \mathscr{C}_M\} \geq d^{-1} \cdot \lambda_A(\psi_* M)$$

by theorem 14.5.43(ii.b). Furthermore, let us choose a surjection $B^{\oplus k} \to M$, whose kernel we write in the form $K := \bigcup_{i \in I} K_i$ where $(K_i \mid i \in I)$ is a filtered family of finitely generated B-submodules of K. Next, by applying (i), proposition 14.5.12(i,iii.b), and theorem 14.5.43(ii.b) we derive :

$$\begin{aligned}\lambda_B(M) &\leq \inf \{\lambda_B(B^{\oplus k}/K_i) \mid i \in I\} = \inf \{d^{-1} \cdot \lambda_A(\psi_*(B^{\oplus k}/K_i)) \mid i \in I\} \\ &= d^{-1} \cdot (\lambda_A(\psi_* B^{\oplus k}) - \sup \{\lambda_A(\psi_* K_i) \mid i \in I\}) \\ &= d^{-1} \cdot (\lambda_A(\psi_* B^{\oplus k}) - \lambda_A(\psi_* K)) \\ &= d^{-1} \cdot \lambda_A(\psi_* M)\end{aligned}$$

whence the claim.

(iv): Let $(N_i \mid i \in I)$ be the filtered system of finitely generated submodules of M_2. For every $i \in I$ we have short exact sequences : $0 \to M_1 \cap N_i \to N_i \to \overline{N}_i \to 0$, where $\overline{N}_i$ is the image of N_i in M_3. In view of the case of (ii) already known, we may then replace M_2 by N_i, and thus assume from start that M_2 is finitely generated, so that we may find a finitely generated $\mathfrak{m}_A$-primary ideal $J \subset A$ that annihilates M_2. By (iii) we have $\lambda_A(M_2) = \lambda_{A/J}(M_2)$, and likewise for M_1 and M_3, hence we may replace A by A/J. By claim 14.5.56, we may then find a morphism $V \to A$ of measurable K^+-algebras with V a valuation ring, inducing a finite residue field extension $\kappa(V) \to \kappa(A)$; then again (iii) reduces to the case where $A = V$, to which one may apply (i) and proposition 14.5.12(i) to conclude the proof.

Next we consider assertion (ii) for the case where the transition maps are surjective. We may assume that I admits a smallest element i_0; for every $i \in I$ let K_i denote the kernel of the transition map $M_{i_0} \to M_i$. We deduce a short exact sequence :

$$0 \to \bigcup_{i \in I} K_i \to M_{i_0} \to \operatorname*{colim}_{i \in I} M_i \to 0$$

and we may then compute using (iv) and the previous case of (ii) :

$$\lambda_A(\operatorname*{colim}_{i \in I} M_i) = \lambda_A(M_{i_0}) - \lambda_A(\bigcup_{i \in I} K_i) = \lim_{i \in I}(\lambda_A(M_{i_0}) - \lambda_A(K_i)) = \lim_{i \in I} \lambda_A(M_{i_0}/K_i)$$

whence the claim.

(v): Since ψ_* is an exact functor which commutes with colimits, we may use (ii) to reduce to the case where M is finitely presented, for which the assertion is already known, in view of theorem 14.5.43(iv). $\square$

Remark 14.5.58. Suppose that the valuation of K is discrete; then one sees easily that theorem 14.5.43(i,iii) still holds (with simpler proof) when A is replaced by any local noetherian K^+-algebra, and by inspecting the definition, the resulting map λ_A is none else than the standard length function for modules supported on $\{s(A)\}$.

Lemma 14.5.59. *Let A be a measurable K^+-algebra, and M an A-module supported at $s(A)$ with $\lambda_A(M) < \infty$. Then*

$$\{a \in K^+ \mid \log|a| > \lambda_A(M)\} \subset \mathrm{Ann}_{K^+}M.$$

Proof. Using proposition 14.5.54(ii), we easily reduce, first, to the case where M is finitely generated, and second, to the case where M is finitely presented. Pick an ideal $I \subset A$ and a valuation ring V mapping onto A/I, as in lemma 14.5.42; by considering the I-adic filtration of M, the additivity properties of λ_A allow to further reduce to the case where M is an A/I-module. Next, by theorem 14.5.43(ii.b) we may replace A by V, and therefore assume that A is a valuation ring whose value group equals Γ. In this case, λ_A is computed by Fitting ideals, so the assertion follows easily from [75, Prop.6.3.6(iii)]. □

14.5.60. Let us consider a K^+-algebra R_∞ that is the colimit of an inductive system

$$R_0 \to R_1 \to R_2 \to \cdots \qquad (14.5.61)$$

of morphisms of measurable K^+-algebras inducing integral ring homomorphisms $\kappa(R_i) \to R_{i+1}/\mathfrak{m}_{R_i}R_i$ for every $i \in \mathbb{N}$. The final step consists in generalizing the definition of normalized length to the category R_∞-$\mathbf{Mod}_{\{s\}}$ of R_∞-modules supported at the closed point $s(R_\infty)$ of $\mathrm{Spec}\, R_\infty$. To this purpose, we shall axiomatize the general situation in which we can solve this problem. Later we shall see that our axioms are satisfied in many interesting cases.

14.5.62. Hence, let R_∞ be as in (14.5.60). After fixing an order-preserving isomorphism

$$(\mathbb{Q} \otimes_{\mathbb{Z}} \log\Gamma)^\wedge \xrightarrow{\sim} \mathbb{R} \qquad (14.5.63)$$

we may regard the mappings λ_A (for any measurable K^+-algebra A) as real-valued functions on A-modules. To ease notation, for every R_n-module N supported on $\{s(R_n)\}$ we shall write $\lambda_n(N)$ instead of $\lambda_{R_n}(N)$. Notice that, for every such N, and every $m \geq n$, the R_m-module $R_m \otimes_{R_n} N$ is supported at $\{s(R_m)\}$, since by assumption the map $R_n \to R_m/\mathfrak{m}_{R_n}R_m$ is integral.

Definition 14.5.64. In the situation of (14.5.62), we say that R_∞ is an *ind-measurable* K^+-algebra, if there exists a sequence of real *normalizing factors* $(d_n > 0 \mid n \in \mathbb{N})$ such that:

(a) For every $n \in \mathbb{N}$ and every object N of R_n-$\mathbf{Mod}_{\mathrm{coh},\{s\}}$, the sequence :

$$m \mapsto d_m^{-1} \cdot \lambda_m(R_m \otimes_{R_n} N)$$

converges to an element $\lambda_\infty(R_\infty \otimes_{R_n} N) \in \mathbb{R}$.

(b) For every $m \in \mathbb{N}$, every finitely generated $\mathfrak{m}_{R_0}$-primary ideal $I \subset R_0$, and every $\varepsilon > 0$ there exists $\delta(m, \varepsilon, I) > 0$ such that the following holds. For every $n \in \mathbb{N}$ and every surjection $N \to N'$ of finitely presented R_n/IR_n-modules generated by m elements, such that

$$|\lambda_\infty(R_\infty \otimes_{R_n} N) - \lambda_\infty(R_\infty \otimes_{R_n} N')| \leq \delta(m, \varepsilon, I)$$

we have :

$$d_n^{-1} \cdot |\lambda_n(N) - \lambda_n(N')| \leq \varepsilon.$$

14.5.65. Assume now that R_∞ is ind-measurable, and let N be a finitely presented R_n-module supported on $\{s(R_n)\}$. The first observation is that $\lambda_\infty(R_\infty \otimes_{R_n} N)$ only depends on the R_∞-module $R_\infty \otimes_{R_n} N$. Indeed, suppose that $R_\infty \otimes_{R_m} M \simeq R_\infty \otimes_{R_n} N$ for some $m \in \mathbb{N}$ and some finitely presented R_m-module M; then there exists $p \geq m, n$ such that $R_p \otimes_{R_m} M \simeq R_p \otimes_{R_n} N$, and then the assertion is clear.

The second observation – contained in the following lemma 14.5.66 – will show that the conditions of definition 14.5.64 impose some non-trivial restrictions on the inductive system $(R_n \mid n \in \mathbb{N})$.

Lemma 14.5.66. *Let $(R_n; d_n \mid n \in \mathbb{N})$ be an inductive system of measurable K^+-algebras and a sequence of positive reals, fulfilling conditions* (a) *and* (b) *of definition* 14.5.64. *Then:*

(i) *The natural map*
$$M \to R_m \otimes_{R_n} M$$
is injective for every $n, m \in \mathbb{N}$ with $m \geq n$ and every R_n-module M.

(ii) *Especially, the transition maps $R_n \to R_{n+1}$ are injective for every $n \in \mathbb{N}$.*

(iii) *Suppose that $(d'_n \mid n \in \mathbb{N})$ is another sequence of positive reals such that conditions* (a) *and* (b) *hold for the datum $(R_n; d'_n \mid n \in \mathbb{N})$. Then the sequence $(d_n/d'_n \mid n \in \mathbb{N})$ converges to a non-zero real number.*

Proof. (i): We reduce easily to the case where M is finitely presented over R_n. Let $N \subset \mathrm{Ker}\,(M \to R_m \otimes_{R_n} M)$ be a finitely generated R_n-module; since R_n is coherent, N is a finitely presented R_n-module. We suppose first that M is in $R_n\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$.

Claim 14.5.67. The natural map $R_m \otimes_{R_n} M \to R_m \otimes_{R_n} (M/N)$ is an isomorphism.

Proof of the claim. On the one hand, the R_m-module $R_m \otimes_{R_n} M$ represents the functor
$$R_m\text{-}\mathbf{Mod} \to \mathbf{Set} \quad : \quad Q \mapsto \mathrm{Hom}_{R_n}(M, Q).$$
On the other hand, the assumption on N implies that $\mathrm{Hom}_{R_n}(M, Q) = \mathrm{Hom}_{R_n}(M/N, Q)$ for every R_m-module Q, so the claim follows easily. ♢

From claim 14.5.67 we deduce that the natural map $R_\infty \otimes_{R_n} M \to R_\infty \otimes_{R_n} (M/N)$ is an isomorphism, and then condition (b) says that $\lambda_n(M) = \lambda_n(M/N)$, hence $\lambda_n(N) = 0$ and finally $N = 0$, as stated. Next, suppose M is any finitely presented R_n-module, and pick a finitely generated $\mathfrak{m}_{R_n}$-primary ideal $I \subset R_n$.

Claim 14.5.68. There exists $c \in \mathbb{N}$ such that $N \cap I^{k+c}M = I^k(N \cap I^c M)$ for every $k \geq 0$.

Proof of the claim. We may find a local ind-étale map $A \to R_n$ of K^+-algebras, where A is an object of $K^+\text{-}\mathbf{m.Alg}_0$, and such that I, M and N descend respectively to a finitely generated ideal $I_0 \subset A$, a finitely presented A-module M_0, and a finitely generated submodule $N_0 \subset M_0$. Then theorem 11.4.46 ensures the existence of $c \in \mathbb{N}$ such that $N_0 \cap I_0^{k+c} M_0 = I_0^k(N_0 \cap I_0^c M_0)$ for every $k \geq 0$. Since R_n is a faithfully flat A-algebra, the claim follows. ♢

Pick $c \in \mathbb{N}$ as in claim 14.5.68; then $N/(N \cap I^{k+c}M)$ is in the kernel of the natural map $M/I^{k+c}M \to R_m \otimes_{R_n} (M/I^{k+c}M)$, hence $N = N \cap I^{k+c}M$ by the foregoing, so that $N \subset I^k N$ for every $k \geq 0$, and finally $N = 0$ by Nakayama's lemma.

(ii) is a special case of (i). To show (iii), let us denote by $\lambda'_\infty(M)$ the normalized length of any object M of $R_\infty\text{-}\mathbf{Mod}_{\mathrm{coh},\{s\}}$, defined using the sequence $(d'_n \mid n \in \mathbb{N})$. From (b) it is clear that $\lambda_\infty(M), \lambda'_\infty(M) \neq 0$ whenever $M \neq 0$. Then, for any such non-zero M, the quotient $\lambda'_\infty(M)/\lambda_\infty(M)$ is the limit of the sequence $(d_n/d'_n \mid n \in \mathbb{N})$. □

Remark 14.5.69. (i) There is another situation of interest which leads to a well-behaved notion of normalized length. Namely, suppose that $R_\bullet := (R_n \mid n \in \mathbb{N})$ is an inductive system of local homomorphisms of local noetherian rings, such that the fibres of the induced morphisms

$\mathrm{Spec}\, R_{n+1} \to \mathrm{Spec}\, R_n$ have dimension zero, and denote by R_∞ the inductive limit of the system $R_\bullet$. For every $n \in \mathbb{N}$, let also λ_n be the usual length function on the set of isomorphism classes of finitely generated R_n-modules supported on $s(R_n)$. Then for every $m, n \in \mathbb{N}$ with $m \geq n$, and every R_n-module M of finite length, the R_m-module $R_m \otimes_{R_n} M$ has again finite length, so the analogues of conditions (a) and (b) of (14.5.62) can be formulated (cp. remark 14.5.58), and if these conditions hold for $R_\bullet$, we shall say that R_∞ is an *ind-measurable ring*. In such situation, lemma 14.5.66 – as well as the forthcoming lemma 14.5.70 and theorem 14.5.75 – still hold, with simpler proofs : we leave the details to the reader.

(ii) In spite of the uniqueness properties expressed by lemma 14.5.66, we do not know to which extent the normalized length of an ind-measurable K^+-algebra depends on the chosen tower of measurable algebras. Namely, suppose that $(R_n \mid n \in \mathbb{N})$ and $(R'_n \mid n \in \mathbb{N})$ are two such towers, with isomorphic colimit R_∞, and suppose that we have found normalizing factors $(d_n \mid n \in \mathbb{N})$ (resp. $(d'_n \mid n \in \mathbb{N})$) for the first (resp. second) tower, whence a normalized length λ_∞ (resp. λ'_∞) for R_∞-modules. Then we do not know whether the ratio of λ_∞ and λ'_∞ is a constant.

Next, for a given finitely generated R_∞-module M supported on $\{s(R_\infty)\}$, we shall proceed as in (14.5.51) : we denote by $\mathscr{C}_M$ the set of isomorphism classes of finitely presented R_∞-modules supported on $\{s(R_\infty)\}$ that admit a surjection $M' \to M$, and we set

$$\lambda^*_\infty(M) := \inf \{\lambda_\infty(M') \mid M' \in \mathscr{C}_M\} \in \mathbb{R}.$$

Directly on the definitions, one checks that $\lambda^*_\infty(M) = \lambda_\infty(M)$ if M is finitely presented.

Lemma 14.5.70. *Let M be a finitely generated R_∞-module, $\Sigma \subset M$ any finite set of generators, $(N_i \mid i \in I)$ any filtered system of objects of R_∞-$\mathbf{Mod}_{\{s\}}$, with surjective transition maps, such that* $\mathrm{colim}_{i\in I} N_i \simeq M$. *Then :*

(i) $\lambda^*_\infty(M) = \lim\limits_{n\to\infty} d_n^{-1} \cdot \lambda_n(\Sigma R_n)$.

(ii) *If every N_i is finitely generated, we have :*

$$\inf \{\lambda^*_\infty(N_i) \mid i \in I\} = \lambda^*_\infty(M).$$

Proof. To start out, we show assertion (ii) in the special case where all the modules N_i are finitely presented. Indeed, let us pick any surjection $\varphi : M' \to M$ with $M' \in \mathscr{C}_M$. We may find $i \in I$ such that φ lifts to a map $\varphi_i : M' \to N_i$ ([75, Prop.2.3.16(ii)]), and up to replacing I by a cofinal subset, we may assume that φ_i is defined for every $i \in I$. Moreover

$$\mathop{\mathrm{colim}}_{i\in I} \mathrm{Coker}\, \varphi_i = \mathrm{Coker}\, \varphi = 0$$

hence there exists $i \in I$ such that φ_i is surjective. It follows easily that $\lambda_\infty(N_i) \leq \lambda_\infty(M')$, whence (ii) in this case.

(i): Let k be the cardinality of Σ, $\varepsilon > 0$ any real number, $Q \subset \mathrm{Ann}_{R_0}\Sigma$ a finitely generated $\mathfrak{m}_{R_0}$-primary ideal, $S := R_\infty/QR_\infty$ and $\beta : S^{\oplus k} \to M$ a surjection that sends the standard basis onto Σ. By filtering $\mathrm{Ker}\, \beta$ by the system $(K_j \mid j \in J)$ of its finitely generated submodules, we obtain a filtered system $(N_j := S^{\oplus k}/K_j \mid j \in J)$ of finitely presented R_∞-modules supported on $\{s(R_\infty)\}$, with surjective transition maps and colimit isomorphic to M. Let $\psi_j : N_j \to M$ be the natural map; by the foregoing, we may find $j_0 \in J$ such that

$$0 \leq \lambda_\infty(N_{j_0}) - \lambda^*_\infty(M) \leq \min(\delta(k, \varepsilon, Q), \varepsilon) \tag{14.5.71}$$

(notation of definition 14.5.64(b)). We can then find $n \in \mathbb{N}$ and a finitely presented R_n-module M'_n supported on $\{s(R_n)\}$ and generated by at most k elements, such that $N_{j_0} = R_\infty \otimes_{R_n} M'_n$; we set $M'_m := R_m \otimes_{R_n} M_n$ for every $m \geq n$ and let M_m be the image of M'_m in M. Up to replacing n by a larger integer, we may assume that $M_m = \Sigma R_m$ for every $m \geq n$. Choose $m \in \mathbb{N}$ so that :

$$|\lambda_\infty(N_{j_0}) - d_m^{-1} \cdot \lambda_m(M'_m)| \leq \varepsilon. \tag{14.5.72}$$

Let $(M_{m,i} \mid i \in I)$ be a filtered system of finitely presented R_m-modules supported at $\{s(R_m)\}$, with surjective transition maps, such that $\mathrm{colim}_{i\in I} M_{m,i} = M_m$. Arguing as in the foregoing, we show that there exists $i \in I$ such that the natural map $\varphi : M'_m \to M_m$ factors through a surjection $\varphi_i : M'_m \to M_{m,i}$, and up to replacing I by a cofinal subset, we may assume that such a surjection φ_i exists for every $i \in I$. We obtain therefore a compatible system of surjections of R_∞-modules :

$$N_{j_0} \simeq R_\infty \otimes_{R_m} M'_m \to R_\infty \otimes_{R_m} M_{m,i} \to M$$

and combining with (14.5.71) we find :

$$|\lambda_\infty(N_{j_0}) - \lambda_\infty(R_\infty \otimes_{R_m} M_{m,i})| \leq \delta(k, \varepsilon, Q) \qquad \text{for every } i \in I.$$

In such situation, condition (b) of definition 14.5.64 ensures that :

$$d_m^{-1} \cdot |\lambda_m(M'_m) - \lambda_m(M_{m,i})| \leq \varepsilon \qquad \text{for every } i \in I.$$

Therefore : $d_m^{-1} \cdot |\lambda_m(M'_m) - \lambda_m(M_m)| \leq \varepsilon$, by proposition 14.5.54(ii). Combining with (14.5.72) and again (14.5.71) we obtain :

$$|\lambda^*_\infty(M) - d_m^{-1} \cdot \lambda_m(M_m)| \leq 3\varepsilon$$

which implies (i).

