Acknowledgements We thank Yves André, Francesco Baldassarri, Niels Borne, Mateo Carmona, Kestutis Cesnavicius, Michel Emsalem, Pierre-Yves Gaillard, Lutz Geissler, W.-P. Heidorn, Laurent Moret-Bailly, Fabrice Orgogozo, Olaf Schnürer and Peter Scholze for pointing out some mistakes in earlier drafts, and for useful suggestions.

CONTENTS

0. Introduction

Both the focus of this monograph and its subject matter have evolved considerably in the last few years. On the one hand, the insistence on making the text self-contained (aside from a reduced canon of basic references, which should ideally contain only EGA and some parts of Bourbaki's *Éléments*), has resulted in a rather weighty mass of material of independent interest, that is applied to, but is completely separate from almost ring theory, and whose relationship to p-adic Hodge theory is thus even more indirect. Rather than stemming from a well-thought-out plan, this part is the outcome of a haphazard process, lumbering between alternating phases of accretion and consolidation, with new topics piled up as dictated by need, or occasionally by whim, when we just branched out from the main flow to pursue a certain line of thought to its logical destination. Nevertheless, a few themes have spontaneously emerged, around which the originally amorphous magma has been able to settle, to the point where by now a distinct shape is finally discernible, and it is perhaps time to pause and take stock of its broad outlines.

Now then, we may distinguish :

• First of all, a rather thorough exposition of the foundations of logarithmic algebraic geometry, comprising chapters 6, 12 and 13. Inevitably, our treatment owes a lot to the works of Kato and his school : our contribution is foremost that of gathering and tidying up the subject, which until now was scattered in a disparate number of research articles, many of them still unpublished and even unfinished. A closer scrutiny would also reveal a few technical innovations that we hope will become standard issue of the working algebraic log-geometer : we may mention the systematic use of pointed monoids and pointed modules, the projective fan associated with a graded monoid, or a definition of α-flatness for log structures which refines and generalizes an older notion of “toric flatness”. Furthermore, we took the occasion to repair a few small (and not so small) mistakes and inaccuracies that we detected in the literature.

• Two other chapters are dedicated to local cohomology and Grothendieck’s duality theory. Early on, the emphasis here was on generalizations : especially, we were interested in removing from the theory the pervasive noetherian assumptions, to pave the way for our recasting of Faltings’s almost purity in the framework of valuation theory. Applications of local cohomology to non-archimedean analytic geometry furnished another influential motivation, though one that has remained, so far, hidden from view. More recently, the noetherian aspects have also become relevant to our project, and this latest release contains a detailed account of the most important properties of noetherian rings endowed with a dualizing complex. The latter, in turn, could be dealt with satisfactorily only after a thorough revisitation of the general theory of the dualizing complex, so that our chapters 10 and 11 can also be regarded as complementary to Conrad’s book [50] (dedicated to the trace morphism and the deeper aspects of duality) : totaling our respective efforts, it should eventually become possible to bypass entirely Hartshorne’s notes [87] which, as is well known, are wanting in many ways.

• Chapters 7 and 9 present (for the time being, anyway) a looser structure : a miscellanea of self-contained units devoted to more or less independent topics. However, there is at least one thread running through several sections, and whose stretch can be traced all the way back to the earliest beginnings of almost ring theory; it connects sections 7.4 and 7.5 – on simplicial homotopy theory – to a section 7.10 dedicated to homotopical algebra, then on to sections 9.6 and 9.7, which make extensive use of the cotangent complex to derive important characterizations of regular and excellent rings, including an up-to-date presentation of classical results due to André, extracted from his monograph [3], and from his paper [4] on localization of formal smoothness. This homotopical algebraic thread resurfaces again in section 14.1, but there we are already squarely into almost ring theory proper.

On the other hand, two recent notable developments are compelling a revision of our understanding of almost ring theory itself, and of its situation within commutative algebra and algebraic geometry at large :

• The first is Scholze’s PhD thesis [149] on *perfectoid spaces*, that contains both a maximal generalization of the almost purity theorem, and a major simplification of its proof, based on his “tilting” technique (and completely different from Faltings’s). However, the range of Scholze’s theory transcends the domain of p-adic Hodge theory (which was not even his original motivation) : to drive the point home, his thesis concludes with a clever application to the long standing weight monodromy conjecture, thus affording the unusual spectacle of a tool which was fashioned out of purely p-adic concerns, and ends up playing a crucial role in the solution of a purely ℓ-adic problem.

• The second spectacular development is Yves André's proof of the direct summand conjecture ([5]); the latter is a deceptively simple assertion that has been a central problem in commutative algebra for the last thirty years : it asserts that every finite injective ring homomorphism $f : A \to B$ from a regular local ring A, admits a A-linear splitting. The relevance of almost purity to this question was first surmised by Paul Roberts in 2001 (after a talk by the second author at the University of Utah), and has been widely advertised by him ever since. André's solution uses perfectoid techniques, and builds on earlier work by Bhargav Bhatt, who in [22] proved the conjecture in the case where A is essentially smooth over a mixed characteristic discrete valuation ring and $f \otimes_{\mathbb{Z}} \mathbb{Q}$ is étale outside a relative normal crossings divisor of $\mathrm{Spec}\, A$. Moreover, Bhatt has subsequently simplified some of André's arguments and shown how the same method yields a more general "derived version" of the conjecture, for proper schemes over any regular ring : see [23].

We see then, that almost ring theory has emancipated itself from its former ancillary role in the exclusive service of p-adic Hodge theory, and is now elbowing out a niche in the wider ecosystem of algebraic geometry.

The present release completes the project announced in the introduction of the 6th release :

• First we introduce a class of topological rings that generalize the perfectoid rings of [149]; it is very easy to say what a (generalized) perfectoid $\mathbb{F}_p$-algebra is : namely, it is just a perfect and complete topological $\mathbb{F}_p$-algebra whose topology is linear, defined by an ideal of finite type. The general definition is somewhat more involved, but we prove the following characterization. For any perfectoid $\mathbb{F}_p$-algebra E, we consider the ring of Witt vectors $W(E)$, and we endow it with a natural topology, induced from that of E; then every perfectoid ring is a topological quotient of the form $A := W(E)/\underline{a}W(E)$, for such a suitable E, and where $\underline{a} \in W(E)$ is what we call a *distinguished element* : see definition 16.1.6. Moreover, just as in Scholze's work, the perfectoid $\mathbb{F}_p$-algebra E can be recovered from A via a *tilting functor* that establishes, more precisely, an equivalence between the category of all perfectoid rings and that of pairs $(E, \mathscr{I})$ consisting of a perfectoid $\mathbb{F}_p$-algebra E and a principal ideal $\mathscr{I} \subset W(E)$ generated by a distinguished element (as it is well known, this construction is rooted in Fontaine and Winterberger's theory of the *field of norms*). The distinguished ideal $\mathscr{I}$ represents an extra parameter that remains hidden in Scholze's original approach : the reason is that he fixes from the start a base perfectoid field K, thereby implicitly fixing as well a distinguished element $\underline{a}$ in the ring of Witt vectors of the tilt of K, and then every perfectoid ring in his work is supposed to be a K-algebra, which – from our viewpoint – amounts to restricting to perfectoid rings whose associated distinguished ideal is generated by $\underline{a}$. Having thus removed the parameter $\mathscr{I}$, he can then also do away with Witt vectors altogether, and the inverse to the tilting construction is obtained in [149] via a more abstract deformation theoretic argument. This route is precluded to us, so we rely instead on direct and rather concrete Witt vectors calculations. A similar strategy has been proposed in [114], and our viewpoint can indeed be described fairly as an interpolation of those of Scholze and Kedlaya-Liu, though we only studied [149] in detail.

• The first three sections of chapter 16 are devoted to exploring this new class of perfectoid rings and its manifold remarkable features. The rest of the chapter then merges the theory of perfectoid rings with Huber's adic spaces, to forge the perfectoid spaces that are the main tool for our proof of almost purity, whose most general form is given by theorem 16.8.44 and applies to *formally perfectoid rings*, *i.e.* to topological rings whose completion is perfectoid. The proof proceeds via several preliminary reductions : first, to the case of a *perfectoid quasi-affinoid ring*, covered by theorem 16.8.32, then – by exploiting the local geometry of adic spaces – to the case of a perfectoid valuation ring, which was treated already in our monograph [75]. What enables here this localization argument is a basic feature of the étale topology of arbitrary adic spaces : the fibred category of finite étale coverings of the affinoid subsets of an adic space is a stack. The latter result is in turn a special case of our theorem 15.7.6.

• We also include a detailed treatment of the foundations of the theory of adic spaces, that essentially follows [98], but contains some modest improvement : notably, the systematic use of *analytically noetherian rings* (borrowed from [71]) allows us to unify the two classes of topological rings that Huber dealt with separately in his work (the strongly noetherian rings and the f-adic rings with a noetherian ring of definition). We also point out a henselian variant of the structure sheaf that is available on the adic spectrum of any f-adic ring, with no restriction whatsoever.

• The last chapter proposes a few applications : in section 17.1 we introduce a class of *model algebras* over any rank one valuation ring K^+ of mixed characteristic $(0, p)$, and we show that when K^+ is deeply ramified, such algebras are formally perfectoid rings for their p-adic topology; hence the theory of chapter 16 immediately yields an almost purity theorem for model algebras. Likewise, section 17.2 proves an almost purity theorem for certain very ramified towers of log-regular rings; again, after some preliminary reductions, the proof amounts to the observation that the inductive limits of such towers are formally perfectoid for their p-adic topology. These instances of almost purity were already contained in a previous draft of our work (Release 6), where they were proven by an extension of Faltings's method, that relied on deep results from logarithmic algebraic geometry, and also entailed the construction of certain *normalized lengths* for torsion modules over model algebras, and respectively over the rings occurring in section 17.2. Neither of these two ingredients intervenes any longer in the new proofs; however, we have found worthwhile to explain how model algebras arise from suitable very ramified towers of log-smooth K^+-algebras, and we have also retained the construction of normalized lengths for model algebras and for limits of towers log-regular rings, since they are sufficiently interesting in their own right, and might be useful for other applications (normalized lengths for torsion K^+-modules are exploited in [150]).

Section 17.3 contains our account of André's work on the direct summand conjecture, which we generalize to the case of a finite injective ring homomorphism $A \to B$ where A is *log-regular* : see theorem 17.3.12, whose proof relies on a refinement of André's *perfectoid Abhyankar's lemma*, which is the main result of section 16.9. In a future release we shall present a corresponding logarithmic generalization of Bhatt's derived version of the direct summand conjecture.

Section 17.4 considers a finite injective map $f : A \to B$ of noetherian rings, where A is again log-regular; if f is étale, $B \otimes_A B$ has a canonical *diagonal idempotent* e_f, so called because its support is the open and closed diagonal in $\mathrm{Spec}\, B \times_{\mathrm{Spec}\, A} \mathrm{Spec}\, B$. When f is only generically étale, e_f is only well defined on some localization $B \otimes_A B[a^{-1}]$ (for some $a \in A$ whose zero locus is nowhere dense in $\mathrm{Spec}\, A$), and the problem we address, is to exhibit an explicit $d \in B \otimes_A B$ such that de_f is *integral*, *i.e.* lies in the image of $B \otimes_A B$. This question has an easy answer when B is a projective A-module : indeed, in this case we have a well defined trace map $B \to A$, whence a *different ideal* $\mathscr{D} \subset B$, and a standard calculation shows that $(b \otimes 1) \cdot e_f$ is integral for every $b \in \mathscr{D}$. If B is not projective, the question seems to be much more difficult : our solution makes an essential use of perfectoid techniques, and especially the perfectoid Abhyankar's lemma of section 16.9 : see theorem 17.4.19 and remark 17.4.44.

Section 17.5 proves the existence and weak functoriality of *big Cohen-Macaulay algebras*, over any local noetherian ring A. The case where A is equicharacteristic was already known before André's work, and is due to Hoschster and Huneke, but our construction is different from theirs, and yields actual functors on suitable subcategories : see remark 17.5.36(ii) and theorem 17.5.45. For the mixed characteristic case, we rely, as in [7], on the perfectoid Abhyankar's lemma, but again, our construction differs from the one given in the latter work; also here we get good functorial properties, but the proofs are much harder and longer than for equicharacteristic rings. A crucial ingredient for both cases, is a simple construction, introduced in (17.5.2) – and inspired by some ultrafilter techniques – whose remarkable property is to transform *almost Cohen-Macaulay* (resp. *almost faithfully flat*) algebras into actual Cohen-Macaulay (resp. faithfully flat) algebras. Lastly, weak functoriality is given by theorem 17.5.90.

The final section 17.6 explains how to apply the existence and weak functoriality of Cohen-Macaulay algebras, to deduce the monomial conjecture, first in its original form due to Hochster (theorem 17.6.1), and then in its more recent strong form (theorem 17.6.6).

1. Basic category theory

The purpose of this chapter is to fix some notation that shall stand throughout this work, and to collect, for ease of reference, a few well known generalities on categories and functors that are frequently used. Our main reference on general nonsense is the treatise [28], and another good reference is the more recent [110].

Sooner or later, any honest discussion of categories and topoi gets tangled up with some foundational issues revolving around the manipulation of large sets. For this reason, to be able to move on solid ground, it is essential to select from the outset a definite set-theoretical framework (among the several currently available), and stick to it unwaveringly.

Thus, *throughout this work we will accept the so-called Zermelo-Fraenkel system of axioms for set theory*. (In this version of set theory, everything is a set, and there is no primitive notion of class, in contrast to other axiomatisations.)

Additionally, following [8, Exp.I, §0], we shall assume that, for every set S, there exists a *universe* V such that $S \in \mathsf{V}$. (For the notion of universe, the reader may also see [28, §1.1].)

Throughout this chapter, we fix some universe U such that $\mathbb{N} \in \mathsf{U}$ (where $\mathbb{N}$ is the set of natural numbers; the latter condition is required, in order to be able to perform some standard set-theoretical operations without leaving U). A set S is U-*small* (resp. *essentially* U-*small*), if $S \in \mathsf{U}$ (resp. if S has the cardinality of a U-small set). If the context is not ambiguous, we shall just write small, instead of U-small.

1.1. **Categories, functors and natural transformations.** A *category* $\mathscr{C}$ is the datum of a set $\mathrm{Ob}(\mathscr{C})$ of *objects* and, for every $A, B \in \mathrm{Ob}(\mathscr{C})$, a set of *morphisms* from A to B, denoted :

$$\mathrm{Hom}_{\mathscr{C}}(A, B)$$

and as usual we write $f : A \to B$ to signify $f \in \mathrm{Hom}_{\mathscr{C}}(A, B)$. Furthermore, we set

$$\mathrm{Morph}(\mathscr{C}) := \{(A, B, f) \mid A, B \in \mathrm{Ob}(\mathscr{C}),\ f \in \mathrm{Hom}_{\mathscr{C}}(A, B)\}.$$

For any $\underline{f} := (A, B, f) \in \mathrm{Morph}(\mathscr{C})$, the object A is called the *source* of $\underline{f}$, and B is the *target* of $\underline{f}$. We also often use the notation

$$\mathrm{End}_{\mathscr{C}}(A) := \mathrm{Hom}_{\mathscr{C}}(A, A)$$

and the elements of $\mathrm{End}_{\mathscr{C}}(A)$ are called the *endomorphisms* of A in $\mathscr{C}$. We say that a pair of elements $(\underline{f}, \underline{g})$ of $\mathrm{Morph}(\mathscr{C})$ is *composable* if the target of $\underline{f}$ equals the source of $\underline{g}$. Moreover, for every $A, B, C \in \mathrm{Ob}(\mathscr{C})$ we have a *composition law*

$$\mathrm{Hom}_{\mathscr{C}}(A, B) \times \mathrm{Hom}_{\mathscr{C}}(B, C) \to \mathrm{Hom}_{\mathscr{C}}(A, C) \quad : \quad (f, g) \mapsto g \circ f$$

fulfilling the following two standard axioms :

- For every $A \in \mathrm{Ob}(\mathscr{C})$ there exists an *identity endomorphism* $\mathbf{1}_A$ of A, such that

$\mathbf{1}_A \circ f = f \quad g \circ \mathbf{1}_A = g$ for every $B, C \in \mathrm{Ob}(\mathscr{C})$ and every $f : B \to A$ and $g : A \to C$.

- The composition law is *associative*, *i.e.* we have
$$(h \circ g) \circ f = h \circ (g \circ f)$$
for every $A, B, C, D \in \mathrm{Ob}(\mathscr{C})$ and every $f : A \to B$, $g : B \to C$ and $h : C \to D$.

Clearly, it follows that $(\mathrm{End}_{\mathscr{C}}(A), \circ, \mathbf{1}_A)$ is a monoid, and we get a group :
$$\mathrm{Aut}_{\mathscr{C}}(A) \subset \mathrm{End}_{\mathscr{C}}(A)$$
of invertible endomorphisms, *i.e.* the *automorphisms* of the object A.

1.1.1. We say that the category $\mathscr{C}$ is U-*small* (or just *small*), if both $\mathrm{Ob}(\mathscr{C})$ and $\mathrm{Morph}(\mathscr{C})$ are small sets. We say that $\mathscr{C}$ *has small* Hom-*sets* if $\mathrm{Hom}_{\mathscr{C}}(A, B) \in \mathsf{U}$ for every $A, B \in \mathrm{Ob}(\mathscr{C})$.

A *subcategory* of $\mathscr{C}$ is a category $\mathscr{B}$ with $\mathrm{Ob}(\mathscr{B}) \subset \mathrm{Ob}(\mathscr{C})$ and $\mathrm{Morph}(\mathscr{B}) \subset \mathrm{Morph}(\mathscr{C})$.

The *opposite category* $\mathscr{C}^o$ is the category with $\mathrm{Ob}(\mathscr{C}^o) = \mathrm{Ob}(\mathscr{C})$, and such that :
$$\mathrm{Hom}_{\mathscr{C}^o}(A, B) := \mathrm{Hom}_{\mathscr{C}}(B, A) \qquad \text{for every } A, B \in \mathrm{Ob}(\mathscr{C})$$
(with composition law induced by that of $\mathscr{C}$, in the obvious way). Given $A \in \mathrm{Ob}(\mathscr{C})$, sometimes we denote by A^o the same object, viewed as an element of $\mathrm{Ob}(\mathscr{C}^o)$; likewise, given a morphism $f : A \to B$ in $\mathscr{C}$, we write f^o for the corresponding morphism $B^o \to A^o$ in $\mathscr{C}^o$.

1.1.2. A morphism $f : A \to B$ in $\mathscr{C}$ is said to be a *monomorphism* if the induced map
$$\mathrm{Hom}_{\mathscr{C}}(X, f) : \mathrm{Hom}_{\mathscr{C}}(X, A) \to \mathrm{Hom}_{\mathscr{C}}(X, B) \qquad g \mapsto f \circ g$$
is injective, for every $X \in \mathrm{Ob}(\mathscr{C})$. Dually, we say that f is an *epimorphism* if f^o is a monomorphism in $\mathscr{C}^o$. Also, f is an *isomorphism* if there exists a morphism $g : B \to A$ such that $g \circ f = \mathbf{1}_A$ and $f \circ g = \mathbf{1}_B$. Obviously, an isomorphism is both a monomorphism and an epimorphism. The converse does not necessarily hold, in an arbitrary category.

Two monomorphisms $f : A \to B$ and $f' : A' \to B$ are *equivalent*, if there exists an isomorphism $h : A \to A'$ such that $f = f' \circ h$. A *subobject* of B is defined as an equivalence class of monomorphisms $A \to B$. Dually, a *quotient* of B is a subobject of B^o in $\mathscr{C}^o$.

One says that $\mathscr{C}$ is *well-powered* if, for every $A \in \mathrm{Ob}(\mathscr{C})$, the set :
$$\mathrm{Sub}(A)$$
of all subobjects of A is essentially small. Dually, $\mathscr{C}$ is *co-well-powered*, if $\mathscr{C}^o$ is well-powered.

1.1.3. Let $\mathscr{A}$ and $\mathscr{B}$ be any two categories; a *functor* $F : \mathscr{A} \to \mathscr{B}$ is a pair of maps
$$\mathrm{Ob}(\mathscr{A}) \to \mathrm{Ob}(\mathscr{B}) \qquad \mathrm{Morph}(\mathscr{A}) \to \mathrm{Morph}(\mathscr{B})$$
both denoted also by F, such that

- F assigns to any morphism $f : A \to A'$ in $\mathscr{A}$, a morphism $Ff : FA \to FA'$ in $\mathscr{B}$
- $F\mathbf{1}_A = \mathbf{1}_{FA}$ for every $A \in \mathrm{Ob}(\mathscr{A})$
- $F(g \circ f) = Fg \circ Ff$ for every $A, A', A'' \in \mathrm{Ob}(\mathscr{A})$ and every pair of morphisms $f : A \to A'$, $g : A' \to A''$ in $\mathscr{A}$.

If $F : \mathscr{A} \to \mathscr{B}$ and $G : \mathscr{B} \to \mathscr{C}$ are any two functors, we get a composition
$$G \circ F : \mathscr{A} \to \mathscr{C}$$
which is the functor whose maps on objects and morphisms are the compositions of the respective maps for F and G. We denote by
$$\mathrm{Fun}(\mathscr{A}, \mathscr{B})$$
the set of all functors $\mathscr{A} \to \mathscr{B}$. Moreover, any such F induces a functor $F^o : \mathscr{A}^o \to \mathscr{B}^o$ with $F^oA^o := (FA)^o$ and $F^of^o := (Ff)^o$ for every $A \in \mathrm{Ob}(\mathscr{A})$ and every $f \in \mathrm{Morph}(\mathscr{A})$.

Definition 1.1.4. Let $F : \mathscr{A} \to \mathscr{B}$ be a functor.

(i) We say that F is *faithful* (resp. *full*, resp. *fully faithful*), if for every $A, A' \in \mathrm{Ob}(\mathscr{A})$ it induces injective (resp. surjective, resp. bijective) maps :

$$\mathrm{Hom}_{\mathscr{A}}(A, A') \to \mathrm{Hom}_{\mathscr{B}}(FA, FA') \quad : \quad f \mapsto Ff.$$

(ii) We say that F *reflects monomorphisms* (resp. *reflects epimorphisms*, resp. *is conservative*) if the following holds. For every morphism $f : A \to A'$ in $\mathscr{A}$, if the morphism Ff of $\mathscr{B}$ is a monomorphism (resp. epimorphism, resp. isomorphism), then the same holds for f.

(iii) If $\mathscr{A}$ is a subcategory of $\mathscr{B}$, and F is the natural inclusion functor, then F is obviously faithful, and we say that $\mathscr{A}$ is a *full subcategory* of $\mathscr{B}$, if F is fully faithful.

(iv) The *essential image of* F is the full subcategory of $\mathscr{B}$ whose objects are the objects of $\mathscr{B}$ that are isomorphic to an object of the form FA, for some $A \in \mathrm{Ob}(\mathscr{A})$. We say that F is *essentially surjective* if its essential image is $\mathscr{B}$.

(v) We say that F is an *equivalence*, if it is fully faithful and essentially surjective.

Remark 1.1.5. For later use, it is convenient to introduce the notion of n*-faithful functor*, for all integers $n \leq 2$. Namely : if $n < 0$, every functor is n-faithful; a functor $F : \mathscr{A} \to \mathscr{B}$ (between any two categories $\mathscr{A}$ and $\mathscr{B}$) is 0-faithful, if it is faithful; F is 1-faithful, if it is fully faithful; finally, we say that F is 2-faithful, if it is an equivalence.

Example 1.1.6. (i) The collection of all small categories, together with the functors between them, forms a category

$$\mathsf{U}\text{-}\mathbf{Cat}.$$

Unless we have to deal with more than one universe, we shall usually omit the prefix U, and write just $\mathbf{Cat}$. It is easily seen that $\mathbf{Cat}$ is a category with small Hom-sets.

(ii) The category of all small sets shall be denoted U-$\mathbf{Set}$ or just $\mathbf{Set}$, if there is no need to emphasize the chosen universe. There is a natural fully faithful embedding :

$$\mathbf{Set} \to \mathbf{Cat}.$$

Indeed, to any set S one may assign its *discrete category* also denoted S, *i.e.* the unique category such that $\mathrm{Ob}(S) = S$ and $\mathrm{Morph}(S) = \{(s, s, \mathbf{1}_s) \mid s \in S\}$. If S and S' are two discrete categories, the datum of a functor $S \to S'$ is clearly the same as a map of sets $\mathrm{Ob}(S) \to \mathrm{Ob}(S')$.

Notice also the natural functor

$$\mathrm{Ob} : \mathbf{Cat} \to \mathbf{Set} \qquad \mathscr{C} \mapsto \mathrm{Ob}(\mathscr{C})$$

that assigns to each functor $F : \mathscr{C} \to \mathscr{D}$ the underlying map $\mathrm{Ob}(\mathscr{C}) \to \mathrm{Ob}(\mathscr{D}) : C \mapsto FC$.

(iii) Recall that a *preordered set* is a pair $(I, \leq)$ consisting of a set I and a binary relation $\leq$ on I which is reflexive and transitive. In this case, we also say that $\leq$ is a *preordering on* I. We say that $(I, \leq)$ is a *partially ordered set*, if $\leq$ is also *antisymmetric*, *i.e.* if we have

$$(x \leq y \text{ and } y \leq x) \Rightarrow x = y \qquad \text{for every } x, y \in I.$$

We say that $(I, \leq)$ is a *totally ordered set*, if it is partially ordered and any two elements are comparable, *i.e.* for every $x, y \in I$ we have either $x \leq y$ or $y \leq x$. An *order-preserving map* $f : (I, \leq) \to (J, \leq)$ between preordered sets is a mapping $f : I \to J$ such that

$$x \leq y \;\Rightarrow\; f(x) \leq f(y) \qquad \text{for every } x, y \in I.$$

We denote by $\mathbf{Preorder}$ (resp. $\mathbf{POSet}$) the category of small preordered (resp. partially ordered) sets, with morphisms given by the order-preserving maps. To any preordered set $(I, \leq)$ one assigns a category whose set of objects is I, and whose morphisms are given as follows. For every $i, j \in I$, the set of morphisms $i \to j$ contains exactly one element when $i \leq j$, and is empty otherwise. Clearly, this rule defines a fully faithful functor

$$\mathbf{Preorder} \to \mathbf{Cat}.$$

Notice that if a category C lies in the essential image of this functor, then the same holds for C^o. Indeed, if C corresponds to the preordered set $(I, \leq)$, then C^o corresponds to the preordered set $(I^o, \leq)$ with $I^o := I$ and $x \leq y$ in I^o if and only if $y \leq x$ in I, for every $x, y \in I$. Clearly $(I, \leq)$ is a partially ordered set if and only if the same holds for $(I^o, \leq)$.

1.1.7. Let $\mathscr{A}$, $\mathscr{B}$ be two categories, $F, G : \mathscr{A} \to \mathscr{B}$ two functors. A *natural transformation*

$$\alpha : F \Rightarrow G \tag{1.1.8}$$

from F to G is a family of morphisms $(\alpha_A : FA \to GA \mid A \in \mathrm{Ob}(\mathscr{A}))$ of $\mathscr{B}$ such that, for every morphism $f : A \to B$ in $\mathscr{A}$, the diagram :

$$\begin{array}{ccc} FA & \xrightarrow{\alpha_A} & GA \\ {\scriptstyle Ff}\downarrow & & \downarrow{\scriptstyle Gf} \\ FB & \xrightarrow{\alpha_B} & GB \end{array} \tag{1.1.9}$$

commutes. If α_A is an isomorphism for every $A \in \mathrm{Ob}(\mathscr{A})$, we say that α is a *natural isomorphism* of functors. For instance, the rule that assigns to any object A the identity morphism $\mathbf{1}_{FA} : FA \to FA$, defines a natural isomorphism $\mathbf{1}_F : F \Rightarrow F$. A natural transformation (1.1.8) is also indicated by a diagram of the type :

$$\mathscr{A} \underset{G}{\overset{F}{\rightrightarrows}} \mathscr{B}. \quad (\Downarrow \alpha)$$

1.1.10. The natural transformations between functors $\mathscr{A} \to \mathscr{B}$ can be composed; namely, if $\alpha : F \Rightarrow G$ and $\beta : G \Rightarrow H$ are two such transformations, we obtain a natural transformation

$$\beta \odot \alpha : F \Rightarrow H \qquad \text{by the rule :} \qquad A \mapsto \beta_A \circ \alpha_A \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A}).$$

With this composition, $\mathrm{Fun}(\mathscr{A}, \mathscr{B})$ is the set of objects of a category which we shall denote

$$\mathsf{Fun}(\mathscr{A}, \mathscr{B}).$$

There is also a second composition law for natural transformations : if $\mathscr{C}$ is another category, and we have a diagram of functors and natural transformations

$$\mathscr{A} \underset{G}{\overset{F}{\rightrightarrows}} \mathscr{B} \underset{G'}{\overset{F'}{\rightrightarrows}} \mathscr{C} \quad (\Downarrow \alpha,\ \Downarrow \alpha')$$

we get a natural transformation

$$\alpha' * \alpha : F' \circ F \Rightarrow G' \circ G \quad : \quad A \mapsto \alpha'_{GA} \circ F'(\alpha_A) = G'(\alpha_A) \circ \alpha'_{FA} \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A})$$

called the *Godement product* of α and α' ([28, Prop.1.3.4]). Especially, if $H : \mathscr{B} \to \mathscr{C}$ (resp. $H : \mathscr{C} \to \mathscr{A}$) is any functor, we write $H * \alpha$ (resp. $\alpha * H$) instead of $\mathbf{1}_H * \alpha$ (resp. $\alpha * \mathbf{1}_H$).

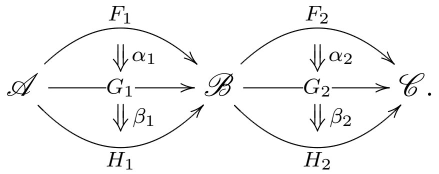
Both composition laws are associative, *i.e.*, if we have additional natural transformations

$$\mathscr{A} \underset{K}{\overset{H}{\rightrightarrows}} \mathscr{B} \quad (\Downarrow \gamma) \qquad \mathscr{C} \underset{G''}{\overset{F''}{\rightrightarrows}} \mathscr{D} \quad (\Downarrow \alpha'')$$

then we get the identities

$$\gamma \odot (\beta \odot \alpha) = (\gamma \odot \beta) \odot \alpha \qquad \alpha'' * (\alpha' * \alpha) = (\alpha'' * \alpha') * \alpha.$$

Moreover, the composition laws are related as follows. Suppose that $\mathscr{A}$, $\mathscr{B}$ and $\mathscr{C}$ are three categories, and we have a diagram of six functors and four natural transformations :



Then we have the identity :

(1.1.11) $$(\beta_2 * \beta_1) \odot (\alpha_2 * \alpha_1) = (\beta_2 \odot \alpha_2) * (\beta_1 \odot \alpha_1).$$

The proofs are left as exercises for the reader (see [28, Prop.1.3.5]).

Remark 1.1.12. (i) In the situation of (1.1.10), if $\mathscr{A}$ and $\mathscr{B}$ are small categories, the same holds for $\mathsf{Fun}(\mathscr{A}, \mathscr{B})$.

(ii) Also, if $\mathscr{A}$ is small, $\mathscr{B}$ has small Hom-sets and $\mathrm{Ob}(\mathscr{B}) \subset \mathsf{U}$, then $\mathsf{Fun}(\mathscr{A}, \mathscr{B})$ has small Hom-sets, and $\mathrm{Ob}(\mathsf{Fun}(\mathscr{A}, \mathscr{B})) \subset \mathsf{U}$.

(iii) Assertion (ii) depends on our choices on how to encode arbitrary maps of sets : according to our (implicit) convention, *a map of sets* $f : S \to S'$ *is the graph* $\Gamma(f) \subset S \times S'$. This does not agree, *e.g.* with the definition found in Bourbaki's treatise [36], where such a map f is the triple $(S, S', \Gamma(f))$. With Bourbaki's convention, assertion (ii) fails. Other references are not so explicit about their choices for encoding maps, but for instance the SGA4 treatise ([8], [9], [10]) appears to follow Bourbaki's conventions, in view of [8, Exp.I, Rem.1.1.2], which states that $\mathrm{Fun}(\mathscr{A}, \mathscr{B})$ is not necessarily a subset of U, and $\mathsf{Fun}(\mathscr{A}, \mathscr{B})$ does not necessarily have small Hom-sets, under the assumptions of (ii). On the other hand, under the same assumptions, it is stated in [76, Ch.II, Prop.1] that $\mathsf{Fun}(\mathscr{A}, \mathscr{B})$ has small Hom-sets, so the set-theoretic conventions of the latter are not compatible with those of SGA4.

1.1.13. *Adjoint pairs of functors.* Let $\mathscr{A}$ and $\mathscr{B}$ be two categories, $F : \mathscr{A} \to \mathscr{B}$ and $G : \mathscr{B} \to \mathscr{A}$ two functors. We say that G is *left adjoint* to F if there exist bijections

$$\vartheta_{A,B} : \mathrm{Hom}_{\mathscr{A}}(GB, A) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{B}}(B, FA) \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A}) \text{ and } B \in \mathrm{Ob}(\mathscr{B})$$

and these bijections are natural in both A and B, *i.e.*

$$\vartheta_{A'B'}(g \circ f \circ Gh) = Fg \circ \vartheta_{AB}(f) \circ h \quad \text{for all morphisms } GB \xrightarrow{f} A \xrightarrow{g} A' \text{ in } \mathscr{A} \text{ and } B' \xrightarrow{h} B \text{ in } \mathscr{B}.$$

Then one also says that F is *right adjoint* to G, that (G, F) is an *adjoint pair of functors*, and that $\vartheta_{\bullet\bullet}$ is an *adjunction* for the pair (G, F).

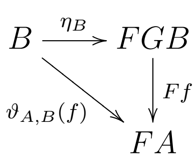
Especially, to any object B of $\mathscr{B}$ (resp. A of $\mathscr{A}$), the adjunction $\vartheta_{\bullet\bullet}$ assigns a morphism $\vartheta_{GB,B}(\mathbf{1}_{GB}) : B \to FGB$ (resp. $\vartheta^{-1}_{A,FA}(\mathbf{1}_{FA}) : GFA \to A$), whence a natural transformation

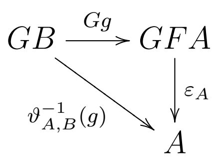
(1.1.14) $$\eta : \mathbf{1}_{\mathscr{B}} \Rightarrow F \circ G \qquad (\text{resp. } \varepsilon : G \circ F \Rightarrow \mathbf{1}_{\mathscr{A}})$$

called the *unit* (resp. *counit*) of the adjunction. The naturality of η follows from the calculation:

$$FG(f) \circ \eta_B = FG(f) \circ \vartheta_{GB,B}(\mathbf{1}_{GB}) = \vartheta_{GB,B'}(Gf \circ \mathbf{1}_{GB}) = \vartheta_{GB,B'}(\mathbf{1}_{GB'} \circ Gf) = \eta_{B'} \circ f$$

for every morphism $f : B \to B'$ in $\mathscr{B}$. A similar computation shows the naturality of ε. The naturality of $\vartheta_{\bullet\bullet}$ implies that we have commutative diagrams





for every morphism $f : GB \to A$ in $\mathscr{A}$ and $g : B \to FA$ in $\mathscr{B}$. Taking $f = \varepsilon_A$ and $g = \eta_B$, we see that the unit and counit are related by the so-called *triangular identities* expressed by the commutative diagrams :

$$\begin{array}{ccc} F & \xRightarrow{\eta * F} & FGF \\ & {}_{\mathbf{1}_F}\searrow\!\!\searrow & \Downarrow{\scriptstyle F*\varepsilon} \\ & & F \end{array} \qquad \begin{array}{ccc} G & \xRightarrow{G * \eta} & GFG \\ & {}_{\mathbf{1}_G}\searrow\!\!\searrow & \Downarrow{\scriptstyle \varepsilon * G} \\ & & G. \end{array}$$

Conversely, we have ([28, Th.3.1.5] or [110, Prop.1.5.4]) :

Proposition 1.1.15. *Let $F : \mathscr{A} \to \mathscr{B}$ and $G : \mathscr{B} \to \mathscr{A}$ be two functors.*

(i) *If η, ε are natural transformations as in* (1.1.14)*, fulfilling the triangular identities of* (1.1.13)*, then there is a unique adjunction for the pair (G,F), with unit η and counit ε.*

(ii) *Suppose that (G, F) is an adjoint pair, and η is the unit (resp. ε is the counit) of an adjunction for (G, F), then there exists a unique natural transformation ε (resp. η) as in* (1.1.14)*, fulfilling the triangular identities of* (1.1.13).

Proof. (i): Let $A \in \mathrm{Ob}(\mathscr{A})$ and $B \in \mathrm{Ob}(\mathscr{B})$ be any two objects; in light of the discussion of (1.1.13), we see that the sought natural bijection $\vartheta_{A,B}$ must be given by the rule :

$$f \mapsto Ff \circ \eta_B \qquad \text{for every } f \in \mathrm{Hom}_{\mathscr{A}}(GB, A)$$

and its inverse must be the mapping

$$g \mapsto \varepsilon_A \circ Gg \qquad \text{for every } g \in \mathrm{Hom}_{\mathscr{B}}(B, FA).$$

So we come down to checking that the triangular identities imply that these rules do induce mutually inverse bijections on the respective Hom-sets. We leave the verification to the reader.

(ii) is clear from the explicit construction of $\vartheta_{\bullet\bullet}$ in (i). □

Example 1.1.16. To every preordered set $(\mathscr{F}, \leq)$ we may attach its *partially ordered quotient*

$$(\mathscr{F}/\!\sim, \leq)$$

where $\sim$ denotes the equivalence relation such that $x \sim y$ if and only if $x \leq y$ and $y \leq x$, for every $x, y \in \mathscr{F}$. The ordering on $\mathscr{F}/\!\sim$ is the unique one such that the quotient map $\mathscr{F} \to \mathscr{F}/\!\sim$ defines a morphism

$$q_{\mathscr{F}} : (\mathscr{F}, \leq) \to (\mathscr{F}/\!\sim, \leq)$$

of preordered sets, and it is easily seen that the rule $(\mathscr{F}, \leq) \mapsto (\mathscr{F}/\!\sim, \leq)$ defines a left adjoint to the inclusion functor

$$\mathbf{POSet} \to \mathbf{Preorder}.$$

Moreover, the rule $(\mathscr{F}, \leq) \mapsto q_{\mathscr{F}}$ is a unit for this adjunction.

The following observations are borrowed from, and are further developed in [81, §I.6].

Remark 1.1.17. (i) Consider two adjoint pairs (G_1, F_1) and (G_2, F_2) :

$$\mathscr{A} \underset{G_1}{\overset{F_1}{\rightleftarrows}} \mathscr{B} \underset{G_2}{\overset{F_2}{\rightleftarrows}} \mathscr{C}$$

and suppose that for $i = 1, 2$ we are given adjunctions $\vartheta_{i,\bullet\bullet}$ for the pair (G_i, F_i). Then clearly $(G_1 \circ G_2, F_2 \circ F_1)$ is an adjoint pair, and we get an induced adjunction for this pair, by the composition :

$$\mathrm{Hom}_{\mathscr{A}}(G_1G_2C, A) \xrightarrow{\vartheta_{1,A,G_2C}} \mathrm{Hom}_{\mathscr{B}}(G_2C, F_1A) \xrightarrow{\vartheta_{2,F_1A,C}} \mathrm{Hom}_{\mathscr{B}}(C, F_2F_1A)$$

for every $A \in \mathrm{Ob}(\mathscr{A})$ and $C \in \mathrm{Ob}(\mathscr{C})$. We denote this adjunction by

$$(\vartheta_2 \circ \vartheta_1)_{\bullet\bullet}$$

and we call it the *composition* of the adjunctions ϑ_1 and ϑ_2. If (η_i, ε_i) are the units and counits of $\vartheta_{i,\bullet\bullet}$ (for $i = 1, 2$), then the unit and counit of $(\vartheta_2 \circ \vartheta_1)_{\bullet\bullet}$ are respectively :

$$(F_2 * \eta_1 * G_2) \odot \eta_2 \qquad \text{and} \qquad \varepsilon_1 \odot (G_1 * \varepsilon_2 * F_1).$$

Moreover, suppose that $\mathscr{C} \underset{G_3}{\overset{F_3}{\rightleftarrows}} \mathscr{D}$ is another adjoint pair of functors, and $\vartheta_{3,\bullet\bullet}$ an adjunction for this pair; with this notation, it is also then clear that

$$(\vartheta_3 \circ (\vartheta_2 \circ \vartheta_1))_{\bullet\bullet} = (\vartheta_3 \circ (\vartheta_2 \circ \vartheta_1))_{\bullet\bullet}.$$

(ii) Suppose that we have two pairs of adjoint functors and two natural transformations

$$\mathscr{A} \underset{G}{\overset{F}{\rightleftarrows}} \mathscr{B} \qquad \mathscr{A} \underset{G'}{\overset{F'}{\rightleftarrows}} \mathscr{B} \qquad \tau : F \Rightarrow F' \qquad \mu : G' \Rightarrow G$$

and let us fix units and counits (η, ε) (resp. (η', ε')) for the adjoint pair (G, F) (resp. (G', F')). Then we obtain *adjoint transformations*

$$\tau^\dagger : G' \Rightarrow G \qquad \mu^\dagger : F \Rightarrow F'$$

given by the compositions :

$$G'B \xrightarrow{G'(\eta_B)} G'FGB \xrightarrow{G'(\tau_{GB})} G'F'GB \xrightarrow{\varepsilon'_{GB}} GB \qquad \text{for every } B \in \mathrm{Ob}(\mathscr{B})$$
$$FA \xrightarrow{\eta'_{FA}} F'G'FA \xrightarrow{F'(\mu_{FA})} F'GFA \xrightarrow{F'(\varepsilon_A)} F'A \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A}).$$

We claim that $(\tau^\dagger)^\dagger = \tau$ and $(\mu^\dagger)^\dagger = \mu$. Indeed, let $\vartheta_{\bullet\bullet}$ (resp. $\vartheta'_{\bullet\bullet}$) be the adjunctions corresponding to (η, ε) (resp. to (η', ε')), and notice that

$$\tau^\dagger_B = \vartheta'^{-1}_{GB,FGB}(\tau_{GB}) \circ G'(\eta_B) \qquad \mu^\dagger_A = F'(\varepsilon_A) \circ \vartheta'_{GFA,FA}(\mu_{FA})$$

so we may compute :

$$\begin{aligned}
(\tau^\dagger)^\dagger_A &= F'(\varepsilon_A) \circ \vartheta'_{GFA,FA}(\vartheta'^{-1}_{GFA,FGFA}(\tau_{GFA}) \circ G'(\eta_{FA})) \\
&= \vartheta'_{A,FA}(\varepsilon_A \circ \vartheta'^{-1}_{GFA,FGFA}(\tau_{GFA}) \circ G'(\eta_{FA})) \\
&= \vartheta'_{A,FA}(\vartheta'^{-1}_{A,FGFA}(F'(\varepsilon_A) \circ \tau_{GFA}) \circ G'(\eta_{FA})) \\
&= \vartheta'_{A,FA}(\vartheta'^{-1}_{A,FGFA}(\tau_A \circ F(\varepsilon_A)) \circ G'(\eta_{FA})) \\
&= \vartheta'_{A,FA}(\vartheta'^{-1}_{A,FA}(\tau_A) \circ G'F(\varepsilon_A) \circ G'(\eta_{FA})) \\
&= \vartheta'_{A,FA}(\vartheta'^{-1}_{A,FA}(\tau_A)) \\
&= \tau_A
\end{aligned}$$

where the second, third and fifth identities follow from the naturality of $\vartheta'_{\bullet\bullet}$, the fourth from the naturality of τ, and the sixth from the triangular identities of (1.1.13). We leave to the reader the similar calculation which gives the second identity. Hence the rule

$$\tau \mapsto \tau^\dagger := (\tau, \vartheta, \vartheta')^\dagger$$

establishes a natural bijection from the set of natural transformations $F \Rightarrow F'$, to the set of natural transformations $G' \Rightarrow G$. Notice that this correspondence depends not only on (G, F) and (G', F'), but also on (η, ε) and (η', ε'). Sometimes we denote this adjoint transformation also by $(\tau, \eta, \eta')^\dagger$.

(iii) Moreover, using the triangular identities of (1.1.13), it is easily seen that the diagrams :

$$\begin{array}{ccc} G'\circ F & \xRightarrow{G'*\tau} & G'\circ F' \\ {\scriptstyle \tau^\dagger * F}\Downarrow & & \Downarrow{\scriptstyle \varepsilon'} \\ G\circ F & \xRightarrow{\ \varepsilon\ } & \mathbf{1}_{\mathscr{A}} \end{array} \qquad\qquad \begin{array}{ccc} \mathbf{1}_{\mathscr{B}} & \xRightarrow{\ \eta\ } & F\circ G \\ {\scriptstyle \eta'}\Downarrow & & \Downarrow{\scriptstyle \tau * G} \\ F'\circ G' & \xRightarrow{F'*\tau^\dagger} & F'\circ G \end{array}$$

commute. Also, $(\tau,\vartheta,\vartheta')^\dagger$ is characterized as the unique natural transformation $G'\Rightarrow G$ such that the following diagram commutes for every $A\in\mathrm{Ob}(\mathscr{A})$ and $B\in\mathrm{Ob}(\mathscr{B})$:

$$\begin{array}{ccc} \mathrm{Hom}_{\mathscr{A}}(GB,A) & \xrightarrow{\ \vartheta_{A,B}\ } & \mathrm{Hom}_{\mathscr{B}}(B,FA) \\ {\scriptstyle \mathrm{Hom}_{\mathscr{A}}(\tau^\dagger_B,A)}\downarrow & & \downarrow{\scriptstyle \mathrm{Hom}_{\mathscr{B}}(B,\tau_A)} \\ \mathrm{Hom}_{\mathscr{A}}(G'B,A) & \xrightarrow{\ \vartheta'_{A,B}\ } & \mathrm{Hom}_{\mathscr{B}}(B,F'A) \end{array} \tag{1.1.18}$$

Indeed, letting $A:=GB$ and recalling that $\vartheta_{GB,B}(\mathbf{1}_{GB})=\eta_B$, we see easily that the commutativity of (1.1.18) determines uniquely $\tau^\dagger$ (details left to the reader). Conversely, if $\tau^\dagger$ is defined as in (i), we may compute, for every morphism $f:GB\to A$ in $\mathscr{A}$:

$$\begin{aligned} \vartheta'_{A,B}(f\circ\tau^\dagger_B) &= \vartheta'_{A,B}(f\circ\vartheta'^{-1}_{GB,FGB}(\tau_{GB})\circ G'(\eta_B)) \\ &= \vartheta'_{A,FGB}(f\circ\vartheta'^{-1}_{GB,FGB}(\tau_{GB}))\circ\eta_B \\ &= \vartheta'_{A,FGB}(\vartheta'^{-1}_{A,FGB}(F'f\circ\tau_{GB}))\circ\eta_B \\ &= F'f\circ\tau_{GB}\circ\eta_B \\ &= \tau_A\circ Ff\circ\eta_B \\ &= \tau_A\circ\vartheta_{A,B}(f). \end{aligned}$$

(iv) Furthermore, suppose we have a third pair of adjoint functors

$$\mathscr{A}\ \underset{G''}{\overset{F''}{\rightleftarrows}}\ \mathscr{B} \qquad \text{and a natural transformation} \qquad \omega : F'\Rightarrow F''$$

and let us fix an adjunction $\vartheta''_{\bullet\bullet}$ for the pair (G'',F''). Then we have :

$$(\omega\odot\tau,\vartheta,\vartheta'')^\dagger = (\tau,\vartheta,\vartheta')^\dagger\odot(\omega,\vartheta',\vartheta'')^\dagger.$$

Indeed, this identity follows easily from the characterization of $\tau^\dagger$, $\omega^\dagger$ and $(\omega\circ\tau)^\dagger$ given in (iii) (details left to the reader).

(v) Lastly, in the situation of (i), suppose moreover that we have two other adjoint pairs

$$\mathscr{A}\ \underset{G'_1}{\overset{F'_1}{\rightleftarrows}}\ \mathscr{B}\ \underset{G'_2}{\overset{F'_2}{\rightleftarrows}}\ \mathscr{C} \qquad \text{and natural transformations} \qquad \tau_1 : F_1\Rightarrow F'_1 \qquad \tau_2 : F_2\Rightarrow F'_2$$

and for $i=1,2$, let us fix an adjunction $\vartheta'_{i,\bullet\bullet}$ for (G'_i,F'_i). Then we get as in (ii) the natural transformations $\tau^\dagger_1 : G'_1\Rightarrow G_1$ and $\tau^\dagger_2 : G'_2\Rightarrow G_2$, and we have the identity

$$(\tau_2*\tau_1,\vartheta_2\circ\vartheta_1,\vartheta'_2\circ\vartheta'_1)^\dagger = (\tau_1,\vartheta_1,\vartheta'_1)^\dagger * (\tau_2,\vartheta_2,\vartheta'_2)^\dagger.$$

Indeed, taking into account (iii) we get the commutative diagram

$$\begin{array}{ccccc}
\mathrm{Hom}_{\mathscr{A}}(G_1G_2C,A) & \xrightarrow{\vartheta_{1,A,G_2C}} & \mathrm{Hom}_{\mathscr{B}}(G_2C,F_1A) & \xrightarrow{\vartheta_{2,F_1A,C}} & \mathrm{Hom}_{\mathscr{C}}(C,F_2F_1A) \\
{\scriptstyle \mathrm{Hom}_{\mathscr{A}}(\tau^\dagger_{1,G_2C},A)}\downarrow & & {\scriptstyle \mathrm{Hom}_{\mathscr{B}}(G_2C,\tau_{1,C})}\downarrow & & \downarrow{\scriptstyle \mathrm{Hom}_{\mathscr{C}}(C,F_2(\tau_{1,C}))} \\
\mathrm{Hom}_{\mathscr{A}}(G'_1G_2C,A) & \xrightarrow{\vartheta'_{1,A,G_2C}} & \mathrm{Hom}_{\mathscr{B}}(G_2C,F'_1A) & \xrightarrow{\vartheta_{2,F'_1A,C}} & \mathrm{Hom}_{\mathscr{C}}(C,F_2F'_1A) \\
{\scriptstyle \mathrm{Hom}_{\mathscr{A}}(G'_1(\tau^\dagger_{1,C}),A)}\downarrow & & {\scriptstyle \mathrm{Hom}_{\mathscr{B}}(\tau^\dagger_{2,C},F'_1A)}\downarrow & & \downarrow{\scriptstyle \mathrm{Hom}_{\mathscr{C}}(C,\tau_{2,F'_1C})} \\
\mathrm{Hom}_{\mathscr{A}}(G'_1G'_2C,A) & \xrightarrow{\vartheta'_{1,A,G'_2C}} & \mathrm{Hom}_{\mathscr{B}}(G'_2C,F'_1A) & \xrightarrow{\vartheta'_{2,F'_1A,C}} & \mathrm{Hom}_{\mathscr{C}}(C,F'_2F'_1A)
\end{array}$$

for every $A \in \mathrm{Ob}(\mathscr{A})$ and $C \in \mathrm{Ob}(\mathscr{C})$. The sought identity follows after invoking again (iii).

(vi) Especially, taking into account the triangular identities of (1.1.13), it is easily seen that :

$$\begin{aligned}
(\mathbf{1}_{F_2},\vartheta_2,\vartheta_2)^\dagger &= \mathbf{1}_{G_2} \\
(F_2 * \tau_1, \vartheta_2\circ\vartheta_1, \vartheta_2\circ\vartheta'_1)^\dagger &= (\tau_1,\vartheta_1,\vartheta'_1)^\dagger * G_2 \\
(\tau_2 * F_1, \vartheta_2\circ\vartheta_1, \vartheta'_2\circ\vartheta_1)^\dagger &= G_1 * (\tau_2,\vartheta_2,\vartheta'_2)^\dagger.
\end{aligned}$$

Remark 1.1.19. (i) For any two categories $\mathscr{C},\mathscr{D}$ we have a natural isomorphism of categories

$$\mathsf{Fun}(\mathscr{C},\mathscr{D})^o \xrightarrow{\sim} \mathsf{Fun}(\mathscr{C}^o,\mathscr{D}^o)$$

that assigns to any functor $H : \mathscr{C} \to \mathscr{D}$ the opposite functor $H^o : \mathscr{C}^o \to \mathscr{D}^o$, and to any natural transformation $\tau : H \Rightarrow K$ the *opposite transformation* $\tau^o : K^o \Rightarrow H^o$ such that $\tau^o_{C^o} := (\tau_C)^o$ for every $C \in \mathrm{Ob}(\mathscr{C})$. Also, in the situation of (1.1.10), notice the identities

$$(\beta\odot\alpha)^o = \alpha^o \odot \beta^o \qquad \text{and} \qquad (\alpha' * \alpha)^o = \alpha'^o * \alpha^o.$$

(ii) Let $\mathscr{B}$ and $\mathscr{E}$ be two other categories, $f : \mathscr{B} \to \mathscr{C}$ and $g : \mathscr{D} \to \mathscr{E}$ two functors; we get an induced functor

$$\mathsf{Fun}(f,g) : \mathsf{Fun}(\mathscr{C},\mathscr{D}) \to \mathsf{Fun}(\mathscr{B},\mathscr{E}) \qquad H \mapsto g\circ H\circ f \qquad (\alpha : H \Rightarrow K) \mapsto g * \alpha * f.$$

Likewise, if $f' : \mathscr{B} \to \mathscr{C}$ and $g' : \mathscr{D} \to \mathscr{E}$ are any two other functors, every pair of natural transformations $\gamma : f \Rightarrow f'$ and $\delta : g \Rightarrow g'$ induces a transformation

$$\mathsf{Fun}(\gamma,\delta) : \mathsf{Fun}(f,g) \Rightarrow \mathsf{Fun}(f',g') \qquad H \mapsto \delta * H * \gamma.$$

We shall usually write $\mathsf{Fun}(f,\mathscr{D})$ (resp. $\mathsf{Fun}(\mathscr{C},g)$) instead of $\mathsf{Fun}(f,\mathbf{1}_{\mathscr{D}})$ (resp. of $\mathsf{Fun}(\mathbf{1}_{\mathscr{C}},g)$). Furthermore, in the situation of (1.1.10), notice the identities

$$\begin{aligned}
\mathsf{Fun}(\beta,\mathscr{D}) \odot \mathsf{Fun}(\alpha,\mathscr{D}) &= \mathsf{Fun}(\beta\odot\alpha,\mathscr{D}) \\
\mathsf{Fun}(\alpha,\mathscr{D}) * \mathsf{Fun}(\alpha',\mathscr{D}) &= \mathsf{Fun}(\alpha' * \alpha,\mathscr{D}).
\end{aligned}$$

(iii) In the situation of (ii), suppose that the functor f admits a left adjoint $g : \mathscr{C} \to \mathscr{B}$. Then $f^* := \mathsf{Fun}(f,\mathscr{D})$ is left adjoint to $g^* := \mathsf{Fun}(g,\mathscr{D})$. More precisely, let η be a unit and ε a counit for the adjoint pair (g,f). From the triangular identities (1.1.13) for (g,f), and taking into account (ii), we deduce commutative diagrams :

$$\begin{array}{ccc}
g^* & \xrightarrow{\mathsf{Fun}(\eta,\mathscr{D})*g^*} & g^*f^*g^* \\
& \searrow{=} & \Downarrow{\scriptstyle g^**\mathsf{Fun}(\varepsilon,\mathscr{D})} \\
& & g^*
\end{array}
\qquad\qquad
\begin{array}{ccc}
f^* & \xrightarrow{f^**\mathsf{Fun}(\eta,\mathscr{D})} & f^*g^*f^* \\
& \searrow{=} & \Downarrow{\scriptstyle \mathsf{Fun}(\varepsilon,\mathscr{D})*f^*} \\
& & f^*
\end{array}$$

which, in light of proposition 1.1.15(i), says that $\mathsf{Fun}(\eta,\mathscr{D})$ is a unit and $\mathsf{Fun}(\varepsilon,\mathscr{D})$ a counit for the adjoint pair (f^*,g^*).

(iv) Let $F : \mathscr{C} \to \mathscr{D}$ be a functor, and $G : \mathscr{D} \to \mathscr{C}$ a left adjoint to F. Then F^o is left adjoint to G^o. More precisely, let η be a unit and ε a counit for the adjoint pair (G,F); then it follows easily from (i) and proposition 1.1.15(i) that ε^o is a unit and η^o is a counit for the adjoint pair (F^o, G^o) : details left to the reader.

Proposition 1.1.20. *Let $F : \mathscr{A} \to \mathscr{B}$ be a functor.*

(i) *The following conditions are equivalent :*
   (a) *F is fully faithful and has a fully faithful left adjoint.*
   (b) *There exist a functor $G : \mathscr{B} \to \mathscr{A}$ and isomorphisms of functors*

$$G \circ F \xrightarrow{\sim} \mathbf{1}_{\mathscr{A}} \qquad \mathbf{1}_{\mathscr{B}} \xrightarrow{\sim} F \circ G.$$

   (c) *F is an equivalence.*

(ii) *Suppose that F admits a left adjoint $G : \mathscr{B} \to \mathscr{A}$, and let $\eta : \mathbf{1}_{\mathscr{B}} \Rightarrow F \circ G$ and $\varepsilon : G \circ F \Rightarrow \mathbf{1}_{\mathscr{A}}$ be a unit and respectively a counit for the adjoint pair (G, F). Then F (resp. G) is faithful if and only if ε_X is an epimorphism for every $X \in \mathrm{Ob}(\mathscr{A})$ (resp. η_Y is a monomorphism for every $Y \in \mathrm{Ob}(\mathscr{B})$).*

(iii) *In the situation of* (ii)*, the following conditions are equivalent :*
   (a) *F (resp. G) is fully faithful.*
   (b) *The counit ε (resp. the unit η) is an isomorphism of functors.*
   (c) *There exists an isomorphism of functors $\varepsilon' : G \circ F \xrightarrow{\sim} \mathbf{1}_{\mathscr{A}}$ (resp. $\eta' : \mathbf{1}_{\mathscr{B}} \xrightarrow{\sim} F \circ G$).*

   Moreover, if (c) *holds, there exists a unique adjunction ϑ' for the pair (G, F) whose counit is ε' (resp. whose unit is η').*

(iv) *Suppose that F admits both a left adjoint $G : \mathscr{B} \to \mathscr{A}$ and a right adjoint $H : \mathscr{B} \to \mathscr{A}$. Then G is fully faithful if and only if H is fully faithful.*

Proof. (ii): In view of remark 1.1.19(iv), it suffices to consider the assertion relative to $\varepsilon_\bullet$. Thus, suppose that $Ff_1 = Ff_2$ for two morphisms $f_1, f_2 : X \to X'$. The naturality of $\varepsilon_\bullet$ yields the identity : $\varepsilon_{X'} \circ GFf_i = f_i \circ \varepsilon_X$ for $i = 1, 2$, and if ε_X is an epimorphism, we deduce $f_1 = f_2$. Conversely, suppose F is faithful and $f_1 \circ \varepsilon_X = f_2 \circ \varepsilon_X$; from the triangular identities we get :

$$Ff_i = F(\varepsilon_{X'}) \circ FGF(f_i) \circ \eta_{FX} = F(f_i \circ \varepsilon_X) \circ \eta_{FX}$$

so $Ff_1 = Ff_2$ and therefore $f_1 = f_2$ which shows that ε_X is an epimorphism.

(iii): Again, remark 1.1.19(iv) reduces to considering the assertion for $\varepsilon_\bullet$. We check first that (iii.a)⇒(iii.b) : indeed, if F is fully faithful, for every $X \in \mathrm{Ob}(\mathscr{A})$, there exists a morphism $\beta_X : X \to GFX$ such that $F\beta_X = \eta_{FX} : FX \to FGFX$. From the triangular identities of (1.1.13) we deduce that $F(\varepsilon_X \circ \beta_X) = F(\varepsilon_X) \circ \eta_{FX} = \mathbf{1}_{FX}$, whence $\varepsilon_X \circ \beta_X = \mathbf{1}_X$, since F is faithful. Next, let ϑ be the unique adjunction for the pair (G, F) whose unit and counit are η and ε; by inspection of the explicit description of ϑ in the proof of proposition 1.1.15(i) we get

$$\vartheta_{GFX,FX}(\beta_X \circ \varepsilon_X) = F(\beta_X \circ \varepsilon_X) \circ \eta_{FX} = \eta_{FX} \circ F(\varepsilon_X) \circ \eta_{FX} = \eta_{FX} = \vartheta_{GFX,FX}(\mathbf{1}_{GFX})$$

whence $\beta_X \circ \varepsilon_X = \mathbf{1}_{GFX}$. Obviously (iii.b)⇒(iii.c). Lastly, suppose that (iii.c) holds; for every $X, Y \in \mathrm{Ob}(\mathscr{A})$ we deduce a bijection

$$\xi_{X,Y} : \mathrm{Hom}_{\mathscr{A}}(X, Y) \xrightarrow{\varphi_{X,Y}} \mathrm{Hom}_{\mathscr{A}}(GFX, Y) \xrightarrow{\vartheta_{GX,Y}} \mathrm{Hom}_{\mathscr{B}}(FX, FY)$$

where $\varphi_{X,Y}(f) := f \circ \varepsilon'_X$ for every morphism $f : X \to Y$ in $\mathscr{A}$. It is easily seen that $\xi_{X,Y}$ is natural in both X and Y; especially, for every $f \in \mathrm{Hom}_{\mathscr{A}}(X, Y)$ we have :

$$\xi_{Y,Y}(\mathbf{1}_Y) \circ Ff = \xi_{X,Y}(\mathbf{1}_Y \circ f) = \xi_{X,Y}(f \circ \mathbf{1}_X) = Ff \circ \xi_{X,X}(\mathbf{1}_X).$$

Letting $X = Y$, and taking $f : X \to X$ with $\xi_{X,X}(f) = \mathbf{1}_{FX}$, we deduce that $\xi_{X,X}(\mathbf{1}_X)$ is an isomorphism in $\mathscr{B}$, for every $X \in \mathrm{Ob}(\mathscr{A})$. Since $\xi_{X,Y}(f) = Ff \circ \xi_{X,X}(\mathbf{1}_X)$ for every $f \in \mathrm{Hom}_{\mathscr{A}}(X, Y)$, we conclude that the rule $f \mapsto Ff$ is a bijection $\mathrm{Hom}_{\mathscr{A}}(X, Y) \xrightarrow{\sim}$

$\mathrm{Hom}_{\mathscr{B}}(FX, FY)$, whence (iii.a). Lastly, let us check the existence and uniqueness of the adjunction ϑ' whose counit is ε'. To this aim, let $\omega : \mathbf{1}_{\mathscr{A}} \stackrel{\sim}{\to} \mathbf{1}_{\mathscr{A}}$ be the automorphism such that $\omega \circ \varepsilon = \varepsilon'$, and set $\eta' := (F * \omega^{-1} * G) \circ \eta$. We compute :

$$\begin{aligned}(F * \varepsilon') \odot (\eta' * F) &= (F * \omega) \odot (F * \varepsilon) \odot (F * \omega^{-1} * GF) \odot (\eta * F) \\ &= (F * \omega) \odot (F * \omega^{-1}) \odot (F * \varepsilon) \odot (\eta * F) = \mathbf{1}_F.\end{aligned}$$

Likewise we check that $(\varepsilon' * G) \odot (G * \eta') = \mathbf{1}_G$, whence the contention, by proposition 1.1.15.

(i): The equivalence (i.a)⇔(i.b) follows immediately from (iii). Moreover, if (i.b) holds, then for every $Y \in \mathrm{Ob}(\mathscr{B})$ we have an isomorphism $Y \stackrel{\sim}{\to} FGY$, so F is essentially surjective. Since we have just seen that (i.b) implies that F is fully faithful, we deduce as well that (i.b)⇒(i.c).

(i.c)⇒(i.a): We construct a left adjoint $G : \mathscr{B} \to \mathscr{A}$ to F as follows. Since F is essentially surjective, for every $B \in \mathrm{Ob}(\mathscr{B})$ we may find an object $A \in \mathrm{Ob}(\mathscr{A})$ with an isomorphism $\eta_B : B \stackrel{\sim}{\to} FA$, and we set $GB := A$. Next, since F is fully faithful, for every morphism $g : B \to B'$ in $\mathscr{B}$ there exists a unique morphism $f : GB \to GB'$ in $\mathscr{A}$ which makes commute the diagram

$$\begin{array}{ccc} B & \xrightarrow{g} & B' \\ {\scriptstyle \omega_B}\downarrow & & \downarrow{\scriptstyle \omega_{B'}} \\ FGB & \xrightarrow{Ff} & FGB' \end{array}$$

and we let $Gg := f$. It is easily seen that these rules yield a well defined functor G as sought, and η is then a natural isomorphism $\mathbf{1}_{\mathscr{B}} \Rightarrow FG$. Moreover from the full faithfulness of F we deduce that G is fully faithful as well (details left to the reader). To conclude we remark, more generally :

Claim 1.1.21. Let $F : \mathscr{A} \to \mathscr{B}$ and $G : \mathscr{B} \to \mathscr{A}$ be two functors, $\eta : \mathbf{1}_{\mathscr{B}} \Rightarrow FG$ an isomorphism of functors, and suppose that F is fully faithful. Then there exists a unique adjunction ϑ for the pair (G, F) whose unit is η.

Proof of the claim. From the proof of proposition 1.1.15 we know that η determines ϑ, by the rule : $\vartheta_{A,B}(f) := Ff \circ \eta_B$ for every $A \in \mathrm{Ob}(\mathscr{A})$, $B \in \mathrm{Ob}(\mathscr{B})$ and every morphism $f : GB \to A$ in $\mathscr{A}$. Conversely, our assumptions easily imply that this rule does yield a natural bijection $\mathrm{Hom}_{\mathscr{A}}(GB, A) \stackrel{\sim}{\to} \mathrm{Hom}_{\mathscr{B}}(B, FA)$, whence the contention (details left to the reader). ◊

(iv): Let $\eta : \mathbf{1}_{\mathscr{B}} \Rightarrow FG$ (resp. $\eta' : \mathbf{1}_{\mathscr{A}} \Rightarrow HF$) be the unit and $\varepsilon : GF \Rightarrow \mathbf{1}_{\mathscr{A}}$ (resp. $\varepsilon' : FH \Rightarrow \mathbf{1}_{\mathscr{B}}$) the counit of a given adjunction for the adjoint pair (G, F) (resp. (F, H)). By remark 1.1.19(iv) we may assume that H is fully faithful, and we show that the same holds for G. By (iii), this is the same as assuming that ε' is an isomorphism, and we need to check that the same holds for η. To this aim, denote $\gamma : FG \Rightarrow \mathbf{1}_{\mathscr{B}}$ the composition

$$FG \xrightarrow{(FG)*\varepsilon'^{-1}} FGFH \xrightarrow{F*\varepsilon*H} FH \xrightarrow{\varepsilon'} \mathbf{1}_{\mathscr{B}}.$$

We show that γ is inverse to η. Indeed we have

$$\gamma \odot \eta = \varepsilon' \odot (F * \varepsilon * H) \odot (\eta * FH) \odot \varepsilon'^{-1} = \varepsilon' \odot \varepsilon'^{-1} = \mathbf{1}_{\mathscr{B}}$$

where the first identity holds by the naturality of η, and the second follows from the triangular identites of (1.1.13). Likewise, we have

$$\begin{aligned}\eta\odot\gamma &= (\varepsilon'*FG)\odot(FH*\eta)\odot(F*\varepsilon*H)\odot(FG*\varepsilon'^{-1})\\ &= (\varepsilon'*FG)\odot(F*\varepsilon*HFG)\odot(FGFH*\eta)\odot(FG*\varepsilon'^{-1})\\ &= (\varepsilon'*FG)\odot(F*\varepsilon*HFG)\odot(FG*\varepsilon'^{-1}*FG)\odot(FG*\eta)\\ &= (\varepsilon'*FG)\odot(F*\varepsilon*HFG)\odot(FGF*\eta'*G)\odot(FG*\eta)\\ &= (\varepsilon'*FG)\odot(F*\eta'*G)\odot(F*\varepsilon*G)\odot(FG*\eta)\\ &= (\mathbf{1}_F*G)\odot(F*\mathbf{1}_G)=\mathbf{1}_{FG}\end{aligned}$$

where the first and third identities follow from the naturality of ε', the second and fifth from that of ε, the fourth and sixth from the triangular identities for the pairs (η',ε') and (η,ε). □

Definition 1.1.22. Let $F:\mathscr{A}\to\mathscr{B}$ be any equivalence of categories. A *quasi-inverse* for F is the datum of a functor $G:\mathscr{B}\to\mathscr{A}$ and an adjunction for the pair (G,F). Then we also say that F is a *quasi-inverse* for G.

Remark 1.1.23. It follows easily from proposition 1.1.20(i,iii) and claim 1.1.21, that a quasi-inverse for an equivalence $F:\mathscr{A}\to\mathscr{B}$ is the same as the datum of a functor $G:\mathscr{B}\to\mathscr{A}$ and an isomorphism of functors $\mathbf{1}_{\mathscr{B}}\xrightarrow{\sim}FG$, and moreover any such G is also an equivalence. Taking into account remark 1.1.19(iv), we see that a quasi-inverse for F is also the same as the datum of such a G and an isomorphism of functors $GF\xrightarrow{\sim}\mathbf{1}_{\mathscr{A}}$.

1.1.24. *Slice categories.* A standard construction attaches to any $X\in\mathrm{Ob}(\mathscr{C})$ a category :

$$\mathscr{C}/X$$

as follows. The objects of $\mathscr{C}/X$ are all the pairs (A,f) where $A\in\mathrm{Ob}(\mathscr{C})$ and $f:A\to X$ is any morphism of $\mathscr{C}$. For any two such objects (A,f), (B,g), the set $\mathrm{Hom}_{\mathscr{C}/X}((A,f),(B,g))$ consists of all the commutative diagrams of morphisms of $\mathscr{C}$:

$$\begin{array}{ccc} A & \xrightarrow{\ h\ } & B \\ & {\scriptstyle f}\searrow \quad \swarrow{\scriptstyle g} & \\ & X & \end{array}$$

with composition of morphisms induced by the composition law of $\mathscr{C}$. We denote sometimes such a morphism of $\mathscr{C}/X$ by

$$h/X:(A,f)\to(B,g).$$

An object (resp. a morphism) of $\mathscr{C}/X$ is also called an X*-object* (resp. an X*-morphism*) of $\mathscr{C}$. Dually, one defines

$$X/\mathscr{C}:=(\mathscr{C}^o/X^o)^o$$

i.e. the objects of $X/\mathscr{C}$ are the pairs (A,f) with $A\in\mathrm{Ob}(\mathscr{C})$ and $f:X\to A$ any morphism of $\mathscr{C}$. We have an obvious faithful *source* functor

$$\mathsf{s}_X:\mathscr{C}/X\to\mathscr{C}\qquad(A,f)\mapsto A\qquad((A,f)\xrightarrow{h/X}(B,g))\mapsto(A\xrightarrow{h}B)$$

and likewise one obtains a *target* functor

$$\mathsf{t}_X:=\mathsf{s}^o_{X^o}:X/\mathscr{C}\to\mathscr{C}.$$

Moreover, any morphism $f:X\to Y$ in $\mathscr{C}$ induces functors :

$$\begin{array}{lcl} f_*:\mathscr{C}/X\to\mathscr{C}/Y & : & (A,g:A\to X)\mapsto(A,f_*g:=f\circ g:A\to Y)\\ f^*:Y/\mathscr{C}\to X/\mathscr{C} & : & (B,h:Y\to B)\mapsto(B,f^*h:=h\circ f:X\to B).\end{array}\tag{1.1.25}$$

Furthermore, given a functor $F : \mathscr{C} \to \mathscr{B}$, any $X \in \mathrm{Ob}(\mathscr{C})$ induces functors :

$$(1.1.26)\qquad \begin{array}{rcl} F_{|X} : \mathscr{C}/X \to \mathscr{B}/FX & : & (A,g) \mapsto (FA, Fg) \\ {}_{X|}F : X/\mathscr{C} \to FX/\mathscr{B} & : & (B,h) \mapsto (FB, Fh). \end{array}$$

1.1.27. The categories $\mathscr{C}/X$ and $X/\mathscr{C}$ are special cases of the following more general construction. Let $F : \mathscr{A} \to \mathscr{B}$ be any functor. For any $B \in \mathrm{Ob}(\mathscr{B})$, we define

$$F\mathscr{A}/B$$

as the category whose objects are all the pairs (A, f), where $A \in \mathrm{Ob}(\mathscr{A})$ and $f : FA \to B$ is a morphism in $\mathscr{B}$. The morphisms $g : (A, f) \to (A', f')$ are the morphisms $g : A \to A'$ in $\mathscr{A}$ such that $f' \circ Fg = f$. There are well-defined functors :

$$F/B : F\mathscr{A}/B \to \mathscr{B}/B \ : \ (A,f) \mapsto (FA, f) \qquad \text{and} \qquad \mathsf{s}_B : F\mathscr{A}/B \to \mathscr{A} \ : \ (A,f) \mapsto A.$$

Dually, we define :

$$B/F\mathscr{A} := (F^o\mathscr{A}^o/B^o)^o$$

and likewise one has natural functors :

$$B/F : B/F\mathscr{A} \to B/\mathscr{B} \qquad \text{and} \qquad \mathsf{t}_B : B/F\mathscr{A} \to \mathscr{A}.$$

Any morphism $g : B' \to B$ induces functors :

$$\begin{array}{rcl} g/F\mathscr{A} : B/F\mathscr{A} \to B'/F\mathscr{A} & : & (A,f) \mapsto (A, f \circ g) \\ F\mathscr{A}/g : F\mathscr{A}/B' \to F\mathscr{A}/B & : & (A,f) \mapsto (A, g \circ f). \end{array}$$

Obviously, the category $\mathscr{C}/X$ (resp. $X/\mathscr{C}$) is the same as $\mathbf{1}_\mathscr{C}\mathscr{C}/X$ (resp. $X/\mathbf{1}_\mathscr{C}\mathscr{C}$).

1.1.28. In the situation of (1.1.27), the categories of the form $F\mathscr{A}/B$ can be faithfully embedded in a single category $F\mathscr{A}/\mathscr{B}$. The latter is the category whose objects are all the triples (A, B, f), where $A \in \mathrm{Ob}(\mathscr{A})$, $B \in \mathrm{Ob}(\mathscr{B})$ are any two objects, and $f : FA \to B$ is any morphism of $\mathscr{B}$. If $f : FA \to B$ and $f' : FA' \to B'$ are any two objects, the set

$$\mathrm{Hom}_{F\mathscr{A}/\mathscr{B}}((A,B,f),(A',B',f'))$$

consists of all pairs (g, g') where g is a morphism in $\mathscr{A}$ and g' a morphism in $\mathscr{B}$, that make commute the diagram :

$$(1.1.29)\qquad \begin{array}{ccc} FA & \xrightarrow{f} & B \\ {\scriptstyle Fg}\downarrow & & \downarrow{\scriptstyle g'} \\ FA' & \xrightarrow{f'} & B' \end{array}$$

with composition of morphisms induced by the composition laws of $\mathscr{A}$ and $\mathscr{B}$, in the obvious way. There are two natural *source* and *target* functors :

$$\mathscr{A} \xleftarrow{\mathsf{s}} F\mathscr{A}/\mathscr{B} \xrightarrow{\mathsf{t}} \mathscr{B}$$

such that $\mathsf{s}(FA \to B) := A$, $\mathsf{t}(FA \to B) := B$ for any object $FA \to B$ of $F\mathscr{A}/\mathscr{B}$, and $\mathsf{s}(g, g') = g$, $\mathsf{t}(g, g') = g'$. Dually, we let

$$\mathscr{B}/F\mathscr{A} := (F^o\mathscr{A}^o/\mathscr{B}^o)^o$$

and the corresponding source and target functors are switched :

$$\mathscr{A} \xleftarrow{\mathsf{t}} \mathscr{B}/F\mathscr{A} \xrightarrow{\mathsf{s}} \mathscr{B}.$$

1.1.30. For the special case of the identity endofunctor $\mathbf{1}_{\mathscr{C}}$ of any category $\mathscr{C}$, we obtain the *category of arrows of* $\mathscr{C}$

$$\mathsf{Morph}(\mathscr{C}) := \mathbf{1}_{\mathscr{C}}\mathscr{C}/\mathscr{C}.$$

So, the set of objects of $\mathsf{Morph}(\mathscr{C})$ is $\mathrm{Morph}(\mathscr{C})$ (notation of (1.1)) and the morphisms are the commutative square diagrams in $\mathscr{C}$. The functor s_X of (1.1.24) is the restriction of $\mathsf{s} : \mathsf{Morph}(\mathscr{C}) \to \mathscr{C}$ to the subcategory $\mathscr{C}/X$, and likewise for t_X. Likewise, in the situation of (1.1.28), the target functor on $F\mathscr{A}/\mathscr{B}$ and the source functor on $\mathscr{B}/F\mathscr{A}$ factor through functors

$$F\mathscr{A}/\mathscr{B} \xrightarrow{\mathsf{T}} \mathsf{Morph}(\mathscr{B}) \xleftarrow{\mathsf{S}} \mathscr{B}/F\mathscr{A}$$

where $\mathsf{T}(A, B, f) := (FA, B, f)$ for every object (A, B, f) of $F\mathscr{A}/\mathscr{B}$, and T assigns to any morphism $(g, g') : (A, B, f) \to (A', B', f')$ the commutative square (1.1.29), regarded as a morphism $(FA, B, f) \to (FA', B', f')$ in $\mathsf{Morph}(\mathscr{B})$. Likewise one describes the functor S.