(ii): With no loss of generality, we may assume that I admits a smallest element i_0. Let us fix a surjection $F := R_\infty^{\oplus k} \to N_{i_0}$, and for every $i \in I$, let C_i denote the kernel of the induced surjection $F \to N_i$. We consider the filtered system $(D_j \mid j \in J)$ consisting of all finitely generated submodules $D_j \subset F$ such that $D_j \subset C_i$ for some $i \in I$. It is clear that $\mathrm{colim}_{j\in J} F/D_j \simeq M$, hence $\lambda^*_\infty(M) = \inf\{\lambda_\infty(F/D_j) \mid j \in J\}$, by (i). On the other, by construction, for every $j \in J$ we may find $i \in I$ such that $\lambda^*_\infty(N_i) \leq \lambda_\infty(F/D_j)$; since clearly $\lambda^*_\infty(N_i) \geq \lambda^*_\infty(M)$ for every $i \in I$, the assertion follows. □

14.5.73. Let now M be an arbitrary object of the category R_∞-$\mathbf{Mod}_{\{s\}}$. We let :

$$\lambda_\infty(M) := \sup\{\lambda^*_\infty(M') \mid M' \subset M \text{ and } M' \text{ is finitely generated}\} \in \mathbb{R} \cup \{+\infty\}.$$

Lemma 14.5.74. *If M is finitely generated, then $\lambda_\infty(M) = \lambda^*_\infty(M)$.*

Proof. Let $N \subset M$ be any finitely generated submodule. We choose finite sets of generators $\Sigma \subset N$ and $\Sigma' \subset M$ with $\Sigma \subset \Sigma'$. In view of proposition 14.5.54(iv) we have $\lambda_n(\Sigma R_n) \leq \lambda_n(\Sigma' R_n)$ for every $n \in \mathbb{N}$, hence $\lambda^*_\infty(N) \leq \lambda^*_\infty(M)$, by lemma 14.5.70(i). The contention follows easily. □

Theorem 14.5.75. (i) *Let $(M_i \mid i \in I)$ be a filtered system of objects of R_∞-$\mathbf{Mod}_{\{s\}}$, and suppose that either :*

(a) *all the transition maps of the system are injections, or*
(b) *all the transition maps are surjections and $\lambda_\infty(M_i) < +\infty$ for every $i \in I$.*

Then :

$$\lambda_\infty(\mathop{\mathrm{colim}}_{i\in I} M_i) = \lim_{i\in I} \lambda_\infty(M_i).$$

(ii) *Let $0 \to M' \to M \to M'' \to 0$ be a short exact sequence in R_∞-$\mathbf{Mod}_{\{s\}}$. Then :*

$$\lambda_\infty(M) = \lambda_\infty(M') + \lambda_\infty(M'').$$

(iii) *Let M be a finitely presented R_∞-module, $N \subset M$ a submodule supported at $s(R_\infty)$. Then $\lambda_\infty(N) = 0$ if and only if $N = 0$.*

Proof. The proof of (i) in case (a) is the same as that of proposition 14.5.54(iii.b).

(ii): We proceed in several steps :

• Suppose first that M and M'' are finitely presented, hence M' is finitely generated ([75, Lemma 2.3.18(ii)]). We may then find an integer $n \in \mathbb{N}$ and finitely presented R_n-modules M_n and M''_n such that $M \simeq R_\infty \otimes_{R_n} M_n$ and $M'' \simeq R_\infty \otimes_{R_n} M''_n$. For every $m \geq n$ we set $M_m := R_m \otimes_{R_n} M_n$ and likewise we define M''_m. Up to replacing n by a larger integer, we may assume that the given map $\varphi : M \to M''$ descends to a surjection $\varphi_n : M_n \to M''_n$, and then φ is the colimit of the induced maps $\varphi_m := \mathbf{1}_{R_m} \otimes_{R_n} \varphi_n$, for every $m \geq n$. Moreover, $M' \simeq \mathrm{colim}_{m \geq n} \mathrm{Ker}\, \varphi_m$, and by the right exactness of the tensor product, the image of $\mathrm{Ker}\, \varphi_m$ generates M' for every $m \geq n$. Furthermore, since the natural maps $M_m \to M_p$ are injective for every $p \geq m \geq n$ (lemma 14.5.66), the same holds for the induced maps $\mathrm{Ker}\, \varphi_m \to \mathrm{Ker}\, \varphi_p$. The latter factors as a composition :

$$\mathrm{Ker}\, \varphi_m \xrightarrow{\alpha} R_p \otimes_{R_m} \mathrm{Ker}\, \varphi_m \xrightarrow{\beta} \mathrm{Ker}\, \varphi_p$$

where α is injective (lemma 14.5.66) and β is surjective. In other words, $R_p \cdot \mathrm{Ker}\, \varphi_m = \mathrm{Ker}\, \varphi_p$ for every $p \geq m \geq n$. In such situation, lemma 14.5.70(i) ensures that :

$$\lambda_\infty(M') = \lim_{m \geq n} d_m^{-1} \cdot \lambda_m(\mathrm{Ker}\, \varphi_m)$$

and likewise :

$$\lambda_\infty(M) = \lim_{m \geq n} d_m^{-1} \cdot \lambda_m(M_m) \qquad \lambda_\infty(M'') = \lim_{m \geq n} d_m^{-1} \cdot \lambda_m(M''_m).$$

To conclude the proof of (ii) in this case, it suffices then to apply proposition 14.5.54(iv).

• Suppose next that M, M' (and hence M'') are finitely generated. We choose a filtered system $(M_i \mid i \in I)$ of finitely presented R_∞-modules, with surjective transition maps, such that $M \simeq \mathrm{colim}_{i \in I} M_i$. After replacing I by a cofinal subset, we may assume that M' is generated by a finitely generated submodule M'_i of M_i, for every $i \in I$, and that $(M'_i \mid i \in I)$ forms a filtered system with surjective transition maps, whose colimit is necessarily M'; set also $M''_i := M_i/M'_i$ for every $i \in I$, so that the colimit of the filtered system $(M''_i \mid i \in I)$ is M''. In view of lemmata 14.5.70(ii) and 14.5.74, we are then reduced to showing the identity :

$$\inf \{\lambda^*_\infty(M_i) \mid i \in I\} = \inf \{\lambda^*_\infty(M'_i) \mid i \in I\} + \inf \{\lambda^*_\infty(M''_i) \mid i \in I\}$$

which follows easily from the previous case.

• Suppose now that M is finitely generated. We let $(M'_i \mid i \in I)$ be the filtered family of finitely generated submodules of M'. Then :

$$M' \simeq \operatorname*{colim}_{i \in I} M'_i \quad \text{and} \quad M'' \simeq \operatorname*{colim}_{i \in I} M/M'_i.$$

Hence :

$$\lambda_\infty(M') = \lim_{i \in I} \lambda_\infty(M'_i) \quad \text{(resp.} \quad \lambda_\infty(M'') = \lim_{i \in I} \lambda_\infty(M/M'_i))$$

by (i.a) (resp. by lemmata 14.5.70(ii) and 14.5.74). However, the foregoing case shows that $\lambda_\infty(M) = \lambda_\infty(M'_i) + \lambda_\infty(M/M'_i)$ for every $i \in I$, so assertion (ii) holds also in this case.

• Finally we deal with the general case. Let $(M_i \mid i \in I)$ be the filtered system of finitely generated submodules of M; we denote by M''_i the image of M_i in M'', and set $M'_i := M' \cap M_i$ for every $i \in I$. By (i.a) we have :

$$\lambda_\infty(M) = \lim_{i \in I} \lambda_\infty(M_i)$$

and likewise for M' and M''. Since we already know that $\lambda_\infty(M_i) = \lambda_\infty(M'_i) + \lambda_\infty(M''_i)$ for every $i \in I$, we are done.

(iii): Let $f \in N$ be any element; in view of (ii) we see that $\lambda_\infty(fR_\infty) = 0$, and it suffices to show that $f = 0$. However, we may find $n \in \mathbb{N}$ and a finitely presented R_n-module M_n such that $M \simeq R_\infty \otimes_{R_n} M_n$; notice that the natural map $M_n \to M$ is injective, by lemma 14.5.66(i). We may also assume that f is in the image of M_n. Let $I \subset \mathrm{Ann}_{R_n}(f)$ be a finitely generated $\mathfrak{m}_{R_n}$-primary ideal; after replacing M by M/IM, we may assume that M_n is supported at $s(R_n)$. In light of (ii), we see that $\lambda_\infty(M) = \lambda_\infty(M/fR_\infty)$, hence $\lambda_n(M_n) = \lambda_n(M_n/fR_n)$, due to condition (b) of definition 14.5.64. Hence $\lambda_n(fR_n) = 0$ by proposition 14.5.54(iv), and finally $f = 0$ by theorem 14.5.43(i,iii.a).

To conclude, we consider assertion (i) in case (b) : set $M := \mathrm{colim}_{i\in I} M_i$; it is clear that $\lambda_\infty(M) \leq \lambda_\infty(M_i) \leq \lambda_\infty(M_j)$ whenever $i \geq j$, hence

$$\lim_{i\in I} \lambda_\infty(M_i) = \inf \{\lambda_\infty(M_i) \mid i \in I\} \geq \lambda_\infty(M).$$

For the converse inequality, fix $\varepsilon > 0$; without loss of generality, we may assume that I admits a smallest element i_0, and we can find a finitely generated submodule $N_{i_0} \subset M_{i_0}$ such that $\lambda_\infty(M_{i_0}) - \lambda_\infty(N_{i_0}) < \varepsilon$. For every $i \in I$, let $N_i \subset M_i$ be the image of N_{i_0}, and let $N \subset M$ be the colimit of the filtered system $(N_i \mid i \in I)$; then M_i/N_i is a quotient of M_{i_0}/N_{i_0}, and the additivity assertion (ii) implies that $\lambda_\infty(M_i) - \lambda_\infty(N_i) < \varepsilon$ for every $i \in I$. According to lemma 14.5.70(ii) (and lemma 14.5.74) we have :

$$\lambda_\infty(M) \geq \lambda_\infty(N) = \inf \{\lambda_\infty(N_i) \mid i \in I\} \geq \inf \{\lambda_\infty(M_i) \mid i \in I\} - \varepsilon$$

whence the claim. □

14.5.76. We wish now to show that the definition of normalized length descends to almost modules (see (14.5)). Namely, we have the following :

Proposition 14.5.77. *Let M, N be two objects of R_∞-$\mathbf{Mod}_{\{s\}}$ such that $M^a \simeq N^a$. Then $\lambda_\infty(M) = \lambda_\infty(N)$.*

Proof. Using additivity (theorem 14.5.75(ii)), we easily reduce to the case where $M^a = 0$, in which case we need to show that $\lambda_\infty(M) = 0$. Using theorem 14.5.75(i) we may further assume that M is finitely generated. Then, in view of lemma 14.5.70(i), we are reduced to showing the following :

Claim 14.5.78. Let A be any measurable K^+-algebra, and M any object of A-$\mathbf{Mod}_{\{s\}}$ such that $M^a = 0$. Then $\lambda_A(M) = 0$.

Proof of the claim. Arguing as in the foregoing we reduce to the case where M is finitely generated. Then, let us pick $I \subset A$ and $\varphi : V \to A/I$ as in lemma 14.5.42. It suffices to show the assertion for the finitely generated module $\bigoplus_{n\in\mathbb{N}} I^n M/I^{n+1}M$, hence we may assume that $I \subset \mathrm{Ann}_A M$, in which case, by proposition 14.5.54(iii) we may replace A by V and assume throughout that A is a valuation ring. Then the claim follows from propositions 14.5.54(i) and 14.5.12(ii). □

14.5.79. Proposition 14.5.77 suggests the following definition. We let R^a_∞-$\mathbf{Mod}_{\{s\}}$ be the full subcategory of R^a_∞-$\mathbf{Mod}$ consisting of all the R^a_∞-modules M such that $M_!$ is supported at $s(R_\infty)$, in which case we say that M *is supported at* $s(R_\infty)$. Then, for every such M we set :

$$\lambda_\infty(M) := \lambda_\infty(M_!).$$

With this definition, it is clear that theorem 14.5.75(i,ii) extends *mutatis mutandis* to almost modules. For future reference we point out :

Lemma 14.5.80. *Let $0 \to M' \to M \to M'' \to 0$ be a short exact sequence of R^a_∞-modules. We have :*

(i) *If M lies in R^a_∞-$\mathbf{Mod}_{\{s\}}$, then $\lambda_\infty(abM) \leq \lambda_\infty(aM') + \lambda_\infty(bM'')$ for every $a, b \in \mathfrak{m}$.*
(ii) *If M is almost finitely presented, and M' is supported at $s(R_\infty)$, then $\lambda_\infty(M') = 0$ if and only if $M' = 0$.*

Proof. (i): To start out, we deduce a short exact sequence : $0 \to bM \cap M' \to bM \to bM'' \to 0$. Next, let $N := \mathrm{Ker}(a : bM \to bM)$, and denote by N' the image of N in bM''; there follows a short exact sequence : $0 \to a(bM \cap M') \to abM \to bM''/N' \to 0$. The claim follows.

(ii): We reduce easily to the case where M' is a cyclic R^a_∞-module, say $M' = R^a_\infty x$ for some $x \in M_!$. In this case, let $I \subset \mathrm{Ann}_{R_0}(x)$ be a finitely generated $\mathfrak{m}_{R_0}$-primary ideal; we may then replace M by M/IM, and assume that M lies in R^a_∞-$\mathbf{Mod}_{\{s\}}$ as well. We remark :

Claim 14.5.81. M is almost finitely presented if and only if, for every $b \in \mathfrak{m}$ there exist a finitely presented R_∞-module N and a morphism $M \to N^a$ whose kernel and cokernel are annihilated by b. Moreover if M is supported at $s(R_\infty)$, one can choose N to be supported at $s(R_\infty)$.

Proof of the claim. The "if" direction is clear. For the "only if" part, we use [75, Cor.2.3.13], which provides us with a morphism $\varphi : N \to M_!$ with N finitely presented over R_∞, such that $b \cdot \mathrm{Ker}\,\varphi = b \cdot \mathrm{Coker}\,\varphi = 0$. Then $b \cdot \mathbf{1}^a_N$ factors through a morphism $\varphi' : \mathrm{Im}\,\varphi^a \to N^a$, and $b \cdot \mathbf{1}_M$ factors through a morphism $\varphi'' : M \to \mathrm{Im}\,\varphi^a$; the kernel and cokernel of $\varphi' \circ \varphi''$ are annihilated by b^2. Finally, suppose that M is supported on $s(R_\infty)$, and let $I \subset R_\infty$ be any finitely generated ideal such that $V(I) = \{s(R_\infty)\}$. By assumption, for every $f \in I$ and every $m \in M_!$ there exists $n \in \mathbb{N}$ such that $f^n m = 0$; it follows that I^n annihilates $\mathrm{Im}\,\varphi$ for every sufficiently large $n \in \mathbb{N}$, and we may then replace N by $N/I^n N$. ◊

Let M and M' be as in (ii), and choose a morphism $\varphi : M \to N^a$ as in claim 14.5.81; by adjunction we get a map $\psi : M'_! \to M_! \to N$ with $b \cdot \mathfrak{m} \cdot \mathrm{Ker}\,\psi = 0$. It follows that $\lambda_\infty(\mathrm{Im}\,\psi) = 0$, hence $\mathrm{Im}\,\psi = 0$, by theorem 14.5.75(iii). Hence $bM' = 0$; since b is arbitrary, the assertion follows. □

Simple examples show that an almost finitely generated (or even almost finitely presented) R^a_∞-module may fail to have finite normalized length. The useful finiteness condition for almost modules is contained in the following :

Definition 14.5.82. Let M be a R^a_∞-module supported at $s(R_\infty)$. We say that M has *almost finite length* if $\lambda_\infty(bM) < +\infty$ for every $b \in \mathfrak{m}$.

Lemma 14.5.83. (i) *The set of isomorphism classes of R^a_∞-modules of almost finite length forms a closed subset of the uniform space $\mathscr{M}(A)$ (notation of* [75, §2.3]*).*

(ii) *Especially, every almost finitely generated R^a_∞-module supported at $s(R_\infty)$ has almost finite length.*

Proof. Assertion (i) boils down to the following :

Claim 14.5.84. Let $a, b \in \mathfrak{m}$, and $f : N \to M$, $g : N \to M'$ morphisms of R^a_∞-modules, such that the kernel and cokernel of f and g are annihilated by $a \in \mathfrak{m}$, and such that $\lambda_\infty(bM) < +\infty$. Then $\lambda_\infty(a^2bM') < +\infty$.

Proof of the claim. By assumption, $\mathrm{Ker}\,f \subset \mathrm{Ker}\,a \cdot \mathbf{1}_N$, whence an epimorphism $f(N) \to aN$; likewise, we have an epimorphism $g(N) \to aM'$. It follows that

$$\lambda_\infty(a^2bM') \leq \lambda_\infty(ab \cdot g(M)) \leq \lambda_\infty(abN) \leq \lambda_\infty(b \cdot f(N)) < +\infty$$

as stated. ◊

(ii) follows from (i) and the obvious fact that every finitely generated R_∞-module supported at $s(R_\infty)$ has finite normalized length. □

14.5.85. For the case of a measurable K^+-algebra A of dimension zero, we can show a further *Lipschitz type* uniform estimate for the normalized length. Namely, for any integer $k > 0$ define the set $\mathscr{M}_k(A^a)$ with its uniform structure as in (14.5.1); *i.e.* we have the fundamental system of entourages

$$(E_r \mid r \in \mathbb{R}_{>0})$$

where each E_r consists of the pairs (N, N') such that there exist a third A^a-module N'' and A^a-linear maps $N'' \to N$, $N'' \to N'$ whose kernel and cokernels are annihilated by any $b \in K^+$ such that $\log |b| \geq r$.

Lemma 14.5.86. *In the situation of* (14.5.85)*, we have :*

$$|\lambda_{A^a}(N) - \lambda_{A^a}(N')| \leq 4k \cdot \mathrm{length}_A(A/\mathfrak{m}A) \cdot r$$

for every $r \in \mathbb{R}_{>0}$ *and every* $(N, N') \in E_r$.

Proof. We begin with the following

Claim 14.5.87. For any finitely generated A-module N, and every $b \in K^+ \setminus \{0\}$ we have

$$\lambda_A(N/bN) \leq \mathrm{length}_A(N/\mathfrak{m}N) \cdot \log |b|.$$

Proof of the claim. Choose a map $\psi : V \to A$ of measurable K^+-algebras, inducing a finite residue field extension $\kappa(V) \to \kappa(A)$, where V is a K^+-flat valuation ring, and the induced map of value groups $\Gamma \to \Gamma_V$ is an isomorphism (claim 14.5.56). Let $d := \dim_{\kappa(V)} N/\mathfrak{m}_V N$; applying Nakayama's lemma, we get a surjection $(V/bV)^{\oplus d} \to N/bN$ of V-modules, for every $b \in K^+$. Hence

$$\lambda_A(N/bN) = \frac{\lambda_V(\psi_*(N/bN))}{[\kappa(V) : \kappa(A)]} \leq \frac{d \log |b|}{[\kappa(V) : \kappa(A)]} = \mathrm{length}_A(N/\mathfrak{m}N) \cdot \log |b|$$

as stated. ◊

Now, suppose that $(N, N') \in E_{\log |b|}$ for some $b \in K^+$, and pick maps $\varphi : N'' \to N$, $\psi : N'' \to N'$ whose kernel and cokernel are annihilated by b. Especially, if $n_1, \dots, n_k \in N_*$ (resp. $n'_1, \dots, n'_k \in N'_*$) is a system of generators for N (resp. for N'), we may find $n''_1, \dots, n''_{2k} \in N''_*$ such that $\varphi(n''_i) = b^2 n_i$ for $i = 1, \dots, k$ and $\psi(n''_i) = b^2 n'_{i-k}$ for $i = k+1, \dots, 2k$. After replacing N'' by its submodule generated by $n''_1, \dots, n''_{2k}$, we may assume that $N'' \in \mathscr{M}_{2k}(A)$, $\mathrm{Ker}\,\varphi$ is still annihilated by b, but $\mathrm{Coker}\,\varphi$ is only annihilated by b^2. On the one hand, we deduce that

$$\lambda_{A^a}(N'') \geq \lambda_{A^a}(\varphi(N'')) \geq \lambda_{A^a}(b^2 N) = \lambda_{A^a}(N) - \lambda_{A^a}(N/b^2 N)$$

therefore

$$\lambda_{A^a}(N) - \lambda_{A^a}(N'') \leq \lambda_{A^a}(N/b^2 N).$$

On the other hand, the map $N'' \to N''$ given by the rule : $n'' \mapsto bn''$ for every $n'' \in N''_*$, factors through $\varphi(N'')$, therefore $\lambda_{A^a}(N) \geq \lambda_{A^a}(bN'')$ so the same calculation yields the inequality

$$\lambda_{A^a}(N'') - \lambda_{A^a}(N) \leq \lambda_{A^a}(N''/bN'').$$

Taking into account claim 14.5.87 (and proposition 14.5.77) we see that

$$|\lambda_{A^a}(N'') - \lambda_{A^a}(N)| \leq 2k \cdot \mathrm{length}_A(A/\mathfrak{m}A) \cdot \log |b|.$$

Of course, the same holds with N replaced by N', and the lemma follows. □

We conclude this section with some basic examples of the situation contemplated in definition 14.5.64.

Example 14.5.88. Suppose that all the transition maps $R_n \to R_{n+1}$ of the inductive system in (14.5.62) are flat. Then, proposition 14.5.54(v) implies that conditions (a) and (b) hold with:

$$d_n := \mathrm{length}_{R_n}(R_n/\mathfrak{m}_{R_0} R_n) \qquad \text{for every } n \in \mathbb{N}.$$

Example 14.5.89. Suppose that $p := \mathrm{char}\,\kappa > 0$. Let $d \in \mathbb{N}$ be any integer, $f : X \to \mathbb{A}^d_{K^+} := \mathrm{Spec}\,K^+[T_1, \dots, T_d]$ an étale morphism. For every $r \in \mathbb{N}$ we consider the cartesian diagram of schemes

$$\begin{array}{ccc} X_r & \xrightarrow{f_r} & \mathbb{A}^d_{K^+} \\ {\scriptstyle \psi_r}\downarrow & & \downarrow{\scriptstyle \varphi_r} \\ X & \xrightarrow{f} & \mathbb{A}^d_{K^+} \end{array}$$

where φ_r is the morphism corresponding to the K^+-algebra homomorphism

$$\varphi_r^\natural : K^+[T_1, \dots, T_d] \to K^+[T_1, \dots, T_d]$$

defined by the rule: $T_j \mapsto T_j^{p^r}$ for $j = 1, \dots, d$. For every $r, s \in \mathbb{N}$ with $r \geq s$, ψ_r factors through an obvious S-morphism $\psi_{rs} : X_r \to X_s$, and the collection of the schemes X_r and transition morphisms ψ_{sr} gives rise to an inverse system $\underline{X} := (X_r \mid r \in \mathbb{N})$, whose inverse limit is representable by an S-scheme X_∞ ([65, Ch.IV, Prop.8.2.3]). Let $g_\infty : X_\infty \to S$ (resp. $g_r : X_r \to S$ for every $r \in \mathbb{N}$) be the structure morphism, $x \in g_\infty^{-1}(s)$ any point, $x_r \in X_r$ the image of x and $R_r := \mathscr{O}_{X_r, x_r}$ for every $r \in \mathbb{N}$. Clearly the colimit R_∞ of the inductive system $(R_r \mid r \in \mathbb{N})$ is naturally isomorphic to $\mathscr{O}_{X_\infty, x}$. Moreover, notice that the restriction $g_{r+1}^{-1}(s) \to g_r^{-1}(s)$ is a radicial morphism for every $r \in \mathbb{N}$. It follows easily that the transition maps $R_r \to R_{r+1}$ are finite; furthermore, by inspection one sees that $\varphi_r^\natural$ is flat and finitely presented, so R_{r+1} is a free R_r-module of rank p^d, for every $r \in \mathbb{N}$. Hence, the present situation is a special case of example 14.5.88, and therefore conditions (a) and (b) hold if we choose the sequence of integers $(d_i \mid i \in \mathbb{N})$ with

$$d_i := p^{id}/[\kappa(x_i) : \kappa(x_0)] \qquad \text{for every } i \in \mathbb{N}.$$

The foregoing discussion then yields a well-behaved notion of normalized length for arbitrary R_∞-modules supported at $\{s(R_\infty)\}$.

Example 14.5.90. In the situation of example 14.5.89, it is easy to construct R^a_∞-modules $M \neq 0$ such that $\lambda_\infty(M) = 0$. For instance, for $d := 1$, let $x \in X_\infty$ be the point of the special fibre where $T_1 = 0$; then we may take $M := R_\infty/I$, where I is the ideal generated by a non-zero element of $\mathfrak{m}_K$ and by the radical of $T_1 R_\infty$. The verification shall be left to the reader.

14.6. **Finite group actions on almost algebras.** In this section we fix a basic setup $(V, \mathfrak{m})$ such that $\widetilde{\mathfrak{m}} := \mathfrak{m} \otimes_V \mathfrak{m}$ is a flat V-module (see [75, §2.1.1]), and we consider some descent problems for V^a-algebras endowed with a finite group of automorphisms. Hence, the results below overlap with those of [75, §4.5].

14.6.1. Let G be a finite group, A a V^a-algebra, and let $S := \mathrm{Spec}\,V^a$, $X := \mathrm{Spec}\,A$. A *right action of* G *on* X is a group homomorphism :

$$\rho : G \to \mathrm{Aut}_{V^a\text{-}\mathsf{Alg}}(A)$$

from G to the group of automorphisms of A. Let G_S be the affine group S-scheme defined by G; hence every $g \in G$ determines a section $g_S : S \to G_S$ of the structure morphism $G_S \to S$, and the resulting morphism:

$$\coprod_{g \in G} g_S : S \amalg \cdots \amalg S \to G_S$$

is an isomorphism of S-schemes. Then ρ can be also regarded as a right action of G_S on X, as defined in [75, §3.3.6]. Especially, ρ induces morphisms of S-schemes :

$$\partial_i : X \times G := X \times_S G_S \to X \qquad i = 0, 1$$

as in *loc. cit.*, and we may define a *G-action on an A-module M* (covering the given action of G on X) as a morphism of quasi-coherent $\mathscr{O}_{X\times G}$-modules :

$$\beta : \partial_0^* M \to \partial_1^* M$$

fulfilling the conditions of [75, §3.3.7]. One also says that (M,β) is a *G-equivariant A-module*. We denote by $A[G]$-$\mathbf{Mod}$ the category of all G-equivariant A-modules and G-equivariant A-linear morphisms. Notice that $A[G]$-$\mathbf{Mod}$ is an abelian tensor category : indeed, for any two objects (M,β), (M,β') we may set $(M,\beta)\otimes_A (M',\beta') := (M\otimes_A M', \beta\otimes_{\mathscr{O}_{X\times G}} \beta')$.

14.6.2. Likewise, if B is any A-algebra, a G-action on B is a morphism $\beta : \partial_0^* B \to \partial_1^* B$ of quasi-coherent $\mathscr{O}_{X\times G}$-algebras, such that the pair (B,β) is a G-equivariant A-module. We say that (B,β) is a *G-equivariant A-algebra*, and we denote by $A[G]$-Alg the category of such pairs, with G-equivariant morphisms of A-algebras. One verifies easily that the datum (B,β) is the same as a morphism $\psi : A \to B$ of V^a-algebras, together with a G-action $\rho_B : G \to \mathrm{Aut}_{V^a\text{-}\mathsf{Alg}}(B)$ on the affine scheme $\mathrm{Spec}\, B$, such that the diagram :

$$\begin{array}{ccc} A & \xrightarrow{\psi} & B \\ {\scriptstyle \rho(g)}\downarrow & & \downarrow{\scriptstyle \rho_B(g)} \\ A & \xrightarrow{\psi} & B \end{array}$$

commutes for every $g\in G$. We shall also consider the full subcategory $A[G]$-$\mathsf{Alg}_{\mathrm{fl}}$ (resp. $A[G]$-$\mathbf{w.\acute{E}t}$, resp. $A[G]$-$\mathbf{\acute{E}t}$, resp. $A[G]$-$\mathbf{\acute{E}t}_{\mathrm{afp}}$) of all such pairs, where B is a flat (resp. weakly étale, resp. étale, resp. étale and almost finitely presented) A-algebra.

14.6.3. The *trivial G-action* on X is the map ρ with $\rho(g) = \mathbf{1}_A$ for every $g\in G$; this is the same as saying that $\partial_0 = \partial_1$. If G acts trivially on X, a G-equivariant A-module (M,β) is the same as a group homomorphism $\overline{\beta} : G \to \mathrm{Aut}_A(M)$ from G to the group of A-linear automorphisms of M. Namely, for every $g\in G$, one lets :

$$\overline{\beta}(g) := (\mathbf{1}_X \times_S g_S)^*\beta \qquad (14.6.4)$$

and conversely, to a given map $\overline{\beta}$ there corresponds a unique pair (M,β) such that (14.6.4) holds.

Under this correspondence, the *trivial G-action* $\overline{\beta}_0$ (such that $\overline{\beta}(g) = \mathbf{1}_M$ for every $g\in G$) corresponds to the identity morphism $\beta_0 : \partial_0^* M \xrightarrow{\sim} \partial_1^* M$.

More generally, let (M,β) be a G-action on an A-module M, covering the trivial G-action on X; for every A_*-valued character $\chi : G \to A_*^\times$ of G, we let

$$M_\chi := \bigcap_{g\in G} \mathrm{Ker}(\overline{\beta}(g) - \chi(g)\cdot \mathbf{1}_M).$$

The restriction of $\overline{\beta}$ defines a G-action on M_χ, such that the monomorphism $M_\chi \subset M$ is G-equivariant. In the special case where χ is the trivial character, we have $M_\chi = (M,\beta)^G$, the largest G-equivariant A-submodule of (M,β) on which β restricts to the trivial G-action (*i.e.* the submodule fixed by G). When the notation is not ambiguous, we shall often just write M^G instead of $(M,\beta)^G$.

14.6.5. If $H\subset G$ is a subgroup, any G-action ρ on X induces by restriction an H-action $\rho_{|H}$; then the morphisms $\partial_i : X\times H \to X$ are just the restrictions of the corresponding morphisms for G (under the natural closed immersion $X\times H \to X\times G$). Similarly, a G-action β on an A-module M induces by restriction an H-action $\beta_{|H}$ on the same module.

Let $Y := \operatorname{Spec} B$ be any affine S-scheme. The G-action ρ induces a G-action $Y \times_S \rho$ on $Y \times_S X$; namely, $Y \times_S \rho(g) := \mathbf{1}_Y \times_S \rho(g)$ for every $g \in G$. In terms of the group scheme G_S, this is the action given by the morphisms :

$$\partial_{Y,i} := \mathbf{1}_Y \times_S \partial_i : (Y \times_S X) \times G \to (Y \times_S X) \qquad i = 0, 1.$$

Let $\pi_X : Y \times_S X \to X$ be the natural morphism; then every G-equivariant A-module (M, β) induces a G-equivariant $B \otimes_{V^a} A$-module $\pi_X^*(M, \beta) := (\pi_X^* M, \pi_X^* \beta)$, whose action covers the G-action $Y \times_S \rho$ on $Y \times_S X$.

14.6.6. Let us set :

$$X/G := \mathrm{Coequal}(X \times G \overset{\partial_1}{\underset{\partial_1}{\rightrightarrows}} X) \quad \text{and} \quad X^{\langle g \rangle} := \mathrm{Equal}(X \overset{\rho(g)}{\underset{\mathbf{1}_X}{\rightrightarrows}} X) \quad \text{for every } g \in G.$$

In other words, $X/G = \operatorname{Spec} A^G$, the subalgebra fixed by G, and $X^{\langle g \rangle}$ is the closed subscheme fixed by the subgroup $\langle g \rangle \subset G$ generated by g. Thus, $X^{\langle g \rangle}$ is the spectrum of a quotient A/I_g of A, where $I_g \subset A$ is the ideal generated by the almost elements of the form $a - \rho(g)(a)$, for every $a \in A_*$.

Let $\pi : X \to X/G$ be the natural morphism, N any quasi-coherent $\mathscr{O}_{X/G}$-module; the pull-back $\pi^* N$ is the quasi-coherent $\mathscr{O}_X$-module $A \otimes_{A^G} N$. By construction, there is a natural isomorphism $\beta_N : \partial_0^*(\pi^* N) \xrightarrow{\sim} \partial_1^*(\pi^* N)$ (deduced from the natural isomorphisms of functors $\partial_i^* \circ \pi^* \simeq (\pi \circ \partial_i)^*$, for $i = 0, 1$), and one verifies easily that β_N is a G-action on $\pi^* N$.

Moreover, let $i_g : X^{\langle g \rangle} \to X$ be the natural closed immersion; if M is any A-module, then $i_g^* M$ is the A/I_g-module $M/I_g M$. Especially, take $M := \pi^* N$; we notice that the restriction $\rho_{|\langle g \rangle}$ of the given action ρ, induces the trivial $\langle g \rangle$-action on $X^{\langle g \rangle}$, and directly from the construction, we see that the natural action $\beta_{N|\langle g \rangle}$ restricts to the trivial $\langle g \rangle$-action on $i_g^* M$.

We are thus led to the :

Definition 14.6.7. Let G be a finite group, A a V^a-algebra, ρ a G-action on $X := \operatorname{Spec} A$.

(i) The category $A[G]\text{-}\mathbf{Mod}_{\mathrm{hor}}$ of *A-modules with horizontal G-action* is the full subcategory of $A[G]\text{-}\mathbf{Mod}$ consisting of all pairs (M, β) subject to the following condition. For every $g \in G$, the restriction $\beta_{|\langle g \rangle}$ induces the trivial action on $i_g^* M$.

(ii) We denote by $A[G]\text{-}\mathbf{Mod}_{\mathrm{hor.fl}}$ the full subcategory of $A[G]\text{-}\mathbf{Mod}_{\mathrm{hor}}$ consisting of the pairs (M, β) as above, such that M is a flat A-module.

(iii) Likewise, we denote by $A[G]\text{-}\mathsf{Alg}_{\mathrm{hor}}$ (resp. $A[G]\text{-}\mathsf{Alg}_{\mathrm{hor.fl}}$, resp. $A[G]\text{-}\mathbf{w.\acute{E}t}_{\mathrm{hor}}$, resp. $A[G]\text{-}\mathbf{\acute{E}t}_{\mathrm{hor}}$, resp. $A[G]\text{-}\mathbf{\acute{E}t}_{\mathrm{hor.afp}}$) the full subcategory of $A[G]\text{-}\mathsf{Alg}$ (resp. $A[G]\text{-}\mathsf{Alg}_{\mathrm{fl}}$, resp. $A[G]\text{-}\mathbf{w.\acute{E}t}$, resp. $A[G]\text{-}\mathbf{\acute{E}t}$, resp. $A[G]\text{-}\mathbf{\acute{E}t}_{\mathrm{afp}}$) consisting of all pairs (B, β) which are horizontal, when regarded as G-equivariant A-modules.

Notice that the tensor product of horizontal modules (resp. algebras) is again horizontal. By the foregoing, the rule $N \mapsto (\pi^* N, \beta_N)$ defines a functor :

$$A^G\text{-}\mathbf{Mod} \to A[G]\text{-}\mathbf{Mod}_{\mathrm{hor}}. \tag{14.6.8}$$

On the other hand, if (M, β) is any G-equivariant A-module, the pair $\pi_*(M, \beta) := (\pi_* M, \pi_* \beta)$ may be regarded as a G-action on $\pi_* M$, covering the trivial G-action on $\operatorname{Spec} A^G$, *i.e.* a group homomorphism $G \to \operatorname{Aut}_{A^G}(M)$ (see (14.6.3)). One verifies easily that the functor $N \mapsto (\pi^* N, \beta_N)$ is left adjoint to the functor $A[G]\text{-}\mathbf{Mod} \to A^G\text{-}\mathbf{Mod} : (M, \beta) \mapsto \pi_*(M, \beta)^G$ (details left to the reader). Hence, also (14.6.8) admits a right adjoint, given by the same rule. Similar assertions hold for the analogous functors :

$$A^G\text{-}\mathsf{Alg} \to A[G]\text{-}\mathsf{Alg}_{\mathrm{hor}} \tag{14.6.9}$$

and the variants considered in definition 14.6.7(iii).

Lemma 14.6.10. *In the situation of definition* 14.6.7*, suppose furthermore that the order* $o(G)$ *of* G *is invertible in* A_**, and let* (M, β) *be any* G*-equivariant* A*-module. Then :*

(i) *For every* A_*^G*-valued character* $\chi : G \to (A_*^G)^\times$*, the natural* A^G*-linear monomorphism* $\pi_* M_\chi \to \pi_* M$ *admits a* G*-equivariant* A^G*-linear right inverse* $\pi_* M \to \pi_* M_\chi$*.*

(ii) *For every* A^G*-module* N*, the unit of adjunction :*

$$\varepsilon_N : N \to (A \otimes_{A^G} N)^G$$

is an isomorphism.

(iii) *Let* $Y := \mathrm{Spec}\, B$ *be any affine* S*-scheme; denote by* $\pi_X : Y \times_S X \to X$ *and* $\pi_{X/G} : Y \times_S (X/G) \to X/G$ *the natural projections. Then the natural morphism :*

$$\pi_{X/G}^*(M, \beta)^G \to (\pi_X^* M, \pi_X^* \beta)^G$$

is an isomorphism of $B \otimes_{V^a} A^G$*-modules.*

Proof. This is standard : for every χ as in (i), the group algebra $A_*[G]$ admits the central idempotent :

$$e_\chi := \frac{1}{o(G)} \cdot \sum_{g \in G} \chi(g) \cdot g \qquad (14.6.11)$$

and $M_\chi = e_\chi M$ for any G-equivariant A-module M. Especially, we may take $M := N \otimes_{A^G} A$, and e_0 the central idempotent associated with the trivial character, in which case $e_0 A = A^G$, and $M = N \oplus (N \otimes_{A^G} (1 - e_0)A)$, so all the claims follow easily. ☐

Definition 14.6.12. Let Γ be any finite abelian group with neutral element $0 \in \Gamma$.

(i) A Γ-*graded* V^a-*algebra* is a pair $\underline{A} := (A, \mathrm{gr}_\bullet A)$ consisting of a V^a-algebra A and a decomposition $A = \bigoplus_{\chi \in \Gamma} \mathrm{gr}_\chi A$ as a direct sum of V^a-modules, such that :

$$1 \in \mathrm{gr}_0 A_* \quad \text{and} \quad \mathrm{gr}_\chi A \cdot \mathrm{gr}_{\chi'} A \subset \mathrm{gr}_{\chi + \chi'} A \qquad \text{for every } \chi, \chi' \in \Gamma$$

(where as usual $\mathrm{gr}_\chi A \cdot \mathrm{gr}_{\chi'} A$ denotes the image of the restriction $\mathrm{gr}_\chi A \otimes_{V^a} \mathrm{gr}_{\chi'} A \to A$ of the multiplication morphism μ_A). Especially, $\mathrm{gr}_0 A$ is a V^a-subalgebra of A, and every submodule $\mathrm{gr}_\chi A$ is a $\mathrm{gr}_0 A$-module.

(ii) A Γ-*graded* $\underline{A}$-*module* is a pair $\underline{N} := (N, \mathrm{gr}_\bullet N)$ consisting of an A-module N and a decomposition $N = \bigoplus_{\chi \in \Gamma} \mathrm{gr}_\chi N$ as a direct sum of V^a-modules, such that :

$$\mathrm{gr}_\chi A \cdot \mathrm{gr}_{\chi'} N \subset \mathrm{gr}_{\chi + \chi'} N \qquad \text{for every } \chi, \chi' \in \Gamma.$$

Of course, a morphism of Γ-graded $\underline{A}$-modules $\underline{N} \to \underline{N}' := (N', \mathrm{gr}_\bullet N')$ is an A-linear morphism $N \to N'$ that respects the gradings.

(iii) For every subgroup $\Delta \subset \Gamma$, let $J_\Delta \subset A$ be the graded ideal generated by $\bigoplus_{\chi \notin \Delta} \mathrm{gr}_\chi A$. We say that $\underline{N}$ is *horizontal* if $\mathrm{gr}_\chi(N/J_\Delta N) := \mathrm{gr}_\chi N / (\mathrm{gr}_\chi N \cap J_\Delta N) = 0$ for every subgroup $\Delta \subset \Gamma$ and every $\chi \notin \Delta$.