Notice also the natural transformation

$$\mathsf{Morph}(\mathscr{C}) \underset{\mathsf{t}}{\overset{\mathsf{s}}{\rightrightarrows}} \mathscr{C} \qquad \Downarrow \mathsf{m}$$

where $\mathsf{m}(A, B, f) := f$ for every $(A, B, f) \in \mathrm{Morph}(\mathscr{C})$. Furthermore, every functor $F : \mathscr{B} \to \mathscr{C}$ induces a functor

$$\mathsf{Morph}(F) : \mathsf{Morph}(\mathscr{B}) \to \mathsf{Morph}(\mathscr{C})$$

which maps $(A, B, f) \in \mathrm{Morph}(\mathscr{B})$ to $(FA, FB, Ff) \in \mathrm{Morph}(\mathscr{C})$ and which sends every commutative square diagram D in $\mathscr{B}$ to the commutative square diagram FD in $\mathscr{C}$.

Notice that a natural transformation α as in (1.1.8) is equivalent to the datum of a functor

$$\widetilde{\alpha} : \mathscr{A} \to \mathsf{Morph}(\mathscr{B}) \qquad \text{such that} \qquad \mathsf{s} \circ \widetilde{\alpha} = F \qquad \text{and} \qquad \mathsf{t} \circ \widetilde{\alpha} = G.$$

Namely, one defines $\widetilde{\alpha}$ by the rule : $A \mapsto (FA, GA, \alpha_A)$ for every $A \in \mathrm{Ob}(\mathscr{A})$, and for every morphism $f : A \to B$ in $\mathscr{A}$, one lets $\widetilde{\alpha}(f)$ be the commutative square diagram (1.1.9).

1.1.31. Let $\mathscr{A}, \mathscr{B}$ be two categories, $F : \mathscr{A} \to \mathscr{B}$ a functor, $G : \mathscr{B} \to \mathscr{A}$ a left adjoint for F, and ϑ an adjunction for the pair (G, F). Then for every $A \in \mathrm{Ob}(\mathscr{A})$ the functor $F_{|A} : \mathscr{A}/A \to \mathscr{B}/FA$ of (1.1.26) admits a left adjoint that we denote

$$G_{|A} : \mathscr{B}/FA \to \mathscr{A}/A.$$

Namely, to every $(f : B \to FA) \in \mathrm{Ob}(\mathscr{B}/FA)$ we assign the object $(\vartheta^{-1}_{AB}(f) : GB \to A) \in \mathrm{Ob}(\mathscr{A}/A)$, and to every morphism $h/FA : (f : B \to FA) \to (f' : B' \to FA)$ in $\mathscr{B}/FA$ we assign the morphism $Gh/A : \vartheta^{-1}_{AB}(f) \to \vartheta^{-1}_{AB'}(f')$ in $\mathscr{A}/A$. Indeed, ϑ induces an adjunction $\vartheta_{|A}$ for the pair $(G_{|A}, F_{|A})$: to every $(f : B \to FA) \in \mathrm{Ob}(\mathscr{B}/FA)$ and $(g : A' \to A) \in \mathrm{Ob}(\mathscr{A}/A)$ we assign the bijection

$$(\vartheta_{|A})_{g,f} : \mathrm{Hom}_{\mathscr{A}/A}(\vartheta^{-1}_{AB}(f), g) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{B}/FA}(f, Fg) \qquad h/A \mapsto \vartheta_{GB,A'}(h)/FA.$$

Dually, since F^o is left adjoint to G^o (remark 1.1.19(iv)), we see that for every $B \in \mathrm{Ob}(\mathscr{B})$ the functor ${}_{B|}G : B/\mathscr{B} \to GB/\mathscr{A}$ of (1.1.26) admits the right adjoint

$${}_{B|}F : GB/\mathscr{A} \to B/\mathscr{B} \qquad (GB \xrightarrow{f} A) \mapsto (B \xrightarrow{\vartheta_{AB}(f)} FA) \qquad GB/h \mapsto B/Fh.$$

The detailed verifications shall be left to the reader. See example 1.2.28 for a related result.

1.1.32. In the situation of (1.1.31) we get furthermore for every $A \in \mathrm{Ob}(\mathscr{A})$ an isomorphism of categories :

$$\vartheta^A : G\mathscr{B}/A \xrightarrow{\sim} \mathscr{B}/FA \qquad (f : GB \to A) \mapsto (\vartheta_{AB}(f) : B \to FA)$$

that assigns to every morphism $g : (f : GB \to A) \to (f' : GB' \to A)$ of $G\mathscr{B}/A$ the morphism $g : (\vartheta_{AB}(f) : B \to FA) \to (\vartheta_{AB'}(f') : B' \to FA)$ of $\mathscr{B}/FA$. Also, for every morphism $h : A \to A'$ of $\mathscr{A}$, we get a commutative diagram of categories :

$$\begin{array}{ccc} G\mathscr{B}/A & \xrightarrow{\vartheta^A} & \mathscr{B}/FA \\ {\scriptstyle G\mathscr{B}/h}\downarrow & & \downarrow{\scriptstyle (Fh)_*} \\ G\mathscr{B}/A' & \xrightarrow{\vartheta^{A'}} & \mathscr{B}/FA'. \end{array}$$

Clearly, the isomorphisms ϑ^A are restrictions of a single isomorphism of categories :

$$G\mathscr{B}/\mathscr{A} \xrightarrow{\sim} \mathscr{B}/F\mathscr{A}.$$

The detailed verifications shall be again left to the reader.

1.2. **Presheaves and limits.** A very important construction associated with every category $\mathscr{C}$ is the category

$$\mathscr{C}^\wedge_{\mathsf{U}} := \mathsf{Fun}(\mathscr{C}^o, \mathsf{U}\text{-}\mathbf{Set})$$

whose objects are called the U-*presheaves* on $\mathscr{C}$ (notation of (1.1.10)). We usually drop the subscript U, unless we have to deal with more than one universe. If U' is another universe with $\mathsf{U} \subset \mathsf{U}'$, the natural inclusion of categories :

$$\mathscr{C}^\wedge_{\mathsf{U}} \to \mathscr{C}^\wedge_{\mathsf{U}'} \tag{1.2.1}$$

is fully faithful (verification left to the reader). For every functor $F : \mathscr{B} \to \mathscr{C}$ and every natural transformation $\alpha : F \Rightarrow G$ we set

$$F^\wedge_{\mathsf{U}} := \mathsf{Fun}(F^o, \mathbf{Set}) : \mathscr{C}^\wedge_{\mathsf{U}} \to \mathscr{B}^\wedge_{\mathsf{U}} \qquad \alpha^\wedge_{\mathsf{U}} := \mathsf{Fun}(\alpha^o, \mathbf{Set}) : G^\wedge_{\mathsf{U}} \Rightarrow F^\wedge_{\mathsf{U}} \tag{1.2.2}$$

(notation of remark 1.1.19(i,ii)). Again, we shall drop the subscript and write simply $F^\wedge$ and $\alpha^\wedge$, unless the omission of U may be a source of ambiguities. Clearly, for every pair of functors $F_1 : \mathscr{A} \to \mathscr{B}$ and $F_2 : \mathscr{B} \to \mathscr{C}$ we have

$$(F_2 \circ F_1)^\wedge = F_1^\wedge \circ F_2^\wedge.$$

Moreover, in the situation of (1.1.10), remark 1.1.19(i,iii) yields the identities

$$(\beta \odot \alpha)^\wedge = \alpha^\wedge \odot \beta^\wedge \qquad \text{and} \qquad (\alpha' * \alpha)^\wedge = \alpha^\wedge * \alpha'^\wedge. \tag{1.2.3}$$

1.2.4. If $\mathscr{C}$ has small Hom-sets (see (1.1.1)), there is a natural functor

$$h_{\mathscr{C}} : \mathscr{C} \to \mathscr{C}^\wedge$$

called the *Yoneda embedding*, which assigns to every $X \in \mathrm{Ob}(\mathscr{C})$ the functor

$$h_X : \mathscr{C}^o \to \mathbf{Set} \qquad Y \mapsto \mathrm{Hom}_{\mathscr{C}}(Y, X) \quad \text{for every } Y \in \mathrm{Ob}(\mathscr{C})$$

and to any morphism $f : X \to X'$ in $\mathscr{C}$, the natural transformation $h_f : h_X \Rightarrow h_{X'}$ such that

$$h_{f,Y}(g) := f \circ g \qquad \text{for every } Y \in \mathrm{Ob}(\mathscr{C}) \text{ and every } g \in \mathrm{Hom}_{\mathscr{C}}(Y, X).$$

Definition 1.2.5. Let $\mathscr{C}$ be a category, and V any universe such that $\mathscr{C}$ has V-small Hom-sets. We say that an object F of $\mathscr{C}^\wedge_{\mathsf{V}}$ is *representable in* $\mathscr{C}$, if there exists an isomorphism

$$h_X \xrightarrow{\sim} F \qquad \text{in } \mathscr{C}^\wedge_{\mathsf{V}}$$

for some $X \in \mathrm{Ob}(\mathscr{C})$, in which case we also say that X *represents* F. From the full faithfulness of (1.2.1), it follows that the representability of a presheaf is independent of the universe V.

Proposition 1.2.6 (Yoneda's lemma)**.** *With the notation of* (1.2.4)*, we have :*

(i) *The functor $h_{\mathscr{C}}$ is fully faithful.*
(ii) *Moreover, for every $F \in \mathrm{Ob}(\mathscr{C}^\wedge)$ and every $X \in \mathrm{Ob}(\mathscr{C})$ there is a natural bijection*

$$F(X) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{C}^\wedge}(h_X, F)$$

functorial in both X and F.

Proof. Clearly it suffices to check (ii). However, the sought bijection is obtained explicitly as follows. To a given $a \in F(X)$, we assign the natural transformation $\tau_a : h_X \Rightarrow F$ such that

$$\tau_{a,Y}(f) := Ff(a) \qquad \text{for every } Y \in \mathrm{Ob}(\mathscr{C}) \text{ and every } f \in h_X(Y).$$

Conversely, to a given natural transformation $\tau : h_X \Rightarrow F$ we assign $\tau_X(\mathbf{1}_X) \in F(X)$. It is easily seen that these rules establish mutually inverse bijections. The functoriality in F is immediate, and the functoriality in the argument X amounts to the commutativity of the diagram

$$\begin{array}{ccc} \mathrm{Hom}_{\mathscr{C}^\wedge}(h_{X'}, F) & \xrightarrow{\sim} & F(X') \\ {\scriptstyle \mathrm{Hom}_{\mathscr{C}^\wedge}(h_\varphi, F)} \downarrow & & \downarrow {\scriptstyle F(\varphi)} \\ \mathrm{Hom}_{\mathscr{C}^\wedge}(h_X, F) & \xrightarrow{\sim} & F(X) \end{array}$$

for every morphism $\varphi : X \to X'$ in $\mathscr{C}$: the verification shall also be left to the reader. □

Example 1.2.7. (i) Every representable presheaf on the category $\mathbf{Set}$ admits a natural representing object. Indeed, let $\mathbb{1}$ denote any set with one element (a canonical choice for $\mathbb{1}$ is the set $\{\varnothing\}$); then for every representable $F \in \mathrm{Ob}(\mathbf{Set}^\wedge)$ we get a natural isomorphism

$$F \xrightarrow{\sim} h_{F(\mathbb{1})}$$

as follows. For any set S, we have a natural bijection $S \xrightarrow{\sim} \mathrm{Hom}_{\mathbf{Set}}(\mathbb{1}, S)$ that assigns to every $s \in S$ the unique map $\mathbb{1}_s : \mathbb{1} \to S$ whose image is $\{s\}$. We deduce a map

$$S \times F(S) \to F(\mathbb{1}) \qquad (s, a) \mapsto F(\mathbb{1}_s)(a)$$

which is the same as a map $F(S) \to \mathrm{Hom}_{\mathbf{Set}}(S, F(\mathbb{1}))$ that realizes the sought isomorphism.

(ii) We may apply Yoneda's lemma to prove the uniqueness of the (left or right) adjoint for a given functor. Indeed, let $G : \mathscr{B} \to \mathscr{A}$ be a functor between any two categories, suppose that F and F' are both right adjoint to G, and fix adjunctions $\vartheta_{\bullet\bullet}$ and $\vartheta'_{\bullet\bullet}$ for F and respectively F'. Choose also a universe U such that both $\mathscr{A}$ and $\mathscr{B}$ are U-small. Then ϑ and ϑ' can be regarded as isomorphisms from the functor $G^\wedge \circ h_{\mathscr{A}}$ to $h_{\mathscr{B}} \circ F$ and respectively to $h_{\mathscr{B}} \circ F'$. In this situation, proposition 1.2.6(i) implies that there exists a unique isomorphism $\omega : F \xrightarrow{\sim} F'$ which makes commute the diagram

$$\begin{array}{ccc} & G^\wedge \circ h_{\mathscr{A}} & \\ {\scriptstyle \vartheta} \swarrow & & \searrow {\scriptstyle \vartheta'} \\ h_{\mathscr{B}} \circ F & \xrightarrow{h_{\mathscr{B}} * \omega} & h_{\mathscr{B}} \circ F'. \end{array}$$

Taking into account remark 1.1.19(iv), a dual argument yields a corresponding uniqueness assertion for left adjoints.

Remark 1.2.8. (i) Let $\mathscr{C}$ be any category, and F_1, F_2 two representable presheaves on $\mathscr{C}$, and pick $X_1, X_2 \in \mathrm{Ob}(\mathscr{C})$ with isomorphisms $\omega_i : h_{X_i} \xrightarrow{\sim} F_i$ ($i = 1, 2$). It follows from proposition 1.2.6(i) that for every morphism $f : F_1 \to F_2$ in $\mathscr{C}^\wedge$ there exists a unique morphism $\varphi : X_1 \to X_2$ in $\mathscr{C}$ that makes commute the diagram

$$\begin{array}{ccc} h_{X_1} & \xrightarrow{h_\varphi} & h_{X_2} \\ \downarrow & & \downarrow \\ F_1 & \xrightarrow{f} & F_2. \end{array}$$

In this situation, we say that φ *represents* the morphism f.

(ii) Likewise, suppose that $G : \mathscr{B} \to \mathscr{C}^\wedge$ is any functor. We say that G is *representable* if there exists a functor $\gamma : \mathscr{B} \to \mathscr{C}$ with an isomorphism $G \xrightarrow{\sim} h_\mathscr{C} \circ \gamma$. It follows easily from (i) that G is representable if and only if $G(B)$ is representable in $\mathscr{C}$ for every $B \in \mathrm{Ob}(\mathscr{B})$. Moreover, any two representatives for G are isomorphic in $\mathsf{Fun}(\mathscr{B}, \mathscr{C})$. Furthermore, if $G, G' : \mathscr{B} \to \mathscr{C}$ are any two representable functors, and $\gamma, \gamma' : \mathscr{B} \to \mathscr{C}$ two corresponding representing functors, then any natural transformation $t : G \Rightarrow G'$ is *represented* uniquely by a natural transformation $\tau : \gamma \Rightarrow \gamma'$, by which we mean that $t = h_\mathscr{C} * \tau$.

1.2.9. *Limits and colimits.* We wish to explain some standard constructions of presheaves that are used pervasively throughout this work. Namely, let I be a small category, $\mathscr{C}$ a category and X any object of $\mathscr{C}$. We denote by $c_X : I \to \mathscr{C}$ the *constant functor* associated with X :

$$c_X(i) := X \quad \text{for every } i \in \mathrm{Ob}(I) \qquad c_X(\varphi) := \mathbf{1}_X \quad \text{for every } \varphi \in \mathrm{Morph}(I).$$

Any morphism $f : X' \to X$ induces a natural transformation

$$c_f : c_{X'} \Rightarrow c_X \qquad \text{by the rule} \ : \ (c_f)_i := f \text{ for every } i \in I.$$

If $F : I \to \mathscr{C}$ is any functor, a *cone of vertex X and basis F* is any natural transformation $c_X \Rightarrow F$. Dually, a *cocone with vertex X and basis F* is a natural transformation $F \Rightarrow c_X$.

Definition 1.2.10. With the notation of (1.2.9), let V be any universe with $\mathsf{U} \subset \mathsf{V}$, such that $\mathscr{C}$ has V-small Hom-sets, and let $F : I \to \mathscr{C}$ be any functor.

(i) The *limit* of F is the V-presheaf on $\mathscr{C}$ denoted

$$\lim_I F : \mathscr{C}^o \to \mathsf{V}\text{-}\mathbf{Set}$$

that assigns to every $X \in \mathrm{Ob}(\mathscr{C})$, the set $\lim_I F(X)$ of all cones $c_X \Rightarrow F$. Any morphism $f : X' \to X$ of $\mathscr{C}$ induces the map

$$\lim_I F(f) : \lim_I F(X) \to \lim_I F(X') \qquad \tau \mapsto \tau \odot c_f \quad \text{for every } \tau : c_X \Rightarrow F.$$

Then we also say that I is the *indexing category* for the limit of F.

(ii) Dually, the *colimit* of F is the V-presheaf on $\mathscr{C}^o$

$$\operatorname*{colim}_I F := \lim_{I^o} F^o.$$

Remark 1.2.11. Let $\mathscr{C}, \mathscr{C}'$ be any two categories with V-small Hom-sets for some universe V such that $\mathsf{U} \subset \mathsf{V}$, and I, I' two small categories.

(i) Any diagram of functors

$$I' \xrightarrow{\varphi} I \xrightarrow{F} \mathscr{C} \xrightarrow{H} \mathscr{C}'$$

induces a natural morphism

$$\lim_\varphi H : \lim_I F \to H^\wedge(\lim_{I'} H \circ F \circ \varphi) \qquad \text{in } \mathscr{C}^\wedge_\mathsf{V}$$

(notation of (1.2.2)) by ruling that

$$\lim_\varphi H(X)(\tau) := H * \tau * \varphi \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C}) \text{ and every cone } \tau : c_X \Rightarrow F$$

(notation of (1.1.10)). If $\psi : I'' \to I'$ and $K : \mathscr{C}' \to \mathscr{C}''$ are any two other functors, with I'' also small and $\mathscr{C}''$ with V-small Hom-sets, the resulting diagram in $\mathscr{C}^\wedge_\mathsf{V}$ commutes :

(1.2.12)
$$\begin{array}{ccc}
\lim_I F & \xrightarrow{\lim_{\varphi\circ\psi} K\circ H} & H^\wedge \circ K^\wedge(\lim_{I''} K \circ H \circ F \circ \varphi \circ \psi) \\
{\scriptstyle \lim_\varphi H}\downarrow & \nearrow {\scriptstyle H^\wedge(\lim_\psi K^\wedge)} & \\
H^\wedge(\lim_{I'} H \circ F \circ \varphi). & &
\end{array}$$

The reader may spell out the corresponding assertions for colimits.

(ii) Any diagram of functors and natural transformations

$$I' \underset{\varphi_2}{\overset{\varphi_1}{\rightrightarrows}} I \underset{F_2}{\overset{F_1}{\rightrightarrows}} \mathscr{C} \qquad (\Downarrow\alpha,\ \Downarrow g)$$

induces commutative diagrams

$$\begin{array}{ccc}
\lim_I F_1 & \xrightarrow{\lim_I g} & \lim_I F_2 \\
{\scriptstyle \lim_{\varphi_1} \mathbf{1}_\mathscr{C}}\downarrow & & \downarrow{\scriptstyle \lim_{\varphi_2} \mathbf{1}_\mathscr{C}} \\
\lim_{I'}(F_1\circ\varphi_1) & \xrightarrow{\lim_{I'}(g*\alpha)} & \lim_{I'}(F_2\circ\varphi_2)
\end{array}
\qquad
\begin{array}{ccc}
\mathrm{colim}_I F_2 & \xrightarrow{\mathrm{colim}_I g} & \mathrm{colim}_I F_1 \\
\downarrow{\scriptstyle \mathrm{colim}_{\varphi_2} \mathbf{1}_\mathscr{C}} & & \downarrow{\scriptstyle \mathrm{colim}_{\varphi_1} \mathbf{1}_\mathscr{C}} \\
\mathrm{colim}_{I'}(F_2\circ\varphi_2) & \xrightarrow{\mathrm{colim}_{I'}(g*\alpha)} & \mathrm{colim}_{I'}(F_1\circ\varphi_1)
\end{array}$$

where the top (resp. bottom) arrow of the left diagram is given by the rule :

$$\tau \mapsto g \odot \tau \qquad (\text{ resp. } \tau \mapsto (g * \alpha) \odot \tau\ )$$

for every $X \in \mathrm{Ob}(\mathscr{C})$ and every cone $\tau : c_X \Rightarrow F_1$ (resp. $\tau : c_X \Rightarrow F_1 \circ \varphi_1$). The top (resp. bottom) arrow of the right diagram is given by the rule

$$\tau \mapsto \tau \odot g \qquad (\text{ resp. } \tau \mapsto \tau \odot (g * \alpha)\ )$$

for every $X \in \mathrm{Ob}(\mathscr{C})$ and every cocone $\tau : F_2 \Rightarrow c_X$ (resp. $\tau : F_2 \circ \varphi_1 \Rightarrow c_X$).

(iii) Suppose that $\lim_I F$ is representable by $L \in \mathrm{Ob}(\mathscr{C})$, so we have an isomorphism

(1.2.13)
$$\omega : h_L \xrightarrow{\sim} \lim_I F \qquad \text{in } \mathscr{C}^\wedge_\mathsf{V}.$$

Notice that the cone $\tau := \omega_L(\mathbf{1}_L)$ determines ω : indeed the latter assigns, to every $X \in \mathrm{Ob}(\mathscr{C})$, the bijection :

$$\omega_X : \mathrm{Hom}_\mathscr{C}(X, L) \xrightarrow{\sim} \lim_I F(X) \qquad f \mapsto \tau \odot c_f.$$

Conversely, we say that a given $\tau : c_L \Rightarrow F$ is a *universal cone*, if the induced map ω_X is a bijection for every $X \in \mathrm{Ob}(\mathscr{C})$, in which case the limit of F is representable by L. Clearly, the universal property for a cone is independent of the choice of auxiliary universe V.

Likewise, if $\mathrm{colim}_I F$ is representable by $C^o \in \mathrm{Ob}(\mathscr{C}^o)$, the choice of an isomorphism

(1.2.14)
$$h_{C^o} \xrightarrow{\sim} \mathrm{colim}_I F \qquad \text{in } (\mathscr{C}^o)^\wedge_\mathsf{V}$$

induces a *universal cocone* $\mu : F \Rightarrow c_C$, which in turns determines (1.2.14) by the rule :

$$\mathrm{Hom}_\mathscr{C}(C, X) \xrightarrow{\sim} \mathrm{colim}_I F(X^o) \qquad f \mapsto c_f \odot \mu.$$

Moreover, with the notation of (ii), suppose that the limits (resp. colimits) of F_1 and F_2 are representable by objects L_1 and L_2 of $\mathscr{C}$ (resp. C_1^o and C_2^o of $\mathscr{C}^o$), and let us fix isomorphisms as (1.2.13) and (1.2.14) for F_1 and F_2. Then :

- The limit of g is represented by a morphism $L_1 \to L_2$ in $\mathscr{C}$.
- The colimit of g is represented by a morphism $C_2^o \to C_1^o$ in $\mathscr{C}^o$, *i.e.* by a morphism $C_1 \to C_2$ in $\mathscr{C}$ (see remark 1.2.8(ii)).

(iv) Every $i \in I$ induces a morphism of presheaves

$$t_i : \lim_I F \to h_{Fi}$$

that assigns to every $X \in \mathrm{Ob}(\mathscr{C})$ and every cone $\tau : c_X \Rightarrow F$ the morphism $\tau_i : X \to Fi$, regarded as an element of $h_{Fi}(X)$. We obtain in this way a natural cone

(1.2.15) $$c_{\lim_I F} \Rightarrow h_{\mathscr{C}} \circ F \qquad i \mapsto t_i$$

where $h_{\mathscr{C}} : \mathscr{C} \to \mathscr{C}^{\wedge}_{\mathsf{V}}$ is the Yoneda embedding. We call (1.2.15) the *tautological cone* associated with F. We claim that the tautological cone is universal. Indeed, say that G is any presheaf on $\mathscr{C}$, and $\tau : c_G \Rightarrow h_{\mathscr{C}} \circ F$ any cone. We define a morphism $f_\tau : G \to \lim_I F$ as follows. To every $i \in \mathrm{Ob}(I)$, the cone τ attaches a morphism of presheaves $\tau_i : G \to h_{Fi}$, which is the datum, for every $X \in \mathrm{Ob}(\mathscr{C})$ of a map $\tau_i^X : G(X) \to \mathrm{Hom}_{\mathscr{C}}(X, Fi)$, and for fixed $s \in G(X)$, the system

$$\tau_\bullet^X(s) := (\tau_i^X(s) : X \to Fi \mid X \in \mathrm{Ob}(\mathscr{C}))$$

is a cone $c_X \Rightarrow F$. Then we let $f_\tau(X) : G(X) \to \lim_I F(X)$ be the map such that $s \mapsto \tau_\bullet^X(s)$ for every $X \in \mathrm{Ob}(\mathscr{C})$ and every $s \in G(X)$. The rule $\tau \mapsto f_\tau$ yields an inverse for the map

$$\omega_G : \mathrm{Hom}_{\mathscr{C}^\wedge}(G, \lim_I F) \to \lim_I h_{\mathscr{C}} \circ F$$

associated, as in (iii), with the cone (1.2.15), whence the claim : details left to the reader.

Dually, with F we may also associate a *tautological cocone*

$$h_{\mathscr{C}^o} \circ F^o \Rightarrow h_{\mathrm{colim}_I F} \qquad \text{in } (\mathscr{C}^o)^\wedge_{\mathsf{V}}$$

which is a universal cocone.

Example 1.2.16. Let V be a universe containing U, and $\mathscr{C}$ any category with V-small Hom-sets.

(i) For $i = 1, 2$, let $f_i : A \to B_i$ be two morphisms in $\mathscr{C}$; the *push-out* or *amalgamated sum* of f_1 and f_2 is the colimit of the functor $F : I \to \mathscr{C}$, defined as follows. The set $\mathrm{Ob}(I)$ consists of three objects s, t_1, t_2 and $\mathrm{Morph}(I)$ consists of two morphisms

$$t_1 \xleftarrow{\varphi_1} s \xrightarrow{\varphi_2} t_2$$

(in addition to the identity morphisms of the objects of I); the functor is given by the rule : $Fs := A$, $Ft_i := B_i$ and $F\varphi_i := f_i$ (for $i = 1, 2$). For any $C \in \mathrm{Ob}(\mathscr{C})$, a cocone $F \Rightarrow c_C$ amounts to a pair of morphisms $f'_i : B_i \to C$ ($i = 1, 2$) such that $f'_1 \circ f_1 = f'_2 \circ f_2$. If the cocone is universal (and thus, C represents the push-out of f_1 and f_2), we say that the resulting commutative diagram :

$$\begin{array}{ccc} A & \xrightarrow{f_1} & B_1 \\ {\scriptstyle f_2}\downarrow & & \downarrow{\scriptstyle f'_1} \\ B_2 & \xrightarrow{f'_2} & C \end{array}$$

is *cocartesian*. Dually one defines the *fibre product* or *pull-back* of two morphisms $g_i : A_i \to B$ ($i = 1, 2$). If $D \in \mathrm{Ob}(\mathscr{C})$ represents this fibre product, a cone with vertex D is given by a pair of morphisms $g'_i : D \to A_i$ ($i = 1, 2$) such that $g_1 \circ g'_1 = g_2 \circ g'_2$, and we say that the diagram :

$$\begin{array}{ccc} D & \xrightarrow{g'_1} & A_1 \\ {\scriptstyle g'_2}\downarrow & & \downarrow{\scriptstyle g_1} \\ A_2 & \xrightarrow{g_2} & B \end{array}$$

is *cartesian* if this cone is universal. The push-out of f_1 and f_2 is a V-presheaf, and is usually just called the amalgamated sum of B_1 and B_2 over A, denoted

$$B_1 \amalg_{(f_1, f_2)} B_2 \qquad \text{or simply} \qquad B_1 \amalg_A B_2$$

unless the notation gives rise to ambiguities. Likewise one writes

$$A_1 \times_{(g_1,g_2)} A_2 \qquad \text{or just} \qquad A_1 \times_B A_2$$

for the fibre product of g_1 and g_2, which is a V-presheaf as well.

(ii) Similarly, consider the category I' with $\mathrm{Ob}(I') = \{s, t\}$, and with $\mathrm{Morph}(I')$ consisting of two morphisms

$$s \overset{\psi_1}{\underset{\psi_2}{\rightrightarrows}} t$$

(in addition to $\mathbf{1}_s$ and $\mathbf{1}_t$). If $A, B \in \mathrm{Ob}(\mathscr{C})$ are any two objects and $f_1, f_2 : A \to B$ any two morphisms, we get a functor $F' : I' \to \mathscr{C}$ by the rule : $s \mapsto A$, $t \mapsto B$ and $\psi_i \mapsto f_i$ for $i = 1, 2$. Then, the colimit of F' is also called the *coequalizer* of f_1 and f_2, and is sometimes denoted

$$\mathrm{Coequal}(f_1, f_2).$$

Dually, the limit of F' is also called the *equalizer* of f_1 and f_2, sometimes denoted

$$\mathrm{Equal}(g_1, g_2).$$

(iii) Let $I \in \mathsf{U}$ be any small set, and $\underline{B} := (B_i \mid i \in I)$ any family of objects of $\mathscr{C}$. We may regard I as a discrete category (see example 1.1.6(ii)), and then the rule $i \mapsto B_i$ yields a functor $I \to \mathscr{C}$, whose limit (resp. colimit) is called the *product* (resp. *coproduct*) of the family $\underline{B}$, and is denoted

$$\prod_{i \in I} B_i \qquad (\text{resp. } \coprod_{i \in I} B_i\ ).$$

If $I = \{1, 2\}$ is a set with exactly two elements, we also write $B_1 \times B_2$ (resp. $B_1 \amalg B_2$) for this limit (resp. colimit), and we call it sometimes a *binary product* (resp. a *binary coproduct*).

(iv) Let $\mathscr{B}$ be any category, and suppose that a given $X \in \mathrm{Ob}(\mathscr{B})$ represents the *empty product* in $\mathscr{B}$, *i.e.* the product of an empty family of objects of $\mathscr{B}$. This means precisely that $\mathrm{Hom}_{\mathscr{B}}(Y, X)$ consists of exactly one element, for every $Y \in \mathrm{Ob}(\mathscr{B})$. Any such X is called a *final object of $\mathscr{B}$*.

Dually, we say that X is an *initial object of $\mathscr{B}$*, if $\mathrm{Hom}_{\mathscr{B}}(X, Y)$ consists of a single element, for every $Y \in \mathrm{Ob}(\mathscr{B})$. Then an object of $\mathscr{B}$ is initial if and only if it represents the *empty coproduct* in $\mathscr{B}$.

Moreover, we shall say that an object X of $\mathscr{B}$ is *disconnected*, if there exist $A, B \in \mathrm{Ob}(\mathscr{B})$, neither of which is an initial object of $\mathscr{B}$, and such that X represents the coproduct $A \amalg B$ (which, again, is well defined in any sufficiently large universe V). We say that X is *connected*, if X is not disconnected and is not an initial object of $\mathscr{B}$.

(v) For instance, the initial object of $\mathbf{Set}$ is the empty set, and any set $\mathbb{1}$ with one element is a final object of $\mathbf{Set}$. More generally, if $\mathscr{B}$ is any category, the initial object of $\mathscr{B}^\wedge$ is the presheaf $\varnothing_{\mathscr{B}}$ such that $\varnothing_{\mathscr{B}}(X) = \varnothing$ for every $X \in \mathrm{Ob}(\mathscr{B})$, and the presheaf $\mathbb{1}_{\mathscr{B}}$ such that $\mathbb{1}_{\mathscr{B}}(X) = \mathbb{1}$ for every $X \in \mathrm{Ob}(\mathscr{B})$ is a final object.

1.2.17. Let $\mathscr{C}$ be a category, $f : A \to B$ a morphism in $\mathscr{C}$; as explained in example 1.2.16(i), the pair of morphisms $B \xleftarrow{\mathbf{1}_B} B \xrightarrow{\mathbf{1}_B} B$ can be regarded as an element $\tau \in (B \amalg_{(f,f)} B)(B)$, which, by Yoneda's lemma (proposition 1.2.6(ii)) corresponds to a morphism

$$\pi_f^o : h_B \to B \amalg_A B \qquad \text{in } (\mathscr{C}^o)^\wedge.$$

If $B \amalg_A B$ is representable in $\mathscr{C}$, this is the same as a morphism

$$\pi_f : B \amalg_A B \to B \qquad \text{in } \mathscr{C}$$

called the *codiagonal of f*. Dually, we have a natural morphism :

$$\iota_f : h_A \to A \times_B A \qquad \text{in } \mathscr{C}^\wedge$$

which – in case $A \times_B A$ is representable in $\mathscr{C}$ – is the same as a *diagonal morphism of f*

$$\iota_f : A \to A \times_B A \qquad \text{in } \mathscr{C}.$$

Proposition 1.2.18. (i) *With the notation of* (1.2.17)*, the following conditions are equivalent :*

(a) *$f : A \to B$ is a monomorphism in $\mathscr{C}$*
(b) *$\iota_f : h_A \to A \times_B A$ is an isomorphism in $\mathscr{C}^\wedge$.*

In case $A \times_B A$ is representable in $\mathscr{C}$, denote by $A \xleftarrow{p_1} A \times_B A \xrightarrow{p_2} A$ the universal cone of this fibre product. Then (a) *and* (b) *are moreover equivalent to :*

(c) *$\iota_f : A \to A \times_B A$ is an isomorphism in $\mathscr{C}$.*
(d) *$\iota_f : A \to A \times_B A$ is an epimorphism in $\mathscr{C}$.*
(e) $p_1 = p_2$.

(ii) *Dually, the following conditions are equivalent :*

(a) *$f : A \to B$ is an epimorphism in $\mathscr{C}$.*
(b) *$\pi^o_f : h_B \to B \amalg_A B$ is an isomorphism in $(\mathscr{C}^o)^\wedge$.*

In case $B \amalg_A B$ is representable in $\mathscr{C}$, denote by $B \xrightarrow{e_1} B \amalg_A B \xleftarrow{e_2} B$ the universal cocone of this amalgamated sum. Then (a) *and* (b) *are moreover equivalent to :*

(c) *$\pi_f : B \amalg_A B \to B$ is an isomorphism in $\mathscr{C}$.*
(d) *$\pi_f : B \amalg_A B \to B$ is a monomorphism in $\mathscr{C}$.*
(e) $e_1 = e_2$.

Proof. (i.a)⇔(i.b): For every $X \in \mathrm{Ob}(\mathscr{C})$ the map $\iota_{f,X} : h_A(X) \to A \times_B A(X)$ is given by the rule : $(X \xrightarrow{g} A) \mapsto (A \xleftarrow{g} X \xrightarrow{g} A)$. Hence, ι_f is an isomorphism if and only if for every $X \in \mathrm{Ob}(\mathscr{C})$ and every pair of morphisms $g_1, g_2 : X \to A$ such that $f \circ g_1 = f \circ g_2$, we have $g_1 = g_2$. This means precisely that f is a monomorphism.

(i.b)⇔(i.c) is clear, since the Yoneda imbedding $h_\mathscr{C}$ is fully faithful.

(i.c)⇒(i.d) is trivial.

(i.d)⇒(i.e): By definition, $p_1 \circ \iota_f = \mathbf{1}_A = p_2 \circ \iota_f$. If ι_f is an epimorphism, then $p_1 = p_2$.

(i.e)⇒(i.c): Set $p := p_1$; since $p \circ \iota_f = \mathbf{1}_A$, it suffices to show that $\iota_f \circ p = \mathbf{1}_{A \times_B A}$. Due to the universality of the cone $A \xleftarrow{p_1} A \times_B A \xrightarrow{p_2} A$, we are then reduced to checking that $p_1 \circ \iota_f \circ p = p_1$ and $p_2 \circ \iota_f \circ p = p_2$, which is clear, since by assumption $p = p_2$.

Assertion (ii) follows from (i) by duality. □

Some special kinds of limits occur frequently in applications; we gather some of them in the following :

Definition 1.2.19. Let I be a category.

(i) We say that I is *finite* if both $\mathrm{Ob}(I)$ and $\mathrm{Morph}(I)$ are finite sets.

(ii) We say that I is *connected*, if $\mathrm{Ob}(I) \neq \varnothing$ and every two objects i, j can be connected by a finite sequence of morphisms in I :

$$i \to k_1 \leftarrow k_2 \to \cdots \leftarrow k_n \to j. \tag{1.2.20}$$

(iii) We say that I is *directed*, if for every $i, j \in \mathrm{Ob}(I)$ there exist $k \in \mathrm{Ob}(\mathscr{C})$ and morphisms $i \to k \leftarrow j$ in I. We say that I is *codirected*, if I^o is directed.

(iv) We say that I is *locally directed* if, for every $i \in \mathrm{Ob}(I)$, the category i/I is directed. We say that I is *locally codirected*, if I^o is locally directed.

(v) We say that I is *pseudo-filtered* if it is locally directed, and the following *coequalizing condition* holds. For any $i, j \in \mathrm{Ob}(I)$, and any two morphisms $f, g : i \to j$, there exist $k \in \mathrm{Ob}(I)$ and a morphism $h : j \to k$ such that $h \circ f = h \circ g$.

(vi) We say that I is *filtered*, if it is pseudo-filtered and connected. We say that I is *cofiltered* if I^o is filtered.

(vii) Let $F : I \to \mathscr{C}$ be a functor to any category $\mathscr{C}$. Then $\lim_I F$ is a well defined V-presheaf, for any sufficiently large universe V, and we say that *the limit of* F *is small* (resp. *connected*, resp. *codirected*, resp. *locally codirected*, resp. *cofiltered*, resp. *finite*), if I is small (resp. connected, resp. codirected, resp. locally codirected, resp. cofiltered, resp. finite). Dually, one defines *small*, *connected*, *directed*, *locally directed*, *filtered* and *finite* colimits.

(viii) We say that a category $\mathscr{C}$ is *complete* (resp. *finitely complete*) if every small limit (resp. finite limit) of $\mathscr{C}$ is representable in $\mathscr{C}$. We say that $\mathscr{C}$ is *cocomplete* (resp. *finitely cocomplete*) if every small colimit (resp. finite colimit) of $\mathscr{C}$ is representable in $\mathscr{C}^o$.

Remark 1.2.21. Let I be any category.

(i) If I is connected and locally directed, then I is directed. Indeed, let i, j be any two objects of I; we have to show that there exist $k \in \mathrm{Ob}(I)$ and morphisms $a : i \to k$ and $b : j \to k$. However, by assumption there exists a sequence (1.2.20), for some $n \in \mathbb{N}$ and objects $k_1, \dots, k_n$ of I. Then, a simple induction reduces the assertion to the case where $n = 2$. But since I is locally directed, we may then find $k \in \mathrm{Ob}(I)$ and morphisms $c : k_1 \to k$, $b : j \to k$, so it suffices to take $a := c \circ d$, where $d : i \to k_1$ is the morphism appearing in (1.2.20). Dually, if I is connected and locally codirected, then I is codirected.

It follows that a category I is filtered if and only if it is directed, satisfies the coequalizing condition of definition 1.2.19(v), and its set of objects is non-empty.

(ii) Let I be a small category. It is easily seen that I is connected if and only if it is a connected object of the category $\mathbf{Cat}$ (see example 1.2.16(iv)). In general, there is a natural decomposition in $\mathbf{Cat}$:

$$I \stackrel{\sim}{\to} \coprod_{s \in S} I_s$$

where each I_s is a connected category, and S is a small set. We call $\{I_s \mid s \in S\}$ the *set of connected components* of I, and we denote it

$$\pi_0(I).$$

Especially, every small pseudo-filtered category is a coproduct of a (small) family of filtered categories. This decomposition induces natural isomorphisms in $\mathscr{A}^\wedge$:

$$\operatorname*{colim}_I F \stackrel{\sim}{\to} \coprod_{s \in S} \operatorname*{colim}_{I_s} F \circ e_s \qquad \lim_I F \stackrel{\sim}{\to} \prod_{s \in S} \lim_{s \in S} F \circ e_s$$

for any functor $F : I \to \mathscr{A}$, where $e_s : I_s \to I$ is the natural inclusion functor, for every $s \in S$. The details shall be left to the reader.

Proposition 1.2.22. *For any category* $\mathscr{C}$ *we have :*

- (i) $\mathscr{C}$ *is complete (resp. finitely complete) if and only if the following conditions hold :*
  - (a) *The product of every small (resp. finite) family of objects is representable in* $\mathscr{C}$.
  - (b) *All equalizers are representable in* $\mathscr{C}$.
- (ii) *Dually,* $\mathscr{C}$ *is cocomplete (resp. finitely cocomplete) if and only if the following holds :*
  - (a) *The coproduct of any small (resp. finite) family of objects is representable in* $\mathscr{C}$.
  - (b) *All coequalizers are representable in* $\mathscr{C}$.

Proof. Clearly it suffices to show (i). Now, conditions (a) and (b) obviously hold if $\mathscr{C}$ is complete. Conversely, suppose that the conditions hold, let I be any small (resp. finite) category, and $F : I \to \mathscr{C}$ any functor. We regard $\mathrm{Ob}(I)$ (resp. $\mathrm{Morph}(I)$) as a discrete subcategory of I (resp. of $\mathsf{Morph}(I)$: see example 1.1.6(ii)), and we consider the diagram

$$\mathrm{Morph}(I) \underset{\mathrm{t}}{\overset{\mathrm{s}}{\rightrightarrows}} \mathrm{Ob}(I) \xrightarrow{\mathrm{ob}} I$$

where s and t are respectively the restrictions of the functors s and t from (1.1.30), and ob is the inclusion functor. We let as well $\mathrm{m} : \mathrm{ob} \circ \mathrm{s} \Rightarrow \mathrm{ob} \circ \mathrm{t}$ be the restriction of the natural transformation m of (1.1.30). By assumption, we may find objects $P, Q \in \mathrm{Ob}(\mathscr{C})$ with isomorphisms

$$\omega_P : h_P \xrightarrow{\sim} L_1 := \lim_{\mathrm{Ob}(I)} F \circ \mathrm{ob} \qquad \omega_Q : h_Q \xrightarrow{\sim} L_2 := \lim_{\mathrm{Morph}(I)} F \circ \mathrm{ob} \circ \mathrm{t} \qquad \text{in } \mathscr{C}^\wedge_{\mathsf{V}}$$

for any universe V such that $\mathscr{C}$ has V-small Hom-sets. We define two morphisms of presheaves $a, b : L_1 \to L_2$ by the rules :

$$a(\mu) := \mu * \mathrm{t} \qquad \text{and} \qquad b(\mu) := (F * \mathrm{m}) \odot (\mu * \mathrm{s})$$

for every $X \in \mathrm{Ob}(\mathscr{C})$ and every cone $\mu : c_X \Rightarrow F \circ \mathrm{ob}$. Then a and b are represented by unique morphisms $\alpha, \beta : P \to Q$ in $\mathscr{C}$ (see example 1.2.8(i)) such that

$$a \circ \omega_P = \omega_Q \circ h_\alpha \qquad \text{and} \qquad b \circ \omega_P = \omega_Q \circ h_\beta.$$

Lastly, let $E := \mathrm{Equal}(\alpha, \beta)$ (notation of example 1.2.16(ii)), and notice that the tautological cone for E yields a monomorphism $E \to h_P$, so we may regard E as a subobject of h_P; it follows easily that ω_P restricts to an isomorphism between $E \subset h_P$ and the presheaf $E' \subset L_1$ such that, for every $X \in \mathrm{Ob}(\mathscr{C})$, the set $E'(X)$ consists of all the cones $\mu : c_X \Rightarrow F \circ \mathrm{ob}$ with $a(\mu) = b(\mu)$. A simple inspection shows that the latter condition describes precisely the cones $c_X \Rightarrow F$; on the other hand, by assumption E is representable in $\mathscr{C}$, so the same holds for the limit of F. □

Example 1.2.23. (i) The category $\mathbf{Set}$ is complete and cocomplete. More precisely, for any small family of sets $S_\bullet := (S_i \mid i \in I)$ we have natural representatives for the product and coproduct of $S_\bullet$: namely, for the product one may take the usual cartesian product of the sets S_i, and for the coproduct one may take the disjoint union

$$\coprod_{i \in I} S_i := \bigcup_{i \in I} (\{i\} \times S_i).$$

Likewise, we have natural representatives for the equalizer and coequalizer of any pair of maps $f, g : S \to S'$: namely, the equalizer of f and g is represented by the subset

$$\mathrm{Equal}(f, g) := \{s \in S \mid f(s) = g(s)\}$$

and the coequalizer is represented by the quotient $S'/\sim$, where $\sim$ is the smallest equivalence relation on S' whose graph contains the subset $\{(f(s), g(s)) \mid s \in S\}$. Taking into account proposition 1.2.22(i,ii), we get natural representatives for all limits and colimits in $\mathbf{Set}$. For instance, by inspecting the proof of proposition 1.2.22(i), we see that the colimit of a functor $F : I \to \mathbf{Set}$ (for any small category I) is represented by the quotient

$$C(F) := \Big(\coprod_{i \in \mathrm{Ob}(I)} Fi \Big) / \sim$$

where $\sim$ is the smallest equivalence relation such that $(i, s) \sim (j, F(\varphi)(s))$ for every morphism $\varphi : i \to j$ in I and every $s \in Fi$. In the special case where I is filtered, this equivalence relation can be described more explicitly : namely $(i, s) \sim (i', s')$ if and only if there exist $j \in \mathrm{Ob}(I)$ and morphisms $\varphi : i \to j$, $\varphi' : i' \to j$ such that $F(\varphi)(s) = F(\varphi')(s')$.

For a general small category I, to every $i \in \mathrm{Ob}(I)$ we may attach a natural map $\tau_i : Fi \to C(F)$: namely, $\tau_i(s)$ is the class of (i, s) in $C(F)$, for every $s \in Fi$; then the system $(\tau_i \mid i \in \mathrm{Ob}(I))$ yields a universal cocone $\tau : F \Rightarrow c_{C(F)}$, in the sense of remark 1.2.11(iii).

(ii) In view of (i) and example 1.2.7, we can also give a more compact description of the limit of any functor $F : I \to \mathbf{Set}$: namely, if $\mathbb{1}$ is any fixed set with one element, the set

$L(F) := \lim_I F(\mathbb{1})$, consisting of all cones $c_{\mathbb{1}} \Rightarrow F$, is another natural representative for the limit of F. More precisely, we get a natural isomorphism

$$h_{L(F)} \xrightarrow{\sim} \lim_I F \qquad \text{in } \mathbf{Set}^\wedge$$

as follows. A map of sets $S \to L(F)$ amounts to a system of cones $\{\tau_s : c_{\mathbb{1}} \Rightarrow F \mid s \in S\}$, and the latter is naturally identified with a cone $c_S \Rightarrow F$ (details left to the reader). We easily deduce the following natural universal cone $\tau : c_{L(F)} \Rightarrow F$. For every $i \in \mathrm{Ob}(I)$, the map $\tau_i : L(F) \to Fi$ assigns to any cone $\mu : c_{\mathbb{1}} \Rightarrow F$ the image of $\mu_i : \mathbb{1} \to Fi$.

Example 1.2.24. (i) More generally, for every category $\mathscr{C}$, the category $\mathscr{C}^\wedge$ is complete and cocomplete. Indeed, let I be any small category, and $F : I \to \mathscr{C}^\wedge$ any functor. For every $X \in \mathrm{Ob}(\mathscr{C})$ we obtain a functor $F_X : I \to \mathbf{Set}$ such that $i \mapsto Fi(X)$ for every $i \in \mathrm{Ob}(I)$ and $(\varphi : i \to j) \mapsto (F\varphi(X) : Fi(X) \to Fj(X))$ for every morphism φ of I; we let LX be the natural representative for $\lim_I F_X$, and $\tau^X : c_{LX} \Rightarrow F_X$ the corresponding universal cone, as described in example 1.2.23(ii). Every morphism $f : X \to Y$ in $\mathscr{C}$ induces a natural transformation $F_f : F_Y \Rightarrow F_X$ by the rule : $i \mapsto Fi(f) : F_Y(i) \to F_X(i)$, whence a natural transformation $\lim_I F_f : \lim_I F_Y \Rightarrow \lim_I F_X$ (remark 1.2.11(ii)) which is in turn represented by a unique map of sets $Lf : LY \to LX$ such that

$$\tau^X \odot c_{Lf} = F_f \odot \tau^Y$$

(remark 1.2.8(ii)). It is then easily seen that the rules : $X \mapsto LX$ and $f \mapsto Lf$ yield a well defined presheaf L on $\mathscr{C}$. Also, for every $i \in \mathrm{Ob}(I)$ the rule $X \mapsto \tau_i^X$ yields a morphism of presheaves $\tau_i^\bullet : L \to Fi$, and the rule $i \mapsto \tau_i^\bullet$ yields a cone $\tau : c_L \Rightarrow F$. Now, let $\eta : c_G \Rightarrow F$ be any cone with vertex $G \in \mathrm{Ob}(\mathscr{C}^\wedge)$. For every $X \in \mathrm{Ob}(\mathscr{C})$ we deduce a cone $\eta^X : c_{G,X} \Rightarrow F_X$ by the rule : $i \mapsto \eta_i(X) : GX = G_X(i) \to F_X(i)$, whence a unique morphism $t_X : GX \to LX$ such that $\tau^X \odot c_{t_X} = \eta^X$. With this notation, a direct inspection shows that the diagram

$$\begin{array}{ccc} c_{G,Y} & \xRightarrow{\eta^Y} & F_Y \\ {\scriptstyle c_{G,f}} \Downarrow & & \Downarrow {\scriptstyle F_f} \\ c_{G,X} & \xRightarrow{\eta^X} & F_X \end{array}$$

commutes for every morphism $f : X \to Y$ of $\mathscr{C}$. Thus, $\tau^X \odot c_{t_X \circ G,f} = F_f \odot \tau^Y \odot c_{t_Y} = \tau^X \odot c_{Lf \circ t_Y}$, whence $t_X \circ Gf = Lf \circ t_Y$, by the universality of τ^X. In other words, the rule : $X \mapsto t_X$ yields a morphism $t : G \to L$ in $\mathscr{C}^\wedge$, and by construction, it is clear that t is the unique such morphism with $\tau \odot c_t = \eta$. This shows that τ is a universal cone, whence the completeness of $\mathscr{C}^\wedge$. A similar argument proves the cocompleteness of $\mathscr{C}^\wedge$: the details are left to the reader.

(ii) Furthermore, let $F : I \to \mathscr{C}$ be a functor from a small category I, whose limit $\mathscr{L}$ (which is an object of $\mathscr{C}^\wedge_{\mathsf{V}}$ for a suitable universe V) is representable by some $L \in \mathrm{Ob}(\mathscr{C})$. Let $\tau : c_L \Rightarrow F$ be a universal cone and denote by $\omega : h_L \xrightarrow{\sim} \mathscr{L}$ the isomorphism corresponding to τ, as in remark 1.2.11(iii).. Then the limit of $h_{\mathscr{C}} \circ F : I \to \mathscr{C}^\wedge_{\mathsf{V}}$ is represented by h_L and $h_{\mathscr{C}} * \tau : c_{h_L} \Rightarrow h_{\mathscr{C}} \circ F$ is a universal cone. Indeed, let $t : c_{\mathscr{L}} \Rightarrow h_{\mathscr{C}} \circ F$ be the tautological cone (remark 1.2.11(iv)); a simple inspection shows that the resulting diagram

$$\begin{array}{ccccc} & & c_{h_L} & & \\ & {\scriptstyle c_\omega} \swarrow & & \searrow {\scriptstyle h_{\mathscr{C}} * \tau} & \\ c_{\mathscr{L}} & & \xRightarrow{\quad t \quad} & & h_{\mathscr{C}} \circ F \end{array}$$

commutes. On the other hand, we know that t is universal, so the same follows for $h_{\mathscr{C}} * \tau$.

Example 1.2.25. (i) Also the category $\mathbf{Cat}$ is complete and cocomplete. Indeed :

• If $F : I \to \mathbf{Cat}$ is any functor from a small category I, the limit of F is representable by the category $\mathscr{C}$ with $\mathrm{Ob}(\mathscr{C}) := \lim_I \mathrm{Ob} \circ F$, where $\mathrm{Ob} : \mathbf{Cat} \to \mathbf{Set}$ is the functor of example 1.1.6(ii). Hence, an object of $\mathscr{C}$ is a family $(C_i \mid i \in \mathrm{Ob}(I))$ where $C_i \in \mathrm{Ob}(\mathscr{C}_i)$ for every $i \in I$, and $F(\varphi)(C_i) = C_j$ for every $\varphi : i \to j$ in I. For any two objects $C_\bullet := (C_i \mid i \in I)$ and $C'_\bullet := (C'_i \mid i \in I)$, notice that the rule $i \mapsto \mathrm{Hom}_{\mathscr{C}_i}(C_i, C'_i)$ defines a functor $H_{C_\bullet, C'_\bullet} : I \to \mathbf{Set}$; namely, to every $\varphi : i \to j$ in I we assign the map $H_{C_\bullet,C'_\bullet}(i) \to H_{C_\bullet,C'_\bullet}(j)$ given by $F(\varphi) : \mathrm{Morph}(\mathscr{C}_i) \to \mathrm{Morph}(\mathscr{C}_j)$. Then we set

$$\mathrm{Hom}_{\mathscr{C}}(C_\bullet, C'_\bullet) := \lim_I H_{C_\bullet,C'_\bullet}.$$

The composition of morphisms in $\mathscr{C}$ is induced by the composition laws of the categories $\mathscr{C}_i$, in the obvious way. The obvious projection functors $\mathscr{C} \to \mathscr{C}_i$ yield a universal cone for $\lim_I F$.

• Especially, for any pair of functors

$$\mathscr{A} \xrightarrow{F} \mathscr{C} \xleftarrow{G} \mathscr{B}$$

the fibre product (in the category $\mathbf{Cat}$) of F and G is represented by the category :

$$\mathscr{A} \times_{(F,G)} \mathscr{B}$$

whose set of objects is $\mathrm{Ob}(\mathscr{A}) \times_{\mathrm{Ob}(\mathscr{C})} \mathrm{Ob}(\mathscr{B})$; the morphisms $(A, B) \to (A', B')$ are the pairs (f, g) where $f : A \to A'$ (resp. $g : B \to B'$) is a morphism in $\mathscr{A}$ (resp. in $\mathscr{B}$), such that $Ff = Gg$. If the notation is not ambiguous, we may also denote this category by $\mathscr{A} \times_{\mathscr{C}} \mathscr{B}$. In case $\mathscr{B}$ is a subcategory of $\mathscr{C}$ and G is the natural inclusion functor, we also write $F^{-1}\mathscr{B}$ instead of $\mathscr{A} \times_{\mathscr{C}} \mathscr{B}$. The two obvious functors $\mathscr{A} \leftarrow \mathscr{A} \times_{\mathscr{C}} \mathscr{B} \to \mathscr{B}$ provide a universal cone.

• If $(\mathscr{C}_i \mid i \in I)$ is any small family of categories, the coproduct $\mathscr{C} := \amalg_{i\in I}\mathscr{C}_i$ is the category whose set of objects is the disjoint union $\amalg_{i\in I}\mathrm{Ob}(\mathscr{C}_i)$ (see example 1.2.23(i)). Hence, an object of $\mathscr{C}$ is a pair (i, C), with $i \in I$ and $C \in \mathrm{Ob}(\mathscr{C}_i)$. For any two such objects (i, C) and (i', C'), we have

$$\mathrm{Hom}_{\mathscr{C}}((i, C), (i', C')) = \begin{cases} \mathrm{Hom}_{\mathscr{C}_i}(C, C') & \text{if } i = i' \\ \varnothing & \text{otherwise.} \end{cases}$$

The obvious inclusion functors $\mathscr{C}_i \to \mathscr{C}$ provide a universal cocone. The proof of the cocompleteness of $\mathbf{Cat}$ shall be postponed to example 1.5.20 (see [28, Prop.5.1.7] for a more constructive proof, and also example 1.5.10).

(ii) For any category $\mathscr{A}$, the objects of the fibre product category $\mathsf{Morph}(\mathscr{A}) \times_{(\mathsf{t},\mathsf{s})} \mathsf{Morph}(\mathscr{A})$ are just the composable pairs of morphisms of $\mathscr{A}$ (notation of (1.1.30)), and the morphisms are the pairs of commutative square diagrams that have one vertical edge in common. Thus, we have a natural *composition functor*

$$\mathsf{c} : \mathsf{Morph}(\mathscr{A}) \times_{(\mathsf{t},\mathsf{s})} \mathsf{Morph}(\mathscr{A}) \to \mathsf{Morph}(\mathscr{A})$$

such that $\mathsf{c}(f, g) := g \circ f$ for every composable pair of morphisms of $\mathscr{A}$, and where c assigns to every pair of commutative square diagrams

$$\begin{array}{ccccc} A & \xrightarrow{f} & B & \xrightarrow{g} & C \\ {\scriptstyle h_1}\downarrow & & {\scriptstyle h_2}\downarrow & & \downarrow{\scriptstyle h_3} \\ A' & \xrightarrow{f'} & B' & \xrightarrow{g'} & C' \end{array}$$

their composition, which is the square diagram whose top (resp. bottom) horizontal arrow is $g \circ f$ (resp. $g' \circ f'$) and whose vertical arrows are h_1 and h_3.

(iii) We can use the constructions of (ii) to rephrase the definition of the composition laws for natural transformations. Indeed, let us return to the situation of (1.1.10), and denote by

$$\widetilde{\alpha}, \widetilde{\beta} : \mathscr{A} \to \mathrm{Morph}(\mathscr{B})$$

the functors attached to α and β as in (1.1.30). Clearly $\mathsf{t} \circ \widetilde{\alpha} = \mathsf{s} \circ \widetilde{\beta}$, whence a unique functor

$$(\widetilde{\alpha}, \widetilde{\beta}) : \mathscr{A} \to \mathsf{Morph}(\mathscr{B}) \times_{(\mathsf{t},\mathsf{s})} \mathsf{Morph}(\mathscr{B})$$

whose composition with the first (second) projection to $\mathsf{Morph}(\mathscr{B})$ equals $\widetilde{\alpha}$ (resp. $\widetilde{\beta}$). Then it is easily seen that $\mathsf{c} \circ (\widetilde{\alpha}, \widetilde{\beta}) : \mathscr{A} \to \mathsf{Morph}(\mathscr{A})$ is the (unique) functor associated with $\beta \odot \alpha$.

The Godement product of two natural transformations α and α' as in (1.1.10) can be similarly described : to this aim, notice that

$$(G' * \alpha) \odot (\alpha' * F) = \alpha' * \alpha = (\alpha' * G) \odot (F' * \alpha)$$

so we are reduced to exhibit the functors $\mathscr{A} \to \mathsf{Morph}(\mathscr{C})$ associated with $G' * \alpha$ and $\alpha' * F$. However, it is easily seen that the latter are respectively $\mathsf{Morph}(G') \circ \widetilde{\alpha}$ and $\widetilde{\alpha}' \circ F$ (details left to the reader). These considerations shall be amplified in section 2.1, in order to construct analogous composition laws for pseudo-natural transformations : see remark 2.2.5.

Example 1.2.26. Let $\mathscr{C}$ be any category, and $\varphi : X \to Y$ any morphism of $\mathscr{C}$. The *image* of φ

$$\mathrm{Im}(\varphi)$$

is defined the smallest of the subobjects $Y' \to Y$ such that φ factors through a (necessarily unique) morphism $X \to Y'$. If the image of φ exists, clearly a subobject $Z' \to Y$ contains $\mathrm{Im}(\varphi)$ if and only if φ factors through Z'.

(i) In this generality, the image of φ does not necessarily exists; however, suppose that all equalizers in $\mathscr{C}$ are representable, and the same for the limit (*i.e.* the intersection) of any system of subobjects of Y in $\mathscr{C}$ (these limits are well defined U-presheaves, for a sufficiently large universe U). Then we claim that φ admits an image $i : Z \to Y$, and the unique morphism $p : X \to Z$ such that $\varphi = i \circ p$ is an epimorphism. Indeed, let $\mathscr{F}$ be the family of subobjects $Y' \to Y$ such that φ factors through Y'; choose – for every equivalence class $c \in \mathscr{F}$ – a representing monomorphism $Y_c \to Y$, and let I be the full subcategory of $\mathscr{C}/Y$ such that $\mathrm{Ob}(I) = \{Y_c \to Y \mid c \in \mathscr{F}\}$. Then I is a U-small category, and we let i (any representing object for) the limit of the inclusion functor $\iota : I \to \mathscr{C}/Y$. The resulting system of morphisms $(X \to Y_c \mid c \in \mathscr{F})$ is a cone on the indexing category I, whence a unique morphism $p : X \to Z$, as required. To show that p is an epimorphism, consider any two morphisms $f, g : Z \to Z'$ (for any $Z' \in \mathrm{Ob}(\mathscr{C})$) such that $f \circ p = g \circ p$, and let $E \in \mathrm{Ob}(\mathscr{C})$ be any object representing the equalizer of f and g. Thus, the induced morphism $\psi : E \to Z$ a monomorphism, hence E is a subobject of Y, and φ still factors through E. By the minimality of Z, we deduce that ψ is an isomorphism, and therefore $f = g$, whence the claim.

(ii) Dually, if all coequalizers in $\mathscr{C}$ are representable, and the same for the colimit of any system of quotients of X in $\mathscr{C}$, then the family of all quotients of X through which φ factors admits a smallest element $\psi' : X \to Z$, so that a quotient Z' of X maps to Z if and only if φ factors through Z'. Arguing as in (i), we see that the resulting morphism $Z' \to Y$ is also a monomorphism. We call Z the *coimage* of φ, and we denote it $\mathrm{Coim}(\varphi)$.

(iii) If both the image and the coimage of φ exist in $\mathscr{C}$, we get a natural factorization of φ

$$X \to \mathrm{Im}(\varphi) \xrightarrow{\omega} \mathrm{Coim}(\varphi) \to Y.$$

But ω is not necessarily an isomorphism, in this generality.

Remark 1.2.27. (i) If all equalizers and all amalgamated sums are representable in the category $\mathscr{C}$, then one can alternatively define the image of any morphism $\varphi : X \to Y$ of $\mathscr{C}$ as the equalizer of the natural morphisms $e_1, e_2 : Y \to Y \amalg_X Y$. This definition does not necessarily agree with that of example 1.2.26(i), but if every monomorphism $i : Z \to Y$ of $\mathscr{C}$ is *regular*, *i.e.* represents the equalizer of a pair of morphisms $f, g : Y \to Y'$, then one can show that the two definitions coincide.

(ii) Dually, if all coequalizers and all fibre products are representable in $\mathscr{C}$, then one has a (dual) alternative definition of coimages, which does not necessarily agree with that of example 1.2.26(ii), unless all the epimorphisms of $\mathscr{C}$ are *regular*, *i.e.* unless all the monomorphisms of $\mathscr{C}$ are regular.

(iii) Moreover, if $\mathscr{C}$ is both finitely complete and finitely cocomplete, then these alternative images $\mathrm{Im}^*(\varphi)$ and coimages $\mathrm{Coim}^*(\varphi)$ as in (i) and (ii) are well defined for every morphism $\varphi : X \to Y$, and we get a natural factorization of φ :

$$X \to \mathrm{Coim}^*(\varphi) \xrightarrow{\omega^*} \mathrm{Im}^*(\varphi) \to Y$$

where, again, ω^* is not necessarily an isomorphism.

Example 1.2.28. (i) In the situation of (1.1.31), let $\eta_\bullet : \mathbf{1}_{\mathscr{B}} \Rightarrow FG$ and $\varepsilon_\bullet : GF \Rightarrow \mathbf{1}_{\mathscr{A}}$ be the unit and counit of the adjunction ϑ, and suppose that *all the fibre products of $\mathscr{B}$ are representable*; then for every $B \in \mathrm{Ob}(\mathscr{B})$ the functor $G_{|B} : \mathscr{B}/B \to \mathscr{A}/GB$ admits a right adjoint, denoted

$$F_{|B} : \mathscr{A}/GB \to \mathscr{B}/B.$$

Indeed, for every object $(g : A \to GB)$ of $\mathscr{A}/GB$ let us fix a cartesian diagram :

$$\begin{array}{ccc} F^*A & \xrightarrow{F^*g} & B \\ {\scriptstyle \eta^*_A}\downarrow & & \downarrow{\scriptstyle \eta_B} \\ FA & \xrightarrow{Fg} & FGB. \end{array}$$

If $h/GB : (g : A \to GB) \to (g' : A' \to GB)$ is a morphism in $\mathscr{A}/GB$, the universal property of the fibre product yields a unique morphism $F^*h : F^*A \to F^*A'$ such that $F^*g' \circ F^*h = F^*g$ and $F^*g' \circ \eta^*_{A'} = Fh \circ \eta^*_A$. With this notation, we set

$$F_{|B}(A, g) := (F^*A, F^*g) \qquad \text{and} \qquad F_{|B}(h/GB) := F^*h/B : F_{|B}(A, g) \to F_{|B}(A', g')$$

for every such (A, g) and h/GB. It is easily seen that these rules define a functor as sought. In order to check that $F_{|B}$ is right adjoint to $G_{|B}$, consider any morphism

$$h/GB : G_{|B}(B' \xrightarrow{f} B) \to (A \xrightarrow{g} GB) \qquad \text{in } \mathscr{A}/GB.$$

Hence, $h : GB' \to A$ is a morphism in $\mathscr{A}$ with $g \circ h = Gf$, and we notice that :

$$Fg \circ \vartheta(h) = Fg \circ Fh \circ \eta_{B'} = FGf \circ \eta_{B'} = \eta_B \circ f.$$

It follows that the pair $(\vartheta_{AB'}(h), f)$ determines a unique morphism $k : B' \to F^*A$ such that $\eta^*_A \circ k = \vartheta_{AB'}(h)$ and $F^*g \circ k = f$. With this notation, we set $(\vartheta_{|B})_{g,f}(h/GB) := k/B : f \to F^*g$ in $\mathscr{B}/B$. Conversely, to every morphism $k/B : (f : B' \to B) \to F_{|B}(g : A \to GB)$ in $\mathscr{B}/B$, we attach the morphism $h := \vartheta^{-1}_{AB'}(\eta^*_A \circ k) : GB' \to A$. Let us show that $h/GB : Gf \to g$ is a morphism in $\mathscr{A}/GB$; recalling that $F^*g \circ k = f$, it suffices to compute :

$$g \circ h = g \circ \varepsilon_A \circ G(\eta^*_A \circ k) = \varepsilon_{GB} \circ GFg \circ G(\eta^*_A \circ k) = \varepsilon_{GB} \circ G(\eta_B \circ F^*g \circ k) = Gf$$

where the last equality follows from the triangular identities of (1.1.13). Hence the map

$$(\vartheta_{|B})_{g,f} : \mathrm{Hom}_{\mathscr{A}/GB}(G_{|B}f, g) \to \mathrm{Hom}_{\mathscr{B}/B}(f, F_{|B}g)$$

is a bijection with inverse given by the rule : $k/B \mapsto \vartheta^{-1}_{AB'}(\eta^*_A \circ k)/GB$. Indeed, by definition $(\vartheta_{|B})_{g,f}(\vartheta^{-1}_{AB'}(\eta^*_A \circ k)/GB)$ is the morphism $f \to F_{|B}g$ of $\mathscr{B}/B$ determined by the pair $(\vartheta_{AB'}\vartheta^{-1}_{AB'}(\eta^*_A \circ k), f) = (\eta^*_A \circ k), f)$, which is just k/B, and on the other hand, $\vartheta^{-1}_{AB'}(\eta^*_A \circ (\vartheta_{|B})_{g,f}(h/GB)) = \vartheta^{-1}_{AB'}\vartheta_{AB'}(h)/GB = h/GB$, whence the contention. The naturality of $(\vartheta_{|B})_{g,f}$ with respect to g and f follows by a simple inspection : details left to the reader.

(ii) Dually, if *all the coproducts of $\mathscr{A}$ are representable*, then the functor ${}_{A|}F : A/\mathscr{A} \to FA/\mathscr{B}$ admits a left adjoint ${}_{A|}G : FA/\mathscr{B} \to A/\mathscr{A}$, which the reader is invited to spell out.

(iii) Keep the situation of (i), and let $F' : \mathscr{B} \to \mathscr{C}$ be another functor with a left adjoint $G' : \mathscr{C} \to \mathscr{B}$. Then we have an isomorphism of functors :

$$F'_{|C} \circ F_{|G'C} \xrightarrow{\sim} (F'F)_{|C} \qquad \text{for every } C \in \mathrm{Ob}(\mathscr{C}).$$

Indeed, clearly we have $G_{|G'C} \circ G'_C = (GG')_{|C}$, so the assertion follows from example 1.2.7(ii).

1.3. **Adjunctions and Kan extensions.** Let $\varphi : I \to J$ be a functor between small categories. The calculation of limits indexed by I can be sometimes simplified by a Fubini-style technique of "integration along the fibres of φ", which replaces any given functor $F : I \to \mathscr{C}$ (to any category $\mathscr{C}$) with another functor $J \to \mathscr{C}^\wedge$ whose limit is isomorphic to that of F. Namely, let V be a universe containing U, such that $\mathscr{C}$ has V-small Hom-sets; notice first that by virtue of remark 1.2.11(ii), the limit construction yields a well defined functor

$$\lim_I : \mathsf{Fun}(I, \mathscr{C}) \to \mathscr{C}^\wedge_\mathsf{V} \qquad F \mapsto \lim_I F.$$

Moreover, if $\mathscr{C}$ is complete (resp. if I is finite and $\mathscr{C}$ is finitely complete), this functor is naturally isomorphic to the composition of the Yoneda embedding $h_\mathscr{C}$ and a functor

$$\mathop{\mathrm{Lim}}_I : \mathsf{Fun}(I, \mathscr{C}) \to \mathscr{C}$$

which is right adjoint to the *constant functor*

(1.3.1) $$c : \mathscr{C} \to \mathsf{Fun}(I, \mathscr{C}) \qquad X \mapsto c_X \qquad (f : X \to Y) \mapsto (c_f : c_X \Rightarrow c_Y)$$

(notation of (1.2.9)), and especially, it is well defined up to isomorphism (example 1.2.7(ii)). We define now as follows a functor

$$\int_\varphi^\wedge : \mathsf{Fun}(I, \mathscr{C}) \to \mathsf{Fun}(J, \mathscr{C}^\wedge_\mathsf{V}).$$

For every functor $F : I \to \mathscr{C}$, every $j \in \mathrm{Ob}(J)$, and every morphism $g : j \to j'$ in J we set

$$\int_\varphi^\wedge F(j) := \lim_{j/\varphi I} F \circ \mathsf{t}_j \qquad \int_\varphi^\wedge F(g) := \lim_{g/\varphi I} \mathbf{1}_\mathscr{C}$$

(notation of (1.1.27) and remark 1.2.11(i)). We may then state :

Proposition 1.3.2. *With the notation of* (1.3)*, the diagram*

$$\begin{array}{ccc} \mathsf{Fun}(I, \mathscr{C}) & \xrightarrow{\lim_I} & \mathscr{C}^\wedge_\mathsf{V} \\ {\scriptstyle \int_\varphi^\wedge} \downarrow & \nearrow_{\mathrm{Lim}_J} & \\ \mathsf{Fun}(J, \mathscr{C}^\wedge_\mathsf{V}) & & \end{array}$$

is essentially commutative, i.e. *there is a natural isomorphism of functors :* $\lim_I \xrightarrow{\sim} \mathrm{Lim}_J \circ \int_\varphi^\wedge$.

Proof. Notice that the functor Lim_J is well defined by virtue of example 1.2.24. Let $F : I \to \mathscr{C}$ be any functor; unwinding the definitions, we see that $\mathrm{Lim}_J \circ \int_\varphi^\wedge F$ is isomorphic to the presheaf that assigns to every $X \in \mathrm{Ob}(\mathscr{C})$ the set of all compatible systems

$$\tau_\bullet^\bullet := (\tau_\bullet^j : c_X \Rightarrow F \circ \mathsf{t}_j \mid j \in \mathrm{Ob}(J))$$

such that $\tau_\bullet^{j'} = \tau_\bullet^j * (g/\varphi I)$ for every morphism $g : j \to j'$ in J. Explicitly, $\tau_\bullet^\bullet$ is the datum, for every $(h : j' \to \varphi i) \in \mathrm{Ob}(J/\varphi I)$, of a morphism $\tau_h^j : X \to Fi$ in $\mathscr{C}$, such that

$$\tau_{h \circ g}^j = \tau_h^{j'} \quad \text{and} \quad Ff \circ \tau_h^j = \tau_{\varphi(f) \circ h}^j$$

for every g as above, and every morphism $f : i \to i'$ in I. Clearly, every such system is determined by the family $(\overline{\tau}_i := \tau_{\mathbf{1}_{\varphi i}}^{\varphi i} \mid i \in \mathrm{Ob}(I))$, and the latter is a cone $\overline{\tau}_\bullet : c_X \Rightarrow F$. Conversely, given any cone $\mu_\bullet : c_X \Rightarrow F$, the family $\overline{\mu}_\bullet^\bullet := (\mu_\bullet * \mathsf{t}_j \mid j \in \mathrm{Ob}(J))$ is a compatible system of the foregoing type. A simple inspection shows that the rules $\tau^\bullet_\bullet \mapsto \overline{\tau}_\bullet$ and $\mu_\bullet \mapsto \overline{\mu}^\bullet_\bullet$ are mutually inverse, whence the proposition. $\square$

Remark 1.3.3. (i) In the situation of (1.3), suppose moreover that $\mathscr{C}$ is complete. Then $\int_\varphi^\wedge$ is isomorphic to the composition of the functor $\mathsf{Fun}(J, h_\mathscr{C})$ (notation of remark 1.1.19(ii) and (1.2.4)) and a functor

$$\int_\varphi : \mathsf{Fun}(I, \mathscr{C}) \to \mathsf{Fun}(J, \mathscr{C})$$

called the *right Kan extension along* φ. Taking into account example 1.2.24(ii), proposition 1.3.2 implies that the resulting diagram

$$\begin{array}{ccc} \mathsf{Fun}(I,\mathscr{C}) & \xrightarrow{\mathrm{Lim}_I} & \mathscr{C} \\ {\scriptstyle \int_\varphi}\downarrow & \nearrow_{\mathrm{Lim}_J} & \\ \mathsf{Fun}(J,\mathscr{C}) & & \end{array}$$

is also essentially commutative (details left to the reader).

(ii) By remark 1.2.11(ii), we may also define a colimit functor

$$\operatorname*{colim}_I : \mathsf{Fun}(I, \mathscr{C}) \to \mathscr{C}^{o\wedge o}_\mathsf{V} \qquad F \mapsto \operatorname*{colim}_I F$$

and notice that the isomorphism of remark 1.1.19(i) identifies this functor with the opposite of the functor $\lim_{I^o}$ defined on $\mathsf{Fun}(I^o, \mathscr{C}^o_\mathsf{V})$. Consequently, if $\mathscr{C}$ is cocomplete (resp. if I is finite and $\mathscr{C}$ is finitely cocomplete), colim_I is isomorphic to the composition of $h^o_{\mathscr{C}^o}$ and of a functor

$$\operatorname*{Colim}_I : \mathsf{Fun}(I, \mathscr{C}) \to \mathscr{C}$$

which is likewise identified with the opposite of the functor $\mathrm{Lim}_{I^o} : \mathsf{Fun}(I^o, \mathscr{C}^o) \to \mathscr{C}^o$. Notice as well that Colim_I is left adjoint to the constant functor (1.3.1). Moreover, the opposite of the functor $\int^\wedge_{\varphi^o}$ on $\mathsf{Fun}(I^o, \mathscr{C}^o)$ is identified with a functor

$$\int_\wedge^\varphi : \mathsf{Fun}(I, \mathscr{C}) \to \mathsf{Fun}(J, \mathscr{C}^{o\wedge o}_\mathsf{V}).$$

Explicitly, we have

$$\int_\wedge^\varphi F(j) = \operatorname*{colim}_{\varphi I/j} F \circ \mathsf{s}_j \qquad \text{for every functor } F : I \to \mathscr{C} \text{ and every } j \in \mathrm{Ob}(J)$$

(where s_j is the source functor) and we get an essentially commutative diagram :

$$\begin{array}{ccc} \mathsf{Fun}(I,\mathscr{C}) & \xrightarrow{\mathrm{colim}_I} & \mathscr{C}^{o\wedge o}_\mathsf{V} \\ {\scriptstyle \int^\varphi_\wedge}\downarrow & \nearrow_{\mathrm{Colim}_J} & \\ \mathsf{Fun}(J,\mathscr{C}^{o\wedge o}_\mathsf{V}) & & \end{array}$$

Notice the natural identification : $\mathscr{C}^{o\wedge o}_\mathsf{V} \xrightarrow{\sim} \mathsf{Fun}(\mathscr{C}^o, \mathsf{V}\text{-}\mathbf{Set}^o)$, again due to remark 1.1.19(i). If $\mathscr{C}$ is cocomplete, the opposite of the functor $\int_{\varphi^o}$ is naturally identified with a functor

$$\int^\varphi : \mathsf{Fun}(I, \mathscr{C}) \to \mathsf{Fun}(J, \mathscr{C})$$

called the *left Kan extension along* φ, fitting into the essentially commutative diagram :

$$\begin{array}{ccc} \mathsf{Fun}(I,\mathscr{C}) & \xrightarrow{\mathrm{Colim}_I} & \mathscr{C} \\ {\scriptstyle \int^\varphi}\downarrow & \nearrow_{\mathrm{Colim}_J} & \\ \mathsf{Fun}(J,\mathscr{C}). & & \end{array}$$

(iii) Notice that the functors $\int_\varphi^\wedge$ and $\int_\wedge^\varphi$ are defined more generally whenever I is small and J has small Hom-sets. Likewise, if $\mathscr{C}$ is complete (resp. cocomplete) the right (resp. left) Kan extension along φ is well defined under the same weakened assumptions.

(iv) In the same vein, if the category $j/\varphi I$ (resp. $\varphi I/j$) is finite for every $j \in \mathrm{Ob}(J)$, for the right (resp. left) Kan extension along φ to be well defined it suffices that $\mathscr{C}$ is finitely complete (resp. finitely cocomplete).

Theorem 1.3.4. *Let I, J and $\mathscr{C}$ be categories fulfilling the conditions of either part* (iii) *or part* (iv) *of remark* 1.3.3*, and $\varphi : I \to J$ any functor. Then the right (resp. left) Kan extension along $\varphi : I \to J$ is right (resp. left) adjoint to the functor*

$$\mathsf{Fun}(\varphi,\mathscr{C}) : \mathsf{Fun}(J,\mathscr{C}) \to \mathsf{Fun}(I,\mathscr{C}) \qquad G \mapsto G \circ \varphi.$$

Proof. (Cp. [28, Th.3.7.2] or [110, Th.2.3.3]). Pick a universe V containing U, and such that $\mathscr{C}$ has V-small Hom-sets. In light of Yoneda's lemma (proposition 1.2.6(ii)) we get for every pair of functors $F : I \to \mathscr{C}$ and $G : J \to \mathscr{C}$ a natural bijection

$$\mathrm{Hom}_{\mathsf{Fun}(J,\mathscr{C})}\Big(G, \int_\varphi F\Big) \xrightarrow{\sim} \mathrm{Hom}_{\mathsf{Fun}(J,\mathscr{C}^\wedge_{\mathsf{V}})}\Big(h_\mathscr{C} \circ G, \int_\varphi^\wedge F\Big)$$

where $h_\mathscr{C} : \mathscr{C} \to \mathscr{C}^\wedge_{\mathsf{V}}$ is the Yoneda embedding of (1.2.4). Hence, in order to prove the assertion for right Kan extensions, it suffices to exhibit a natural bijection :

$$\mathrm{Hom}_{\mathsf{Fun}(I,\mathscr{C})}(G \circ \varphi, F) \xrightarrow{\sim} \mathrm{Hom}_{\mathsf{Fun}(J,\mathscr{C}^\wedge_{\mathsf{V}})}\Big(h_\mathscr{C} \circ G, \int_\varphi^\wedge F\Big). \tag{1.3.5}$$

Notice that, by virtue of proposition 1.2.6(ii), if $X \in \mathrm{Ob}(\mathscr{C})$ and $j \in \mathrm{Ob}(J)$ are any two objects, a morphism $h_X \to \int_\varphi^\wedge F(j)$ in $\mathscr{C}^\wedge_{\mathsf{V}}$ is the same as the datum of a cone $c_X \Rightarrow F \circ \mathsf{t}_j$, where $\mathsf{t}_j : j/\varphi I \to I$ is the target functor. Now, let $\tau : G \circ \varphi \Rightarrow F$ be any natural transformation; for every $j \in \mathrm{Ob}(J)$ and every $(i, f : j \to \varphi(i)) \in \mathrm{Ob}(j/\varphi I)$ we set

$$\tau'_{j,(i,f)} := \tau_i \circ Gf : Gj \to Fi.$$

It is easily seen that, for fixed $j \in \mathrm{Ob}(J)$, the system $(\tau'_{j,(i,f)} \mid (i,f) \in \mathrm{Ob}(j/\varphi I))$ gives a cone $\tau'_j : c_{Gj} \Rightarrow F \circ \mathsf{t}_X$, *i.e.* a morphism $h_{Gj} \to \int_\varphi^\wedge F(j)$ in $\mathscr{C}^\wedge_{\mathsf{V}}$, and the rule $j \mapsto \tau'_j$ for every $j \in \mathrm{Ob}(J)$ yields a natural transformation $\tau' : h_\mathscr{C} \circ G \Rightarrow \int_\varphi^\wedge F$. Conversely, if $\mu : h_\mathscr{C} \circ G \Rightarrow \int_\varphi^\wedge F$ is any such transformation, every $j \in \mathrm{Ob}(J)$ yields a cone $\mu_j : c_{Gj} \Rightarrow F \circ \mathsf{t}_j$, and we define a natural transformation $\mu' : G \circ \varphi \Rightarrow F$ by setting

$$\mu'_i := \mu_{\varphi(i),(i,\mathbf{1}_{\varphi(i)})} : G \circ \varphi(i) \to Fi \qquad \text{for every } i \in \mathrm{Ob}(I).$$

The reader can check that $(\tau')' = \tau$ and $(\mu')' = \mu$ for every τ and μ as above, and clearly the resulting bijections (1.3.5) are functorial in both F and G. The assertion for left Kan extensions, in case $\mathscr{C}$ is cocomplete, is dual to the foregoing, by virtue of remark 1.1.19(i). □

Remark 1.3.6. (i) Let $F : \mathscr{B} \to \mathscr{C}$ be a functor from a small category $\mathscr{B}$ to any category $\mathscr{C}$ with small Hom-sets; from theorem 1.3.4 we obtain both a left and a right adjoint for $F^\wedge_{\mathsf{U}} = \mathsf{Fun}(F^o, \mathsf{U}\text{-}\mathbf{Set})$, denoted respectively

$$F_{\mathsf{U}!} : \mathscr{B}^\wedge_{\mathsf{U}} \to \mathscr{C}^\wedge_{\mathsf{U}} \qquad \text{and} \qquad F_{\mathsf{U}*} : \mathscr{B}^\wedge_{\mathsf{U}} \to \mathscr{C}^\wedge_{\mathsf{U}}.$$

As usual, we drop the subscript U, unless the omission may cause ambiguities.

(ii) With the notation of (i), notice that the diagram of functors :

$$\begin{array}{ccc} \mathscr{B} & \xrightarrow{h_{\mathscr{B}}} & \mathscr{B}^\wedge \\ {\scriptstyle F}\downarrow & & \downarrow{\scriptstyle F_!} \\ \mathscr{C} & \xrightarrow{h_{\mathscr{C}}} & \mathscr{C}^\wedge \end{array} \tag{1.3.7}$$

(whose horizontal arrows are the Yoneda embeddings) is *essentially commutative*, *i.e.* the two compositions $F_! \circ h_{\mathscr{B}}$ and $h_{\mathscr{C}} \circ F$ are isomorphic functors. Indeed – by proposition 1.2.6(ii) – for every $B \in \mathrm{Ob}(\mathscr{B})$, the objects $F_! h_B$ and h_{FB} both represent the functor

$$\mathscr{C}^\wedge \to \mathbf{Set} \quad : \quad \varphi \mapsto \varphi(FB)$$

(the latter is a V-presheaf on $\mathscr{C}^{\wedge o}$, for any universe V such that $\mathscr{C}^\wedge$ has small Hom-sets).

(iii) Moreover, taking into account example 1.2.23 we see that there are natural choices for the left and right adjoints of the functor $F^\wedge$. Namely :

- For any presheaf f on $\mathscr{B}$, the presheaf $F_! f$ on $\mathscr{C}$ can be given canonically by the rule :

$$C \mapsto \operatorname*{colim}_{(C/F\mathscr{B})^o} f \circ \mathsf{t}^o_C \qquad \text{for every } C \in \mathrm{Ob}(\mathscr{C}) \tag{1.3.8}$$

where the colimits in this expression denote (by abuse of notation) the natural representatives for the corresponding presheaves, as described in example 1.2.23(i). Therefore, every element of $F_! f(C)$ is the equivalence class of a pair $(\psi : C \to FB, s)$, where ψ is any object of $C/F\mathscr{B}$ and $s \in fB$ is any element. If $\varphi : C' \to C$ is any morphism of $\mathscr{C}$, the induced map $F_! f(\varphi) : F_! f(C) \to F_! f(C')$ assigns to any such pair the equivalence class of the pair $(\psi \circ \varphi : C' \to FB, s)$. Furthermore, the adjunction for the pair $(F_!, F^\wedge)$ provided by the proof of theorem 1.3.4 comes down to the natural bijection

$$\mathrm{Hom}_{\mathscr{B}^\wedge}(f, F^\wedge g) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{C}^\wedge}(F_! f, g) \qquad \text{for every } f \in \mathrm{Ob}(\mathscr{B}^\wedge) \text{ and } g \in \mathrm{Ob}(\mathscr{C}^\wedge)$$

which, to any morphism $\tau : f \to F^\wedge g$ in $\mathscr{B}^\wedge$ and to any $C \in \mathrm{Ob}(\mathscr{C})$ assigns the map of sets $F_! f(C) \to gC$ given by the rule :

$$(\psi : C \to FB, s) \mapsto g(\psi) \circ \tau_B(s) \qquad \text{for every } (B, \psi) \in \mathrm{Ob}(C/F\mathscr{B}) \text{ and every } s \in fB.$$

The inverse to this bijection assigns to any morphism $\mu : F_! f \to g$ and any $B \in \mathrm{Ob}(\mathscr{B})$ the map $f(B) \to g(FB)$ given by the rule :

$$s \mapsto \mu_{FB}(\mathbf{1}_{FB}, s) \qquad \text{for every } s \in f(B).$$

- And the presheaf $F_* f$ can be chosen canonically by the rule :

$$C \mapsto \lim_{(F\mathscr{B}/C)^o} f \circ \mathsf{s}^o_C(\mathbb{1}) \qquad \varphi \mapsto \lim_{(F\mathscr{B}/\varphi)^o} \mathbf{1}_{\mathscr{B}}(\mathbb{1})$$

for every $C \in \mathrm{Ob}(\mathscr{C})$ and every morphism $\varphi : C' \to C$ in $\mathscr{C}$ (notation of (1.1.27), and $\mathbb{1}$ is any fixed set with one element). More explicitly, under this identification, the map $F_* f(\varphi) : F_* f(C) \to F_* f(C')$ is given by the rule :

$$(\tau : c_{\mathbb{1}} \Rightarrow f \circ \mathsf{s}^o_C) \mapsto (\tau * (F\mathscr{B}/\varphi)^o : c_{\mathbb{1}} \Rightarrow f \circ \mathsf{s}^o_{C'}).$$

(iv) Let V be a universe such that $\mathsf{U} \subset \mathsf{V}$. Notice that, with the canonical choices of (iii), we get a commutative diagram of categories

$$\begin{array}{ccccc} \mathscr{C}^\wedge_{\mathsf{U}} & \xleftarrow{F_{\mathsf{U}*}} & \mathscr{B}^\wedge_{\mathsf{U}} & \xrightarrow{F_{\mathsf{U}!}} & \mathscr{C}^\wedge_{\mathsf{U}} \\ \downarrow & & \downarrow & & \downarrow \\ \mathscr{C}^\wedge_{\mathsf{V}} & \xleftarrow{F_{\mathsf{V}*}} & \mathscr{B}^\wedge_{\mathsf{V}} & \xrightarrow{F_{\mathsf{V}!}} & \mathscr{C}^\wedge_{\mathsf{V}} \end{array}$$

whose vertical arrows are the inclusion functors.

(v) Lastly, with the canonical choices in (iii), we can make (ii) more precise : we get a natural identification

$$F_! h_B \xrightarrow{\sim} h_{FB} \qquad \text{for every } B \in \mathrm{Ob}(\mathscr{B}).$$

Namely, to any pair $(\psi' : Y \to FB', s : B' \to B)$ consisting of an object of $Y/F\mathscr{B}$ and an element $s \in h_B(B')$, we attach the element $\beta(\psi', s) := F(s) \circ \psi' \in h_{FB}(Y)$, and it is easily seen that $\beta(\psi', s)$ depends only on the class of (ψ', s) in $F_! h_B(Y)$, whence the required functorial bijection (details left to the reader). Notice as well that – under these identifications – the unit of the adjunction for the pair $(F_!, F^\wedge)$ explicited in (iii) becomes the natural morphism

$$h_B \to F^\wedge h_B \quad : \quad (s : B' \to B) \mapsto (Fs : FB' \to FB) \qquad \text{for every } B \in \mathrm{Ob}(B).$$

Example 1.3.9. Let $\mathbb{1}_{\mathscr{B}}$ be a final object of $\mathscr{B}^\wedge$ (see example 1.2.16(v)); by specializing the explicit description of $F_!$ provided by remark 1.3.6(iii), we get a natural isomorphism

$$F_!(\mathbb{1}_{\mathscr{B}}) \xrightarrow{\sim} \pi_0(\bullet/F\mathscr{B}) \qquad \text{in } \mathscr{C}^\wedge$$

where $\pi_0(\bullet/F\mathscr{B})$ is the presheaf that assigns to any $C \in \mathrm{Ob}(\mathscr{C})$ the set $\pi_0(C/F\mathscr{B})$, and to any morphism $\varphi : C' \to C$ in $\mathscr{C}$ the map $\pi_0(\varphi/F\mathscr{B}) : \pi_0(C/F\mathscr{B}) \to \pi_0(C'/F\mathscr{B})$ induced by $\varphi/F\mathscr{B}$ in the obvious way (notation of (1.1.27) : we leave the verification to the reader).

1.3.10. For many questions, it is useful to know whether a given functor commutes with a certain limit, or more generally with a prescribed class of limits (or colimits), in the sense explained by the following :

Definition 1.3.11. Let I, $\mathscr{C}$ and $\mathscr{D}$ be any three categories, and $F : I \to \mathscr{C}$, $f : \mathscr{C} \to \mathscr{D}$ two functors. Pick also a universe V such that I, $\mathscr{C}$ and $\mathscr{D}$ are V-small.

(i) According to remark 1.2.11(i) we have a natural morphism in $\mathscr{C}^\wedge_{\mathsf{V}}$

$$\lim_I F \to f^\wedge_{\mathsf{V}} \lim_I (f \circ F) \tag{1.3.12}$$

whence – by the explicit adjunction of remark 1.3.6(iii) – a morphism in $\mathscr{D}^\wedge_{\mathsf{V}}$

$$f_{\mathsf{V}!}(\lim_I F) \to \lim_I (f \circ F). \tag{1.3.13}$$

Then, we say that f *commutes with the limit of* F, if (1.3.13) is an isomorphism.

(ii) We say that f *commutes with the colimit of* F, if the dual condition holds, *i.e.* if f^o commutes with the limit of F^o, so the natural morphism

$$f^o_{\mathsf{V}!}(\operatorname*{colim}_I F) \to \operatorname*{colim}_I (f \circ F)$$

is an isomorphism.

(iii) We say that the functor f is *left exact*, if f commutes with all finite limits. Dually, we say that f is *right exact* if it commutes with all finite colimits. Finally, we say that f is *exact* if it is both left and right exact.

It follows easily from remark (1.3.6)(iv) that these definitions depend only on f and F, and not on the choice of the universe V.

Remark 1.3.14. (i) Keep the situation of definition 1.3.11. The most interesting case is that where the limit of F is representable, say by an object L of $\mathscr{C}$, so we have an isomorphism $\beta : h_L \xrightarrow{\sim} \lim_I F$. Indeed, in this case, by remark 1.3.6(v) we deduce a morphism

$$\gamma : h_{fL} \xrightarrow{\sim} f_! h_L \xrightarrow{\sim} f_! \lim_I F \to \lim_I (f \circ F)$$

that is an isomorphism if and only if f commutes with the limit of F, in which case we see that the limit of $f \circ F$ is representable by fL. More precisely, let $\tau := \beta_L(\mathbf{1}_L) : c_L \Rightarrow F$ be the universal cone deduced from β; we claim that

$$\gamma_{fL}(\mathbf{1}_{fL}) = f * \tau : c_{fL} \Rightarrow f \circ F$$

so f commutes with the limit of F if and only if $f * \tau$ is a universal cone for $f \circ F$. Indeed, notice that the composition $h_L \to f^\wedge_\vee \lim_I(f \circ F)$ of β and (1.3.12) assigns, to any $C \in \mathrm{Ob}(\mathscr{C})$ and any morphism $s : C \to L$ in $\mathscr{C}$, the cone $(f * \tau) \odot c_{fs} : c_{fC} \Rightarrow f \circ F$. In light of remark 1.3.6(iii), it follows that the adjoint morphism $f_! h_L \to \lim_I f \circ F$ assigns, to every $D \in \mathrm{Ob}(\mathscr{D})$ and every pair $(\psi : D \to fC, s : C \to L)$ the cone $(f * \tau) \odot c_{fs} \odot c_\psi : c_D \Rightarrow f \circ F$. Lastly, notice that the isomorphism $f_! h_L \xrightarrow{\sim} h_{fL}$ provided from remark 1.3.6(v) maps the pair $(\mathbf{1}_{fL}, \mathbf{1}_L)$ to $\mathbf{1}_{fL} \in h_{fL}(fL)$; we conclude that $\gamma_{fL}(\mathbf{1}_{fL}) = (f * \tau) \odot c_{f\mathbf{1}_L} \odot c_{\mathbf{1}_{fL}} = f * \tau$, as claimed.

(ii) Dually, suppose that the colimit of F is representable by an object C^o of $\mathscr{C}^o$, and pick any universal cocone $\mu : F \Rightarrow c_C$. Then f commutes with the colimit of F if and only if $f * \mu$ is a universal cocone for $f \circ F$.

Example 1.3.15. (i) Let $\mathscr{C}$ be any category, V a universe such that $\mathscr{C}$ has V-small Hom-sets, and $f : \mathscr{C}^o \to \mathsf{V}\text{-}\mathbf{Set}$ a representable functor. Then it is easily seen that for every small category I, every functor $F : I \to \mathscr{C}$ and every universal cocone $\tau : F \Rightarrow c_X$, the induced cone $f * \tau^o : c_{fX} \Rightarrow f \circ F^o$ is universal. In view of remark 1.3.14(i), we conclude that f commutes with all the representable limits of $\mathscr{C}^o$ (which are the representable colimits of $\mathscr{C}$). On the other hand, if $\mathscr{C}$ has small Hom-sets and all small products of $\mathscr{C}$ are representable, then f commutes even with non-representable colimits of $\mathscr{C}$: see example 1.4.4(i).

(ii) Dually, if $f : \mathscr{C} \to \mathbf{Set}$ is a functor representable by some object Y^o of the opposite category $\mathscr{C}^o$, then f commutes with all representable limits of $\mathscr{C}$, and even with non-representable limits, if all small coproducts of $\mathscr{C}$ are representable and $\mathscr{C}$ has small Hom-sets.

Example 1.3.16. (i) Let $\mathscr{A}$ be any finitely complete category, and $F : \mathscr{A} \to \mathscr{B}$ any left exact functor. Then the category $B/F\mathscr{A}$ is cofiltered, for every $B \in \mathrm{Ob}(\mathscr{B})$. Indeed, if $\varphi_i : B \to FA_i$ $(i = 1, 2)$ are any two objects of $B/F\mathscr{A}$, the product $A_1 \times A_2$ is representable by some object A of $\mathscr{A}$, and a universal cone is given by a pair of morphisms $(p_i : A \to A_i \mid i = 1, 2)$; by remark 1.3.14(i), it follows that the pair $(Fp_i : FA \to FA_i \mid i = 1, 2)$ is still a universal cone for the product $FA_1 \times FA_2$, whence a unique morphism $\varphi : B \to FA$ such that $Fp_i \circ \varphi = \varphi_i$ for $i = 1, 2$. This shows that $B/F\mathscr{A}$ is codirected. Moreover, if A is any final object of $\mathscr{A}$, then FA is a final object of $\mathscr{B}$, hence $\mathrm{Ob}(B/F\mathscr{A})$ is non-empty. By remark 1.2.21(i), it then remains only to check that $B/F\mathscr{A}$ satisfies the equalizing condition dual to that of definition 1.2.19(v). Namely, let φ_1 and φ_2 as in the foregoing, and suppose we have a pair of morphisms $\psi, \psi' : A_1 \to A_2$ such that $F\psi \circ \varphi_1 = \varphi_2 = F\psi' \circ \varphi_1$. The equalizer of ψ and ψ' is representable by some object E of $\mathscr{A}$, and a universal cone for E is given by a morphism $\beta : E \to A_1$ such that $\psi \circ \beta = \psi' \circ \beta$; by remark 1.3.14(i), FE represents the equalizer of $F\psi$ and $F\psi'$, and $F\beta : FE \to FA_1$ still yields a universal cone. There follows a unique morphism $\gamma : B \to FE$ in $\mathscr{B}$ such that $F\beta \circ \gamma = \varphi_1$, whence the claim.

(ii) Dually, if $\mathscr{A}$ is finitely cocomplete and F is right exact, then the category $F\mathscr{A}/B$ is filtered for every $B \in \mathrm{Ob}(\mathscr{B})$.

Proposition 1.3.17. *Let I, $\mathscr{C}$, $\mathscr{D}$ and $\mathscr{E}$ be four categories, and $F : I \to \mathscr{C}$, $f : \mathscr{C} \to \mathscr{D}$ and $g : \mathscr{D} \to \mathscr{E}$ any three functors. The following holds :*

- (i) *If f commutes with the limit of F, and g commutes with the limit of $f \circ F$, then $g \circ f$ commutes with the limit of F.*
- (ii) *Especially, if both f and g are left (resp. right) exact, then the same holds for $g \circ f$.*

Proof. Clearly it suffices to show (i), and after replacing U by a larger universe, we may assume that the four categories of the proposition are small. Set $L := \lim_I F$, $L' := \lim_I(f \circ F)$, $L'' := \lim_I(g \circ f \circ F)$, and denote

$$\omega_{f,F} : L \to f^\wedge L' \qquad \text{and} \qquad \omega_{g,f\circ F} : L' \to g^\wedge L''$$

the morphisms provided by remark 1.2.11(i). Let also (ε^f, η^f) (resp. (ε^g, η^g)) be the units and counits associated with the explicit adjunction ϑ_f (resp ϑ_g) for the pair $(f_!, f^\wedge)$ (resp. $(g_!, g^\wedge)$) provided by remark 1.3.6(iii); by assumption, the adjoint morphisms

$$\omega^*_{f,F} := \varepsilon^f_{L'} \circ (f_!\omega_{f,F}) : f_!L \to L' \qquad \text{and} \qquad \omega^*_{g,f\circ F} := \varepsilon^g_{L''} \circ (g_!\omega_{g,f\circ F}) : g_!L' \to L''$$

are isomorphisms, so the same holds for $\omega^{**}_{g\circ f,F} := \omega^*_{g,f\circ F} \circ g_!\omega^*_{f,F} : g_! \circ f_!L \to L''$. However :

$$\omega^{**}_{g\circ f,F} = \varepsilon^g_{L''} \circ g_!(\omega_{g,f\circ F} \circ \omega^*_{f,F})$$

corresponds, under the adjunction ϑ_g, to the morphism $\omega_{g,f\circ F} \circ \omega^*_{f,F} : f_!L \to g^\wedge L''$. The latter, in turns, corresponds – under the adjunction ϑ_f – to the morphism

$$\omega_{g\circ f,F} := f^\wedge(\omega_{g,f\circ F} \circ \omega^*_{f,F}) \circ \eta^f_L : L \to f^\wedge \circ g^\wedge L'' = (g \circ f)^\wedge L''$$

and notice that $f^\wedge(\omega^*_{f,F}) \circ \eta^f_L = \omega_{f,F}$. Taking into account (1.2.12), we conclude that $\omega_{g\circ f,F}$ is precisely the natural morphism denoted $\lim_{\mathbf{1}_I}(g \circ f)$ in remark 1.2.11(i).

Summing up, we have shown that, under the adjunction $\vartheta_g \circ \vartheta_f$ for the pair $(g_! \circ f_!, (g \circ f)^\wedge)$ (notation of remark 1.1.17(i)), the morphism $\omega_{g\circ f,F}$ corresponds to the isomorphism $\omega^{**}_{g\circ f,F}$. Then the assertion follows from example 1.2.7(ii). □

Proposition 1.3.18. *Let $\mathscr{C}, \mathscr{D}$ be two categories, $F : \mathscr{C} \to \mathscr{D}$ a functor, and $\varphi : X \to Y$ a morphism in $\mathscr{C}$. The following holds :*

(i) *If F commutes with pull backs and φ is a monomorphism, then $F\varphi$ is a monomorphism.*
(ii) *If F commutes with push-outs and φ is an epimorphism, then $F\varphi$ is an epimorphism.*

Proof. (i): After replacing U by a larger universe, we may assume that $\mathscr{C}$ and $\mathscr{D}$ have small Hom-sets. Notice then that the tautological cone of $X \times_Y X$ amounts to a pair of morphisms

$$p_1, p_2 : X \times_Y X \to h_X \qquad \text{in } \mathscr{C}^\wedge$$

such that $h_\varphi \circ p_1 = h_\varphi \circ p_2$ (see remark 1.2.11(iv)), and the diagonal morphism $\iota_\varphi : h_X \to X \times_Y X$ (see (1.2.17)) is characterized as the unique morphism in $\mathscr{C}^\wedge$ such that $p_1 \circ \iota_\varphi = \mathbf{1}_{h_X} = p_2 \circ \iota_\varphi$. Likewise we can characterize $\iota_{F\varphi}$. Now, by assumption there exist unique morphisms j and q_i for $i = 1, 2$, fitting into a commutative diagram

(1.3.19)
$$\begin{array}{ccccc} F_!h_X & \xrightarrow{F_!\iota_\varphi} & F_!(X \times_Y X) & \xrightarrow{F_!p_i} & F_!h_X \\ \downarrow & & \downarrow & & \downarrow \\ h_{FX} & \xrightarrow{j} & FX \times_{FY} FX & \xrightarrow{q_i} & h_{FX} \end{array}$$

whose leftmost and rightmost vertical arrows are the natural identifications of remark 1.3.6(v), and whose central vertical arrow is the isomorphism given by definition 1.3.11(i). Taking into account proposition 1.2.18(i), we see that the assertion will follow, once we know that $j = \iota_{F\varphi}$. However, the composition of the two top horizontal arrows equals $\mathbf{1}_{F_!h_X}$, so the composition of the bottom horizontal arrows is $\mathbf{1}_{h_{FX}}$, and thus we come down to showing :

Claim 1.3.20. q_1 and q_2 are the two morphisms defining the tautological cone for $FX \times_{FY} FX$.

Proof of the claim. Notice that, for any $Z \in \mathrm{Ob}(\mathscr{C})$, an element of $X \times_Y X(Z)$ is the same as the datum of a pair of morphisms $\alpha, \beta : Z \to X$ such that $\varphi \circ \alpha = \varphi \circ \beta$. The natural morphism $X \times_Y X \to F^\wedge(FX \times_{FY} FX)$ of (1.3.12) sends such a pair (α, β) to the pair $(F\alpha, F\beta)$.

Therefore, the central vertical arrow of (1.3.19) is the map that assigns to any $W \in \mathrm{Ob}(\mathscr{D})$ and any pair $(\psi : W \to FZ, (\alpha, \beta : Z \to X))$ the pair $(F\alpha \circ \psi, F\beta \circ \psi : W \to FX)$. Then, q_1 (resp. q_2) sends such a pair to $F\alpha \circ \psi$ (resp. to $F\beta \circ \psi$). On the other hand, $F_! p_1$ (resp. $F_! p_2$) sends $(\psi, (\alpha, \beta))$ to the pair (ψ, α) (resp. to (ψ, β)). Now the claim follows by inspecting the explicit definition of the rightmost vertical arrow of (1.3.19). ◊

(ii) follows by dualizing the foregoing argument (details left to the reader). □

Proposition 1.3.21. (i) *Let $\mathscr{C}, \mathscr{D}$ be two categories, $F : \mathscr{C} \to \mathscr{D}$ a left exact (resp. right exact) functor; suppose that $\mathscr{C}$ is finitely complete (resp. finitely cocomplete), and consider the following conditions :*

(a) *F is conservative (see definition* 1.1.4(ii)*)*
(b) *F is faithful*
(c) *F reflects epimorphisms (resp. monomorphisms)*
(d) *F reflects monomorphisms (resp. epimorphisms).*

Then (a)⇒(b)⇒(c)⇒(d).

(ii) *Suppose moreover that the isomorphisms in $\mathscr{C}$ are the morphisms that are both monomorphisms and epimorphisms. Then* (c)⇒(a).

Proof. We prove the assertions in case f is left exact and $\mathscr{C}$ is finitely complete; the assertions for the case where F is right exact and $\mathscr{C}$ is finitely cocomplete will follow by considering $F^o : \mathscr{C}^o \to \mathscr{D}^o$.

(i.a)⇒(i.b): Let $f; g : A \to B$ be two morphisms in $\mathscr{C}$; by assumption, the equalizer of f and g is representable in $\mathscr{C}$ by some object E, and the universal cone is the datum of a morphism $h : E \to A$ such that $f \circ h = g \circ h$. Moreover, FE represents the equalizer of Ff and Fg, and $Fh : FE \to FA$ is a universal cone for this equalizer, by remark 1.3.14(i). Now, suppose that $Ff = Fg$; then Fh is an isomorphism, hence the same holds for h, and therefore $f = g$.

(i.b)⇒(i.c): Let $f : A \to B$ and $g, h : B \to C$ be three morphisms in $\mathscr{C}$ with $g \circ f = h \circ f$, and suppose that Ff is an epimorphism; since $Fg \circ Ff = Fh \circ Ff$, it follows that $Fg = Fh$, and then $g = h$, since F is faithful. This shows that f is an epimorphism.

(i.c)⇒(i.d): Let $f : A \to B$ be a morphism in $\mathscr{C}$ such that $Ff : FA \to FB$ is a monomorphism; by assumption the fibre product $A \times_B A$ is representable in $\mathscr{C}$, and if $p_1, p_2 : A \times_B A \to A$ are the natural projections, then $F(A \times_B A)$ represents $FA \times_{FB} FA$, and $Fp_1, Fp_2 : F(A \times_B A) \to FA$ provide a universal cone for this fibre product. It follows easily that if $\iota_f : A \to A \times_B A$ is the diagonal of f, then $F\iota_f : FA \to F(A \times_B A)$ is the diagonal of Ff, hence $F\iota_f$ is an isomorphism in $\mathscr{D}$, by proposition 1.2.18(i). By assumption, ι_f is then an epimorphism, so f is a monomorphism, again by proposition 1.2.18(i).

(ii): Let $f : A \to B$ be a morphism such that Ff is an isomorphism; in particular, Ff is an epimorphism, so by assumption f is an epimorphism. But Ff is also a monomorphism, hence the same holds for f, because we know already that (i.c)⇒(i.d). Then f is an isomorphism, under our assumption on $\mathscr{C}$. □

Proposition 1.3.22. *Let $\mathscr{C}, \mathscr{D}$ be any two categories, and $f : \mathscr{C} \to \mathscr{D}$ any functor.*

(i) *Suppose that*
  (a) *f commutes with equalizers and with products (resp. and with finite products)*
  (b) *all small products (resp. all finite products) are representable in $\mathscr{C}$.*
  Then f commutes with all limits of $\mathscr{C}$ (resp. f is left exact).

(ii) *Dually, suppose that*
  (a) *f commutes with equalizers and with coproducts (resp. and with finite coproducts)*
  (b) *all small coproducts (resp. all finite coproducts) are representable in $\mathscr{C}$.*
  Then f commutes with all colimits of $\mathscr{C}$ (resp. f is right exact).

Proof. (i): With the notation of the proof of proposition 1.2.22(i), we have shown that the rule

$$(\mu : c_X \Rightarrow F) \mapsto \omega_P^{-1}(\mu * \mathrm{ob}) \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C}) \text{ and } \mu \in \lim_I F(X)$$

defines an isomorphism $g : \lim_I F \xrightarrow{\sim} E \subset h_P$. Also, since by assumption f commutes with products (resp. with finite products), the isomorphisms ω_P and ω_Q induce isomorphisms

$$\gamma_P : h_{fP} \xrightarrow{\sim} \lim_{\mathrm{Ob}(I)} f \circ F \circ \mathrm{ob} \qquad \gamma_Q : h_{fQ} \xrightarrow{\sim} \lim_{\mathrm{Morph}(I)} f \circ F \circ \mathrm{ob} \circ \mathrm{t}$$

as explained in remark 1.3.14(i). We set $E' := \mathrm{Equal}(f\alpha, f\beta)$, and we identify E' as well with a subobject of h_{fP}, via the monomorphism $E' \to h_{fP}$ provided by the tautological cone. Then we define likewise a morphism $g' : \lim_I(f \circ F) \to E'$ by the rule :

$$(\mu : c_Y \Rightarrow f \circ F) \mapsto \gamma_P^{-1}(\mu * \mathrm{ob}) \qquad \text{for every } Y \in \mathrm{Ob}(\mathscr{D}) \text{ and } \mu \in \lim_I (f \circ F)(Y).$$

Consider now the diagram of presheaves on $\mathscr{D}$:

(1.3.23)
$$\begin{array}{ccc} f_! \lim_I F & \xrightarrow{f_! g} & f_! E \\ {\scriptstyle d}\downarrow & & \downarrow{\scriptstyle e} \\ \lim_I f \circ F & \xrightarrow{g'} & E' \end{array}$$

whose vertical arrows are the morphisms (1.3.13).

Claim 1.3.24. Diagram (1.3.23) commutes.

Proof of the claim. Let $\tau : c_P \Rightarrow F \circ \mathrm{ob}$ be the universal cone arising from the isomorphism ω_P; according to remark 1.3.14(i), for every $X \in \mathrm{Ob}(\mathscr{C})$ and every cone $\mu : c_X \Rightarrow F$ (resp. every $Y \in \mathrm{Ob}(\mathscr{D})$ and every cone $\mu' : c_Y \Rightarrow f \circ F \circ \mathrm{ob}$), the morphism $g(\mu)$ (resp. $g'(\mu')$) is characterized as the unique one such that

$$\tau \odot c_{g(\mu)} = \mu * \mathrm{ob} \qquad (\text{resp. } (f * \tau) \odot c_{g'(\mu')} = \mu' * \mathrm{ob}\ ).$$

Now, let $(\psi : Y \to fX, \mu : c_X \Rightarrow F)$ be the representative of any given element $s \in f_! \lim_I F(Y)$. Then $f_! g(s)$ is represented by the pair $(\psi, g(\mu))$, and

$$d(s) = (f * \mu) \odot c_\psi \qquad e(f_! g(s)) = f(g(\mu)) \circ \psi$$

(remark 1.3.6(iii)), and the foregoing yields the identities

$$\begin{aligned} (f * \tau) \odot c_{g'((f*\mu)\circ c_\psi)} &= ((f * \mu) \odot c_\psi) * \mathrm{ob} \\ &= (f * \mu * \mathrm{ob}) \odot c_\psi \\ &= (f * (\tau \odot c_{g(\mu)})) \odot c_\psi \\ &= (f * \tau) \odot (f * c_{g(\mu)}) \odot c_\psi \\ &= (f * \tau) \odot c_{f(g(\mu))\circ\psi} \end{aligned}$$

whence $e(f_! g(s)) = g'(d(s))$, as claimed. ◇

Now, by assumption both $f_! g$ and e are isomorphisms; in light of claim 1.3.24, it then suffices to check that g' is an isomorphism. By unwinding the definitions, we see that the latter assertion amounts to the following. For every $Y \in \mathrm{Ob}(\mathscr{D})$ he rule $\mu \mapsto \mu * \mathrm{ob}$ yields a bijection from the set of all cones $\mu : c_Y \Rightarrow f \circ F$ onto the set of all cones $\lambda : c_Y \Rightarrow f \circ F \circ \mathrm{ob}$ such that $\lambda * \mathrm{t} = ((f \circ F) * \mathrm{m}) \odot (\lambda * \mathrm{s})$. In turns, this follows by a direct inspection. □

Proposition 1.3.25. *Let $\mathscr{A}, \mathscr{B}$ be two categories, $F : \mathscr{A} \to \mathscr{B}$ a functor that admits a left adjoint $G : \mathscr{B} \to \mathscr{A}$. The following holds :*

(i) *If $\mathscr{A}$ and $\mathscr{B}$ are small, we have natural isomorphisms of functors*

$$F^\wedge \xrightarrow{\sim} G_* \qquad F_! \xrightarrow{\sim} G^\wedge.$$

(ii) *If $\mathscr{A}$ and $\mathscr{B}$ have small* Hom-*sets, then for every small category I and every functor $\varphi : I \to \mathscr{A}$, there is a natural isomorphism of presheaves*

$$G^\wedge(\lim_I \varphi) \stackrel{\sim}{\to} \lim_I (F \circ \varphi).$$

(iii) *F commutes with all limits of $\mathscr{A}$.*
(iv) *Dually, G commutes with all colimits of $\mathscr{B}$.*
(v) *F transforms monomorphisms into monomorphisms, and G transforms epimorphisms into epimorphisms.*

Proof. (i): In view of example 1.2.7(ii), the assertion means that $G^\wedge$ is left adjoint to $F^\wedge$; however F^o is left adjoint to G^o (remark 1.1.19(iv)), so it suffices to apply remark 1.1.19(iii), which shows more precisely that $\varepsilon^\wedge$ and $\eta^\wedge$ are respectively the unit and counit of a unique adjunction for the pair $(G^\wedge, F^\wedge)$.

(ii): We are easily reduced to the case where $\mathscr{A}$ and $\mathscr{B}$ are small. Set $L := \lim_I F \circ \varphi$. According to remark 1.2.11(i), we have a natural morphism $\omega : \lim_I \varphi \to F^\wedge L$, to which the adjunction exhibited in the proof of (i) attaches a unique morphism $\omega^* : G^\wedge(\lim_I \varphi) \to L$. We shall show more precisely that ω^* is an isomorphism of presheaves. Indeed, let $B \in \mathrm{Ob}(\mathscr{B})$ be any object; by unwinding the definitions, we see that ω^*_B is given by the rule

$$\mu \mapsto \mu^* := ((F * \mu) \odot c_{\eta_B} : c_B \Rightarrow F \circ \varphi) \qquad \text{for every cone } \mu : c_{GB} \Rightarrow \varphi$$

(notation of (1.2.9)). We provide an explicit inverse for the rule $\mu \mapsto \mu^*$, by setting

$$\tau^* := (\varepsilon * \varphi) \odot (G * \tau) : c_{GB} \Rightarrow \varphi \qquad \text{for every cone } \tau : c_B \Rightarrow F \circ \varphi.$$

Clearly the rule $\tau \mapsto \tau^*$ defines a morphism of presheaves $L \to G^\wedge(\lim_I \varphi)$. Then, for every such τ the triangular identities of (1.1.13) give :

$$\begin{aligned}(\tau^*)^* &= (F * ((\varepsilon * \varphi) \odot (G * \tau))) \odot c_{\eta_B} \\ &= (F * \varepsilon * \varphi) \odot (F * G * \tau) \odot c_{\eta_B} \\ &= (F * \varepsilon * \varphi) \odot (\eta * F * \varphi) \odot \tau \\ &= \tau.\end{aligned}$$

Likewise one sees that $(\mu^*)^* = \mu$ for every cone $\mu : c_{GB} \Rightarrow \varphi$, as needed.

(iii): Again, we can assume that $\mathscr{A}$ and $\mathscr{B}$ are small. We have just seen that the adjunction for the pair $(G^\wedge, F^\wedge)$ exhibited in (i) transforms the morphism ω into an isomorphism ω^*. By example 1.2.7(ii), it follows that any adjunction for the pair $(F_!, F^\wedge)$ will also transform ω into an isomorphism, whence the contention. (Notice that $F_!$ is – *a priori* – well defined only as a functor on V-presheaves, for some universe V such that $\mathscr{A}$ and $\mathscr{B}$ are small V-categories, but (i) implies that actually it is – up to natural isomorphism – already defined on U-presheaves.)

(iv) follows as usual, by considering the opposite categories and taking into account remark 1.1.19(iv). Lastly, (v) follows from (iii),(iv) and proposition 1.3.18. □

Let $\mathscr{A}$ be a subcategory of a category $\mathscr{B}$, and $\varphi : I \to \mathscr{A}$ a functor from a small category I, whose limit is representable in $\mathscr{A}$ by an object A. In this situation – and even in case $\mathscr{A}$ is a full subcategory of $\mathscr{B}$ – it is not necessarily true that A represents the limit of the composition $I \to \mathscr{B}$ of φ with the inclusion functor $\mathscr{A} \to \mathscr{B}$. We have nevertheless the following result :

Corollary 1.3.26. *Let $\mathscr{A}, \mathscr{B}$ be two categories, $F : \mathscr{A} \to \mathscr{B}$ a fully faithful functor admitting a left adjoint $G : \mathscr{B} \to \mathscr{A}$, and $\varphi : I \to \mathscr{A}$ a functor from a small category I. We have :*

(i) *If the limit of $F \circ \varphi$ is representable by some $L \in \mathrm{Ob}(\mathscr{B})$, then the limit of φ is representable by some object $M \in \mathrm{Ob}(\mathscr{A})$.*
(ii) *In the situation of* (i), *there exist isomorphisms $L \stackrel{\sim}{\to} FM$ in $\mathscr{B}$ and $M \stackrel{\sim}{\to} GL$ in $\mathscr{A}$.*
(iii) *Especially, if $\mathscr{B}$ is complete, the same holds for $\mathscr{A}$.*

Proof. Let $\eta : \mathbf{1}_{\mathscr{B}} \Rightarrow F \circ G$ be a unit and $\varepsilon : G \circ F \Rightarrow \mathbf{1}_{\mathscr{A}}$ a counit for the pair (G, F), and $\tau : c_L \Rightarrow F \circ \varphi$ a universal cone; set $\tau^* := (\varepsilon * \varphi) \odot (G * \tau) : c_{GL} \Rightarrow \varphi$. There exists a unique morphism $f : FGL \to L$ in $\mathscr{B}$ such that $\tau \odot c_f = F * \tau^*$. We have :

$$\tau \odot c_{f \circ \eta_L} = \tau \odot c_f \odot c_{\eta_L} = (F * \tau^*) \odot (\eta * c_L) = (F * \varepsilon * \varphi) \odot (FG * \tau) \odot (\eta * c_L)$$
$$= (F * \varepsilon * \varphi) \odot (\eta * F\varphi) \odot \tau = \tau$$

whence $f \circ \eta_L = \mathbf{1}_L$, by the universality of τ. On the other hand, since F is fully faithful, there exists a morphism $h : GL \to GL$ in $\mathscr{A}$ such that $Fh = \eta_L \circ f : FGL \to FGL$. Now, the adjunction of the pair (G, F) assigns to h the morphism $Fh \circ \eta_L = \eta_L \circ f \circ \eta_L = F(\mathbf{1}_{GL}) \circ \eta_L$ (see (1.1.13)), so we must have $h = \mathbf{1}_{GL}$, therefore f is an isomorphism. Lastly, since F is fully faithful, we deduce easily that GL represents the limit of F, whence the corollary. □

1.4. **Special properties of the categories of presheaves.** In this section we gather some results concerning the structure of categories of presheaves and the exactness properties of various natural functors between such categories. We begin with a corollary of proposition 1.3.25 :

Corollary 1.4.1. *Let $\mathscr{A}$ and $\mathscr{B}$ be two categories. We have :*

(i) *If $\mathscr{A}$ is small and $\mathscr{B}$ has small* Hom*-sets, the category* $\mathsf{Fun}(\mathscr{A}, \mathscr{B})$ *has small* Hom*-sets.*

(ii) *Suppose that $\mathscr{B}$ is complete or cocomplete. Then, for every $A \in \mathrm{Ob}(\mathscr{A})$ the functor*

$$\varepsilon_A : \mathsf{Fun}(\mathscr{A}, \mathscr{B}) \to \mathscr{B} \qquad F \mapsto FA \qquad (\eta : F \Rightarrow G) \mapsto (\eta_A : FA \to GA)$$

commutes with all colimits and with all limits.

(iii) *If $\mathscr{B}$ is finitely complete (resp. finitely cocomplete) then ε_A commutes with finite limits (resp. with finite colimits), for every $A \in \mathrm{Ob}(\mathscr{A})$.*

(iv) *If $\mathscr{B}$ is complete (resp. cocomplete, resp. finitely complete, resp. finitely cocomplete), the same holds for* $\mathsf{Fun}(\mathscr{A}, \mathscr{B})$.

Proof. (i): If $F, G : \mathscr{A} \to \mathscr{B}$ are any two functors, then $\mathrm{Hom}_{\mathsf{Fun}(\mathscr{A},\mathscr{B})}(F, G)$ is a subset of the product $\prod_{A \in \mathrm{Ob}(\mathscr{A})} \mathrm{Hom}_{\mathscr{B}}(FA, GA)$, hence it is a small set.

(iv): Let I be any small category, and

$$F : I \to \mathsf{Fun}(\mathscr{A}, \mathscr{B}) \qquad i \mapsto (F_i : \mathscr{A} \to \mathscr{B}) \qquad (\varphi : i \to j) \mapsto (F_\varphi : F_i \Rightarrow F_j)$$

any functor. For every $A \in \mathrm{Ob}(\mathscr{A})$ we obtain a functor $F_A : I \to \mathscr{B}$ by the rule

$$F_A(i) := F_i A \qquad F_A(\varphi) := (F_\varphi)_A : F_i A \to F_j A$$

for every $i, j \in \mathrm{Ob}(I)$ and every $\varphi \in \mathrm{Hom}_I(i, j)$. If $\mathscr{B}$ is complete, for every such A we may find $LA \in \mathrm{Ob}(\mathscr{B})$ and a universal cone $\gamma_A : c_{LA} \Rightarrow F_A$. Next, if $g : A \to A'$ is any morphism in $\mathscr{A}$, we obtain a natural transformation $F_g : F_A \Rightarrow F_{A'}$ by the rule

$$(F_g)_i := F_i(g) : F_i A \to F_i A' \qquad \text{for every } i \in \mathrm{Ob}(I)$$

and the limit of F_g is represented by a morphism $Lg : LA \to LA'$ in $\mathscr{B}$ such that

$$F_g \circ \gamma_A = \gamma_{A'} \circ c_{Lg}.$$

It is then easily seen that the rules $A \mapsto LA$ and $g \mapsto Lg$ amount to a well defined functor $\mathscr{A} \to \mathscr{B}$ that represents the limit of F : details left to the reader. Lastly, if $\mathscr{B}$ is cocomplete (resp. finitely cocomplete), $\mathscr{B}^o$ is complete (resp. finitely complete), so the same holds for $\mathsf{Fun}(\mathscr{A}^o, \mathscr{B}^o)$, by the foregoing; then $\mathsf{Fun}(\mathscr{A}, \mathscr{B})$ is cocomplete (resp. finitely complete), by remark 1.1.19(i).

(ii): Suppose that $\mathscr{B}$ is complete (resp. cocomplete); in this case, the proof of (iv) already shows that ε_A commutes with all limits (resp. colimits). Hence, it remains only to check that ε_A commutes as well with all colimits (resp. limits). To this aim, we may assume that $\mathscr{A}$ and $\mathscr{B}$ are both small, and we denote by $\mathbf{1}$ the category with one object and one morphism; we let

$i_A : \mathbf{1} \to \mathscr{A}$ be the (unique) functor that sends the object of $\mathbf{1}$ to A. We have a commutative diagram of functors

$$\begin{array}{ccc} \mathsf{Fun}(\mathscr{A}, \mathscr{B}) & \xrightarrow{\mathsf{Fun}(i_A, \mathscr{B})} & \mathsf{Fun}(\mathbf{1}, \mathscr{B}) \\ & \searrow^{\varepsilon_A} & \downarrow \\ & & \mathscr{B} \end{array}$$

whose vertical arrow is an obvious isomorphism of categories. It then suffices to check that the functor $\mathsf{Fun}(i_A, \mathscr{B})$ commutes with all colimits (resp. limits). However, by theorem 1.3.4, the functor $\mathsf{Fun}(i_A, \mathscr{B})$ admits a right (resp. left) adjoint, so it suffices to invoke proposition 1.3.25(ii,iii).

(iii) follows likewise from the proof of (iv). □

Remark 1.4.2. (i) By inspecting the proof of theorem 1.3.4, it is easily seen that, more generally, the functors ε_A of corollary 1.4.1 commute with limits when $\mathscr{B}$ is a category with representable coproducts. Dually, if all products of $\mathscr{B}$ are representable, ε_A commutes with colimits.

(ii) In the same vein, suppose moreover that $\mathrm{Hom}_{\mathscr{A}}(A, A')$ is a finite set for every $A, A' \in \mathrm{Ob}(\mathscr{A})$. Then, again by inspection of the proof of theorem 1.3.4 we see that for the functors ε_A to commute with limits (resp. colimits) it suffices that all finite coproducts (resp. finite products) of $\mathscr{B}$ are representable.

(iii) Furthermore, the proof of corollary 1.4.1(iv) shows more precisely the following. If $F : I \to \mathrm{Fun}(\mathscr{A}, \mathscr{B})$ is a functor from a small category I, and the limit (resp. colimit) of $\varepsilon_A \circ F$ is representable in $\mathscr{B}$ for every $A \in \mathrm{Ob}(\mathscr{A})$, then the limit (resp. colimit) of F is representable in $\mathrm{Fun}(\mathscr{A}, \mathscr{B})$, and ε_A commutes with this limit (resp. colimit), for every $A \in \mathrm{Ob}(\mathscr{A})$.

Corollary 1.4.3. *Let $\mathscr{C}$ be any small category, and $f : F \to G$ a morphism in $\mathscr{C}^\wedge$.*

(i) *$\mathscr{C}^\wedge$ has small* Hom*-sets and is both well-powered and co-well-powered (see* (1.1.2)*).*

(ii) *For every $X \in \mathrm{Ob}(\mathscr{C})$, the functor*

$$\mathscr{C}^\wedge \to \mathbf{Set} \quad : \quad F \mapsto FX \qquad (f : F \to G) \mapsto (f_X : FX \to GX)$$

commutes with all limits and all colimits (in other words, the limits and colimits in $\mathscr{C}^\wedge$ are computed argumentwise).

(iii) *f is a monomorphism (resp. an epimorphism) if and only if the map $f_X : FX \to GX$ is injective (resp. surjective) for every $X \in \mathrm{Ob}(\mathscr{C})$.*

(iv) *f is an isomorphism if and only if it is both a monomorphism and an epimorphism.*

(v) *Let $f(F) \in \mathrm{Ob}(\mathscr{C}^\wedge)$ be the subobject of F with $f(F)(X) := \mathrm{Im}(f_X : FX \to GX)$ for every $X \in \mathrm{Ob}(\mathscr{C})$. Then $f(F) = \mathrm{Im}(f) = \mathrm{Coim}(f)$ (see example* 1.2.26*).*

(vi) *The Yoneda embedding $h_{\mathscr{C}} : \mathscr{C} \to \mathscr{C}^\wedge$ commutes with all representable limits of $\mathscr{C}$.*

(vii) *If $\mathscr{D}$ is any category with small* Hom*-sets and $\varphi : \mathscr{C} \to \mathscr{D}$ any functor, then $\varphi^\wedge$ commutes with all limits and all colimits of $\mathscr{D}^\wedge$, and $\varphi_!$ (resp. φ_*) commutes with all colimits (resp. with all limits) of $\mathscr{C}^\wedge$.*

Proof. (i): The first assertion is a special case of corollary 1.4.1(i). Next, to see that $\mathscr{C}^\wedge$ is well-powered notice that for every presheaf F on $\mathscr{C}$, and every $X \in \mathrm{Ob}(\mathscr{C})$, the set of subsets of $F(X)$ is small, and a subobject of F is just a compatible system of subsets $F'(X) \subset F(X)$, for X ranging over the small set of objects of $\mathscr{C}$. Likewise one sees that $\mathscr{C}^\wedge$ is co-well-powered.

(ii) is a special case of corollary 1.4.1(ii), but it is also already clear from example 1.2.24(i).

(iii): It is easily seen that if f_X is injective (resp. surjective) for every $X \in \mathrm{Ob}(\mathscr{C})$, then f is a monomorphism (resp. an epimorphism). The converse follows from (ii) and proposition 1.3.18.

(iv) is an immediate consequence of (iii).

(v): It follows from (iii) that the induced morphism $F \to f(F)$ is a quotient of F, and the sequence $F \to f(F) \to G$ is the unique factorization of f (up to unique isomorphism) as a composition of an epimorphism followed by a monomorphism, whence the assertion.

(vi) follows directly from example 1.2.24(ii) and remark 1.3.14(i).

(vii) is a special case of proposition 1.3.22(iii,iv). □

Example 1.4.4. Let $\mathscr{C}$ be a category with small Hom-sets, and $Y \in \mathrm{Ob}(\mathscr{C})$ any object.

(i) Suppose that all the products of small families of objects of $\mathscr{C}$ are representable, and consider the functor

$$Y^\bullet : \mathbf{Set}^o \to \mathscr{C}^\wedge$$

which to any (U-small) set S assigns the product in $\mathscr{C}$ of S copies of Y, *i.e.* the limit of the functor $\varphi_Y^S : S \to \mathscr{C}$ such that $\varphi_Y(s) := Y$ for every $s \in S$ (where S is regarded as a discrete category), and to any map of sets $f : T \to S$, attaches the morphism of presheaves $Y^f := \lim_f \varphi_Y$. The assumption on $\mathscr{C}$ implies that $Y^\bullet$ is representable by a functor which we denote as well

$$Y^\bullet : \mathbf{Set}^o \to \mathscr{C}$$

(see remark 1.2.8(ii)). On the other hand, we have the functor $h_Y : \mathscr{C}^o \to \mathbf{Set}$ such that $h_Y(X^o) := \mathrm{Hom}_{\mathscr{C}}(X, Y)$ for every $X \in \mathrm{Ob}(\mathscr{C})$, and notice the natural identifications :

$$\mathrm{Hom}_{\mathscr{C}^o}((Y^S)^o, X^o) = \mathrm{Hom}_{\mathscr{C}}(X, Y^S) \xrightarrow{\sim} \mathrm{Hom}_{\mathbf{Set}}(S, h_Y(X^o))$$

which say that h_Y is right adjoint to the functor $(Y^\bullet)^o$. By proposition 1.3.25(iii) it follows that h_Y commutes with all small limits of $\mathscr{C}^o$.

(ii) Likewise, if all the small coproducts of $\mathscr{C}$ are representable, we may apply (i) to the functor $h_{Y^o} : \mathscr{C} \to \mathbf{Set}$. We find that h_{Y^o} commutes with all small limits of $\mathscr{C}$.

(iii) Especially, let $I, \mathscr{C}$ be two small categories, $F : I \to \mathscr{C}$ a functor, and G any presheaf on $\mathscr{C}$. From (i),(ii), example 1.2.24(i) and corollary 1.4.3(vi) we get natural isomorphisms :

$$(1.4.5) \qquad \lim_{I^o} \mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{C}}^o \circ F^o, G) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{C}^\wedge}(\operatorname*{colim}_I h_{\mathscr{C}} \circ F, G)$$

$$(1.4.6) \qquad \lim_{I} \mathrm{Hom}_{\mathscr{C}^\wedge}(G, h_{\mathscr{C}} \circ F) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{C}^\wedge}(G, \lim_I F)$$

(more precisely, the limit on the left is represented by the set on the right, in both cases). Furthermore, since the tautological cone τ (resp. the tautological cocone μ) for F is universal, we get the universal cone $\mathrm{Hom}_{\mathscr{C}^\wedge}(\tau, G)$ (resp. $\mathrm{Hom}_{\mathscr{C}^\wedge}(G, \mu)$) for the limit appearing in (1.4.5) (resp. in (1.4.6) : see remarks 1.2.11(iv)) and 1.3.14(i)).

1.4.7. It is an important fact that *every presheaf on a small category is the colimit of a system of representable presheaves*; more generally, for any category $\mathscr{C}$ and every $F \in \mathrm{Ob}(\mathscr{C}^\wedge)$, let us consider the *category of elements of* F :

$$\mathscr{F}ib(F)$$

whose objects are the pairs (X, s) where $X \in \mathrm{Ob}(\mathscr{C})$ and $s \in FX$ (the notation shall be explained in (3.1.15)). The morphisms $f : (X, s) \to (Y, t)$ in $\mathscr{F}ib(F)$ are the morphisms $f : X \to Y$ of $\mathscr{C}$ such that $Ff(t) = s$. We have an obvious *source functor*

$$\mathsf{s}_F : \mathscr{F}ib(F) \to \mathscr{C} \qquad (X, s) \mapsto X \qquad ((X, s) \xrightarrow{f} (Y, t)) \mapsto (X \xrightarrow{f} Y).$$

Notice that if $\mathscr{C}$ is small, the same holds for $\mathscr{F}ib(F)$. Also, if $\mathscr{C}$ has small Hom-sets, Yoneda's lemma naturally identifies $\mathscr{F}ib(F)$ with the category $h_{\mathscr{C}}\mathscr{C}/F$ (notation of (1.1.27) and (1.2.4)); namely, a pair (X, s) corresponds to the unique morphism of presheaves

$$h_{(X,s)} : h_X \to F \qquad \text{such that} \qquad h_{(X,s),X}(\mathbf{1}_X) = s.$$

Moreover, in this case s_F is identified with the source functor $\mathsf{s}_F : h_{\mathscr{C}}\mathscr{C}/F \to \mathscr{C}$ of (1.1.27). We have a natural cocone

$$h^F : h_{\mathscr{C}} \circ \mathsf{s}_F \Rightarrow c_F \qquad (X, s) \mapsto h_{(X,s)}.$$

Lemma 1.4.8. *With the notation of* (1.4.7)*, for every category* $\mathscr{C}$ *and every presheaf* F *on* $\mathscr{C}$*, the cocone* h^F *is universal.*

Proof. Let G be any presheaf on $\mathscr{C}$. A natural transformation $\tau : h_{\mathscr{C}} \circ \mathsf{s}_F \Rightarrow c_G$ is a rule that assigns to every $(X, s) \in \mathrm{Ob}(h_{\mathscr{C}}\mathscr{C}/F)$ a morphism of presheaves $h_X \to G$; the latter is naturally identified with an element $\tau_{(X,s)} \in GX$. Thus, τ induces a map $\tau_{(X,\bullet)} : FX \to GX$ for every $X \in \mathrm{Ob}(\mathscr{C})$, by the rule : $(X, s) \mapsto \tau_{(X,s)}$. Moreover, the naturality of τ implies that

$$Gf(\tau_{(Y,s)}) = \tau_{(X,s)} \qquad \text{for every morphism } f : (X, s) \to (Y, t) \text{ in } h_{\mathscr{C}}\mathscr{C}/F$$

(details left to the reader); *i.e.* the rule $X \mapsto \tau_{(X,\bullet)}$ for every $X \in \mathrm{Ob}(\mathscr{C})$ yields a morphism of presheaves $h^\tau : F \to G$, and it is easily seen that $\tau = c_{h^\tau} \odot h^F$, whence the contention. □

Example 1.4.9. (i) Let $\mathscr{C}$ be a small category, and $\mathbb{1}_{\mathscr{C}}$ a final object of $\mathscr{C}^\wedge$ (see example 1.2.16(v)); since the source functor $\mathsf{s}_{\mathbb{1}_{\mathscr{C}}} : h_{\mathscr{C}}\mathscr{C}/\mathbb{1}_{\mathscr{C}} \to \mathscr{C}$ is an isomorphism of categories, we deduce from lemma 1.4.8 a natural isomorphism

$$\operatorname*{colim}_{\mathscr{C}} h_{\mathscr{C}} \xrightarrow{\sim} \mathbb{1}_{\mathscr{C}} \qquad \text{in } \mathscr{C}^\wedge.$$

(ii) Let $\mathscr{C}$ be a category with small Hom-sets, $X \in \mathrm{Ob}(\mathscr{C})$, and $h_X : \mathscr{C}^o \to \mathbf{Set}$ the corresponding presheaf (notation of (1.2.4)). By inspecting the definition, we find that

$$\mathscr{F}ib(h_X) = \mathscr{C}/X$$

and under this identification, the source functor s_{h_X} of (1.4.7) corresponds to the source functor s_X of (1.1.24). So, lemma 1.4.8 in this case shows that X represents in $\mathscr{C}$ the colimit of $h_{\mathscr{C}} \circ \mathsf{s}_X$.

(iii) More generally, if $\mathscr{A}$ and $\mathscr{B}$ are two categories, $F : \mathscr{A} \to \mathscr{B}$ any functor, we have

$$\mathscr{F}ib(h_B \circ F) = F\mathscr{A}/B \qquad \text{for every } B \in \mathrm{Ob}(\mathscr{B})$$

(notation of (1.1.27)) and again, the respective source functors agree, under this identification. Hence, if $\mathscr{A}$ is small and $\mathscr{B}$ has small Hom-sets, then the presheaf $h_B \circ F$ on $\mathscr{A}$ is isomorphic to the colimit of the functor $h_{\mathscr{A}} \circ \mathsf{s}_B : F\mathscr{A}/B \to \mathscr{A}^\wedge$.

1.4.10. We conclude this section with a few observations concerning presheaves on the slice categories of (1.1.24). Thus, let $\mathscr{C}$ be a category, X any object of $\mathscr{C}$, denote by $\mathsf{s}_X : \mathscr{C}/X \to \mathscr{C}$ the source functor of (1.1.24), and suppose that $\mathscr{C}$ is V-small, for some universe V. To begin with, a direct inspection of (1.3.8) yields a natural isomorphism :

(1.4.11) $$(\mathsf{s}_X)_{\mathsf{V}!}F(Y) \xrightarrow{\sim} \{(\varphi, a) \mid \varphi \in \mathrm{Hom}_{\mathscr{C}}(Y, X),\ a \in F(\varphi)\}$$

for every V-presheaf F on $\mathscr{C}/X$ and every $Y \in \mathrm{Ob}(\mathscr{C})$. Indeed, from *loc.cit.* we see that every element of $(\mathsf{s}_X)_{\mathsf{V}!}F(Y)$ is the equivalence class of a datum

$$(\psi : Y \to Z, \alpha : Z \to X, s \in F(\alpha))$$

and such a datum is equivalent to $(\mathbf{1}_Y, \alpha \circ \psi : Y \to X, F(\psi)(s) \in F(\alpha \circ \psi))$. If $\psi : Z \to Y$ is any morphism of $\mathscr{C}$, the corresponding map $(\mathsf{s}_X)_{\mathsf{V}!}F(Y) \to (\mathsf{s}_X)_{\mathsf{V}!}F(Z)$ is given by the rule :

(1.4.12) $$(\varphi, a) \mapsto (\varphi \circ \psi, F(\psi)(a)) \qquad \text{for every } \varphi : Y \to X \text{ and } a \in F(\varphi).$$

Moreover, under this natural identification the adjoint pair $((\mathsf{s}_X)_{\mathsf{V}!}, \mathsf{s}_X^\wedge)$ assigns to any morphism $t : F \to \mathsf{s}_X^\wedge G$ of presheaves on $\mathscr{C}/X$ the morphism $t^* : (\mathsf{s}_X)_{\mathsf{V}!}F \to G$ in $\mathscr{C}^\wedge$ given by the rule :

$$(\varphi, a) \mapsto t(\varphi)(a) \qquad \text{for every } Y \in \mathrm{Ob}(\mathscr{C}), \varphi : Y \to X \text{ and } a \in F(\varphi).$$

Proposition 1.4.13. *Let* $\mathscr{C}$ *be any category and* X *any object of* $\mathscr{C}$*.*

(i) *The source functor* $\mathsf{s}_X : \mathscr{C}/X \to \mathscr{C}$ *commutes with all connected limits and with the colimit of every functor* $F : I \to \mathscr{C}/X$ *such that* $\mathrm{colim}_I\, \mathsf{s}_X \circ F$ *is representable in* $\mathscr{C}$.
(ii) *Dually, the target functor* $\mathsf{t}_X : X/\mathscr{C} \to \mathscr{C}$ *commutes with all connected colimits and with the limit of every functor* $F : I \to X/\mathscr{C}$ *such that* $\lim_I \mathsf{t}_X \circ F$ *is representable in* $\mathscr{C}$.
(iii) *If all the binary products of* $\mathscr{C}$ *are representable,* s_X *admits a right adjoint, and therefore it commutes with all colimits of* $\mathscr{C}/X$.
(iv) *Dually, if all the binary coproducts of* $\mathscr{C}$ *are representable,* t_X *admits a left adjoint, and therefore it commutes with all limits of* $X/\mathscr{C}$.
(v) *If* $\mathscr{C}$ *is complete (resp. cocomplete, resp. finitely complete, resp. finitely cocomplete), then the same holds for both* $\mathscr{C}/X$ *and* $X/\mathscr{C}$.
(vi) *Suppose that* $\mathscr{C}$ *has small* Hom*-sets. Then the following holds :*
  (a) *The functor* $\mathsf{s}_X^\wedge$ *admits a left adjoint* $\mathsf{s}_{X!} : (\mathscr{C}/X)^\wedge \to \mathscr{C}^\wedge$.
  (b) *Moreover* $\mathsf{s}_{X!}$ *factors as the composition of an equivalence of categories*

$$e_X : (\mathscr{C}/X)^\wedge \to \mathscr{C}^\wedge/h_X$$

  and the source functor $\mathsf{s}_{h_X} : \mathscr{C}^\wedge/h_X \to \mathscr{C}^\wedge$ *(notation of* (1.2.4)*).*
  (c) $\mathsf{s}_{X!}$ *commutes with fibre products and preserves monomorphisms.*

Proof. (v): Suppose that $\mathscr{C}$ is complete (resp. finitely complete); to show that the same holds for $\mathscr{C}/X$, we may apply the criterion of proposition 1.2.22(i). Indeed, suppose that $p_\bullet := (p_i : Y_i \to X \mid i \in I)$ is any family (resp. any finite family) of objects of $\mathscr{C}/X$, indexed by a small set I, which we regard as a discrete category. We consider the category I_X whose set of objects is the disjoint union of I and $\{X\}$, and with

$$\mathrm{Morph}(I_X) = \mathrm{Morph}(I) \cup \{(X, X, \mathbf{1}_X)\} \cup \{(i, X, p_i) \mid i \in I\}$$

so that X is the unique final object of I_X. Next, we define a functor $F : I_X \to \mathscr{C}$, by letting

$$FX := X \qquad \text{and} \qquad Fi := Y_i \quad Fp_i := p_i \qquad \text{for every } i \in I.$$

Any universal cone $\tau : c_L \Rightarrow F$ yields a morphism $\tau_X : L \to X$, and it is easily seen that the object τ_X of $\mathscr{C}/X$ represents the product of the family $p_\bullet$. Lastly, let $p_i : Y_i \to X$ ($i = 1, 2$) be two objects of $\mathscr{C}/X$, and $f, g : p_1 \to p_2$ two morphisms in $\mathscr{C}/X$. Denote by E any object of $\mathscr{C}$ representing the equalizer of $\mathsf{s}_X(f), \mathsf{s}_X(g) : Y_1 \to Y_2$ in $\mathscr{C}$, where $\mathsf{s}_X : \mathscr{C}/X \to \mathscr{C}$ is the source functor. The corresponding universal cone yields a morphism $h : E \to Y_1$ such that $\mathsf{s}_X(f) \circ h = \mathsf{s}_X(g) \circ h$, and it is easily seen that the object $p_1 \circ h : E \to X$ of $\mathscr{C}/X$ represents the equalizer of f and g (details left to the reader).

Next, suppose that $\mathscr{C}$ is cocomplete (resp. finitely cocomplete), and let $F : I \to \mathscr{C}/X$ be a functor from a small (resp. finite) category I. Let also C be any object of $\mathscr{C}$ representing the colimit of $\mathsf{s}_X \circ F$; the functor F can be regarded as a cocone $\mathsf{s}_X \circ F \Rightarrow c_X$, which corresponds to a morphism $\tau : C \to X$, and it is easily seen that $\tau \in \mathrm{Ob}(\mathscr{C}/X)$ represents the colimit of F.

The assertions for $X/\mathscr{C}$ follows as usual, by considering the opposite categories.

(vi.a): The discussion of (1.4.10) yields a left adjoint $(\mathsf{s}_X)_{\mathsf{V}!}$ to $(\mathsf{s}_X)^\wedge_{\mathsf{V}}$, for any universe V such that $\mathscr{C}$ has V-small Hom-sets. However, by inspecting (1.4.11), we see that if $\mathscr{C}$ has small Hom-sets and F is a U-presheaf on $\mathscr{C}/X$, then $(\mathsf{s}_X)_{\mathsf{V}!}F$ is a U-presheaf. Since the inclusion $(\mathscr{C}/X)^\wedge_{\mathsf{U}} \to (\mathscr{C}/X)^\wedge_{\mathsf{V}}$ is fully faithful, we deduce that the target of (1.4.11) can be used to define the sought left adjoint $(\mathsf{s}_X)_! : (\mathscr{C}/X)^\wedge_{\mathsf{U}} \to \mathscr{C}^\wedge_{\mathsf{U}}$ to $(\mathsf{s}_X)^\wedge_{\mathsf{U}}$.

(vi.b): Notice that the presheaf $\mathbb{1}_{\mathscr{C}/X} := h_{\mathbf{1}_X}$ is a final object of $(\mathscr{C}/X)^\wedge$: indeed, for every object $f : Y \to X$ of $\mathscr{C}/X$ we have $\mathbb{1}_{\mathscr{C}/X}(f) = \{f/X\}$ (notation of (1.1.24)). Then remark 1.3.6(v) yields a natural isomorphism :

$$\mathsf{s}_{X!}(\mathbb{1}_{\mathscr{C}/X}) \xrightarrow{\sim} h_X$$

that identifies the unit of adjunction with the morphism of presheaves :

$$(1.4.14)\qquad \mathbb{1}_{\mathscr{C}/X} \to \mathsf{s}_X^\wedge(h_X) \qquad \text{such that} \qquad f/X \mapsto f \qquad \text{for every } f \in \mathrm{Ob}(\mathscr{C}/X).$$

Now, every presheaf F on $\mathscr{C}/X$ admits a unique morphism $F \to \mathbb{1}_{\mathscr{C}/X}$, whence a natural morphism $\mathsf{s}_{X!}F \to h_X$, so we see already that $\mathsf{s}_{X!}$ factors through s_{h_X} and a functor e_X as required; more precisely, (1.4.12), says that the morphism $e_X(F) : \mathsf{s}_{X!}F \to h_X$ is given by the rule : $(f, a) \mapsto f$ for every $Y \in \mathrm{Ob}(\mathscr{C})$ and every $(f, a) \in \mathsf{s}_{X!}F(Y)$. To check that e_X is an equivalence, we exhibit an explicit quasi-inverse : namely, to every object $\varphi : F \to h_X$ of $\mathscr{C}^\wedge/h_X$ we assign the presheaf

$$e'_X(\varphi) := \mathsf{s}_X^\wedge(F) \times_{\mathsf{s}_X^\wedge(h_X)} \mathbb{1}_{\mathscr{C}/X}$$

defined via (1.4.14) and the morphism $\mathsf{s}_X^\wedge(\varphi) : \mathsf{s}_X^\wedge(F) \to \mathsf{s}_X^\wedge(h_X)$. Now, let F be any presheaf on $\mathscr{C}/X$, and $f : Y \to X$ any object of $\mathscr{C}/X$; by unwinding the definitions, we see that

$$(e'_X \circ e_X(F))(f) = \mathsf{s}_{X!}F(Y) \times_{h_X(Y)} \{f/X\}$$

which is the set of all pairs (f, a) with $a \in Ff$. Thus we get an obvious isomorphism of presheaves $e'_X \circ e_X(F) \xrightarrow{\sim} F$, natural with respect to F. Likewise, for every object $\varphi : G \to h_X$ of $\mathscr{C}^\wedge/h_X$ and every $Y \in \mathrm{Ob}(\mathscr{C})$ we get the map

$$(e_X \circ e'_X(\varphi))_Y : \mathsf{s}_{X!}(\mathsf{s}_X^\wedge(F) \times_{\mathsf{s}_X^\wedge(h_X)} \mathbb{1}_{\mathscr{C}/X})(Y) \to h_X(Y)$$

which is described as follows. First, $\mathsf{s}_{X!}(\mathsf{s}_X^\wedge(F) \times_{\mathsf{s}_X^\wedge(h_X)} \mathbb{1}_{\mathscr{C}/X})(Y)$ is the set of all pairs (f, a) with $f : Y \to X$ a morphism of $\mathscr{C}$, and $a \in GY \times_{h_X(Y)} \{f/X\}$; *i.e.* the pairs (f, a) with $\varphi_Y(a) = f$. Then, the map $(e_X \circ e'_X(\varphi))_Y$ is given by the rule : $(f, a) \mapsto f$ for every such pair (f, a). Again, we deduce an obvious isomorphism $e_X \circ e'_X(\varphi) \xrightarrow{\sim} \varphi$ of h_X-objects of $\mathscr{C}^\wedge$, natural with respect to φ, as required.

(vi.c) follows from the explicit description of $\mathsf{s}_{X!}$ given in (1.4.10), together with corollary 1.4.3(ii,iii).

(i): The assertion for representable colimits follows from the proof of (v) (together with remark 1.3.14(i)). Next, let $F : I \to \mathscr{C}/X$ be any functor from a connected small category I; taking into account examples 1.2.7(ii) and (1.4.10) it suffices to show that the natural morphism

$$((\mathsf{s}_X)_{\mathsf{V}!} \lim_I F)(Z) \to (\lim_I \mathsf{s}_X \circ F)(Z) \qquad (\varphi : Z \to X, \tau : c_\varphi \Rightarrow F) \mapsto (\mathsf{s}_X * \tau : c_Z \Rightarrow \mathsf{s}_X \circ F)$$

is an isomorphism for every $Z \in \mathrm{Ob}(\mathscr{C})$ and any sufficiently large universe V. Now, let $\tau : c_Z \Rightarrow \mathsf{s}_X \circ F$ be any cone (with vertex an arbitrary $Z \in \mathrm{Ob}(\mathscr{C})$); we remark :

Claim 1.4.15. For every $i, j \in \mathrm{Ob}(I)$ we have $Fi \circ \tau_i = Fj \circ \tau_j : Z \to X$.

Proof of the claim. Since I is connected, a simple induction argument reduces to the case where there exists $k \in \mathrm{Ob}(I)$ with morphisms $a : k \to i$ and $b : k \to j$. In this case, we may compute directly : $Fi \circ \tau_i = Fi \circ \mathsf{s}_X(Fa) \circ \tau_k = F_k \circ \tau_k = Fj \circ \mathsf{s}_X(Fb) \circ \tau_k = Fj \circ \tau_j$. ◊

Hence, pick any $i \in \mathrm{Ob}(I)$ (recall that this set is non-empty), and set $\varphi := Fi \circ \tau_i$; claim 1.4.15 says that τ lifts uniquely to a cone $\tau_{/X} : c_\varphi \Rightarrow F$, such that $\mathsf{s}_X * \tau_{/X} = \tau$, whence the contention.

(iv): Pick a universe V such that $\mathscr{C}$ has V-small Hom-sets. For every $Y \in \mathrm{Ob}(\mathscr{C})$, the functor

$$\mathscr{C} \to \mathscr{C}_{\mathsf{V}}^\wedge \qquad Y \mapsto X \amalg Y$$

is then representable by a functor $\mathscr{C} \to \mathscr{C}$, and we abuse notation, by denoting both functors in the same way. Moreover, the universal cocone for the coproduct consists of a pair of morphisms $X \xrightarrow{i_{X,Y}} X \amalg Y \xleftarrow{i'_{X,Y}} Y$ whence a functor

$$i_X : \mathscr{C} \to X/\mathscr{C} \quad : \quad Y \mapsto i_{X,Y} \qquad \text{for every } Y \in \mathrm{Ob}(\mathscr{C}).$$

It is easily seen that i_X is left adjoint to t_X (details left to the reader). Thus, the assertion follows from proposition 1.3.25(i,iii).