(iv) If $\Delta \subset \Gamma$ is any subgroup, $p : \Gamma \to \Gamma/\Delta$ the natural projection, and $\rho \in \Gamma/\Delta$ any element, we let :

$$\mathrm{gr}_\rho^{\Gamma/\Delta} N := \bigoplus_{\chi \in p^{-1}(\rho)} \mathrm{gr}_\chi N$$

and set $\underline{N}_{\Gamma/\Delta} := (N, \mathrm{gr}_\bullet^{\Gamma/\Delta} N)$. Then $\underline{A}_{\Gamma/\Delta}$ is a Γ/Δ-graded V^a-algebra, and $\underline{N}_{\Gamma/\Delta}$ is a Γ/Δ-graded $\underline{A}_\Delta$-module. Moreover, let also $\underline{N}_{|\Delta}$ be the pair consisting of $N_{|\Delta} := \mathrm{gr}_0^{\Gamma/\Delta} N$ together with its decomposition $N_{|\Delta} = \bigoplus_{\chi \in \Delta} \mathrm{gr}_\chi N$; then $\underline{A}_{|\Delta}$ is a Δ-graded V^a-algebra, and $\underline{N}_{|\Delta}$ is a Δ-graded $\underline{A}_{|\Delta}$-module.

Proposition 14.6.13. *In the situation of definition* 14.6.12*, let* $\underline{N}$ *be any* Γ*-graded* $\underline{A}$*-module. Then the following conditions are equivalent :*

(a) $\underline{N}$ *is horizontal.*
(b) *The natural morphism* $A \otimes_{\mathrm{gr}_0 A} \mathrm{gr}_0 N \to N$ *is an epimorphism.*

Proof. (b)⇒(a): The assertion is obvious for the Γ-graded $\underline{A}$-module consisting of $A \otimes_{\mathrm{gr}_0 A} \mathrm{gr}_0 N$ and its natural grading deduced from $\mathrm{gr}_\bullet A$; however any (graded) quotient of a horizontal module is horizontal, hence the assertion follows also for $\underline{N}$.

(a)⇒(b): We argue by induction on $o(\Gamma)$. The first case is covered by the following :

Claim 14.6.14. The proposition holds if $o(\Gamma)$ is a prime number.

Proof of the claim. Indeed, suppose that $\underline{N}$ is horizontal. We may replace N by $N/(A \cdot \mathrm{gr}_0 N)$, which is a horizontal Γ-graded $\underline{A}$-module, when endowed with the grading induced from $\mathrm{gr}_\bullet N$. Then $\mathrm{gr}_0 N = 0$, and we have to show that $N = 0$. By assumption, $N \subset J_{\{0\}} N$, *i.e.* :

$$\mathrm{gr}_\chi N \subset \sum_{\sigma \neq 0, \chi} \mathrm{gr}_\sigma A \cdot \mathrm{gr}_{\chi - \sigma} N \qquad \text{for every } \chi \neq 0.$$

For every $n > 0$, the symmetric group S_n acts on the set $(\Gamma \setminus \{0\})^n$ by permutations; we let $Q_n := (\Gamma \setminus \{0\})^n / S_n$, the set of equivalence classes under this action. For every $\underline{\sigma} := (\sigma_1, \dots, \sigma_n) \in Q_n$, let $|\underline{\sigma}| := \sum_{i=1}^n \sigma_i$. By an easy induction, it follows that :

$$\mathrm{gr}_\chi N \subset \sum_{\underline{\sigma} \in Q_n} \mathrm{gr}_{\sigma_1} A \cdots \mathrm{gr}_{\sigma_n} A \cdot \mathrm{gr}_{\chi - |\underline{\sigma}|} N.$$

Since every element of $\Gamma \setminus \{0\}$ generates Γ, it is also clear that there exists $n \in \mathbb{N}$ large enough such that every sequence $\underline{\sigma}$ in Q_n admits a subsequence, say $\underline{\tau} := (\tau_1, \dots, \tau_m)$ for some $m \leq n$, with $|\underline{\tau}| = \chi$ (details left to the reader). Up to a permutation, we may assume that $\underline{\tau}$ is the final segment of $\underline{\sigma}$; then we have :

$$\mathrm{gr}_{\sigma_1} A \cdots \mathrm{gr}_{\sigma_n} A \cdot \mathrm{gr}_{\chi - |\underline{\sigma}|} N \subset \mathrm{gr}_{\sigma_1} A \cdots \mathrm{gr}_{\sigma_{n-m}} A \cdot \mathrm{gr}_0 N = 0$$

whence the claim. ◊

Next, suppose that the assertion is already known for every subgroup $\Gamma' \subset \Gamma$, every graded Γ'-algebra $\underline{B}$, and every Γ'-graded $\underline{B}$-module $\underline{P}$. We choose a subgroup $\Gamma' \subset \Gamma$ such that $(\Gamma : \Gamma')$ is a prime number. We shall use the following :

Claim 14.6.15. Let G be a group, $0 \in G$ the neutral element, $H \subset G$ a subgroup. For every subgroup $L \subset G$ with $H \cap L = \{0\}$, choose an element $g_L \in G \setminus L$; denote by S the subgroup generated by all these elements g_L. Then $S \cap H \neq \{0\}$.

Proof of the claim. Indeed, if $S \cap H = \{0\}$, we would have $g_S \in S$, a contradiction. ◊

Claim 14.6.16. Suppose that $\underline{N}$ is horizontal. Then $\underline{N}_{|\Gamma'}$ is a horizontal Γ'-graded $\underline{A}_{|\Gamma'}$-module.

Proof of the claim. For any given subgroup $\Delta \subset \Gamma'$, let $J'_\Delta \subset A_{|\Gamma'}$ be the ideal generated by $\bigoplus_{\chi \in \Gamma' \setminus \Delta} \mathrm{gr}_\chi A$; have to show that $\mathrm{gr}_\chi(N/J'_\Delta N) = 0$ for every $\chi \in \Gamma' \setminus \Delta$. To this aim, we may replace Γ, Γ', $\underline{A}$, $\underline{A}_{|\Gamma'}$, $\underline{N}$ and $\underline{N}_{|\Gamma'}$, by respectively Γ/Δ, Γ'/Δ, $\underline{A}_{\Gamma/\Delta}$, $(\underline{A}_{|\Gamma'})_{\Gamma'/\Delta}$, $\underline{N}_{\Gamma/\Delta}$ and $(\underline{N}_{|\Gamma'})_{\Gamma'/\Delta}$, which allows to assume that $\Delta = \{0\}$. In this case, we have to show that :

$$N_{|\Gamma'} = \mathrm{gr}_0 N + J'_{\{0\}} \cdot N_{|\Gamma'}. \tag{14.6.17}$$

Notice that $A_{|\Gamma'} \cdot \mathrm{gr}_0 N = \mathrm{gr}_0 N + J'_{\{0\}} \cdot \mathrm{gr}_0 N$; the quotient $P := N/(A \cdot \mathrm{gr}_0 N)$ carries a unique Γ-grading $\mathrm{gr}_\bullet P$ such that the projection $\underline{N} \to \underline{P} := (P, \mathrm{gr}_\bullet P)$ is a morphism of Γ-graded $\underline{A}$-modules (namely, $\mathrm{gr}_\chi P := N_\chi / \mathrm{gr}_\chi A \cdot \mathrm{gr}_0 N$ for every $\chi \in \Gamma$). Moreover, P is horizontal, $\mathrm{gr}_0 P = 0$, and (14.6.17) is equivalent to : $P_{|\Gamma'} = J'_{\{0\}} \cdot P_{|\Gamma'}$. Therefore we may replace $\underline{N}$ by $\underline{P}$, and assume from start that $\mathrm{gr}_0 N = 0$. Similarly, notice that $J'_{\{0\}} \cdot N$ is a Γ-graded $\underline{A}$-submodule of $\underline{N}$, and the pair $\underline{Q}$ consisting of $Q := N/(J'_{\{0\}} \cdot N)$ and its quotient grading, is horizontal.

Moreover, $\mathrm{gr}_\chi Q = \mathrm{gr}_\chi(N_{|\Gamma'}/J'_{\{0\}}N_{|\Gamma'})$, for every $\chi \in \Gamma'$. Hence, we may replace N by Q, which allows to assume as well that

$$J'_{\{0\}}N_{|\Gamma'} = 0 \qquad (14.6.18)$$

in which case, we are reduced to showing that $N = 0$. Now, by assumption, for every subgroup $H \subset \Gamma$ we have :

$$N = N_{|H} + J_H N.$$

Let $\mathscr{C}$ be the set of all subgroups $H \subset \Gamma$ with $H \cap \Gamma' = \{0\}$; we deduce that :

$$\mathrm{gr}_\chi N \subset \sum_{\sigma\notin H} \mathrm{gr}_\sigma A \cdot \mathrm{gr}_{\chi-\sigma} N \qquad \text{for every } \chi \in \Gamma' \setminus \{0\} \text{ and every } H \in \mathscr{C}. \qquad (14.6.19)$$

Moreover, in view of (14.6.18) we may omit from the sum in (14.6.19) all the elements σ that lie in Γ'; for the remaining elements we have $\chi - \sigma \notin \Gamma'$, hence we may apply claim 14.6.14 to the horizontal Γ/Γ'-graded $\underline{A}_{\Gamma/\Gamma'}$-module $\underline{N}_{\Gamma/\Gamma'}$, to deduce that :

$$\mathrm{gr}_{\chi-\sigma} N \subset \sum_{\delta\in\Gamma'\setminus\{0\}} \mathrm{gr}_{\chi-\sigma-\delta} A \cdot \mathrm{gr}_\delta N.$$

Therefore :

$$\mathrm{gr}_\chi N \subset \sum_{\sigma\notin H\cup\Gamma'} \sum_{\delta\in\Gamma'\setminus\{0\}} \mathrm{gr}_\sigma A \cdot \mathrm{gr}_{\chi-\sigma-\delta} A \cdot \mathrm{gr}_\delta N \qquad \text{for every } \chi \in \Gamma' \setminus \{0\} \text{ and every } H \in \mathscr{C}.$$

However – again due to (14.6.18) – we may omit from this sum all the terms corresponding to the pairs (σ, δ) with $\chi \neq \delta$, hence we conclude that :

$$\mathrm{gr}_\chi N \subset \sum_{\sigma\notin H\cup\Gamma'} \mathrm{gr}_\sigma A \cdot \mathrm{gr}_{-\sigma} A \cdot \mathrm{gr}_\chi N \qquad \text{for every } \chi \in \Gamma' \setminus \{0\} \text{ and every } H \in \mathscr{C}.$$

Denote by Σ the set of all mappings $\underline{\sigma} : \mathscr{C} \to \Gamma$ such that $\underline{\sigma}(H) \notin H \cup \Gamma'$ for every $H \in \mathscr{C}$. Moreover, for every $\underline{\sigma} \in \Sigma$, set :

$$B_{\underline{\sigma}} := \prod_{H\in\mathscr{C}} \mathrm{gr}_{\underline{\sigma}(H)} A \cdot \mathrm{gr}_{-\underline{\sigma}(H)} A$$

(this is an ideal of $\mathrm{gr}_0 A$) and let $S_{\underline{\sigma}} \subset \Gamma$ be the subgroup generated by the image of $\underline{\sigma}$. By an easy induction we deduce that :

$$\mathrm{gr}_\chi N \subset \sum_{\underline{\sigma}\in\Sigma} B^n_{\underline{\sigma}} \cdot \mathrm{gr}_\chi N \qquad \text{for every } n > 0.$$

By claim 14.6.15, for every $\underline{\sigma} \in \Sigma$ we may find $\gamma(\underline{\sigma}) \in S_{\underline{\sigma}} \cap \Gamma' \setminus \{0\}$. On the other hand, since Γ is finite and abelian, it is easy to verify that there exists $n \in \mathbb{N}$ large enough such that

$$B^n_{\underline{\sigma}} \subset \mathrm{gr}_{\gamma(\underline{\sigma})} A \cdot \mathrm{gr}_{-\gamma(\underline{\sigma})} A \qquad \text{for every } \underline{\sigma} \in \Sigma$$

(details left to the reader). But (14.6.18) implies that $\mathrm{gr}_{\gamma(\underline{\sigma})} A \cdot \mathrm{gr}_\chi N = 0$ whenever $\chi \in \Gamma' \setminus \{0\}$, so the claim follows. ◊

To conclude, we apply first claim 14.6.14 to the horizontal Γ/Γ'-graded $\underline{A}_{\Gamma/\Gamma'}$-module $\underline{N}_{\Gamma/\Gamma'}$, to see that $N_{|\Gamma/\Gamma'}$ generates the A-module N, and then claim 14.6.16 – together with our inductive assumption – to deduce that $\mathrm{gr}_0 N$ generates that $A_{|\Gamma/\Gamma'}$-module $N_{|\Gamma/\Gamma'}$. The proposition follows. □

14.6.20. Recall that a morphism $M \to N$ of A-modules is said to be *pure* if the natural morphism $Q \otimes_A M \to Q \otimes_A N$ is a monomorphism for every A-module Q. A morphism $A \to B$ of V^a-algebras is called *pure* if it is pure when regarded as a morphism of A-modules.

Lemma 14.6.21. *Let $f : A \to B$ be a pure morphism of V^a-algebras, M an A-module. Then :*

(i) *If $B \otimes_A M$ is a flat B-module, then M is a flat A-module (*i.e. *f descends flatness).*

(ii) *If $B \otimes_A M$ is almost finitely generated (resp. almost finitely presented) as a B-module, then M is almost finitely generated (resp. almost finitely presented) as an A-module.*

Proof. (i): To begin with, we remark :

Claim 14.6.22. Let R be any V-algebra such that $A = R^a$.

(i) A morphism $\varphi : M_1 \to M_2$ of A-modules is pure if and only if the same holds for the induced morphism $\varphi_! : M_{1!} \to M_{2!}$ of R-modules.

(ii) A morphism $g : A \to B'$ of V^a-algebras is pure if and only if the same holds for the induced morphism $g_{!!} : A_{!!} \to B'_{!!}$.

Proof of the claim. (i): Suppose that φ is pure, and let Q be any R-module. Then $Q \otimes_R M_{i!} \simeq (Q^a \otimes_A M_i)_!$ for $i = 1, 2$. Since the functor $M \mapsto M_!$ is exact ([75, Cor.2.2.24(i)]), we deduce that $\varphi_!$ is pure. The converse is easy, and shall be left to the reader.

(ii): From (i) we already see that g is pure whenever $g_{!!}$ is. Next, suppose that g is pure; we may assume that $R = A_{!!}$, and then (i) says that $g_!$ is a pure morphism of $A_{!!}$-modules. However, the natural diagram of $A_{!!}$-modules :

$$\begin{array}{ccc} A_! & \longrightarrow & B'_! \\ \downarrow & & \downarrow \\ A_{!!} & \longrightarrow & B'_{!!} \end{array}$$

is cofibred; since tensor products are right exact functors, the claim follows. ◊

The assertion now follows from claim 14.6.22(ii) and [86, Partie II, Lemme 1.2.1].

(ii): Suppose first that $B \otimes_A M$ is an almost finitely generated B-module. The assumption on f implies that $\mathrm{Ann}_A(B \otimes_A M) \subset \mathrm{Ann}_A M$; then [75, Rem.3.2.26(i)] shows that M is an almost finitely generated A-module.

Finally, we suppose that $B \otimes_A M$ is an almost finitely presented B-module, and we wish to show that M is an almost finitely presented A-module. To this aim, let $\varphi : N \to N'$ be a morphism of A-modules. The assumption on f implies that the natural morphism $\mathrm{Ker}\,\varphi \to \mathrm{Ker}(\mathbf{1}_B \otimes_A \varphi)$ is a monomorphism; especially :

$$\mathrm{Ann}_A(\mathrm{Ker}(\mathbf{1}_B \otimes_A \varphi)) \subset \mathrm{Ann}_A(\mathrm{Ker}\,\varphi).$$

Then one may easily adapt the proof of [75, Lemma 3.2.25(iii)], to derive the assertion. □

Theorem 14.6.23. *In the situation of definition* 14.6.7*, suppose furthermore that G is abelian and the order $o(G)$ of G is invertible in A_*. Then the following holds :*

(i) *Let M be any G-equivariant A-module. The G-action on M is horizontal if and only if the counit of adjunction :*

$$\eta_M : A \otimes_{A^G} M^G \to M$$

is an epimorphism (of A-modules).

(ii) *The functor* (14.6.8) *restricts to an equivalence on the full subcategory of flat A^G-modules :*

$$A^G\text{-}\mathbf{Mod}_{\mathrm{fl}} \stackrel{\sim}{\to} A[G]\text{-}\mathbf{Mod}_{\mathrm{hor.fl}}. \tag{14.6.24}$$

Proof. (i): For $m := o(G)$, let $\boldsymbol{\mu}_m \subset \overline{\mathbb{Q}}^\times$ be the group of m-th roots of 1, and set $B := V^a[\boldsymbol{\mu}_m] := (V[T]/(T^m - 1))^a$. Since B is a faithfully flat V^a-algebra, lemma 14.6.10(iii) allows to replace A by $B \otimes_{V^a} A$ and M by $B \otimes_{V^a} M$, and therefore we may assume from start that $\boldsymbol{\mu}_m \subset (A_*^G)^\times$. Set $\Gamma := \mathrm{Hom}_\mathbb{Z}(G, \boldsymbol{\mu}_m)$. For every $\chi \in \Gamma$, let $e_\chi \in A_*[G]$ be the central idempotent defined as in (14.6.11). A standard calculation shows that :

$$\sum_{\chi \in \Gamma} e_\chi = 1.$$

Hence, every G-equivariant A^G-module (N, β) admits the G-equivariant decomposition :

$$N \simeq \bigoplus_{\chi \in \Gamma} N_\chi. \tag{14.6.25}$$

Especially, $A = \bigoplus_{\chi \in \Gamma} A_\chi$, and clearly the datum $\underline{A}$ consisting of A and its decomposition, is a Γ-graded V^a-algebra. Furthermore, the datum $\underline{N}$ consisting of N and its decomposition (14.6.25) is a Γ-graded $\underline{A}$-module.

Claim 14.6.26. The functor $(N, \beta) \mapsto \underline{N}$ is an equivalence from $A[G]$-$\mathbf{Mod}$ to the category of Γ-graded $\underline{A}$-modules.

Proof of the claim. Indeed, if Q is a Γ-graded $\underline{A}$-module, we may define a G-action on Q by requiring that $Q_\chi = \mathrm{gr}_\chi Q$, the χ-graded direct summand of Q. This gives a quasi-inverse for the functor $(N, \beta) \mapsto \underline{N}$. (Details left to the reader.) ◊

Claim 14.6.27. Let (N, β) be any G-equivariant A-module, and $\underline{N}$ its associated Γ-graded $\underline{A}$-module. The following conditions are equivalent :

(a) (N, β) is horizontal.
(b) $\underline{N}$ is horizontal.

Proof of the claim. For every $g \in G$, let $\Delta(g) \subset \Gamma$ be the subgroup consisting of all $\chi \in \Gamma$ such that $\chi(g) = 1$; a direct inspection of the definitions shows that $J_{\Delta(g)}$ is the ideal I_g, as defined in (14.6.6), and (N, β) is horizontal if and only if $N_\chi/(N_\chi \cap I_g N) = 0$ for every $g \in G$ and every $\chi \notin \Delta(g)$. This already shows that (b)⇒(a); it also shows that condition (b) holds for the subgroups $\Delta(g)$, when (N, β) is horizontal. However, every subgroup of Γ can be written in the form $\Delta = \Delta(g_1) \cap \cdots \cap \Delta(g_n)$, for appropriate $g_1, \ldots, g_n \in G$, and then $J_{\Delta(g_1)} + \cdots + J_{\Delta(g_n)} \subset J_\Delta$, hence (b) follows for all subgroups. ◊

Assertion (i) now follows from claim 14.6.27 and proposition 14.6.13.

(ii): Let (M, β) be any object of $A[G]$-$\mathbf{Mod}_{\mathrm{hor.fl}}$, and denote by L the kernel of the counit η_M. Since M is a flat A-module and η_M is an epimorphism by (i), it follows that $i_g^* L$ is the kernel of $i_g^* \eta_M$, for every $g \in G$ (notation of (14.6.6)). Since the category $A[G]$-$\mathbf{Mod}_{\mathrm{hor}}$ is abelian, we deduce that the natural G-action on L is horizontal, and then (i) says that L is generated by L^G. But lemma 14.6.10(ii) easily implies that $L^G = 0$, so η_M is an isomorphism. Next, letting $M := A$ in lemma 14.6.10(i), we deduce easily that the natural morphism $A^G \to A$ is pure, hence M^G is a flat A^G-module, by lemma 14.6.21(i). Now the assertion follows from lemma 14.6.10(ii) and [28, Prop.3.4.3]. □

Corollary 14.6.28. *In the situation of theorem* 14.6.23*, the following holds :*

(i) *The functor* (14.6.24) *restricts to an equivalence from the subcategory of flat, almost finitely generated (resp. almost finitely presented) A^G-modules, onto the subcategory of G-equivariant, flat, horizontal and almost finitely generated (resp. almost finitely presented) $A[G]$-modules.*

(ii) *The functor* (14.6.9) *restricts to an equivalence :*

$$A^G\text{-}\mathsf{Alg}_{\text{fl}} \to A[G]\text{-}\mathsf{Alg}_{\text{hor.fl}}$$

and likewise for the subcategories of weakly étale (resp. étale, resp. étale and almost finitely presented) algebras.

Proof. (i) follows from theorem 14.6.23(ii), lemma 14.6.21(ii), and the fact that the morphism $A^G \to A$ is pure.

(ii): The assertion concerning A^G-Alg_{fl} is an immediate consequence of theorem 14.6.23. Next, let (B, β) be an object of $A[G]$-$\mathbf{w.\acute{E}t}$; by the foregoing, B descends to a flat A^G-algebra B^G with a G-equivariant isomorphism : $B \simeq A \otimes_{A^G} B^G$. However, on the one hand, B is – by assumption – a flat $B \otimes_A B$-algebra, and on the other hand, $B \otimes_A B$ underlies a flat, horizontal $A[G]$-algebra with $(B \otimes_A B)^G \simeq B^G \otimes_{A^G} B^G$; theorem 14.6.23 then says that B^G is a flat $B^G \otimes_{A^G} B^G$-algebra, whence the assertion for A^G-$\mathbf{w.\acute{E}t}$. Next, since an almost finitely generated module is almost projective if and only if it is flat and almost finitely presented ([75, Prop.2.4.18]), the assertion for A^G-$\mathbf{\acute{E}t}$ follows from the same assertion for A^G-$\mathbf{w.\acute{E}t}$ and lemma 14.6.21(ii). Likewise, the assertion for étale almost finitely presented A^G-algebras follows from the assertion for A^G-$\mathbf{\acute{E}t}$ and lemma 14.6.21(ii). □

Remark 14.6.29. In case the G-action on X is *free*, *i.e.* when $(\partial_0, \partial_1) : X \times G \to X \times_S X$ is a monomorphism, corollary 14.6.28 also follows from [75, Prop.4.5.25].

14.7. **Almost Witt vectors.** In this section we show that the construction of the ring of Witt vectors descends to almost rings, and we study some properties of the resulting functor of *almost Witt vectors*. We begin with some general observation concerning liftings of basic setups (in the sense of [75, §2.1.1]) along ring homomorphisms. These preliminaries shall then be applied to find natural basic setups on truncated rings of Witt vectors of arbitrary rings R, by lifting given setups on R along the 0-th ghost map.

Lemma 14.7.1. *Let A be a ring, $I \subset A$ a nilpotent ideal, $\pi : A \to A_0 := A/I$ the projection, and $\mathfrak{m}_0 \subset A_0$ an ideal such that $\mathfrak{m}_0 = \mathfrak{m}_0^2$. We have :*

(i) *There exists a unique ideal $\mathfrak{m} \subset A$ such that $\mathfrak{m}^2 = \mathfrak{m}$ and $\pi(\mathfrak{m}) = \mathfrak{m}_0$.*
(ii) *$\mathfrak{m}$ is the smallest of the ideals $J \subset A$ such that $\pi(J) = \mathfrak{m}_0$.*
(iii) *$\mathfrak{m}$ fulfills condition* $(\mathbf{B})$ *of* [75, §2.1.6] *if and only if the same holds for $\mathfrak{m}_0$.*

Proof. (i): Say that $I^N = 0$ for some $N \in \mathbb{N}$, and set $J := \pi^{-1}\mathfrak{m}_0$. We remark :

Claim 14.7.2. $J^{2N+1} = J^{2N+2}$.

Proof of the claim. Indeed, let $a_1, \dots, a_{2N+1} \in J$; we may find an integer $r \geq 0$ and elements $b_{1i}, c_{1i}, \dots, b_{ri}, c_{ri} \in \mathfrak{m}_0$ for every $i = 1, \dots, 2N+1$, such that $\pi(a_i) = \sum_{j=1}^r b_{ji}c_{ji}$. Lift each b_{ji} and each c_{ji} to elements $b'_{ji}, c'_{ji} \in J$; it follows that $x_i := a_i - \sum_{j=1} b'_{ji}c'_{ji} \in I$ for every $i = 1, \dots, 2N+1$. Thus :

$$\prod_{i=1}^{2N+1} a_i = \prod_{i=1}^{2N+1} \Big(x_i + \sum_{j=1}^{r} b'_{ji}c'_{ji} \Big) \in J^{2(N+1)} + I^N = J^{2N+2}$$

whence the claim. ◊

Set $\mathfrak{m} := J^{2N+1}$; claim 14.7.2 implies that $\mathfrak{m} = \mathfrak{m}^2$, and clearly $\pi(\mathfrak{m}) = \mathfrak{m}_0^{2N+1} = \mathfrak{m}$. Next, let $\mathfrak{m}' \subset A$ be any ideal such that $\mathfrak{m}'^2 = \mathfrak{m}'$ and $\pi(\mathfrak{m}') = \mathfrak{m}_0$; it follows that

$$\mathfrak{m}' = \mathfrak{m}'^{2N+1} \subset J^{2N+1} = (\mathfrak{m}' + I)^{2N+1} \subset \mathfrak{m}'^{N+1} = \mathfrak{m}'$$

whence $\mathfrak{m}' = \mathfrak{m}$.

(ii): Let $J \subset A$ be any ideal such that $\pi(J) = \mathfrak{m}_0$; it follows that

$$\mathfrak{m} = \mathfrak{m}^N \subset (J+I)^N \subset J + I^N = J.$$

(iii): It is clear that if $\mathfrak{m}$ fulfills condition $(\mathbf{B})$, then the same holds for $\mathfrak{m}_0$. Conversely, if condition $(\mathbf{B})$ holds for $\mathfrak{m}_0$, then for every integer $k > 1$ the system of elements $(x^k \mid x \in \mathfrak{m})$ generates an ideal $J \subset A$ such that $\pi(J) = \mathfrak{m}_0$ and $J \subset \mathfrak{m}$. By (ii), we must then have $J = \mathfrak{m}$, which shows that condition $(\mathbf{B})$ holds for $\mathfrak{m}$. □

Let us also point out the following result, which shall not be needed in the sequel :

Lemma 14.7.3. *Let* $(A, \mathfrak{m})$ *be a basic setup and* $f : B \to A$ *a ring homomorphism such that :*

(a) $p^k A = 0$ *for some integer* $k \in \mathbb{N}$.
(b) $\mathfrak{m}$ *fulfills condition* $(\mathbf{B})$ *of* [75, §2.1.6].
(c) $f \otimes_{\mathbb{Z}} \mathbb{F}_p$ *is invertible up to* Φ^n *for some* $n \in \mathbb{N}$, *in the sense of* [75, Def.3.5.8].

Then there exists a unique basic setup $(B, \mathfrak{n})$ *with* $\mathfrak{n}A = \mathfrak{m}$ *and with* $\mathfrak{n}$ *fulfilling condition* $(\mathbf{B})$.

Proof. Using lemma 14.7.1, we are easily reduced to the case where A and B are $\mathbb{F}_p$-algebras, and f is invertible up to Φ^n. The latter means that there exists a morphism $g : A \to B$ such that $g \circ f = \Phi^n_B$ and $f \circ g = \Phi^n_A$.

Suppose first that $A = B$ and $f = \Phi^n_A$; in this case, we claim that $\mathfrak{n} := \mathfrak{m}$ will do. Indeed, obviously $\mathfrak{n}^2 = \mathfrak{n}$, and assumption (b) says that $\Phi^n_A(\mathfrak{m})$ generates the ideal $\mathfrak{m}$; moreover, if $\mathfrak{n}' \subset A$ is another ideal fulfilling these conditions, we see that $x^p \in \mathfrak{m}$ for every $x \in \mathfrak{n}'$, whence $\mathfrak{n}' \subset \mathfrak{m}$, since $\mathfrak{n}'$ fulfills condition $(\mathbf{B})$, and conversely, $\mathfrak{m} = \Phi^n_A(\mathfrak{n}') \cdot A \subset \mathfrak{n}'$.

In the general case, we claim that $\mathfrak{n} := g(\mathfrak{m}) \cdot B$ will do. Indeed, clearly $\mathfrak{n}^2 = \mathfrak{n}$ and $f(\mathfrak{n}) \cdot A = \Phi^n_A(\mathfrak{m}) \cdot A = \mathfrak{m}$, due to assumption (b); it is also easily seen that $\mathfrak{n}$ fulfills condition $(\mathbf{B})$. Moreover, if $\mathfrak{n}' \subset B$ is another ideal fulfilling these conditions, it follows that

$$\Phi^n_B(\mathfrak{n}') \cdot B = g(f(\mathfrak{n}') \cdot A) \cdot B = g(\mathfrak{m}) \cdot B = \mathfrak{n}$$

whence $\mathfrak{n} = \mathfrak{n}'$, by the foregoing case. □

14.7.4. Consider now a cartesian diagram of rings

$$\begin{array}{ccc} A & \xrightarrow{p_1} & A_1 \\ {\scriptstyle p_2}\downarrow & & \downarrow{\scriptstyle \pi_1} \\ A_2 & \xrightarrow{\pi_2} & A_3 \end{array}$$

such that π_2 (and hence p_1) is surjective.

Proposition 14.7.5. (i) *In the situation of* (14.7.4)*, let* $\mathfrak{m}_1 \subset A_1$, $\mathfrak{m}_2 \subset A_2$ *be two ideals with*

$$\mathfrak{m}_1^2 = \mathfrak{m}_1 \qquad \mathfrak{m}_2^2 = \mathfrak{m}_2 \qquad \mathfrak{m}_1 A_3 = \mathfrak{m}_2 A_3.$$

Then there exists a unique ideal $\mathfrak{m} \subset A$ *such that*

$$\mathfrak{m}^2 = \mathfrak{m} \qquad \mathfrak{m}A_1 = \mathfrak{m}_1 \qquad \mathfrak{m}A_2 = \mathfrak{m}_2. \tag{14.7.6}$$

(ii) *Moreover,* $\mathfrak{m}$ *is the smallest of the ideals* $J \subset A$ *such that* $JA_1 = \mathfrak{m}_1$ *and* $JA_2 = \mathfrak{m}_2$.
(iii) *Furthermore,* $\mathfrak{m}$ *fulfills condition* $(\mathbf{B})$ *if and only if the same holds for both* $\mathfrak{m}_1$ *and* $\mathfrak{m}_2$.

Proof. (i): We shall regard A as a subset of $A_1 \times A_2$, in the natural fashion. Now, set $I := \mathfrak{m}_1 \times_{A_3} \mathfrak{m}_2$; then I is an ideal of A, and we remark :

Claim 14.7.7. $IA_1 = \mathfrak{m}_1$ and $IA_2 = \mathfrak{m}_2$.

Proof of the claim. Since π_2 is surjective, it is easily seen that p_1 restricts to a surjection $I \to \mathfrak{m}_1$. Next, let $a \in \mathfrak{m}_2$ be any element; we may find an integer $r \in \mathbb{N}$ and elements $x_1, \dots, x_r \in \mathfrak{m}_1$ and $y_1, \dots, y_r \in A_3$ such that $\pi_2(a) = \sum_{i=1}^r y_i \cdot \pi_1(x_i)$. For every $i = 1, \dots, r$, pick $b_i \in \mathfrak{m}_2$ and $c_i \in A_2$ such that $\pi_2(b_i) = \pi_1(x_i)$ and $\pi_2(c_i) = y_i$; then $(x_i, b_i) \in I$ for $i = 1, \dots, r$, and $a - \sum_{i=1}^r p_2(x_i, b_i) \cdot c_i \in \operatorname{Ker} \pi_2$. However, $0 \times (\mathfrak{m}_2 \cap \operatorname{Ker} \pi_2) \subset I$, whence $IA_2 = \mathfrak{m}_2$. ◊

Claim 14.7.8. Let $J \subset A$ be any ideal such that $JA_1 = \mathfrak{m}_1$ and $JA_2 = \mathfrak{m}_2$. Then

$$(A_1 \times_{A_3} \mathfrak{m}_2) \cdot (\mathfrak{m}_1 \times_{A_3} A_2) \subset J.$$

Proof of the claim. Indeed, let $(a_1, a_2), (b_1, b_2) \in A$ be two elements such that $a_2 \in \mathfrak{m}_2$ and $b_1 \in \mathfrak{m}_1$. Since p_1 is surjective, we may find $x \in A_2$ such that $(b_1, x) \in J$, so $\pi_2(x) = \pi_1(b_1)$, and we have

$$(a_1, a_2) \cdot (b_1, b_2) - (a_1, a_2) \cdot (b_1, x) = (a_1, a_2) \cdot (0, b_2 - x) = (0, a_2 \cdot y)$$

where $y := b_2 - x \in \operatorname{Ker} \pi_2$. We are thus reduced to checking that $(0, ab) \in J$ for every $a \in \mathfrak{m}_2$ and $b \in \operatorname{Ker} \pi_2$. However, say that $a = \sum_{i=1}^r p_2(c_i) d_i$ for elements $c_1, \dots, c_r \in J$ and $d_1, \dots, d_r \in A_2$; it follows that $(0, d_i b) \in A$ for every $i = 1, \dots, r$, and $\sum_{i=1}^r c_i \cdot (0, d_i b) = (0, ab)$, whence the contention. ◊

From claim 14.7.7 we deduce that $I^3 A_1 = \mathfrak{m}_1^3 = \mathfrak{m}_1$, and likewise, $I^3 A_2 = \mathfrak{m}_2$; from claim 14.7.8, it then follows that $(\mathfrak{m}_1 \times_{A_3} A_2) \cdot (A_1 \times_{A_3} \mathfrak{m}_2) \subset I^3$. Especially, $I^2 \subset I^3$, so that $I^3 = I^2$, and therefore the ideal $\mathfrak{m} := I^2$ fulfills conditions (14.7.6).

(ii): For every ideal J as in claim 14.7.8 we also get : $\mathfrak{m} \subset J \subset \mathfrak{m}_1 \times_{A_3} \mathfrak{m}_2$; if we have as well $J^2 = J$, it follows that $J \subset \mathfrak{m}$, *i.e.* $J = \mathfrak{m}$, as required.

(iii): Due to [75, Claim 2.19], it suffices to show, for every prime p, that the following conditions are equivalent :

(a) The A-module $\mathfrak{m}/p\mathfrak{m}$ is generated by the p-th powers of its elements
(b) For $i = 1, 2$, the A_i-module $\mathfrak{m}_i/p\mathfrak{m}_i$ is generated by the p-th powers of its elements.

However, it is easily seen that (a)⇒(b). For the converse, consider the ideal $J \subset A$ generated by the system $\{x^p \mid x \in \mathfrak{m}\} \cup \{px \mid x \in \mathfrak{m}\}$; since p_1 is surjective, (b) implies that $JA_1 = \mathfrak{m}_1$. Likewise, $JA_2 = \mathfrak{m}_2$: indeed, since $\mathfrak{m}_2/p\mathfrak{m}_2$ is generated by the p-th powers of its elements, it suffices to check that for every $a \in \mathfrak{m}_2$ we have $a^p \in JA_2$. But say that $a = \sum_{j=1}^n x_i a_i$ for some $x_1, \dots, x_n \in \mathfrak{m}$ and $a_1, \dots, a_n \in A_2$; then $a^p = \sum_{i=1} x_i^p a_i^p + py$ for some $y \in \mathfrak{m}_2$, whence the contention. In view of (ii), we conclude that $J = \mathfrak{m}$, whence (a). □

14.7.9. Henceforth, we fix a prime number p, and the notation $W(A)$ and $W_{n+1}(A)$ will refer to the ring of *p-typical* Witt vector of section (9.3), for every ring A and every integer $n \in \mathbb{N}$. Notice that the functors W and W_{n+1} introduced in section 9.3 are defined on the category of topological rings; however, in this section we shall be interested only in the underlying rings, and the topologies will play no role; if one wishes, one may assume that all the rings in this section carry the discrete topology. We consider first the case where p is nilpotent on A :

Corollary 14.7.10. *Let A be any ring such that $p^k A = 0$ for some $k \in \mathbb{N}$, and $\mathfrak{m} \subset A$ an ideal with $\mathfrak{m}^2 = \mathfrak{m}$. For every $n \in \mathbb{N}$ we have :*

(i) *There exists a unique ideal $\mathfrak{n}_{n+1} \subset W_{n+1}A$ such that*

$$\mathfrak{n}_{n+1}^2 = \mathfrak{n}_{n+1} \qquad \textit{and} \qquad \overline{\boldsymbol{\omega}}_0(\mathfrak{n}_{n+1}) = \mathfrak{m}.$$

(ii) *The image of $\mathfrak{n}_{n+2}$ under the projection $W_{n+2}A \to W_{n+1}A$ agrees with $\mathfrak{n}_{n+1}$.*

Proof. (See remark 9.3.28(i) for the definition of the ring homomorphism $\overline{\boldsymbol{\omega}}_0$.)

(i) follows immediately from corollary 9.3.32 and lemma 14.7.1.