(iii): Notice that the source functor $\mathsf{s}_X : \mathscr{C}/X \to \mathscr{C}$ equals $\mathsf{t}^o_{X^o}$ and the coproducts of $\mathscr{C}^o$ are representable; then the assertion follows from (iv) and remark 1.1.19(iv). The same argument shows that (i) implies (ii). □

Remark 1.4.16. Let $\mathscr{C}$ and X be as in proposition 1.4.13(vi).

(i) The functor $\mathsf{s}_{X!}$ does not generally preserve final objects, hence it is not generally exact.

(ii) The quasi-inverse to e_X constructed in the proof of proposition 1.4.13(vi.b), can be described more compactly as the functor that assigns to any object $g : F \to h_X$ of $\mathscr{C}^\wedge/h_X$ the presheaf given by the rule :

$$(Y \xrightarrow{\varphi} X) \mapsto \mathrm{Hom}_{\mathscr{C}^\wedge/h_X}((h_Y \xrightarrow{h_\varphi} h_X), g).$$

Example 1.4.17. (i) Let $\mathscr{C}$ be a category whose binary products are representable, and pick a universe V such that $\mathscr{C}$ has V-small Hom-sets. For every $X \in \mathrm{Ob}(\mathscr{C})$, we have a functor

$$p_X : \mathscr{C} \to \mathscr{C}^\wedge_{\mathsf{V}} \qquad Y \mapsto X \times Y$$

and the assumption on $\mathscr{C}$ implies that p_X is representable by a functor $\pi_X : \mathscr{C} \to \mathscr{C}$ (remark 1.2.8(ii)). Let now $F : I \to \mathscr{C}$ be a functor from a small category I; we say that *the colimit of F commutes with products*, if π_X commutes with the colimit of F, for every $X \in \mathrm{Ob}(\mathscr{C})$.

(ii) A more restricted class of colimits plays a role in applications. Namely, suppose now that all fibre products of $\mathscr{C}$ are representable. Let F be as in (i), and consider any cone $\tau : F \Rightarrow c_X$, for any $X \in \mathrm{Ob}(\mathscr{C})$. Notice that τ is the same as the datum of a functor $F_\tau : I \to \mathscr{C}/X$ which *lifts F, i.e.* such that $\mathsf{s}_X \circ F_\tau = F$, where $\mathsf{s}_X : \mathscr{C}/X \to \mathscr{C}$ is the source functor. Moreover, the assumption on $\mathscr{C}$ implies that the products are representable in $\mathscr{C}/X$, for every such X. In this situation, we shall then say that the colimit of F is *universal*, if the colimit of F_τ commutes with products, for every X and τ as above.

(iii) Suppose moreover that the colimit of F is representable by an object C^o of $\mathscr{C}^o$, and fix a universal cocone $\mu : F \Rightarrow c_C$. Then any τ as in (ii) corresponds to a unique morphism $f : C \to X$, and μ lifts to a universal cocone $\mu_\tau : F_\tau \Rightarrow c_f$. For every morphism $g : Y \to X$ in $\mathscr{C}$ we may consider the functor

$$F \times_{(\tau,g)} Y := \mathsf{s}_X \circ \pi_g \circ F_\tau : I \to \mathscr{C}$$

(that is, $F \times_{(\tau,g)} Y(i)$ represents $Fi \times_{(\tau_i,g)} Y$ for every $i \in \mathrm{Ob}(I)$). Likewise, we abuse notation and write $C \times_{(f,g)} Y$ to denote the representative $\mathsf{s}_X \circ \pi_g(f)$ for this fibre product; taking into account proposition 1.4.13(v), we see that the colimit of F is universal if and only if the cocone

$$(\mathsf{s}_X \circ \pi_g) * \mu_\tau : F \times_{(\tau,g)} Y \Rightarrow c_{C \times_{(f,g)} Y}$$

is universal for every such X, τ and g.

(iv) For instance, from the explicit descriptions of example 1.2.23(i) one may deduce that all colimits in $\mathbf{Set}$ are universal. In view of example 1.2.24(i) and corollary 1.4.3(ii), it follows easily that all colimits in $\mathscr{B}^\wedge$ are universal, for any small category $\mathscr{B}$.

1.4.18. Let $F : \mathscr{A} \to \mathscr{B}$ be a functor from a small category $\mathscr{A}$ to a category $\mathscr{B}$ with small Hom-sets. By remark 1.3.6(ii), for every object $A \in \mathrm{Ob}(\mathscr{A})$ we have a natural isomorphism $h_{FA} \xrightarrow{\sim} F_!A$; combining with example 1.2.28(i), we deduce that the adjoint pair of functors $F^\wedge : \mathscr{B}^\wedge \to \mathscr{A}^\wedge$ and $F_! : \mathscr{A}^\wedge \to \mathscr{B}^\wedge$ induces an adjoint pair :

$$(F^\wedge)_{|h_A} : \mathscr{B}^\wedge/h_{FA} \xrightarrow{\sim} \mathscr{B}^\wedge/F_!h_A \to \mathscr{A}^\wedge/h_A \qquad (F_!)_{|h_A} : \mathscr{A}^\wedge/h_A \to \mathscr{B}^\wedge/F_!h_A \xrightarrow{\sim} \mathscr{B}^\wedge/h_{FA}.$$

For every category I, let $I_\circ$ be the category such that

- $\mathrm{Ob}(I_\circ)$ is the disjoint union of $\mathrm{Ob}(I)$ with a set $\{i_\circ\}$

- $i_\circ$ is the unique final object of $I_\circ$
- I is a full subcategory of $I_\circ$ (more precisely, the full subcategory of $I_\circ$ whose set of objects is $\mathrm{Ob}(I)$ coincides with I).

It is clear that these conditions determine uniquely $I_\circ$. Moreover, for every category $\mathscr{C}$ and every $C \in \mathrm{Ob}(\mathscr{C})$, every functor $\varphi : I \to \mathscr{C}/C$ extends uniquely to a well defined functor $\varphi_\circ : I_\circ \to \mathscr{C}/C$ such that $\varphi_\circ(i_\circ) = \mathbf{1}_C$.

Proposition 1.4.19. (i) *With the notation of* (1.4.18)*, for every* $A \in \mathrm{Ob}(\mathscr{A})$ *we have* essentially commutative *diagrams :*

$$\begin{array}{ccc} (\mathscr{B}/FA)^\wedge & \xrightarrow{(F_{|A})^\wedge} & (\mathscr{A}/A)^\wedge \\ {\scriptstyle e_{FA}}\downarrow & & \downarrow{\scriptstyle e_A} \\ \mathscr{B}^\wedge/h_{FA} & \xrightarrow{(F^\wedge)_{|h_A}} & \mathscr{A}^\wedge/h_A \end{array} \qquad \begin{array}{ccc} (\mathscr{A}/A)^\wedge & \xrightarrow{(F_{|A})_!} & (\mathscr{B}/FA)^\wedge \\ {\scriptstyle e_A}\downarrow & & \downarrow{\scriptstyle e_{FA}} \\ \mathscr{A}^\wedge/h_A & \xrightarrow{(F_!)_{|h_A}} & \mathscr{B}^\wedge/h_{FA} \end{array}$$

where e_A *and* e_{FA} *are the equivalences of proposition* 1.4.13(vi.b).

(ii) *Let moreover* $\varphi : I \to \mathscr{A}/A$ *be any functor. Then* $F_{|A}$ *commutes with the limit of* φ *if and only if* F *commutes with the limit of* $\mathsf{s}_A \circ \varphi_\circ : I_\circ \to \mathscr{A}$.

Proof. (i): The assertion means that there exists an isomorphism of functors $e_A \circ (F_{|A})^\wedge \xrightarrow{\sim} (F^\wedge)_{|h_A} \circ e_{FA}$, and likewise for the second diagram. Let $\varphi : K \to h_{FA}$ be any object of $\mathscr{B}^\wedge/h_{FA}$; with e'_A and e'_{FA} as in the proof of proposition 1.4.13(vi.b), we get :

$$\begin{aligned} (F_{|A})^\wedge \circ e'_{FA}(\varphi) &= (F_{|A})^\wedge(\mathsf{s}^\wedge_{FA} K \times_{\mathsf{s}^\wedge_{FA} h_{FA}} \mathbb{1}_{\mathscr{B}/FA}) \\ &\xrightarrow{\sim} (\mathsf{s}_{FA} \circ F_{|A})^\wedge K \times_{(\mathsf{s}_{FA}\circ F_{|A})^\wedge h_{FA}} \mathbb{1}_{\mathscr{A}/A} \\ &\xrightarrow{\sim} \mathsf{s}^\wedge_A \circ F^\wedge K \times_{\mathsf{s}^\wedge_A \circ F^\wedge h_{FA}} \mathbb{1}_{\mathscr{A}/A} \\ &\xrightarrow{\sim} e'_A(u^\wedge K \times_{F^\wedge h_{FA}} h_A \to h_A) \\ &\xrightarrow{\sim} e'_A \circ (F^\wedge)_{|h_A}(\varphi) \end{aligned}$$

whence the essential commutativity of the left square diagram. Since e_A and e_{FA} are equivalences, and since $(F_!)_{|h_A}$ is left adjoint to $(F^\wedge)_{|h_A}$, we deduce the essential commutativity for the right square diagram as well.

(ii): Let $j : I \to I_\circ$ be the inclusion functor; notice first that for every category $\mathscr{C}$, every $C \in \mathrm{Ob}(\mathscr{C})$ and every functor $\psi : I \to \mathscr{C}$ we have $\psi = \psi_\circ j$, and the morphism of presheaves

$$\lim_j \mathbf{1}_{\mathscr{C}} : \lim_{I_\circ} \psi_\circ \to \lim_I \psi$$

is an isomorphism (notation of remark 1.2.11(i)). Moreover, it is clear that $F_{|A} \circ \varphi_\circ = (F_{|A} \circ \varphi)_\circ$. There follows a commutative diagram of presheaves :

$$\begin{array}{ccc} (F_{|A})_!(\lim_{I_\circ} \varphi_\circ) & \longrightarrow & \lim_{I_\circ} F_{|A} \circ \varphi_\circ \\ \downarrow & & \downarrow \\ (F_{|A})_!(\lim_I \varphi) & \longrightarrow & \lim_I F_{|A} \circ \varphi. \end{array}$$

whose vertical arrows are isomorphisms, and whose horizontal arrows are the morphisms of definition 1.3.11(i). Especially, $F_{|A}$ commutes with the limit of φ if and only if it commutes with the limit of $\varphi_\circ$. We are thus reduced to checking the following more general :

Claim 1.4.20. Let J be a connected category, and $\psi : J \to \mathscr{A}/A$ a functor. Then $F_{|A}$ commutes with the limit of ψ if and only if F commutes with the limit of $\mathsf{s}_A \circ \psi$.

Proof of the claim. Recall first that $\mathsf{s}_{FA!} = \mathsf{s}_{h_{FA}} \circ e_{FA}$. Since $\mathsf{s}_{h_{FA}}$ is obviously conservative, and e_{FA} is an equivalence, it follows that $\mathsf{s}_{FA!}$ is conservative. Recall moreover that s_A and s_{FA} commute with every connected limit (proposition 1.4.13(i)); summing up, we see that $F_{|A}$ commutes with the limit of ψ if and only if the morphism

$$\mathsf{s}_{FA!} \circ (F_{|A})_!(\lim_J \psi) \xrightarrow{\mathsf{s}_{FA!}(\omega)} \mathsf{s}_{FA!}(\lim_J F_{|A} \circ \psi) \xrightarrow{\omega'} \lim_J \mathsf{s}_{FA} \circ F_{|A} \circ \psi$$

is an isomorphism, where $\omega : (F_{|A})_!(\lim_J \psi) \to \lim_J F_{|A} \circ \psi$ and ω' are the morphisms of definition 1.3.11(i). But this composition is, up to isomorphism, the same as the morphism

$$(F \circ \mathsf{s}_A)_!(\lim_J \psi) \to \lim_J F \circ \mathsf{s}_A \circ \psi \qquad (1.4.21)$$

of definition 1.3.11(i), relative to the functor $\mathsf{s}_{FA} \circ F_{|A} = F \circ \mathsf{s}_A$ and the limit of ψ (see the proof of proposition 1.3.17(i)). By the same token, (1.4.21) is also the composition $\omega''' \circ F_!(\omega'')$ of the same type, where $\omega'' : \mathsf{s}_{A!}(\lim_J \psi) \to \lim_J \mathsf{s}_A \circ \psi$ is an isomorphism (since J is connected), and $\omega''' : F_!(\lim_J \psi) \to \lim_J F \circ \psi$ is an isomorphism if and only if F commutes with J. □

1.5. **Coinitial and cofinal functors.** Let I be a small category, $\mathscr{C}$ a category, and $F : I \to \mathscr{C}$ any functor. For the computation of the limit or colimit of F, it may sometimes be desirable to replace the indexing category I by simpler ones. That is, we would like to be able to detect whether a given functor $\varphi : J \to I$ induces an isomorphism from the colimit of F to that of $F \circ \varphi$, and if possible, to construct useful functors of this type, to aid with the calculation of limits or colimits. Concerning the first aim, one has a general criterion, for which we shall need the following :

Definition 1.5.1. Let I, J be any two categories, and $\varphi : J \to I$ any functor.

(i) We say that φ is *cofinal* if the category $i/\varphi J$ is connected, for every $i \in \mathrm{Ob}(I)$ (see definition 1.2.19(ii)).
(ii) We say that φ is *coinitial* if $\varphi^o : J^o \to I^o$ is cofinal.
(iii) If φ is the inclusion functor of a subcategory J of I, and φ is cofinal (resp. coinitial) we also say that J is *cofinal in* I (resp. *coinitial in* I).
(iv) We say that the category I is *coinitially small* (resp. *cofinally small*), if there exists a coinitial (resp. cofinal) functor $\varphi : J \to I$ with J a small category. (See corollary 1.6.5.)

Proposition 1.5.2. *Let $\varphi : J \to I$ be any functor between small categories. Then the following conditions are equivalent :*

(a) *For every category $\mathscr{C}$ with small* Hom*-sets, and every functor $F : I \to \mathscr{C}$, the functor φ induces an isomorphism of presheaves on I^o (see remark* 1.2.11(i)*) :*

$$\operatorname*{colim}_{\varphi} \mathbf{1}_{\mathscr{C}} : \operatorname*{colim}_I F \xrightarrow{\sim} \operatorname*{colim}_J F \circ \varphi. \qquad (1.5.3)$$

(b) *The functor φ is cofinal.*

Proof. (a)⇒(b): We fix $i \in \mathrm{Ob}(I)$ and we apply the definition to the functor

$$h_{i^o} : I \to \mathbf{Set} \qquad i' \mapsto \mathrm{Hom}_I(i, i')$$

whose colimit is a presheaf on the category $\mathbf{Set}^o$. Then the assertion is an immediate consequence of the following :

Claim 1.5.4. For every $i \in \mathrm{Ob}(I)$ we have :

(i) The colimit of h_{i^o} is representable by a set with one element.
(ii) The colimit of $h_{i^o} \circ \varphi$ is representable by $\pi_0(i/\varphi J)$ (notation of remark 1.2.21(ii)).

Proof of the claim. Notice that (i) is the special case of (ii) for $\varphi = \mathbf{1}_I$, since the category i/I admits an initial object, and hence is connected.

(ii): Let $h_I : I \to I^\wedge$ be the Yoneda embedding and choose a representative $L \in \mathrm{Ob}(I^\wedge)$ for the colimit of the functor $h_I \circ \varphi$. By corollary 1.4.3(ii) and remark 1.3.14(i), the set $L(i)$ represents the colimit of $h_{i^o} \circ \varphi$. On the other hand, from remark 1.3.6(ii) we see that L represents as well the colimit of $\varphi_! \circ h_J$. Moreover, recall that the colimit of h_J is represented by the coinitial object $\mathbb{1}_J$ of $J^\wedge$ (example 1.4.9(i)); by corollary 1.4.3(vii) and remark 1.3.14(i) we deduce that L is isomorphic to $\varphi_!(\mathbb{1}_J)$. Then the assertion follows from example 1.3.9. ◊

(b)⇒(a): Let $F : I \to \mathscr{C}$ be any functor; recall that the colimit of F is the functor $L : \mathscr{C} \to \mathbf{Set}$ that assigns to any $X \in \mathrm{Ob}(\mathscr{C})$ the set $L(X)$ of all cocones $F \Rightarrow c_X$, *i.e.* all the compatible systems of morphisms $(\tau_i : Fi \to X \mid i \in \mathrm{Ob}(I))$ in $\mathscr{C}$, such that

$$\tau_{i'} \circ Fg = \tau_i \qquad \text{for every morphism } g : i \to i' \text{ in } I.$$

Likewise, the colimit of $F \circ \varphi$ is the functor $L' : \mathscr{C} \to \mathbf{Set}$ that assigns to any $X \in \mathrm{Ob}(\mathscr{C})$ the set $L'(X)$ of all compatible systems $(\mu_j : F\varphi(j) \to X \mid j \in \mathrm{Ob}(J))$ in $\mathscr{C}$, such that

$$\mu_{j'} \circ F\varphi(h) = \mu_j \qquad \text{for every morphism } h : j \to j' \text{ in } J.$$

Under these identifications, (1.5.3) is the map that assigns to a given τ as above, the compatible system $\tau * \varphi$, such that $(\tau * \varphi)_j := \tau_{\varphi(j)}$ for every $j \in \mathrm{Ob}(J)$. We have to check that the rule $\tau \mapsto \tau * \varphi$ is a bijection $\beta_X : L(X) \xrightarrow{\sim} L'(X)$. However, say that $\tau * \varphi = \tau' * \varphi$ for given $\tau, \tau' \in L(X)$, and consider any $i \in \mathrm{Ob}(I)$; since $i/\varphi J$ is non-empty, we may find $j \in \mathrm{Ob}(J)$ and a morphism $g : i \to \varphi(j)$ in I, whence

$$\tau_i = \tau_{\varphi(j)} \circ Fg = \tau'_{\varphi(j)} \circ Fg = \tau'_i$$

hence β_X is injective. Next, let $\mu \in L'(X)$ be any compatible system; we consider the map

$$\tau^* : \mathrm{Ob}(I/\varphi J) \to \mathrm{Morph}(\mathscr{C}) \qquad (g : i \to \varphi(j)) \mapsto \mu_j \circ Fg$$

(notation of (1.1.28) and (1.1.30)). We claim that τ^* factors through the map

$$\mathrm{Ob}(I/\varphi J) \to \mathrm{Ob}(I) \quad : \quad (g : i \to \varphi(j)) \mapsto i.$$

Indeed, say that $g : i \to \varphi(j)$ and $g' : i \to \varphi(j')$ are any two morphisms in I; we have to show that $\tau^*_g = \tau^*_{g'}$. To this aim, since $i/\varphi J$ is connected, we may assume that there exists a morphism $h : g \to g'$ in $i/\varphi J$; then

$$\tau^*_g = \mu_j \circ Fg = \mu_{j'} \circ F\varphi(h) \circ Fg = \mu_{j'} \circ Fg' = \tau^*_{g'}$$

as stated. Thus, let $\tau : \mathrm{Ob}(I) \to \mathrm{Morph}(\mathscr{C})$ be the resulting map; we claim that τ is an element of $L(X)$. Indeed, say that $h : i \to i'$ is any morphism in I, and pick any $j, j' \in \mathrm{Ob}(J)$ with morphisms $g : i \to \varphi(j)$, $g' : i' \to \varphi(j')$ in I; we have just seen that $\tau^*_{g' \circ h} = \tau^*_g$, which translates as the identity : $\tau_i = \tau_{i'} \circ Fh$, whence the claim. Lastly, by construction we have $\beta_X(\tau) = \mu$, so β_X is also surjective. □

Remark 1.5.5. (i) If $\varphi : I \to J$ and $\psi : J \to K$ are cofinal functors, the same holds for $\psi \circ \varphi$. For the proof, we may replace our universe U by a larger one, after which we may assume that I, J, K are small categories, and then the assertion follows directly from proposition 1.5.2.

(ii) Let $\varphi : J \to I$ be a functor between small categories. Then φ is coinitial if and only if it induces isomorphisms of presheaves on I

$$\lim_I F \xrightarrow{\sim} \lim_J F \circ \varphi \tag{1.5.6}$$

for every category $\mathscr{C}$ with small Hom-sets, and every functor $F : I \to \mathscr{C}$.

(iii) Let $\varphi : J \to I$ and $F : I \to \mathscr{C}$ be any two functors; suppose that the induced morphism of presheaves $\mathrm{colim}_\varphi \mathbf{1}_\mathscr{C} : \mathrm{colim}_I F \to \mathrm{colim}_J F \circ \varphi$ is an isomorphism, and let $\tau : F \Rightarrow c_L$ be a cocone. Then τ is universal if and only if the same holds for $\tau * \varphi : F \circ \varphi \Rightarrow c_L$. Indeed, τ and $\tau * \varphi$ determine morphisms of presheaves $t : h_{L^o} \to \mathrm{colim}_I F$ and $t' : h_{L^o} \to \mathrm{colim}_J F \circ \varphi$ on $\mathscr{C}^o$ that assign to every $X \in \mathrm{Ob}(\mathscr{C})$ and every section $f : L \to X$ of $h_{L^o}(X^o)$ the cocone $\tau \odot c_f \in \mathrm{colim}_I F(X^o)$ and respectively the cocone $(\tau * \varphi) \odot c_f \in \mathrm{colim}_J F \circ \varphi(X)$, and t (resp. t') is an isomorphism if and only if τ (resp. $\tau * \varphi$) is universal. However, $(\mathrm{colim}_\varphi \mathbf{1}_{\mathscr{C}}) \circ t$ is the morphism of presheaves $h_{L^o} \xrightarrow{\sim} \mathrm{colim}_J F \circ \varphi$ that assigns to every such X and f the cone $(\tau \odot c_f) * \varphi = (\tau * \varphi) \odot c_f$, i.e. $t' = (\mathrm{colim}_\varphi \mathbf{1}_{\mathscr{C}}) \circ t$. So t is an isomorphism if and only if the same holds for t', whence the contention. Likewise, if (1.5.6) is an isomorphism, a cone $\tau' : c_{L'} \Rightarrow F$ is universal if and only if the same holds for $\tau' * \varphi : c_{L'} \Rightarrow F \circ \varphi$.

Lemma 1.5.7. *Let I, J be two categories, and $\varphi : J \to I$ a functor. We have :*

- (i) *If J is filtered, then φ is cofinal if and only if the following two conditions hold :*
  - (a) *For every $i \in \mathrm{Ob}(I)$ there exist $j \in \mathrm{Ob}(J)$ and a morphism $i \to \varphi(j)$ in I.*
  - (b) *For every $i \in \mathrm{Ob}(I)$, every $j \in \mathrm{Ob}(J)$ and every pair of morphisms $f, g : i \to \varphi(j)$ in I, there exists a morphism $h : j \to j'$ in J such that $\varphi(h) \circ f = \varphi(h) \circ g$.*
- (ii) *If J is filtered and φ is cofinal, then I is filtered.*
- (iii) *Suppose that I is filtered, and condition* (i.a) *is fulfilled. Then the following holds :*
  - (a) *If φ is full, then φ is cofinal and J is directed.*
  - (b) *If φ is fully faithful, J is filtered.*

Proof. (i): Indeed, suppose that the categories $i/\varphi J$ are connected for every $i \in \mathrm{Ob}(I)$; then (a) clearly holds. To check that (b) holds as well, notice that, since J is filtered, $i/\varphi J$ is locally directed for every $i \in \mathrm{Ob}(I)$ (details left to the reader), and therefore it is directed, by remark 1.2.21(i). This implies that, for given f, g as in (b), there exist $j' \in \mathrm{Ob}(J)$ and morphisms $h_1, h_2 : j \to j'$ such that $\varphi(h_1) \circ f = \varphi(h_2) \circ g$. But since J is filtered, we may then find a morphism $h' : j' \to j''$ in J such that $h' \circ h_1 = h' \circ h_2$, so (b) holds with $h := h' \circ h_1$.

Conversely, if (a) holds, then $i/\varphi J$ is non-empty for every $i \in \mathrm{Ob}(I)$. Next, let $g : i \to \varphi(k)$ and $g' : i \to \varphi(k')$ be any two objects of $i/\varphi J$; since J is directed we may find morphisms $h : k \to j$ and $h' : k' \to j$ for some $j \in \mathrm{Ob}(J)$, whence objects $\varphi(h) \circ g, \varphi(h') \circ g' : i \to \varphi(j)$ of $i/\varphi J$, and using (b) we deduce that there exist an object $g'' : i \to \varphi(j')$ and morphisms $g \to g''$, $g' \to g''$, *i.e.* $i/\varphi J$ is directed.

(ii): Let us check that I is directed : if i and i' are two objects of I, in view of condition (i.a), we may find $j, j' \in \mathrm{Ob}(J)$ and morphisms $f : i \to \varphi(j)$, $f' : i' \to \varphi(j')$ in I, and since J is directed, we have as well morphisms $g : j \to j''$ and $g' : j' \to j''$ in J, for some $j'' \in \mathrm{Ob}(J)$, whence morphisms $\varphi(g) \circ f : i \to \varphi(j'')$ and $\varphi(g') \circ f' : i' \to \varphi(j'')$ in I. By remark 1.2.21(i) it remains to check the coequalizing condition of definition 1.2.19(v), but the latter is an immediate consequence of conditions (i.a) and (i.b).

(iii.a): It has already been remarked that condition (i.a) says that the category $i/\varphi J$ is non-empty for every $i \in \mathrm{Ob}(I)$. Next, let $g : i \to \varphi(k)$ and $g' : i \to \varphi(k')$ be two objects of $i/\varphi J$. Since I is filtered, we may find $i' \in \mathrm{Ob}(I)$ and morphisms $h : \varphi(k) \to i'$ and $h' : \varphi(k') \to i'$ of I such that $f := h \circ g = h' \circ g'$, and since (i.a) holds, we may find $k'' \in \mathrm{Ob}(J)$ with a morphism $l : i' \to \varphi(k'')$ in I; then, since φ is full, there exist morphisms $t : k \to k''$ and $t' : k' \to k''$ in J such that $\varphi(t) = l \circ h$ and $\varphi(t') = l \circ h'$. Then $l \circ f : i \to \varphi(k'')$ is an object of $i/\varphi J$ with morphisms $t : g \to l \circ f$ and $t' : g' \to l \circ f$, so $i/\varphi J$ is directed, and this shows that φ is cofinal.

Next, let $j, j' \in \mathrm{Ob}(J)$; since I is filtered, there exists $i \in \mathrm{Ob}(I)$ with morphisms $g : \varphi(j) \to i$ and $g' : \varphi(j') \to i$ in I. Since (i.a) holds, there exists a morphism $h : i \to \varphi(k)$ in I, and since φ is full, there exist morphisms $t : j \to k$ and $t' : j' \to k$ in J with $\varphi(t) = h \circ g$ and $\varphi(t') = h \circ g'$; this shows that J is directed.

(iii.b): Clearly the assumptions show that $\mathrm{Ob}(J) \neq \varnothing$, and we know already that J is directed, by (iii.a). Next, let $g, g' : j \to j'$ be two morphisms in J; since I is filtered, we have a morphism $h : \varphi(j') \to i$ in I such that $h \circ \varphi(g) = h \circ \varphi(g')$, and since (i.a) holds, there exists $j'' \in \mathrm{Ob}(J)$ with a morphism $l : i \to \varphi(j'')$ in I. Since φ is full, there exists a morphism $t : j' \to j''$ such that $\varphi(t) = l \circ h$, so that $\varphi(t \circ g) = \varphi(t \circ g')$, and since φ is faithful, we must then have $t \circ g = t \circ g'$, so J is filtered, by remark 1.2.21(i). □

Remark 1.5.8. In light of lemma 1.5.7(i), we see that if I is a filtered (resp. cofiltered) preordered set and J is a subset, then J is cofinal (resp. coinitial) in I in the sense of [36, Ch.III, §8, n.7] if and only if the inclusion functor $J \to I$ is cofinal (resp. coinitial) in the sense of our definition 1.5.1(i,ii).

Example 1.5.9. (i) For instance, if I is a filtered category, and i is any object of I, the category i/I is again filtered, and the target functor $\mathsf{t}_i : i/I \to I$ is cofinal; indeed, one checks easily that t_i fulfills conditions (a) and (b) of lemma 1.5.7(i). Dually, if I is cofiltered, the category I/i is again cofiltered, and the source functor $\mathsf{s}_i : I/i \to I$ is coinitial.

(ii) If I admits a final object i_0, then the (full) subcategory J of I with $\mathrm{Ob}(J) = \{i_0\}$ fulfills conditions (a) and (b) of lemma 1.5.7(i), so the inclusion functor $J \to I$ is cofinal (and I is trivially filtered). Then, let $F : I \to \mathscr{C}$ be any functor, and $\tau : F \Rightarrow c_L$ a universal cocone; taking into account remark 1.5.5(iii), we see that Fi_0 represents the colimit of F, and $\tau_{i_0} : Fi \to L$ is an isomorphism in $\mathscr{C}$. Dually, if i'_0 is any initial object of I, and $\tau' : c_{L'} \Rightarrow F$ any universal cone, then Fi'_0 represents the limit of F and $\tau_{i'_0} : L' \to Fi'_0$ is an isomorphism.

Example 1.5.10. As an application, we give an explicit construction of the filtered colimits of $\mathbf{Cat}$. Thus, let I be a small filtered category, and consider a functor

$$\mathscr{C}_\bullet : I \to \mathbf{Cat} \qquad i \mapsto \mathscr{C}_i \qquad (\varphi : i \to j) \mapsto (\mathscr{C}_\varphi : \mathscr{C}_i \to \mathscr{C}_j).$$

We deduce a functor $\mathrm{Ob}(\mathscr{C}_\bullet) : I \to \mathbf{Set}$ that assigns to every $i \in \mathrm{Ob}(I)$ the set $\mathrm{Ob}(\mathscr{C}_i)$, and to every morphism $\varphi : i \to j$ in I the map $\mathrm{Ob}(\mathscr{C}_i) \to \mathrm{Ob}(\mathscr{C}_j)$ defined by $\mathscr{C}_\varphi$. We set

$$L := \operatorname*{colim}_I \mathrm{Ob}(\mathscr{C}_\bullet).$$

According to example 1.2.23(i) – and since I is filtered – the elements of L are the equivalence classes $[i, X]$ of pairs (i, X), where $i \in \mathrm{Ob}(I)$ and $X \in \mathrm{Ob}(\mathscr{C}_i)$, for the equivalence relation such that $(i, X) \sim (j, Y)$ if and only if there exist $k \in \mathrm{Ob}(I)$ and morphisms $\varphi_1 : i \to k$ and $\varphi_2 : j \to k$ such that $\mathscr{C}_{\varphi_1} X = \mathscr{C}_{\varphi_2} Y$. For every $i \in \mathrm{Ob}(I)$, let $\mathsf{t}_i : i/I \to I$ be the target functor (see (1.1.24)); notice that for every pair of objects $i, j \in \mathrm{Ob}(I)$, the objects of the category $(i, j)/I := i/I \times_{(\mathsf{t}_i,\mathsf{t}_j)} j/I$ are the pairs $i \xrightarrow{\varphi_1} k \xleftarrow{\varphi_2} j$ of morphisms of I, and the morphisms

$$(1.5.11) \qquad (i, j)/\nu : (i \xrightarrow{\varphi_1} k \xleftarrow{\varphi_2} j) \to (i \xrightarrow{\varphi'_1} k' \xleftarrow{\varphi'_2} j)$$

are the morphisms $\nu : k \to k'$ of I such that $\nu \circ \varphi_r = \varphi'_r$ for $r = 1, 2$. For every couple of pairs $((i, X), (j, Y))$ as in the foregoing, we get a functor $h(i, X, j, Y) : (i, j)/I \to \mathbf{Set}$ that assigns to every $(i \xrightarrow{\varphi_1} k \xleftarrow{\varphi_2} j) \in \mathrm{Ob}((i, j)/I)$ the set $\mathrm{Hom}_{\mathscr{C}_k}(\mathscr{C}_{\varphi_1} X, \mathscr{C}_{\varphi_2} Y)$, and to every morphism $(i, j)/\nu$ as in (1.5.11) the induced map

$$\mathrm{Hom}_{\mathscr{C}_k}(\mathscr{C}_{\varphi_1} X, \mathscr{C}_{\varphi_2} Y) \to \mathrm{Hom}_{\mathscr{C}_{k'}}(\mathscr{C}_{\varphi'_1} X, \mathscr{C}_{\varphi'_2} Y) \qquad f \mapsto \mathscr{C}_\nu(f)$$

and we set

$$H(i, X, j, Y) := \operatorname*{colim}_{(i,j)/I} h(i, X, j, Y).$$

Let also $\mathsf{t}_{i,j} : (i, j)/I \to I$ be the target functor given by the rules : $(i \xrightarrow{\varphi_1} k \xleftarrow{\varphi_2} j) \mapsto k$, and $(i, j)/\nu \mapsto \nu$; for every $i, j, k \in \mathrm{Ob}(I)$ we set as well $(i, j, k)/I := (i, j)/I \times_{(\mathsf{t}_{i,j},\mathsf{t}_k)} k/I$. Explicitly, the objects of this category are all the systems $\varphi_\bullet := (\varphi_1 : i \to t, \varphi_2 : j \to t, \varphi_3 : k \to t)$ of morphisms of I with a common target t that we call *the target of* $\varphi_\bullet$. The morphisms

$$(i, j, k)/\nu : \varphi_\bullet \to \varphi'_\bullet$$

are the morphisms ν of I with $\nu \circ \varphi_r = \varphi'_r$ for $r = 1, 2, 3$. With this notation, for every third pair (k, Z) as in the foregoing, we get a system of composition maps

$$h(i,X,j,Y)(\varphi_\bullet) \times h(j,Y,k,Z)(\varphi_\bullet) \to h(i,X,k,Z)(\varphi_\bullet) \qquad \text{for every } \varphi_\bullet \in \mathrm{Ob}((i,j,k)/I)$$

given by the composition law of the category $\mathscr{C}_t$, where t is the target of $\varphi_\bullet$. Clearly this system of maps is natural with respect to morphisms of $(i,j,k)/I$; moreover we have obvious projection functors $(i,k)/I \leftarrow (i,j,k)/I \to (i,j)/I$ and $(i,j,k)/I \to (j,k)/I$, and using the criterion of lemma 1.5.7(i) it is easily seen all that these three functors are cofinal. Therefore, taking colimits over $(i,j,k)/I$ of the foregoing compatible system of composition maps yields a well defined map

$$H(i,X,j,Y) \times H(j,Y,k,Z) \to H(i,X,k,Z) \qquad (f,g) \mapsto g \circ f$$

and a simple inspection of the construction shows that this composition law is associative : if $h \in H(k,Z,t,W)$ is any other element, we have $h \circ (g \circ f) = (h \circ g) \circ f$ (details left to the reader); likewise, the class of $\mathbf{1}_X$ in $H(i,X,i,X)$ yields a left and right unit for this composition law. Hence, let us choose for every $A \in L$ a representative (i_A, X_A); we obtain a well defined category $\mathscr{L}$ with $\mathrm{Ob}(\mathscr{L}) = L$ and with $\mathrm{Hom}_{\mathscr{L}}(A,B) := H(i_A, X_A, i_B, X_B)$ for every $A, B \in L$, with the composition law thus defined. Moreover, for every $i \in I$ we obtain a well defined functor $G_i : \mathscr{C}_i \to \mathscr{L}$ by setting $GX := [i, X]$ for every $X \in \mathrm{Ob}(\mathscr{C}_i)$, and by assigning to every morphism $X \to Y$ of $\mathscr{C}_i$ its class in $H(i,X,i,Y)$. Lastly, let $F : \mathscr{C}_\bullet \Rightarrow \mathscr{D}$ be a cocone with basis $\mathscr{C}_\bullet$ and whose vertex is any category $\mathscr{D}$. The induced cocone $\mathrm{Ob}(\mathscr{C}_\bullet) \Rightarrow \mathrm{Ob}(\mathscr{D})$ yields a well defined map $L \to \mathrm{Ob}(\mathscr{D})$. Moreover, for every two pairs (i,X) and (j,Y) and every object $(i \xrightarrow{\varphi_1} k \xleftarrow{\varphi_2} j)$ of $(i,j)/I$, the functor F_k yields a map

$$\mathrm{Hom}_{\mathscr{C}_k}(\mathscr{C}_{\varphi_1}X, \mathscr{C}_{\varphi_2}Y) \to \mathrm{Hom}_{\mathscr{D}}(F_k \circ \mathscr{C}_{\varphi_1}X, F_k \circ \mathscr{C}_{\varphi_2}Y) = \mathrm{Hom}_{\mathscr{D}}(F_iX, F_jY)$$

which defines a cocone with vertex $\mathrm{Hom}_{\mathscr{D}}(F_iX, F_jY)$ and for basis the functor $h(i,X,j,Y)$, whence a well defined map

$$F_{i,X,j,Y} : H(i,X,j,Y) \to \mathrm{Hom}_{\mathscr{D}}(F_iX, F_jY).$$

A simple inspection shows that $F_{i,X,k,Z}(g \circ f) = F_{j,Y,k,Z}(g) \circ F_{i,X,j,Y}(f)$ for every f, g as in the foregoing (details left to the reader). We obtain therefore a well defined functor $F : \mathscr{L} \to \mathscr{D}$ by the rule : $A \mapsto F_{i_A}X_A$ and $F_{AB}f := F_{i_A,X_A,i_B,X_B}(f)$ for every $A, B \in L$ and every $f \in \mathrm{Hom}_{\mathscr{L}}(A,B)$. By construction, we have $F \circ G_i = F_i$ for every $i \in I$, and F is clearly the unique functor fulfilling this system of identities, so the proof is concluded.

Remark 1.5.12. (i) Let I be a coinitially small category, $\mathscr{C}$ a category with small Hom-sets, and $F : I \to \mathscr{C}$ any functor. By definition, there exists a coinitial functor $\varphi : J \to I$ with J a small category, and therefore we may define the presheaf

$$L_{F,\varphi} := \lim_J F \circ \varphi.$$

We claim that $L_{F,\varphi}$ is independent - up to natural isomorphism - of the choice of φ. To see this, let us choose a universe U' such that $\mathsf{U} \subset \mathsf{U}'$ and such that I is a small U'-category. By remark 1.5.5(i), the induced morphism of U'-presheaves

$$\omega_\varphi : \lim_I F \to L_{F,\varphi}$$

is an isomorphism. Therefore, if $\varphi' : J' \to I$ is any other coinitial functor with J' also small, we get an isomorphism of U'-presheaves $\omega_{\varphi'} \circ \omega_\varphi^{-1} : L_{F,\varphi} \xrightarrow{\sim} L_{F,\varphi'}$. Since the inclusion (1.2.1) is fully faithful, the latter is actually an isomorphism of U-presheaves, as required.

(ii) In view of (i), we may define the *limit of* F as $L_{F,\varphi}$, for any choice of φ. This presheaf is therefore well defined, up to natural isomorphism, and we denote it as usual by

$$\lim_I F.$$

We also say that $\lim_I F$ is a *coinitially small limit* of $\mathscr{C}$. Of course, if I is already small, we can choose $\varphi := \mathbf{1}_I$, so the above notation is compatible with that of definition 1.2.10(i).

(iii) Dually, if I is cofinally small, we can define the *colimit of* F

$$\operatorname*{colim}_I F := \operatorname*{colim}_J F \circ \varphi$$

for any choice of cofinal functor $\varphi : J \to I$ with J small, and again the resulting presheaf is well defined up to natural isomorphism, and we also say that it is a *cofinally small colimit* of $\mathscr{C}$. Clearly, if $\mathscr{C}$ is complete (resp. cocomplete), then every coinitially small (resp. cofinally small) limit is representable in $\mathscr{C}$. As an application, we may prove Freyd's *adjoint functor theorem*, which is the following partial converse of proposition 1.3.25(iii) :

Theorem 1.5.13. *Let $\mathscr{A}$ be a complete category, $F : \mathscr{A} \to \mathscr{B}$ a functor, and suppose that $\mathscr{A}$ and $\mathscr{B}$ have small* Hom*-sets (see* (1.1.1)*). The following conditions are equivalent :*

(a) *F admits a left adjoint.*

(b) *F commutes with all the limits of $\mathscr{A}$, and every object B of $\mathscr{B}$ admits a* solution set, i.e. *an essentially small subset $S_B \subset \mathrm{Ob}(\mathscr{A})$ such that, for every $A \in \mathrm{Ob}(\mathscr{A})$, every morphism $f : B \to FA$ admits a factorization of the form*

$$f = Fh \circ g$$

for $h : A' \to A$ a morphism in $\mathscr{A}$ with $A' \in S_B$, and $g : B \to FA'$ a morphism in $\mathscr{B}$.

Proof. If F admits a left adjoint G, then F commutes with all limits of $\mathscr{A}$, by proposition 1.3.25(iii), and it is easily seen that $\{GB\}$ is a solution set for every object $B \in \mathrm{Ob}(\mathscr{B})$.

Conversely, fix any $B \in \mathrm{Ob}(\mathscr{B})$; under the stated assumptions, example 1.3.16(i) says that the category $B/F\mathscr{A}$ is cofiltered. Denote by $\mathscr{E}_B$ the full subcategory of $B/F\mathscr{A}$ whose objects are all the morphisms $B \to FA$ with $A \in S_B$. Then condition (b) means that for every object X of $B/F\mathscr{A}$ there exists an object $X' \in \mathscr{E}_B$ with a morphism $X' \to X$ of $B/F\mathscr{A}$. It follows easily that $\mathscr{E}_B$ is cofiltered as well; then the inclusion functor $\mathscr{E}_B \to B/F\mathscr{A}$ is coinitial, by lemma 1.5.7(i), and $\mathscr{E}_B$ is small, hence $B/F\mathscr{A}$ is coinitially small. Following remark 1.5.12(ii), we may thus define

$$G'B := \lim_{B/F\mathscr{A}} \mathsf{t}_B \qquad G'f := \lim_{f/F\mathscr{A}} \mathbf{1}_{\mathscr{A}}$$

for any $B \in \mathrm{Ob}(\mathscr{B})$ and any morphism $f : B' \to B$ (notation of (1.1.27)). Next, since $\mathscr{A}$ is complete, G' is representable by some functor $G : \mathscr{B} \to \mathscr{A}$ (remark 1.2.8(ii)), and we claim that G is the sought left adjoint. To check this assertion, we may replace the universe U by a larger one, after which we may assume that $\mathscr{A}$ and $\mathscr{B}$ are small, and therefore $G'B$ is the usual limit of definition 1.2.10(i). We shall then exhibit explicit unit and counit for the adjoint pair (G, F), as follows. Let $\tau^B : c_{GB} \Rightarrow \mathsf{t}_B$ be a universal cone; since F commutes with limits, the cone $F * \tau^B : c_{FGB} \Rightarrow F \circ \mathsf{t}_B$ is still universal (remark 1.3.14(i)); on the other hand, the functor $B/F : B/F\mathscr{A} \to B/\mathscr{B}$ can be regarded as a cone $B/F : c_B \Rightarrow F \circ \mathsf{t}_B$, so there exists a unique morphism $\eta_B : B \to FGB$ such that $B/F = (F * \tau^B) \odot c_{\eta_B}$. Likewise, for any $A \in \mathrm{Ob}(\mathscr{A})$ we get a morphism $\varepsilon_A := \tau^{FA}_{(A, \mathbf{1}_{FA})} : GFA \to A$. It is easily seen that η (resp. ε) is a natural transformation $\mathbf{1}_{\mathscr{B}} \Rightarrow FG$ (resp. $GF \Rightarrow \mathbf{1}_{\mathscr{A}}$), and the identity $(F * \varepsilon) \odot (\eta * F) = \mathbf{1}_F$ is immediate from the construction. Lastly, we fix $B \in \mathrm{Ob}(\mathscr{B})$ and we check that $(\varepsilon * G)_B \circ (G * \eta)_B = \mathbf{1}_{G(B)}$; to this aim, and due the universality of τ^B, it suffices to show that

$$\tau^B_\psi = \tau^B_\psi \circ \varepsilon_{GB} \circ G(\eta_B) \qquad \text{for every object } \psi : B \to FA \text{ of } B/F\mathscr{A}.$$

However, notice that the construction of Gf yields the identity

$$(1.5.14) \qquad \tau^{B'}_\psi \circ Gf = \tau^B_{\psi \circ f} \qquad \text{for all morphisms } f : B \to B' \text{ and } \psi : B' \to FA \text{ in } \mathscr{C}.$$

Thus, we may compute :

$$\tau^B_\psi \circ \varepsilon_{GB} \circ G(\eta_B) = \tau^B_\psi \circ \tau^{FGB}_{\mathbf{1}_{FGB}} \circ G(\eta_B) = \tau^{FGB}_{F(\tau^B_\psi)} \circ G(\eta_B) = \tau^B_{F(\tau^B_\psi)\circ\eta_B} = \tau^B_\psi$$

where the second equality holds by the naturality of τ^{FGB}, the third follows from (1.5.14), and the fourth comes from the construction of η_B. □

Of course, the "dual" of theorem 1.5.13 yields a criterion for the existence of right adjoints.

Example 1.5.15. (i) Let J and K be any two small categories; set $I := J \times K$ and let $\pi : I \to J$ be the projection functor. For every $j \in \mathrm{Ob}(J)$ we have an induced functor

$$\iota_j : K \to j/\pi I \qquad k \mapsto ((j,k), \mathbf{1}_j) \qquad (g : k \to k') \mapsto (\mathbf{1}_j, g)$$

and we claim that ι_j is coinitial (definition 1.5.1(ii)). Indeed, for any $((j_0,k_0), f_0 : j \to j_0) \in \mathrm{Ob}(j/\pi I)$, the category $\iota_j K/((j_0,k_0), f_0)$ is isomorphic to K/k_0, which is obviously connected, whence the claim.

(ii) Moreover, every morphism $f : j \to j'$ in J induces a natural transformation

$$\beta^f : \iota_j \Rightarrow (f/\pi I) \circ \iota_{j'}$$

which assigns to every $k \in \mathrm{Ob}(K)$ the morphism $(f, \mathbf{1}_k) : ((j,k), \mathbf{1}_j) \to ((j',k), f)$. Then, $\mathtt{t}_j * \beta^f$ is a natural transformation $\mathtt{t}_j \circ \iota_j \Rightarrow \mathtt{t}_j \circ (f/\pi I) \circ \iota_{j'} = \mathtt{t}_{j'} \circ \iota_{j'}$ and a direct inspection of the definitions yields a commutative diagram for every functor $F : I \to \mathscr{C}$

$$\begin{array}{ccc}
\int^\wedge_\pi F(j) & \xrightarrow{\int^\wedge_\pi F(f)} & \int^\wedge_\pi F(j') \\
\downarrow & & \downarrow \\
\lim_K F \circ \mathtt{t}_j \circ \iota_j & \xrightarrow{\lim_K (F * \mathtt{t}_j * \beta^f)} & \lim_K F \circ \mathtt{t}_{j'} \circ \iota_{j'}
\end{array}$$

whose vertical arrows are the natural isomorphisms provided by (i) and remark 1.5.5(ii) and whose bottom arrow is given by remark 1.2.11(ii). In other words, the functor $\int^\wedge_\pi$ is naturally isomorphic to the one that assigns to every such F the functor

$$\int^\wedge_K F : J \to \mathscr{C}^\wedge \qquad j \mapsto \lim_K F \circ \mathtt{t}_j \circ \iota_j \qquad (f : j \to j') \mapsto \lim_K (F * \mathtt{t}_j * \beta^f).$$

Lastly, proposition 1.3.2 can be restated in this case more synthetically, as the existence of a natural isomorphism in $\mathscr{C}^\wedge$

$$\lim_{J\times K} F \xrightarrow{\sim} \operatorname*{Lim}_J \int^\wedge_K F \qquad \text{for every functor } F : J \times K \to \mathscr{C}.$$

(iii) On the other hand, we may also apply the same considerations to the second projection functor $I \to K$. Summing up, we deduce a natural isomorphism

$$\operatorname*{Lim}_J \int^\wedge_K F \xrightarrow{\sim} \operatorname*{Lim}_K \int^\wedge_J F \qquad \text{for every functor } F : J \times K \to \mathscr{C}$$

which expresses the well known *interchange property* for double limits.

(iv) Dually, we obtain as well an interchange property for double colimits, that states the existence of natural isomorphisms

$$\operatorname*{Colim}_J \int^K_\wedge F \xrightarrow{\sim} \operatorname*{Colim}_{J\times K} F \xrightarrow{\sim} \operatorname*{Colim}_K \int^J_\wedge F \qquad \text{for every functor } F : J \times K \to \mathscr{C}$$

where $\int^K_\wedge$ is the opposite of the functor $\int^\wedge_{K^o}$ (and likewise for $\int^J_\wedge$: details left to the reader).

Remark 1.5.16. (i) Keep the situation of example 1.5.15, and suppose moreover that $\mathscr{C}$ is complete (resp. cocomplete). Then the functor $\int_K^\wedge$ (resp. $\int_\wedge^K$) is isomorphic to the composition of $\mathsf{Fun}(J, h_\mathscr{C})$ (resp. of $\mathsf{Fun}(J, h^o_{\mathscr{C}^o})$) and a functor

$$\int_K : \mathsf{Fun}(I, \mathscr{C}) \to \mathsf{Fun}(J, \mathscr{C}) \qquad \text{(resp. } \int^K : \mathsf{Fun}(I, \mathscr{C}) \to \mathsf{Fun}(J, \mathscr{C}))$$

that is well defined up to isomorphism, and is isomorphic to $\int_\pi$ (resp. to $\int^\pi$), so the interchange properties of example 1.5.15(iii,iv) can, in this case, be expressed also in terms of these new functors (details left to the reader).

(ii) Furthermore, if $\mathscr{C}$ is both complete and cocomplete, we get a natural morphism

$$\text{(1.5.17)} \qquad \operatorname*{Colim}_J \int_K F \to \operatorname*{Lim}_K \int^J F \qquad \text{for every functor } F : J \times K \to \mathscr{C}$$

as follows. First, for every $(j, k) \in \mathrm{Ob}(J \times K)$ we have a natural morphism

$$\omega_{j,k} : \int_K F(j) \to F(j, k) \to \int^J F(k)$$

given by the choice of a universal cone and cocone for the limit and colimit that are represented respectively by the source and target of this morphism. By inspecting the constructions, we then check easily that, for fixed $j \in \mathrm{Ob}(J)$, the system $(\omega_{j,k} \mid k \in \mathrm{Ob}(K))$ is a cone with vertex $\int_K F(j)$; the choice of a universal cone for the functor $\int^K F$ then determines a unique morphism

$$\omega_j : \int_K F(j) \to \operatorname*{Lim}_J \int^K F \qquad \text{for every } j \in \mathrm{Ob}(J).$$

In turns, the system $(\omega_j \mid j \in \mathrm{Ob}(J))$ is a cocone which determines (1.5.17), after fixing a universal cocone for the functor $\int_K F$. Of course, (1.5.17) depends on the choices of all these universal cones and cocones, but two different sets of such choices will modify the morphism by left and right composition with uniquely determined isomorphisms.

(iii) The question rises, whether (1.5.17) is an isomorphism. This is not always the case. If (1.5.17) is an isomorphism for every functor $F : J \times K \to \mathscr{C}$, we say that in the category $\mathscr{C}$ *the limits indexed by K commute with the colimits indexed by J.*

(iv) For instance, if K is finite and J is filtered, then the limits indexed by K commute with the colimits indexed by J in the category $\mathbf{Set}$ ([28, Th.2.13.4]). We say briefly that *the finite limits commute with the filtered colimits* in $\mathbf{Set}$.

Taking into account example 1.2.24(i), we deduce more generally that, for any category $\mathscr{C}$, the finite limits in $\mathscr{C}^\wedge$ commute with all filtered colimits.

Here is another useful application to Kan extensions :

Proposition 1.5.18. *In the situation of theorem* 1.3.4*, suppose that φ is fully faithful. Then the same holds for the right (resp. left) Kan extension along φ.*

Proof. Consider the right Kan extension along φ (and hence, we assume that the relevant completeness conditions for $\mathscr{C}$ as in remark 1.3.3(iii,iv) are fulfilled). Let $F : I \to \mathscr{C}$ be any functor, and to ease notation set $K := \int_\varphi F$; by proposition 1.1.20(iii), it suffices to exhibit an isomorphism of functors $\varepsilon : K \circ \varphi \xrightarrow{\sim} F$. Now, recall that $Kj \in \mathscr{C}$ represents the limit of the functor $F \circ \mathsf{t}_j : j/\varphi I \to \mathscr{C}$, for every $j \in \mathrm{Ob}(J)$, and the construction of K involves the choice of a universal cone $\tau^j : c_{Kj} \Rightarrow F \circ \mathsf{t}_j$ for every such j. However, notice that $(i, \mathbf{1}_{\varphi(i)})$ is an initial object of $\varphi(i)/\varphi I$: indeed, let $(i', f : \varphi(i) \to \varphi(i'))$ be any other object; since φ is fully faithful, there exists a unique morphism $g : i \to i'$ in J such that $\varphi(g) = f$, and then $(g, \mathbf{1}_f)$ is the unique morphism $(i, \mathbf{1}_{\varphi(i)}) \to (i', f)$ in $\varphi(i)/\varphi I$. By example 1.5.9(ii), it follows that

$$\varepsilon_i := \tau^{\varphi(i)}_{(i,\mathbf{1}_{\varphi(i)})} : K \circ \varphi(i) \to Fi$$

is an isomorphism for every $i \in \mathrm{Ob}(I)$. It remains to check the naturality of the rule : $i \mapsto \varepsilon_i$. Hence, let $g : i \to i'$ be any morphism of I; by construction, for every $X \in \mathrm{Ob}(\mathscr{C})$ we have a commutative diagram of sets :

$$\begin{array}{ccc} h_{K\varphi(i)}(X) & \longrightarrow & \lim_{\varphi(i)/\varphi I} F \circ \mathsf{t}_{\varphi(i)}(X) \\ {\scriptstyle h_{K\varphi(g)}}\downarrow & & \downarrow \\ h_{K\varphi(i')}(X) & \longrightarrow & \lim_{\varphi(i')/\varphi I} F \circ \mathsf{t}_{\varphi(i')}(X) \end{array}$$

where h denotes as usual the Yoneda embedding, and where the top and bottom horizontal arrows are the bijections induced by τ^i and $\tau^{i'}$ respectively. The right vertical arrow is the map that sends every cone $\beta : c_X \Rightarrow F \circ \mathsf{t}_{\varphi(i)}$ to the cone $\beta * (\varphi g/\varphi I) : c_X \Rightarrow F \circ \mathsf{t}_{\varphi(i')}$, where $\varphi g/\varphi I : \varphi(i')/\varphi I \to \varphi(i)/\varphi I$ is the functor defined as in (1.1.27). Taking $X := K\varphi(i)$, we see that the top horizontal (resp. left vertical) arrow maps $\mathbf{1}_{K\varphi(i)}$ to $\tau^{\varphi(i)}$ (resp. to $K\varphi(g)$); then we get the identity :

$$\tau^{\varphi(i')} \odot c_{K\varphi(g)} = \tau^{\varphi(i)} * (\varphi g/\varphi I)$$

whence $\varepsilon^{i'} \circ K\varphi(g) = \tau^{\varphi(i)}_{(i',\varphi(g))} : K\varphi(i) \to Fi'$. Lastly, the morphism g induces a morphism $\varphi(i)/g : (i, \mathbf{1}_{\varphi(i)}) \to (i', \varphi(g))$ of $\varphi(i)/\varphi I$, whence the identity : $\tau^{\varphi(i)}_{(i',\varphi(g))} = Fg \circ \tau^{\varphi(i)}_{(i,\mathbf{1}_{\varphi(i)})}$. Summing up, we conclude that

$$\varepsilon^{i'} \circ K\varphi(g) = Fg \circ \varepsilon^i$$

as required. The assertion for left Kan extensions admits the dual proof. □

Corollary 1.5.19. *Let $\mathscr{B}$, $\mathscr{C}$ be two small categories, and $F : \mathscr{B} \to \mathscr{C}$ a functor. We have :*

(i) *If $\mathscr{B}$ is finitely complete and F is left exact, then $F_!$ is exact.*

(ii) *F is fully faithful $\Leftrightarrow$ $F_!$ is fully faithful $\Leftrightarrow$ F_* is fully faithful.*

Proof. (i): Under these assumptions, the category $Y/F\mathscr{B}$ is cofiltered for every $Y \in \mathrm{Ob}(\mathscr{C})$ (example 1.3.16(i)), hence $(Y/F\mathscr{B})^o$ is filtered. However, the filtered colimits in the category $\mathbf{Set}$ commute with all finite limits (see remark 1.5.16(iv)), so the assertion follows from remark 1.3.6(iii) and proposition 1.3.25(iv).

(ii): By proposition 1.5.18 we know that if F is fully faithful, the same holds for $F_!$ and F_*. Also, by proposition 1.1.20(iv), $F_!$ is fully faithful if and only if the same holds for F_*. Lastly, if $F_!$ is fully faithful, then (1.3.7) and the full faithfulness of the Yoneda embeddings, imply that F is fully faithful. □

Example 1.5.20. Let I be any small category; we wish to apply Freyd's adjoint theorem 1.5.13 in order to exhibit a left adjoint

$$\mathop{\mathrm{Colim}}_{I} : \mathsf{Fun}(I, \mathbf{Cat}) \to \mathbf{Cat}$$

for the corresponding constant functor c for the category $\mathbf{Cat}$. In particular, this will prove that all the colimits indexed by I are representable in $\mathbf{Cat}$, and since I is arbitrary, we will conclude that $\mathbf{Cat}$ is cocomplete. Now, we know already that $\mathbf{Cat}$ is complete (example 1.2.25(i)), and c commutes with all limits of $\mathbf{Cat}$, by virtue of corollary 1.4.1(ii). It remains to check that every functor $\mathscr{C}_\bullet : I \to \mathbf{Cat}$ admits a solution set $S \subset \mathrm{Ob}(\mathbf{Cat})$. To this aim, let $\mathscr{D} := \amalg_{i\in\mathrm{Ob}(I)}\mathscr{C}_i$ be the coproduct of the family of categories $(\mathscr{C}_i \mid i \in \mathrm{Ob}(I))$, as in example 1.2.25(i); for every small category $\mathscr{B}$ and every co-cone $F_\bullet : \mathscr{C}_\bullet \Rightarrow \mathscr{B}$, let $F : \mathscr{D} \to \mathscr{B}$ be the resulting functor, and denote by $\mathrm{Im}(F) \subset \mathscr{B}$ the image of F, defined as in example 1.2.26 (it is easily seen that $\mathbf{Cat}$ is well-powered, so the image is well defined). The system of categories

$$\mathscr{F} := (\mathrm{Im}(F) \mid \mathscr{B} \in \mathrm{Ob}(\mathbf{Cat}), F_\bullet : \mathscr{C}_\bullet \to \mathscr{B})$$

is not small, but if we pick in $\mathscr{F}$ a representative for each isomorphism class, we do get a small family (details left to the reader); it is easily seen that any such choice of representatives yields a solution set for $\mathscr{C}_\bullet$.

In applications, often the indexing category of a limit (or colimit) is a partially ordered set, and usually such limits are easier to handle than limits over general indexing categories. Now, given such a general indexing category I, one may try to find a cofinal functor $J \to I$ from a partially ordered set J. The following proposition – whose part (ii) is due to Deligne ([8, Exp.I, Prop.8.1.6]) – says that this can always be achieved.

Proposition 1.5.21. *Let I be any category. The following holds :*

(i) *There exists a cofinal functor $e : J \to I$, with J a partially ordered set.*
(ii) *If moreover I is filtered, we can find a cofinal functor e as in* (i)*, with J filtered as well.*
(iii) *In the situation of* (i) *or* (ii)*, if furthermore I is small, we can take J to be also small.*

Proof. (i): Let $\mathbb{N}$ be the filtered category associated with the totally ordered set of natural numbers, and $\mathscr{P}_0(\mathbb{N})$ the set of finite non-empty subsets of $\mathbb{N}$; we endow each $\Sigma \in \mathscr{P}_0(\mathbb{N})$ with the restriction of the ordering of $\mathbb{N}$, so that Σ is a full subcategory of $\mathbb{N}$. If $\Sigma' \subset \Sigma$ are two elements of $\mathscr{P}_0(\mathbb{N})$, and $F : \Sigma \to I$ is any functor, we let $F_{|\Sigma'} : \Sigma' \to I$ be the restriction of F. We endow

$$J := \bigcup_{\Sigma \in \mathscr{P}_0(\mathbb{N})} \mathrm{Fun}(\Sigma, I)$$

with the partial ordering such that :

$$(F' : \Sigma' \to I) \leq (F : \Sigma \to I) \Leftrightarrow \Sigma' \subset \Sigma \text{ and } F' = F_{|\Sigma'}.$$

We define a functor $e : J \to I$ as follows. For every $(F : \Sigma \to I) \in J$, we let

$$e(F) := F(s) \qquad \text{where } s \text{ is the largest element of } \Sigma.$$

For every pair $(F' : \Sigma' \to I) \leq (F : \Sigma \to I)$ of elements of J, let $s \in \Sigma$ and $s' \in \Sigma'$ be the respective maximal elements, and $\psi_{s',s} : s' \to s$ (resp. $\varphi_{F',F} : F' \to F$) the corresponding unique morphism of Σ (resp. of J); then we let

$$e(\varphi_{F',F}) := F(\psi_{s',s}).$$

Let now $i \in \mathrm{Ob}(I)$; we need to check that the category i/eJ is connected. To this aim, let $F_i : \{0\} \to I$ be the unique functor such that $F_i(0) := i$; clearly $(\mathbf{1}_i : i \to e(F_i)) \in \mathrm{Ob}(i/eJ)$, so $\mathrm{Ob}(i/eJ)$ is non-empty. Next, let $(F : \Sigma \to I) \in J$ and $\beta : i \to i' := e(F)$ be any morphism of I; we construct step-by-step a chain of morphisms in i/eJ connecting (β, F) with $(\mathbf{1}_i, F_i)$. First, let s be the largest element of Σ; if $s = 0$, we take $\Delta := \{0, 1\}$, and consider the functor $G : \Delta \to I$ such that $G(0) = G(1) := i'$, and $G(\psi_{0,1}) := \mathbf{1}_{i'}$. Thus, $F \leq G$, and $(\beta : i \to e(G)) \in \mathrm{Ob}(i/eJ)$, so we may replace F by G, and assume from start that $s > 0$. Then we have $F' := F_{|\{s\}} \leq F$, and $(\beta : i \to e(F')) \in \mathrm{Ob}(i/eJ)$. Define $F'' : \{0, s\} \to I$ by : $F''(0) = i$, $F''(s) := i'$, and $F''(\psi_{0,s}) := \beta$; again, $F' \leq F''$, and $(\beta : i \to e(F'')) \in \mathrm{Ob}(i/eJ)$. Lastly, $F_i \leq F''$, and this completes the sought chain of morphisms.

(ii): Let us say that I admits a *largest object*, if there exists $i \in \mathrm{Ob}(I)$ such that $\mathrm{Hom}_I(i', i) \neq \varnothing$ for every $i' \in \mathrm{Ob}(I)$. We notice :

Claim 1.5.22. Let $j \in \mathrm{Ob}(I)$ be any object, and $(f_t : i_t \to j \mid t = 1, \dots, n)$ any finite system of morphisms in I. If I does not have a largest object, there exists a morphism $j \to i$ in I such that $i \neq i_t$ for every $t = 1, \dots, n$.

Proof of the claim. Suppose the claim fails, in which case we may assume that $j = i_1$. Since I is filtered, for every $k \in \mathrm{Ob}(I)$ we may find morphisms $g : k \to k'$ and $j \to k'$, and the assumption implies that $k' = i_{n(k)}$ for some $n(k) \in \{1, \dots, n\}$. Set $h := f_{n(k)} \circ g$, so h is a morphism $k \to i_1$, and especially $\mathrm{Hom}_I(k, i_1) \neq \varnothing$ for every $k \in \mathrm{Ob}(I)$, which is absurd, since I does not have a largest object. ◊

Next, define the filtered category $\mathbb{N}$ as in the proof of (i); we remark that if I is any filtered category, then $\mathbb{N} \times I$ is still filtered, and it does not admit a largest object; moreover, one checks easily that the projection functor $\mathbb{N} \times I \to I$ fulfills conditions (a) and (b) of lemma 1.5.7(i), so it is cofinal. In light of remark 1.5.5(i), we may then replace I by $\mathbb{N} \times I$, and assume from start that I does not have a largest object.

Let us say that a *diagram* of I is any pair $D := (A, B)$ with $A \subset \mathrm{Ob}(I)$, $B \subset \mathrm{Morph}(I)$, and such that, for every $f \in B$, the source and target of f lie in A. We say that A (resp. B) is the set of *objects* (resp. *morphisms*) of D. An element e of A is said to be *final* in (A, B) if the following holds :

- for every $i \in \mathrm{Ob}(I)$, the set $\mathrm{Hom}_I(i, e) \cap B$ contains exactly one element f_i^D
- $f_e^D = \mathbf{1}_e$, and for every morphism $g : i \to j$ in B we have $f_j^D \circ g = f_i^D$.

Denote by J the set consisting of all diagrams (A, B) which admit a unique final element $e(A, B)$, and such that A and B are finite sets. We order J by inclusion, *i.e.* $(A, B) \leq (A', B')$ if and only if $A \subset A'$ and $B \subset B'$. Then, if $D, D' \in J$ and $D \leq D'$, there exists a unique morphism $e(D, D') : e(D) \to e(D')$ in the set of morphisms of D', and if $D \leq D' \leq D''$, then clearly $e(D, D'') = e(D', D'') \circ e(D, D')$. Thus, the rule $D \mapsto e(D)$ yields a well defined functor $e : J \to I$, and we have to prove that e is cofinal.

To this aim, we check that conditions (a) and (b) of lemma 1.5.7(i) hold for e. Now, if i is any object of I, the diagram $D_i := (\{i\}, \{\mathbf{1}_i\})$ lies in J, and $\mathbf{1}_i : i \to e(D_i)$ is a morphism in I, so condition (a) holds. Next, let $D = (A, B) \in J$ be any diagram, $i \in \mathrm{Ob}(I)$ any object, and $f, g : i \to e(D)$ any two morphisms in I; we notice :

Claim 1.5.23. There exist $i' \in \mathrm{Ob}(I) \setminus A$ and a morphism $h : e(D) \to i'$ such that $h \circ f = h \circ g$.

Proof of the claim. Since I is filtered, we can find a morphism $h : e(D) \to i'$ that coequalizes f and g, and claim 1.5.22 says that we may choose $i \notin A$. ◊

Now, let i' be as in claim 1.5.23, and D' the diagram of I whose set of objects is $A \cup \{i'\}$, and whose set of morphisms is $B \cup \{h \circ f_j \mid j \in A\}$. It is easily seen that $D' \in J$, and by construction, $e(D') = i'$ and $e(D, D') = h$, so (b) holds.

It remains to show that J is filtered. However, say that $D = (A, B)$ and $D' = (A', B')$ are any two elements of J; we notice :

Claim 1.5.24. There exist $i \in \mathrm{Ob}(I) \backslash (A \cup A')$ and morphisms $f : e(D) \to i$ and $f' : e(D') \to i$ in I.

Proof of the claim. This is similar to the proof of claim 1.5.23 : we can always find $f : e(D) \to i$ and $f' : e(D') \to i$, and by claim 1.5.22 we may arrange that $i \notin A \cup A'$. ◊

Hence, let f, f' be as in claim 1.5.24, and denote $D(f, f')$ the diagram whose set of objects is $A \cup A' \cup \{i\}$, and whose set of morphisms is $B \cup B' \cup \{f \circ f_j^D \mid j \in A\} \cup \{f' \circ f_{j'}^{D'} \mid j' \in A'\}$. Clearly, the assertion will follow from :

Claim 1.5.25. We can choose f and f' so that $D(f, f') \in J$.

Proof of the claim. It amounts to checking that, for suitable f and f', we have $f \circ f_j^D = f' \circ f_j^D$ for every $j \in A \cap A'$. However, if f and f' as in claim 1.5.24, have been picked, a simple induction on the cardinality of $A \cap A'$ shows that we may find $h : i \to i'$ such that

$$h \circ f \circ f_j^D = h \circ f' \circ f_j^D \qquad \text{for every } j \in A \cap A'$$

and by claim 1.5.22, we may arrange that $i' \notin A \cup A'$. Then the diagram $D(h \circ f, h \circ f')$ will do. ◊

Lastly, if I is small, clearly the same holds for J as exhibited in the proofs of (i) and (ii). □

Example 1.5.26. Let us say that a category I is *countable* if both $\mathrm{Ob}(I)$ and $\mathrm{Morph}(I)$ are countable sets. A simple inspection of the proof of proposition 1.5.21(ii) shows that if I is a filtered countable category, there exist a countable filtered partially ordered set $J := \{j_n \mid n \in \mathbb{N}\}$ and a cofinal functor $J \to I$. But it is easy to construct a cofinal functor $f : \mathbb{N} \to J$ (where $\mathbb{N}$ is endowed with its standard total ordering) : indeed, we may choose $f(0) := j_0$, and then pick inductively for every $n \in \mathbb{N}$ an element $f(n+1) \in J$ larger than j_{n+1} and $f(n)$. Summing up, we see that for every countable filtered category I there exists a cofinal functor $\mathbb{N} \to I$.

1.6. **Localizations of categories.** Given a category $\mathscr{C}$ and an arbitrary set of morphisms $\Sigma \subset \mathrm{Morph}(\mathscr{C})$, we wish to describe a general procedure that adds formally to $\mathscr{C}$ an inverse f^{-1} for every $f \in \Sigma$. More details can be found in [28, Ch.5]. We begin with the following :

Definition 1.6.1. (i) A *graph* $\mathscr{G}$ is the datum of

- a set $V(\mathscr{G})$, whose elements are called the *vertices* of $\mathscr{G}$
- for every $A, B \in V(\mathscr{G})$ a set $\mathscr{G}(A, B)$, whose elements are called the *arrows* from A to B. If $f \in \mathscr{G}(A, B)$, we say also that A is the *source* and B is the *target* of f.

(ii) A *morphism* of graphs $F : \mathscr{G} \to \mathscr{G}'$ consists of

- A map of sets $F : V(\mathscr{G}) \to V(\mathscr{G}')$
- For every $A, B \in V(\mathscr{G})$, a map of sets $\mathscr{G}(A, B) \to \mathscr{G}'(FA, FB) : f \mapsto Ff$.

(iii) A graph is *small* if $V(\mathscr{G})$ is a small set, and $\mathscr{G}(A, B)$ is a small set for all $A, B \in V(\mathscr{G})$.

Obviously, morphisms of graphs can be composed. so we have a category

$$\mathsf{U}\text{-}\mathbf{Graph}$$

whose objects are all the small graphs. As usual, we shall omit the prefix U, unless we have to deal with more than one universe. Clearly, there is a natural functor

$$\mathbf{Cat} \to \mathbf{Graph} \tag{1.6.2}$$

which assigns to any category $\mathscr{C}$ its underlying graph, whose vertices are the objects of $\mathscr{C}$, and whose arrows are the morphisms of $\mathscr{C}$, and simply forgets the composition law of $\mathscr{C}$. We are going to construct an explicit left adjoint for the functor (1.6.2). To this aim, let $\mathscr{G}$ be any graph and $n \in \mathbb{N}$ any integer; a *path of length* n in $\mathscr{G}$ is a sequence

$$p := (A_0, f_1, A_1, f_2, \dots, A_n)$$

alternating vertices $A_0, \dots, A_n$ of $\mathscr{G}$ and arrows $f_1, \dots, f_n$, such that the source and target of f_i are respectively A_{i-1} and A_i for every $i = 1, \dots, n$. Then A_0 is called the *source* and A_n the *target* of p. Given paths $p := (A_0, f_1, A_1, \dots, A_n)$ and $p' := (A_n, f_{n+1}, A_{n+1}, \dots, A_{n+m})$ of lengths respectively n and m, and such that the target of p equals the source of p', we obtain a path of length $n + m$, by the rule :

$$p' \circ p := (A_0, f_1, \dots, A_n, f_n, \dots, A_{n+m}).$$

Denote by $P(\mathscr{G})$ the set of all paths of $\mathscr{G}$ (of arbitrary length); with this composition law, clearly $P(\mathscr{G})$ is the set of morphisms of a *path category* whose set of objects is $V(\mathscr{G})$ (for any $A \in V(\mathscr{G})$, the path (A) of length zero serves as the identity endomorphism of A). Also, if $F : \mathscr{G} \to \mathscr{G}'$ is any morphism of graphs, we have an induced functor

$$P(F) : (V(\mathscr{G}), P(\mathscr{G})) \to (V(\mathscr{G}'), P(\mathscr{G}'))$$

whose map on objects is F, and such that $P(F)p := (FA_0, Ff_1, \dots, FA_n)$ for every path $p := (A_0, f_1, \dots, A_n)$ of $\mathscr{G}$. We have thus defined a functor

$$\textbf{Graph} \to \textbf{Cat} \qquad \mathscr{G} \mapsto (V(\mathscr{G}), P(\mathscr{G})). \tag{1.6.3}$$

Proposition 1.6.4. *The functor* (1.6.3) *is left adjoint to the forgetful functor* (1.6.2).

Proof. Indeed, given a graph $\mathscr{G}$, a category $\mathscr{C}$ and a morphism of graphs $F : \mathscr{G} \to \mathscr{C}$, define a functor $G : (V(\mathscr{G}), P(\mathscr{G})) \to \mathscr{C}$ by the rule

$$GA := FA \qquad Gp := Ff_n \circ \cdots Ff_1$$

for every $A \in V(\mathscr{G})$ and every $p := (A_0, f_1, \dots, A_n) \in P(\mathscr{G})$. Clearly G is the unique functor whose restriction to $\mathscr{G}$ agrees with F, whence the contention. □

Corollary 1.6.5. *A category $\mathscr{C}$ is coinitially (resp. cofinally) small if and only if it admits a small coinitial (resp. cofinal) subcategory.*

Proof. Indeed, the condition is obviously sufficient. Conversely, suppose that $\varphi : I \to \mathscr{C}$ is a coinitial (resp. cofinal) functor, with I small; the datum $\mathscr{G} := (\varphi(\mathrm{Ob}(I)), \varphi(\mathrm{Morph}(I)))$ is a subgraph of the category $\mathscr{C}$ (see (1.6)), and the inclusion morphism into $\mathscr{C}$ extends to a functor $\varphi' : I' \to \mathscr{C}$, where I' is the path category of $\mathscr{G}$ (proposition 1.6.4). It is then easily seen that the graph $(\varphi(\mathrm{Ob}(I')), \varphi'(\mathrm{Morph}(I')))$ is actually a coinitial (resp. cofinal) small subcategory of $\mathscr{C}$ (details left to the reader). □

The path category of a graph $\mathscr{G}$ is a sort of free category generated by $\mathscr{G}$. We explain next how to define equivalence relations on such a path category, and how to form the corresponding quotient categories. To this aim, let $\mathscr{G}$ be any graph; we shall call a *commutativity condition* on $\mathscr{G}$ any pair of paths of $\mathscr{G}$ with the same sources and targets. A *conditional graph* is a pair $(\mathscr{G}, C)$ consisting of a graph $\mathscr{G}$ and a set C of commutativity conditions on $\mathscr{G}$. A *morphism* $F : (\mathscr{G}, C) \to (\mathscr{G}', C')$ of conditional graphs is a morphism $F : \mathscr{G} \to \mathscr{G}'$ of graphs, which induces a map $C \to C' : (p_1, p_2) \mapsto (P(F)p_1, P(F)p_2)$. With this composition rule, the conditional graphs form also a category, and we say that a conditional graph is *small* if its underlying graph is small. We denote

$$\mathsf{U}\text{-}\textbf{CondGraph}$$

the category of all small conditional graphs, and as usual we drop the subscript U, unless ambiguities are likely to arise from this omission.

1.6.6. We may attach to any small category $\mathscr{C}$ a natural set of commutativity conditions; namely, one takes the set $C_\mathscr{C}$ consisting of all pairs of paths $((A_0, f_1, \dots, A_n), (B_0, g_1, \dots, B_m))$ in $\mathscr{C}$ such that $A_0 = B_0$, $A_n = B_m$, and $f_n \circ \cdots \circ f_1 = g_m \circ \cdots \circ g_1$. (Especially, for $n = 1$ and $m = 0$, we get the pairs $((A, \mathbf{1}_A, A), (A))$, for A ranging over all the objects of $\mathscr{C}$).