(ii) follows immediately from (i). □

For a general ring A, we may state :

Proposition 14.7.11. *Let A be a ring, $n \in \mathbb{N}$ an integer, $\mathfrak{m} \subset A$ an ideal with $\mathfrak{m} = \mathfrak{m}^2$ and fulfilling condition $(\mathbf{B})$ of* [75, §2.1.6]. *Set $\mathfrak{n}_{n+1} = \{\underline{a} \in W_{n+1}A \mid a_0, \dots, a_n \in \mathfrak{m}\}$. We have :*

(i) *$\mathfrak{n}_{n+1}$ is an ideal of $W_{n+1}A$ with $\mathfrak{n}_{n+1}^2 = \mathfrak{n}_{n+1}$ and fulfilling condition $(\mathbf{B})$.*
(ii) *Moreover, $\mathfrak{n}_{n+1}$ is the unique ideal with $\mathfrak{n}_{n+1}^2 = \mathfrak{n}_{n+1}$ and such that*

$$\overline{\boldsymbol{\omega}}_i(\mathfrak{n}_{n+1}) \cdot A = \mathfrak{m} \qquad \text{for } i = 0, \dots, n. \tag{14.7.12}$$

Proof. We consider the ring homomorphism

$$\pi_n : W_{n+1}A \to A^{n+1}$$

of proposition 9.3.30(i). By proposition 9.3.30(i), the kernel of the surjection $W_{n+1}A \to R := \operatorname{Im} \pi_n$ is nilpotent, hence every basic setup $(R, \mathfrak{m}_R)$ lifts uniquely to a basic setup $(W_{n+1}A, \widetilde{\mathfrak{m}})$, and $\widetilde{\mathfrak{m}}$ satisfies condition $(\mathbf{B})$ if and only if the same holds for $\mathfrak{m}_R$ (lemma 14.7.1(i,iii)). Moreover, by proposition 9.3.30(ii), the subring R of A^{n+1} contains the ideal $p^{n+1}A^{n+1}$, and lies in the larger subring $S \subset A^{n+1}$ consisting of all sequences $(a_0, \dots, a_n)$ such that $a_i \equiv a_0^{p^i}$ $(\mathrm{mod}\ pA)$ for $i = 0, \dots, n$; there follows a cartesian diagram of rings

$$\begin{array}{ccc} R & \longrightarrow & R_0 := R/p^{n+1}A^{n+1} \\ \downarrow & & \downarrow \\ S & \longrightarrow & S_0 := S/p^{n+1}A^{n+1} \end{array} \tag{14.7.13}$$

whose horizontal arrows are surjections. By proposition 14.7.5(i,iii), the datum of $(R, \mathfrak{m}_R)$ is then equivalent to that of a pair of basic setups $(R_0, \mathfrak{m}_{R_0})$ and $(S, \mathfrak{m}_S)$ with $\mathfrak{m}_{R_0}S_0 = \mathfrak{m}_S S_0$. Also, $\mathfrak{m}_R$ fulfills condition $(\mathbf{B})$ if and only if the same holds for both $\mathfrak{m}_{R_0}$ and $\mathfrak{m}_S$. Next, set $A_0 := A/pA$, and notice that we have a cartesian diagram of rings

$$\begin{array}{ccc} S & \longrightarrow & A^{n+1} \\ {\scriptstyle\psi}\downarrow & & \downarrow \\ A_0 & \xrightarrow{\ \varphi\ } & A_0^{n+1} \end{array} \tag{14.7.14}$$

where φ is given by the rule : $x \mapsto (x, x^p, \dots, x^{p^n})$ for every $x \in A_0$; the top horizontal arrow is the inclusion map, and the right vertical arrow is the projection. Moreover, ψ is a surjection. Hence – again by virtue of proposition 14.7.5(i) – the datum of $(S, \mathfrak{m}_S)$ is equivalent to that of a system of basic setups $(A, \mathfrak{m}_i)$ such that

$$\mathfrak{m}_i A_0 = \Phi^i_{A_0}(\mathfrak{m}_0 A_0) \cdot A_0 \qquad \text{for } i = 1, \dots, n$$

where $\Phi_{A_0} : A_0 \to A_0$ is the Frobenius endomorphism. Especially, if $(A, \mathfrak{m})$ is a basic setup on A such that $\mathfrak{m}$ fulfills condition $(\mathbf{B})$, then we can take $\mathfrak{m}_i := \mathfrak{m}$ for every $i = 0, \dots, n$, and in this way we obtain a natural basic setup $(S, \mathfrak{m}_S)$ on S with $\mathfrak{m}_S A^{n+1} = \mathfrak{m}^{n+1}$, and such that condition $(\mathbf{B})$ still holds for $\mathfrak{m}_S$. Furthermore, the restriction of ψ to R factors through a surjection $R_0 \to A_0$ whose kernel is also nilpotent, so that the basic setup $(A_0, \mathfrak{m}A_0)$ lifts uniquely to a basic setup $(R_0, \mathfrak{m}_{R_0})$ with $\mathfrak{m}_{R_0}$ fulfilling condition $(\mathbf{B})$ (lemma 14.7.1(i)). Lastly, both ideals $\mathfrak{m}_{R_0}S_0$ and $\mathfrak{m}_S S_0$ lift $\mathfrak{m}A_0$ along the map $S_0 \to A_0$ induced by ψ, whose kernel is also nipotent; by invoking again 14.7.1(i), we deduce that $\mathfrak{m}_{R_0}S_0 = \mathfrak{m}_S S_0$. Summing up, we have finally associated with the basic setup $(A, \mathfrak{m})$ a natural basic setup $(W_{n+1}A, \widetilde{\mathfrak{m}})$ which is the unique one with property (14.7.12), and with $\widetilde{\mathfrak{m}}$ fulfilling condition $(\mathbf{B})$. To conclude the proof of both (i) and (ii), it then suffices to check that $\widetilde{\mathfrak{m}} = \mathfrak{n}_{n+1}$. However, it is clear that $\mathfrak{n}_{n+1}$ is an ideal of $W_{n+1}A$ enjoying property (14.7.12), since $\overline{\boldsymbol{\omega}}_i(\mathfrak{n}_{n+1})$ is contained in $\mathfrak{m}$ and contains the system $(x^{p^i} \mid x \in \mathfrak{m})$, which generates $\mathfrak{m}$, under condition $(\mathbf{B})$. It remains to check that $\mathfrak{n}_{n+1} = \mathfrak{n}_{n+1}^2$. Now, let us define a descending filtration by subideals of $\mathfrak{n}_{n+1}$, by setting $\mathrm{Fil}_i\mathfrak{n}_{n+1} := \mathfrak{n}_{n+1} \cap \overline{V}_iA$, where $\overline{V}_iA := V_iA/V_{n+1}A$ for every $i = 0, \dots, n$. Let also $\mathrm{gr}_\bullet\mathfrak{n}_{n+1}$ be the associated graded W_{n+1}-module. We are then further reduced to showing that $\mathfrak{n}_{n+1} \cdot \mathrm{gr}_i\mathfrak{n}_{n+1} = \mathrm{gr}_i\mathfrak{n}_{n+1}$ for $i = 0, \dots, n$. However, we have a natural identification of $W_{n+1}A$-modules : $\mathrm{gr}_i\mathfrak{n}_{n+1} \xrightarrow{\sim} \mathfrak{m}$, for the $W_{n+1}A$-module structure on $\mathfrak{m}$ induced by restriction of scalars along the ghost map $\overline{\boldsymbol{\omega}}_i : W_{n+1}A \to A$ (claim 9.3.31). Since $\mathfrak{m}^2 = \mathfrak{m}$, we then come down to the assertion that $\overline{\boldsymbol{\omega}}_i(\mathfrak{n}_{n+1}) \cdot A = \mathfrak{m}$, which was already remarked. □

14.7.15. Let $(A, \mathfrak{m})$ be a basic setup such that either $p^kA = 0$ for some integer $k \in \mathbb{N}$, or else such that $\mathfrak{m}$ fulfills condition $(\mathbf{B})$. For every $n \in \mathbb{N}$ let $\mathfrak{n}_{n+1} \subset W_{n+1}A$ be the ideal provided by corollary 14.7.10(i), or respectively by proposition 14.7.11; especially, $(W_{n+1}A, \mathfrak{n}_{n+1})$ is also a basic setup. Let also $f : B \to C$ be a morphism of A-algebras such that $f^a : B^a \to C^a$ is an isomorphism of $(A, \mathfrak{m})^a$-algebras. Then we claim that f induces an isomorphism of $(W_{n+1}A, \mathfrak{n}_{n+1})^a$-algebras

$$(W_{n+1}f)^a : (W_{n+1}B)^a \xrightarrow{\sim} (W_{n+1}C)^a \qquad \text{for every } n \in \mathbb{N}.$$

Indeed, arguing by induction on $n \in \mathbb{N}$, we are easily reduced to checking that f induces an isomorphism of $(W_{n+1}A)^a$-modules $(V_nB/V_{n+1}B)^a \xrightarrow{\sim} (V_nC/V_{n+1}C)^a$ for every $n \in \mathbb{N}$. However, in light of claim 9.3.31 we have a commutative diagram of $W_{n+1}A$-modules

$$\begin{array}{ccc} B & \longrightarrow & V_nB/V_{n+1}B \\ {\scriptstyle f}\downarrow & & \downarrow \\ C & \longrightarrow & V_nC/V_{n+1}C \end{array}$$

whose horizontal arrows are isomorphisms of $W_{n+1}A$-modules, and where the $W_{n+1}A$-module structures on B and C are induced by the n-th ghost maps. By assumption, $\mathfrak{m}$ annihilates $\mathrm{Ker}\, f$ and $\mathrm{Coker}\, f$; since $\overline{\boldsymbol{\omega}}_n(\mathfrak{n}_{n+1}) \subset \mathfrak{m}$, it follows that $\mathfrak{n}_{n+1}$ annihilates these $W_{n+1}A$-modules as well, whence the contention. Thus, we obtain a well defined functor

$$W_{n+1} : (A, \mathfrak{m})^a\text{-}\mathsf{Alg} \to (W_{n+1}A, \mathfrak{n}_{n+1})^a\text{-}\mathsf{Alg} \qquad B^a \mapsto (W_{n+1}B)^a \qquad \text{for every } n \in \mathbb{N}.$$

Moreover, for every $k \leq n$, the ghost component $\overline{\boldsymbol{\omega}}_k : W_nB \to B$ induces pull-back functors

$$\overline{\boldsymbol{\omega}}_k^* : B^a\text{-}\mathsf{Alg} \to W_{n+1}B^a\text{-}\mathsf{Alg} \qquad \overline{\boldsymbol{\omega}}_k^* : B^a\text{-}\mathbf{Mod} \to W_{n+1}B^a\text{-}\mathbf{Mod}.$$

Namely, for every B-algebra C we let $\overline{\boldsymbol{\omega}}_k^*C$ be the $W_{n+1}B$-algebra whose underlying ring is C, and whose structure morphism is the composition of $\overline{\boldsymbol{\omega}}_k$ and the structure morphism $B \to C$ of C. Since $\overline{\boldsymbol{\omega}}_k(\mathfrak{n}_{n+1}) \subset \mathfrak{m}$, it is clear that this functor on B-algebras descends to a well defined functor $\overline{\boldsymbol{\omega}}_k^*$ on B^a-algebras, as stated. Likewise one argues to define the functor $\overline{\boldsymbol{\omega}}_k^*$ on B^a-modules. Furthermore, we have a well defined ideal

$$\overline{V}_kB^a := (V_kB/V_{n+1}B)^a \subset W_{n+1}B^a \qquad \text{for every } k = 0, \dots, n$$

and claim 9.3.31 yields a natural isomorphism of $W_{n+1}B^a$-modules :

$$\overline{V}_kB^a/\overline{V}_{k+1}B^a \xrightarrow{\sim} \overline{\boldsymbol{\omega}}_k^*B^a \qquad \text{for every } k = 0, \dots, n. \tag{14.7.16}$$

14.7.17. In the situation of (14.7.15), suppose that $\mathfrak{m}$ fulfills condition $(\mathbf{B})$, and let B be any A-algebra; denote by

$$B^a_{!!} \xrightarrow{\varepsilon_B} B \xrightarrow{\eta_B} B^a_* \qquad \text{and} \qquad (W_{n+1}B)^a_{!!} \xrightarrow{\varepsilon_{W_{n+1}B}} W_{n+1}B \xrightarrow{\eta_{W_{n+1}B}} (W_{n+1}B)^a_*$$

the units and counits of adjunction. We have :

Proposition 14.7.18. *In the situation of* (14.7.17)*, the following holds :*

(i) *There exist isomorphisms of $W_{n+1}A$-algebras*

$$\omega : W_{n+1}(B^a_*) \xrightarrow{\sim} (W_{n+1}B)^a_* \qquad \textit{and} \qquad \tau : W_{n+1}(B^a_{!!}) \xrightarrow{\sim} (W_{n+1}B)^a_{!!}$$

such that $\omega \circ W_{n+1}(\eta_B) = \eta_{W_{n+1}(B)}$ *and* $\varepsilon_{W_{n+1}(B)} \circ \tau = W_{n+1}(\varepsilon_B)$.

(ii) *Moreover, we have a natural isomorphism of non-unital rings (see remark* 9.3.16*)*

$$\widetilde{\mathfrak{n}}_{n+1} := \mathfrak{n}_{n+1} \otimes_{W_{n+1}A} \mathfrak{n}_{n+1} \xrightarrow{\sim} W_{n+1}(\widetilde{\mathfrak{m}}).$$

Proof. (i): We consider the commutative diagrams

$$\begin{array}{ccc} W_{n+1}B & \xrightarrow{W_{n+1}(\eta_B)} & W_{n+1}(B^a_*) \\ {\scriptstyle \eta_{W_{n+1}B}}\downarrow & & \downarrow{\scriptstyle \eta_{W_{n+1}(B^a_*)}} \\ (W_{n+1}B)^a_* & \xrightarrow{(W_{n+1}\eta_B)^a_*} & W_{n+1}(B^a_*)^a_* \end{array} \qquad \begin{array}{ccc} W_{n+1}(B^a_{!!})^a_{!!} & \xrightarrow{(W_{n+1}\varepsilon_B)^a_{!!}} & W_{n+1}(B)^a_{!!} \\ {\scriptstyle \varepsilon_{W_{n+1}(B^a_{!!})}}\downarrow & & \downarrow{\scriptstyle \varepsilon_{W_{n+1}(B)}} \\ W_{n+1}(B^a_{!!}) & \xrightarrow{W_{n+1}(\varepsilon_B)} & W_{n+1}(B) \end{array}$$

and notice that $(W_{n+1}\eta_B)^a_*$ and $(W_{n+1}\varepsilon_B)^a_{!!}$ are isomorphisms, by the discussion of (14.7.15). Hence, it suffices to show that $\eta_{W_{n+1}(B^a_*)}$ and $\varepsilon_{W_{n+1}(B^a_{!!})}$ are isomorphisms, which follows from :

Claim 14.7.19. If η_B (resp. ε_B) is an isomorphism, the same holds for $\eta_{W_{n+1}B}$ (resp. $\varepsilon_{W_{n+1}B}$).

Proof of the claim. Let $\mathrm{gr}_\bullet(W_{n+1}B)$ be the graded ring associated with the filtration $(\overline{V}_k B \mid k = 0, \dots, n)$ of $W_{n+1}B$; consider also the filtration $((\overline{V}_k B^a)_* \mid k = 0, \dots, n)$ of $(W_{n+1}B)^a_*$, and let $\mathrm{gr}_\bullet(W_{n+1}B)^a_*$ be the associated graded ring. We get a commutative diagram

$$\begin{array}{ccc} & \mathrm{gr}_i(W_{n+1}B) & \\ {\scriptstyle \mathrm{gr}_i(\eta_{W_{n+1}B})}\swarrow & & \searrow{\scriptstyle \eta_{\mathrm{gr}_i(W_{n+1}B)}} \\ \mathrm{gr}_i(W_{n+1}B)^a_* & \longrightarrow & (\mathrm{gr}_i W_{n+1}B)^a_* \end{array}$$

whose bottom horizontal arrow is injective, since the functor $(-)^a_*$ is left exact. Here $\eta_{\mathrm{gr}_i(W_{n+1}B)}$ is again the unit of adjunction, which, by virtue of (14.7.16), is naturally identified with the unit of adjunction

$$\eta_{\overline{\boldsymbol{\omega}}^*_i B} : \overline{\boldsymbol{\omega}}^*_i B \to (\overline{\boldsymbol{\omega}}^*_i B)^a_* \qquad \text{for every } i = 0, \dots, n.$$

Let now $\mathscr{B}$ be the category of basic setups, and $\mathscr{B}$-$\mathsf{Alg} \to \mathscr{B}$ (resp. $\mathscr{B}^a$-$\mathsf{Alg} \to \mathscr{B}$) the fibred and cofibred category of $\mathscr{B}$-algebras (resp. of almost $\mathscr{B}$-algebras), as in [75, §3.5]. The localization $\mathscr{B}$-$\mathsf{Alg} \to \mathscr{B}^a$-$\mathsf{Alg}$ admits a right adjoint

$$(-)_* : \mathscr{B}^a\text{-}\mathsf{Alg} \to \mathscr{B}\text{-}\mathsf{Alg} \qquad ((V, \mathfrak{m}), R) \mapsto ((V, \mathfrak{m}), R_*)$$

which is a $\mathscr{B}$-cartesian functor ([75, §3.5.4]). By (14.7.12), we have the morphism $\overline{\boldsymbol{\omega}}_i : (W_{n+1}A, \mathfrak{n}_{n+1}) \to (A, \mathfrak{m})$ in $\mathscr{B}$, whence a commutative diagram in $\mathscr{B}$-Alg :

$$\begin{array}{ccc} ((W_{n+1}A, \mathfrak{n}_{n+1}), \overline{\boldsymbol{\omega}}^*_i B) & \longrightarrow & ((A, \mathfrak{m}), B) \\ {\scriptstyle \eta_{\overline{\boldsymbol{\omega}}^*_i B}}\downarrow & & \downarrow{\scriptstyle \eta_B} \\ ((W_{n+1}A, \mathfrak{n}_{n+1}), (\overline{\boldsymbol{\omega}}^*_i B)^a_*) & \longrightarrow & ((A, \mathfrak{m}), B^a_*) \end{array}$$

whose top horizontal arrow is given by the identity map of $\overline{\boldsymbol{\omega}}^*_i B$, and is therefore a cartesian morphism of $\mathscr{B}$-Alg. Then also the bottom vertical arrow is a cartesian morphism, since $(-)_*$ is a cartesian functor. We conclude that $\eta_{\mathrm{gr}_i(W_{n+1}B)}$ is an isomorphism, under our assumptions. Then the same holds for $\mathrm{gr}_i(\eta_{W_{n+1}B})$, for every $i = 0, \dots, n$, whence the assertion for $\eta_{W_{n+1}B}$.

To show the assertion concerning $\varepsilon_{W_{n+1}B}$, we argue by induction on $n \in \mathbb{N}$; the case $n = 0$ is trivial. Let then $n > 0$, and suppose that the assertion is already known for $\varepsilon_{W_n B}$; recall that for every $i \in \mathbb{N}$, the ring $(W_{i+1}B)^a_{!!}$ is the cokernel of a map of $W_{i+1}A$-modules

$$\delta_i : \widetilde{\mathfrak{n}}_{i+1} \to W_{i+1}A \oplus (\widetilde{\mathfrak{n}}_{i+1} \otimes_{W_{i+1}A} W_{i+1}B) \qquad x_\bullet \otimes y_\bullet \mapsto (x_\bullet \cdot y_\bullet, x_\bullet \otimes y_\bullet \otimes 1).$$

We consider the commutative ladder with right exact rows :

$$\begin{array}{ccccccc} \widetilde{\mathfrak{n}}_{n+1} & \xrightarrow{\delta_n} & W_{n+1}A \oplus (\widetilde{\mathfrak{n}}_{n+1} \otimes_{W_{n+1}A} W_{n+1}B) & \longrightarrow & (W_{n+1}B)^a_{!!} & \longrightarrow & 0 \\ \downarrow{\scriptstyle\alpha} & & \downarrow{\scriptstyle\beta} & & \downarrow{\scriptstyle\gamma} & & \\ \widetilde{\mathfrak{n}}_n & \xrightarrow{\delta_{n-1}} & W_nA \oplus (\widetilde{\mathfrak{n}}_n \otimes_{W_nA} W_nB) & \longrightarrow & (W_nB)^a_{!!} & \longrightarrow & 0 \end{array}$$

whose vertical arrows are induced by the projections $\pi^A_n : W_{n+1}A \to W_nA$ and $\pi^B_n : W_{n+1}B \to W_nB$ (notice that the almost structure used to compute $(W_{n+1}B)^a_{!!}$ is the one relative to the basic setup $(W_{n+1}A, \mathfrak{n}_{n+1})$, whereas for $(W_nB)^a_{!!}$ we use the almost structure relative to the basic setup $(W_nA, \mathfrak{n}_n)$). Since $\pi^A_n(\mathfrak{n}_{n+1}) = \mathfrak{n}_n$, by [75, Rem.2.1.4(ii)] we have a natural isomorphism

$$\widetilde{\mathfrak{n}}_{n+1} \otimes_{W_{n+1}A} W_nA \xrightarrow{\sim} \widetilde{\mathfrak{n}}_n \qquad x_\bullet \otimes y_\bullet \otimes a_\bullet \mapsto a_\bullet \cdot \pi^A_n(x_\bullet) \otimes \pi^A_n(y_\bullet)$$

which identifies α with $\widetilde{\mathfrak{n}}_{n+1} \otimes_{W_{n+1}A} \pi^A_n$, and β with $\pi^A_n \oplus (\widetilde{\mathfrak{n}}_{n+1} \otimes_{W_{n+1}A} \pi^B_n)$. Taking claim 9.3.31 into account, we deduce natural $W_{n+1}A$-linear surjections :

$$(14.7.20) \qquad \widetilde{\mathfrak{n}}_{n+1} \otimes_{W_{n+1}A} \overline{\boldsymbol{\omega}}^*_n(A) \to \operatorname{Ker}\alpha \qquad \overline{\boldsymbol{\omega}}^*_n(A) \oplus (\widetilde{\mathfrak{n}}_{n+1} \otimes_{W_{n+1}A} \overline{\boldsymbol{\omega}}^*_n(B)) \to \operatorname{Ker}\beta.$$

Then, in light of (14.7.12) and [75, Rem.2.1.4(ii)], we have as well the natural isomorphism

$$\widetilde{\mathfrak{n}}_{n+1} \otimes_{W_{n+1}A} \overline{\boldsymbol{\omega}}^*_n(A) \xrightarrow{\sim} \widetilde{\mathfrak{m}} \qquad x_\bullet \otimes y_\bullet \otimes a \mapsto a \cdot \overline{\boldsymbol{\omega}}_n(x_\bullet) \otimes \overline{\boldsymbol{\omega}}_n(y_\bullet)$$

which identifies (14.7.20) with $W_{n+1}A$-linear surjections :

$$(14.7.21) \qquad \overline{\boldsymbol{\omega}}^*_n(\widetilde{\mathfrak{m}}) \to \operatorname{Ker}\alpha \qquad \overline{\boldsymbol{\omega}}^*_n(A \oplus (\widetilde{\mathfrak{m}} \otimes_A B)) \to \operatorname{Ker}\beta.$$