Clearly, every functor $F : \mathscr{C} \to \mathscr{C}'$ induces a map $C_\mathscr{C} \to C_{\mathscr{C}'}$, whence a forgetful functor

$$\textbf{Cat} \to \textbf{CondGraph} \qquad \mathscr{C} \mapsto (\mathscr{C}, C_\mathscr{C}). \tag{1.6.7}$$

Proposition 1.6.8. *The forgetful functor* (1.6.7) *admits a left adjoint.*

Proof. Given a conditional graph $(\mathscr{G}, C)$, denote by $\mathscr{P}$ the path category of $\mathscr{G}$, and by $\mathscr{Q}$ the category such that

- $\mathrm{Ob}(\mathscr{Q}) = V(\mathscr{G})$
- for every $A, B \in \mathrm{Ob}(\mathscr{Q})$, the set $\mathrm{Hom}_\mathscr{Q}(A, B)$ consists of all pairs $(p_1, p_2) \in P(\mathscr{G}) \times P(\mathscr{G})$ such that the source (resp. the target) of both p_1 and p_2 is A (resp. is B)
- the composition law of $\mathscr{Q}$ is given by the rule : $(p_1, p_2) \circ (p'_1, p'_2) := (p_1 \circ p'_1, p_2 \circ p'_2)$ for every pair of composable morphisms $(p_1, p_2), (p'_1, p'_2) \in \mathrm{Morph}(\mathscr{Q})$

and notice that $C \subset \mathrm{Morph}(\mathscr{Q})$. Consider the family S_C of all subcategories $\mathscr{S}$ of $\mathscr{Q}$ such that

- $\mathrm{Ob}(\mathscr{S}) = \mathrm{Ob}(\mathscr{Q})$ and $C \subset \mathrm{Morph}(\mathscr{S})$
- $\mathrm{Morph}(\mathscr{S})$ is an equivalence relation on $P(\mathscr{G}) = \mathrm{Morph}(\mathscr{P})$.

Clearly $\mathscr{Q} \in S_C$, so $S_C \neq \varnothing$, and S_C admits a smallest element, namely the subcategory $\mathscr{R}$ whose set of objects is $\mathrm{Ob}(\mathscr{Q})$ and whose set of morphisms is $\bigcap_{\mathscr{S}\in S_C} \mathrm{Morph}(\mathscr{S})$. We may then form a category

$$\mathscr{P}/C$$

whose set of objects is $\mathrm{Ob}(\mathscr{P}) = V(\mathscr{G})$, and such that

$$\mathrm{Hom}_{\mathscr{P}/C}(A, B) := \mathrm{Hom}_{\mathscr{P}}(A, B)/\sim_C$$

where $\sim_C$ is the equivalence relation induced by $\mathscr{R}$ on $\mathrm{Hom}_{\mathscr{P}}(A, B)$. The composition law for morphisms is the unique one such that the resulting pair of maps

$$\mathrm{Ob}(\mathscr{P}) \to \mathrm{Ob}(\mathscr{P}/C) \qquad \mathrm{Morph}(\mathscr{P}) \to \mathrm{Morph}(\mathscr{P}/C)$$

(which is the identity map on objects, and the natural projection on morphisms) is a functor

$$\mathscr{P} \to \mathscr{P}/C.$$

To check that this law is well defined, say that $p, q : A \to A'$ and $p', q' : A' \to A''$ are two pairs of morphisms in $\mathscr{P}$, such that $p \sim_C q$ and $p' \sim_C q'$; since $\mathscr{R}$ is a subcategory, it follows easily that $p' \circ p \sim_C q' \circ p \sim_C q' \circ q$, whence the claim. Lastly, let $\mathscr{C}$ be any small category, and $F : (\mathscr{G}, C) \to (\mathscr{C}, C_{\mathscr{C}})$ a given morphism of conditional graphs; by proposition 1.6.4, the morphism F extends to a functor $G : \mathscr{P} \to \mathscr{C}$. Let $\mathscr{S} \subset \mathscr{Q}$ be the subcategory such that $\mathrm{Ob}(\mathscr{S}) = \mathrm{Ob}(\mathscr{Q})$ and whose morphisms are all the pairs of paths (p, p') such that $(P(F)p, P(F)p') \in C_{\mathscr{C}}$; by construction, $\mathscr{S} \in S_C$, so $\mathscr{S}$ contains $\mathscr{R}$; it follows that G factors uniquely through $\mathscr{P}/C$, whence the proposition. □

Theorem 1.6.9. *Let $\mathscr{C}$ be any category and $\Sigma \subset \mathrm{Morph}(\mathscr{C})$ any subset. Then there exist a category $\mathscr{C}[\Sigma^{-1}]$ and a* localization functor

$$L : \mathscr{C} \to \mathscr{C}[\Sigma^{-1}]$$

with the following properties :

(i) *Lf is an isomorphism in $\mathscr{C}[\Sigma^{-1}]$, for every $f \in \Sigma$.*

(ii) *For every category $\mathscr{B}$ and any functor $G : \mathscr{C} \to \mathscr{B}$ such that Gf is an isomorphism in $\mathscr{B}$ for every $f \in \Sigma$, there exists a unique functor $G' : \mathscr{C}[\Sigma^{-1}] \to \mathscr{B}$ such that $G = G' \circ L$.*

Proof. Pick any universe U' containing U, and such that $\mathscr{C}$ is U'-small; after replacing U by U', we may assume that $\mathscr{C}$ is small. We consider the graph $\mathscr{G}$ such that

- $V(\mathscr{G}) = \mathrm{Ob}(\mathscr{C})$
- $\mathscr{G}(A, B)$ is the disjoint union of $\mathrm{Hom}_{\mathscr{C}}(A, B)$ and $\mathrm{Hom}_{\mathscr{C}}(B, A) \cap \Sigma$, for every $A, B \in V(\mathscr{G})$.

For every $f \in \mathrm{Hom}_{\mathscr{C}}(B, A) \cap \Sigma$, we write $f^{-1} : A \to B$ for the corresponding arrow of $\mathscr{G}$. Next, we endow $\mathscr{G}$ with the set Θ consisting of the following commutativity conditions :

- For every $A \in \mathrm{Ob}(\mathscr{C})$, the pair $((A, \mathbf{1}_A, A), (A))$
- for every $A, B, C \in \mathrm{Ob}(\mathscr{C})$, every $f \in \mathrm{Hom}_{\mathscr{C}}(A, B)$ and every $g \in \mathrm{Hom}_{\mathscr{C}}(B, C)$, the pair $((A, f, B, g, C), (A, g \circ f, C))$
- the pairs $((A, f^{-1}, B, f, A), (A, \mathbf{1}_A, A))$ and $((B, f, A, f^{-1}, B), (B, \mathbf{1}_B, B))$, for every $A, B \in \mathrm{Ob}(\mathscr{C})$ and every $f \in \mathrm{Hom}_{\mathscr{C}}(B, A) \cap \Sigma$.

By proposition 1.6.8, the left adjoint of (1.6.7) maps the conditional graph $(\mathscr{G}, \Theta)$ to a category which we denote $\mathscr{C}[\Sigma^{-1}]$. Now, suppose that $G : \mathscr{C} \to \mathscr{B}$ is a functor such that Gf is an isomorphism in $\mathscr{B}$, for every $f \in \Sigma$. We define a morphism of graphs $H : \mathscr{G} \to \mathscr{B}$ by the rule :

- $H(A) := GA$ for every $A \in V(\mathscr{G})$
- $H(f) := Gf$ for every $A, B \in V(\mathscr{G})$ and every $f \in \mathrm{Hom}_{\mathscr{C}}(A, B)$

- $H(f) := (Gf)^{-1}$ for every $A, B \in V(\mathscr{G})$ and every $f \in \mathrm{Hom}_{\mathscr{C}}(B, A) \cap \Sigma$.

It is easily seen that H induces a morphism of conditional graphs

$$(\mathscr{G}, \Theta) \to (\mathscr{B}, C_{\mathscr{B}})$$

which, under the adjunction of proposition 1.6.8, corresponds to a unique functor $\mathscr{C}[\Sigma^{-1}] \to \mathscr{B}$ with the sought properties. □

Remark 1.6.10. (i) Clearly conditions (i) and (ii) of theorem 1.6.9 characterize $\mathscr{C}[\Sigma^{-1}]$ up to isomorphism of categories. We call a *localization of* $\mathscr{C}$ *relative to* Σ the datum of a functor $G : \mathscr{C} \to \mathscr{D}$ and an equivalence of categories $H : \mathscr{C}[\Sigma^{-1}] \to \mathscr{D}$ such that $H \circ L = G$, where $L : \mathscr{C} \to \mathscr{C}[\Sigma^{-1}]$ is the localization functor of theorem 1.6.9.

(ii) For any subset $\Sigma \subset \mathrm{Morph}(\mathscr{C})$, let us set $\Sigma^o := \{s^o \mid s \in \Sigma\} \subset \mathrm{Morph}(\mathscr{C}^o)$ (notation of (1.1.1)). In view of (i), we see that the localization functor $\mathscr{C}^o \to \mathscr{C}^o[\Sigma^{o-1}]$ extends uniquely to an isomorphism of categories :

$$\mathscr{C}[\Sigma^{-1}]^o \xrightarrow{\sim} \mathscr{C}^o[\Sigma^{o-1}].$$

Corollary 1.6.11. *In the situation of theorem* 1.6.9*, the localization functor* L *induces a fully faithful functor*

$$\mathsf{Fun}(L, \mathscr{B}) : \mathsf{Fun}(\mathscr{A}[\Sigma^{-1}], \mathscr{B}) \to \mathsf{Fun}(\mathscr{A}, \mathscr{B}) \qquad \textit{for every category } \mathscr{B}.$$

Proof. Let $F, G : \mathscr{A}[\Sigma^{-1}] \to \mathscr{B}$ be two functors; recall that a natural transformation $\alpha : F \Rightarrow G$ is the same as the datum of a functor $\widetilde{\alpha} : \mathscr{A}[\Sigma^{-1}] \to \mathsf{Morph}(\mathscr{B})$ with $\mathsf{s} \circ \widetilde{\alpha} = F$ and $\mathsf{t} \circ \widetilde{\alpha} = G$ (see (1.1.30)). Notice also that a morphism (g, g') of $\mathsf{Morph}(\mathscr{B})$ is invertible if and only if both $\mathsf{s}(g, g') := g$ and $\mathsf{t}(g, g') := g'$ are invertible in $\mathscr{B}$. Combining with the universal property of F from theorem 1.6.9, we conclude that the datum of α is equivalent to that of a functor $\widetilde{\beta} : \mathscr{A} \to \mathsf{Morph}(\mathscr{B})$ such that $\mathsf{s} \circ \widetilde{\beta} = F \circ L$ and $\mathsf{t} \circ \widetilde{\beta} = G \circ L$; but the latter is the same as a natural transformation $F \circ L \Rightarrow G \circ L$, whence the contention. □

Example 1.6.12. Let $\mathscr{C}$ be a category that admits either a final or an initial object, and let Σ be the set of all morphisms of $\mathscr{C}$. Then $\mathscr{C}[\Sigma^{-1}]$ is (isomorphic to) the category $\overline{\mathscr{C}}$ whose set of objects is $\mathrm{Ob}(\mathscr{C})$ and such that for every $X, Y \in \mathrm{Ob}(\mathscr{C})$ the set $\mathrm{Hom}_{\overline{\mathscr{C}}}(X, Y)$ contains exactly one element. Indeed, there exists a unique functor $p : \mathscr{C} \to \overline{\mathscr{C}}$ which is the identity on objects; since every morphism of $\overline{\mathscr{C}}$ is an isomorphism, p factors uniquely through a functor $\mathscr{C}[\Sigma^{-1}] \to \overline{\mathscr{C}}$ that is still the identity on objects. On the other hand, say that X_0 is a final object for $\mathscr{C}$, and for every $X \in \mathrm{Ob}(\mathscr{C})$, let $t_X : X \to X_0$ be the unique morphism; denote by $[t_X]$ the class of t_X in $\mathscr{C}[\Sigma^{-1}]$. Then we have also a functor $q : \overline{\mathscr{C}} \to \mathscr{C}[\Sigma^{-1}]$ that is identity on objects, and sends every morphism $X \to Y$ of $\overline{\mathscr{C}}$ to the morphism $\tau_{XY} := [t_Y]^{-1} \circ [t_X] : X \to Y$ of $\mathscr{C}[\Sigma^{-1}]$. Clearly $p \circ q = \mathbf{1}_{\overline{\mathscr{C}}}$, and to conclude, it suffices to check that if $f : Y \to X$ is any morphisms of $\mathscr{C}$, then the class $[f] : X \to Y$ of f in $\mathscr{C}[\Sigma^{-1}]$ coincides with τ_{XY}. But the latter assertion is clear, since $t_Y \circ f = t_X$ in $\mathscr{C}$. One argues likewise in case $\mathscr{C}$ admits an initial object.

Proposition 1.6.13. *Let* $\mathscr{C}, \mathscr{D}$ *be two categories,* $F : \mathscr{C} \to \mathscr{D}$, $G : \mathscr{D} \to \mathscr{C}$ *two functors, and set*

$$\Sigma_F := \{f \in \mathrm{Morph}(\mathscr{C}) \mid Ff \textit{ is an isomorphism}\}.$$

Suppose that G *is fully faithful, and is either right or left adjoint to* F*. Then* F *factors uniquely through the localization* $L : \mathscr{C} \to \mathscr{C}[\Sigma_F^{-1}]$ *and an equivalence*

$$F' : \mathscr{C}[\Sigma_F^{-1}] \xrightarrow{\sim} \mathscr{D}.$$

Proof. To ease notation, set $\mathscr{C}' := \mathscr{C}[\Sigma_F^{-1}]$, and notice that $\Sigma_{F^o} = \Sigma_F^o$ (notation of remark 1.6.10(ii)), whence a natural isomorphism of categories :

$$\mathscr{C}'^o \xrightarrow{\sim} \mathscr{C}^o[\Sigma_{F^o}^{-1}]$$

that identifies $L^o : \mathscr{C}^o \to \mathscr{C}'^o$ with the localization $\mathscr{C}^o \to \mathscr{C}^o[\Sigma_{F^o}^{-1}]$; moreover, recall that (F, G) is an adjoint pair if and only if the same holds for the pair (G^o, F^o) (remark 1.1.19(iv)). Thus, we may assume that G is right adjoint to F. Now, the existence and uniqueness of F' is clear from the universal property of the localization; it remains to check that F' is an equivalence. To this aim, set as well $G' := L \circ G : \mathscr{D} \to \mathscr{C}'$, and let (η, ε) be the unit and counit of an adjunction for the pair (F, G). Since $F = F' \circ L$, we get $F' \circ G' = F \circ G$, hence ε is also a natural transformation $F'G' \Rightarrow \mathbf{1}_{\mathscr{D}}$. On the other hand, by corollary 1.6.11 there exists a unique natural transformation

$$\eta' : \mathbf{1}_{\mathscr{C}'} \Rightarrow G'F' \qquad \text{such that} \qquad \eta' * L = L * \eta.$$

Using the triangular identities of (1.1.13), we compute :

$$(G' * \varepsilon) \odot (\eta' * G') = (LG * \varepsilon) \odot (L * \eta * G) = L * ((G * \varepsilon) \odot (\eta * G)) = L * \mathbf{1}_G = \mathbf{1}_{G'}.$$

Likewise, let us show that $(\varepsilon * F') \odot (F' * \eta') = \mathbf{1}_{F'}$; to this aim, again by virtue of corollary 1.6.11, it suffices to check that

$$((\varepsilon * F') \odot (F' * \eta')) * L = \mathbf{1}_{F'} * L = \mathbf{1}_F.$$

However, the left-hand side equals $(\varepsilon * F'L) \odot (F' * \eta' * L) = (\varepsilon * L) \odot (F'L * \eta)$, so the sought identity follows again from (1.1.13). By proposition 1.1.15(i), it follows that (F', G') is an adjoint pair of functors, with unit η' and counit ε. Lastly, since G is fully faithful, ε is an isomorphism of functors (proposition 1.1.20(i)); invoking again the triangular identities (1.1.13), we deduce that $F * \eta$ is an isomorphism of functors, hence $\eta_X \in \Sigma_F$ for every $X \in \mathrm{Ob}(\mathscr{C})$. Since $\mathrm{Ob}(\mathscr{C}) = \mathrm{Ob}(\mathscr{C}')$, it follows easily that η' is an isomorphism of functors, whence the proposition. □

Definition 1.6.14. Let $\mathscr{C}$ be a category, $\Sigma \subset \mathrm{Morph}(\mathscr{C})$ a set of morphisms.

(i) We say that Σ *admits a right calculus of fractions* if the following conditions hold :

(CF1) $\mathbf{1}_A \in \Sigma$, for every $A \in \mathrm{Ob}(\mathscr{C})$.

(CF2) For every $s : A \to B$ and $t : B \to C$ with $s, t \in \Sigma$, we have $t \circ s \in \Sigma$ as well.

(CF3) For every morphism $f : A \to B$ in $\mathscr{C}$ and every $s : C \to B$ in Σ, there exist $g : D \to C$ in $\mathscr{C}$ and $t : D \to A$ in Σ such that $f \circ t = s \circ g$.

(CF4) If $f, g : A \to B$ are any two morphisms in $\mathscr{C}$ such that $s \circ f = s \circ g$ for some $s : B \to C$ in Σ, then there exists $t : D \to A$ in Σ such that $f \circ t = g \circ t$.

(ii) We say that Σ *admits a left calculus of fractions* if the subset $\Sigma^o := \{s^o \mid s \in \Sigma\}$ admits a right calculus of fractions (notation of remark 1.6.10(ii)).

(iii) For every $A \in \mathrm{Ob}(\mathscr{C})$, let Σ_A be the full subcategory of $\mathscr{C}/A$ whose objects are the elements of Σ with target equal to A (notation of (1.1.24)). We say that Σ is *right cofinally small*, if Σ_A is cofinally small for every $A \in \mathrm{Ob}(\mathscr{C})$ (see definition 1.5.1(iv)).

1.6.15. Let now $\mathscr{C}$ and Σ be as in definition 1.6.14, and suppose that $\mathscr{C}$ has small Hom-sets, and Σ admits a right calculus of fractions. For every $A, B \in \mathrm{Ob}(\mathscr{C})$, let us consider the functor

$$H_{A,B} : \Sigma_A^o \to \mathbf{Set} \qquad (s : I \to A) \mapsto \{(s, f) \mid f \in \mathrm{Hom}_{\mathscr{C}}(I, B)\}$$

where, for every morphism $h/A : s \to t$ in Σ_A, the mapping $H_{A,B}(h/A)$ is given by the rule

$$H_{A,B}(t) \to H_{A,B}(s) \quad : \quad (t, f) \mapsto (s, f \circ h).$$

Furthermore, we define a mapping

$$c_s^{A,B} : H_{A,B}(s) \to \mathrm{Hom}_{\mathscr{C}[\Sigma^{-1}]}(A, B) \qquad (s, f) \mapsto f \circ s^{-1} \qquad \text{for every } s \in \mathrm{Ob}(\Sigma_A).$$

Proposition 1.6.16. *In the situation of* (1.6.15)*, the following holds :*

(i) *For every $A \in \mathrm{Ob}(\mathscr{C})$, the category Σ_A^o is filtered.*

(ii) *For every* $A, B \in \mathrm{Ob}(\mathscr{C})$*, the rule :*

$$s \mapsto c_s^{A,B} \qquad \text{for every } s \in \mathrm{Ob}(\Sigma_A)$$

defines a universal cocone with basis $H_{A,B}$ *and vertex* $\mathrm{Hom}_{\mathscr{C}[\Sigma^{-1}]}(A, B)$*.*

(iii) *If* Σ *is right cofinally small, The category* $\mathscr{C}[\Sigma^{-1}]$ *has small* Hom*-sets.*

Proof. (i): First, Σ_A^o is not empty, due to (CF1). Next, say that $s, s' \in \mathrm{Ob}(\Sigma_A)$, and denote by I and I' the sources of s and respectively s'; due to (CF3), we may find $I'' \in \mathrm{Ob}(\mathscr{C})$, a morphism $f : I'' \to I$ in $\mathscr{C}$, and an element $g : I'' \to I'$ of Σ such that $s \circ f = s' \circ g$. Then, (CF2) says that $s' \circ g$ lies in Σ, and therefore it defines an object s'' of Σ_A, with morphisms $f : s \to s''$ and $g : s' \to s''$ in Σ_A^o. Lastly, say that $f, f' : s \to s'$ are any two morphisms in Σ_A^o, and denote by I' the source of s'. By (CF4), we may find $g : I'' \to I'$ in Σ such that $f \circ g = f' \circ g$; clearly $s' \circ g$ defines a morphism $h : s' \to s''$ in Σ_A^o such that $h \circ f = h \circ f'$. Now the assertion follows from remark 1.2.21(i).

(ii): Let $s : I \to A$ and $s' : I' \to A$ be two objects of Σ_A, and $g : I' \to I$ a morphism $s \to s'$ in Σ_A^o. Given $f : I \to B$, set $f' := f \circ g$; we notice :

Claim 1.6.17. $f \circ s^{-1} = f' \circ s'^{-1}$ in $\mathscr{C}[\Sigma^{-1}]$.

Proof of the claim. Due to (CF3), we may find $I'' \in \mathrm{Ob}(\mathscr{C})$, an element $t : I'' \to I$ of Σ and a morphism $t' : I'' \to I'$ such that $s \circ t = s' \circ t'$. We compute :

$$s \circ g \circ t' = s' \circ t' = s \circ t$$

whence, by (CF4), an element $h : I''' \to I''$ of Σ, such that $g \circ t' \circ h = t \circ h$. It follows that $g \circ t' = t$ in $\mathscr{C}[\Sigma^{-1}]$ and therefore

$$f \circ t = f \circ g \circ t' = f' \circ t' \qquad \text{in } \mathscr{C}[\Sigma^{-1}].$$

Consequently :

$$f \circ s^{-1} = f' \circ t' \circ t^{-1} \circ s^{-1} = f' \circ s'^{-1} \circ s \circ t \circ t^{-1} \circ s^{-1} = f' \circ s'^{-1} \qquad \text{in } \mathscr{C}[\Sigma^{-1}]$$

as stated. ◊

Claim 1.6.17 says already that $c_\bullet^{A,B}$ is a well defined cocone. To check the universality property, we define a new category $\mathscr{D}$ with $\mathrm{Ob}(\mathscr{D}) = \mathrm{Ob}(\mathscr{C})$ and such that $\mathrm{Hom}_{\mathscr{D}}(A, B)$ is the colimit of the functor $H_{A,B}$, for every $A, B \in \mathrm{Ob}(\mathscr{C})$. From (i) and example 1.2.23(i) we see that this is the set of equivalence classes $[s, f]$ of pairs $(s, f) \in H_{A,B}(s)$ with s ranging over all objects of Σ_A; two such pairs (s, f) and (s', f') are equivalent, if there exist $t \in \mathrm{Ob}(\Sigma_A)$ and morphisms $h : t \to s$, $h' : t \to s'$ in Σ_A such that $f \circ h = f' \circ h'$. The composition of morphisms in $\mathscr{D}$ is defined as follows. Let $A, B, C \in \mathrm{Ob}(\mathscr{C})$ be any three objects, $s : I \to A$, $t : J \to B$ any elements of Σ, and $(s, f) \in H_{A,B}(s)$, $(t, g) \in H_{B,C}(t)$; by (CF3) we find $D \in \mathrm{Ob}(\mathscr{C})$, a morphism $f' : D \to J$ in $\mathscr{C}$ and an element $t' : D \to I$ of Σ such that $t \circ f' = f \circ t'$. We define

$$(t, g) \circ (s, f) := [s \circ t', g \circ f'] \in \mathrm{Hom}_{\mathscr{D}}(A, C). \tag{1.6.18}$$

Let us check that this class does not depend on the choice of D, f' and t'. Indeed, suppose that $D' \in \mathrm{Ob}(\mathscr{C})$ is another object and $t'' : D' \to I$ in Σ, $f'' : D' \to J$ in $\mathscr{C}$ satisfy the condition $t \circ f'' = f \circ t''$; by (CF3) we may then find $D'' \in \mathrm{Ob}(\mathscr{C})$, $h : D'' \to D$ in Σ and $h' : D'' \to D'$ in $\mathscr{C}$ such that $t' \circ h = t'' \circ h'$. We compute :

$$t \circ f' \circ h = f \circ t' \circ h = f \circ t'' \circ h' = t \circ f'' \circ h'.$$

By (CF4), it follows that there exist $D''' \in \mathrm{Ob}(\mathscr{C})$ and an element $u : D''' \to D''$ of Σ such that $f' \circ h \circ u = f'' \circ h' \circ u$. By (CF2), we may then replace D'' by D''' and h, h' with $h \circ u$ and respectively $h' \circ u$, after which we may assume as well that $f'' \circ h' = f' \circ h$. Finally, we find :

$$[s \circ t', g \circ f'] = [s \circ t' \circ h, g \circ f' \circ h] = [s \circ t'' \circ h', g \circ f'' \circ h'] = [s \circ t'', g \circ f'']$$

as required. It also follows that $[s \circ t', g \circ f']$ depends only on $[s, f]$ and $[t, g]$; indeed, say that $u : I' \to I$ is any element of Σ, and set $(s', f'') := (s \circ u, f \circ u)$. Suppose also that $f'' \circ t'' = t \circ f'$ for some $t'' : D \to I'$ in Σ; then $(s' \circ t'', g \circ f') = (s \circ u \circ t'', g \circ f')$, and the foregoing shows that the latter pair is equivalent to $(s \circ t', g \circ f')$, which shows the independence on the chosen representative for $[s, f]$; similarly one checks the independence on the representative for $[t, g]$.

We next check the associativity of the composition law thus obtained. To this aim, say that $A, B, C, D \in \mathrm{Ob}(\mathscr{C})$ are any four objects, $s : I \to A$, $t : J \to B$, $u : K \to C$ any three elements of Σ, and $f : I \to B$, $g : J \to C$, $h : K \to D$ any three morphisms of $\mathscr{C}$. Choose $E \in \mathrm{Ob}(\mathscr{C})$ with an element $t' : E \to I$ of Σ and a morphism $f' : E \to J$ of $\mathscr{C}$ such that $f \circ t' = t \circ f'$, and therefore

$$[t, g] \circ [s, f] = [s \circ t', g \circ f'].$$

Then, choose $F \in \mathrm{Ob}(\mathscr{C})$ with $u' : F \to J$ in Σ and $g' : F \to K$ in $\mathscr{C}$ such that $g \circ u' = u \circ g'$, and therefore

$$[u, h] \circ [t, g] = [t \circ u', h \circ g'].$$

By (CF3) we may find $G \in \mathrm{Ob}(\mathscr{C})$, $u'' : G \to E$ in Σ and $f'' : G \to F$ in $\mathscr{C}$ such that $u' \circ f'' = f' \circ u''$. By (CF2), $t' \circ u''$ lies in Σ, and therefore it is easily seen that the pair $(s \circ t' \circ u'', h \circ g' \circ f'')$ represents both $[t \circ u', h \circ g'] \circ [s, f]$ and $[u, h] \circ [s \circ t', g \circ f']$, whence the assertion. Let us also remark that – due to (CF1) – for every $A \in \mathrm{Ob}(\mathscr{C})$, the class $[\mathbf{1}_A, \mathbf{1}_A]$ is the identity endomorphism of A, seen as an object of $\mathscr{D}$. This completes the construction of the category $\mathscr{D}$. Next, we claim that the system of cocones $c_\bullet^{\bullet\bullet}$ yields a functor

$$F : \mathscr{D} \to \mathscr{C}[\Sigma^{-1}]$$

whose map on objects is the identity mapping of $\mathrm{Ob}(\mathscr{C})$, and such that

$$F[s, f] := f \circ s^{-1} \qquad \text{for every morphism } [s, f] \text{ in } \mathscr{D}.$$

Indeed, claim 1.6.17 implies that the foregoing rule yields a well defined map

$$\mathrm{Hom}_{\mathscr{D}}(A, B) \to \mathrm{Hom}_{\mathscr{C}[\Sigma^{-1}]}(A, B) \qquad \text{for every } A, B \in \mathrm{Ob}(\mathscr{C}).$$

It is also clear that $F\mathbf{1}_A = \mathbf{1}_A$ for every $A \in \mathrm{Ob}(\mathscr{C})$, hence it remains only to check that F respects the composition laws of the two categories; however, say that s, f, t, g are as in (1.6.18); then we have

$$(g \circ f') \circ (s \circ t')^{-1} = (g \circ t^{-1} \circ f \circ t') \circ t'^{-1} \circ s^{-1} = (g \circ t^{-1}) \circ (f \circ s^{-1}) \qquad \text{in } \mathscr{C}[\Sigma^{-1}]$$

whence the contention. Likewise, we have a functor

$$G : \mathscr{C} \to \mathscr{D}$$

which is the identity mapping on objects, and such that $Gf := [\mathbf{1}_A, f]$ for every $A, B \in \mathrm{Ob}(\mathscr{C})$ and every morphism $f : A \to B$ in $\mathscr{C}$. Moreover, the identities

$$[\mathbf{1}_I, s] \circ [s, \mathbf{1}_I] = [\mathbf{1}_A, \mathbf{1}_A] \qquad [s, \mathbf{1}_I] \circ [\mathbf{1}_I, s] = [\mathbf{1}_I, \mathbf{1}_I] \qquad \text{for every } s : I \to A \text{ in } \Sigma$$

show that Fs is invertible in $\mathscr{D}$, for every such s. By theorem 1.6.9, it follows that G factors through a unique functor $G' : \mathscr{C}[\Sigma^{-1}] \to \mathscr{D}$, and a simple inspection shows that $F \circ G'$ is the identity endofunctor of $\mathscr{C}[\Sigma^{-1}]$. Likewise, it is easily seen that $G' \circ F = \mathbf{1}_{\mathscr{D}}$, so F establishes an isomorphism of categories, and (ii) follows.

(iii) is an immediate consequence of (ii). □

Remark 1.6.19. Proposition 1.6.16(ii) means that $c_\bullet^{A,B}$ induces a natural identification

$$\operatorname*{colim}_{\Sigma_A^o} H_{A,B} \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{C}[\Sigma^{-1}]}(A, B) \qquad \text{for every } A, B \in \mathrm{Ob}(\mathscr{C}).$$

The dual of this assertion provides a corresponding computation of the morphisms in $\mathscr{C}[\Sigma^{-1}]$ in terms of left fractions. Namely, suppose that Σ admits a left calculus of fractions; for every

$A \in \mathrm{Ob}(\mathscr{C})$ we let Σ^A be the full subcategory of $A/\mathscr{C}$ whose objects are the elements of Σ with source equal to A, and we say that Σ is *left cofinally small* if Σ^A is cofinally small for every such A. For every other object B of $\mathscr{C}$ we consider the functor

$$H_{B,A} : \Sigma^A \to \mathbf{Set} \qquad (s : A \to I) \mapsto \{(f, s) \mid f \in \mathrm{Hom}_{\mathscr{C}}(B, I)\}$$

where, for every morphism $h : s \to t$ in Σ^A, the mapping $H_{B,A}(h)$ is given by the rule

$$H_{B,A}(s) \to H_{B,A}(t) \quad : \quad (f, s) \mapsto (h \circ f, t).$$

Then Σ^A is a filtered category, and if Σ is left cofinally small, $\mathscr{C}[\Sigma^{-1}]$ has small Hom-sets; more precisely, we have a natural identification :

$$\operatorname*{colim}_{\Sigma^A} H_{B,A} \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{C}[\Sigma^{-1}]}(B, A) \qquad (f, s) \mapsto s^{-1} \circ f.$$

1.6.20. Let $\mathscr{A}$ be a category, $\mathscr{A}_0$ a full subcategory of $\mathscr{A}$, $\Sigma \subset \mathrm{Ob}(\mathscr{A})$ any subset, and set

$$\Sigma_0 := \Sigma \cap \mathrm{Morph}(\mathscr{A}_0).$$

Clearly, the inclusion functor $i : \mathscr{A}_0 \to \mathscr{A}$ extends uniquely to a functor

$$i[\Sigma_0^{-1}] : \mathscr{A}_0[\Sigma_0^{-1}] \to \mathscr{A}[\Sigma^{-1}].$$

Proposition 1.6.21. *In the situation of* (1.6.20)*, suppose that :*

(a) *For every $A \in \mathrm{Ob}(\mathscr{A})$, $A_0 \in \mathrm{Ob}(\mathscr{A}_0)$ and every morphism $f : A \to iA_0$ that lies in Σ, there exist $A'_0 \in \mathrm{Ob}(\mathscr{A}_0)$ and a morphism $g : iA'_0 \to A$ such that $f \circ g \in \Sigma$.*

(b) *Σ admits a right calculus of fractions.*

Then the set Σ_0 admits a right calculus of fractions in $\mathscr{A}_0$, and the functor $i[\Sigma_0^{-1}]$ is fully faithful.

Proof. As usual, after replacing our universe U by a larger one, we may assume that $\mathscr{A}$ is small. Let us check that Σ_0 admits a right calculus of fractions. (CF1) and (CF2) are obviously fulfilled by Σ_0. Next, suppose that we have $A, B, C \in \mathrm{Ob}(\mathscr{A}_0)$, $D \in \mathrm{Ob}(\mathscr{A})$ and a commutative diagram in $\mathscr{A}$

$$\begin{array}{ccc} D & \xrightarrow{g} & iC \\ {\scriptstyle t}\downarrow & & \downarrow{\scriptstyle is} \\ iA & \xrightarrow{if} & iB \end{array} \qquad \text{with } s, t \in \Sigma. \tag{1.6.22}$$

By (a), it follows that there exists a morphism $u : iD_0 \to D$ for some $D_0 \in \mathrm{Ob}(\mathscr{A}_0)$, such that $t' := t \circ u : iD_0 \to iA$ lies in Σ_0, $g' := g \circ u : iD_0 \to iC$ lies in $\mathrm{Hom}_{\mathscr{A}_0}(D_0, C)$, and clearly $f \circ t' = s \circ g'$, whence (CF3). Lastly, suppose that $A, B \in \mathrm{Ob}(\mathscr{A}_0)$, $D \in \mathrm{Ob}(\mathscr{A})$, and we have morphisms $f, g : A \to B$ and $t : D \to iA$ such that $i(f) \circ t = i(g) \circ t$ and with $t \in \Sigma$. Pick $u : iD_0 \to D$ as in the foregoing, and let again $t' := t \circ u$; then $f \circ t' = g \circ t'$, and we have just seen that $t' \in \Sigma_0$, whence (CF4).

Next, let us check that $i[\Sigma_0^{-1}]$ is fully faithful. In light of propositions 1.6.16(ii) and 1.5.2, it suffices to show that the inclusion functor

$$\Sigma^o_{0,A} \to \Sigma^o_{iA} \tag{1.6.23}$$

is cofinal for every $A \in \mathrm{Ob}(\mathscr{A}_0)$ (notation of (1.6.15)). To this aim, in view of proposition 1.6.16(i), it suffices to check that the functor (1.6.23) fulfills conditions (a) and (b) of lemma 1.5.7(i). However, condition (a) of *loc.cit.* translates directly as the assumption (a) of the proposition. Next, consider any pair of morphisms $f, g : iD_0 \to D$ and any element $s : D \to iA$ in Σ such that $s \circ f = s \circ g$. By (CF4), there exists $t : E \to iD_0$ in Σ such that $f \circ t = g \circ t$, and then assumption (a) yields a morphism $u : iE_0 \to E$ such that $t' := t \circ u$ lies in Σ_0, and $f \circ i(t') = g \circ i(t')$, which shows that condition (b) of lemma 1.5.7(iv) holds as well. $\square$

Remark 1.6.24. Taking into account remarks 1.6.10(ii) and 1.6.19, we see that the dual of proposition 1.6.21 holds as well; *i.e.* in the situation of (1.6.20), suppose that

(a) For every $A \in \mathrm{Ob}(\mathscr{A})$, $A_0 \in \mathrm{Ob}(\mathscr{A}_0)$ and every morphism $f : iA_0 \to A$ that lies in Σ, there exist $A'_0 \in \mathrm{Ob}(\mathscr{A})$ and a morphism $g : A \to iA'_0$ such that $g \circ f \in \Sigma$.

(b) Σ admits a left calculus of fractions.

Then the set Σ_0 admits a left calculus of fractions in $\mathscr{A}_0$, and the functor $i[\Sigma_0^{-1}]$ is fully faithful.

Proposition 1.6.25. *Let $\mathscr{C}$ be a category with small* Hom*-sets, $\Sigma \subset \mathrm{Morph}(\mathscr{C})$ a set of morphisms admitting a right calculus of fractions, $F : \mathscr{C} \to \mathscr{C}[\Sigma^{-1}]$ the localization. We have:*

(i) *For every $X \in \mathrm{Ob}(\mathscr{C}[\Sigma^{-1}])$ the category $X/F\mathscr{C}$ is cofiltered.*

(ii) *If $\mathscr{C}$ is small, the functor $F_! : \mathscr{C}^\wedge \to \mathscr{C}[\Sigma^{-1}]^\wedge$ is exact (notation of remark* 1.3.6(i)*).*

Proof. (i): Let $((Y_i, f_i : X \to FY_i) \mid i = 1, 2)$ be a pair of objects of $X/F\mathscr{C}$. For $i = 1, 2$, we may write $f_i = g_i \circ s_i^{-1}$ with some morphism $s_i : Z_i \to X$ in Σ and some morphism $g_i : Z_i \to Y_i$ in $\mathscr{C}$. By condition (CF3) of definition 1.6.14 we may then find a morphism $t_1 : Z \to Z_1$ in Σ and a morphism $t_2 : Z \to Z_2$ in $\mathscr{C}$ such that $s := s_1 \circ t_1 = s_2 \circ t_2$, and notice that $s \in \Sigma$, by condition (CF2). For $i = 1, 2$, the composition $t_i \circ g_i$ then yields a morphism $(Z, s^{-1} : X \to FZ) \to (Y_i, f_i)$ in $X/F\mathscr{C}$. Next, let $h_1, h_2 : (Y_1, f_1) \to (Y_2, f_2)$ be two morphisms in $X/F\mathscr{C}$; this means that $h_i : Y_1 \to Y_2$ is a morphism in $\mathscr{C}$ for $i = 1, 2$, and $Fh_1 \circ f_1 = Fh_2 \circ f_1 = f_2$ in $\mathscr{C}[\Sigma^{-1}]$. Thus, $F(h_1 \circ g_1) = F(h_2 \circ g_1)$, and therefore there exists $(u : Z' \to Z_1) \in \Sigma$ such that $h_1 \circ g_1 \circ u = h_2 \circ g_1 \circ u$ in $\mathscr{C}$. Then the composition $g := g_1 \circ u$ yields a morphism $g : (Z', (s_1 \circ u)^{-1} : X \to FZ') \to (Y_1, f_1)$ in $X/F\mathscr{C}$ such that $h_1 \circ g = h_2 \circ g$. The assertion then follows from remark 1.2.21(i).

(ii): The assertion follows from (i), arguing as in the proof of corollary 1.5.19(i). □

2. 2-Category theory

In dealing with categories, the notion of equivalence is much more central than the notion of isomorphism. On the other hand, equivalence of categories is usually not preserved by the standard categorical operations discussed thus far. For instance, consider the following :

Example 2.0.1. Let $\mathscr{C}$ be the category with $\mathrm{Ob}(\mathscr{C}) = \{a, b\}$, and whose only morphisms are $\mathbf{1}_a$, $\mathbf{1}_b$ and $u : a \to b$, $v : b \to a$. Then necessarily $u \circ v = \mathbf{1}_b$ and $v \circ u = \mathbf{1}_a$. Let $\mathscr{C}_a$ (resp. $\mathscr{C}_b$) be the unique subcategory of $\mathscr{C}$ with $\mathrm{Ob}(\mathscr{C}_a) = \{a\}$ (resp. $\mathrm{Ob}(\mathscr{C}_b) = \{b\}$). Clearly both inclusion functors $\mathscr{C}_a \to \mathscr{C} \leftarrow \mathscr{C}_b$ are equivalences. However, $\mathscr{C}_a \times_{\mathscr{C}} \mathscr{C}_b$ is the empty category; especially, this fibre product is not equivalent to $\mathscr{C} = \mathscr{C} \times_{\mathscr{C}} \mathscr{C}$.

It is therefore natural to seek a new framework for the manipulation of categories and functors "up to equivalences", and thus more consonant with the very spirit of category theory. Precisely such a framework is provided by the theory of 2-categories, the subject of this chapter.

2.1. 2-Categories and pseudo-functors.

The category $\mathbf{Cat}$, together with the category structure on the sets $\mathrm{Fun}(-, -)$ (as in (1.1.10)), provides the first example of a 2*-category*. The latter is the datum of :

- A set $\mathrm{Ob}(\mathscr{A})$, whose elements are called the *objects of* $\mathscr{A}$.
- For every $A, B \in \mathrm{Ob}(\mathscr{A})$, a category $\mathscr{A}(A, B)$. The objects of $\mathscr{A}(A, B)$ are called 1*-cells* or *arrows*, and are designated by the usual arrow notation $f : A \to B$. Given $f, g \in \mathrm{Ob}(\mathscr{A}(A, B))$, we shall write $f \Rightarrow g$ to denote a morphism from f to g in $\mathscr{A}(A, B)$. Such morphisms are called 2*-cells*. The composition of 2-cells $\alpha : f \Rightarrow g$ and $\beta : g \Rightarrow h$ shall be denoted by $\beta \odot \alpha : f \Rightarrow h$.
- For every $A, B, C \in \mathrm{Ob}(\mathscr{A})$, a *composition bifunctor* :

$$c_{ABC} : \mathscr{A}(A, B) \times \mathscr{A}(B, C) \to \mathscr{A}(A, C).$$

Given 1-cells $A \xrightarrow{f} B \xrightarrow{g} C$, we write $g \circ f := c_{ABC}(f, g)$.
Given two 2-cells $\alpha : f \Rightarrow g$ and $\beta : h \Rightarrow k$, respectively in $\mathscr{A}(A, B)$ and $\mathscr{A}(B, C)$, we use the notation

$$\beta * \alpha := c_{ABC}(\alpha, \beta) : h \circ f \Rightarrow k \circ g.$$

Also, if h is any 1-cell of $\mathscr{A}(B, C)$, we usually write $h * \alpha$ instead of $\mathbf{1}_h * \alpha$. Likewise, we set $\beta * f := \beta * \mathbf{1}_f$, for every 1-cell f in $\mathscr{A}(A, B)$.

- For every element $A \in \mathrm{Ob}(\mathscr{A})$, a *unit functor* :

$$u_A : \mathbf{1} \to \mathscr{A}(A, A)$$

where $\mathbf{1} := (*, \mathbf{1}_*)$ is the final object of $\mathbf{Cat}$. Hence u_A is the datum of an object:

$$\mathbf{1}_A \in \mathrm{Ob}(\mathscr{A}(A, A))$$

and its identity endomorphism, which we shall denote by $i_A : \mathbf{1}_A \to \mathbf{1}_A$.

The bifunctors c_{ABC} are required to satisfy an *associativity axiom*, which says that the diagram:

$$\begin{array}{ccc}
\mathscr{A}(A,B) \times \mathscr{A}(B,C) \times \mathscr{A}(C,D) & \xrightarrow{\mathbf{1} \times c_{BCD}} & \mathscr{A}(A,B) \times \mathscr{A}(B,D) \\
{\scriptstyle c_{ABC} \times \mathbf{1}} \downarrow & & \downarrow {\scriptstyle c_{ABD}} \\
\mathscr{A}(A,C) \times \mathscr{A}(C,D) & \xrightarrow{c_{ACD}} & \mathscr{A}(A,D)
\end{array}$$

commutes for every $A, B, C, D \in \mathrm{Ob}(\mathscr{A})$. Likewise, the functor u_A is required to satisfy a *unit axiom*; namely, the diagram :

$$\begin{array}{ccccc}
\mathbf{1} \times \mathscr{A}(A,B) & \xleftarrow{\sim} & \mathscr{A}(A,B) & \xrightarrow{\sim} & \mathscr{A}(A,B) \times \mathbf{1} \\
{\scriptstyle u_A \times \mathbf{1}_{\mathscr{A}(A,B)}} \downarrow & & \| & & \downarrow {\scriptstyle \mathbf{1}_{\mathscr{A}(A,B)} \times u_B} \\
\mathscr{A}(A,A) \times \mathscr{A}(A,B) & \xrightarrow{c_{AAB}} & \mathscr{A}(A,B) & \xleftarrow{c_{ABB}} & \mathscr{A}(A,B) \times \mathscr{A}(B,B)
\end{array}$$

commutes for every $A, B \in \mathrm{Ob}(\mathscr{A})$.

Remark 2.1.1. (i) In any 2-category, consider a diagram with two 2-cells :

$$A \underset{g}{\overset{f}{\rightrightarrows}} B \underset{g'}{\overset{f'}{\rightrightarrows}} C. \qquad (\Downarrow\alpha,\ \Downarrow\alpha')$$

In this situation, we have the following commutation identity :

$$(\alpha' * g) \odot (f' * \alpha) = \alpha' * \alpha = (g' * \alpha) \odot (\alpha' * f)$$

which is sometimes useful, to perform certain verifications. To see this, notice that $\alpha' * \alpha = (\alpha' \odot \mathbf{1}_{f'}) * (\mathbf{1}_g \odot \alpha)$, whence the first stated identity, by functoriality of the composition for 2-cells. Likewise, we get $\alpha' * \alpha = (\mathbf{1}_{g'} \odot \alpha') * (\alpha \odot \mathbf{1}_f)$, whence the second identity.

(ii) As already announced, the category $\mathbf{Cat}$ becomes naturally a 2-category, by letting

$$\mathbf{Cat}(\mathscr{A}, \mathscr{B}) := \mathsf{Fun}(\mathscr{A}, \mathscr{B}) \qquad \text{for every } \mathscr{A}, \mathscr{B} \in \mathrm{Ob}(\mathbf{Cat})$$

with composition bifunctor defined as in (1.1.10). Indeed, by spelling out the definitions, we see that the functoriality of the Godement product boils down precisely to the identity (1.1.11).

On the other hand, from every 2-category $\mathscr{A}$ we obtain a category, simply by forgetting the 2-cells : the set of objects of this *underlying category of* $\mathscr{A}$ is $\mathrm{Ob}(\mathscr{A})$, and the morphisms are the 1-cells of $\mathscr{A}$, with composition law induced by the composition bifunctor of $\mathscr{A}$.

(iii) We shall say that a 2-category $\mathscr{A}$ *has* U*-small* Hom*-categories* if $\mathscr{A}(A, B)$ is a U-small category for every $A, B \in \mathrm{Ob}(\mathscr{A})$. We shall say that $\mathscr{A}$ is U*-small* if it has U-small Hom-categories and $\mathrm{Ob}(\mathscr{A})$ is U-small. As usual, the universe U will be dropped from the notation, unless there is a danger of ambiguities. For instance, the 2-category $\mathbf{Cat}$ has small Hom-categories.

2.1.2. If $\mathscr{A}$ is a 2-category, we have three distinct constructions of *opposite* 2*-categories* associated with $\mathscr{A}$. Namely we have :

- The 2-category $\mathscr{A}^o$ such that $\mathrm{Ob}(\mathscr{A}^o) := \{A^o \mid A \in \mathrm{Ob}(\mathscr{A})\}$ (cp. (1.1.1)) and with
$$\mathscr{A}^o(A^o, B^o) := \mathscr{A}(B, A) \qquad \text{for every } A^o, B^o \in \mathrm{Ob}(\mathscr{A}^o).$$
For any 1-cell $f : B \to A$ in $\mathscr{A}$, we denote $f^o : A^o \to B^o$ the corresponding 1-cell in $\mathscr{A}^o$. The composition bifunctor $c^o_{\bullet\bullet\bullet}$ and unit functors $u^o_\bullet$ of $\mathscr{A}^o$ are given by the rules :
$$c^o_{A^oB^oC^o} := c_{CBA} \qquad \mathbf{1}_{A^o} := \mathbf{1}^o_A \qquad \text{for every } A^o, B^o, C^o \in \mathrm{Ob}(\mathscr{A}^o).$$
Notice that to any 2-cell $\alpha : f \Rightarrow g$ in $\mathscr{A}$ there corresponds a 2-cell $\alpha^o : f^o \Rightarrow g^o$ in $\mathscr{A}^o$. The associativity and unit axioms for $\mathscr{A}^o$ follow formally from the corresponding properties for $\mathscr{A}$.
- The 2-category ${}^o\mathscr{A}$ such that $\mathrm{Ob}({}^o\mathscr{A}) := \{{}^oA \mid A \in \mathrm{Ob}(\mathscr{A})\}$ and with
$${}^o\mathscr{A}({}^oA, {}^oB) := \mathscr{A}(A, B)^o \qquad \text{for every } {}^oA, {}^oB \in \mathrm{Ob}({}^o\mathscr{A}).$$
For any 1-cell $f : A \to B$ in $\mathscr{A}$, we denote ${}^of : {}^oA \to {}^oB$ the corresponding 1-cell in ${}^o\mathscr{A}$. The composition bifunctor ${}^oc_{\bullet\bullet\bullet}$ and unit functors ${}^ou_\bullet$ of ${}^o\mathscr{A}$ are given by the rules :
$${}^oc_{{}^oA{}^oB{}^oC} := c^o_{ABC} \qquad \mathbf{1}_{{}^oA} := {}^o\mathbf{1}_A \qquad \text{for every } {}^oA, {}^oB, {}^oC \in \mathrm{Ob}({}^o\mathscr{A}).$$
Then to any 2-cell $\alpha : f \Rightarrow g$ in $\mathscr{A}$ there corresponds a 2-cell ${}^o\alpha : {}^og \Rightarrow {}^of$ in ${}^o\mathscr{A}$. The associativity and unit axioms for ${}^o\mathscr{A}$ are also immediately deduced from those of $\mathscr{A}$.
- Lastly, we may combine the two foregoing constructions to get the 2-category ${}^o\mathscr{A}^o$, which inverts the direction of both 1-cells and 2-cells.

Definition 2.1.3. Let $\mathscr{A}$ be any 2-category, and $f : A \to B$ any 1-cell of $\mathscr{A}$.

(i) A 2-cell $\beta : f \Rightarrow f'$ of $\mathscr{A}$ is *invertible*, if it is an isomorphism in the category $\mathscr{A}(A, B)$.

(ii) We say that the 1-cell $g : B \to A$ of $\mathscr{A}$ is *right adjoint* to f, if there exist 2-cells $\eta : \mathbf{1}_A \Rightarrow g \circ f$ and $\varepsilon : f \circ g \Rightarrow \mathbf{1}_B$ fulfilling the *triangular identities*
$$(g * \varepsilon) \odot (\eta * g) = \mathbf{1}_g \qquad (\varepsilon * f) \odot (f * \eta) = \mathbf{1}_f.$$
(see [28, Def.7.1.2]). In this case, we also say that g is *right adjoint* to f, and that (f, g) is an *adjoint pair of* 1*-cells*; moreover, we say that (η, ε) is an *adjunction* for (f, g). Then η is called the *unit* and ε the *counit* of the adjunction (η, ε).

(iii) We say that a 1-cell $f : A \to B$ of $\mathscr{A}$ is an *equivalence* if there exist 1-cells $g, h : B \to A$ and invertible 2-cells $\mathbf{1}_A \Rightarrow g \circ f$ and $f \circ h \Rightarrow \mathbf{1}_B$. In this case, we also say that g and h are *quasi-inverse* 1-cells for f.

Remark 2.1.4. (i) Let f, g and h be as in definition 2.1.3(iii), so we have invertible 2-cells $\eta : \mathbf{1}_A \Rightarrow g \circ f$ and $\varepsilon : f \circ h \Rightarrow \mathbf{1}_B$. Then we have the invertible 2-cell $\beta := (g * \varepsilon) \odot (h * \eta) : h \Rightarrow g$, whence the invertible 2-cell $\varepsilon \circ (f * \beta^{-1}) : f \circ g \Rightarrow \mathbf{1}_B$. In other words, we may as well assume that $g = h$ in definition 2.1.3(iii).

(ii) A composition of equivalences is an equivalence. Indeed, let $f_1 : A_1 \to A_2$ and $f_2 : A_2 \to A_3$ be two equivalences, $g_1 : A_2 \to A_1$ (resp. $g_2 : A_3 \to A_2$) a quasi-inverse for f_1 (resp. for f_2) so that we have invertible 2-cells $\alpha_i : \mathbf{1}_{A_i} \Rightarrow g_i \circ f_i$ and $\beta_i : f_i \circ g_i \Rightarrow \mathbf{1}_{A_{i+1}}$ for $i = 1, 2$. Then $g := g_1 \circ g_2$ is a quasi-inverse for $f := f_2 \circ f_1$, since we have the invertible 2-cells $(g_1 * \alpha_2 * f_1) \odot \alpha_1 : \mathbf{1}_{A_1} \Rightarrow g \circ f$ and $\beta_2 \odot (f_2 * \beta_1 * g_2) : f \circ g \Rightarrow \mathbf{1}_{A_3}$.

(iii) Let $f, f' : A \to B$ be two 1-cells of $\mathscr{A}$, and $\beta : f \xrightarrow{\sim} f'$ an invertible 2-cell. Then f is an equivalence if and only if the same holds for f'. Indeed, suppose we have a 1-cell $g : B \to A$ with an invertible 2-cells $\alpha : \mathbf{1}_A \xrightarrow{\sim} g \circ f$ and $\alpha' : f \circ g \xrightarrow{\sim} \mathbf{1}_B$; then we get the invertible 2-cells $(g * \beta) \odot \alpha : \mathbf{1}_A \xrightarrow{\sim} g \circ f'$ and $\alpha' \odot (\beta^{-1} * g) : f' \circ g \xrightarrow{\sim} \mathbf{1}_B$, so f' is an equivalence.

(iv) Likewise, if (f, g) is an adjoint pair of 1-cells of $\mathscr{A}$ and we have invertible 2-cells $\alpha : g \stackrel{\sim}{\to} g'$ and $\beta : f \stackrel{\sim}{\to} f'$, then (f', g') is an adjoint pair of 1-cells. Indeed, by assumption we have 2-cells $\eta : \mathbf{1}_A \Rightarrow g \circ f$ and $\varepsilon : f \circ g \Rightarrow \mathbf{1}_B$ fulfilling the triangular identities of definition 2.1.3(ii); it suffices to check that $\eta' := (\alpha * \beta) \odot \eta$ and $\varepsilon' := \varepsilon \odot (\beta * \alpha)^{-1}$ are a unit and a counit for the pair (f', g'). However, we have :

$$\begin{aligned}(g' * \varepsilon') \odot (\eta' * g') &= (g' * (\varepsilon \odot (\beta * \alpha)^{-1})) \odot (((\alpha * \beta) \odot \eta) * g') \\ &= (g' * \varepsilon) \odot (g' * \beta * \alpha)^{-1} \odot (\alpha * \beta * g') \odot (\eta * g') \\ &= (g' * \varepsilon) \odot (\alpha * f * \alpha^{-1}) \odot (\eta * g') \\ &= (g' * \varepsilon) \odot (\alpha * f * g) \odot (g * f * \alpha^{-1}) \odot (\eta * g') \\ &= \alpha \odot (g * \varepsilon) \odot (\eta * g) \odot \alpha^{-1} \\ &= \alpha \odot \alpha^{-1} = \mathbf{1}_{g'}\end{aligned}$$

where the third, fourth and fifith equalities follow from remark 2.1.1(i). Likewise one checks the other required triangular identity.

(v) Furthermore, if $f : A \to B$ is a 1-cell in $\mathscr{A}$ and $g, g' : B \to A$ are both right adjoint to f, then we have an invertible 2-cell $\alpha : g \stackrel{\sim}{\to} g'$. Indeed, let (η, ε) (resp. (η', ε')) be an adjunction for the pair (f, g) (resp. for the pair (f, g')). We set

$$\alpha := (g' * \varepsilon) \odot (\eta' * g) : g \Rightarrow g' \qquad \beta := (g * \varepsilon') \odot (\eta * g') : g' \Rightarrow g.$$

Applying repeatedly remark 2.1.1(i), we compute :

$$\begin{aligned}\beta \odot \alpha &= (g * \varepsilon') \odot (g * f * g' * \varepsilon) \odot (\eta * g' * f * g) \odot (\eta' * g) \\ &= (g * \varepsilon) \odot (g * \varepsilon' * f * g) \odot (g * f * \eta' * g) \odot (\eta * g) \\ &= (g * \varepsilon) \odot (g * ((\varepsilon' * f) \odot (f * \eta')) * g) \odot (\eta * g) \\ &= (g * \varepsilon) \odot (\eta * g) = \mathbf{1}_g.\end{aligned}$$

Likewise one checks that $\alpha \odot \beta = \mathbf{1}_{g'}$, whence the contention.

2.1.5. Let $\mathscr{A}$ be any 2-category; an *oriented square in $\mathscr{A}$* is a (not necessarily commutative) diagram of the type :

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ {\scriptstyle g}\downarrow & \swarrow_{\alpha} & \downarrow{\scriptstyle h} \\ A' & \xrightarrow[f']{} & B' \end{array} \tag{2.1.6}$$

where $f, f'g, h$ are any four 1-cells and $\alpha : h \circ f \Rightarrow f' \circ g$ is any 2-cell of $\mathscr{A}$. If α is an invertible 2-cell, we also say that the square (2.1.6) is *essentially commutative*. We say that α *orients* the square (2.1.6), and often we refer to such a square just by naming its orienting 2-cell; when dealing with complex diagrams, this shorthand may lead to unacceptable ambiguities, but in these cases usually one may resolve such ambiguities just by specifying two of the opposite sides of the square, for which we shall employ a fractional notation : thus, the square (2.1.6) shall be denoted, depending on the context, in either of the following three manners :

$$\alpha \qquad \frac{\alpha}{f|f'} \qquad \frac{\alpha}{g|h}.$$

One basic operation consists in combining two squares that share one edge, to obtain a new square, essentially by omitting the common edge of the squares. Namely, suppose we have two squares α and β as in the diagram :

(2.1.7)
$$\begin{array}{ccccc} A & \xrightarrow{g} & A' & \xrightarrow{k} & A'' \\ {\scriptstyle f}\downarrow & {}^{\alpha}\Nearrow & \downarrow{\scriptstyle f'} & {}^{\beta}\Nearrow & \downarrow{\scriptstyle f''} \\ B & \xrightarrow[h]{} & B' & \xrightarrow[i]{} & B'' \end{array}$$

Then we say that α and β are *vertically composable*, and we define the square

$$\beta \boxbar \alpha \qquad : \qquad \begin{array}{ccc} A & \xrightarrow{k\circ g} & A'' \\ {\scriptstyle f}\downarrow & {}^{\gamma}\Nearrow & \downarrow{\scriptstyle f''} \\ B & \xrightarrow[i\circ h]{} & B'' \end{array} \qquad \text{where } \gamma := (\beta * g) \odot (i * \alpha).$$

In this operation, we have joined to the square α of (2.1.6) another square β that shares the edge f'. Clearly, if β' is another square that shares with α the edge f, the same operation can be performed to obtain the square $\alpha \boxbar \beta'$ which omits the edge f. On the other hand, the rule to join to α a square that shares one of the two remaining edges g or h, is slightly different. Namely, suppose we have the diagram of two squares :

$$\begin{array}{ccccc} A & \xrightarrow{f} & B & \xrightarrow{i} & C \\ {\scriptstyle g}\downarrow & \Swarrow_{\alpha} & \downarrow{\scriptstyle h} & \Swarrow_{\gamma} & \downarrow{\scriptstyle k} \\ A' & \xrightarrow[f']{} & B' & \xrightarrow[i']{} & C'. \end{array}$$

Then we say that α and γ are *horizontally composable*, and we set

$$\frac{\gamma}{i|i'} \boxminus \frac{\alpha}{f|f'} := \frac{(i' * \alpha) \odot (\gamma * f)}{i \circ f | i' \circ f'}.$$

However, notice that the second join operation is turned into the first one, when we replace $\mathscr{A}$ by its opposite 2-categories; namely, we have the identities :

(2.1.8)
$$(\gamma \boxminus \alpha)^o = \alpha^o \boxbar \gamma^o \qquad {}^o(\gamma \boxminus \alpha) = {}^o\gamma \boxbar {}^o\alpha$$

The following proposition establishes the two basic rules of the algebra of oriented squares.

Proposition 2.1.9. *With the notation of* (2.1.5)*, the following holds :*

(i) *The join operation is associative,* i.e. *for any diagram of three squares*

$$\begin{array}{ccccccc} A & \xrightarrow{g} & A' & \xrightarrow{k} & A'' & \xrightarrow{l} & A''' \\ {\scriptstyle f}\downarrow & {}^{\alpha}\Nearrow & \downarrow{\scriptstyle f'} & {}^{\beta}\Nearrow & \downarrow{\scriptstyle f''} & {}^{\gamma}\Nearrow & \downarrow{\scriptstyle f'''} \\ B & \xrightarrow[h]{} & B' & \xrightarrow[i]{} & B'' & \xrightarrow[m]{} & B''' \end{array}$$

we have

$$\gamma \boxbar (\beta \boxbar \alpha) = (\gamma \boxbar \beta) \boxbar \alpha.$$

(ii) *For every (not necessarily commutative) diagram*

$$\begin{array}{ccccc} A & \xrightarrow{f} & B & \xrightarrow{g} & C \\ {\scriptstyle h}\downarrow & \swarrow_{\alpha} & \downarrow{\scriptstyle k} & \swarrow_{\beta} & \downarrow{\scriptstyle i} \\ A' & \xrightarrow{f'} & B' & \xrightarrow{g'} & C' \\ {\scriptstyle h'}\downarrow & \swarrow_{\alpha'} & \downarrow{\scriptstyle k'} & \swarrow_{\beta'} & \downarrow{\scriptstyle i'} \\ A'' & \xrightarrow[f'']{} & B'' & \xrightarrow[g'']{} & C''. \end{array}$$

we have

$$(\beta' \boxbar \beta) \boxminus (\alpha' \boxbar \alpha) = (\beta' \boxminus \alpha') \boxbar (\beta \boxminus \alpha).$$

Proof. (i): We compute :

$$\begin{aligned} \gamma \boxbar (\beta \boxbar \alpha) &= \gamma \boxbar ((\beta * g) \odot (i * \alpha)) \\ &= ((\gamma * (k \circ g)) \odot (m * ((\beta * g) \odot (i * \alpha))) \\ &= ((\gamma * (k \circ g)) \odot (m * (\beta * g)) \odot (m * (i * \alpha)) \\ &= (((\gamma * k) \odot (m * \beta)) * g) \odot ((m \circ i) * \alpha) \\ &= (\gamma \boxbar \beta) \boxbar \alpha. \end{aligned}$$

(ii): We compute :

$$\begin{aligned} (\beta' \boxbar \beta) \boxminus (\alpha' \boxbar \alpha) &= (g'' * ((\alpha' * h) \odot (k' * \alpha))) \odot (((\beta' * k) \odot (i' * \beta)) * f) \\ &= (g'' * \alpha' * h) \odot (g'' * k' * \alpha) \odot (\beta' * k * f) \odot (i' * \beta * f) \\ &= (g'' * \alpha' * h) \odot (\beta' * f * h) \odot (i' * g' * \alpha) \odot (i' * \beta * f) \\ &= ((\beta' \boxminus \alpha') * h) \odot (i' * (\beta \boxminus \alpha)) \\ &= (\beta' \boxminus \alpha') \boxbar (\beta \boxminus \alpha) \end{aligned}$$

where the fourth equality follows from the commutation rule of remark 2.1.1(i). □

Remark 2.1.10. Proposition 2.1.5(i) establishes explicitly only the associativity of the join operation $\boxbar$, but in light of (2.1.8) we also get immediately the associativity of $\boxminus$.

Example 2.1.11. (i) Let $\mathscr{A}$ be any 2-category. We may construct a new 2-category

$$\mathsf{2\text{-}Morph}(\mathscr{A})$$

which is the 2-categorical counterpart of the category of arrows (see (1.1.30)). Namely :

- the objects of $\mathsf{2\text{-}Morph}(\mathscr{A})$ are the 1-cells of $\mathscr{A}$.
- If $f : A \to B$ and $f' : A' \to B'$ are any two 1-cells of $\mathscr{A}$, the arrows $f \to f'$ in $\mathsf{2\text{-}Morph}(\mathscr{A})$ are all the oriented squares (2.1.6).
- For 1-cells $(g_1, h_1, \alpha_1), (g_2, h_2, \alpha_2) : f \to f'$, the 2-cells $(g_1, h_1, \alpha_1) \Rightarrow (g_2, h_2, \alpha_2)$ are all the pairs

$$(\beta : g_1 \Rightarrow g_2, \gamma : h_1 \Rightarrow h_2) \qquad \text{such that} \qquad \frac{\alpha_1}{h_1|g_1} \boxminus \frac{\beta}{g_1|g_2} = \frac{\gamma}{h_1|h_2} \boxminus \frac{\alpha_2}{h_2|g_2}.$$

- For f as in the foregoing, the unit functor $\mathbf{1} \to \mathsf{2\text{-}Morph}(f, f)$ is given by the 2-cell

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ {\scriptstyle \mathbf{1}_A}\downarrow & \swarrow_{\mathbf{1}_f} & \downarrow{\scriptstyle \mathbf{1}_B} \\ A & \xrightarrow[f]{} & B \end{array} \tag{2.1.12}$$

and its identity endomorphism (i_A, i_B).

For f and f' as in the foregoing, the composition law in 2-$\mathsf{Morph}(\mathscr{A})(f, f')$ is given by the rule

$$(\beta', \gamma') \odot (\beta, \gamma) := (\beta' \odot \beta, \gamma' \odot \gamma)$$

for every composable pair $((\beta, \gamma), (\beta', \gamma'))$ of 2-cells in 2-$\mathsf{Morph}(\mathscr{A})$. The composition bifunctor is given by the composition law for squares; *i.e.*, given 1-cells $f \to f$' and $f' \to f''$ in 2-$\mathsf{Morph}(\mathscr{A})$ as in (2.1.7), we set

$$(\beta, k, i) \circ (\alpha, g, h) := (\beta \boxdot \alpha, k \circ g, i \circ h).$$

Lastly, given 2-cells (β, γ) in 2-$\mathsf{Morph}(\mathscr{A})(f, f')$ and (β', γ') in 2-$\mathsf{Morph}(\mathscr{A})(f', f'')$ we set

$$(\beta', \gamma') * (\beta, \gamma) := (\beta' * \beta, \gamma' * \gamma).$$

The functoriality and associativity properties of the composition laws for 2-cells are then immediate from the definitions. The associativity of the composition law for 1-cells holds by proposition 2.1.9(i).

(ii) Just as in (1.1.24), for every $X \in \mathrm{Ob}(\mathscr{A})$ we may consider the 2-subcategories $\mathscr{A}/X$ and $X/\mathscr{A}$ of 2-$\mathsf{Morph}(\mathscr{A})$. Explicitly, the objects of $\mathscr{A}/X$ are the 1-cells $A \to X$ of $\mathscr{A}$. Given two such objects f, f', the 1-cells $f \to f'$ of $\mathscr{A}/X$ are all the diagrams in $\mathscr{A}$ of the type

$$\begin{array}{ccc} A & \xrightarrow{f} & X \\ {\scriptstyle g}\downarrow & \swarrow_{\alpha} & \| \\ A' & \xrightarrow[f']{} & X \end{array}$$

and for 1-cells $(g_1, \alpha_1), (g_2, \alpha_2) : f \to f'$, the 2-cells of $\mathscr{A}/X$ are the 2-cells $\beta : g_1 \Rightarrow g_2$ of $\mathscr{A}$ such that $(f' * \beta) \odot \alpha_1 = \alpha_2$. A similar description applies to $X/\mathscr{A}$.

(iii) To every 1-cell $h : X \to Y$ in $\mathscr{A}$ we attach functors

$$h^Z_* : \mathscr{A}(Z, X) \to \mathscr{A}(Z, Y) \qquad \text{for every } Z \in \mathrm{Ob}(\mathscr{A})$$

by ruling that $h^Z_*(k) := h \circ k$ and $h^Z_*(\beta) := h * \beta$ for every 1-cell $k : Z \to X$ of $\mathscr{A}$ and every morphism $\beta : k \Rightarrow k'$ in $\mathscr{A}(Z, X)$. Let $\nu : h \Rightarrow h'$ be any 2-cell in $\mathscr{A}$; we claim that the rule

$$k \mapsto (\nu^Z_{*k} := \nu * k : h^Z_*(k) \Rightarrow h'^Z_*(k)) \qquad \text{for every } (k : Z \to X) \in \mathrm{Ob}(\mathscr{A}(Z, X))$$

defines a natural transformation

$$\nu^Z_* : h^Z_* \Rightarrow h'^Z_* \qquad \text{for every } Z \in \mathrm{Ob}(\mathscr{A}).$$

Indeed, let $k, k' : Z \to X$ be any two objects of $\mathscr{A}(Z, X)$, and $\mu : k \Rightarrow k'$ a 2-cell; we need to show that the resulting diagram commutes in $\mathscr{A}$:

$$\begin{array}{ccc} h^Z_*(k) & \xrightarrow{\nu * k} & h'^Z_*(k) \\ {\scriptstyle h*\mu}\Downarrow & & \Downarrow{\scriptstyle h'*\mu} \\ h^Z_*(k') & \xrightarrow{\nu * k'} & h'^Z_*(k') \end{array}$$

But this follows directly from remark 2.1.1(i). Likewise, we may attach to f the functors

$$h^*_Z : \mathscr{A}(Y, Z) \to \mathscr{A}(X, Z) \qquad k \mapsto k \circ h \qquad \beta \mapsto \beta * h \qquad \text{for every } Z \in \mathrm{Ob}(\mathscr{A})$$

and then ν induces as well a natural transformation

$$\nu^*_Z : h^*_Z \Rightarrow h'^*_Z \qquad k \mapsto k * \nu \qquad \text{for every } Z \in \mathrm{Ob}(\mathscr{A}).$$

We apply these constructions to prove the following result, which generalizes propositions 1.1.15(ii) and 1.1.20(i) to arbitrary 2-categories :

Lemma 2.1.13. *Let $\mathscr{A}$ be a 2-category, $f : A \to B$, $g : B \to A$ two 1-cells in $\mathscr{A}$. We have :*

(i) *Suppose that f is an equivalence, and g a quasi-inverse for f. Then, for every invertible 2-cell $\eta : \mathbf{1}_A \Rightarrow g \circ f$ there exists a unique invertible 2-cell $\varepsilon : f \circ g \Rightarrow \mathbf{1}_B$ such that (η, ε) is an adjunction for the pair (f, g).*

(ii) *Suppose that (f, g) is an adjoint pair, and that (η, ε) and (η', ε') are two adjunctions for (f, g). Then $\eta = \eta'$ if and only if $\varepsilon = \varepsilon'$.*

(iii) *The following conditions are equivalent :*
  (a) *f is an equivalence.*
  (b) *For every $Z \in \mathrm{Ob}(\mathscr{A})$ the functor $f^*_Z : \mathscr{A}(B, Z) \to \mathscr{A}(A, Z)$ is an equivalence.*
  (c) *For every $Z \in \mathrm{Ob}(\mathscr{A})$ the functor $f^Z_* : \mathscr{A}(Z, A) \to \mathscr{A}(Z, B)$ is an equivalence.*

Proof. (i): By assumption, there exists an invertible 2-cell $\varepsilon' : f \circ g \Rightarrow \mathbf{1}_B$. Now, since η and ε' are invertible 2-cells, it is clear that η^Z_* and ε'^Z_* are isomorphisms of functors for every $Z \in \mathrm{Ob}(\mathscr{A})$, so f^Z_* and g^Z_* are equivalences of categories (proposition 1.1.20(i)); therefore there exists a unique adjunction for the pair (f^Z_*, g^Z_*) whose unit is η^Z_* (claim 1.1.21) and we denote by ε^Z_* the unique counit for this adjunction. Then also ε^Z_* is an isomorphism of functors (proposition 1.1.20(iii)), and we define the invertible 2-cell $\varepsilon := \varepsilon^B_{\mathbf{1}_B} : f \circ g \Rightarrow \mathbf{1}_B$. Lastly, the triangular identities (1.1.13) for the pair $(\eta^Z_*, \varepsilon^Z_*)$ immediately imply the corresponding identities for (η, ε).

(ii): As in the foregoing, we obtain for every $Z \in \mathrm{Ob}(\mathscr{A})$ an adjoint pair of functors (f^Z_*, g^Z_*), and two adjunctions $(\eta^Z_*, \varepsilon^Z_*)$, $(\eta'^Z_*, \varepsilon'^Z_*)$ for (f^Z_*, g^Z_*). Then proposition 1.1.15(ii) implies that $\eta^Z_* = \eta'^Z_*$ if and only if $\varepsilon^Z_* = \varepsilon'^Z_*$. The assertion is an immediate consequence.

(iii.a)⇒(iii.b),(iii.c): Indeed, let $g : B \to A$ be a quasi-inverse for f; it is easily seen that the functor g^*_Z is a quasi-inverse for f^*_Z and g^Z_* is a quasi-inverse for f^Z_*.

(iii.b)⇒(iii.a): Since f^*_A is an equivalence, we find a 1-cell $g : B \to A$ of $\mathscr{A}$ with an isomorphism $g \circ f = f^*_A(g) \xrightarrow{\sim} \mathbf{1}_A$. There follows an isomorphism $f^*_B(f \circ g) = f \circ g \circ f \xrightarrow{\sim} f = f^*_B(\mathbf{1}_B)$, and since f^*_B is an equivalence, we deduce an isomorphism $f \circ g \xrightarrow{\sim} \mathbf{1}_B$, whence the contention. Likewise one shows that (iii.c)⇒(iii.a), or alternatively one can deduce this implication from the foregoing one, by considering the opposite 2-categories. □

Definition 2.1.14. ([28, Def.7.5.1]) Let $\mathscr{A}$ and $\mathscr{B}$ be two 2-categories.

(i) A *pseudo-functor* $F : \mathscr{A} \to \mathscr{B}$ is the datum of :

- For every $A \in \mathrm{Ob}(\mathscr{A})$, an object $FA \in \mathrm{Ob}(\mathscr{B})$.
- For every $A, B \in \mathrm{Ob}(\mathscr{A})$, a functor :

$$F_{AB} : \mathscr{A}(A, B) \to \mathscr{B}(FA, FB).$$

  We shall often omit the subscript, and write only Ff instead of $F_{AB}f : FA \to FB$, for a 1-cell $f : A \to B$, and likewise for 2-cells.

- For every $A, B, C \in \mathrm{Ob}(\mathscr{A})$, a natural isomorphism γ_{ABC} between two functors $\mathscr{A}(A, B) \times \mathscr{A}(B, C) \to \mathscr{B}(FA, FC)$ as indicated by the (not necessarily commutative) diagram :

$$\begin{array}{ccc} \mathscr{A}(A,B) \times \mathscr{A}(B,C) & \xrightarrow{c_{ABC}} & \mathscr{A}(A,C) \\ {\scriptstyle F_{AB}\times F_{BC}}\downarrow & \gamma_{ABC} \nearrow & \downarrow{\scriptstyle F_{AC}} \\ \mathscr{B}(FA,FB) \times \mathscr{B}(FB,FC) & \xrightarrow[c_{FA,FB,FC}]{} & \mathscr{B}(FA,FC). \end{array} \tag{2.1.15}$$

  To ease notation, for every $(f, g) \in \mathscr{A}(A, B) \times \mathscr{A}(B, C)$, we shall write $\gamma_{f,g}$ instead of $(\gamma_{ABC})_{(f,g)} : c_{FA,FB,FC}(F_{AB}f, F_{BC}g) \Rightarrow F_{AC}(c_{ABC}(f, g))$.

- For every $A \in \mathrm{Ob}(\mathscr{A})$, a natural isomorphism δ_A between functors $\mathbf{1} \to \mathscr{B}(FA, FA)$, as indicated by the (not necessarily commutative) diagram :

$$\begin{array}{ccc} \mathbf{1} & \xrightarrow{u_A} & \mathscr{A}(A,A) \\ \| & \delta_A \nearrow & \downarrow{\scriptstyle F_{AA}} \\ \mathbf{1} & \xrightarrow[u_{FA}]{} & \mathscr{B}(FA,FA). \end{array} \tag{2.1.16}$$

The system $(\delta_\bullet, \gamma_{\bullet\bullet\bullet})$ is called the *coherence constraint* for F. This datum is required to satisfy:

- A *composition axiom*, which says that the diagram

$$\begin{array}{ccc} Fh \circ Fg \circ Ff & \xRightarrow{Fh*\gamma_{f,g}} & Fh \circ F(g \circ f) \\ {\scriptstyle \gamma_{g,h}*Ff}\Downarrow & & \Downarrow{\scriptstyle \gamma_{g\circ f,h}} \\ F(h \circ g) \circ Ff & \xRightarrow{\gamma_{f,h\circ g}} & F(h \circ g \circ f) \end{array}$$

  commutes for every sequence of arrows $A \xrightarrow{f} B \xrightarrow{g} C \xrightarrow{h} D$ in $\mathscr{A}$. We will write

$$\gamma_{f,g,h} : Fh \circ Fg \circ Ff \Rightarrow F(h \circ g \circ f)$$

  for the common composition of these two pairs of cells.

- A *unit axiom*, which says that the diagrams :

$$\begin{array}{ccc} Ff \circ \mathbf{1}_{FA} & \xRightarrow{Ff*\delta_A} & Ff \circ F\mathbf{1}_A \\ {\scriptstyle \mathbf{1}_{Ff}}\Downarrow & & \Downarrow{\scriptstyle \gamma_{\mathbf{1}_A,f}} \\ Ff & \xRightarrow{\mathbf{1}_{Ff}} & F(f \circ \mathbf{1}_A) \end{array} \qquad \begin{array}{ccc} \mathbf{1}_{FB} \circ Ff & \xRightarrow{\delta_B*Ff} & F(\mathbf{1}_B) \circ Ff \\ {\scriptstyle \mathbf{1}_{Ff}}\Downarrow & & \Downarrow{\scriptstyle \gamma_{f,\mathbf{1}_B}} \\ Ff & \xRightarrow{\mathbf{1}_{Ff}} & F(\mathbf{1}_B \circ f) \end{array}$$

  commute for every arrow $f : A \to B$ (where, to ease notation, we have written δ_A instead of $(\delta_A)_* : \mathbf{1}_{FA} \Rightarrow F_{AA}\mathbf{1}_A$, and likewise for δ_B).

(ii) A pseudo-functor F as in (i) is called *strict* if (2.1.15) and (2.1.16) both commute, and γ_{ABC} and δ_A are the identity natural transformations for every $A, B, C \in \mathrm{Ob}(\mathscr{A})$.

Remark 2.1.17. With the notation of definition 2.1.14, we have :

(i) The functoriality of F_{AB}, for every $A, B \in \mathrm{Ob}(\mathscr{A})$, comes down to the identities

$$F(\mathbf{1}_f) = \mathbf{1}_{Ff} \qquad F(\beta \odot \alpha) = F\beta \odot F\alpha \qquad \text{for every 1-cell } f \text{ and 2-cells } \alpha, \beta \text{ of } \mathscr{A}(A,B).$$

(ii) Likewise, the naturality of γ_{ABC} boils down to the commutativity of the diagram

$$\begin{array}{ccc} Fg \circ Ff & \xRightarrow{\gamma_{f,g}} & F(g \circ f) \\ {\scriptstyle F\beta*F\alpha}\Downarrow & & \Downarrow{\scriptstyle F(\beta*\alpha)} \\ Fg' \circ Ff' & \xRightarrow{\gamma_{f',g'}} & F(g' \circ f') \end{array}$$

for every 1-cells $f, f' : A \to B$, $g, g' : B \to C$ and 2-cells $\alpha : f \Rightarrow f'$, $\beta : g \Rightarrow g'$.

(iii) If $h : C \to D$ and $h' : C' \to D'$ are any two other 1-cells, and $\mu : h \Rightarrow h'$ is any 2-cell, it follows easily that the diagram

$$\begin{array}{ccc} Fh \circ Fg \circ Ff & \xRightarrow{\gamma_{f,g,h}} & F(h \circ g \circ f) \\ {\scriptstyle F\mu*F\beta*F\alpha}\Downarrow & & \Downarrow{\scriptstyle F(\mu*\beta*\alpha)} \\ Fh' \circ Fg' \circ Ff' & \xRightarrow{\gamma_{f',g',h'}} & F(h' \circ g' \circ f') \end{array}$$

commutes : details left to the reader.

(iv) The pseudo-functor F induces *opposite pseudo-functors*

$$F^o : \mathscr{A}^o \to \mathscr{B}^o \qquad \text{and} \qquad {}^oF : {}^o\mathscr{A} \to {}^o\mathscr{B}$$

(as well as the functor ${}^oF^o$, by combining the two operations). Namely, F^o is given by the rules

$$F^o(A^o) := (FA)^o \qquad F^o(f^o) := (Ff)^o \qquad F^o(\beta^o) := (F\beta)^o$$

for every $A \in \mathrm{Ob}(\mathscr{A})$, every 1-cell f and every 2-cell β of $\mathscr{A}$. The coherence constraint of F^o is the pair (γ^o, δ^o) such that

$$\gamma^o_{g^o,f^o} := (\gamma_{f,g})^o \qquad \text{and} \qquad \delta^o_{A^o} := (\delta_A)^o$$

for every composable pair of 1-cells f, g of $\mathscr{A}$, and every $A \in \mathrm{Ob}(\mathscr{A})$. The composition and unit axioms for F^o follow immediately from the same for F. Likewise, ${}^oF$ is given by the rules

$${}^oF({}^oA) := {}^o(FA) \qquad {}^oF({}^of) := {}^o(Ff) \qquad {}^oF({}^o\beta) := {}^o(F\beta)$$

for every A, f, β as in the foregoing. The coherence constraint for ${}^oF$ is the pair $({}^o\gamma, {}^o\delta)$ with

$${}^o\gamma_{{}^of,{}^og} := {}^o(\gamma_{f,g})^{-1} \qquad \text{and} \qquad {}^o\delta_{{}^oA} := {}^o(\delta_A)^{-1}$$

whose composition and unit axioms are again derived straightforwardly from the same for F.

(v) Let $\mathscr{C}$ be a third 2-category, and $G : \mathscr{B} \to \mathscr{C}$ another pseudo-functor. We may define a composition $G \circ F : \mathscr{A} \to \mathscr{B}$, which is the pseudo-functor such that

$$G \circ F(A) := G(FA) \qquad \text{and} \qquad (G \circ F)_{AB} := G_{FA,FB} \circ F_{AB} \qquad \text{for every } A, B \in \mathrm{Ob}(\mathscr{A}).$$

Denote by (δ^F, γ^F) and (δ^G, γ^G) the coherence constraints of F and respectively G; the coherence constraint of $G \circ F$ is then the pair $(\delta^{G\circ F}, \gamma^{G\circ F})$ such that

$$\delta^{G\circ F}_A := G(\delta^F_A) \odot \delta^G_{FA} \qquad \gamma^{G\circ F}_{f,g} := G(\gamma^F_{f,g}) \odot \gamma^G_{Ff,Fg}$$

for every $A, B, C \in \mathrm{Ob}(\mathscr{A})$ and every 1-cell f of $\mathscr{A}(A, B)$ and g of $\mathscr{A}(B, C)$. Let us verify the composition axiom for $\gamma^{G\circ F}$: given a composable sequence of 1-cells f, g, h, we have

$$\begin{aligned}
\gamma^{G\circ F}_{g\circ f,h} \odot (GFh * \gamma^{G\circ F}_{f,g}) &= G(\gamma^F_{g\circ f,h}) \odot \gamma^G_{F(g\circ f),Fh} \odot (GFh * (G(\gamma^F_{f,g}) \odot \gamma^G_{Ff,Fg})) \\
&= G(\gamma^F_{g\circ f,h}) \odot \gamma^G_{F(g\circ f),Fh} \odot (GFh * G(\gamma^F_{f,g})) \odot (GFh * \gamma^G_{Ff,Fg}) \\
&= G(\gamma^F_{g\circ f,h}) \odot G(Fh * \gamma^F_{f,g}) \odot \gamma^G_{Fg\circ Ff,Fh} \odot (GFh * \gamma^G_{Ff,Fg}) \\
&= G(\gamma^F_{g\circ f,h} \odot (Fh * \gamma^F_{f,g})) \odot \gamma^G_{Ff,Fh\circ Fg} \odot (\gamma^G_{Fg,Fh} * GFf) \\
&= G(\gamma^F_{f,h\circ g} \odot (\gamma^F_{g,h} * Ff)) \odot \gamma^G_{Ff,Fh\circ Fg} \odot (\gamma^G_{Fg,Fh} * GFf) \\
&= G(\gamma^F_{f,h\circ g}) \odot G(\gamma^F_{g,h} * Ff) \odot \gamma^G_{Ff,Fh\circ Fg} \odot (\gamma^G_{Fg,Fh} * GFf) \\
&= G(\gamma^F_{f,h\circ g}) \odot \gamma^G_{Ff,F(h\circ g)} \odot (G(\gamma^F_{g,h}) * GFf) \odot (\gamma^G_{Fg,Fh} * GFf) \\
&= \gamma^{G\circ F}_{f,h\circ g} \odot ((G(\gamma^F_{g,h}) \odot \gamma^G_{Fg,Fh}) * GFf) \\
&= \gamma^{G\circ F}_{f,h\circ g} \odot (\gamma^{G\circ F}_{g,h} * GFf)
\end{aligned}$$

where the third and seventh equalities follow from (ii) (applied to G), the fourth from (i) and the composition axiom for G, the fifth from the composition axiom for F, the sixth from (i).

Next, to check the unit axiom, we compute :

$$\begin{aligned}\gamma^{G\circ F}_{\mathbf{1}_A,f} \odot (GFf * \delta^{G\circ F}_A) &= G(\gamma^F_{\mathbf{1}_A,f}) \odot \gamma^G_{F\mathbf{1}_A,Ff} \odot (GFf * (G(\delta^F_A) \odot \delta^G_{FA})) \\ &= G(\gamma^F_{\mathbf{1}_A,f}) \odot \gamma^G_{F\mathbf{1}_A,Ff} \odot (GFf * G(\delta^F_A)) \odot (GFf * \delta^G_{FA}) \\ &= G(\gamma^F_{\mathbf{1}_A,f}) \odot G(Ff * \delta^F_A) \odot \gamma^G_{\mathbf{1}_{FA},Ff} \odot (GFf * \delta^G_{FA}) \\ &= G(\gamma^F_{\mathbf{1}_A,f} \odot (Ff * \delta^F_A)) \\ &= G(\mathbf{1}_{Ff}) \\ &= \mathbf{1}_{GFf}\end{aligned}$$

where the third equality follows from (ii), the fourth from (i) and the unit axiom for G, and the fifth from the unit axiom for F. Similarly one verifies the commutativity of the remaining diagram required for the unit axiom : details left to the reader.

(vi) Also, if $H : \mathscr{C} \to \mathscr{D}$ is any other pseudo-functor, then $H \circ (G \circ F) = (H \circ G) \circ F$. Indeed, taking into account (i) we may compute :

$$\begin{aligned}\gamma^{H\circ(G\circ F)}_{f,g} &= H(\gamma^{G\circ F}_{f,g}) \odot \gamma^H_{G\circ Ff,G\circ Fg} \\ &= H\circ G(\gamma^F_{f,g}) \odot H(\gamma^G_{Ff,Gf}) \odot \gamma^H_{G\circ Ff,G\circ Fg} \\ &= H\circ G(\gamma^F_{f,g}) \odot \gamma^{H\circ G}_{Ff,Gf} \\ &= \gamma^{(H\circ G)\circ F}_{f,g}.\end{aligned}$$

Similarly one checks that $\delta^{H\circ(G\circ F)}_A = \delta^{(H\circ G)\circ F}_A$ for every $A \in \mathrm{Ob}(\mathscr{A})$, whence the assertion.

(vii) Notice as well that if F and G are strict, then the same holds for $G \circ F$.

Remark 2.1.18. (i) Remark 2.1.17(v) shows that the set of all U-small 2-categories together with all pseudo-functors between them forms a category with small Hom-sets that we denote

$$\mathsf{U}\text{-}2\text{-}\mathbf{Cat}$$

(and as always, we shall usually drop the universe U from the notation). We do not know whether 2-$\mathbf{Cat}$ is a complete category : for instance, if $F : \mathscr{A} \to \mathscr{B}$ and $F' : \mathscr{A}' \to \mathscr{B}$ are any two pseudo-functors, it is not clear whether the fibre product of F and F' is always representable in 2-$\mathbf{Cat}$. However, in case F and F' are both strict, this fibre product is indeed representable by a 2-category that we denote

$$\mathscr{A} \times_{(F,F')} \mathscr{A}'$$

(or simply $\mathscr{A} \times_{\mathscr{B}} \mathscr{A}'$, if the notation is not ambiguous). Namely, the objects of $\mathscr{A} \times_{\mathscr{B}} \mathscr{A}'$ are all the pairs (A, A') consisting of objects A of $\mathscr{A}$ and A' of $\mathscr{A}'$ such that $FA = F'A'$, and the Hom-categories are given by the rule :

$$\mathscr{A} \times_{\mathscr{B}} \mathscr{A}'((A_1, A'_1), (A_2, A'_2)) := \mathscr{A}(A_1, A_2) \times_{\mathscr{B}(FA_1,FA_2)} \mathscr{A}(A_2, A'_2)$$

for every pair of objects $(A_1, A'_1), (A_2, A'_2)$ of $\mathscr{A} \times_{\mathscr{B}} \mathscr{A}'$ (see example 1.2.25(i)). The composition laws and unit functors for $\mathscr{A} \times_{\mathscr{B}} \mathscr{A}'$ are deduced from those of $\mathscr{A}$ and $\mathscr{A}'$, in the obvious fashion. A universal cone for this fibre product is provided by the two projections $\mathscr{A} \leftarrow \mathscr{A} \times_{\mathscr{B}} \mathscr{A}' \to \mathscr{A}'$, *i.e.* the strict pseudo-functors defined in the obvious fashion.

(ii) For instance, just as in (1.1.30), for every 2-category $\mathscr{A}$ we have two natural *source* and *target* strict pseudo-functors :

$$\mathscr{A} \xleftarrow{\mathsf{s}} 2\text{-}\mathsf{Morph}(\mathscr{A}) \xrightarrow{\mathsf{t}} \mathscr{A}$$

(notation of example 2.1.11(i)). Namely, s assigns to every 1-cell $f : A \to B$ the object A of $\mathscr{A}$, to every diagram (2.1.6) the 1-cell $g : \mathsf{s}(f) \to \mathsf{s}(f')$ of $\mathscr{A}$, and to every 2-cell (β, γ) of

$\mathsf{2\text{-}Morph}(\mathscr{A})$, the 2-cell β of $\mathscr{A}$. The reader may likewise spell out the definition of t. Then we have as well a natural *composition* strict pseudo-functor

$$\mathsf{c} : \mathsf{2\text{-}Morph}(\mathscr{A}) \times_{(\mathsf{t},\mathsf{s})} \mathsf{2\text{-}Morph}(\mathscr{A}) \to \mathsf{2\text{-}Morph}(\mathscr{A})$$

which assigns :

- to every pair of 1-cells (f, g) such that $\mathsf{t}(f) = \mathsf{s}(g)$, the composition $\mathsf{c}(f, g) := g \circ f$
- to every pair of 1-cells of $\mathsf{2\text{-}Morph}(\mathscr{A})$:

(2.1.19)
$$\begin{array}{ccccc} A & \xrightarrow{f} & B & \xrightarrow{g} & C \\ {\scriptstyle h}\big\downarrow & \not\Swarrow_{\alpha} & \big\downarrow{\scriptstyle k} & \not\Swarrow_{\beta} & \big\downarrow{\scriptstyle i} \\ A' & \xrightarrow[f']{} & B' & \xrightarrow[g']{} & C' \end{array}$$

  the 1-cell of $\mathsf{2\text{-}Morph}(\mathscr{A})$

$$\mathsf{c}((\alpha, h, k), (\beta, k, i)) := (\beta \boxminus \alpha, h, i)$$

- for $(f, g), (f', g')$ as in (2.1.19), and every 2-cells $(\varphi_1, \varphi_2) : (\alpha_1, h_1, k_1) \Rightarrow (\alpha_2, h_2, k_2)$ in $\mathsf{2\text{-}Morph}(f, f')$ and $(\varphi_2, \varphi_3) : (\beta_1, k_1, i_1) \Rightarrow (\beta_2, k_2, i_2)$ in $\mathsf{2\text{-}Morph}(g, g')$, the pair

$$\mathsf{c}((\varphi_1, \varphi_2), (\varphi_2, \varphi_3)) := (\varphi_1, \varphi_3)$$

  which is a well defined 2-cell $\mathsf{c}((\alpha_1, h_1, k_1), (\beta_1, k_1, i_1)) \Rightarrow \mathsf{c}((\alpha_2, h_2, k_2), (\beta_2, k_2, i_2))$ in $\mathsf{2\text{-}Morph}(g \circ f, g' \circ f')$, since by assumption we have

$$\frac{\alpha_1}{h_1|g_1} \boxminus \frac{\varphi_1}{g_1|g_2} = \frac{\varphi_2}{h_1|h_2} \boxminus \frac{\alpha_2}{h_2|g_2} \qquad \frac{\beta_1}{k_1|h_1} \boxminus \frac{\varphi_2}{h_1|h_2} = \frac{\varphi_3}{k_1|k_2} \boxminus \frac{\beta_2}{k_2|h_2}$$

  and therefore

$$\begin{aligned}(\beta_1 \boxminus \alpha_1) \boxminus \varphi_1 &= \beta_1 \boxminus (\alpha_1 \boxminus \varphi_1) \\ &= \beta_1 \boxminus (\varphi_2 \boxminus \alpha_2) \\ &= (\beta_1 \boxminus \varphi_2) \boxminus \alpha_2 \\ &= (\varphi_3 \boxminus \beta_2) \boxminus \alpha_2 \\ &= \varphi_3 \boxminus (\beta_2 \boxminus \alpha_2).\end{aligned}$$

With these rules, the functoriality of c for 2-cells is immediate. To check the functoriality of c for 1-cells, consider a diagram as in proposition 2.1.9(ii), and to ease notation, set $\underline{\alpha} := (\alpha, h, k)$ and define likewise $\underline{\alpha}'$, $\underline{\beta}$ and $\underline{\beta}'$. Then proposition 2.1.9(ii) translates as the identity

$$\mathsf{c}(\underline{\alpha}' \circ \underline{\alpha}, \underline{\beta}' \circ \underline{\beta}) = \mathsf{c}(\underline{\alpha}', \underline{\beta}') \circ \mathsf{c}(\underline{\alpha}, \underline{\beta})$$

as required.

Example 2.1.20. (i) Let $\mathscr{A}$, $\mathscr{B}$ be two 2-categories, and $F : \mathscr{A} \to \mathscr{B}$ any pseudo-functor, with coherence constraint (γ^F, δ^F). Then F induces a pseudo-functor

$$\mathsf{2\text{-}Morph}(F) : \mathsf{2\text{-}Morph}(\mathscr{A}) \to \mathsf{2\text{-}Morph}(\mathscr{B})$$

by the following rule. To every 1-cell $f : A \to B$ in $\mathscr{A}$ we assign the 1-cell $Ff : FA \to FB$. To every diagram (2.1.6) we assign the diagram

$$\begin{array}{ccc} FA & \xrightarrow{Ff} & FB \\ {\scriptstyle Fg}\big\downarrow & \not\Swarrow_{\alpha^F} & \big\downarrow{\scriptstyle Fh} \\ FA' & \xrightarrow[Ff']{} & FB' \end{array} \qquad \text{where } \alpha^F := (\gamma^F_{g,f'})^{-1} \odot F\alpha \odot \gamma^F_{f,h}$$

and to any 2-cell $(\beta, \delta) : (g_1, h_1, \alpha_1) \Rightarrow (g_2, h_2, \alpha_2)$ in 2-$\mathsf{Morph}(f, f')$, we assign the pair $(F\beta, F\delta)$. Indeed, let us check that the latter is a well defined 2-cell in 2-$\mathsf{Morph}(Ff, Ff')$; the assertion boils down to the identity :

$$(\gamma^F_{g_2,f'})^{-1} \odot F\alpha_2 \odot \gamma^F_{f,h_2} \odot (F\delta * Ff) = (Ff' * F\beta) \odot (\gamma_{g_1,f'})^{-1} \odot F\alpha_1 \odot \gamma^F_{f,h_1}.$$

However, from remark 2.1.17(ii) we get

$$(Ff' * F\beta) \odot (\gamma^F_{g_1,f'})^{-1} = (\gamma^F_{g_2,f'})^{-1} \odot F(f' * \beta)$$

hence it suffices to check that

$$F\alpha_2 \odot \gamma^F_{f,h_2} \odot (F\delta * Ff) = F(f' * \beta) \odot F\alpha_1 \odot \gamma^F_{f,h_1}.$$

But by assumption, we know that $(f' * \beta) \odot \alpha_1 = \alpha_2 \odot (\delta * f)$, so – taking into account remark 2.1.17(i) – we are further reduced to showing that

$$\gamma^F_{f,h_2} \odot (F\delta * Ff) = F(\delta * f) \odot \gamma^F_{f,h_1}$$

which follows again from remark 2.1.17(ii). Lastly, the coherence constraint of 2-$\mathsf{Morph}(F)$ assigns to any diagram (2.1.12) (resp. (2.1.7)) the pair

(2.1.21) $$(\delta^F_A, \delta^F_B) \qquad \text{(resp. } (\gamma^F_{g,k}, \gamma^F_{h,i}) \text{).}$$

Indeed, let us check that (δ^F_A, δ^F_B) is a well defined 2-cell in 2-$\mathsf{Morph}(Ff, Ff)$: the assertion boils down to the identity

$$(Ff * \delta^F_A) \odot \mathbf{1}^F_f = \mathbf{1}^F_f \odot (\delta^F_B * Ff) \qquad \text{where} \qquad \mathbf{1}^F_f := (\gamma^F_{\mathbf{1}_A,f})^{-1} \odot \gamma^F_{f,\mathbf{1}_B}$$

which in turns follows easily from the unit axiom for δ^F. Likewise, the assertion that $(\gamma^F_{g,k}, \gamma^F_{h,i})$ is a well defined 2-cell in 2-$\mathsf{Morph}(Ff, Ff'')$ comes down to the identity

(2.1.22) $$\gamma^F_{g,k} \boxminus (\beta^F \boxed{} \alpha^F) = (\beta \boxed{} \alpha)^F \boxminus \gamma^F_{h,i}.$$

However, by definition, the left-hand side of (2.1.22) equals

$$(Ff'' * \gamma^F_{g,k}) \odot ((\gamma^F_{k,f''})^{-1} * Fg) \odot (F\beta * Fg) \odot (\gamma^F_{f',i} * Fg) \odot (Fi * (\gamma^F_{g,f'})^{-1}) \odot (Fi * (F\alpha \odot \gamma^F_{f,h}))$$

and the composition axiom for F yields the identities :

$$(Ff'' * \gamma^F_{g,k}) \odot ((\gamma^F_{k,f''})^{-1} * Fg) = (\gamma^F_{k\circ g,f''})^{-1} \odot \gamma^F_{g,f''\circ k}$$
$$(\gamma^F_{f',i} * Fg) \odot (Fi * (\gamma^F_{g,f'})^{-1}) = (\gamma^F_{g,i\circ f'})^{-1} \odot \gamma^F_{f'\circ g,i}.$$

So the left-hand side of (2.1.22) also equals

$$(\gamma^F_{k\circ g,f''})^{-1} \odot \gamma^F_{g,f''\circ k} \odot (F\beta * Fg) \odot (\gamma^F_{g,i\circ f'})^{-1} \odot \gamma^F_{f'\circ g,i} \odot (Fi * (F\alpha \odot \gamma^F_{f,h})).$$

Next, remark 2.1.17(ii) yields the identities

$$(F\beta * Fg) \odot (\gamma^F_{g,i\circ f'})^{-1} = (\gamma^F_{g,f''\circ k})^{-1} \odot F(\beta * g)$$
$$\gamma^F_{f'\circ g,i} \odot (Fi * F\alpha) = F(i * \alpha) \odot \gamma^F_{h\circ f,i}.$$

So we have to show that the right-hand side of (2.1.22) equals

$$(\gamma^F_{k\circ g,f''})^{-1} \odot F(\beta * g) \odot F(i * \alpha) \odot \gamma^F_{h\circ f,i} \odot (Fi * \gamma^F_{f,h}).$$

But by unwinding the definition, we see that the right-hand side of (2.1.22) equals

$$(\gamma^F_{k\circ g,f''})^{-1} \odot F(\beta \boxed{} \alpha) \odot \gamma^F_{f,i\circ h} \odot (\gamma^F_{h,i} * Ff) = (\gamma^F_{k\circ g,f''})^{-1} \odot F(\beta \boxed{} \alpha) \odot \gamma^F_{h\circ f,i} \odot (Fi * \gamma^F_{f,h})$$

(where the equality holds by the composition axiom). Thus, we come down to checking that

$$F(\beta * g) \odot F(i * \alpha) = F(\beta \boxed{} \alpha)$$

which follows from remark 2.1.17(i). With these rules, the functoriality of 2-$\mathsf{Morph}(F)$ is clear from remark 2.1.17(i), and the naturality of (2.1.21), as well as the composition and unit axioms for the latter, follow from the respective properties of (γ^F, δ^F), by a direct inspection.

(ii) In the situation of (i), let $f : A \to B$ be any 1-cell of $\mathscr{A}$. Then the unit axiom for the coherence constraint (γ^F, δ^F) implies the identity :

$$\mathbf{1}^F_f = (Ff * \delta^F_A) \odot ((\delta^F_B)^{-1} * Ff).$$

(iii) Let $\mathscr{C}$ be a third 2-category, and $G : \mathscr{B} \to \mathscr{G}$ another pseudo-functor; then we have

$$\mathsf{2\text{-}Morph}(G \circ F) = \mathsf{2\text{-}Morph}(G) \circ \mathsf{2\text{-}Morph}(F)$$

(details left to the reader).

Example 2.1.23. Let $\mathscr{A}$ be any 2-category.

(i) We have a natural strict isomorphism of 2-categories

$${}^o(\mathsf{2\text{-}Morph}(\mathscr{A}))^o \xrightarrow{\sim} \mathsf{2\text{-}Morph}({}^o\mathscr{A}^o)$$

that assigns :

- to every object $f : A \to B$ of $\mathsf{2\text{-}Morph}(\mathscr{A})$ the object ${}^of^o : {}^oB^o \to {}^oA^o$
- to every oriented square (2.1.6) the corresponding oriented square ^{o}(2.1.6)^o, which is a 1-cell ${}^o\alpha^o : {}^of'^o \to {}^of^o$ in $\mathsf{2\text{-}Morph}({}^o\mathscr{A}^o)$
- to every 2-cell (β, γ) in $\mathsf{2\text{-}Morph}(\mathscr{A})(f, f')$ the pair $({}^o\gamma^o, {}^o\beta^o)$ which is a 2-cell in $\mathsf{2\text{-}Morph}({}^o\mathscr{A}^o)({}^of'^o, {}^of^o)$.

(ii) We deduce from (i) a strict isomorphism of 2-categories

$$(\mathsf{2\text{-}Morph}(\mathscr{A}^o))^o \xrightarrow{\sim} {}^o(\mathsf{2\text{-}Morph}({}^o\mathscr{A})).$$

These latter 2-categories can be described as follows. The objects are the same as those of $\mathsf{2\text{-}Morph}(\mathscr{A})$, and the 1-cells $f \to f'$ are the oriented squares just like (2.1.6), but *with reversed direction of the orienting arrow*, *i.e.* α is replaced by a 2-cell $f' \circ g \Rightarrow h \circ f$. Given two 1-cells $(g_1, h_1, \alpha_1), (g_2, h_2, \alpha_2) : f \to f'$ in $\mathsf{2\text{-}Morph}(\mathscr{A}^o)^o(f, f')$, the 2-cells $(g_1, h_1, \alpha_1) \Rightarrow (g_2, h_2, \alpha_2)$ are still all the pairs $(\beta : g_1 \Rightarrow g_2, \gamma : h_1 \Rightarrow h_2)$ such that $\alpha_1 \boxminus \beta = \gamma \boxminus \alpha_2$, and the composition rule for such 2-cells is the same as in $\mathsf{2\text{-}Morph}(\mathscr{A})$. However, the composition law for 1-cells in $\mathsf{2\text{-}Morph}(\mathscr{A}^o)^o$ is given by the join operation $\boxminus$ instead of $\boxbar$: details left to the reader.

Example 2.1.24. We have a natural strict isomorphism of 2-categories :

$$(-)^o : {}^o\mathbf{Cat} \xrightarrow{\sim} \mathbf{Cat}$$

that assigns to every small category $\mathscr{C}$ the opposite category $\mathscr{C}^o$, to every functor $F : \mathscr{B} \to \mathscr{C}$ the opposite functor $F^o : \mathscr{B}^o \to \mathscr{C}^o$, and to every natural transformation $\beta : F \Rightarrow G$ the opposite transformation $\beta^o : G^o \Rightarrow F^o$.

2.2. **Pseudo-natural transformations and their modifications.** The following definition introduces the 2-categorical analogue of a natural transformation between functors.

Definition 2.2.1. Consider two pseudo-functors $F, G : \mathscr{A} \to \mathscr{B}$ between 2-categories $\mathscr{A}$, $\mathscr{B}$.

(i) A *lax-natural transformation* $\alpha : F \Rightarrow G$ is the datum of :

- For every object A of $\mathscr{A}$, a 1-cell $\alpha_A : FA \to GA$.
- For every $A, B \in \mathrm{Ob}(\mathscr{A})$, a natural transformation τ_{AB} between two functors $\mathscr{A}(A, B) \to \mathscr{B}(FA, GB)$, as shown by the (not necessarily commutative) diagram

(2.2.2)
$$\begin{array}{ccc} \mathscr{A}(A,B) & \xrightarrow{F_{AB}} & \mathscr{B}(FA,FB) \\ {\scriptstyle G_{AB}}\downarrow & \overset{\tau_{AB}}{\nearrow} & \downarrow{\scriptstyle H_{\mathscr{B}}(\mathbf{1}_{FA},\alpha_B)} \\ \mathscr{B}(GA,GB) & \xrightarrow[H_{\mathscr{B}}(\alpha_A,\mathbf{1}_{GB})]{} & \mathscr{B}(FA,GB) \end{array}$$

where $H_{\mathscr{B}}(\mathbf{1}_{FA}, \alpha_B)$ and $H_{\mathscr{B}}(\alpha_A, \mathbf{1}_{GB})$ are as in example 2.2.7. The datum $\tau_{\bullet\bullet}$ is called the *coherence constraint* for α, and is required to satisfy the following *coherence axioms* (in which we denote by (δ^F, γ^F) and (δ^G, γ^G) the coherence constraints for F and respectively G) :

- For every $A \in \mathrm{Ob}(\mathscr{A})$, the following diagram commutes :

$$\begin{array}{ccccc} \alpha_A & \xRightarrow{\mathbf{1}_{\alpha_A}} & \mathbf{1}_{GA} \circ \alpha_A & \xRightarrow{\delta^G_A * \alpha_A} & G(\mathbf{1}_A) \circ \alpha_A \\ {\scriptstyle \mathbf{1}_{\alpha_A}} \Downarrow & & & & \Downarrow {\scriptstyle \tau_{\mathbf{1}_A}} \\ \alpha_A \circ \mathbf{1}_{FA} & & \xRightarrow{\alpha_A * \delta^F_A} & & \alpha_A \circ F(\mathbf{1}_A). \end{array}$$

- For each pair of 1-cells $A \xrightarrow{f} B \xrightarrow{g} C$ in $\mathscr{A}$, the following diagram commutes :

$$\begin{array}{ccccc} Gg \circ Gf \circ \alpha_A & \xRightarrow{Gg * \tau_f} & Gg \circ \alpha_B \circ Ff & \xRightarrow{\tau_g * Ff} & \alpha_C \circ Fg \circ Ff \\ {\scriptstyle \gamma^G_{f,g} * \alpha_A} \Downarrow & & & & \Downarrow {\scriptstyle \alpha_C * \gamma^F_{f,g}} \\ G(g \circ f) \circ \alpha_A & & \xRightarrow{\tau_{g \circ f}} & & \alpha_C \circ F(g \circ f). \end{array}$$

(ii) A lax-natural transformation α as in (i) is called a *pseudo-natural transformation* (resp. *strict*) if τ_{AB} is an isomorphism of functors (resp. if (2.2.2) commutes and τ_{AB} is the identity natural transformation) for every $A, B \in \mathrm{Ob}(\mathscr{A})$.

(iii) A pseudo-natural transformation α as in (i) is called a *pseudo-natural isomorphism* if α_A is an invertible 1-cell, for every $A \in \mathrm{Ob}(\mathscr{A})$.

Example 2.2.3. For any 2-category $\mathscr{C}$, denote by

$$p_{\mathscr{C}}, p'_{\mathscr{C}} : \text{2-Morph}(\mathscr{C}) \times_{(\mathsf{t},\mathsf{s})} \text{2-Morph}(\mathscr{C}) \to \text{2-Morph}(\mathscr{C})$$

the projections, *i.e.* the strict pseudo-functors that yield a universal cone for this fibre product, where t and s are the target and source pseudo-functors for 2-Morph$(\mathscr{C})$ as in remark 2.1.18(ii). Now, let $\mathscr{A}, \mathscr{B}$ be two 2-categories, and $F : \mathscr{A} \to \mathscr{B}$ a pseudo-functor; it is easily seen that

$$\mathsf{t} \circ \text{2-Morph}(F) \circ p_{\mathscr{A}} = \mathsf{s} \circ \text{2-Morph}(F) \circ p'_{\mathscr{A}}$$

where 2-Morph(F) is defined as in example 2.1.20(i). There follows a unique pseudo-functor

$$\text{2-Morph}(F, F) : \text{2-Morph}(\mathscr{A}) \times_{(\mathsf{t},\mathsf{s})} \text{2-Morph}(\mathscr{A}) \to \text{2-Morph}(\mathscr{B}) \times_{(\mathsf{t},\mathsf{s})} \text{2-Morph}(\mathscr{B})$$

such that

$$p_{\mathscr{B}} \circ \text{2-Morph}(F, F) = \text{2-Morph}(F) \circ p_{\mathscr{A}} \qquad \text{and} \qquad p'_{\mathscr{B}} \circ \text{2-Morph}(F, F) = \text{2-Morph}(F) \circ p'_{\mathscr{A}}$$

and we claim that the coherence constraint γ^F of F can be viewed as a strict pseudo-natural isomorphism

$$\begin{array}{ccc} \text{2-Morph}(\mathscr{A}) \times_{(\mathsf{t},\mathsf{s})} \text{2-Morph}(\mathscr{A}) & \xrightarrow{\mathsf{c}} & \text{2-Morph}(\mathscr{A}) \\ {\scriptstyle \text{2-Morph}(F,F)} \downarrow & \gamma^F \nearrow\!\!\!\nearrow & \downarrow {\scriptstyle \text{2-Morph}(F)} \\ \text{2-Morph}(\mathscr{B}) \times_{(\mathsf{t},\mathsf{s})} \text{2-Morph}(\mathscr{B}) & \xrightarrow[\mathsf{c}]{} & \text{2-Morph}(\mathscr{B}). \end{array}$$

Namely, for every pair of composable 1-cells (f, g) of $\mathscr{A}$, we regard $\gamma^F_{f,g} : Fg \circ Ff \Rightarrow F(g \circ f)$ as a 1-cell of 2-Morph$(\mathscr{B})$. Then the strictness of γ^F boils down to the identity

$$\gamma^F_{f',g'} \boxplus (\beta^F \boxminus \alpha^F) = (\beta \boxminus \alpha)^F \boxplus \gamma^F_{f,g}$$

for every diagram (2.1.19) in $\mathscr{A}$. For the verification, notice that the associativity constraint for the functor $(\text{2-Morph}(F^o))^o$ assigns to (2.1.19) the pair $(\gamma^o_{f,g}, \gamma^o_{f',g'})^o = (\gamma_{f,g}, \gamma_{f',g'})$ (see remark 2.1.17(iv) and example 2.1.20(i)), and then the foregoing identity just translates the assertion that $(\gamma_{f,g}, \gamma_{f',g'})$ is a well defined 2-cell in $\mathsf{2\text{-}Morph}(F^o h^o, F^o i^o)^o$ (see example 2.1.23(ii)). The coherence axioms for γ^F follow easily, by unwinding the definitions.

Example 2.2.4. (i) Any category $\mathscr{A}$ can be regarded as a 2-category in a natural way : namely, for any two objects A and B of $\mathscr{A}$ one lets $\mathscr{A}(A, B)$ be the discrete category $\mathrm{Hom}_{\mathscr{A}}(A, B)$; hence the only 2-cells of $\mathscr{A}$ are the identities $\mathbf{1}_f : f \Rightarrow f$, for every morphism $f : A \to B$. The composition bifunctor c_{ABC} is of course given (on 1-cells) by the composition law for morphisms of $\mathscr{A}$. Likewise, the functor u_A assigns to every object A its identity endomorphism.

(ii) In the same vein, every functor between usual categories is a strict pseudo-functor between the corresponding 2-categories as in (i). Finally, every natural transformation of usual functors can be regarded naturally as a strict pseudo-natural transformation between the corresponding strict pseudo-functors.

Remark 2.2.5. With the notation of definition 2.2.1, we have :

(i) The coherence constraint of α can be regarded as a system of oriented squares

$$\begin{array}{ccc} FA & \xrightarrow{\alpha_A} & GA \\ {\scriptstyle Ff}\downarrow & \swarrow\!\!\!\!/ \, \tau_f & \downarrow{\scriptstyle Gf} \\ FB & \xrightarrow[\alpha_B]{} & GB \end{array} \qquad \text{for every 1-cell } f : A \to B \text{ of } \mathscr{A}.$$

Then α is a pseudo-natural transformation if and only if the orientation τ_f is invertible for every 1-cell f of $\mathscr{A}$. The naturality of $\tau_{\bullet\bullet}$ comes down to the commutativity of the diagram

$$\begin{array}{ccc} Gf \circ \alpha_A & \xRightarrow{\tau_f} & \alpha_B \circ Ff \\ {\scriptstyle G\beta * \alpha_A}\Downarrow & & \Downarrow{\scriptstyle \alpha_B * F\beta} \\ Gf' \circ \alpha_A & \xRightarrow{\tau_{f'}} & \alpha_B \circ Ff' \end{array}$$

for every $A, B \in \mathrm{Ob}(\mathscr{A})$ and every 2-cell $\beta : f \Rightarrow f'$ in $\mathscr{A}(A, B)$. The latter can be also be written as the identity

$$\tau_f \boxminus F\beta = G\beta \boxminus \tau_{f'}.$$

Likewise, the coherence axioms can be written as the identities

$$\delta^G_A \boxminus \tau_{\mathbf{1}_A} = \mathbf{1}_{\alpha_A} \boxminus \delta^F_A \qquad (\tau_g \boxbar \tau_f) \boxminus \gamma^F_{f,g} = \gamma^G_{f,g} \boxminus \tau_{g\circ f}$$

for every $A \in \mathrm{Ob}(\mathscr{A})$ and every composable pair (f, g) of 1-cells of $\mathscr{A}$.

(ii) The foregoing list of requirements becomes more intelligible, when we observe that a lax-natural transformation $\alpha : F \Rightarrow G$ is equivalent to the datum of a pseudo-functor

$$\widetilde{\alpha} : \mathscr{A} \to \mathsf{2\text{-}Morph}(\mathscr{B}) \qquad \text{such that} \qquad \mathsf{s} \circ \widetilde{\alpha} = F \qquad \text{and} \qquad \mathsf{t} \circ \widetilde{\alpha} = G$$

and α is a pseudo-natural transformation if and only if $\widetilde{\alpha}(f)$ is an invertible 2-cell for every 1-cell f of $\mathscr{A}$. Namely, in light of (i) we obtain such $\widetilde{\alpha}$ by setting

$$\widetilde{\alpha}(A) := \alpha_A \qquad \widetilde{\alpha}(f) := \tau_f \qquad \widetilde{\alpha}(\beta) := (F\beta, G\beta)$$

for every $A \in \mathrm{Ob}(\mathscr{A})$, every 1-cell f of $\mathscr{A}$, and every 2-cell β of $\mathscr{A}$. The coherence constraint (δ, γ) of $\widetilde{\alpha}$ are defined by setting

$$\delta_A := (\delta^F_A, \delta^G_A) \qquad \gamma_{f,g} := (\gamma^F_{f,g}, \gamma^G_{f,g})$$

for every $A \in \mathrm{Ob}(\mathscr{A})$ and every composable pair (f, g) of 1-cells of $\mathscr{A}$. Especially, $\widetilde{\alpha}$ is a strict pseudo-functor if and only if the same holds for both F and G.

(iii) If $\alpha : F \Rightarrow G$ and $\beta : G \Rightarrow H$ are two lax-natural transformations, let $\widetilde{\alpha}, \widetilde{\beta} : \mathscr{A} \to$ 2-$\mathsf{Morph}(\mathscr{B})$ be the associated pseudo-functors, as in (ii); then we may proceed as in example 1.2.25(iii) to define the composition

$$\beta \odot \alpha : F \Rightarrow H.$$

Namely, it shall be the lax-natural transformation associated with the pseudo-functor

$$\mathscr{A} \xrightarrow{(\widetilde{\alpha},\widetilde{\beta})} \text{2-}\mathsf{Morph}(\mathscr{A}) \times_{(\mathsf{t},\mathsf{s})} \text{2-}\mathsf{Morph}(\mathscr{A}) \xrightarrow{\mathsf{c}} \text{2-}\mathsf{Morph}(\mathscr{A})$$

(notation of remark 2.1.18(ii)). Unwinding the definitions, we see that this is the lax-natural transformation given by the rule

$$A \mapsto \beta_A \circ \alpha_A \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A})$$

and with coherence constraint $\tau^{\beta\odot\alpha}_{\bullet\bullet}$ given by the rule (notation of remark 2.1.18(ii)) :

$$(f : A \to B) \mapsto \tau^{\beta}_f \boxminus \tau^{\alpha}_f \qquad \text{for every 1-cell } f \text{ of } \mathscr{A}$$

where $\tau^{\alpha}_{\bullet\bullet}$ (resp. $\tau^{\beta}_{\bullet\bullet}$) denotes the coherence constraint of α (resp. of β). Hence, if both α and β are pseudo-natural (resp. strict), the same holds for $\beta \odot \alpha$. Since the composition law $\boxminus$ is associative (proposition 2.1.9(i) and remark 2.1.10), we deduce that

$$\lambda \odot (\beta \odot \alpha) = (\lambda \odot \beta) \odot \alpha$$

for every lax-natural transformation $\lambda : H \Rightarrow K$ (and any pseudo-functor $K : \mathscr{A} \to \mathscr{B}$).

(iv) If $\mathscr{C}$ is a third 2-category, $F', G' : \mathscr{B} \to \mathscr{C}$ two other pseudo-functors, and $\alpha' : F' \Rightarrow G'$ another lax-natural transformation, we may likewise define the *Godement products*

$$\alpha' * F : F' \circ F \Rightarrow G' \circ F \qquad G' * \alpha : G' \circ F \Rightarrow G' \circ G.$$

Namely, they shall be the pseudo-natural transformations attached to the pseudo-functors

$$\widetilde{\alpha}' \circ F \qquad \text{and respectively} \qquad \text{2-}\mathsf{Morph}(G') \circ \widetilde{\alpha}$$

where $\widetilde{\alpha}' : \mathscr{B} \to$ 2-$\mathsf{Morph}(\mathscr{C})$ is the pseudo-functor associated with α', as in (i), and we define 2-$\mathsf{Morph}(G')$ as in example 2.1.20(i). If α (resp. α') is pseudo-natural, the same holds for $G' * \alpha$ (resp. for $\alpha' * F$). In view of example 2.1.20(iii) and remark 2.1.17(vi), it is then clear that

$$\alpha' * (F \circ K) = (\alpha' * F) * K \qquad \text{and} \qquad (K' \circ G') * \alpha = K' * (G' * \alpha)$$

for any other 2-category $\mathscr{D}$, and every pseudo-functors $K : \mathscr{D} \to \mathscr{A}$ and $K' : \mathscr{C} \to \mathscr{D}$. Furthermore, if β is as in (ii), and $\beta' : G' \Rightarrow H'$ is another lax-natural transformation (to a target pseudo-functor $H' : \mathscr{B} \to \mathscr{C}$), then we get straightforwardly :

$$(G' * \alpha) * K = G' * (\alpha * K) \qquad \text{and} \qquad (\beta' \odot \alpha') * F = (\beta' * F) \odot (\alpha' * F).$$

On the other hand, example 2.2.3 says that the coherence constraint $\gamma^{G'}$ of G' induces a pseudo-natural isomorphism from the pseudo-functor associated with $(G' * \beta) \odot (G' * \alpha)$ to the pseudo-functor associated with $G' * (\beta \odot \alpha)$. Thus, if G' is a strict pseudo-functor, then these two lax-natural transformations coincide, but in general they will be different.

(v) In the same vein, it is tempting to mimick example 1.2.25(iii), in order to define a full Godement product $\alpha' * \alpha$ of any two lax-natural transformations as in (iv) : namely, one could for example declare this product to be $(G' * \alpha) \odot (\alpha' * F)$. However, notice that this lax-natural transformation shall be, in general, different from $(\alpha' * G) \odot (F' * \alpha)$, which would be another plausible definition. More precisely, we have a 2-cell

$$\tau^{\alpha'}_{\alpha_A} : ((G' * \alpha) \odot (\alpha' * F))_A \Rightarrow ((\alpha' * G) \odot (F' * \alpha))_A \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A})$$

where $\tau^{\alpha'}_{\bullet\bullet}$ denotes the coherence constraint of α'. Thus, the two possible definition will in general coincide only in case α' is a strict pseudo-natural transformation.

(vi) Taking into account remark 2.1.1(i) and the observations in (iv) and (v), we conclude that the datum of all small 2-categories, all pseudo-functors between such 2-categories, and all lax-natural (or pseudo-natural) transformations, does *not* form a 2-category, at least not with Godement products defined as in the foregoing. Rather, the pseudo-natural isomorphisms exhibited in (iv) hint at a higher order structure, whose full explication would require the introduction of a 3-categorical formalism that lies beyond the bounds of our treatise. Instead, we will venture only as far as needed to reach the notion of *modification* of pseudo-natural transformations (see definition 2.2.9), which will leave us just outside the threshold of 3-category theory, but still will provide a workable language for expressing the foregoing higher order compatibilities, and others as well of a similar nature, that will be encountered in this section.

(vii) Let us also mention that the datum of all small 2-categories, all strict pseudo-functors between such categories, and all strict pseudo-natural transformations of such pseudo-functors, does carry a natural 2-category structure, with the composition laws for pseudo-functors and pseudo-natural transformations defined above : the easy verification shall be left to the reader.

Example 2.2.6. (i) Consider two pseudo-functors $F, G : \mathscr{A} \to \mathscr{B}$ between 2-categories, and $\beta : F \Rightarrow G$ a pseudo-natural transformation. Denote by (γ^F, δ^F) (resp. (γ^G, δ^G), resp. τ^β) the coherence constraint of F (resp. G, resp. β). We deduce from β pseudo-natural transformations

$$\beta^o : G^o \Rightarrow F^o \qquad {}^o\beta : {}^oF \Rightarrow {}^oG$$

with coherence constraints given by the rules

$$(f^o : A^o \to A'^o) \mapsto \tau^{\beta^o}_{f^o} := (\tau^{\beta\ -1}_f)^o : F^o f^o \circ \beta^o_{A'^o} \Rightarrow \beta^o_{A^o} \circ G^o f^o$$
$$({}^of : {}^oA \to {}^oA') \mapsto \tau^{{}^o\beta}_{f^o} := {}^o(\tau^{\beta\ -1}_f) : {}^oG^o f \circ {}^o\beta_{{}^oA} \Rightarrow {}^o\beta_{{}^oA'} \circ {}^oF^o f.$$

Indeed, the coherence axioms for τ^β imply the identities

$$(\tau^{\beta\ -1}_{\mathbf{1}_A})^o \boxminus (\delta^{G\ -1}_A)^o = (\delta^{F\ -1}_A)^o \boxminus \mathbf{1}^o_{\beta_A} \qquad (\gamma^{F\ -1}_{f,f'})^o \boxminus ((\tau^{\beta\ -1}_f)^o \boxdot (\tau^{\beta\ -1}_{f'})^o) = (\tau^{\beta\ -1}_{f'\circ f})^o \boxminus (\gamma^{G\ -1}_{f,f'})^o$$

whence :

$$(\delta^F_A)^o \boxminus (\tau^{\beta\ -1}_{\mathbf{1}_A})^o = \mathbf{1}^o_{\beta_A} \boxminus (\delta^{G\ -1}_A)^o \qquad ((\tau^{\beta\ -1}_f)^o \boxdot (\tau^{\beta\ -1}_{f'})^o) \boxminus (\gamma^G_{f,f'})^o = (\gamma^F_{f,f'})^o \boxminus (\tau^{\beta\ -1}_{f'\circ f})^o$$

which in view, of remark 2.1.17(iv), shows that $\tau^{\beta^o}_\bullet$ fulfills the required coherence axioms. Likewise one verifies easily the naturality condition, whence the assertion. The corresponding verifications for ${}^o\beta$ are similar, and shall be left to the reader.

(ii) By virtue of (i), one can say that – just as for usual natural transformation between functors – the datum of a pseudo-natural transformation $\beta : F \Rightarrow G$ is equivalent to that of a pseudo-natural transformation $\beta^o : F^o \Rightarrow G^o$, and also to that of a pseudo-natural transformation ${}^o\beta : {}^oF \Rightarrow {}^oG$. On the other hand, these equivalences *does not extend to general lax-natural transformations*. By inspecting the definition, we see that a lax-natural transformation $\alpha : {}^oF \Rightarrow {}^oG$ is the datum of a system of 1-cells $(\alpha_A : FA \to GA \mid A \in \mathrm{Ob}(\mathscr{A}))$ together with oriented squares as in remark 2.2.5(i), but *whose orientation is reversed*, hence τ_f is a 2-cell $\alpha_B \circ Ff \Rightarrow Gf \circ \alpha_A$ in $\mathscr{B}$. The naturality and coherence conditions for such a system of oriented squares must be likewise suitably reoriented : the details shall be left to the reader. In some literature, such data $(\alpha_\bullet, \tau_{\bullet\bullet})$ are called *oplax-natural transformations*, but we shall not use this terminology.

Example 2.2.7. (i) Let $\mathscr{C}$ be any 2-category, and pick a universe U such that $\mathscr{C}$ is U-small; according to remark 2.1.18(i) the product $\mathscr{C}^o \times \mathscr{C}$ is representable in U-2-$\mathbf{Cat}$. Then we get the strict pseudo-functor

$$H_{\mathscr{C}} : \mathscr{C}^o \times \mathscr{C} \to \mathsf{U}\text{-}\mathbf{Cat}$$

(for the natural 2-category structure on U-$\mathbf{Cat}$ discussed in remark 2.1.1(ii)) that assigns :

- to every $C, C' \in \mathrm{Ob}(\mathscr{C})$, the category $H_{\mathscr{C}}(C, C') := \mathscr{C}(C, C')$

- to every pair of 1-cells $f : C_2 \to C_1$ and $f' : C'_1 \to C'_2$ of $\mathscr{C}$, the functor
$$H_{\mathscr{C}}(f, f') : \mathscr{C}(C_1, C'_1) \to \mathscr{C}(C_2, C'_2) \qquad g \mapsto f' \circ g \circ f \quad \alpha \mapsto f' * \alpha * f$$
where $g : C_1 \to C'_1$ is any 1-cell and α any 2-cell in $\mathscr{C}(C_1, C'_1)$
- to every pair of 2-cells $\beta : f \Rightarrow g$, $\beta' : f' \Rightarrow g'$ (with 1-cells $f, g : C_2 \to C_1$ and $f', g' : C'_1 \to C'_2$), the natural transformation
$$H_{\mathscr{C}}(\beta, \beta') : H_{\mathscr{C}}(f, f') \Rightarrow H_{\mathscr{C}}(g, g') \qquad (h : C_1 \to C'_1) \mapsto \beta' * h * \beta.$$

(ii) If $F : \mathscr{A} \to \mathscr{C}$ and $G : \mathscr{B} \to \mathscr{C}$ are any two pseudo-functors, we also define
$$H_{\mathscr{B}}(F, G) := H_{\mathscr{B}} \circ (F^o \times G) : \mathscr{A}^o \times \mathscr{B} \to \mathsf{U}\text{-}\mathbf{Cat}.$$
Likewise, if $F' : \mathscr{A} \to \mathscr{C}$ and $G' : \mathscr{B} \to \mathscr{C}$ is another pair of pseudo-functors, and $\alpha : F \Rightarrow F'$, $\beta : G \Rightarrow G'$ two pseudo-natural transformations, we let
$$H_{\mathscr{B}}(\alpha, \beta) := H_{\mathscr{B}} * (\alpha^o \times \beta) : H_{\mathscr{B}}(F, G) \Rightarrow H_{\mathscr{B}}(F', G').$$

Example 2.2.8. (i) For every 2-category $\mathscr{A}$ and every $X \in \mathrm{Ob}(\mathscr{A})$, the restriction $\mathsf{s}_X : \mathscr{A}/X \to \mathscr{A}$ (resp. $\mathsf{t}_X : X/\mathscr{A} \to \mathscr{A}$) of the pseudo-functor s (resp. t) of remark 2.1.18(ii) is a well defined strict pseudo-functor on the 2-category $\mathscr{A}/X$ (resp. $X/\mathscr{A}$ of example 2.1.11(ii)). Every 1-cell $h : X \to X'$ induces a strict pseudo-functor
$$h_* : \mathscr{A}/X \to \mathscr{A}/X' \qquad (A \xrightarrow{g} X) \mapsto (A \xrightarrow{h \circ g} X').$$
To every pair of objects $f : A \to X$ and $f' : A' \to X$ and every 1-cell $(g, \alpha) : f \Rightarrow f'$ of $\mathscr{A}/X$, the pseudo-functor h_* assigns the 1-cell $(g, h * \beta) : h_* f \Rightarrow h_* f'$ of $\mathscr{A}/X'$; lastly, for every pair of 1-cells $(g_1, \alpha_1), (g_2, \alpha_2) : f \to f'$ and every 2-cell $\beta : g_1 \Rightarrow g_2$, we have $h_*\beta := h * \beta$.

Additionally, every 2-cell $\beta : h \Rightarrow h'$ between 1-cells $h, h' : X \to X'$ induces a strict pseudo-natural transformation
$$\beta_* : h_* \Rightarrow h'_*$$
which assigns to every $(A \xrightarrow{g} X) \in \mathrm{Ob}(\mathscr{A}/X)$, the 1-cell $(\mathbf{1}_A, \beta * g) : h \circ g \to h' \circ g$ of $\mathscr{A}/X'$.

Lastly, notice that ${}^o({}^o\mathscr{A}^o/{}^oX^o)^o = X/\mathscr{A}$; we get therefore a strict pseudo-functor
$$h^* := {}^o(({}^oh^o)_*)^o : X'/\mathscr{A} \to X/\mathscr{A} \qquad (X' \xrightarrow{g} A) \mapsto (X \xrightarrow{g \circ h} A)$$
and the 2-cell β as in the foregoing induces as well a strict pseudo-natural transformation
$$\beta^* := {}^o(({}^o\beta^o)_*)^o : h^* \Rightarrow h'^*.$$

(ii) More generally, if $F : \mathscr{A} \to \mathscr{B}$ is any pseudo-functor with coherence constraint (δ^F, γ^F), and $B \in \mathrm{Ob}(\mathscr{B})$ any object, we may define a 2-category
$$F\mathscr{A}/B$$
whose objects are the pairs $(A, f : FA \to B)$ where $A \in \mathrm{Ob}(\mathscr{A})$ and f is a 1-cell of $\mathscr{B}$. The 1-cells $(g, \alpha) : (A, f) \to (A', f')$ consist of a 1-cell $g : A \to A'$ of $\mathscr{A}$ and a 2-cell $\alpha : f \Rightarrow f' \circ Fg$. For 1-cells $(g_1, \alpha_1), (g_2, \alpha_2) : (A, f) \to (A', f')$, the 2-cells $\beta : (g_1, \alpha_1) \Rightarrow (g_2, \alpha_2)$ are the 2-cells $\beta : g_1 \Rightarrow g_2$ such that $(f' * F\beta) \odot \alpha_1 = \alpha_2$. The composition law for 1-cells assigns to every pair of 1-cells $(A, f) \xrightarrow{(g,\alpha)} (A', f') \xrightarrow{(g',\alpha')} (A'', f'')$ the 1-cell
$$(g', \alpha') \circ (g, \alpha) := \Big(g' \circ g, \Big(\frac{\alpha'}{f'|f''} \boxminus \frac{\alpha}{f|f'}\Big) \boxminus \frac{\gamma^F_{g,g'}}{\mathbf{1}_{FA}|\mathbf{1}_{FA''}}\Big).$$

Let us check the associativity property : let $(A'', f'') \xrightarrow{(g'',\alpha'')} (A''', f''')$ be another 1-cell; then

$$\begin{aligned}(g'',\alpha'')\circ((g',\alpha')\circ(g,\alpha)) &= (\alpha''\boxminus((\alpha'\boxminus\alpha)\boxminus\gamma^F_{g,g'}))\boxminus\gamma^F_{g'\circ g,g''}\\ &=((\alpha''\boxminus\mathbf{1}_{Fg''})\boxminus((\alpha'\boxminus\alpha)\boxminus\gamma^F_{g,g'}))\boxminus\gamma^F_{g'\circ g,g''}\\ &=(\alpha''\boxminus\alpha'\boxminus\alpha)\boxminus(\mathbf{1}_{Fg''}\boxminus\gamma^F_{g,g'})\boxminus\gamma^F_{g'\circ g,g''}.\end{aligned}$$

On the other hand, a similar calculation yields :

$$((g'',\alpha'')\circ(g',\alpha'))\circ(g,\alpha) = (\alpha''\boxminus\alpha'\boxminus\alpha)\boxminus(\gamma^F_{g',g''}\boxminus\mathbf{1}_{Fg})\boxminus\gamma^F_{g,g''\circ g'}$$

and the coherence axiom for F translates as : $(\mathbf{1}_{Fg''}\boxminus\gamma^F_{g,g'})\boxminus\gamma^F_{g'\circ g,g''} = (\gamma^F_{g',g''}\boxminus\mathbf{1}_{Fg})\boxminus\gamma^F_{g,g''\circ g'}$, whence the contention. Then it is easily seen that the identity 1-cell of any object (A, f) is given by the pair $(\mathbf{1}_A, \delta^F_A)$: details left to the reader. The composition laws for 2-cells in $F\mathscr{A}/B$ are induced by those of $\mathscr{A}$, in the obvious way; then the required associativity and functoriality properties follow straightforwardly. Lastly we define :

$$B/F\mathscr{A} := {}^o({}^oF^o({}^o\mathscr{A}^o)/{}^oB^o)^o.$$

The source and target pseudo-functors of (i) generalize as well : we get strict pseudo-functors

$$\begin{aligned}\mathsf{s}_B &: F\mathscr{A}/B\to\mathscr{A} \quad : \quad (A, f: FA\to B)\mapsto A\\ \mathsf{t}_B &: B/F\mathscr{A}\to\mathscr{A} \quad : \quad (A, f: B\to FA)\mapsto A\end{aligned}$$

and every 1-cell $h : B \to B'$ of $\mathscr{B}$ induces strict pseudo-functors

$$\begin{aligned}h_* &: F\mathscr{A}/B\to F\mathscr{A}/B' \quad : \quad (A, f: FA\to B)\mapsto (A, h\circ f)\\ h^* &: B'/F\mathscr{A}\to B/F\mathscr{A} \quad : \quad (A, f: B'\to FA)\mapsto (A, f\circ h).\end{aligned}$$

Likewise, if $h' : B \to B'$ is another 1-cell of $\mathscr{B}$, every 2-cell $\beta : h' \Rightarrow h'$ of $\mathscr{B}'$ induces strict pseudo-natural transformations :

$$\begin{aligned}\beta_* &: h_*\Rightarrow h'_* \quad : \quad (A, f: FA\to B)\mapsto (\mathbf{1}_A, \beta * f)\\ \beta^* &: h^*\Rightarrow h'^* \quad : \quad (A, f: B\to FA)\mapsto (\mathbf{1}_A, f * \beta).\end{aligned}$$

Definition 2.2.9. Consider two pseudo-functors $F, G : \mathscr{A} \to \mathscr{B}$ between 2-categories $\mathscr{A}$, $\mathscr{B}$, and two lax-natural transformations $\alpha, \beta : F \Rightarrow G$. A *modification* $\Xi : \alpha \rightsquigarrow \beta$ is a family

$$\Xi_A : \alpha_A \Rightarrow \beta_A \qquad \text{for every } A\in \mathrm{Ob}(\mathscr{A})$$

of 2-cells of $\mathscr{B}$ that satisfies the *compatibility condition* :

$$(\Xi_{A'} * Ff)\odot\tau^\alpha_f = \tau^\beta_f\odot(Gf*\Xi_A) \qquad \text{every 1-cell } f: A\to A' \text{ of } \mathscr{A}$$

where $\tau^\alpha_{\bullet\bullet}$ (resp. $\tau^\beta_{\bullet\bullet}$) denotes the coherence constraint for α (resp. for β).

Remark 2.2.10. In the situation of definition 2.2.9, let $\Xi : \alpha \rightsquigarrow \beta$ be any modification.

(i) For any pair of 1-cells $f, g : A \to A'$ of $\mathscr{A}$, and any 2-cell $\gamma : f \Rightarrow g$ we have the identity:

$$(\Xi_{A'} * F\gamma)\odot\tau^\alpha_f = \tau^\beta_g\odot(G\gamma*\Xi_A).$$

Indeed, we may compute :

$$\begin{aligned}(\Xi_{A'} * F\gamma)\odot\tau^\alpha_f &= (\beta_{A'} * F\gamma)\odot(\Xi_{A'}*Ff)\odot\tau^\alpha_f\\ &=(\beta_{A'}*F\gamma)\odot\tau^\beta_f\odot(Gf*\Xi_A)\\ &=\tau^\beta_g\odot(G\gamma*\beta_A)\odot(Gf*\Xi_A)\\ &=\tau^\beta_g\odot(G\gamma*\Xi_A)\end{aligned}$$

where the first and the last identities follow from remark 2.1.1(i), and the third one from remark 2.2.5(i). Notice also that the condition of definition 2.2.9 can be restated as the identity

$$\frac{\Xi_{A'}}{\alpha_{A'}|\beta_{A'}} \boxbar \frac{\tau_f^\alpha}{\alpha_A|\alpha_{A'}} = \frac{\tau_f^\beta}{\beta_A|\beta_{A'}} \boxbar \frac{\Xi_A}{\alpha_A|\beta_A}. \tag{2.2.11}$$

(ii) Let $\widetilde{\alpha}, \widetilde{\beta} : \mathscr{A} \to 2\text{-}\mathsf{Morph}(\mathscr{B})$ be the pseudo-functors attached to α and β as in remark 2.2.5(ii). By unwinding the definitions, it is easily seen that Ξ is equivalent to the datum of a strict pseudo-natural transformation

$$\widetilde{\widetilde{\Xi}} : \widetilde{\alpha} \Rightarrow \widetilde{\beta} \qquad \text{such that } \mathsf{s} * \widetilde{\widetilde{\Xi}} = \mathbf{1}_F \text{ and } \mathsf{t} * \widetilde{\widetilde{\Xi}} = \mathbf{1}_G.$$

Namely, we obtain such a $\widetilde{\widetilde{\Xi}}$ by assigning, to every object A of $\mathscr{A}$, the 1-cell of $2\text{-}\mathsf{Morph}(\mathscr{B})$:

$$\begin{array}{ccc} FA & \xrightarrow{\alpha_A} & GA \\ \| & \Swarrow_{\Xi_A} & \| \\ FA & \xrightarrow[\beta_A]{} & GA. \end{array}$$

(iii) If $\gamma : F \Rightarrow G$ is any other lax-natural transformation, and $\Theta : \beta \rightsquigarrow \gamma$ any other modification, we can define the composition

$$\Theta \odot \Xi : \alpha \rightsquigarrow \gamma \quad : \quad A \mapsto \Theta_A \odot \Xi_A \quad \text{for every } A \in \mathrm{Ob}(\mathscr{A}).$$

In order to check that $\Theta \odot \Xi$ is indeed a well defined modification, we may notice that if $\widetilde{\widetilde{\Xi}}$ and $\widetilde{\Theta}$ are defined as in (ii), then $\Xi \odot \Theta$ is the modification corresponding to the pseudo-natural transformation

$$\widetilde{\Theta} \odot \widetilde{\widetilde{\Xi}} : \mathscr{A} \to 2\text{-}\mathsf{Morph}(\mathscr{B})$$

with the composition rule $\odot$ for pseudo-natural transformations given by remark 2.2.5(iii). It is clear that this composition law is associative for any triple of composable modifications.

(iv) Likewise, if $H : \mathscr{A} \to \mathscr{B}$ is another pseudo-functor, $\alpha', \beta' : G \Rightarrow H$ two other lax-natural transformations, and $\Xi' : \alpha' \rightsquigarrow \beta'$ any modification, we can define the modification

$$\Xi' * \Xi : \alpha' \odot \alpha \rightsquigarrow \beta' \odot \beta \qquad A \mapsto \Xi'_A * \Xi_A \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A}).$$

To see that $\Xi' * \Xi$ is well defined, consider – for any 1-cell $f : A \to A'$ in $\mathscr{A}$ – the diagram

$$\begin{array}{ccccc} FA & \xrightarrow{\alpha_A} & GA & \xrightarrow{\alpha'_A} & HA \\ {\scriptstyle Ff}\downarrow & \Swarrow_{\tau_f^\alpha} & \downarrow{\scriptstyle Gf} & \Swarrow_{\tau_f^{\alpha'}} & \downarrow{\scriptstyle Hf} \\ FA' & \xrightarrow{\alpha_{A'}} & GA' & \xrightarrow{\alpha'_{A'}} & HA' \\ \| & \Swarrow_{\Xi_{A'}} & \| & \Swarrow_{\Xi'_{A'}} & \| \\ FA' & \xrightarrow[\beta_{A'}]{} & GA' & \xrightarrow[\beta'_{A'}]{} & HA'. \end{array}$$

We compute :

$$\begin{aligned} (\Xi'_{A'} * \Xi_{A'} * Ff) \odot \tau_f^{\alpha' \circ \alpha} &= (\Xi'_{A'} \boxminus \Xi_{A'}) \boxbar (\tau_f^{\alpha'} \boxminus \tau_f^\alpha) \\ &= (\Xi'_{A'} \boxbar \tau_f^{\alpha'}) \boxminus (\Xi_{A'} \boxbar \tau_f^\alpha) \\ &= (\tau_f^{\beta'} \boxbar \Xi'_A) \boxminus (\tau_f^\beta \boxbar \Xi_A) \\ &= (\tau_f^{\beta'} \boxminus \tau_f^\beta) \boxbar (\Xi'_A \boxminus \Xi_A) \\ &= \tau_f^{\beta' \circ \beta} \odot (Hf * \Xi'_A * \Xi_A) \end{aligned}$$

where the second and fourth equalities follow from proposition 2.1.9(ii), and the third follows from (2.2.11). The contention follows. This operation is clearly associative. As usual, we write $\alpha * \Xi$ and $\Xi * \alpha'$ instead of $\mathbf{1}_\alpha * \Xi$ and respectively $\Xi * \mathbf{1}_{\alpha'}$, for any lax-natural transformations $\alpha : G \Rightarrow H$ and $\alpha' : E \Rightarrow F$.

(v) There is a third type of operation for modifications : namely, let $\mathscr{C}$ be another 2-category and $I : \mathscr{C} \to \mathscr{A}$ any pseudo-functor; then we obtain the modification

$$\Xi \circ I : \alpha * I \Rightarrow \beta * I \qquad C \mapsto \Xi_{IC} \qquad \text{for every } C \in \mathrm{Ob}(\mathscr{C}).$$

To check that $\Xi \circ I$ is indeed a modification, it suffices to notice that the coherence constraint of $\alpha * I$ is given by the system of 2-cells τ^α_{If}, for f ranging over the 1-cells of $\mathscr{C}$, and correspondingly for the coherence constraint of $\beta * I$.

(vi) Likewise, if $K : \mathscr{B} \to \mathscr{C}$ is any pseudo-functor, we get the modification

$$K \circ \Xi : K * \alpha \rightsquigarrow K * \beta \qquad A \mapsto K(\Xi_A) \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A}).$$

Indeed, notice that the coherence constraints of $K*\alpha$ and $K*\beta$ attach to every 1-cell $f : A \to A'$ in $\mathscr{A}$ the 2-cells

$$\tau^{K*\alpha}_f := \gamma^{K\ -1}_{Ff,\alpha_{A'}} \odot K(\tau^\alpha_f) \odot \gamma^K_{\alpha_A,Gf} \qquad \tau^{K*\beta}_f := \gamma^{K\ -1}_{Ff,\beta_{A'}} \odot K(\tau^\beta_f) \odot \gamma^K_{\beta_A,Gf}.$$

Hence we may compute :

$$\begin{aligned}
(K(\Xi_{A'}) * KFf) \odot \tau^{K*\alpha}_f &= (K(\Xi_{A'}) * KFf) \odot \gamma^{K\ -1}_{Ff,\alpha_{A'}} \odot K(\tau^\alpha_f) \odot \gamma^K_{\alpha_A,Gf} \\
&= \gamma^{K\ -1}_{Ff,\beta_{A'}} \odot K(\Xi_{A'} * Ff) \odot K(\tau^\alpha_f) \odot \gamma^K_{\alpha_A,Gf} \\
&= \gamma^{K\ -1}_{Ff,\beta_{A'}} \odot K((\Xi_{A'} * Ff) \odot \tau^\alpha_f) \odot \gamma^K_{\alpha_A,Gf} \\
&= \gamma^{K\ -1}_{Ff,\beta_{A'}} \odot K(\tau^\beta_f \odot (\Xi_A * Gf)) \odot \gamma^K_{\alpha_A,Gf} \\
&= \gamma^{K\ -1}_{Ff,\beta_{A'}} \odot K(\tau^\beta_f) \odot K(\Xi_A * Gf) \odot \gamma^K_{\alpha_A,Gf} \\
&= \gamma^{K\ -1}_{Ff,\beta_{A'}} \odot K(\tau^\beta_f) \odot \gamma^K_{\beta_A,Gf} \odot (K(\Xi_A) * KGf) \\
&= \tau^{K*\beta}_f \odot (K(\Xi_A) * KGf)
\end{aligned}$$

where the second and sixth equality follows from remark 2.1.17(ii), and the third and fifth follow from remark 2.1.17(i).

(vii) Let Θ and Ξ be as in (iii), and I and K like in (v) and (vi); then it is easily seen that

$$(\Theta \odot \Xi) \circ I = (\Theta \circ I) \odot (\Xi \circ I) \qquad K \circ (\Theta \odot \Xi) = (K \circ \Theta) \odot (K \circ \Xi).$$

Indeed, the first identity is immediate, and the second follows directly from remark 2.1.17(i). Furthermore, if Ξ and Ξ' are as in (iv), we have the identities

$$(\Xi' * \Xi) \circ I = (\Xi' \circ I) * (\Xi \circ I) \qquad K \circ (\Xi' * \Xi) \odot \gamma^K_{\alpha,\alpha'} = \gamma^K_{\beta,\beta'} \odot ((K \circ \Xi') * (K \circ \Xi)).$$

Indeed, the first identity is immediate, and the second follows directly from remark 2.1.17(ii).

Definition 2.2.12. Let $\mathscr{A}$ and $\mathscr{B}$ be two 2-categories.

(i) For every pair of pseudo-functors $F, G : \mathscr{A} \to \mathscr{B}$ we have a category

$$\mathsf{PsNat}(F, G)$$

whose objects are the pseudo-natural transformations $F \Rightarrow G$, and whose morphisms are the modifications $\alpha \rightsquigarrow \beta$ between them, with the composition rule $\odot$ given by remark 2.2.10(iii).

(ii) The pseudo-functors $\mathscr{A} \to \mathscr{B}$ are the objects of a 2-category :

$$\mathsf{PsFun}(\mathscr{A}, \mathscr{B})$$

whose 1-cells $F \to G$ are the pseudo-natural transformations $F \Rightarrow G$ of, and whose 2-cells are the modifications. For fixed $F, G : \mathscr{A} \to \mathscr{B}$, the category structure on the set of 1-cells $F \to G$ is the one of $\mathsf{PsNat}(F, G)$. The composition functor

$$\mathsf{PsNat}(F, G) \times \mathsf{PsNat}(G, H) \to \mathsf{PsNat}(F, H)$$

assigns, to any two modifications $\Xi : \alpha \rightsquigarrow \beta$ and $\Xi' : \alpha' \rightsquigarrow \beta'$, the modification $\Xi' * \Xi$. The associativity and unit axioms for this composition functor follow by a simple inspection.

(iii) The strict pseudo-functors $\mathscr{A} \to \mathscr{B}$ are the objects of a 2-category :

$$\mathsf{stPsFun}(\mathscr{A}, \mathscr{B})$$

defined as the sub-2-category of $\mathsf{PsFun}(\mathscr{A}, \mathscr{B})$ whose 1-cells are the strict pseudo-natural transformations, and whose 2-cells are all the modifications.

2.2.13. In the situation of definition 2.2.9, suppose that α and β are pseudo-natural; in view of example 2.2.6(i), the modification Ξ induces modifications :

$$\begin{aligned} \Xi^o &: \alpha^o \rightsquigarrow \beta^o & A^o &\mapsto ((\Xi^o_A : \alpha^o_{A^o} \Rightarrow \beta^o_{A^o}) \\ {}^o\Xi &: {}^o\beta \rightsquigarrow {}^o\alpha & {}^oA &\mapsto ({}^o(\Xi_A) : {}^o\beta_{{}^oA} \Rightarrow {}^o\alpha_{{}^oA}). \end{aligned}$$

The detailed verification shall be left to the reader. With the notation of definition 2.2.12, it follows that the rules : $(F : \mathscr{A} \to \mathscr{B}) \mapsto (F^o : \mathscr{A}^o \to \mathscr{B}^o)$, $(\beta : F \Rightarrow G) \mapsto (\beta^o : F^o \Rightarrow G^o)$ and $(\Xi : \alpha \rightsquigarrow \beta) \mapsto (\Xi^o : \alpha^o \rightsquigarrow \beta^o)$ yield a strict isomorphism of 2-categories :

$$\mathsf{PsFun}(\mathscr{A}, \mathscr{B})^o \xrightarrow{\sim} \mathsf{PsFun}(\mathscr{A}^o, \mathscr{B}^o).$$

Likewise, the rules $F \mapsto {}^oF$, $\beta \mapsto {}^o\beta$ and $\Xi \mapsto {}^o\Xi$ yield a strict isomorphism of 2-categories :

$${}^o\mathsf{PsFun}(\mathscr{A}, \mathscr{B}) \xrightarrow{\sim} \mathsf{PsFun}({}^o\mathscr{A}, {}^o\mathscr{B}).$$

Remark 2.2.14. (i) The isomorphisms of the category $\mathsf{PsFun}(\mathscr{A}, \mathscr{B})$ are precisely the pseudo-natural isomorphisms of pseudo-functors. Indeed, if $\alpha : F \Rightarrow G$ is such a pseudo-natural isomorphism, and τ is its coherence constraint, we obtain a pseudo-natural isomorphism $\alpha^{-1} : G \Rightarrow F$ by the rule that assigns to every $A \in \mathrm{Ob}(\mathscr{A})$ the 1-cell $(\alpha_A)^{-1} : GA \to FA$, and to every 1-cell $f : A \to A'$ the oriented square

$$\begin{array}{ccc} GA & \xrightarrow{\alpha_A^{-1}} & FA \\ {\scriptstyle Gf}\downarrow & \swarrow\!\!\!\!\!/ \, \tau'_f & \downarrow{\scriptstyle Ff} \\ GA' & \xrightarrow[\alpha_{A'}^{-1}]{} & FA' \end{array} \qquad \text{where } \tau'_f := \alpha_{A'}^{-1} * \tau_f^{-1} * \alpha_A^{-1}.$$

Indeed, let us check the coherence axioms for α^{-1}; first, we compute, for every $A \in \mathrm{Ob}(\mathscr{A})$:

$$\begin{aligned} \tau'_{\mathbf{1}_A} \odot (\delta^F_A * \alpha_A^{-1}) = (\alpha_A^{-1} * \tau_{\mathbf{1}_A}^{-1} * \alpha_A^{-1}) \odot (\delta^F_A * \alpha_A^{-1}) &= ((\alpha_A^{-1} * \tau_{\mathbf{1}_A}^{-1}) \odot \delta^F_A) * \alpha_A^{-1} \\ &= \alpha_A^{-1} * (\tau_{\mathbf{1}_A}^{-1} \odot (\alpha_A * \delta^F_A)) * \alpha_A^{-1} \\ &= \alpha_A^{-1} * (\delta^F_A * \alpha_A) * \alpha_A^{-1} \\ &= \alpha_A^{-1} * \delta^F_A \end{aligned}$$

which proves the first axiom. Next, for every pair of 1-cells $A \xrightarrow{f} A' \xrightarrow{g} A''$ of $\mathscr{A}$ we have :

$$\begin{aligned} (\tau'_g \boxplus \tau'_f) \boxminus \gamma^G_{f,g} &= (\alpha_{A''}^{-1} * \gamma^G_{f,g}) \odot (\alpha_{A''}^{-1} * \tau_g^{-1} * \alpha_{A'}^{-1} * Gf) \odot (Fg * \alpha_{A'}^{-1} * \tau_f^{-1} * \alpha_A^{-1}) \\ &= (\alpha_{A''}^{-1} * \gamma^G_{f,g}) \odot (\alpha_{A''}^{-1} * Gg * \tau_f^{-1} * \alpha_A^{-1}) \odot (\alpha_{A''}^{-1} * \tau_g^{-1} * Ff * \alpha_A^{-1}) \\ &= \alpha_{A''}^{-1} * (\gamma^G_{f,g} \odot (Gg * \tau_f^{-1} * \alpha_A^{-1}) \odot (\tau_g^{-1} * Ff * \alpha_A^{-1})) \\ &= \alpha_{A''}^{-1} * ((\gamma^G_{f,g} * \alpha_A) \odot (Gg * \tau_f^{-1}) \odot (\tau_g^{-1} * Ff)) * \alpha_A^{-1} \end{aligned}$$

and on the other hand

$$\gamma^F_{f,g} \boxminus \tau'_{g\circ f} = (\alpha^{-1}_{A''} * \tau^{-1}_{g\circ f} * \alpha^{-1}_A) \odot (\gamma^F_{f,g} * \alpha^{-1}_A) = \alpha^{-1}_{A''} * (\tau^{-1}_{g\circ f} \odot (\alpha_{A''} * \gamma^F_{f,g})) * \alpha^{-1}_A$$

so we are reduced to showing that

$$(\gamma^G_{f,g} * \alpha_A) \odot (Gg * \tau^{-1}_f) \odot (\tau^{-1}_g * Ff) = \tau^{-1}_{g\circ f} \odot (\alpha_{A''} * \gamma^F_{f,g})$$

which is equivalent to the second coherence axiom for α. Conversely, it is clear that every isomorphism in $\mathsf{PsFun}(\mathscr{A}, \mathscr{B})$ must be a pseudo-natural isomorphism.