By a direct inspection, we then get a commutative diagram :

$$\begin{array}{ccc} \overline{\boldsymbol{\omega}}^*_n(\widetilde{\mathfrak{m}}) & \xrightarrow{\overline{\boldsymbol{\omega}}^*_n(\delta_0)} & \overline{\boldsymbol{\omega}}^*_n(A \oplus (\widetilde{\mathfrak{m}} \otimes_A B)) \\ \downarrow & & \downarrow \\ \operatorname{Ker}\alpha & \xrightarrow{\delta'_n} & \operatorname{Ker}\beta \end{array}$$

whose vertical arrows are the surjections (14.7.21), and δ'_n is the restriction of δ_n. Since α and β are surjective, the induced map $\operatorname{Coker}\delta'_n \to \operatorname{Ker}\gamma$ is bijective, by the snake lemma, and γ is surjective, so finally we get a right exact sequence of $W_{n+1}A$-modules :

$$\overline{\boldsymbol{\omega}}^*_n(B^a_{!!}) \xrightarrow{\rho} (W_{n+1}B)^a_{!!} \xrightarrow{\gamma} (W_nB)^a_{!!} \to 0.$$

We consider then the diagram of $W_{n+1}A$-modules :

$$\begin{array}{ccccccccc} & & \overline{\boldsymbol{\omega}}^*_n(B^a_{!!}) & \xrightarrow{\rho} & (W_{n+1}B)^a_{!!} & \xrightarrow{\gamma} & (W_nB)^a_{!!} & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle\overline{\boldsymbol{\omega}}^*_n\varepsilon_B} & & \downarrow{\scriptstyle\varepsilon_{W_{n+1}B}} & & \downarrow{\scriptstyle\varepsilon_{W_nB}} & & \\ 0 & \longrightarrow & \overline{\boldsymbol{\omega}}^*_nB & \xrightarrow{\rho'} & W_{n+1}B & \xrightarrow{\gamma'} & W_nB & \longrightarrow & 0 \end{array}$$

where γ' is the projection, and ρ' is the natural identification of $\overline{\boldsymbol{\omega}}^*_nB$ with $\operatorname{Ker}\gamma'$ given by claim 9.3.31. Thus, the bottom horizontal sequence is exact, and by inductive assumption the first and third vertical arrows are bijective; therefore, in order to conclude the proof, it will suffice to check the diagram commutes. The commutativity of the right square subdiagram is clear. To see the commutativity of the left square subdiagram, let $w \in \overline{\boldsymbol{\omega}}^*_n(B^a_{!!})$ be any element; hence w is the class $[a, z]$ of a pair $(a, z) \in A \oplus (\widetilde{\mathfrak{m}} \otimes_A B)$, and we may assume that $z = x \otimes y \otimes b$ for some $x, y \in \mathfrak{m}$ and $b \in B$. Then, by inspecting the constructions, we see that $w' := \rho(w)$ is the class $[(0, \dots, 0, a), (0, \dots, 0, xyb)]$ of the corresponding pair in $W_{n+1}A \oplus (\widetilde{\mathfrak{n}}_{n+1} \otimes_{W_{n+1}A} W_{n+1}B)$. On the other hand, $\overline{\boldsymbol{\omega}}^*_n\varepsilon_B(w) = a + xyb$; then, again by claim 9.3.31, we deduce that $\varepsilon_{W_{n+1}B}(w') = (0, \dots, 0, a + xyb) = \rho'(a + xyb)$, as required. ◊

(ii): For every $n \in \mathbb{N}$, we have a natural map of non-unital $W_{n+1}A$-algebras :

$$\mu_n : W_{n+1}(\mathfrak{m}) \otimes_{W_{n+1}A} W_{n+1}(\mathfrak{m}) \to W_{n+1}(\widetilde{\mathfrak{m}}) \qquad a_\bullet \otimes b_\bullet \mapsto (P_i(a_\bullet \otimes 1, 1 \otimes b_\bullet) \mid i = 0, \dots, n)$$

for the non-unital ring structure of $W_{n+1}(\mathfrak{m}) = \mathfrak{n}_{n+1}$ and $W_{n+1}(\widetilde{\mathfrak{m}})$ induced by those of $\mathfrak{m}$ and respectively $\widetilde{\mathfrak{m}}$ (remark 9.3.16). We show by induction on $n \in \mathbb{N}$, that μ_n is an isomorphism; the assertion is trivial for $n = 0$, since $\mu_0 = \mathbf{1}_{\widetilde{\mathfrak{m}}}$. Thus, let $n > 0$, and suppose that the assertion is already known for $n - 1$; we consider the commutative diagram of $W_{n+1}A$-modules :

$$\begin{array}{ccc} \mathfrak{n}_{n+1} \otimes_{W_{n+1}A} \mathfrak{n}_{n+1} & \xrightarrow{\mu_n} & W_{n+1}(\widetilde{\mathfrak{m}}) \\ \downarrow{\scriptstyle \alpha} & & \downarrow{\scriptstyle \beta} \\ \mathfrak{n}_n \otimes_{W_n A} \mathfrak{n}_n & \xrightarrow{\mu_{n-1}} & W_n(\widetilde{\mathfrak{m}}) \end{array}$$

whose left vertical arrows is induced by the projection $W_{n+1}(\mathfrak{m}) \to W_n(\mathfrak{m})$, and whose right vertical arrow is likewise the natural projection. Claim 9.3.31 yields a natural isomorphism of $W_{n+1}A$-modules :

$$(14.7.22) \qquad \overline{\boldsymbol{\omega}}_n^*(\widetilde{\mathfrak{m}}) \xrightarrow{\sim} \operatorname{Ker} \beta.$$

Claim 14.7.23. We have a commutative diagram of $W_{n+1}A$-modules :

$$\begin{array}{ccc} \overline{\boldsymbol{\omega}}_n^*(\widetilde{\mathfrak{m}}) & \xrightarrow{\overline{\boldsymbol{\omega}}_n^*(\mu_0)} & \overline{\boldsymbol{\omega}}_n^*(\widetilde{\mathfrak{m}}) \\ \downarrow & & \downarrow \\ \operatorname{Ker} \alpha & \longrightarrow & \operatorname{Ker} \beta \end{array}$$

whose bottom horizontal arrow is the restriction of μ_n, and whose right (resp. left) vertical arrow is (14.7.22) (resp. is (14.7.21)).

Proof of the claim. By construction, the left vertical arrow is characterized as the map such that $a \cdot \overline{\boldsymbol{\omega}}_n(x_\bullet) \otimes \overline{\boldsymbol{\omega}}_n(y_\bullet) \mapsto (0, \dots, 0, a) \cdot (x_\bullet \otimes y_\bullet)$ for every $a \in A$ and every $x_\bullet, y_\bullet \in \mathfrak{n}_{n+1}$. On the other hand, the right vertical arrow is the map such that $x \otimes y \mapsto (0, \dots, 0, x \otimes y)$ for every $x, y \in \mathfrak{m}$. Hence, we need to check the identity :

$$\mu_n((0, \dots, 0, a) \cdot (x_\bullet \otimes y_\bullet)) = (0, \dots, 0, a \cdot \overline{\boldsymbol{\omega}}_n(x_\bullet) \otimes \overline{\boldsymbol{\omega}}_n(y_\bullet))$$

for every $a \in A$ and every $x_\bullet, y_\bullet \in \mathfrak{n}_{n+1}$. To this aim, endow $R := A \oplus \mathfrak{m}$ with its natural A-algebra structure as in remark 9.3.16(iii), and recall that μ_n is the restriction of the map of unital $W_{n+1}A$-algebras

$$W_{n+1}R \otimes_{W_{n+1}A} W_{n+1}R \to W_{n+1}(R \otimes_A R) \qquad x_\bullet \otimes y_\bullet \mapsto (x_\bullet \otimes 1) \cdot (1 \otimes y_\bullet).$$

Thus, we are reduced to checking that

$$((V_R^n(\tau_R(a)) \cdot x_\bullet) \otimes 1) \cdot (1 \otimes y_\bullet) = V_{R\otimes_A R}^n(\tau_{R\otimes_A R}(a \cdot \overline{\boldsymbol{\omega}}_n(x_\bullet) \otimes \overline{\boldsymbol{\omega}}_n(y_\bullet)))$$

for every $a \in A$ and every $x_\bullet, y_\bullet \in W_{n+1}R$, where V_R and τ_R denote respectively the Verschiebung and the Teichmüller maps, and likewise for $V_{R\otimes_A R}$ and $\tau_{R\otimes_A R}$ (see (9.3.18)). Let also F_R be the Frobenius map; using proposition 9.3.22(ii) we compute :

$$\begin{aligned} ((V_R^n(\tau_R(a)) \cdot x_\bullet) \otimes 1) \cdot (1 \otimes y_\bullet) &= (V_R^n(\tau_R(a) \cdot F_R^n(x_\bullet)) \otimes 1) \cdot (1 \otimes y_\bullet) \\ &= V_R^n((\tau_R(a) \cdot F_R^n(x_\bullet)) \otimes 1) \cdot (1 \otimes y_\bullet) \\ &= V_{R\otimes_A R}^n(((\tau_R(a) \cdot F_R^n(x_\bullet)) \otimes 1) \cdot (1 \otimes F_R^n(y_\bullet))) \\ &= V_{R\otimes_A R}^n(\tau_{R\otimes_A R}(a) \cdot F_{R\otimes_A R}^n(x_\bullet \otimes 1) \cdot F_{R\otimes_A R}^n(1 \otimes y_\bullet)). \end{aligned}$$

Hence, we are reduced to checking that :

$$\overline{\boldsymbol{\omega}}_n(x_\bullet) \otimes \overline{\boldsymbol{\omega}}_n(y_\bullet) = \overline{\boldsymbol{\omega}}_0(F_{R\otimes_A R}^n(x_\bullet \otimes 1) \cdot F_{R\otimes_A R}^n(1 \otimes y_\bullet)) \qquad \text{in } W_{n+1}(R \otimes_A R).$$

The latter follows easily from (9.3.19) : details left to the reader. ◊

Claim 14.7.23 implies that also (14.7.21) is an isomorphism, and the same for μ_{n-1}, by inductive assumption; so the same follows for μ_n and the proof is concluded. □

14.7.24. Let now A_0 be any $\mathbb{F}_p$-algebra, $(A_0, \mathfrak{m}_0)$ any basic setup, and R any A_0-algebra. Recall that the Frobenius endomorphism $\Phi_R : R \to R$ induces an endofunctor

$$\Phi_R^{k*} : R\text{-}\mathsf{Alg} \to R\text{-}\mathsf{Alg} \qquad \text{for every } k \in \mathbb{N}$$

that assigns to every R-algebra S the R-algebra $\Phi_R^{k*}S$ whose underlying ring is the same as S, and whose structure morphism is the composition of Φ_R^k with the structure morphism $R \to S$ of S. Moreover, the Frobenius endomorphism Φ_S^k induces a natural transformation

$$\Phi_{S/R}^k : S \otimes_R \Phi_R^{k*}R \to \Phi_R^{k*}S \qquad x \otimes y \mapsto x^{p^k}y \qquad \text{for every } R\text{-algebra } S$$

Let R^a be the $(A_0, \mathfrak{m})^a$-algebra represented by R; then Φ_R^{k*} descends to an endofunctor

$$\Phi_{R^a}^{k*} : R^a\text{-}\mathsf{Alg} \to R^a\text{-}\mathsf{Alg}$$

that assigns to every R^a-algebra S^a the R^a-algebra $\Phi_{R^a}^{k*}(S^a) := (\Phi_R^{k*}S)^a$, where S is any R-algebra representing S^a : see [75, §3.5.7]. Likewise, the Frobenius endomorphism Φ_S^k induces a natural transformation

$$\Phi_{S^a/R^a}^k := (\Phi_{S/R}^k)^a : (S^a \otimes_{R^a} \Phi_{R^a}^{k*}R^a) \to \Phi_{R^a}^{k*}S^a \qquad \text{for every } R^a\text{-algebra } S^a.$$

Moreover, notice that Φ_{S^a/R^a}^{k+1} also equals the composition of $\Phi_{S^a/R^a} \otimes_{\Phi_{R^a}^* R^a} \Phi_{R^a}^{k+1*}R^a$:

$$S^a \otimes_{R^a} \Phi_{R^a}^{k+1*}R^a \xrightarrow{\sim} S^a \otimes_{R^a} \Phi_{R^a}^{*}R^a \otimes_{\Phi_{R^a}^* R^a} \Phi_{R^a}^{k+1*}R^a \to \Phi_{R^a}^{*}S^a \otimes_{\Phi_{R^a}^* R^a} \Phi_{R^a}^{k+1*}R^a$$

together with $\Phi_{R^a}^*(\Phi_{S^a/R^a}^k) : \Phi_{R^a}^*S^a \otimes_{\Phi_{R^a}^* R^a} \Phi_{R^a}^{k+1*}R^a = \Phi_{R^a}^*(S^a \otimes_{R^a} \Phi_{R^a}^{k*}R^a) \to \Phi_{R^a}^{k+1*}S^a$. Especially, if Φ_{S^a/R^a} is an isomorphism, the same holds for Φ_{S^a/R^a}^k, for every $k \in \mathbb{N}$.

Remark 14.7.25. In the situation of (14.7.24), suppose that $\mathfrak{m}$ fulfills condition $(\mathbf{B})$ of [75, §2.1.6], and let $f : R \to S$ be any weakly étale morphism of A_0^a-algebras. Then $\Phi_{S/R}$ is an isomorphism. Indeed, the assertion is [75, Th.3.5.13(ii)] in case $\mathfrak{m} \otimes_{A_0} \mathfrak{m}$ is a flat A_0-module, but by direct inspection one sees easily that the proof of *loc.cit.* is valid more generally, whenever condition $(\mathbf{B})$ holds.

Theorem 14.7.26. *In the situation of* (14.7.15)*, let $f : B \to C$ be a flat morphism of A^a-algebras; set $B_0 := B/pB$, $C_0 := C/pC$, and suppose that Φ_{C_0/B_0} is an isomorphism. Then:*

(i) *f induces a flat morphism of $W_{n+1}A^a$-algebras*

$$W_{n+1}f : W_{n+1}B \to W_{n+1}C \qquad \textit{for every } n \in \mathbb{N}.$$

(ii) *For every $n \in \mathbb{N}$ and every $i = 0, \dots, n$, the following diagram is cocartesian :*

$$\begin{array}{ccc} W_{n+1}B & \xrightarrow{W_{n+1}f} & W_{n+1}C \\ {\scriptstyle\overline{\boldsymbol{\omega}}_i}\downarrow & & \downarrow{\scriptstyle\overline{\boldsymbol{\omega}}_i} \\ \overline{\boldsymbol{\omega}}_i^*B & \xrightarrow{\overline{\boldsymbol{\omega}}_i^*f} & \overline{\boldsymbol{\omega}}_i^*C. \end{array}$$

Proof. We prove first both assertions in the case where $p^kA = 0$ for some integer $k \in \mathbb{N}$. For every $j \in \mathbb{N}$, and every A^a-algebra R set

$$W_{n,j}R := W_{n+1}(R)/p^j\overline{V}_n(R) \qquad \text{with } \overline{V}_n(R) := V_nR/V_{n+1}R \subset W_{n+1}R.$$

Hence, $W_{n,0}R = W_nR$, and in light of corollary 9.3.32, we see that $W_{n,j}R = W_{n+1}R$ for every sufficiently large $j \in \mathbb{N}$. We shall show, by induction on j and n, the following assertions :

$(\mathrm{a})_{n,j}$ The induced map $W_{n,j}f : W_{n,j}B \to W_{n,j}C$ is flat for every $j, n \in \mathbb{N}$.

$(\mathrm{b})_{n,j}$ The morphism f induces a cocartesian diagram of $W_{n+1}B$-algebras :

$$\begin{array}{ccc} W_{n,j}B & \longrightarrow & \overline{\boldsymbol{\omega}}_0^*B \\ {\scriptstyle W_{n,j}f}\downarrow & & \downarrow{\scriptstyle \overline{\boldsymbol{\omega}}_0^*f} \\ W_{n,j}C & \longrightarrow & \overline{\boldsymbol{\omega}}_0^*C. \end{array}$$

Both assertions are trivial for $n = 0$ and every $j \in \mathbb{N}$. Let then $n, j \in \mathbb{N}$ be any integers, and suppose that $(\mathrm{a})_{n,j}$ and $(\mathrm{b})_{n,j}$ hold. According to (14.7.16), the kernel $K_{n,j}$ of the projection $W_{n,j+1}B \to W_{n,j}B$ is isomorphic, as a $W_{n+1}B$-module, to $\overline{\boldsymbol{\omega}}_n^*(p^jB/p^{j+1}B)$. Likewise for the kernel $K'_{n,j}$ of the projection $W_{n,j+1}C \to W_{n,j}C$, and the induced morphism $K_{n,j} \to K'_{n,j}$ corresponds to the restriction of $\overline{\boldsymbol{\omega}}_n^*(f \otimes_{\mathbb{Z}} \mathbb{Z}/p^{j+1}\mathbb{Z})$, under these identifications. By the (almost version of the) local flatness criterion (see [126, Th.22.3]), assertion $(\mathrm{a})_{n,j+1}$ will follow from :

Claim 14.7.27. The induced morphism $\overline{\boldsymbol{\omega}}_n^*(p^jB/p^{j+1}B) \otimes_{W_{n,j}B} W_{n,j}C \to \overline{\boldsymbol{\omega}}_n^*(p^jC/p^{j+1}C)$ is an isomorphism.