(ii) In the same vein, with the notation of definition 2.2.12(i), it is easily seen that the isomorphisms in the category $\mathsf{PsNat}(F, G)$ are the modifications $\Xi : \alpha \rightsquigarrow \beta$ such that $\Xi_A : \alpha_A \Rightarrow \beta_A$ is an isomorphism in $\mathscr{B}(FA, GA)$ for every $A \in \mathrm{Ob}(\mathscr{A})$: the details are left to the reader.

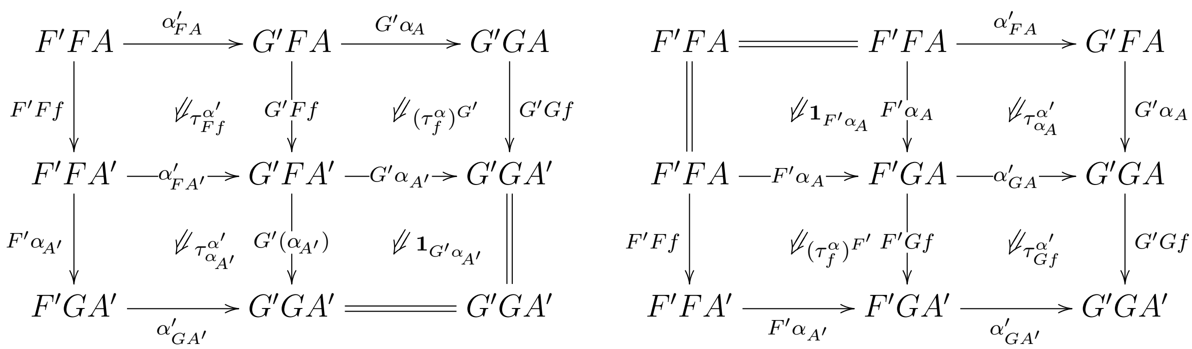
Example 2.2.15. (i) With the notation of remark 2.2.5(iv), we may now say that the coherence constraint $\gamma^{G'}$ furnishes an invertible modification

$$\gamma^{G'}_{\alpha,\beta} : (G' * \beta) \odot (G' * \alpha) \rightsquigarrow G' * (\beta \odot \alpha).$$

(ii) Likewise, let us check that the 2-cell of remark 2.2.5(v) yields a modification

$$\tau^{\alpha'}_\alpha : (G' * \alpha) \odot (\alpha' * F) \rightsquigarrow (\alpha' * G) \odot (F' * \alpha)$$

which is invertible if α' is pseudo-natural. To this aim, for any 1-cell $f : A \to A'$ in $\mathscr{A}$ we consider the diagrams :



(notation of example 2.1.20(i)) and notice that

$$\begin{aligned}
(\tau^{\alpha'}_{\alpha_{A'}} * F'Ff) \odot \tau^{(G'*\alpha)\odot(\alpha'*F)}_f = \lambda &:= (\mathbf{1}_{G'\alpha_{A'}} \boxminus \tau^{\alpha'}_{\alpha_{A'}}) \boxbar ((\tau^\alpha_f)^{G'} \boxminus \tau^{\alpha'}_{Ff}) \\
&= (\mathbf{1}_{G'\alpha_{A'}} \boxbar (\tau^\alpha_f)^{G'}) \boxminus (\tau^{\alpha'}_{\alpha_{A'}} \boxbar \tau^{\alpha'}_{Ff}) \\
\tau^{(\alpha'*G)\odot(F'*\alpha)}_f \odot (G'Gf * \tau^{\alpha'}_{\alpha_A}) = \mu &:= (\tau^{\alpha'}_{Gf} \boxminus (\tau^{\alpha'}_f)^{F'}) \boxbar (\tau^{\alpha'}_{\alpha_A} \boxminus \mathbf{1}_{F'\alpha_A}) \\
&= (\tau^{\alpha'}_{Gf} \boxbar \tau^{\alpha'}_{\alpha_A}) \boxminus ((\tau^{\alpha'}_f)^{F'} \boxbar \mathbf{1}_{F'\alpha_A}).
\end{aligned}$$

So we have only to check that

$$\lambda \boxminus \frac{\mathbf{1}_{F'\alpha_{A'}\circ F'Ff}}{\mathbf{1}_{F'FA}|F'\alpha_{A'}} = \frac{\mathbf{1}_{G'Gf\circ G'\alpha_A}}{G'\alpha_A|\mathbf{1}_{G'GA}} \boxminus \mu.$$

However, the definition of $2\text{-}\mathsf{Morph}(G')$ and the coherence axiom for α' yield respectively

$$\mathbf{1}_{G'\alpha_{A'}} \boxbar (\tau^\alpha_f)^{G'} = \frac{\gamma^{G'}_{\alpha_A,Gf}}{G'(\alpha_A)|\mathbf{1}_{G'GA'}} \boxminus \frac{G'(\tau^\alpha_f)}{\mathbf{1}_{G'FA}|\mathbf{1}_{G'GA'}} \boxminus \frac{(\gamma^{G'}_{Ff,\alpha_{A'}})^{-1}}{\mathbf{1}_{G'FA}|\mathbf{1}_{G'GA'}}$$

$$\tau^{\alpha'}_{\alpha_{A'}} \boxbar \tau^{\alpha'}_{Ff} = \frac{\gamma^{G'}_{Ff,\alpha_{A'}}}{\mathbf{1}_{G'FA}|\mathbf{1}_{G'GA'}} \boxminus \frac{\tau^{\alpha'}_{\alpha_{A'}\circ Ff}}{\alpha'_{FA}|\alpha'_{GA'}} \boxminus \frac{(\gamma^{F'}_{Ff,\alpha_{A'}})^{-1}}{\mathbf{1}_{F'FA}|\mathbf{1}_{F'GA'}}$$

therefore :

$$\begin{aligned}\lambda &= \gamma^{G'}_{\alpha_A,Gf} \boxminus G'(\tau^\alpha_f) \boxminus \tau^{\alpha'}_{\alpha_{A'}\circ Ff} \boxminus (\gamma^{F'}_{Ff,\alpha_{A'}})^{-1} \\ &= \gamma^{G'}_{\alpha_A,Gf} \boxminus \frac{\tau^{\alpha'}_{Gf\circ\alpha_A}}{\alpha'_{FA}|\alpha'_{GA'}} \boxminus \frac{F'(\tau^\alpha_f)}{\mathbf{1}_{F'FA}|\mathbf{1}_{F'GA'}} \boxminus (\gamma^{F'}_{Ff,\alpha_{A'}})^{-1} \\ &= \frac{\mathbf{1}_{G'Gf\circ G'\alpha_A}}{G'\alpha_A|\mathbf{1}_{G'GA'}} \boxminus (\tau^{\alpha'}_{Gf} \boxplus \tau^{\alpha'}_{\alpha_A}) \boxminus \frac{(\gamma^{F'}_{\alpha_A,Gf})}{\mathbf{1}_{F'FA}|\mathbf{1}_{F'GA'}} \boxminus \frac{(\gamma^{F'}_{\alpha_A,Gf})^{-1}}{\mathbf{1}_{F'FA}|\mathbf{1}_{F'GA'}} \boxminus \frac{(\tau^\alpha_f)^{F'}}{\mathbf{1}_{F'FA}|\mathbf{1}_{F'GA'}} \\ &= \frac{\mathbf{1}_{G'Gf\circ G'\alpha_A}}{G'\alpha_A|\mathbf{1}_{G'GA'}} \boxminus (\tau^{\alpha'}_{Gf} \boxplus \tau^{\alpha'}_{\alpha_A}) \boxminus \frac{(\tau^\alpha_f)^{F'}}{\mathbf{1}_{F'FA}|\mathbf{1}_{F'GA'}}\end{aligned}$$

where the second equality follows from remark 2.2.5(i) and the coherence axiom for α'. The sought identity follows straightforwardly.

(iii) For every 2-category $\mathscr{A}$, we denote by $i_\mathscr{A}$ the identity (strict) pseudo-natural transformation of $\mathbf{1}_\mathscr{A}$. In other words, $i_\mathscr{A}$ assigns to every $A \in \mathrm{Ob}(\mathscr{A})$ the 1-cell $\mathbf{1}_A$. Let $\mathscr{B}, \mathscr{C}$ be any other 2-categories, and $F : \mathscr{A} \to \mathscr{B}$, $G : \mathscr{C} \to \mathscr{A}$ any two pseudo-functors; clearly

$$i_\mathscr{A} * G = \mathbf{1}_G.$$

On the other hand, $F * i_\mathscr{A}$ is a pseudo-natural transformation that assigns to every $A \in \mathrm{Ob}(\mathscr{A})$ the 1-cell $F\mathbf{1}_A : FA \to FA$. If (δ^F, γ^F) is the coherence constraint for F, the coherence constraint of $F * i_\mathscr{A}$ assigns to every 1-cell $f : A \to A'$ of $\mathscr{A}$ the 2-cell $\mathbf{1}^F_f := \gamma^{F\,-1}_{f,\mathbf{1}_{A'}} \odot \gamma^F_{\mathbf{1}_A,f}$. Then, the unit axiom for F implies that the system of 2-cells $(\delta^F_A \mid A \in \mathrm{Ob}(\mathscr{A}))$ defines an invertible modification

$$\delta^F : \mathbf{1}_F \rightsquigarrow F * i_\mathscr{A}.$$

Remark 2.2.16. As already pointed out (remark 2.2.5(vi)), the datum of the category 2-$\mathbf{Cat}$ and the system of categories $(\mathsf{PsFun}(\mathscr{A}, \mathscr{B}) \mid \mathscr{A}, \mathscr{B} \in \mathrm{Ob}(2\text{-}\mathbf{Cat}))$ does not amount to a 2-category. However, example 2.2.15 suggests a straightforward variation that does result in an interesting 2-category. Namely, for every pair of categories $\mathscr{A}$ and $\mathscr{B}$, let us denote by

$$\overline{\mathsf{PsFun}}(\mathscr{A}, \mathscr{B})$$

the category whose objects are the pseudo-functors $\mathscr{A} \to \mathscr{B}$ and whose morphisms are the equivalence classes $[\beta]$ of pseudo-natural transformations β between such pseudo-functors, where we declare that two pseudo-natural transfomations $\alpha, \beta : F \Rightarrow G$ are equivalent if and only if there exists an invertible modification $\alpha \rightsquigarrow \beta$. The composition law for such equivalence classes is given by the rule

$$[\beta] \odot [\beta'] := [\beta \odot \beta']$$

for every two pseudo-natural transformations $\beta : F \Rightarrow G$, $\beta' : G \Rightarrow H$ of pseudo-functors $F, G, H : \mathscr{A} \to \mathscr{B}$. Then, if $\mathscr{C}$ is another 2-category, $F', G' : \mathscr{B} \to \mathscr{C}$ and $\alpha : F' \Rightarrow G'$ another pseudo-natural transformation, we set

$$[\alpha] * [\beta] := [(G' * \beta) \odot (\alpha * F)].$$

By virtue of example 2.2.15, this operation yields then a well defined functor

$$\overline{\mathsf{PsFun}}(\mathscr{A}, \mathscr{B}) \times \overline{\mathsf{PsFun}}(\mathscr{B}, \mathscr{C}) \to \overline{\mathsf{PsFun}}(\mathscr{A}, \mathscr{C})$$

that satisfies the associativity axiom for the composition bifunctor in a 2-category (see (2.1)). Thus, for every universe U', the U'-small 2-categories are the objects of a 2-category

$$\mathsf{U}'\text{-}\overline{2\text{-}\mathbf{Cat}}$$

that we call the *reduced* 2*-category of* U'*-small* 2*-categories*, whose 1-cells are the pseudo-functors and whose Hom-categories are the foregoing categories $\overline{\mathsf{PsFun}}(-, -)$. As usual, when $\mathsf{U}' = \mathsf{U}$ we write simply $\overline{2\text{-}\mathbf{Cat}}$ for this 2-category.

Remark 2.2.17. (i) Let $\mathscr{A}$ and $\mathscr{B}$ be two 2-categories. Every pair of pseudo-functors $F : \mathscr{A}' \to \mathscr{A}$ and $G : \mathscr{B} \to \mathscr{B}'$ induces a pseudo-functor

$$\mathsf{PsFun}(F, G) : \mathsf{PsFun}(\mathscr{A}, \mathscr{B}) \to \mathsf{PsFun}(\mathscr{A}', \mathscr{B}') \qquad (H : \mathscr{A} \to \mathscr{B}) \mapsto G \circ H \circ F$$

that assigns to every pseudo-natural transformation $\beta : H \Rightarrow H'$ between pseudo-functors $H, H' : \mathscr{A} \to \mathscr{B}$ the pseudo-natural transformation $G * \beta * F : G \circ H \circ F \Rightarrow G \circ H' \circ F$, and to every modification $\Xi : \beta \rightsquigarrow \beta'$ between such pseudo-natural transformations β, β', the modification $G \circ \Xi \circ F : G * \beta * F \rightsquigarrow G * \beta' * F$. The coherence constraint of $\mathsf{PsFun}(F, G)$ is the pair $(\delta^{(F,G)}_\bullet, \gamma^{(F,G)}_{\bullet\bullet})$ defined as follows :

$$\delta^{(F,G)}_H := \delta^G \circ H \circ F : \mathbf{1}_{GHF} \rightsquigarrow G * \mathbf{1}_{HF} \qquad \text{for every pseudo-functor } H : \mathscr{A} \to \mathscr{B}$$

where $\delta^G : \mathbf{1}_G \rightsquigarrow G * i_{\mathscr{A}}$ is the invertible modification provided by example 2.2.15(iii), and

$$\gamma^{(F,G)}_{\beta,\beta'} := \gamma^G_{\beta,\beta'} \circ F : (G * \beta' * F) \odot (G * \beta * F) \rightsquigarrow G * (\beta' \odot \beta) * F$$

for every pair of pseudo-natural transformations $\beta : H \Rightarrow H'$ and $\beta' : H' \Rightarrow H'$, where $\gamma^G \beta, \beta'$ is the invertible modification as in example 2.2.15(i). The verification is straightforward, in view of remark 2.2.10(vii). In case $F = \mathbf{1}_{\mathscr{A}}$ (resp. $G = \mathscr{B}$), we also write $\mathsf{PsFun}(\mathscr{A}, G)$ (resp. $\mathsf{PsFun}(F, \mathscr{B})$) for this pseudo-functor. Notice that $\mathsf{PsFun}(F, \mathscr{B})$ is strict for every pseudo-functor F, whereas $\mathsf{PsFun}(\mathscr{A}, G)$ is strict only if G is strict.

(ii) Every pseudo-natural transformation $\alpha : F \Rightarrow F'$ between pseudo-functors $F, F' : \mathscr{A}' \to \mathscr{A}$ induces a pseudo-natural transformation

$$\mathsf{PsFun}(\alpha, \mathscr{B}) : \mathsf{PsFun}(F, \mathscr{B}) \Rightarrow \mathsf{PsFun}(F', \mathscr{B}) \qquad (H : \mathscr{A} \to \mathscr{B}) \mapsto (H * \alpha : H \circ F \Rightarrow H \circ F')$$

whose coherence constraint assigns to every pseudo-natural transformation $\beta : H \Rightarrow H'$ the oriented square :

$$\begin{array}{ccc} H \circ F & \xRightarrow{H * \alpha} & H \circ F' \\ {\scriptstyle \beta * F} \Downarrow & \swarrow\!\!\!\!\!\! /_{(\tau^\beta_\alpha)^{-1}} & \Downarrow {\scriptstyle \beta * F'} \\ H' \circ F & \xRightarrow[H' * \alpha]{} & H' \circ F' \end{array}$$

where τ^β_α is the invertible modification provided by example 2.2.15(ii). Indeed, the naturality of the rule $\beta \mapsto (\tau^\beta_\alpha)^{-1}$ with respect to modifications $\Xi : \beta \rightsquigarrow \beta'$ follows directly from the compatibility condition for Ξ. To check the coherence axioms, notice first that $\tau^{\mathbf{1}_H}_\alpha = \mathbf{1}_{H * \alpha}$ for every pseudo-functor $H : \mathscr{A} \Rightarrow \mathscr{B}$. Lastly, if $\beta : H \Rightarrow H'$ and $\beta' : H' \Rightarrow H''$ are two pseudo-natural transformations, we need to show the identity

$$(\tau^{\beta'}_\alpha)^{-1} \boxbar (\tau^\beta_\alpha)^{-1} = (\tau^{\beta' \odot \beta}_\alpha)^{-1}$$

or equivalently : $\tau^{\beta'}_\alpha \boxminus \tau^\beta_\alpha = \tau^{\beta' \odot \beta}_\alpha$, which follows by direct inspection.

(iii) Likewise, every pseudo-natural transformation $\lambda : G \Rightarrow G'$ between pseudo-functors $G, G' : \mathscr{B} \to \mathscr{B}'$ induces a pseudo-natural transformation

$$\mathsf{PsFun}(\mathscr{A}, \lambda) : \mathsf{PsFun}(\mathscr{A}, G) \Rightarrow \mathsf{PsFun}(\mathscr{A}, G') \qquad (H : \mathscr{A} \to \mathscr{B}) \mapsto (\lambda * H : G \circ F \Rightarrow G' \circ F)$$

whose coherence constraint assigns to every pseudo-natural transformation $\beta : H \Rightarrow H'$ the oriented square τ^λ_β provided by example 2.2.15(ii). Indeed, the naturality of the rule : $\beta \mapsto \tau^\lambda_\beta$ with respect to modifications $\Xi : \beta \rightsquigarrow \beta'$ follows from the naturality of τ^λ, applied to the 2-cells $\Xi_A : \beta_A \to \beta'_A$, for every $A \in \mathrm{Ob}(\mathscr{A})$. The coherence condition for $\tau^\lambda_{\mathbf{1}_H}$ follows from the coherence condition for τ^λ_{HA}, for every pseudo-functor $H : \mathscr{A} \to \mathscr{B}$ and every $A \in \mathrm{Ob}(\mathscr{A})$. Likewise, the coherence condition relative to a composable pair of pseudo-natural transformations $\beta : H \Rightarrow H'$, $\beta' : H' \Rightarrow H''$ follows from the coherence condition for τ^λ, relative to the composable pair of 1-cells β_A, β'_A, for every $A \in \mathrm{Ob}(\mathscr{A})$.

(iv) Furthermore, for every F, F' as in (ii), every modification $\Xi : \alpha \rightsquigarrow \beta$ between pseudo-natural transformations $\alpha, \beta : F \Rightarrow F'$ induces a modification

$$\mathsf{PsFun}(\Xi, \mathscr{B}) : \mathsf{PsFun}(\alpha, \mathscr{B}) \rightsquigarrow \mathsf{PsFun}(\beta, \mathscr{B}) \qquad (G : \mathscr{A} \to \mathscr{B}) \mapsto (G \circ \Xi : G * \alpha \rightsquigarrow G * \beta).$$

Indeed, the compatibility condition for this modification amounts to the identity :

$$(G'(\Xi_X) * \gamma_{FX}) \odot (\tau^\gamma_{\alpha_X})^{-1} = (\tau^\gamma_{\beta_X})^{-1} \odot (\gamma_{F'X} * G(\Xi_X)) \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{A})$$

which follows easily from the naturality of τ^γ.

(v) Suppose moreover that $\mathscr{B}$ is small; then we deduce a strict pseudo-functor

$$\mathsf{PsFun}(-, \mathscr{B}) : \overline{2\text{-}\mathbf{Cat}}^o \to \overline{2\text{-}\mathbf{Cat}} \qquad \mathscr{A} \mapsto \mathsf{PsFun}(\mathscr{A}, \mathscr{B})$$

acting on the 1-cells and 2-cells of $\overline{2\text{-}\mathbf{Cat}}^o$ as explicited in (i) and (ii). Indeed, if $F : \mathscr{A}' \to \mathscr{A}$ and $F' : \mathscr{A}'' \to \mathscr{A}'$ are two pseudo-functors between small 2-categories, a simple inspection shows that $\mathsf{PsFun}(F', \mathscr{B}) \circ \mathsf{PsFun}(F, \mathscr{B}) = \mathsf{PsFun}(F \circ F', \mathscr{B})$. Moreover, (iv) implies that if $\alpha, \beta : F \Rightarrow F'$ are pseudo-natural transformations with $[\alpha] = [\beta]$ in $\overline{2\text{-}\mathbf{Cat}}$, then $[\mathsf{PsFun}(\alpha, \mathscr{B})] = [\mathsf{PsFun}(\beta, \mathscr{B})]$. Next, for every three pseudo-functors $F, F', F'' : \mathscr{A}' \to \mathscr{A}$ and every pseudo-natural transformations $\alpha : F \Rightarrow F'$ and $\alpha' : F' \Rightarrow F''$, with the notation of remark 2.2.16, we need to check that :

$$(2.2.18) \qquad [\mathsf{PsFun}(\alpha', \mathscr{B}) \odot \mathsf{PsFun}(\alpha, \mathscr{B})] = [\mathsf{PsFun}(\alpha' \odot \alpha, \mathscr{B})].$$

Now, to every pseudo-functor $G : \mathscr{A} \to \mathscr{B}$, the left-hand side of (2.2.18) assigns the class of $(G*\alpha')\odot(G*\alpha)$, whereas the right-hand side assigns the class of $G*(\alpha'\odot\alpha)$. These two pseudo-natural transformations are related by the invertible modification $\gamma^G_{\alpha,\alpha'}$ of example 2.2.15(i), so we come down to checking that the rule : $G \mapsto \gamma^G_{\alpha,\alpha'}$ defines an invertible modification $\mathsf{PsFun}(\alpha', \mathscr{B}) \odot \mathsf{PsFun}(\alpha, \mathscr{B}) \rightsquigarrow \mathsf{PsFun}(\alpha' \odot \alpha, \mathscr{B})$. The latter assertion is an immediate consequence of the coherence axioms for τ^β : details left to the reader. Lastly, let us check that for every two pairs of pseudo-functors $F_1, F'_1 : \mathscr{A}' \to \mathscr{A}$, $F_2, F'_2 : \mathscr{A}'' \to \mathscr{A}'$ and every pseudo-natural transformations $\alpha_1 : F_1 \Rightarrow F'_1$, $\alpha_2 : F_2 \Rightarrow F'_2$ we have :

$$(2.2.19) \qquad [\mathsf{PsFun}(\alpha_2, \mathscr{B})] * [\mathsf{PsFun}(\alpha_1, \mathscr{B})] = [\mathsf{PsFun}([\alpha_1] * [\alpha_2], \mathscr{B})].$$

We may consider separately the case where $F_2 = F'_2$ and $\alpha_2 = \mathbf{1}_{F_2}$, and the case where $F_1 = F'_1$ and $\alpha_1 = \mathbf{1}_{F_1}$. In the first case, the left-hand side assigns to every $G : \mathscr{A} \to \mathscr{B}$ the pseudo-natural transformation $(G * \alpha_1) * F_2$, whereas the right-hand side assigns $G * (\alpha_1) * F_2$; but these coincide, and likewise, the coherence constraints of both sides is given by the rule : $\beta \mapsto (\tau^\beta_{\alpha_1 * F_2})^{-1}$. One argues similarly in the second case : details left to the reader.

2.3. **The formalism of base change.** Let $\mathscr{A}$ be a 2-category, and A, B two objects of $\mathscr{A}$. A *link from A to B in $\mathscr{A}$* is a datum

$$\mathscr{L} := (F, G, \eta, \varepsilon) : A \to B$$

consisting of :

- 1-cells $F : A \to B$ and $G : B \to A$
- 2-cells $\eta : \mathbf{1}_B \Rightarrow F \circ G$ and $\varepsilon : G \circ F \Rightarrow \mathbf{1}_A$

such that η and ε are related by the *triangular identities* :

$$(F * \varepsilon) \odot (\eta * F) = \mathbf{1}_F \qquad \text{and} \qquad (\varepsilon * G) \odot (G * \eta) = \mathbf{1}_G.$$

Especially, (G, F) is an adjoint pair of 1-cells of $\mathscr{A}$. We say that η and ε are the *unit* and *counit* of the link $\mathscr{L}$. We define a composition law for links as follows. With $\mathscr{L}$ as in the foregoing, a third object C of $\mathscr{A}$ and a second link $\mathscr{L}' := (F', G', \eta', \varepsilon') : B \to C$ we let

$$\mathscr{L}' \circ \mathscr{L} := (F' \circ F, G \circ G', \eta^{\mathscr{L}' \circ \mathscr{L}}, \varepsilon^{\mathscr{L}' \circ \mathscr{L}}) : A \to C$$

where $\eta^{\mathscr{L}'\circ\mathscr{L}} := (F' * \eta * G') \odot \eta'$ and $\varepsilon^{\mathscr{L}'\circ\mathscr{L}} := \varepsilon \odot (G * \varepsilon' * F)$. We need to check that $\alpha := (F'F * (\varepsilon \odot G * \varepsilon' * F)) \odot ((F' * \eta * G' \odot \eta') * F'F) = \mathbf{1}_{F'F}$. We compute :

$$\begin{aligned}\alpha &= (F' * ((F * \varepsilon) \odot (FG * \varepsilon' * F))) \odot (((F' * \eta * G'F') \odot (\eta' * F')) * F) \\ &= (F' * ((F * \varepsilon) \odot (\eta * F))) \odot (((F' * \varepsilon') \odot (\eta' * F')) * F) \\ &= (F' * \mathbf{1}_F) \odot (\mathbf{1}_{F'} * F) \\ &= \mathbf{1}_{F'F}\end{aligned}$$

where the second equality holds by remark 2.1.1(i) and the third follows from the triangular identities for (η, ε) and (η', ε'). Likewise one checks the second triangular identity for (η'', ε'') (the details are left to the reader).

Remark 2.3.1. (i) Notice that the composition law for links is associative; namely, in the situation of (2.3), if $\mathscr{L}'' := (F'', G'', \eta'', \varepsilon'') : C \to D$ is another link, we have $(\mathscr{L}'' \circ \mathscr{L}') \circ \mathscr{L} = \mathscr{L}'' \circ (\mathscr{L}' \circ \mathscr{L})$. Indeed, the assertion boils down to the identities :

$$\begin{aligned}(F'' * ((F' * \eta * G') \odot \eta') * G'') \odot \eta'' &= (F''F' * \eta * G'G'') \odot (F'' * \eta' * G'') \odot \eta'' \\ \varepsilon \odot (G * \varepsilon' * F) \odot (GG' * \varepsilon'' * F'F) &= \varepsilon \odot (G * (\varepsilon' \odot (G' * \varepsilon'' * F')) * F)\end{aligned}$$

which are both clear.

(ii) Notice also that every link $\mathscr{L} := (F, G, \eta, \varepsilon) : A \to B$ induces two *opposite links*

$$\begin{aligned}\mathscr{L}^o &:= (G^o, F^o, \eta^o, \varepsilon^o) : A^o \to B^o && \text{in } \mathscr{A}^o \\ {}^o\mathscr{L} &:= ({}^oG, {}^oF, {}^o\varepsilon, {}^o\eta) : {}^oB \to {}^oA && \text{in } {}^o\mathscr{A}.\end{aligned}$$

2.3.2. Let $\mathscr{L}, \mathscr{L}' : A \to B$ be two links, with $\mathscr{L} = (F, G, \eta, \varepsilon)$ and $\mathscr{L}' = (F', G', \eta', \varepsilon')$; a *transformation from $\mathscr{L}$ to $\mathscr{L}'$*, denoted

$$\beta : \mathscr{L} \Rightarrow \mathscr{L}'$$

is defined as a 2-cell $\beta : F \Rightarrow F'$. The standard operations on 2-cells can be upgraded easily to transformations of links :

- If $\mathscr{L}'' : A \to B$ is another link and $\beta' : \mathscr{L}' \Rightarrow \mathscr{L}''$ a second transformation, we get the transformation

$$\beta' \odot \beta : \mathscr{L} \Rightarrow \mathscr{L}''.$$

- For a diagram of links and transformations of links :

$$(2.3.3) \qquad A \underset{\mathscr{L}'}{\overset{\mathscr{L}}{\rightrightarrows}} \!\!\Downarrow\!\beta\; B \underset{\mathscr{P}'}{\overset{\mathscr{P}}{\rightrightarrows}} \!\!\Downarrow\!\alpha\; C$$

we get the transformation

$$\alpha * \beta : \mathscr{P} \circ \mathscr{L} \Rightarrow \mathscr{P}' \circ \mathscr{L}'.$$

For $\alpha = \mathbf{1}_{\mathscr{P}}$ (resp. for $\beta = \mathbf{1}_{\mathscr{L}}$) we also denote this transformation by $\mathscr{P} * \beta$ (resp. by $\alpha * \mathscr{L}$). Thus, the links of $\mathscr{A}$ are the 1-cells of a 2-category

$$\mathsf{Link}(\mathscr{A})$$

whose objects are the objects of $\mathscr{A}$ and whose 2-cells are the transformations of links, with the compositions laws for 1-cells and 2-cells given in the foregoing.

- For a transformation $\beta : \mathscr{L} \Rightarrow \mathscr{L}'$, we define an *adjoint* 2-cell of $\mathscr{A}$:

$$\beta^\dagger := (\varepsilon' * G) \odot (G' * \beta * G) \odot (G' * \eta) : G' \Rightarrow G.$$

The operations of remark 2.3.1(ii) can be combined with this adjoint construction to produce natural isomorphisms of 2-categories; indeed, we have :

Proposition 2.3.4. *For every 2-category $\mathscr{A}$ we have strict isomorphisms of 2-categories :*

$$^o\mathsf{Link}(\mathscr{A}) \stackrel{\sim}{\to} \mathsf{Link}(\mathscr{A}^o) \qquad \mathsf{Link}(\mathscr{A})^o \stackrel{\sim}{\to} \mathsf{Link}(^o\!\mathscr{A}).$$

Proof. Indeed, the first strict pseudo-functor is given by the rules :

$$A \mapsto A^o \qquad (\mathscr{L} : A \to B) \mapsto (\mathscr{L}^o : A^o \to B^o) \qquad (\beta : \mathscr{L} \Rightarrow \mathscr{L}') \mapsto (\beta^{\dagger o} : \mathscr{L}'^o \Rightarrow \mathscr{L}^o)$$

and the second one is given by the rules :

$$A \mapsto {}^o\!A \qquad (\mathscr{L} : A \to B) \mapsto ({}^o\mathscr{L} : {}^oB \to {}^o\!A) \qquad (\beta : \mathscr{L} \Rightarrow \mathscr{L}') \mapsto ({}^o\beta^\dagger : {}^o\mathscr{L} \Rightarrow {}^o\mathscr{L}')$$

for every object A, every 1-cell $\mathscr{L}$ and every 2-cell β of $\mathsf{Link}(\mathscr{A})$. The verification that these rules yield strict pseudo-functors comes down to the following :

Claim 2.3.5. (i) Let $\mathscr{L}, \mathscr{L}', \mathscr{L}'' : A \to B$ be three links of $\mathscr{A}$, and $\beta : \mathscr{L} \Rightarrow \mathscr{L}'$, $\beta' : \mathscr{L}' \Rightarrow \mathscr{L}''$ two transformations. Then we have $\beta^\dagger \odot \beta'^\dagger = (\beta' \odot \beta)^\dagger$.
(ii) In the situation of diagram (2.3.3) we have $(\alpha * \beta)^\dagger = \beta^\dagger * \alpha^\dagger$.

Proof of the claim. Say that $\mathscr{L} = (F, G, \eta, \varepsilon)$, $\mathscr{L}' = (F', G', \eta', \varepsilon')$, $\mathscr{L}'' = (F'', G'', \eta'', \varepsilon'')$. Recall that every 1-cell $f : X \to Y$ of $\mathscr{A}$ induces functors

$$f_*^Z : \mathscr{A}(Z, X) \to \mathscr{A}(Z, Y) \qquad (h : Z \to X) \mapsto f \circ h \qquad (\nu : h \Rightarrow h') \mapsto f * \nu$$

for every $Z \in \mathrm{Ob}(\mathscr{A})$, and every 2-cell $\lambda : f \Rightarrow g$ of $\mathscr{A}$ induces natural transformations

$$\lambda_*^Z : f_*^Z \Rightarrow g_*^Z \qquad (h : Z \to X) \mapsto (\lambda * h : f_*^Z(h) \Rightarrow g_*^Z(h))$$

(see the proof of lemma 2.1.13(i)). Then it is clear that for every $Z \in \mathrm{Ob}(\mathscr{A})$, every link $\mathscr{P} := (H, K, \eta^{\mathscr{P}}, \varepsilon^{\mathscr{P}})$ induces an adjoint pair of functors (H_*^Z, K_*^Z) with unit $(\eta^{\mathscr{P}})^Z$ and counit $(\varepsilon^{\mathscr{P}})^Z$. With this notation, it is easily seen that

$$(2.3.6) \qquad (\beta^\dagger)_*^Z = (\beta_*^Z, \eta_*^Z, \eta'^Z_*)^\dagger$$

where the right-hand side is the adjoint of the natural transformation β_*^Z, defined as in remark 1.1.17(ii) : the details are left to the reader. Then both (i) and (ii) follow straightforwardly from remark 1.1.17(iv,v). ◊

Lastly, in order to see that these pseudo-functors are isomorphisms of 2-categories, it suffices to show more precisely that for every transformation of links $\beta : \mathscr{L} \Rightarrow \mathscr{L}'$ we have :

$$(\beta^\dagger)^\dagger = \beta.$$

Again, by virtue of (2.3.6), the assertion is reduced to the corresponding identity for adjoints of natural transformations, and the latter is known by virtue of remark 1.1.17(ii). □

2.3.7. Notice that every 1-cell $F : A \to B$ of the 2-category $\mathscr{A}$ induces a strict pseudo-functor

$$F_* : \mathscr{A}/A \to \mathscr{A}/B \qquad (g : X \to A) \mapsto (F \circ g : X \to B)$$

that maps every 1-cell $(h, \alpha) : (X \xrightarrow{g} A) \to (Y \xrightarrow{g'} A)$ of $\mathscr{A}/A$ to the 1-cell of $\mathscr{A}/B$

$$F * (h, \alpha) := (h, F * \alpha)$$

and every 2-cell $\beta : (h_1, \alpha_1) \Rightarrow (h_2, \alpha_2)$ of $\mathscr{A}/A$ to the 2-cell $\beta : (h_1, F * \alpha_1) \Rightarrow (h_2, F * \alpha_2)$ of $\mathscr{A}/B$ (notation of example 2.1.11(ii)). With this notation, we claim that every link $\mathscr{L} := (F, G, \eta, \varepsilon) : A \to B$ of $\mathscr{A}$ induces an adjunction for the pair of functors $F_* : \mathscr{A}/A \to \mathscr{A}/B$ and $G_* : \mathscr{A}/B \to \mathscr{A}/A$. Namely, we have a natural bijection :

$$\vartheta^{\mathscr{L}}_{g,f} : \mathscr{A}/B(Y \xrightarrow{g} B, X \xrightarrow{F \circ f} B) \stackrel{\sim}{\to} \mathscr{A}/A(Y \xrightarrow{G \circ g} A, X \xrightarrow{f} A) \quad (h, \alpha) \mapsto (h, (\varepsilon * f) \odot (G * \alpha))$$

whose inverse $\mu^{\mathscr{L}}_{g,f} : \mathscr{A}/A(G \circ g, f) \stackrel{\sim}{\to} \mathscr{A}/B(g, F \circ f)$ is given by the rule :

$$(k, \beta) \mapsto (k, (F * \beta) \odot (\eta * g)).$$

The verification of the naturality of $\vartheta^{\mathscr{L}}_{f,g}$ with respect to f and g shall be left to the reader. Let us check that $\mu^{\mathscr{L}}_{g,f} \circ \vartheta^{\mathscr{L}}_{g,f}$ is the identity map on the set $\mathscr{A}/B(g, F \circ f)$: indeed, for every 1-cell (h, α), this composition is computed as the composition of the following oriented squares :

$$\begin{array}{ccccc}
Y & \xrightarrow{h} & X & = & X \\
{\scriptstyle g}\downarrow & & {\scriptstyle f}\downarrow & \mathbf{1}\Nearrow & \downarrow{\scriptstyle f} \\
B & \alpha\Nearrow & A & = & A \\
\| & & {\scriptstyle F}\downarrow & \varepsilon\Nearrow & \| \\
B & = & B & \xrightarrow{G} & A \\
\| & \mathbf{1}\Nearrow & \| & \eta\Nearrow & \downarrow{\scriptstyle F} \\
B & = & B & = & B.
\end{array}$$

Then the assertion follows easily, by applying the triangular identities for the pair (η, ε) and invoking as usual proposition 2.1.9. Likewise we check that $\vartheta^{\mathscr{L}}_{g,f} \circ \mu^{\mathscr{L}}_{g,f}$ is the identity on $\mathscr{A}/A(G \circ g, f)$: the details shall be left to the reader.

2.3.8. Consider now an *oriented square* $\mathscr{D}$ of links, together with its *adjoint squares* :

$$\mathscr{D}\ :\ \begin{array}{ccc}
A' & \xrightarrow{\mathscr{L}'} & B' \\
{\scriptstyle \mathscr{M}'}\downarrow & \swarrow\!\!\!\!\!\!/\ {\scriptstyle\beta} & \downarrow{\scriptstyle \mathscr{M}} \\
A & \xrightarrow[\mathscr{L}]{} & B
\end{array}
\qquad
\mathscr{D}^\dagger\ :\ \begin{array}{ccc}
A'^o & \xrightarrow{\mathscr{L}'^o} & B'^o \\
{\scriptstyle \mathscr{M}'^o}\downarrow & {\scriptstyle\beta^{\dagger o}}\Nearrow & \downarrow{\scriptstyle \mathscr{M}^o} \\
A^o & \xrightarrow[\mathscr{L}^o]{} & B^o
\end{array}
\qquad
{}^\dagger\mathscr{D}\ :\ \begin{array}{ccc}
{}^oB & \xrightarrow{{}^o\mathscr{L}} & {}^oA \\
{\scriptstyle {}^o\mathscr{M}}\downarrow & {\scriptstyle {}^o\beta^{\dagger}}\Nearrow & \downarrow{\scriptstyle {}^o\mathscr{M}'} \\
{}^oB' & \xrightarrow[{}^o\mathscr{L}']{} & {}^oA'
\end{array}$$

i.e. the orientation $\beta : \mathscr{M} \circ \mathscr{L}' \Rightarrow \mathscr{L} \circ \mathscr{M}'$ is a transformation of links, so that ${}^o\beta^\dagger$ is the adjoint transformation ${}^o\mathscr{L}' \circ {}^o\mathscr{M} \Rightarrow {}^o\mathscr{M}' \circ {}^o\mathscr{L}$, and likewise for $\beta^{\dagger o}$. Say that $\mathscr{L} = (L_*, L^*, \eta^L, \varepsilon^{\mathscr{L}})$, $\mathscr{L}' = (L'_*, L'^*, \eta^{\mathscr{L}'}, \varepsilon^{\mathscr{L}'})$, $\mathscr{M} = (M_*, M^*, \eta^M, \varepsilon^{\mathscr{M}})$ and $\mathscr{M}' = (M'_*, M'^*, \eta^{\mathscr{M}'}, \varepsilon^{\mathscr{M}'})$. Notice that for horizontally composable oriented squares of links we have the identities :

$$(2.3.9)\qquad (\mathscr{D}' \boxminus \mathscr{D})^\dagger = \mathscr{D}'^\dagger \boxplus \mathscr{D}^\dagger \qquad {}^\dagger(\mathscr{D}' \boxminus \mathscr{D}) = {}^\dagger\mathscr{D} \boxplus {}^\dagger\mathscr{D}'.$$

Thus, the operation $\mathscr{D} \mapsto \mathscr{D}^\dagger$ for oriented squares of links differs in this respect from the analogous operation for oriented squares in the 2-category $\mathscr{A}$: see (2.1.8).

With this notation, we attach to the oriented square $\mathscr{D}$ the *base change oriented square* in $\mathscr{A}$:

$$\Upsilon(\mathscr{D})\ :\ \begin{array}{ccc}
B' & \xrightarrow{M_*} & B \\
{\scriptstyle L'^*}\downarrow & \swarrow\!\!\!\!\!\!/\ {\scriptstyle\Upsilon(\beta)} & \downarrow{\scriptstyle L^*} \\
A' & \xrightarrow[M'_*]{} & A
\end{array}$$

whose orientation is the *base change transformation*

$$\Upsilon(\beta) := (\varepsilon^{\mathscr{L}} * M'_* L'^*) \odot (L^* * \beta * L'^*) \odot (L^* M_* * \eta^{\mathscr{L}'}) : L^* M_* \Rightarrow M'_* L'^*.$$

Proposition 2.3.10. *With the notation of* (2.3.8)*, we have :*

$$\Upsilon(\mathscr{D})^o = \Upsilon(\mathscr{D}^\dagger) \qquad {}^o\Upsilon(\mathscr{D}) = \Upsilon({}^\dagger\mathscr{D}).$$

Proof. The sought identity for $\Upsilon({}^\dagger\mathscr{D})$ will be proven by inspecting the following diagram :

$$\begin{array}{ccccccccccc}
B' & \xrightarrow{M_*} & B & = & B & = & B & = & B & = & B \\
\| & \Swarrow_{\varepsilon^{\mathscr{M}}} & \downarrow{\scriptstyle M^*} & \Swarrow_{\mathbf{1}_{M^*}} & \downarrow{\scriptstyle M^*} & \Swarrow_{\mathbf{1}_{M^*}} & \downarrow{\scriptstyle M^*} & \Swarrow_{\eta^{\mathscr{M}}} & \| & \Swarrow_{i_B} & \| \\
B' & = & B' & = & B' & = & B' & \xrightarrow{M_*} & B & = & B \\
{\scriptstyle L'^*}\downarrow & \Swarrow_{\mathbf{1}_{L'^*}} & \downarrow{\scriptstyle L'^*} & \Swarrow_{\mathbf{1}_{L'^*}} & \downarrow{\scriptstyle L'^*} & \Swarrow_{\eta^{\mathscr{L}'}} & \| & \Swarrow_{\mathbf{1}_{M_*}} & \| & \Swarrow_{i_B} & \| \\
A' & = & A' & = & A' & \xrightarrow{L'_*} & B' & \xrightarrow{M_*} & B & = & B \\
\| & \Swarrow_{i_{A'}} & \| & \Swarrow_{\mathbf{1}_{M'_*}} & \downarrow{\scriptstyle M'_*} & \Swarrow_{\beta} & \downarrow{\scriptstyle M_*} & \Swarrow_{\mathbf{1}_{M_*}} & \| & \Swarrow_{i_B} & \| \\
A' & = & A' & \xrightarrow{M'_*} & A & \xrightarrow{L_*} & B & = & B & = & B \\
\| & \Swarrow_{i_{A'}} & \| & \Swarrow_{\mathbf{1}_{M_*}} & \| & \Swarrow_{\varepsilon^{\mathscr{L}}} & \downarrow{\scriptstyle L^*} & \Swarrow_{\mathbf{1}_{L^*}} & \downarrow{\scriptstyle L^*} & \Swarrow_{\mathbf{1}_{L^*}} & \downarrow{\scriptstyle L^*} \\
A' & = & A' & \xrightarrow{M'_*} & A & = & A & = & A & = & A \\
\| & \Swarrow_{i_{A'}} & \| & \Swarrow_{\varepsilon^{\mathscr{M}'}} & \downarrow{\scriptstyle M'^*} & \Swarrow_{\mathbf{1}_{M'^*}} & \downarrow{\scriptstyle M'^*} & \Swarrow_{\mathbf{1}_{M'^*}} & \downarrow{\scriptstyle M'^*} & \Swarrow_{\eta^{\mathscr{M}'}} & \| \\
A' & = & A' & = & A' & = & A' & = & A' & \xrightarrow[M'_*]{} & A.
\end{array}$$

Indeed, since the unit $\eta^{{}^o\mathscr{M}}$ of ${}^o\mathscr{M}$ is ${}^o(\varepsilon^{\mathscr{M}})$ and the counit $\varepsilon^{{}^o\mathscr{M}'}$ of ${}^o\mathscr{M}'$ is ${}^o(\eta^{\mathscr{M}'})$, we have :

$$\begin{aligned}
\Upsilon({}^\dagger\mathscr{D}) &= (\varepsilon^{{}^o\mathscr{M}'} * {}^oL^*\,{}^oM_*) \odot ({}^oM'_* * {}^o\beta^\dagger * {}^oM_*) \odot ({}^oM'_*\,{}^oL'^* * \eta^{{}^o\mathscr{M}}) \\
&= {}^o((M'_*L'^* * \varepsilon^{\mathscr{M}}) \odot (M'_* * \beta^\dagger * M_*) \odot (\eta^{\mathscr{M}'} * L^*M_*))
\end{aligned}$$

and if $\eta^{\mathscr{M}\circ\mathscr{L}'}$ is the unit of $\mathscr{M}\circ\mathscr{L}'$ and $\varepsilon^{\mathscr{L}\circ\mathscr{M}'}$ is the counit of $\mathscr{L}\circ\mathscr{M}'$, we have

$$\eta^{\mathscr{M}\circ\mathscr{L}'} = (M_* * \eta^{\mathscr{L}'} * M^*) \odot \eta^{\mathscr{M}} \qquad \varepsilon^{\mathscr{L}\circ\mathscr{M}'} = \varepsilon^{\mathscr{M}'} \odot (M'^* * \varepsilon^{\mathscr{L}} * M'_*)$$
$$\beta^\dagger = (\varepsilon^{\mathscr{L}\circ\mathscr{M}'} * L'^*M^*) \odot (M'^*L^* * \beta * L'^*M^*) \odot (M'^*L^* * \eta^{\mathscr{M}\circ\mathscr{L}'}).$$

Thus, if in the foregoing diagram we initially disregard the first and last columns, we find that the composition of the six remaining squares in the uppermost two rows equals precisely $\eta^{\mathscr{M}\circ\mathscr{L}'}$, and the composition of the six squares in the bottom two rows equals $\varepsilon^{\mathscr{L}\circ\mathscr{M}'}$. Therefore, if we further compose these two blocks of six squares with the central row of three squares, we get precisely $\beta^\dagger$. And if we finally compose the result with the two omitted left and right columns, we then get ${}^o\Upsilon({}^\dagger\mathscr{D})$. But according to proposition 2.1.9 we may compose these squares in a different order : notice then that the composition of the five squares in the uppermost row equals $\mathbf{1}_{M_*}$, and the composition of the five square in the bottom row equals $\mathbf{1}_{M'_*}$. So, we may disregard these two rows; but in the remaining three central rows, we may likewise disregard everything except the central column, since the squares outside the central column are all identities. So, finally we are left with the vertical composition of the squares in the central column, and that gives precisely $\Upsilon(\mathscr{D})$, as required. Lastly, we have :

$$\begin{aligned}
\Upsilon(\mathscr{D}^\dagger) &= (\varepsilon^{\mathscr{M}^o} * L'^{*o}\,M'^o_*) \odot (M^o_* * \beta^{\dagger o} * M'^o_*) \odot (M^o_*\,L^{*o} * \eta^{\mathscr{M}'^o}) \\
&= ((M'_*L'^* * \varepsilon^{\mathscr{M}}) \odot (M'_* * \beta^\dagger * M_*) \odot (\eta^{\mathscr{M}'} * L^*M_*))^o
\end{aligned}$$

so the sought identity for $\Upsilon(\mathscr{D}^\dagger)$ follows from that for $\Upsilon({}^\dagger\mathscr{D})$. □

Remark 2.3.11. In the situation of (2.3.8), suppose that β is an invertible 2-cell of $\mathscr{A}$ and that both L_* and L'_* (resp. both M_* and M'_*) are equivalences in $\mathscr{A}$. Then it follows easily from the definition (resp. and from proposition 2.3.10) that also $\Upsilon(\beta)$ is an invertible 2-cell.

Proposition 2.3.12. *Consider two oriented squares of links :*

$$\mathscr{D}\ :\quad \begin{array}{ccc} A' & \xrightarrow{\mathscr{L}'} & B' \\ {\scriptstyle \mathscr{M}'}\big\downarrow & \not\swarrow_{\beta} & \big\downarrow{\scriptstyle \mathscr{M}} \\ A & \xrightarrow[\mathscr{L}]{} & B \end{array} \qquad\qquad \mathscr{D}'\ :\quad \begin{array}{ccc} C' & \xrightarrow{\mathscr{P}'} & D' \\ {\scriptstyle \mathscr{Q}'}\big\downarrow & \not\swarrow_{\alpha} & \big\downarrow{\scriptstyle \mathscr{Q}} \\ C & \xrightarrow[\mathscr{P}]{} & D. \end{array}$$

(i) *Suppose that $A = C'$, $B = D'$ and $\mathscr{L} = \mathscr{P}'$, so that $\mathscr{D}' \boxminus\!\!\!\!\mid\ \mathscr{D}$ is well defined. Then :*

$$\Upsilon(\mathscr{D}' \,\square\!\!\!\!\mid\,\, \mathscr{D}) = \Upsilon(\mathscr{D}') \boxminus \Upsilon(\mathscr{D}).$$

(ii) *Suppose that $B = C$, $B' = C'$ and $\mathscr{M} = \mathscr{Q}'$, so that $\mathscr{D}' \boxminus \mathscr{D}$ is well defined. Then :*

$$\Upsilon(\mathscr{D}' \boxminus \mathscr{D}) = \Upsilon(\mathscr{D}) \,\square\!\!\!\!\mid\,\, \Upsilon(\mathscr{D}').$$

Proof. (i): Say that $\mathscr{L} = (L_*, L^*, \eta^{\mathscr{L}}, \varepsilon^{\mathscr{L}})$, $\mathscr{P} = (P_*, P^*, \eta^{\mathscr{P}}, \varepsilon^{\mathscr{P}})$, $\mathscr{Q} = (Q_*, Q^*, \eta^{\mathscr{Q}}, \varepsilon^{\mathscr{Q}})$, $\mathscr{M}' = (M'_*, M'^*, \eta^{\mathscr{M}'}, \varepsilon^{\mathscr{M}'})$, $\mathscr{M} = (M_*, M^*, \eta^{\mathscr{M}}, \varepsilon^{\mathscr{M}})$ and $\mathscr{Q}' = (Q'_*, Q'^*, \eta^{\mathscr{Q}'}, \varepsilon^{\mathscr{Q}'})$. We consider the following diagram :

$$\begin{array}{ccccccccccc}
B' & \xrightarrow{L'^*} & A' & \xrightarrow{M'_*} & A & = & A & \xrightarrow{Q'^*} & C & = & C \\
\| & \eta^{\mathscr{L}'}\Uparrow & \big\downarrow{\scriptstyle L'_*} & \beta\Uparrow & \big\downarrow{\scriptstyle L_*} & \varepsilon^{\mathscr{L}}\Uparrow & \| & \mathbf{1}_{Q'^*}\Uparrow & \| & i_C\Uparrow & \| \\
B' & = & B' & \xrightarrow{M_*} & B & \xrightarrow{L^*} & A & \xrightarrow{Q'^*} & C & = & C \\
\| & i_{B'}\Uparrow & \| & \mathbf{1}_{M_*}\Uparrow & \| & \eta^{\mathscr{L}}\Uparrow & {\scriptstyle L_*}\big\downarrow & \alpha\Uparrow & {\scriptstyle P_*}\big\downarrow & \varepsilon^{\mathscr{P}}\Uparrow & \| \\
B' & = & B' & \xrightarrow[M_*]{} & B & = & B & \xrightarrow[Q_*]{} & D & \xrightarrow[P^*]{} & C
\end{array}$$

and notice that the composition of the five squares of the top (resp. bottom) row equals $\Upsilon(\mathscr{D})$ (resp. $\Upsilon(\mathscr{D}')$), so the composition of all the square in the diagram is precisely $\Upsilon(\mathscr{D}') \boxminus \Upsilon(\mathscr{D})$. On the other hand, the composition of the two squares in the first (resp. second, resp. third, resp. fourth, resp. fifth) column from the left equals $\eta^{\mathscr{L}'}$ (resp. β, resp. $\mathbf{1}_{L_*}$, resp. α, resp. $\varepsilon^{\mathscr{P}}$), and then the composition of these five columns also equals $\Upsilon(\mathscr{D}' \,\square\!\!\!\!\mid\,\, \mathscr{D})$, as stated.

(ii): We compute :

$$\begin{aligned}
\Upsilon(\mathscr{D}' \boxminus \mathscr{D}) = \Upsilon(\mathscr{D}'^{\dagger\dagger} \boxminus \mathscr{D}^{\dagger\dagger}) = \Upsilon((\mathscr{D}'^{\dagger} \,\square\!\!\!\!\mid\,\, \mathscr{D}^{\dagger})^{\dagger}) &= \Upsilon(\mathscr{D}'^{\dagger} \,\square\!\!\!\!\mid\,\, \mathscr{D}^{\dagger})^{o} \\
&= (\Upsilon(\mathscr{D}'^{\dagger}) \boxminus \Upsilon(\mathscr{D}^{\dagger}))^{o} \\
&= \Upsilon(\mathscr{D}^{\dagger})^{o} \boxminus \Upsilon(\mathscr{D}'^{\dagger})^{o} \\
&= \Upsilon(\mathscr{D}^{\dagger\dagger}) \boxminus \Upsilon(\mathscr{D}'^{\dagger\dagger}) \\
&= \Upsilon(\mathscr{D}) \boxminus \Upsilon(\mathscr{D}')
\end{aligned}$$

where the second equality follows from (2.3.9), the third and sixth follow from proposition 2.3.10, and the fourth follows from (i), and the fifth follows from (2.1.8). □

2.3.13. In the situation of (2.3.8), the links $\mathscr{L}$ and $\mathscr{L}'$ induce adjunctions $\vartheta^{\mathscr{L}}$ and $\vartheta^{\mathscr{L}'}$ for the pairs of functors $((L^*)_*, (L_*)_*)$ and respectively $((L'^*)_*, (L'_*)_*)$, as in (2.3.7). The base change transformation $\Upsilon(\beta)$ relates these adjunctions, as explained by the following :

Proposition 2.3.14. *With the notation of* (2.3.13)*, for every $(X \xrightarrow{f} A') \in \mathrm{Ob}(\mathscr{A}/A')$, every $(Y \xrightarrow{g} B') \in \mathrm{Ob}(\mathscr{A}/B')$, and every 1-cell $(h, \alpha) : g \to L'_* \circ f$ of $\mathscr{A}/B'$ we have the identity :*

$$(M'_* * \vartheta^{\mathscr{L}'}_{f,g}(h, \alpha)) \circ (\mathbf{1}_Y, \Upsilon(\beta) * g) = \vartheta^{\mathscr{L}}_{M'_* \circ f, M_* \circ g}((\mathbf{1}_X, \beta * f) \circ (h, M_* * \alpha)) \qquad \text{in } \mathscr{A}/A.$$

Proof. The left-hand side of the stated identity is computed as the composition of the following oriented squares :

$$\begin{array}{ccccccccc}
Y & \xrightarrow{h} & X & = & X & = & & = & X \\
{\scriptstyle g}\downarrow & & {\scriptstyle f}\downarrow & \mathbf{1}\nearrow & \downarrow{\scriptstyle f} & & & & \| \\
B' & \alpha\nearrow & A' & = & A' & & \mathbf{1}\nearrow & & \| \\
\| & & {\scriptstyle L'_*}\downarrow & \varepsilon^{\mathscr{L}'}\nearrow & \| & & & & \| \\
B' & = & B' & \xrightarrow{L'^*} & A' & \xrightarrow{M'_*} & A & = & A \\
\| & \mathbf{1}\nearrow & \| & \eta^{\mathscr{L}'}\nearrow & {\scriptstyle L'_*}\downarrow & \beta\nearrow & {\scriptstyle L_*}\downarrow & \varepsilon^{\mathscr{L}}\nearrow & \| \\
B' & = & B' & = & B' & \xrightarrow{M_*} & B & \xrightarrow{L^*} & A.
\end{array}$$

By applying as usual proposition 2.1.9, and the triangular identities for the pair $(\eta^{\mathscr{L}'}, \varepsilon^{\mathscr{L}'})$, we easily see that the same composition of squares yields as well the right-hand side of the sought identity : the details are left to the reader. □

2.3.15. Recall that the links of $\mathscr{A}$ are the objects of the 2-category $2\text{-}\mathsf{Morph}(\mathsf{Link}(\mathscr{A}))$: see example 2.1.11(i). An oriented square $\mathscr{D}$ as in (2.3.8) yields a 1-cell in this 2-category

$$\mathscr{D}(\beta, \mathscr{M}, \mathscr{M}') : \mathscr{L}' \to \mathscr{L}.$$

Given a pair of oriented squares $\mathscr{D}_1(\beta_1, \mathscr{M}_1, \mathscr{M}'_1), \mathscr{D}_2(\beta_2, \mathscr{M}_2, \mathscr{M}'_2) : \mathscr{L}' \to \mathscr{L}$, a 2-cell $(\alpha, \alpha') : \mathscr{D}_1 \Rightarrow \mathscr{D}_2$ is the datum of a pair of 2-cells of the 2-category $\mathsf{Link}(\mathscr{A})$

$$(2.3.16) \qquad \alpha : \mathscr{M}_1 \Rightarrow \mathscr{M}_2 \quad \alpha' : \mathscr{M}'_1 \Rightarrow \mathscr{M}'_2 \quad \text{such that} \quad \beta_2 \odot (\alpha * \mathscr{L}') = (\mathscr{L} * \alpha') \odot \beta_1.$$

Theorem 2.3.17. *The rules :*

$$\mathscr{L} := (L_*, L^*, \eta, \varepsilon) \mapsto L^{*o} \qquad \mathscr{D} \mapsto \Upsilon(\mathscr{D})^o \qquad (\alpha, \alpha') \mapsto (\alpha^o, \alpha'^o)$$

for every link $\mathscr{L}$, every oriented square $\mathscr{D}$ of $\mathsf{Link}(\mathscr{A})$, and every 2-cell (α, α') as in (2.3.15) *define a strict pseudo-functor :*

$$\Upsilon_{\mathscr{A}} : 2\text{-}\mathsf{Morph}(\mathsf{Link}(\mathscr{A}))^o \to 2\text{-}\mathsf{Morph}(\mathscr{A}^o).$$

Proof. The functoriality of Υ for composition of 1-cells is already clear from proposition 2.3.12. Let us next check that for every 2-cell $(\alpha, \alpha') : \mathscr{D}_1 \Rightarrow \mathscr{D}_2$ as in (2.3.15), the pair (α^o, α'^o) is a 2-cell $\Upsilon(\mathscr{D}_1)^o \Rightarrow \Upsilon(\mathscr{D}_2)^o$ in $2\text{-}\mathsf{Morph}(\mathscr{A}^o)$. We come down to showing the identity

$$(2.3.18) \qquad \Upsilon(\beta_2)^o \odot (\alpha^o * L'^{*o}) = (L'^{*o} * \alpha') \odot \Upsilon(\beta_1)^o.$$

To this aim, for every $X \in \mathrm{Ob}(\mathscr{A})$ let $\mathbb{1}_X : X \to X$ be the link $(\mathbf{1}_X, \mathbf{1}_X, i_X, i_X)$ (where i_X is the identity automorphism of $\mathbf{1}_X$); also, for $i = 1, 2$ let $\mathscr{P}_i := (P_{i*} : X \to Y, P_i^*, \eta_i, \varepsilon_i)$ be a link of $\mathscr{A}$, and $\tau : P_{1*} \Rightarrow P_{2*}$ a 2-cell of $\mathscr{A}$. We consider the following oriented squares of $\mathsf{Link}(\mathscr{A})$ and of $\mathscr{A}^o$:

$$\mathscr{D}_\tau \ : \ \begin{array}{ccc} X & \xrightarrow{\mathbb{1}_X} & X \\ {\scriptstyle \mathscr{P}_2}\downarrow & \swarrow_\tau & \downarrow{\scriptstyle \mathscr{P}_1} \\ Y & \xrightarrow[\mathbb{1}_Y]{} & Y \end{array} \qquad\qquad \mathscr{E}_\tau \ : \ \begin{array}{ccc} Y^o & \xrightarrow{\mathbf{1}_{Y^o}} & Y^o \\ {\scriptstyle P^o_{2*}}\downarrow & \swarrow_{\tau^o} & \downarrow{\scriptstyle P^o_{1*}} \\ X^o & \xrightarrow[\mathbf{1}_{X^o}]{} & X^o. \end{array}$$

With this notation, by applying proposition 2.3.10 it is easily seen that

$$\Upsilon(\mathscr{D}_\tau)^o = \mathscr{E}_\tau$$

and (2.3.18) is equivalent to the identity :

$$\Upsilon(\mathscr{D}_1)^o \boxminus \mathscr{E}_{\alpha'} = \mathscr{E}_\alpha \boxminus \Upsilon(\mathscr{D}_2)^o.$$

In view of (2.3.9) and proposition 2.3.12 we are then reduced to checking that

$$\mathscr{D}_1 \boxminus \mathscr{D}_{\alpha'} = \mathscr{D}_\alpha \boxminus \mathscr{D}_2$$

which follows immediately from (2.3.16). Lastly, the functoriality of Υ for the two types of compositions of 2-cells is obvious from the definition. □

2.3.19. Resume the situation of (2.3.8), and notice that the units and counits for $\mathscr{M}$ and $\mathscr{M}'$ do not play any role in the definition of $\Upsilon(\beta)$, and neither do the 1-cells M^* and M'^*. This leads to the following variant of theorem 2.3.17. We replace $2\text{-}\mathsf{Morph}(\mathsf{Link}(\mathscr{A}))$ by the 2-category

$$\mathsf{wLink}(\mathscr{A})$$

of *weak links in* $\mathscr{A}$, whose objects are still the links of $\mathscr{A}$; for any two links $\mathscr{L} := (L_* : A \to B, L^*, \eta^{\mathscr{L}}, \varepsilon^{\mathscr{L}})$ and $\mathscr{L}' := (L'_* : A' \to B', L'^*, \eta^{\mathscr{L}'}, \varepsilon^{\mathscr{L}'})$, the 1-cells $\mathscr{L} \to \mathscr{L}'$ are the 1-cells $(M_*, M'_*, \beta) : L_* \to L'_*$ of the 2-category $2\text{-}\mathsf{Morph}(\mathscr{A})$, *i.e.* the oriented squares

$$\mathscr{D} \ : \quad \begin{array}{ccc} A' & \xrightarrow{L'_*} & B' \\ {\scriptstyle M'_*}\downarrow & \swarrow_{\beta} & \downarrow{\scriptstyle M_*} \\ A & \xrightarrow[L_*]{} & B. \end{array}$$

The 2-cells of $\mathsf{wLink}(\mathscr{A})$, and the composition laws for 1-cells and 2-cells are then the same as for $2\text{-}\mathsf{Morph}(\mathscr{A})$. For any such 1-cell $\mathscr{D}$, we may then define the 2-cell $\Upsilon(\beta)$ and the oriented square $\Upsilon(\mathscr{D})$ as in (2.3.8). A direct inspection shows that part (i) of proposition 2.3.12 still holds for weak links, with the same proof. The proof of part (ii) of proposition 2.3.12 does not apply to weak links, but we may check the assertion directly. Indeed, consider another 1-cell $\mathscr{P}' := (P'_*, P'^*, \eta^{\mathscr{P}'}, \varepsilon^{\mathscr{P}'}) \to \mathscr{P} := (P_*, P^*, \eta^{\mathscr{P}}, \varepsilon^{\mathscr{P}})$ of $\mathsf{wLink}(\mathscr{A})$:

$$\mathscr{D}' \ : \quad \begin{array}{ccc} B' & \xrightarrow{M_*} & C' \\ {\scriptstyle Q_*}\downarrow & \swarrow_{\alpha} & \downarrow{\scriptstyle Q_*} \\ B & \xrightarrow[P_*]{} & C. \end{array}$$

Set :

$$X := \varepsilon^{\mathscr{L}} * M'_* L'^* P'^* \qquad\qquad Y := L^* P^* Q_* * \eta^{\mathscr{P}'}$$

$$\delta := (P_* * \beta) \odot (\alpha * L'_*) \qquad \alpha' := P^* * \alpha * P'^* \qquad \beta' := L^* * \beta * L'^*.$$

By definition we have :

$$\Upsilon(\mathscr{D}' \boxminus \mathscr{D}) = X \odot (L^* * \varepsilon^{\mathscr{P}} * L_* M'_* L'^* P'^*) \odot (L^* P^* * \delta * L'^* P'^*) \odot (L^* P^* Q_* P'_* * \eta^{\mathscr{L}'} * P'^*) \odot Y$$

$$\Upsilon(\mathscr{D}) \boxdot \Upsilon(\mathscr{D}') = X \odot ((\beta' \odot (L^* M_* * \eta^{\mathscr{L}'})) * P'^*) \odot (L^* * ((\varepsilon^{\mathscr{P}} * M_* P'^*) \odot \alpha')) \odot Y.$$

Hence we are reduced to checking that

$$Z := (\varepsilon^{\mathscr{P}} * L_* M'_* L'^*) \odot (P^* * \delta * L'^*) \odot (P^* Q_* P'_* * \eta^{\mathscr{L}'})$$

equals

$$Z' := ((\beta * L'^*) \odot (M_* * \eta^{\mathscr{L}'})) \odot (\varepsilon^{\mathscr{P}} * M_*) \odot (P^* * \alpha).$$

The latter follows by applying repeatedly remark 2.1.1(i) : the details shall be left to the reader. With these preliminaries, we may then also repeat the proof of theorem 2.3.17 : summing up, we obtain a strict pseudo-functor :

$$\Upsilon : \mathsf{wLink}(\mathscr{A})^o \to 2\text{-}\mathsf{Morph}(\mathscr{A}^o)$$

given by the same rules as for the previously defined one on $2\text{-}\mathsf{Morph}(\mathsf{Link}(\mathscr{A}))^o$.

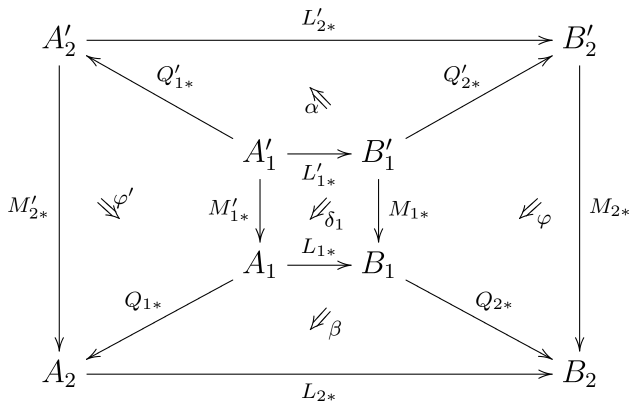
Remark 2.3.20. In the situation of (2.3.8), notice that the base change oriented square $\Upsilon(\mathscr{D})$ can be regarded as a 1-cell $\mathscr{M} \to \mathscr{M}'$ in the 2-category of weak links. By the discussion of (2.3.19), the oriented square $\Upsilon(\Upsilon(\mathscr{D}))$ is then well defined. A straightforward computation that we shall leave to the reader yields the identity :

$$\Upsilon(\Upsilon(\mathscr{D})) = \beta^\dagger.$$

2.3.21. Let us consider two 1-cells in the 2-category of weak links in $\mathscr{A}$:

$$(M'_{1*}, M_{1*}, \delta_1) : \mathscr{L}'_1 := (L'_{1*}, L'^*_1, \eta^{\mathscr{L}'_1}, \varepsilon^{\mathscr{L}'_1}) \to \mathscr{L}_1 := (L_{1*}, L^*_1, \eta^{\mathscr{L}_1}, \varepsilon^{\mathscr{L}_1})$$
$$(M'_{2*}, M_{2*}, \delta_2) : \mathscr{L}'_2 := (L'_{2*}, L'^*_2, \eta^{\mathscr{L}'_2}, \varepsilon^{\mathscr{L}'_2}) \to \mathscr{L}_2 := (L_{2*}, L^*_2, \eta^{\mathscr{L}_2}, \varepsilon^{\mathscr{L}_2})$$

and a diagram of 2-cells :



so that α and β are 1-cells $\mathscr{L}'_1 \to \mathscr{L}'_2$ and $\mathscr{L}_1 \to \mathscr{L}_2$ in $\mathsf{wLink}(\mathscr{A})$. We complete the diagram by adding as well the 2-cell δ_2 (the reader should picture this as a cubical diagram whose faces are oriented by the given 2-cells), and we suppose moreover that the resulting diagram *commutes on* 2*-cells, i.e.* we have :

$$(\delta_2 \boxdot \alpha) \boxminus \varphi' = \varphi \boxminus (\beta \boxdot \delta_1).$$

We may then regard α and β as 1-cells of $\mathsf{wLink}(\mathscr{A})$:

$$(Q'_{1*}, Q'_{2*}, \alpha) : \mathscr{L}'_1 \to \mathscr{L}'_2 \qquad (Q_{1*}, Q_{2*}, \beta) : \mathscr{L}_1 \to \mathscr{L}_2$$

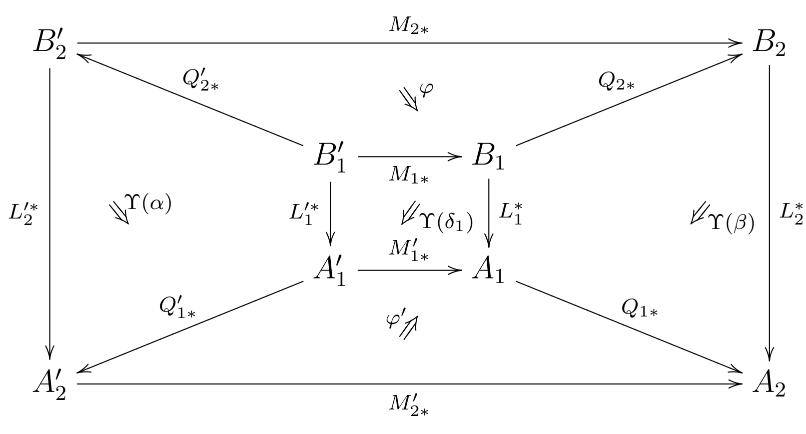
and the pair (φ', φ) as a 2-cell of $\mathsf{wLink}(\mathscr{A})$:

$$(\varphi', \varphi) : (M'_{2*}, M_{2*}, \delta_2) \circ (Q'_{1*}, Q'_{2*}, \alpha) \Rightarrow (Q_{1*}, Q_{2*}, \beta) \circ (M'_{1*}, M_{1*}, \delta_1).$$

The pseudo-functor Υ of (2.3.19) then yields the 2-cell :

$$(\varphi'^o, \varphi^o) : \Upsilon(M'_{2*}, M_{2*}, \delta_2)^o \circ \Upsilon(Q'_{1*}, Q'_{2*}, \alpha)^o \Rightarrow \Upsilon(Q_{1*}, Q_{2*}, \beta)^o \circ \Upsilon(M'_{1*}, M_{1*}, \delta_1)^o$$

which in turns translates as the diagram of 2-cells



completed to a cubical diagram, by adding in the 2-cell $\Upsilon(M'_{2*}, M_{2*}, \delta_2)$, and commuting again on 2-cells, *i.e.* verifying the identity :

$$(\Upsilon(\beta) \boxminus \Upsilon(\delta_1)) \boxbar \varphi = \varphi' \boxbar (\Upsilon(\delta_2) \boxminus \Upsilon(\alpha)).$$

Remark 2.3.22. (i) In the situation of (2.3.21), suppose that $\Upsilon(\alpha)$, $\Upsilon(\beta)$, $\Upsilon(\delta_1)$, φ and φ' are invertible 2-cells of $\mathscr{A}$. In this case, we deduce that the same holds for $\Upsilon(\delta_2) * Q'_2$, and if Q'_2 is an equivalence in $\mathscr{A}$, we conclude easily that also $\Upsilon(\delta_2)$ is an invertible 2-cell.

(ii) For instance, consider the case where $L_{1*} = L_{2*}$, $L'_{1*} = L'_{2*}$, $M_{1*} = M_{2*}$, $M'_{1*} = M'_{2*}$ and where all the 1-cells $Q_{1*}, Q_{2*}, Q'_{1*}, Q'_{2*}$ and all the 2-cells α, β, φ and φ' are identities (and then $\delta_1 = \delta_2$). In this case, applying (i) we conclude that $\Upsilon(\delta_1 : \mathscr{L}'_1 \to \mathscr{L}_1)$ is invertible if and only if the same holds for $\Upsilon(\delta_2 : \mathscr{L}'_2 \to \mathscr{L}_2)$.

(iii) We may also consider the variant where we invert the orientation of the 2-cells φ and φ' (and keep unchanged the others); then the commutativity on 2-cells becomes the condition :

$$\varphi \boxminus (\delta_2 \boxbar \alpha) = (\beta \boxbar \delta_1) \boxminus \varphi'$$

so that the pair (φ, φ') can be regarded as a 1-cell of $\mathsf{wLink}(\mathscr{A})$ as in the foregoing, but with reversed direction. After applying Υ, we deduce the identity

$$\varphi' \boxbar (\Upsilon(\beta) \boxminus \Upsilon(\delta_1)) = (\Upsilon(\delta_2) \boxminus \Upsilon(\alpha)) \boxbar \varphi.$$

Especially, (i) applies *verbatim* to this variant as well.

2.3.23. Lastly, let $\mathscr{A}$ and $\mathscr{B}$ be two 2-categories, and $\varphi : \mathscr{A} \to \mathscr{B}$ a pseudo-functor with coherence constraints $(\delta_\bullet, \gamma_\bullet)$. Then φ induces a pseudo-functor :

$$\mathsf{Link}(\varphi) : \mathsf{Link}(\mathscr{A}) \to \mathsf{Link}(\mathscr{B}) \qquad A \mapsto \varphi A$$

that assigns to every link $\mathscr{L} := (F, G, \eta^{\mathscr{L}}, \varepsilon^{\mathscr{L}}) : A \to B$ of $\mathscr{A}$ the datum

$$\varphi(\mathscr{L}) := (\varphi F, \varphi G, \eta^{\varphi(\mathscr{L})}, \varepsilon^{\varphi(\mathscr{L})})$$

where $\eta^{\varphi(\mathscr{L})}$ and $\varepsilon^{\varphi(\mathscr{L})}$ are the unique 2-cells that make commute the diagrams

$$\begin{array}{ccc} \mathbf{1}_{\varphi B} & \xRightarrow{\eta^{\varphi(\mathscr{L})}} & \varphi F \circ \varphi G \\ {\scriptstyle \delta_B}\Downarrow & & \Downarrow{\scriptstyle \gamma_{F,G}} \\ \varphi \mathbf{1}_B & \xRightarrow{\varphi(\eta^{\mathscr{L}})} & \varphi(F \circ G) \end{array} \qquad \begin{array}{ccc} \varphi G \circ \varphi F & \xRightarrow{\varepsilon^{\varphi(\mathscr{L})}} & \mathbf{1}_{\varphi A} \\ {\scriptstyle \gamma_{G,F}}\Downarrow & & \Downarrow{\scriptstyle \delta_A} \\ \varphi(G \circ F) & \xRightarrow{\varphi(\varepsilon^{\mathscr{L}})} & \varphi \mathbf{1}_A. \end{array}$$

We leave to the reader the verification that $\varphi(\mathscr{L})$ is indeed a link $\varphi A \to \varphi B$ in $\mathscr{B}$. To every transformation of links $\beta : \mathscr{L} \Rightarrow \mathscr{L}'$, the pseudo-functor $\mathsf{Link}(\varphi)$ assigns the transformation $\varphi(\beta) : \varphi(\mathscr{L}) \Rightarrow \varphi(\mathscr{L}')$. The associativity constraint of $\mathsf{Link}(\varphi)$ assigns to every composable pair of morphisms of links $\mathscr{L} := (F, G, \eta^{\mathscr{L}}, \varepsilon^{\mathscr{L}}) : A \to B$, $\mathscr{L}' := (F', G', \eta^{\mathscr{L}'}, \varepsilon^{\mathscr{L}'}) : B \to C$ the 2-cell $\gamma^*_{\mathscr{L},\mathscr{L}'} := \gamma_{F,F'} : \varphi(\mathscr{L}') \circ \varphi(\mathscr{L}) \Rightarrow \varphi(\mathscr{L}' \circ \mathscr{L})$. Likewise, the unit constraint of $\mathsf{Link}(\varphi)$ assigns to every object A of $\mathscr{A}$ the 2-cell $\delta^*_A := \delta_A$.