Proof of the claim. Clearly $\overline{\boldsymbol{\omega}}_n^*(p^jB/p^{j+1}B)$ is a $\overline{\boldsymbol{\omega}}_n^*B_0$-module and $\overline{\boldsymbol{\omega}}_n^*(p^jC/p^{j+1}C)$ is a C_0-module, and notice that $\overline{\boldsymbol{\omega}}_n^*(B_0) = \overline{\boldsymbol{\omega}}_0^* \circ \Phi_{B_0}^{n*}(B_0)$, and likewise for $\overline{\boldsymbol{\omega}}_n^*(C_0)$. Then the stated morphism agrees with the composition

$$\begin{aligned} \overline{\boldsymbol{\omega}}_n^*(p^jB/p^{j+1}B) \otimes_{W_{n,j}B} W_{n,j}C &\xrightarrow{\sim} \overline{\boldsymbol{\omega}}_0^*\Phi_{B_0}^{n*}(p^jB/p^{j+1}B) \otimes_{\overline{\boldsymbol{\omega}}_0^*B_0} \overline{\boldsymbol{\omega}}_0^*B_0 \otimes_{W_{n,j}B} W_{n,j}C \\ &\xrightarrow{\sim} \overline{\boldsymbol{\omega}}_0^*\Phi_{B_0}^{n*}(p^jB/p^{j+1}B) \otimes_{\overline{\boldsymbol{\omega}}_0^*B_0} \overline{\boldsymbol{\omega}}_0^*C_0 \\ &= \overline{\boldsymbol{\omega}}_0^*(\Phi_{B_0}^{n*}(p^jB/p^{j+1}B) \otimes_{B_0} C_0) \\ &\xrightarrow{\sim} \overline{\boldsymbol{\omega}}_0^*(\Phi_{B_0}^{n*}(p^jB/p^{j+1}B) \otimes_{\Phi_{B_0}^{n*}B_0} \Phi_{B_0}^{n*}B_0 \otimes_{B_0} C_0) \\ &\xrightarrow{\sim} \overline{\boldsymbol{\omega}}_0^*(\Phi_{B_0}^{n*}(p^jB/p^{j+1}B) \otimes_{\Phi_{B_0}^{n*}B_0} \Phi_{B_0}^{n*}C_0) \\ &= \overline{\boldsymbol{\omega}}_0^*\Phi_{B_0}^{n*}((p^jB/p^{j+1}B) \otimes_{B_0} C_0) \\ &\xrightarrow{\sim} \overline{\boldsymbol{\omega}}_0^*\Phi_{B_0}^{n*}(p^jC/p^{j+1}C) \\ &= \overline{\boldsymbol{\omega}}_n^*(p^jC/p^{j+1}C) \end{aligned}$$

where the second isomorphism follows from $(\mathrm{b})_{n,j}$, the fourth follows from our assumption about Φ_{C_0/B_0}, and the fifth follows from the flatness of f. ◊

Claim 14.7.27 also implies that the diagram

$$\begin{array}{ccc} W_{n,j+1}B & \longrightarrow & W_{n,j}B \\ {\scriptstyle W_{n,j+1}f}\downarrow & & \downarrow{\scriptstyle W_{n,j}f} \\ W_{n,j+1}C & \longrightarrow & W_{n,j}C \end{array}$$

is cocartesian; combining with $(\mathrm{b})_{n,j}$, we see that $(\mathrm{b})_{n,j+1}$ holds. Thus, we conclude that $(\mathrm{a})_{n,j}$ and $(\mathrm{b})_{n,j}$ hold for every $j \in \mathbb{N}$; for large values of j, we deduce that $(\mathrm{a})_{n+1,0}$ and $(\mathrm{b})_{n+1,0}$ both hold. By induction on $n \in \mathbb{N}$, the assertion follows. This concludes the proof of (i) in case $p^kA = 0$. To prove (ii) under the same assumption, we show first that the natural morphism

$$\overline{\boldsymbol{\omega}}_i^*B_0 \otimes_{W_{n+1}B} W_{n+1}C \to \overline{\boldsymbol{\omega}}_i^*C_0 \tag{14.7.28}$$

is an isomorphism. Indeed, notice that $\overline{\boldsymbol{\omega}}_i^* B_0 = \overline{\boldsymbol{\omega}}_0^*(\Phi_{B_0}^{i*} B_0)$, and likewise for $\overline{\boldsymbol{\omega}}_i^* C_0$. Then the foregoing morphism is the composition :

$$\begin{aligned}\overline{\boldsymbol{\omega}}_i^* B_0 \otimes_{W_{n+1}B} W_{n+1}C &= \overline{\boldsymbol{\omega}}_0^*(\Phi_{B_0}^{i*} B_0) \otimes_{W_{n+1}B} W_{n+1}C \\ &\stackrel{\sim}{\to} \overline{\boldsymbol{\omega}}_0^*(\Phi_{B_0}^{i*} B_0) \otimes_{\overline{\boldsymbol{\omega}}_0^* B_0} \overline{\boldsymbol{\omega}}_0^* B_0 \otimes_{W_{n+1}B} W_{n+1}C \\ &\stackrel{\sim}{\to} \overline{\boldsymbol{\omega}}_0^*(\Phi_{B_0}^{i*} B_0) \otimes_{\overline{\boldsymbol{\omega}}_0^* B_0} \overline{\boldsymbol{\omega}}_0^* C_0 \\ &= \overline{\boldsymbol{\omega}}_0^*(\Phi_{B_0}^{i*} B_0 \otimes_{B_0} C_0) \\ &\stackrel{\sim}{\to} \overline{\boldsymbol{\omega}}_0^*(\Phi_{B_0}^{i*} C_0) \\ &= \overline{\boldsymbol{\omega}}_i^* C_0\end{aligned}$$

where the second isomorphism follows from the foregoing condition $(\mathrm{b})_{n+1,0}$, and the third isomorphism follows from our assumption on Φ_{C_0/B_0}. Now, since $p^k B = 0$, the assertion follows from the isomorphism (14.7.28) together with the following :

Claim 14.7.29. Let $g : R \to S$ be a flat morphism of A^a-algebras, $I \subset R$ a nilpotent ideal, and suppose that $g \otimes_R R/I$ is an isomorphism. Then g is an isomorphism.

Proof of the claim. By a simple induction, we are reduced to the case where $I^2 = 0$. Then we have the commutative ladder with exact rows :

$$\begin{array}{ccccccccc} 0 & \to & I & \to & R & \to & R/I & \to & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \to & I \otimes_R S & \to & S & \to & S/IS & \to & 0 \end{array}$$

and a natural identification $I \otimes_R S \stackrel{\sim}{\to} I \otimes_{R/I} S/IS \stackrel{\sim}{\to} I$. Thus, the first and third vertical arrows are both isomorphisms, and the same then follows for the middle one. ◊

We consider next the case where A is a general ring, and $\mathfrak{m}$ fulfills condition $(\mathbf{B})$. We shall use the following criterion :

Claim 14.7.30. Let $(V, \mathfrak{m}_V)$ be any basic setup, R a $(V, \mathfrak{m}_V)^a$-algebra and M an R-module. Set

$$M_{\mathrm{tor}} := \bigcup_{n \in \mathbb{N}} \mathrm{Ann}_M(p^n) \qquad R_{\mathrm{tor}} := \bigcup_{n \in \mathbb{N}} \mathrm{Ann}_R(p^n).$$

Then M is a flat R-module if and only if the following three conditions hold :

(a) $M/p^i M$ is a flat $R/p^i R$-module for every $i \in \mathbb{N}$.
(b) $M \otimes_R R[p^{-1}]$ is a flat $R[p^{-1}]$-module.
(c) The natural morphism $R_{\mathrm{tor}} \otimes_R M \to M_{\mathrm{tor}}$ is an isomorphism.

Proof of the claim. Clearly if M is flat, conditions (a)–(c) hold. Thus, suppose that (a)–(c) hold; according to [75, Lemma 5.2.1] it suffices to prove that

(14.7.31) $$\mathrm{Tor}_i^R(M, R/pR) = 0 \qquad \text{for } i = 1, 2.$$

However, a standard calculation shows that

$$\mathrm{Tor}_1^R(M, R/pR) = \frac{\mathrm{Ann}_M(p)}{\mathrm{Ann}_R(p)M} \qquad \text{and} \qquad \mathrm{Tor}_2^R(M, R/pR) = \mathrm{Ker}\,(\mathrm{Ann}_R(p) \otimes_R M \to M).$$

Let us then consider the commutative ladder :

$$\begin{array}{ccccccc} 0 & \to & \mathrm{Ann}_R(p) \otimes_R M & \to & R_{\mathrm{tor}} \otimes_R M & \xrightarrow{p} & R_{\mathrm{tor}} \otimes_R M \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \to & \mathrm{Ann}_M(p) & \to & M_{\mathrm{tor}} & \xrightarrow{p} & M_{\mathrm{tor}} \end{array}$$

whose bottom horizontal row is exact, and whose central and right vertical arrows are isomorphisms; in order to verify (14.7.31), it suffices therefore to check that the top horizontal row is also exact; the latter is the inductive limit of the system of morphisms :

$$\mathrm{Ann}_R(p) \otimes_R M \to \mathrm{Ann}_R(p^n) \otimes_R M \to \mathrm{Ann}_R(p^n) \otimes_R M \qquad \text{for every } n \in \mathbb{N}.$$

But clearly $\mathrm{Ann}_R(p^i) \otimes_R M = \mathrm{Ann}_R(p^i) \otimes_{R/p^nR} M/p^nM$ for every $i, n \in \mathbb{N}$ with $i \leq n$; in view of (a), the assertion follows. ◊

Now, example 9.3.38(ii), implies easily that $W_{n+1}(C)[p^{-1}]$ is a flat $W_{n+1}(B)[p^{-1}]$-algebra. Next, for every $k \in \mathbb{N}$ let $\pi_k : C \to C/p^kC$ be the projection; from example 9.3.37(iii) we get

$$\mathrm{Ker}\, W_{n+1}(\pi_{n+k}) \subset p^k W_{n+1}(C) \qquad \text{for every } k \in \mathbb{N}$$

so that π_{n+k} induces an isomorphism of $W_{n+1}A^a$-algebras

$$W_{n+1}(C) \otimes_{\mathbb{Z}} \mathbb{Z}/p^k\mathbb{Z} \xrightarrow{\sim} W_{n+1}(C/p^{n+k}C) \otimes_{\mathbb{Z}} \mathbb{Z}/p^k\mathbb{Z} \qquad \text{for every } k \in \mathbb{N}. \tag{14.7.32}$$

But, by the foregoing case, we know already that $W_{n+1}(C/p^{n+k}C)$ is a flat $W_{n+1}(B/p^{n+k}B)$-algebra for every $k \in \mathbb{N}$, so we conclude that $W_{n+1}(C) \otimes_{\mathbb{Z}} \mathbb{Z}/p^k\mathbb{Z}$ is a flat $W_{n+1}(B) \otimes_{\mathbb{Z}} \mathbb{Z}/p^k\mathbb{Z}$-algebra for every $k \in \mathbb{N}$. In light of claim 14.7.30, we are therefore reduced to checking that the natural morphism

$$W_{n+1}(B)_{\mathrm{tor}} \otimes_{W_{n+1}B} W_{n+1}C \to W_{n+1}(C)_{\mathrm{tor}}$$

is an isomorphism. More precisely, we shall show, by descending induction on i, that :

- the induced morphism $(\overline{V}_iB)_{\mathrm{tor}} \otimes_{W_{n+1}B} W_{n+1}C \to (\overline{V}_iC)_{\mathrm{tor}}$ is an isomorphism of $W_{n+1}B$-modules for every $i = 0, \dots, n+1$
- the induced morphism $(\overline{V}_{i+1}B)_{\mathrm{tor}} \otimes_{W_{n+1}B} W_{n+1}C \to (\overline{V}_iB)_{\mathrm{tor}} \otimes_{W_{n+1}B} W_{n+1}C$ is a monomorphism of $W_{n+1}B$-modules for $i = 0, \dots, n$.

Indeed, both assertions are trivial for $i = n+1$. Suppose that both assertions are already known for some strictly positive integer $i \leq n+1$; from the commutative diagram

$$\begin{array}{ccc} (\overline{V}_iB)_{\mathrm{tor}} \otimes_{W_{n+1}B} W_{n+1}C & \longrightarrow & (\overline{V}_iC)_{\mathrm{tor}} \\ \downarrow & & \downarrow \\ (\overline{V}_{i-1}B)_{\mathrm{tor}} \otimes_{W_{n+1}B} W_{n+1}C & \longrightarrow & (\overline{V}_{i-1}C)_{\mathrm{tor}} \end{array}$$

we then deduce that the left vertical arrow is a monomorphism, *i.e.* the second assertion holds for $i-1$. Moreover, in order to prove the first assertion for $i-1$, it suffices to check that the induced morphism

$$(\overline{V}_{i-1}B)_{\mathrm{tor}}/(\overline{V}_iB)_{\mathrm{tor}} \otimes_{W_{n+1}B} W_{n+1}C \to (\overline{V}_{i-1}C)_{\mathrm{tor}}/(\overline{V}_{i-1}C)_{\mathrm{tor}}$$

is an isomorphism of $W_{n+1}B$-modules. On the other hand, from example 9.3.38(i) we see that $W_{n+1}(B)_{\mathrm{tor}}$ is the kernel of the natural morphism $W_{n+1}B \to W_{n+1}(B[p^{-1}])$, and likewise for $W_{n+1}(C)_{\mathrm{tor}}$; taking into account (14.7.16), we deduce a natural isomorphism :

$$(\overline{V}_{i-1}B)_{\mathrm{tor}}/(\overline{V}_iB)_{\mathrm{tor}} \xrightarrow{\sim} (\overline{\boldsymbol{\omega}}^*_{i-1}B)_{\mathrm{tor}}$$

of $W_{n+1}B$-modules, and likewise for $(\overline{V}_{i-1}C)_{\mathrm{tor}}/(\overline{V}_{i-1}C)_{\mathrm{tor}}$. We are then further reduced to checking that the induced morphism

$$\overline{\boldsymbol{\omega}}^*_{i-1}(\mathrm{Ann}_B(p^k)) \otimes_{W_{n+1}(B)} W_{n+1}C \to \overline{\boldsymbol{\omega}}^*_{i-1}\mathrm{Ann}_C(p^k)$$

is an isomorphism for every $k \in \mathbb{N}$. However, the latter is the composition of the isomorphisms

$$\begin{aligned}\overline{\boldsymbol{\omega}}^*_{i-1}(\mathrm{Ann}_B(p^k)) \otimes_{W_{n+1}(B)} W_{n+1}C &\xrightarrow{\sim} \overline{\boldsymbol{\omega}}^*_{i-1}(\mathrm{Ann}_B(p^k)) \otimes_{W_{n+1}(B/p^{n+k}B)} W_{n+1}(C/p^{n+k}C) \\ &\xrightarrow{\sim} \overline{\boldsymbol{\omega}}^*_{i-1}(\mathrm{Ann}_B(p^k)) \otimes_{\overline{\boldsymbol{\omega}}^*_{i-1}(B/p^{n+k}B)} \overline{\boldsymbol{\omega}}^*_{i-1}(C/p^{n+k}C) \\ &= \overline{\boldsymbol{\omega}}^*_{i-1}(\mathrm{Ann}_B(p^k) \otimes_B C) \\ &\xrightarrow{\sim} \overline{\boldsymbol{\omega}}^*_{i-1}\mathrm{Ann}_C(p^k)\end{aligned}$$

where the first isomorphism is due to (14.7.32), the second one follows from the part of assertion (ii) that we have already proved, and the third one follows from the flatness of f.

To conclude the proof of (ii) for a general ring A, we shall need the following :

Claim 14.7.33. Let $(V, \mathfrak{m}_V)$ be a basic setup, R a $(V, \mathfrak{m})^a$-algebra and $\varphi : M \to N$ a morphism of flat R-modules. Suppose that :

(a) $\varphi \otimes_{\mathbb{Z}} \mathbb{F}_p$ is an isomorphism of R/pR-modules.
(b) $\varphi \otimes_{\mathbb{Z}} \mathbb{Z}[p^{-1}]$ is an isomorphism of $R[p^{-1}]$-modules.

Then φ is an isomorphism.

Proof of the claim. Denote by $C_\bullet$ the complex of R-modules $[M \xrightarrow{\varphi} N]$, say with M placed in degree 0. Consider as well the acyclic complex

$$D_\bullet \quad : \quad 0 \to \mathrm{Ann}_R(p) \to R \xrightarrow{p\mathbf{1}_R} R \to R/pR \to 0.$$

Since $C_\bullet$ is flat in every degree, the complex $D_\bullet \otimes_R C_\bullet$ is still exact; the latter is also the total complex of the double complex

$$0 \to E_\bullet := \mathrm{Ann}_R(p) \otimes_{R/pR} (C_\bullet \otimes_{\mathbb{Z}} \mathbb{F}_p) \to C_\bullet \xrightarrow{p\mathbf{1}_{C_\bullet}} C_\bullet \to C_\bullet \otimes_{\mathbb{Z}} \mathbb{F}_p \to 0.$$

On the other hand, assumption (a) says that $C_\bullet \otimes_{\mathbb{Z}} \mathbb{F}_p$ is an acyclic complex of flat R/pR-modules, hence also $E_\bullet$ is acyclic. Summing up, we find that the morphism of complexes $p\mathbf{1}_{C_\bullet} : C_\bullet \to C_\bullet$ is a quasi-isomorphism, and hence induces isomorphisms $p \cdot \mathbf{1}_{H_i(C_\bullet)} : H_i(C_\bullet) \xrightarrow{\sim} H_i(C_\bullet)$ for $i = 0, 1$. In other words, $H_i(C_\bullet) = H_i(C_\bullet) \otimes_{\mathbb{Z}} \mathbb{Z}[p^{-1}]$ for $i = 0, 1$; combining with assumption (b), we conclude that $\mathrm{Ker}\,\varphi = \mathrm{Coker}\,\varphi = 0$, whence the claim. ◊

Now, we need to show that the morphism

$$\varphi_f : \overline{\boldsymbol{\omega}}^*_i B \otimes_{W_{n+1}B} W_{n+1}C \to \overline{\boldsymbol{\omega}}^*_i C$$

resulting from the diagram of (ii) is an isomorphism of $W_{n+1}B$-modules; however, set as well $g := f \otimes_{\mathbb{Z}} \mathbb{Z}/p^{n+1}\mathbb{Z} : B/p^{n+1}B \to C/p^{n+1}C$; according to the part of (ii) that has already been proved, the corresponding morphism

$$\varphi_g : \overline{\boldsymbol{\omega}}^*_i(B/p^{n+1}B) \otimes_{W_{n+1}(B/p^{n+1}B)} W_{n+1}(C/p^{n+1}C) \to \overline{\boldsymbol{\omega}}^*_i(C/p^{n+1}C)$$

is an isomorphism; on the other hand, in view of (14.7.32) the morphism $\varphi_f \otimes_{\mathbb{Z}} \mathbb{F}_p$ is naturally identified with $\varphi_g \otimes_{\mathbb{Z}} \mathbb{F}_p$, so $\varphi_f \otimes_{\mathbb{Z}} \mathbb{F}_p$ is an isomorphism as well. Next, recall that the ghost map induces an isomorphism of $W_{n+1}A^a$-algebras

$$(W_{n+1}B)[p^{-1}] \xrightarrow{\sim} B[p^{-1}]^{n+1} := \prod_{i=0}^{n} \overline{\boldsymbol{\omega}}^*_i B[p^{-1}]$$

and likewise for $(W_{n+1}C)[p^{-1}]$ (example 9.3.38(ii)); under these isomorphisms, the morphism $\overline{\boldsymbol{\omega}}_i \otimes_{\mathbb{Z}} \mathbb{Z}[p^{-1}]$ on $(W_{n+1}B)[p^{-1}]$ is identified with the projection $\pi_i : B[p^{-1}]^{n+1} \to B[p^{-1}]$ on the $(i+1)$-th factor, and likewise for the corresponding morphism on $(W_{n+1}C)[p^{-1}]$. Thus, $\varphi_f \otimes_{\mathbb{Z}} \mathbb{Z}[p^{-1}]$ is identified with the natural isomorphism of $B[p^{-1}]^{n+1}$-modules

$$\pi^*_i B[p^{-1}] \otimes_{B[p^{-1}]^{n+1}} C[p^{-1}]^{n+1} \xrightarrow{\sim} \pi^*_i C[p^{-1}].$$

From claim 14.7.33 and (i) we deduce that φ_f is an isomorphism, as required. □

Corollary 14.7.34. *In the situation of theorem* 14.7.26*, for every $n \in \mathbb{N}$ we have :*

(i) *Every B-algebra D induces a cocartesian diagram of $W_{n+1}A^a$-algebras :*

$$\begin{array}{ccc} W_{n+1}B & \longrightarrow & W_{n+1}C \\ \downarrow & & \downarrow \\ W_{n+1}D & \longrightarrow & W_{n+1}(C \otimes_B D). \end{array}$$

(ii) *The $W_{n+1}B$-module $W_{n+1}C$ is almost finitely generated (resp. almost finitely presented, resp. almost projective) if and only if the same holds for the B-module C.*

(iii) *Suppose that condition* $(\mathbf{B})$ *of* [75, §2.1.6] *holds for* $\mathfrak{m}$*. Then $W_{n+1}(f)$ is étale (resp. weakly étale) if and only if the same holds for the morphism f.*

(iv) *The projection $W_{n+2}C \to W_{n+1}C$ induces an isomorphism of $W_{n+1}B$-algebras :*

$$W_{n+2}C \otimes_{W_{n+2}B} W_{n+1}B \xrightarrow{\sim} W_{n+1}C.$$

Proof. (i): Notice that the natural morphism $h : W_{n+1}C \otimes_{W_{n+1}B} W_{n+1}D \to W_{n+1}(C \otimes_B D)$ restricts to morphisms of $W_{n+1}B$-modules

$$W_{n+1}C \otimes_{W_{n+1}B} \overline{V}_k D \to \overline{V}_k(C \otimes_B D) \qquad \text{for every } k = 0, \dots, n.$$

Taking into account (14.7.16), we are then reduced to checking that h induces isomorphisms

$$\mathrm{gr}_k h : W_{n+1}C \otimes_{W_{n+1}B} \overline{\boldsymbol{\omega}}_k^* D \to \overline{\boldsymbol{\omega}}_k^*(C \otimes_B D) \qquad \text{for every } k = 0, \dots, n.$$

However, a simple inspection shows that $\mathrm{gr}_k h$ agrees with the composition