Proposition 2.3.24. *In the situation of* (2.3.23)*, the following diagram commutes :*

$$\begin{array}{ccc} \mathsf{2\text{-}Morph}(\mathsf{Link}(\mathscr{A}))^o & \xrightarrow{\Upsilon_{\mathscr{A}}} & \mathsf{2\text{-}Morph}(\mathscr{A}^o) \\ {\scriptstyle \mathsf{2\text{-}Morph}(\mathsf{Link}(\varphi))^o}\downarrow & & \downarrow{\scriptstyle \mathsf{2\text{-}Morph}(\varphi^o)} \\ \mathsf{2\text{-}Morph}(\mathsf{Link}(\mathscr{B}))^o & \xrightarrow{\Upsilon_{\mathscr{B}}} & \mathsf{2\text{-}Morph}(\mathscr{B}^o). \end{array}$$

Proof. The commutativity on objects and 2-cells of $\mathsf{2\text{-}Morph}(\mathsf{Link}(\mathscr{A}))^o$ is immediate from the definition. To check commutativity on 1-cells, consider a diagram $\mathscr{D}$ as in (2.3.8); we come down to verifying that the 2-cell of $\mathscr{B}$:

$$X := (\varepsilon^{\varphi(\mathscr{L})} * \varphi M'_* \varphi L'^*) \odot (\varphi L^* * (\gamma^{-1}_{M'_*, L_*} \odot \varphi(\beta) \odot \gamma_{L'_*, M_*}) * \varphi L'^*) \odot (\varphi L^* \varphi M_* * \eta^{\varphi(\mathscr{L}')})$$

equals the 2-cell :

$$Y := \gamma^{-1}_{M'_*,L'^*} \odot \varphi((\varepsilon^{\mathscr{L}} * M'_*L'^*) \odot (L^* * \beta * L'^*) \odot (L^*M_* * \eta^{\mathscr{L}'})) \odot \gamma_{L^*,M_*}.$$

To this aim, set

$$Z := ((\delta_A^{-1} \odot \varphi(\varepsilon^{\mathscr{L}}) \odot \gamma_{L^*,L_*}) * \varphi M'_*) \odot (\varphi L^* * \gamma^{-1}_{M'_*,L_*})$$
$$Z' := (\gamma_{L'_*,M_*} * \varphi L'^*) \odot (\varphi M_* * (\gamma^{-1}_{L'_*,L'^*} \odot \varphi(\eta^{\mathscr{L}'}) \odot \delta_{B'}))$$

so that $X = (Z * \varphi L'^*) \odot X' \odot (\varphi L^* * Z')$, with $X' := \varphi L^* * \varphi(\beta) * \varphi L'^*$. We compute :

$$\begin{aligned} Z &= \gamma_{\mathbf{1}_A,M'_*} \odot (\varphi(\varepsilon^{\mathscr{L}}) * \varphi M'_*) \odot (\gamma_{L^*,L_*} * \varphi M'_*) \odot (\varphi L^* * \gamma^{-1}_{M'_*,L_*}) \\ &= \gamma_{\mathbf{1}_A,M'_*} \odot (\varphi(\varepsilon^{\mathscr{L}}) * \varphi M'_*) \odot \gamma^{-1}_{L^*L_*,M'_*} \odot \gamma_{L^*,L_*M'_*} \\ &= \varphi(\varepsilon^{\mathscr{L}} * M'_*) \odot \gamma_{L^*,L_*M'_*} \\ Z' &= (\gamma_{L'_*,M_*} * \varphi L'^*) \odot (\varphi M_* * \gamma^{-1}_{L'_*,L'^*}) \odot (\varphi M_* * \varphi(\eta^{\mathscr{L}'})) \odot \gamma^{-1}_{M_*,\mathbf{1}_B} \\ &= \gamma^{-1}_{M_*L'_*,L'^*} \odot \gamma_{M_*,L'_*L'^*} \odot (\varphi M_* * \varphi(\eta^{\mathscr{L}'})) \odot \gamma^{-1}_{M_*,\mathbf{1}_B} \\ &= \gamma^{-1}_{M_*L'_*,L'^*} \odot \varphi(M_* * \eta^{\mathscr{L}'}). \end{aligned}$$

On the other hand, we have :

$$\gamma^{-1}_{M'_*,L'^*} \odot \varphi(\varepsilon^{\mathscr{L}} * M'_*L'^*) = (\varphi(\varepsilon^{\mathscr{L}} * M'_*) * \varphi L'^*) \odot \gamma^{-1}_{L^*L_*M'_*,L'^*}$$
$$\varphi(L^*M_* * \eta^{\mathscr{L}'}) \odot \gamma_{L^*,M_*} = \gamma_{L^*,M_*L'_*L'^*} \odot (\varphi L^* * \varphi(M_* * \eta^{\mathscr{L}'}))$$

so we are reduced to showing the identity :

$$(\gamma_{L^*,L_*M'_*} * \varphi L'^*) \odot X' \odot (\varphi L^* * \gamma^{-1}_{M_*L'_*,L'^*}) = \gamma^{-1}_{L^*L_*M'_*,L'^*} \odot \varphi(L^* * \beta * L'^*) \odot \gamma_{L^*,M_*L'_*L'^*}.$$

The latter is the same as the identity : $\gamma_{L^*,L_*M'_*,L'^*} \odot X' = \varphi(L^* * \beta * L'^*) \odot \gamma_{L^*,M_*L'_*,L'^*}$, which holds by virtue of remark 2.1.17(iii). □

2.3.25. We conclude with a further construction derived from the formalism of base change, that shall help us in the following section. First, to every 2-category $\mathscr{A}$ we attach the 2-category

$$\mathsf{Equiv}(\mathscr{A})$$

defined as the sub-2-category of 2-$\mathsf{Morph}(\mathscr{A})$ whose objects are the equivalences in $\mathscr{A}$ (see definition 2.1.3(iii)); for any two equivalences $f : X \to Y$ and $f' : X' \to Y'$ in $\mathscr{A}$, the 1-cells $f \to f'$ in $\mathsf{Equiv}(\mathscr{A})$ are the essentially commutative oriented squares :

(2.3.26)
$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ {\scriptstyle g'}\downarrow & \swArrow_{\beta} & \downarrow{\scriptstyle g} \\ X' & \xrightarrow[f']{} & Y' \end{array}$$

and the 2-cells between such 1-cells are as in 2-$\mathsf{Morph}(\mathscr{A})$. We define a pseudo-functor

$$\mathsf{L} : \mathsf{Equiv}(\mathscr{A}) \to \mathsf{wLink}(\mathscr{A})$$

as follows. For any $(f : X \to Y) \in \mathrm{Ob}(\mathsf{Equiv}(\mathscr{A}))$ we choose a quasi-inverse $f^\dagger : Y \to X$ (see definition 2.1.3(iii)) and the unit η^f and counit ε^f of an adjunction for $(f^\dagger, f)$, and we set

$$\mathsf{L}(f) := (f^\dagger, f, \eta^f, \varepsilon^f) \in \mathrm{Ob}(\mathsf{wLink}(\mathscr{A})).$$

Then every 1-cell $(g, g', \beta) : f \to f'$ as in (2.3.26) yields a 1-cell $\mathsf{L}(f) \to \mathsf{L}(f')$ in $\mathsf{wLink}(\mathscr{A})$ which we denote $\mathsf{L}(g, g', \beta)$; likewise, L is the identity on 2-cells. Then of course the coherence constraints of L are given by identities, but L *is not* necessarily strict, since we do not necessarily have $(g \circ f)^\dagger = f^\dagger \circ g^\dagger$ for every $f, g \in \mathrm{Ob}(\mathsf{Equiv}(\mathscr{A}))$.

2.3.27. Moreover, we have a natural strict isomorphism of 2-categories :

$$\mathsf{Equiv}(\mathscr{A}) \stackrel{\sim}{\to} \mathsf{Equiv}(\mathscr{A}^o)^o.$$

Namely, to every equivalence $f : X \to Y$ of $\mathscr{A}$ we assign the equivalence $f^o : Y^o \to X^o$ of $\mathscr{A}^o$, and to every 1-cell (2.3.26) we assign the following 1-cell $f'^o \to f^o$ of $\mathsf{Equiv}(\mathscr{A}^o)^o$:

$$\begin{array}{ccc} Y'^o & \xrightarrow{f'^o} & X'^o \\ {\scriptstyle g^o}\downarrow & \Downarrow_{(\beta^o)^{-1}} & \downarrow{\scriptstyle g'^o} \\ Y^o & \xrightarrow[f^o]{} & X^o. \end{array}$$

Lastly, let $(h, h', \beta') : f \to f'$ be another 1-cell of $\mathsf{Equiv}(\mathscr{A})$, and $(\alpha_1, \alpha_2) : (g, g', \beta) \Rightarrow (h, h', \beta')$ any 2-cell; recall that the latter is a pair of 2-cells $\alpha_1 : g' \Rightarrow h'$ and $\alpha_2 : g \Rightarrow h$ of $\mathscr{A}$ such that $\alpha_1 \odot \beta = \beta' \odot \alpha_2$. Then our strict isomorphism assigns to (α_1, α_2) the pair (α_2^o, α_1^o), which is easily seen to be a 2-cell $(g'^o, g^o, (\beta^o)^{-1}) \Rightarrow (h'^o, h^o, (\beta'^o)^{-1})$ of $\mathsf{Equiv}(\mathscr{A}^o)^o$.

Next, by composing the pseudo-functors L of (2.3.25) and Υ of (2.3.19) we get a pseudo-functor $\Upsilon^o \circ \mathsf{L} : \mathsf{Equiv}(\mathscr{A}) \to 2\text{-}\mathsf{Morph}(\mathscr{A}^o)^o$, and taking into account remark 2.3.11 we see that $\Upsilon^o \circ \mathsf{L}$ factors through the inclusion strict pseudo-functor $\mathsf{Equiv}(\mathscr{A}^o)^o \to 2\text{-}\mathsf{Morph}(\mathscr{A}^o)^o$. Therefore, we can further compose with the foregoing isomorphism to deduce a pseudo-functor

$$\widetilde{\Upsilon} : \mathsf{Equiv}(\mathscr{A}) \to \mathsf{Equiv}(\mathscr{A}) \qquad f \mapsto f^\dagger \qquad (g, g', \beta) \mapsto \Upsilon(g, g', \beta)^{-1}.$$

2.4. **Adjunctions in 2-categories.** We begin by introducing two constructions that will often allow us to reduce the proof of assertions concerning general pseudo-functors, to the special case of strict, or at least *unital* pseudo-functors, in the sense of definition 2.4.1.

Definition 2.4.1. Let $\mathscr{A}$ and $\mathscr{B}$ be two 2-categories, and $F : \mathscr{A} \to \mathscr{B}$ a pseudo-functor with coherence constraint $(\delta^F_\bullet, \gamma^F_{\bullet\bullet})$. We say that F is *unital* if $F\mathbf{1}_A = \mathbf{1}_{FA}$ and $\delta^F_A = i_{FA}$ for every $A \in \mathrm{Ob}(\mathscr{A})$. Since the component $\delta^F_\bullet$ is determined by the these conditions, we shall usually say that the coherence constraint of a unital pseudo-functor F is the component $\gamma^F_{\bullet\bullet}$.

Remark 2.4.2. Let $F : \mathscr{A} \to \mathscr{B}$ be a unital pseudo-functor with coherence constraint γ^F.

(i) Directly from the composition axiom we see that for every pair of 1-cells $A \xrightarrow{f} B \xrightarrow{g} C$ of $\mathscr{A}$, the 2-cell $\gamma^F_{f,g}$ equals $\mathbf{1}_{Fg}$ if $f = \mathbf{1}_A$, and equals $\mathbf{1}_{Ff}$ if $g = \mathbf{1}_B$.

(ii) Let $G : \mathscr{A} \to \mathscr{B}$ be another unital pseudo-functor, and $\alpha : F \Rightarrow G$ any pseudo-natural transformation with coherence constraint τ. From the first coherence axiom for α it is clear that $\tau_{\mathbf{1}_A} = \mathbf{1}_{\alpha_A}$ for every $A \in \mathrm{Ob}(\mathscr{A})$.

Proposition 2.4.3. *For every pseudo-functor $F : \mathscr{A} \to \mathscr{B}$ there exists a unital pseudo-functor $F^u : \mathscr{A} \to \mathscr{B}$ with a pseudo-natural isomorphism $F \stackrel{\sim}{\to} F^u$.*

Proof. Let (δ^F, γ^F) be the coherence constraint of F; for every 1-cell $f : A \to B$ of $\mathscr{A}$, we define the 2-cell of $\mathscr{B}$

$$\omega_f := \begin{cases} \mathbf{1}_{Ff} & \text{if } f \neq \mathbf{1}_A \\ \delta^F_A & \text{if } f = \mathbf{1}_A \end{cases} \qquad F^u f \Rightarrow Ff.$$

We shall show more precisely, that there exists a unique well-defined unital pseudo-functor $F^u : \mathscr{A} \to \mathscr{B}$ with coherence constraint γ^{F^u} such that :

- $F^u A = FA$ for every $A \in \mathrm{Ob}(\mathscr{A})$
- $F^u f = Ff$ for every $A, B \in \mathrm{Ob}(\mathscr{A})$ every 1-cell $f : A \to B$ such that $f \neq \mathbf{1}_A$
- for every pair of 1-cells $A \xrightarrow{f} B \xrightarrow{g} C$ of $\mathscr{A}$ we have

$$\gamma^{F^u}_{f,g} = \omega^{-1}_{g \circ f} \odot \gamma^F_{f,g} \odot (\omega_g * \omega_f)$$

- for every pair of 1-cells $f, f' : A \to B$ of $\mathscr{A}$ and every 2-cell $\beta : f \Rightarrow f'$, we have
$$F^u\beta = \omega_{f'}^{-1} \odot F\beta \odot \omega_f.$$

Indeed, the uniqueness of such F^u is obvious; it is also clear that for every $A, B \in \mathrm{Ob}(\mathscr{A})$ the stated rules yield a well-defined functor $F^u_{AB} : \mathscr{A}(A, B) \to \mathscr{B}(F^uA, F^uB)$. For the naturality of γ^{F^u} consider 1-cells $f, f' : A \to B$ and $g, g' : B \to C$ in $\mathscr{A}$ and 2-cells $\beta_1 : f \Rightarrow f'$ and $\beta_2 : g \Rightarrow g'$; we notice that

$$\begin{aligned} F^u\beta_2 * F^u\beta_1 &= (\omega_{g'}^{-1} \odot F\beta_2 \odot \omega_g) * (\omega_{f'}^{-1} \odot F\beta_1 \odot \omega_f) \\ &= (\omega_{g'}^{-1} * \omega_{f'}^{-1}) \odot (F\beta_2 * F\beta_1) \odot (\omega_g * \omega_f) \end{aligned}$$

whence

$$\begin{aligned} F^u(\beta_2 * \beta_1) \odot \gamma^{F^u}_{f,g} &= \omega^{-1}_{g'\circ f'} \odot F(\beta_2 * \beta_1) \odot \gamma^F_{f,g} \odot (\omega_g * \omega_f) \\ &= \omega^{-1}_{g'\circ f'} \odot \gamma^F_{f',g'} \odot (F\beta_2 * F\beta_1) \odot (\omega_g * \omega_f) \\ &= \gamma^{F^u}_{f',g'} \odot (F^u\beta_2 * F^u\beta_1) \end{aligned}$$

which is the contention, by remark 2.1.17(ii). Next, let us check the composition axiom for γ^{F^u}; we consider three 1-cells $A \xrightarrow{f} B \xrightarrow{g} C \xrightarrow{h} D$ of $\mathscr{A}$, and we need to show the identity

$$X := \gamma^{F^u}_{f,h\circ g} \odot (\gamma^{F^u}_{g,h} * F^uf) = Y := \gamma^{F^u}_{g\circ f,h} \odot (F^uh * \gamma^{F^u}_{f,g}).$$

We compute, on the one hand :

$$\begin{aligned} X &= \omega^{-1}_{h\circ g\circ f} \odot \gamma^F_{f,h\circ g} \odot (\omega_{h\circ g} \odot \omega_f) \odot ((\omega^{-1}_{h\circ g} \odot \gamma^F_{g,h} * (\omega_h * \omega_g)) * F^uf) \\ &= \omega^{-1}_{h\circ g\circ f} \odot \gamma^F_{f,h\circ g} \odot (\omega_{h\circ g} * \omega_f) \odot (\omega^{-1}_{h\circ g} * F^uf) \odot ((\gamma^F_{g,h} \odot (\omega_h * \omega_g)) * F^uf) \\ &= \omega^{-1}_{h\circ g\circ f} \odot \gamma^F_{f,h\circ g} \odot (F(h\circ g) * \omega_f) \odot ((\gamma^F_{g,h} \odot (\omega_h * \omega_g)) * F^uf) \\ &= \omega^{-1}_{h\circ g\circ f} \odot \gamma^F_{f,h\circ g} \odot (F(h\circ g) * \omega_f) \odot (\gamma^F_{g,h} * F^uf) \odot (\omega_h * \omega_g * F^uf) \\ &= \omega^{-1}_{h\circ g\circ f} \odot \gamma^F_{f,h\circ g} \odot (\gamma^F_{g,h} * Ff) \odot (Fh * Fg * \omega_f) \odot (\omega_h * \omega_g * F^uf) \\ &= \omega^{-1}_{h\circ g\circ f} \odot \gamma^F_{f,h\circ g} \odot (\gamma^F_{g,h} * Ff) \odot (\omega_h * \omega_g * \omega_f) \\ &= \omega^{-1}_{h\circ g\circ f} \odot \gamma^F_{g\circ f,h} \odot (Fh * \gamma^F_{f,g}) \odot (\omega_h * \omega_g * \omega_f) \end{aligned}$$

and on the other hand :

$$\begin{aligned} Y &= \omega^{-1}_{h\circ g\circ f} \odot \gamma^F_{g\circ f,h} \odot (\omega_h * \omega_{g\circ f}) \odot (F^uh * (\omega^{-1}_{g\circ f} \odot \gamma^F_{f,g} \odot (\omega_g * \omega_f))) \\ &= \omega^{-1}_{h\circ g\circ f} \odot \gamma^F_{g\circ f,h} \odot (\omega_h * \omega_{g\circ f}) \odot (F^uh * \omega^{-1}_{g\circ f}) \odot (F^uh * (\gamma^F_{f,g} \odot (\omega_g * \omega_f))) \\ &= \omega^{-1}_{h\circ g\circ f} \odot \gamma^F_{g\circ f,h} \odot (\omega_h * F(g\circ f)) \odot (F^uh * \gamma^F_{f,g}) \odot (F^uh * \omega_g * \omega_f) \\ &= \omega^{-1}_{h\circ g\circ f} \odot \gamma^F_{g\circ f,h} \odot (Fh * \gamma^F_{f,g}) \odot (\omega_h * Fg * Fh) \odot (F^uh * \omega_g * \omega_f) \\ &= \omega^{-1}_{h\circ g\circ f} \odot \gamma^F_{g\circ f,h} \odot (Fh * \gamma^F_{f,g}) \odot (\omega_h * \omega_g * \omega_f) \end{aligned}$$

whence the contention. Lastly, the unit axiom can be verified by a simple inspection.

The sought pseudo-isomorphism is given by the rule that assigns $\alpha_A := \mathbf{1}_{FA} : FA \to F^uA$ to every $A \in \mathrm{Ob}(\mathscr{A})$, and the oriented square

$$\begin{array}{ccc} FA & \xrightarrow{\alpha_A} & F^uA \\ {\scriptstyle Ff}\downarrow & \swarrow_{\omega_f} & \downarrow{\scriptstyle F^uf} \\ FB & \xrightarrow[\alpha_B]{} & F^uB \end{array} \qquad \text{to every 1-cell } f : A \to B \text{ of } \mathscr{A}.$$

The naturality of ω_f and the coherence axioms follow by a simple inspection. □

Remark 2.4.4. (i) For any two 2-categories $\mathscr{A}$ and $\mathscr{B}$, let us denote by

$$\mathsf{uniPsFun}(\mathscr{A},\mathscr{B})$$

the sub-2-category of $\mathsf{PsFun}(\mathscr{A},\mathscr{B})$ whose objects are the unital pseudo-functors $\mathscr{A} \to \mathscr{B}$, and whose Hom-categories are given by the categories $\mathsf{PsNat}(F,G)$, for any two such unital pseudo-functors F,G. For every pseudo-functor $F : \mathscr{A} \to \mathscr{B}$, let also $\alpha^F : F \xrightarrow{\sim} F^u$ be the pseudo-natural isomorphism furnished by proposition 2.4.3. It is easily seen that the rules $F \mapsto F^u$ for every pseudo-functor $F : \mathscr{A} \to \mathscr{B}$, $(\beta : F \Rightarrow G) \mapsto \beta^u := \alpha^G \odot \beta \odot (\alpha^F)^{-1}$ for every pseudo-natural transformation β, and $(\Xi : \beta \rightsquigarrow \beta') \mapsto \Xi^u := \alpha^G * \Xi * (\alpha^F)^{-1}$ for every modification Ξ, define a strict 2-equivalence of 2-categories

$$(-)^u : \mathsf{PsFun}(\mathscr{A},\mathscr{B}) \xrightarrow{\sim} \mathsf{uniPsFun}(\mathscr{A},\mathscr{B})$$

(details left to the reader). Likewise, if $i : \mathsf{uniPsFun}(\mathscr{A},\mathscr{B}) \to \mathsf{PsFun}(\mathscr{A},\mathscr{B})$ denotes the inclusion strict pseudo-functor, the rule : $F \mapsto \alpha^F$ for every pseudo-functor $F : \mathscr{A} \to \mathscr{B}$ yields a strict pseudo-natural isomorphism of strict pseudo-functors :

$$\mathbf{1}_{\mathsf{PsFun}(\mathscr{A},\mathscr{B})} \xrightarrow{\sim} i \circ (-)^u. \tag{2.4.5}$$

(ii) Let $F : \mathscr{A} \to \mathscr{B}$ and $G : \mathscr{B} \to \mathscr{C}$ be two pseudo-functors, $\alpha^F : F \xrightarrow{\sim} F^u$, $\alpha^G : G \xrightarrow{\sim} G^u$, $\alpha^{G\circ F} : G \circ F \xrightarrow{\sim} (G \circ F)^u$ the corresponding pseudo-natural isomorphisms as in (i). Since α^F and α^G are not strict, we have distinct pseudo-natural isomorphisms

$$(\alpha^G * F^u) \odot (G * \alpha^F), (G^u * \alpha^F) \odot (\alpha^G * F) : G \circ F \xrightarrow{\sim} G^u \circ F^u$$

that are related by an invertible modification (see example 2.2.15(ii)). By composing with $(\alpha^{G\circ F})^{-1}$, we get therefore two pseudo-natural isomorphisms of unital pseudo-functors

$$(G \circ F)^u \xrightarrow{\sim} G^u \circ F^u$$

but in general these pseudo-functors are different.

Proposition 2.4.6. *For every pseudo-functor $F : \mathscr{A} \to \mathscr{B}$ there exist :*

(a) *A 2-category $\mathscr{A}^F$ and strict pseudo-functors $\mathscr{A} \xleftarrow{\pi^F} \mathscr{A}^F \xrightarrow{F^\flat} \mathscr{B}$.*
(b) *With an isomorphism of pseudo-functors $\omega^F : F \circ \pi^F \xrightarrow{\sim} F^\flat$.*
(c) *A pseudo-functor $\sigma^F : \mathscr{A} \to \mathscr{A}^F$ such that :*

$$\pi^F \circ \sigma^F = \mathbf{1}_{\mathscr{A}} \qquad F^\flat \circ \sigma^F = F \qquad \omega^F * \sigma^F = \mathbf{1}_F.$$

(d) *A pseudo-natural equivalence $\mu^F : \sigma^F \circ \pi^F \xrightarrow{\sim} \mathbf{1}_{\mathscr{A}^F}$.*

Proof. We let $\mathscr{A}^F$ be the 2-category with $\mathrm{Ob}(\mathscr{A}^F) = \mathrm{Ob}(\mathscr{A})$, and whose 1-cells

$$(f,g,\lambda) : X \to Y \qquad \text{for every } X,Y \in \mathrm{Ob}(\mathscr{A})$$

are all the data consisting of a 1-cell $f : X \to Y$ of $\mathscr{A}$, a 1-cell $g : FX \to FY$ of $\mathscr{B}$, and an invertible 2-cell $\lambda : g \xrightarrow{\sim} Ff$. Given two such 1-cells $(f,g,\lambda),(f',g',\lambda') : X \to Y$, the 2-cells

$$(f,g,\lambda) \Rightarrow (f',g',\lambda')$$

are the pairs (α,β) where $\alpha : f \Rightarrow f'$ (resp. $\beta : g \Rightarrow g'$) is a 2-cell of $\mathscr{A}$ (resp. of $\mathscr{B}$), such that

$$\lambda' \odot \beta = F\alpha \odot \lambda.$$

The composition of two 1-cells $X \xrightarrow{(f_1,g_1,\lambda_1)} Y \xrightarrow{(f_2,g_2,\lambda_2)} Z$ is the 1-cell

$$(f_2,g_2,\lambda_2) \circ (f_1,g_1,\lambda_1) := (f_2 \circ f_1, g_2 \circ g_1, \gamma^F_{f_1,f_2} \odot (\lambda_2 * \lambda_1))$$

where (δ^F,γ^F) denotes the coherence constraint of the pseudo-functor F. The associativity of this composition law follows easily from the composition axiom for γ^F : the details are left to the reader. Especially, for every $X \in \mathrm{Ob}(\mathscr{A})$ the triple $(\mathbf{1}_X, \mathbf{1}_{FX}, \delta^F_X)$ is the identity 1-cell of X in $\mathscr{A}^F$. Given three 1-cells $(f,g,\lambda),(f',g',\lambda'),(f'',g'',\lambda''):X\to Y$, and two 2-cells $(\alpha,\beta):(f,g,\lambda)\Rightarrow(f',g',\lambda')$ and $(\alpha',\beta'):(f',g',\lambda')\Rightarrow(f'',g'',\lambda'')$, we let

$$(\alpha',\beta')\odot(\alpha,\beta):=(\alpha'\odot\alpha,\beta'\odot\beta)$$

which is a well defined 2-cell $(f,g,\lambda)\Rightarrow(f'',g'',\lambda'')$. Lastly, if $(f_1,g_1,\lambda_1),(f'_1,g'_1,\lambda'_1):X\to Y$ and $(f_2,g_2,\lambda_2),(f'_2,g'_2,\lambda'_2):Y\to Z$ are four given 1-cells, and $(\alpha_1,\beta_1):(f_1,g_1,\lambda_1)\Rightarrow(f'_1,g'_1,\lambda'_1)$, $(\alpha_2,\beta_2):(f_2,g_2,\lambda_2)\Rightarrow(f'_2,g'_2,\lambda'_2)$ are two 2-cells, we set :

$$(\alpha_2,\beta_2)*(\alpha_1,\beta_1):=(\alpha_2*\alpha_1,\beta_2*\beta_1)$$

which is a well defined 2-cell $(f_2,g_2,\lambda_2)\circ(f_1,g_1,\lambda_1)\Rightarrow(f'_2,g'_2,\lambda'_2)\circ(f'_1,g'_1,\lambda'_1)$. The associativity of these two composition laws are obvious, and it is then easily seen that $\mathscr{A}^F$ is a well defined 2-category with such laws for 1-cells and 2-cells : the details are left to the reader.

The sought strict pseudo-functors $F^\flat$ and π^F are given by the rules :

$$\begin{array}{rlrll}
F^\flat X & :=FX & \pi^F X & :=X & \text{for every } X\in\mathrm{Ob}(\mathscr{A}^F)\\
F^\flat(f,g,\lambda) & :=g & \pi^F(f,g,\lambda) & :=f & \text{for every 1-cell } (f,g,\lambda)\\
F^\flat(\alpha,\beta) & :=\beta & \pi^F(\alpha,\beta) & :=\alpha & \text{for every 2-cell } (\alpha,\beta).
\end{array}$$

The isomorphism ω^F is given by the rule : $X\mapsto\mathbf{1}_{FX}$ for every $X\in\mathrm{Ob}(\mathscr{A}^F)$, and its coherence costraint assigns to every 1-cell $(f,g,\lambda):X\to Y$ the oriented square

$$\begin{array}{ccc}
FX & = & FX\\
{\scriptstyle Ff}\downarrow & \swarrow_{\lambda} & \downarrow{\scriptstyle g}\\
FY & = & FY.
\end{array}$$

Next, the pseudo-functor σ^F is given by the rules :

$$X\mapsto X\qquad f\mapsto(f,Ff,\mathbf{1}_{Ff})\qquad \alpha\mapsto(\alpha,F\alpha)$$

for every $X\in\mathrm{Ob}(\mathscr{A})$, every 1-cell f, and every 2-cell α of $\mathscr{A}$. The coherence constraints of σ^F are given by the rules :

$$X\mapsto(i_X,\delta^F_X)\qquad (f,f')\mapsto(\mathbf{1}_{f'\circ f},\gamma^F_{f,f'})$$

for every $X\in\mathrm{Ob}(\mathscr{A})$ and every composable pair of 1-cells (f,f') of $\mathscr{A}$. The required coherence axioms are easily verified, and the desired identities as in (c) follow straightforwardly : details left to the reader. Lastly, we define $\mu^F_X:=\mathbf{1}_{\sigma^F X}=(\mathbf{1}_X,\mathbf{1}_{FX},\delta^F_X)$ for every $X\in\mathrm{Ob}(\mathscr{A}^F)$. For every 1-cell $(f,g,\lambda):X\to Y$ of $\mathscr{A}^F$, notice that $\sigma^F\circ\pi^F(f,g,\lambda)=(f,Ff,\mathbf{1}_{Ff})$; then the coherence constraint of μ^F assigns to (f,g,λ) the oriented square in $\mathscr{A}^F$:

$$\begin{array}{ccc}
X & \xrightarrow{(\mathbf{1}_X,\mathbf{1}_{FX},\delta^F_X)} & X\\
{\scriptstyle (f,Ff,\mathbf{1}_{Ff})}\downarrow & \swarrow_{(\mathbf{1}_f,\lambda)} & \downarrow{\scriptstyle (f,g,\lambda)}\\
Y & \xrightarrow[(\mathbf{1}_Y,\mathbf{1}_{FY},\delta^F_Y)]{} & Y.
\end{array}$$

A little diagram chase that we leave to the reader shows that these rules yield the sought pseudo-natural equivalence. □

Proposition 2.4.7. (i) *Let $\mathscr{A},\mathscr{B}$ be two 2-categories, $F:\mathscr{A}\to\mathscr{B}$ and $G:\mathscr{B}\to\mathscr{A}$ two pseudo-functors. Then there exist :*

(a) *Two 2-categories $\mathscr{A}^{F,G}$ and $\mathscr{B}^{G,F}$, and a diagram of strict pseudo-functors :*

$$\mathscr{A}\xleftarrow{\pi^{F,G}}\mathscr{A}^{F,G}\underset{G^\flat}{\overset{F^\flat}{\rightleftarrows}}\mathscr{B}^{G,F}\xrightarrow{\pi^{G,F}}\mathscr{B}.$$

(b) *With two isomorphisms of pseudo-functors :*

$$\omega^{F,G} : F \circ \pi^{F,G} \xrightarrow{\sim} \pi^{G,F} \circ F^\flat \qquad \textit{and} \qquad \omega^{G,F} : G \circ \pi^{G,F} \xrightarrow{\sim} \pi^{F,G} \circ G^\flat.$$

(c) *Two pseudo-functors* $\sigma^{F,G} : \mathscr{A} \to \mathscr{A}^{F,G}$ *and* $\sigma^{G,F} : \mathscr{B} \to \mathscr{B}^{G,F}$ *such that :*

$$\begin{aligned} \pi^{F,G} \circ \sigma^{F,G} &= \mathbf{1}_{\mathscr{A}} & F^\flat \circ \sigma^{F,G} &= \sigma^{G,F} \circ F & \omega^{F,G} * \sigma^{F,G} &= \mathbf{1}_F \\ \pi^{G,F} \circ \sigma^{G,F} &= \mathbf{1}_{\mathscr{B}} & G^\flat \circ \sigma^{G,F} &= \sigma^{F,G} \circ G & \omega^{G,F} * \sigma^{G,F} &= \mathbf{1}_G. \end{aligned}$$

(d) *With two isomorphisms of pseudo-functors :*

$$\psi^{F,G} : \sigma^{F,G} \circ \pi^{F,G} \xrightarrow{\sim} \mathbf{1}_{\mathscr{A}^{F,G}} \quad \textit{and} \quad \psi^{G,F} : \sigma^{G,F} \circ \pi^{G,F} \xrightarrow{\sim} \mathbf{1}_{\mathscr{B}^{G,F}}$$

(ii) *Suppose moreover that* F *and* G *are unital. Then we have as well :*

$$G^\flat * \psi^{G,F} = (\psi^{F,G} * G^\flat) \odot (\sigma^{F,G} * \omega^{G,F}) \qquad F^\flat * \psi^{F,G} = (\psi^{G,F} * F^\flat) \odot (\sigma^{G,F} * \omega^{F,G}).$$

Proof. (i): To begin with, for every $k, n \in \mathbb{N}$ let us set :

$$H_{2k} := G \qquad H_{2k+1} := F \qquad K_0 := \mathbf{1}_{\mathscr{A}} \qquad K_{n+1} := H_{n+1} \circ H_{n-1} \circ \cdots \circ H_1.$$

Then we let $\mathscr{A}^{F,G}$ be the 2-category with $\mathrm{Ob}(\mathscr{A}^{F,G}) = \mathrm{Ob}(\mathscr{A})$, and whose 1-cells

$$(f_\bullet, \lambda_\bullet) : X \to Y \qquad \text{for every } X, Y \in \mathrm{Ob}(\mathscr{A})$$

are all the systems of 1-cells $(f_n : K_n X \to K_n Y \mid n \in \mathbb{N})$, and of invertible 2-cells $(\lambda_n : f_{n+1} \xrightarrow{\sim} H_{n+1} f_n \mid n \in \mathbb{N})$. Given such 1-cells $(f_\bullet, \lambda_\bullet), (f'_\bullet, \lambda'_\bullet) : X \to Y$, the 2-cells

$$\alpha_\bullet : (f_\bullet, \lambda_\bullet) \Rightarrow (f'_\bullet, \lambda'_\bullet)$$

are the systems of 2-cells $(\alpha_n : f_n \to f'_n \mid k \in \mathbb{N})$ such that :

$$H_{n+1}(\alpha_n) \odot \lambda_n = \lambda'_n \odot \alpha_{n+1} \qquad \text{for every } n \in \mathbb{N}. \tag{2.4.8}$$

The composition of two 1-cells $X \xrightarrow{(f_{1,\bullet}, \lambda_{1,\bullet})} Y \xrightarrow{(f_{2,\bullet}, \lambda_{2,\bullet})} Z$ is the 1-cell

$$(f_{2,\bullet}, \lambda_{1,\bullet}) \circ (f_{1,\bullet}, \lambda_{1,\bullet}) := (f_{2,n} \circ f_{1,n}, \gamma^{H_{n+1}}_{f_{1,n}, f_{2,n}} \odot (\lambda_{2,n} * \lambda_{1,n}) \mid n \in \mathbb{N})$$

where $(\delta^{H_n}, \gamma^{H_n})$ denotes the coherence constraint of the pseudo-functor H_n, for every $n \in \mathbb{N}$. Just as in the proof of proposition 2.4.6, the associativity of this rule follows easily from the composition axioms for γ^{H_n}, and for every $X \in \mathrm{Ob}(\mathscr{A})$, the identity 1-cell of X in $\mathscr{A}^{F,G}$ is the datum $\mathbf{1}^{F,G}_X := (\mathbf{1}_{K_n X}, \delta^{H_{n+1}}_{K_n X} \mid n \in \mathbb{N})$. Given three 1-cells $(f_\bullet, \lambda_\bullet), (f'_\bullet, \lambda'_\bullet), (f''_\bullet, \lambda''_\bullet) : X \to Y$, and two 2-cells $\alpha_\bullet : (f_\bullet, \lambda_\bullet) \Rightarrow (f'_\bullet, \lambda'_\bullet)$ and $\alpha'_\bullet : (f'_\bullet, \lambda'_\bullet) \Rightarrow (f''_\bullet, \lambda''_\bullet)$, we let

$$\alpha'_\bullet \odot \alpha_\bullet := (\alpha'_n \odot \alpha_n \mid n \in \mathbb{N})$$

which is a well defined 2-cell $(f_\bullet, \lambda_\bullet) \Rightarrow (f''_\bullet, \lambda''_\bullet)$. Lastly, if $(f_{1,\bullet}, \lambda_{1,\bullet}), (f'_{1,\bullet}, \lambda'_{1,\bullet}) : X \to Y$ and $(f_{2,\bullet}, \lambda_{2,\bullet}), (f'_{2,\bullet}, \lambda'_{2,\bullet}) : Y \to Z$ are four given 1-cells, and $\alpha_{1,\bullet} : (f_{1,\bullet}, \lambda_{1,\bullet}) \Rightarrow (f'_{1,\bullet}, \lambda'_{1,\bullet})$, $\alpha_{2,\bullet} : (f_{2,\bullet}, \lambda_{2,\bullet}) \Rightarrow (f'_{2,\bullet}, \lambda'_{2,\bullet})$ are two 2-cells, we set :

$$\alpha_{2,\bullet} * \alpha_{1,\bullet} := (\alpha_{2,n} * \alpha_{1,n} \mid n \in \mathbb{N})$$

which is a well defined 2-cell $(f_{2,\bullet}, \lambda_{2,\bullet}) \circ (f_{1,\bullet}, \lambda_{1,\bullet}) \Rightarrow (f'_{2,\bullet}, \lambda'_{2,\bullet}) \circ (f'_{1,\bullet}, \lambda'_{1,\bullet})$. The associativity of these two composition laws are obvious, and it is then easily seen that $\mathscr{A}^{F,G}$ is a well defined 2-category with such laws for 1-cells and 2-cells : the details are left to the reader.

We define $\mathscr{B}^{G,F}$ by exactly the same rules, after swapping $\mathscr{A}$ and F with respectively $\mathscr{B}$ and G. Then the sought strict pseudo-functors $F^\flat$ and $\pi^{F,G}$ are given by the rules :

$$\begin{aligned} F^\flat X &:= FX & \pi^{F,G} X &:= X & &\text{for every } X \in \mathrm{Ob}(\mathscr{A}^{F,G}) \\ F^\flat(f_\bullet, \lambda_\bullet) &:= (f_{n+1}, \lambda_{n+1} \mid n \in \mathbb{N}) & \pi^{F,G}(f_\bullet, \lambda_\bullet) &:= f_0 & &\text{for every 1-cell } (f_\bullet, \lambda_\bullet) \\ F^\flat(\alpha_\bullet) &:= (\alpha_{n+1} \mid n \in \mathbb{N}) & \pi^{F,G}(\alpha_\bullet) &:= \alpha_0 & &\text{for every 2-cell } \alpha_\bullet \end{aligned}$$

and again, $G^\flat$ and $\pi^{G,F}$ are defined by the same rules, after swapping F and G.

The isomorphism $\omega^{F,G}$ is given by the rule : $X \mapsto \mathbf{1}_{FX}$ for every $X \in \mathrm{Ob}(\mathscr{A}^F)$, and its coherence costraint assigns to every 1-cell $(f_\bullet, \lambda_\bullet) : X \to Y$ the oriented square

$$\begin{array}{ccc} FX & = & FX \\ {\scriptstyle Ff_0}\downarrow & \swarrow_{\lambda_0} & \downarrow{\scriptstyle f_1} \\ FY & = & FY. \end{array}$$

Lastly, the pseudo-functor $\sigma^{F,G}$ is given by the rules :

$$X \mapsto X \qquad f \mapsto (K_n f, \mathbf{1}_{K_{n+1}f} \mid n \in \mathbb{N}) \qquad \alpha \mapsto (K_n\alpha \mid n \in \mathbb{N})$$

for every $X \in \mathrm{Ob}(\mathscr{A})$, every 1-cell f, and every 2-cell α of $\mathscr{A}$. For every $n \in \mathbb{N}$, let $(\delta^{K_n}, \gamma^{K_n})$ be the coherence constraint of K_n; the coherence constraint of $\sigma^{F,G}$ is given by the rules :

$$X \mapsto (\delta^{K_n}_X \mid n \in \mathbb{N}) \qquad (f, f') \mapsto (\gamma^{K_n}_{f,f'} \mid n \in \mathbb{N})$$

for every $X \in \mathrm{Ob}(\mathscr{A})$ and every composable pair of 1-cells (f, f') of $\mathscr{A}$, where H. The required coherence axioms are verified as in the proof of the corresponding assertions of the proposition 2.4.6, and shall again be left to the reader. Likewise, one defines $\omega^{G,F}$ and $\sigma^{G,F}$ by the same rules, after swapping the roles of F and G. Then the desired identities in (c) follow straightforwardly. It remains to exhibit an isomorphism of pseudo-functors $\psi^{F,G} : \sigma^{F,G} \circ \pi^{F,G} \xrightarrow{\sim} \mathbf{1}_{\mathscr{A}^{F,G}}$. To this aim, notice that $\sigma^{F,G} \circ \pi^{F,G}$ is given by the rules :

$$X \mapsto X \qquad (f_\bullet, \lambda_\bullet) \mapsto (K_n f_0, \mathbf{1}_{K_{n+1}f_0} \mid n \in \mathbb{N}) \qquad \alpha_\bullet \mapsto (K_n\alpha_0 \mid n \in \mathbb{N})$$

for every object X, every 1-cell $(f_\bullet, \lambda_\bullet)$ and every 2-cell $\alpha_\bullet$ of $\mathscr{A}^{F,G}$; then we let $\psi^{F,G}_X := \mathbf{1}^{F,G}_X$ for every such X, and to every such $(f_\bullet, \lambda_\bullet)$ we attach the coherence constraint

$$\tau^{\psi^{F,G}}_{(f_\bullet,\lambda_\bullet),\bullet} : (f_\bullet, \lambda_\bullet) \to (K_n f_0, \mathbf{1}_{K_{n+1}f_0} \mid n \in \mathbb{N})$$

defined inductively by the rules :

$$\tau^{\psi^{F,G}}_{(f_\bullet,\lambda_\bullet),0} := \mathbf{1}_{f_0} \qquad \tau^{\psi^{F,G}}_{(f_\bullet,\lambda_\bullet),n+1} := H_{n+1}(\tau^{\psi^{F,G}}_{(f_\bullet,\lambda_\bullet),n}) \odot \lambda_n \qquad \text{for every } n \in \mathbb{N}.$$

The coherence axioms for τ^ψ amount to the identities :

$$\left.\begin{array}{r} \tau^{\psi^{F,G}}_{\mathbf{1}^{F,G}_X,n} = \delta^{K_n}_X \\ A_n := \gamma^{K_n}_{f_0,f'_0} \odot (\tau^{\psi^{F,G}}_{(f'_\bullet,\lambda'_\bullet),n} * \tau^{\psi^{F,G}}_{(f_\bullet,\lambda_\bullet),n}) = B_n := \tau^{\psi^{F,G}}_{(f''_\bullet,\lambda''_\bullet),n} \end{array}\right. \qquad \text{for every } n \in \mathbb{N}$$

for every object X of $\mathscr{A}$ and every composable pair of 1-cells $(f_\bullet, \lambda_\bullet)$ and $(f'_\bullet, \lambda'_\bullet)$, with $(f''_\bullet, \lambda''_\bullet) := (f'_\bullet, \lambda'_\bullet) \circ (f_\bullet, \lambda_\bullet)$. The first identity is checked easily by induction on n, recalling that $\delta^{K_{n+1}}_X = H_{n+1}(\delta^{K_n}_X) \odot \delta^{H_{n+1}}_{K_n X}$ for every $n \in \mathbb{N}$. The second identity is obvious for $n = 0$. Suppose then that the second identity is known for some $n \in \mathbb{N}$; we compute :

$$\begin{aligned} A_{n+1} &= H_{n+1}(\gamma^{K_n}_{f_0,f'_0}) \odot \gamma^{H_{n+1}}_{K_n f_0, K_n f'_0} \odot ((H_{n+1}(\tau^\psi_{(f'_\bullet,\lambda'_\bullet),n}) \odot \lambda'_n) * (H_{n+1}(\tau^\psi_{(f_\bullet,\lambda_\bullet),n}) \odot \lambda_n)) \\ &= H_{n+1}(\gamma^{K_n}_{f_0,f'_0}) \odot \gamma^{H_{n+1}}_{K_n f_0, K_n f'_0} \odot (H_{n+1}(\tau^\psi_{(f'_\bullet,\lambda'_\bullet),n}) * H_{n+1}(\tau^\psi_{(f_\bullet,\lambda_\bullet),n})) \odot (\lambda'_n * \lambda_n) \\ &= H_{n+1}(\gamma^{K_n}_{f_0,f'_0}) \odot H_{n+1}(\tau^\psi_{(f'_\bullet,\lambda'_\bullet),n} * \tau^\psi_{(f_\bullet,\lambda_\bullet),n}) \odot \gamma^{H_{n+1}}_{f_0,f'_0} \odot (\lambda'_n * \lambda_n) \\ &= H_{n+1}(A_n) \odot \lambda''_n \\ &= H_{n+1}(B_n) \odot \lambda''_n \\ &= B_{n+1} \end{aligned}$$

where the first equality follows after recalling that $\gamma^{K_{n+1}}_{f_0,f'_0} = H_{n+1}(\gamma^{K_n}_{f_0,f'_0}) \odot \gamma^{H_{n+1}}_{K_n f_0, K_n f'_0}$. The same rules yield, *mutatis mutandis*, the sought isomorphism $\psi^{G,F} : \sigma^{G,F} \circ \pi^{G,F} \xrightarrow{\sim} \mathbf{1}_{\mathscr{B}^{G,F}}$.

(ii): Let us set as well :

$$H'_{2k} := F \qquad H'_{2k+1} := G \qquad K'_0 := \mathbf{1}_{\mathscr{B}} \qquad K'_{n+1} := H'_{n+1} \circ H'_{n-1} \circ \cdots \circ H'_1.$$

With this notation, since F are unital, we have :

$$\begin{aligned}(G^\flat * \psi^{G,F})_X &= G^\flat(\mathbf{1}^{G,F}_X) = (\mathbf{1}_{K'_{n+1}X}, i_{K'_{n+2}X} \mid n \in \mathbb{N}) \\ (\psi^{F,G} * G^\flat)_X &= \psi^{F,G}_{GX} = (\mathbf{1}_{K_n GX}, i_{K_{n+1}GX} \mid n \in \mathbb{N}) \\ (\sigma^{F,G} * \omega^{G,F})_X &= \sigma^{F,G}_{GX} = (\mathbf{1}_{K_n GX}, i_{K_{n+1}GX} \mid n \in \mathbb{N}).\end{aligned}$$

Noticing that $K'_{n+2} = K_{n+1}G$ and $\gamma^{H_{n+1}}_{\mathbf{1}_{K_nGX},\mathbf{1}_{K_nGX}} = \delta^{H_{n+1}}_{K_nGX} = i_{K_nGX}$, we deduce :

$$(\psi^{F,G} * G^\flat)_X \circ (\sigma^{F,G} * \omega^{G,F})_X = (G^\flat * \psi^{G,F})_X \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{B}^{G,F}).$$

Next, the coherence constraint of $\sigma^{F,G} * \omega^{G,F}$ is given by the rule :

$$(X \xrightarrow{(f_\bullet,\lambda_\bullet)} Y) \mapsto ((\gamma^{K_n}_{Gf_0,\mathbf{1}_{GY}})^{-1} \odot K_n\lambda_0 \odot \gamma^{K_n}_{\mathbf{1}_{GX},f_1} \mid n \in \mathbb{N}) = (K_n\lambda_0 \mid n \in \mathbb{N})$$

whereas the ones of $\psi^{F,G} * G^\flat$ and respectively $G^\flat * \psi^{G,F}$ are defined by the rules :

$$(f_\bullet,\lambda_\bullet) \mapsto (\tau^{\psi^{F,G}}_{(f_{n+1},\lambda_{n+1} \mid n\in\mathbb{N}),n} \mid n \in \mathbb{N}) \qquad (f_\bullet,\lambda_\bullet) \mapsto (\tau^{\psi^{G,F}}_{(f_\bullet,\lambda_\bullet),n+1} \mid n \in \mathbb{N}).$$

Hence we are reduced to showing that

$$K_n\lambda_0 \odot \tau^{\psi^{F,G}}_{(f_{n+1},\lambda_{n+1} \mid n\in\mathbb{N}),n} = \tau^{\psi^{G,F}}_{(f_\bullet,\lambda_\bullet),n+1} \qquad \text{for every } n \in \mathbb{N}.$$

The latter follows by an easy induction on n : details left to the reader. □

Definition 2.4.9. Let $\mathscr{A}$, $\mathscr{B}$ be two 2-categories, and $F, F' : \mathscr{A} \to \mathscr{B}$ two pseudo-functors.

(i) We say that a pseudo-natural transformation $F \Rightarrow F'$ is a *pseudo-natural equivalence* if it is an equivalence in the 2-category $\mathsf{PsFun}(\mathscr{A},\mathscr{B})$ (in the sense of definition 2.1.3(iii)).

(ii) We say that F is *fully faithful* (resp. *strongly faithful*) if for every $A, A' \in \mathrm{Ob}(\mathscr{A})$, the functor $F_{AA'} : \mathscr{A}(A,A') \to \mathscr{B}(FA,FA')$ is an equivalence (resp. is an isomorphism of categories).

(iii) We say that $\mathscr{A}$ is a *full sub-2-category* (resp. a *strong sub-2-category*) of $\mathscr{B}$, if it is a sub-2-category and the inclusion pseudo-functor $\mathscr{A} \to \mathscr{B}$ is fully (resp. strongly) faithful.

(iv) We say that F is a *2-equivalence* (resp. a *strong 2-equivalence*) from $\mathscr{A}$ to $\mathscr{B}$ if it is fully faithful (resp. strongly faithful), and for every $B \in \mathrm{Ob}(\mathscr{B})$ there exists $A \in \mathrm{Ob}(\mathscr{A})$ with an equivalence (resp. an isomorphism) $FA \to B$.

Remark 2.4.10. Consider a square diagram of 2-categories and pseudo-functors

$$\mathscr{D} \quad : \quad \begin{array}{ccc} \mathscr{A} & \xrightarrow{F} & \mathscr{B} \\ {\scriptstyle H}\downarrow & & \downarrow{\scriptstyle G} \\ \mathscr{C} & \xrightarrow{K} & \mathscr{D}. \end{array}$$

We shall say that $\mathscr{D}$ is *essentially commutative* (resp. *pseudo-commutative*) if there exists an isomorphism of pseudo-functors (resp. a pseudo-natural equivalence) $\alpha : G \circ F \Rightarrow K \circ H$. Even though the set of (small) 2-categories does not form a 2-category, the datum $(\mathscr{D}, \alpha)$ is a type of oriented square analogous to those contemplated in (2.1.5). Especially, two such data $(\mathscr{D}, \alpha)$ and $(\mathscr{D}', \alpha')$ can be composed if they share a side, in exactly the same way as for usual oriented square. Then, it is clear that a horizontal or vertical composition of essentially commutative (resp. pseudo-commutative) squares is again essentially commutative (resp. pseudo-commutative). On the other hand, the discussion of remark 2.2.5(iv,v) shows that the identities of proposition 2.1.9 hold only up to isomorphism of pseudo-natural transformations, *i.e.* up to invertible modifications.

Lemma 2.4.11. *Let $\mathscr{A}, \mathscr{B}$ be two 2-categories, $F : \mathscr{A} \to \mathscr{B}$ a pseudo-functor, and $f : A \to B$ a 1-cell in $\mathscr{A}$. We have :*

(i) *If f admits a right adjoint g, then Ff admits the right adjoint Fg.*
(ii) *If f is an equivalence in $\mathscr{A}$, then Ff is an equivalence in $\mathscr{B}$, and if g is a quasi-inverse for f, then Fg is a quasi-inverse for Ff.*
(iii) *If F is fully faithful, then f is an equivalence if and only if Ff is an equivalence in $\mathscr{B}$.*

Proof. (i): Indeed, let $\varepsilon : f \circ g \Rightarrow \mathbf{1}_B$ and $\eta : \mathbf{1}_A \Rightarrow g \circ f$ be the unit and counit of an adjunction for the pair (f, g). We consider the 2-cells

$$\varepsilon' := \delta_B^{F\ -1} \odot F(\varepsilon) \odot \gamma^F_{g,f} : Ff \circ Fg \Rightarrow \mathbf{1}_{FB} \qquad \eta' := \gamma^{F\ -1}_{f,g} \odot F(\eta) \odot \delta^F_A : \mathbf{1}_{FA} \Rightarrow Fg \circ Ff$$

and we compute :

$$\begin{aligned}(Fg * F\varepsilon') \odot (F\eta' * Fg) &= (Fg * \delta^F_B)^{-1} \odot (Fg * F\varepsilon) \odot \gamma^{F\ -1}_{f\circ g, g} \odot \gamma^F_{g, g\circ f} \odot (F\eta * Fg) \odot (\delta^F_A * Fg) \\ &= (Fg * \delta^F_B)^{-1} \odot \gamma^{F\ -1}_{\mathbf{1}_B, g} \odot F(g * \varepsilon) \odot F(\eta * g) \odot \gamma^F_{g, \mathbf{1}_B} \odot (\delta^F_A * Fg) \\ &= \mathbf{1}_{Fg}.\end{aligned}$$

Likewise we check that $(F\varepsilon * Ff) \odot (Ff * F\eta) = \mathbf{1}_{Ff}$: the details are left to the reader.

(ii): It is clear from the proof of (i) that if ε and η are invertible 2-cells, the same holds for η' and ε', whence the contention.

(iii): Due to (ii), we may assume that Ff is an equivalence in $\mathscr{B}$, and we check that f is an equivalence in $\mathscr{A}$. To this aim, let $g : FB \to FA$ be a quasi-inverse for Ff, and $\eta : \mathbf{1}_{FB} \to Ff \circ g$ and $\varepsilon : g \circ Ff \Rightarrow \mathbf{1}_{FA}$ two invertible 2-cells. Since F_{AB} is an equivalence, we have a 1-cell $h : B \to A$ and an invertible 2-cell $\beta : Fh \Rightarrow g$, whence the invertible 2-cell

$$\begin{aligned}\varepsilon' &:= \delta^F_A \odot \varepsilon \odot (\beta * Ff) \odot \gamma^{F\ -1}_{f,h} : F(h \circ f) \Rightarrow F\mathbf{1}_A \\ \eta' &:= \eta' := 1\gamma^F_{h,f} \odot (Ff * \beta^{-1}) \odot \eta \odot \delta_B^{F\ -1} : F\mathbf{1}_B \Rightarrow F(f \circ h).\end{aligned}$$

Again, since F_{AB} is an equivalence, we deduce invertible 2-cells $\varepsilon'' : h \circ f \Rightarrow \mathbf{1}_A$ and $\eta'' : \mathbf{1}_B \Rightarrow f \circ h$ such that $F\varepsilon'' = \varepsilon'$ and $F\eta'' = \eta'$, whence the contention. □

Theorem 2.4.12. *Let $\mathscr{A}, \mathscr{B}$ be two 2-categories, $F, G : \mathscr{A} \to \mathscr{B}$ two pseudo-functors, and $\alpha : F \Rightarrow G$ a pseudo-natural transformation. The following conditions are equivalent :*

(a) *α is a pseudo-natural equivalence of pseudo-functors.*
(b) *The 1-cell $\alpha_A : FA \to GA$ is an equivalence in $\mathscr{B}$, for every $A \in \mathrm{Ob}(\mathscr{A})$.*

Proof. Let $\mathscr{A}^F$ be the 2-category associated with F as in proposition 2.4.6, together with the strict pseudo-functors $F^\flat : \mathscr{A}^F \to \mathscr{B}$ and $\pi^F : \mathscr{A}^F \to \mathscr{A}$, the pseudo-functor $\sigma^F : \mathscr{A} \to \mathscr{A}^F$ and the pseudo-natural isomorphism $\omega^F : F \circ \pi^F \xrightarrow{\sim} F^\flat$. Set $\alpha' := (\alpha * \pi^F) \odot \omega^{F\ -1} : F^\flat \Rightarrow G \circ \pi^F$, and suppose that there exists a pseudo-natural transformation $\beta' : G \circ \pi^F \Rightarrow F^\flat$ with invertible modifications $\Xi_1 : \mathbf{1}_{F^\flat} \rightsquigarrow \beta' \odot \alpha'$ and $\Xi_2 : \mathbf{1}_{G\circ\pi^F} \rightsquigarrow \alpha' \odot \beta'$. Then notice that $\alpha' * \sigma^F = \alpha$, and set $\beta := \beta' * \pi^F$; we deduce invertible modifications $\Xi_1 \circ \pi^F : \mathbf{1}_F \rightsquigarrow \beta \odot \alpha$ and $\Xi_2 \circ \pi^F : \mathbf{1}_G \rightsquigarrow \alpha \odot \beta$. Thus, we may replace $\mathscr{A}$, F, G and α by $\mathscr{A}^F$, $F^\flat$, $G \circ \pi^F$ and α', and assume from start that F is strict. Arguing likewise with $\mathscr{A}^G$ and $G^\flat$, we may then reduce to the case where both F and G are strict.

(b)⇒(a): Notice that the pseudo-functor $\widetilde{\alpha} : \mathscr{A} \to \text{2-}\mathsf{Morph}(\mathscr{B})$ associated with α (see remark 2.2.5(ii)) factors through the inclusion pseudo-functor $\mathsf{Equiv}(\mathscr{B}) \to \text{2-}\mathsf{Morph}(\mathscr{B})$ (notation of (2.3.25)); then define $\widetilde{\beta}$ as the composition

$$\mathscr{A} \xrightarrow{\widetilde{\alpha}} \mathsf{Equiv}(\mathscr{B}) \xrightarrow{\widetilde{\Upsilon}} \mathsf{Equiv}(\mathscr{B})$$

(notation of (2.3.27)). Notice as well that the coherence constraints of $\widetilde{\Upsilon}$ are given by identities, and $\widetilde{\alpha}$ is strict (since F and G are strict), therefore the coherence constraints of $\widetilde{\beta}$ are given as well by identities, so $\widetilde{\beta}$ is strict. Furthermore, a simple inspection shows that $\mathsf{s} \circ \widetilde{\beta} = G$ and $\mathsf{t} \circ \widetilde{\beta} = F$, where s and t are the restrictions to $\mathsf{Equiv}(\mathscr{A})$ of the source and target pseudo-functors of remark 2.1.18(ii). We conclude that $\widetilde{\beta}$ is the pseudo-functor associated as in remark 2.2.5(ii) with a pseudo-natural transformation $\beta : G \Rightarrow F$. We can describe the coherence constraint τ^β of β as follows. Let τ^α be the coherence constraint of α, which assigns to every 1-cell $f : A \to B$ of $\mathscr{A}$ the oriented square τ^α_f as in remark 2.2.5(i). Recall that the pseudo-functor L of (2.3.25) assigns to every 1-cell $g : X \to Y$ of $\mathscr{B}$ a link $\mathsf{L}(g) := (g^\dagger, g, \eta^g, \varepsilon^g) : X \to Y$; then τ^α_f yields the 1-cell $\mathsf{L}(\tau^\alpha_f) : \mathsf{L}(\alpha_A) \to \mathsf{L}(\alpha_B)$ in the 2-category $\mathsf{wLink}(\mathscr{B})$. With this notation, we have $\beta_A := (\alpha_A)^\dagger$ for every $A \in \mathrm{Ob}(\mathscr{A})$, and τ^β assigns to f the oriented square

$$\tau^\beta_f \quad : \quad \begin{array}{ccc} GA & \xrightarrow{\ \beta_A\ } & FA \\ {\scriptstyle Gf}\downarrow & \swArrow \Upsilon(\mathsf{L}(\tau^\alpha_f))^{-1} & \downarrow{\scriptstyle Ff} \\ GB & \xrightarrow[\ \beta_B\ ]{} & FB. \end{array}$$

To conclude, it remains to check that the systems of 2-cells :

$$\lambda_A := (\varepsilon^{\alpha_A})^{-1} \qquad \text{and} \qquad \mu_A := (\eta^{\alpha_A})^{-1} \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A})$$

amount to two invertible modifications

$$\lambda_\bullet : \mathbf{1}_F \rightsquigarrow \beta \odot \alpha \qquad \mu_\bullet : \alpha \odot \beta \rightsquigarrow \mathbf{1}_G.$$

However, if $\tau^{\alpha\odot\beta}$ denotes the coherence constraint of $\alpha \odot \beta$, the compatibility condition for $\mu_\bullet$ comes down to the identity :

$$(2.4.13) \qquad (\mu_B * Gf) \odot \tau^{\alpha\odot\beta}_f = Gf * \mu_A \qquad \text{for every 1-cell } f : A \to B \text{ of } \mathscr{A}.$$

Let us then consider the diagram :

$$\begin{array}{ccccccccc}
GA & \xrightarrow{\beta_A} & FA & = & FA & = & FA & \xrightarrow{\alpha_A} & GA \\
\| & \swArrow \mathbf{1}_{\beta_A} & \| & \swArrow \mathbf{1}_{Ff} & \downarrow{\scriptstyle Ff} & \swArrow \mathbf{1}_{Ff} & \downarrow{\scriptstyle Ff} & \swArrow \tau^\alpha_f & \downarrow{\scriptstyle Gf} \\
GA & \xrightarrow{\beta_A} & FA & \xrightarrow{Ff} & FB & = & FB & \xrightarrow{\alpha_B} & GB \\
\| & \swArrow \mu_A & \downarrow{\scriptstyle \alpha_A} & \swArrow \mathsf{L}(\tau^\alpha_f)^{-1} & \downarrow{\scriptstyle \alpha_B} & \swArrow \lambda_B & \| & \swArrow \mathbf{1}_{\alpha_B} & \| \\
GA & = & GA & \xrightarrow{Gf} & GB & \xrightarrow{\beta_B} & FB & \xrightarrow{\alpha_B} & GB \\
{\scriptstyle Gf}\downarrow & \swArrow \mathbf{1}_{Gf} & \downarrow{\scriptstyle Gf} & \swArrow \mathbf{1}_{Gf} & \| & \swArrow \mu_B & \downarrow{\scriptstyle \alpha_B} & \swArrow \mathbf{1}_{\alpha_B} & \| \\
GB & = & GB & = & GB & = & GB & = & GB.
\end{array}$$

We see that the composition of the squares of the top row equals $\tau^\alpha_f * \beta_A$, and the composition of the squares of the middle row equals $\alpha_B * \tau^\beta_f$. Hence the composition of the squares of the top and middle rows equals $\tau^{\alpha\odot\beta}_f$, and by further composing with the squares of the bottom row we get the left hand-side of (2.4.13). On the other hand, by proposition 2.1.9 we can also compose the squares column by column : then notice that the composition of the squares in the third column from the left equals the identity of $\alpha_B \circ Ff$. Thus, we may disregard this column, and then notice that the composition of the squares of the second column equals the inverse of the composition of the squares of the fourth column. So we may disregard all columns except the first from the left; but the composition of the squares of the latter equals the right-hand side of (2.4.13), as required. The verification for $\lambda_\bullet$ is similar, and shall be left to the reader.

(a)⇒(b) is immediate from the definitions. □

Corollary 2.4.14. *Let $\mathscr{A}, \mathscr{B}$ be two 2-categories, $F, F' : \mathscr{A} \to \mathscr{B}$ two pseudo-functors, and $\alpha : F \Rightarrow F'$ a pseudo-natural equivalence. We have :*

(i) *For every* 2*-category* $\mathscr{A}'$ *and every pseudo-functor* $G : \mathscr{A}' \to \mathscr{A}$*, the composition* $\alpha * G : F \circ G \Rightarrow F' \circ G$ *is a pseudo-natural equivalence (notation of remark* 2.2.5(iv)*).*
(ii) *For every* 2*-category* $\mathscr{B}'$ *and every pseudo-functor* $H : \mathscr{B} \to \mathscr{B}'$*, the composition* $H * \alpha : H \circ F \Rightarrow H \circ F'$ *is a pseudo-natural equivalence.*
(iii) *If* $F' : \mathscr{A} \to \mathscr{B}$ *is any other pseudo-functor, and* $\alpha' : F' \Rightarrow F''$ *any other pseudo-natural equivalence, then the composition* $\alpha' \odot \alpha : F \Rightarrow F''$ *is a pseudo-natural equivalence as well (notation of remark* 2.2.5(iii)*).*

Proof. Assertions (i) and (ii) follow immediately from theorem 2.4.12 and lemma 2.4.11(ii). Assertion (iii) follows from theorem 2.4.12 and lemma 2.1.4(ii) : details left to the reader. □

Definition 2.4.15. Let $\mathscr{A}$, $\mathscr{B}$ be two 2-categories, $F : \mathscr{A} \to \mathscr{B}$, $G : \mathscr{B} \to \mathscr{A}$ two pseudo-functors. We say that G is a *right* 2*-adjoint to* F (resp. a *strong right* 2*-adjoint to* F) if there exists a pseudo-natural equivalence (resp. a pseudo-natural isomorphism) of pseudo-functors

$$\vartheta : H_{\mathscr{B}}(F, \mathbf{1}_{\mathscr{B}}) \Rightarrow H_{\mathscr{A}}(\mathbf{1}_{\mathscr{A}}, G)$$

(definition 2.4.9(i)). In this case, we say that (F, G) is a 2*-adjoint pair* (resp. a *strong* 2*-adjoint pair*) of pseudo-functors, and ϑ is a 2*-adjunction* (resp. a *strong* 2*-adjunction*) for (F, G).

Remark 2.4.16. According to theorem 2.4.12 and remark 2.2.5(i), the datum of a 2-adjunction as in definition 2.4.15 is equivalent to that of :

- a system of equivalences of categories

$$\vartheta_{AB} : \mathscr{B}(FA, B) \to \mathscr{A}(A, GB) \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A}) \text{ and } B \in \mathrm{Ob}(\mathscr{B})$$

- and for every pair of 1-cells $f : A' \to A$ in $\mathscr{A}$, $g : B \to B'$ in $\mathscr{B}$, a natural isomorphism of functors

$$\begin{array}{ccc} \mathscr{B}(FA, B) & \xrightarrow{\vartheta_{AB}} & \mathscr{A}(A, GB) \\ {\scriptstyle \mathscr{B}(Ff,g)}\downarrow & \swarrow \tau^{\vartheta}_{(f,g)} & \downarrow{\scriptstyle \mathscr{A}(f,Gg)} \\ \mathscr{B}(FA', B') & \xrightarrow[\vartheta_{A'B'}]{} & \mathscr{A}(A', GB') \end{array}$$

- such that, for every 2-cells $\beta : f \Rightarrow f'$ in $\mathscr{A}$ and $\lambda : g \Rightarrow g'$ in $\mathscr{B}$, we have the identity

$$\tau^{\vartheta}_{(f,g)} \boxminus H_{\mathscr{B}}(F\beta, \lambda) = H_{\mathscr{A}}(\beta, G\lambda) \boxminus \tau^{\vartheta}_{(f',g')} \tag{2.4.17}$$

- and for every composable pairs of 1-cells $A'' \xrightarrow{f'} A' \xrightarrow{f} A$ in $\mathscr{A}$, and $B \xrightarrow{g} B' \xrightarrow{g'} B''$ in $\mathscr{B}$, we have the identities

$$(\tau^{\vartheta}_{(f',g')} \boxdot \tau^{\vartheta}_{(f,g)}) \boxminus H_{\mathscr{B}}(\gamma^F_{f',f}, \mathbf{1}_{g' \circ g}) = H_{\mathscr{A}}(\mathbf{1}_{f \circ f'}, \gamma^G_{g,g'}) \boxminus \tau^{\vartheta}_{(f \circ f', g' \circ g)}$$
$$H_{\mathscr{A}}(i_A, \delta^G_B) \boxminus \tau^{\vartheta}_{(\mathbf{1}_A, \mathbf{1}_B)} = \mathbf{1}_{\vartheta_{AB}} \boxminus H_{\mathscr{B}}(\delta^F_A, i_B)$$

where (δ^F, γ^F) (resp. (δ^G, γ^G)) denote by coherence constraint for F (resp. for G).

We wish to attach to every 2-adjunction suitable units and counits, as for usual adjoint pairs of functors; we shall see that the triangular identities will have to be replaced by certain invertible modifications. We begin with a few auxiliary lemmata :

Lemma 2.4.18. *Let* $\mathscr{A}$,$\mathscr{B}$ *be any two* 2*-categories,* $F, F' : \mathscr{A} \to \mathscr{B}$ *two strict pseudo-functors,* $\beta : F \Rightarrow F'$ *a pseudo-natural transformation. We have :*

(i) F *induces a strict pseudo-natural transformation (notation of example* 2.2.7(ii)*) :*

$$H_F : H_{\mathscr{A}} \Rightarrow H_{\mathscr{B}}(F, F) \qquad (A, A') \mapsto (F_{AA'} : \mathscr{A}(A, A') \to \mathscr{B}(FA, FA')).$$

(ii) *The coherence constraint τ^β of β induces an invertible modification*

$$H_\beta : H_{\mathscr{B}}(\beta, \mathbf{1}_{F'}) \odot H_{F'} \rightsquigarrow H_{\mathscr{B}}(\mathbf{1}_F, \beta) \odot H_F$$

that assigns to every object (A_1, A_2) of $\mathscr{A}^o \times \mathscr{A}$ the natural transformation

$$\tau^\beta_{A_1A_2} : H_{\mathscr{B}}(\beta_{A_1}, \mathbf{1}_{F'A_2}) \circ F'_{A_1A_2} \Rightarrow H_{\mathscr{B}}(\mathbf{1}_{FA_1}, \beta_{A_2}) \circ F_{A_1A_2}.$$

(iii) *If F is fully faithful, H_F is a pseudo-natural equivalence.*

Proof. Assertion (i) is straightforward, and (iii) follows immediately from theorem 2.4.12.

(ii): For every 1-cell $(f_1, f_2) : (A_1, A_2) \to (A'_1, A'_2)$ of $\mathscr{A}^o \times \mathscr{A}$ we consider the diagrams

$$\begin{array}{ccccc}
\mathscr{A}(A_1, A_2) & \xrightarrow{H_{F'}} & \mathscr{B}(F'A_1, F'A_2) & \xrightarrow{\mathscr{B}(\beta_{A_1}, \mathbf{1}_{F'A_2})} & \mathscr{B}(FA_1, F'A_2) \\
{\scriptstyle \mathscr{A}(f_1,f_2)}\downarrow & \Downarrow \mathbf{1} & \downarrow{\scriptstyle \mathscr{B}(F'f_1, F'f_2)} & \Downarrow \mathscr{B}((\tau^\beta_{f_1})^{-1}, \mathbf{1}_{F'f_2}) & \downarrow{\scriptstyle \mathscr{B}(Ff_1, F'f_2)} \\
\mathscr{A}(A'_1, A'_2) & \xrightarrow[H_{F'}]{} & \mathscr{B}(F'A'_1, F'A'_2) & \xrightarrow[\mathscr{B}(\beta_{A'_1}, \mathbf{1}_{F'A'_2})]{} & \mathscr{B}(FA'_1, F'A'_2) \\
\| & & \Downarrow \tau^\beta_{A'_1A'_2} & & \| \\
\mathscr{A}(A'_1, A'_2) & \xrightarrow[H_F]{} & \mathscr{B}(FA'_1, FA'_2) & \xrightarrow[\mathscr{B}(\mathbf{1}_{FA'_1}, \beta_{A_2})]{} & \mathscr{B}(FA'_1, F'A'_2)
\end{array}$$

$$\begin{array}{ccccc}
\mathscr{A}(A_1, A_2) & \xrightarrow{H_{F'}} & \mathscr{B}(F'A_1, F'A_2) & \xrightarrow{\mathscr{B}(\beta_{A_1}, \mathbf{1}_{F'A_2})} & \mathscr{B}(FA_1, F'A_2) \\
\| & & \Downarrow \tau^\beta_{A_1A_2} & & \| \\
\mathscr{A}(A_1, A_2) & \xrightarrow{H_F} & \mathscr{B}(FA_1, FA_2) & \xrightarrow{\mathscr{B}(\mathbf{1}_{FA_1}, \beta_{A_2})} & \mathscr{B}(FA_1, F'A_2) \\
{\scriptstyle \mathscr{A}(f_1,f_2)}\downarrow & \Downarrow \mathbf{1} & \downarrow{\scriptstyle \mathscr{B}(Ff_1, Ff_2)} & \Downarrow \mathscr{B}(\mathbf{1}_{Ff_1}, \tau^\beta_{f_2}) & \downarrow{\scriptstyle \mathscr{B}(Ff_1, F'f_2)} \\
\mathscr{A}(A'_1, A'_2) & \xrightarrow[H_F]{} & \mathscr{B}(FA'_1, FA'_2) & \xrightarrow[\mathscr{B}(\mathbf{1}_{FA'_1}, \beta_{A'_2})]{} & \mathscr{B}(FA'_1, F'A'_2)
\end{array}$$

and notice that the coherence constraint of $H_{\mathscr{B}}(\beta, \mathbf{1}_{F'}) \odot H_{F'}$ is given by the compositions of oriented squares on the top row of the first diagram (see example 2.2.6). Likewise, the coherence constraint of $H_{\mathscr{B}}(\mathbf{1}_F, \beta) \odot H_F$ is given by the composition of the oriented squares on the bottom row of the second diagram. Therefore, we come down to checking that the composition of the oriented squares of the first diagram equals the composition of the oriented squares of the second diagram. The latter translates as the identity :

$$\tau^\beta_{f_2 \circ t \circ f_1} \odot (F'(f_2 \circ t) * \tau^{\beta\,-1}_{f_1}) = (\tau^\beta_{f_2} * F(t \circ f_1)) \odot (F'f_2 * \tau^\beta_t * Ff_1)$$

for every 1-cell $t : A_1 \to A_2$ in $\mathscr{A}$. However, the coherence axiom for β yields the identities :

$$\begin{aligned}
(\tau^\beta_t * Ff_1) \odot (F't * \tau^\beta_{f_1}) &= \tau^\beta_{t \circ f_1} \\
(\tau^\beta_{f_2} * F(t \circ f_1)) \odot (F'f_2 * \tau^\beta_{t \circ f_1}) &= \tau^\beta_{f_2 \circ t \circ f_1}.
\end{aligned}$$

The sought identity is an immediate consequence. □

2.4.19. Conversely, consider now two strict pseudo-functors $F, G : \mathscr{A} \to \mathscr{B}$, and a pseudo-natural transformation $\lambda : H_{\mathscr{A}} \Rightarrow H_{\mathscr{B}}(F, G)$ with coherence constraint $\tau_\bullet$. We set

$$\lambda^\vee_A := \lambda_{(A,A)}(\mathbf{1}_A) : FA \to GA \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A})$$

and for every 1-cell $f : A \to A'$ in $\mathscr{A}$ we let

$$\tau^\vee_f : Gf \circ \lambda^\vee_A \Rightarrow \lambda^\vee_{A'} \circ Ff$$

be the unique 2-cell of $\mathscr{B}$ that fits into the commutative diagram

$$\begin{array}{ccccc} Gf \circ \lambda^\vee_A & & \xRightarrow{\tau^\vee_f} & & \lambda^\vee_{A'} \circ Ff \\ \| & & & & \| \\ Gf \circ \lambda^\vee_A \circ F\mathbf{1}_A & \xRightarrow{\tau_{(\mathbf{1}_A,f),\mathbf{1}_A}} & \lambda_{(A,A')}(f) & \xLeftarrow{\tau_{(f,\mathbf{1}_{A'}),\mathbf{1}_{A'}}} & G\mathbf{1}_{A'} \circ \lambda^\vee_{A'} \circ Ff. \end{array}$$

Lemma 2.4.20. *With the notation of* (2.4.19)*, the following holds :*

(i) *The system of* 1*-cells* $(\lambda^\vee_A \mid A \in \mathrm{Ob}(\mathscr{A}))$ *defines a pseudo-natural transformation*

$$\lambda^\vee : F \Rightarrow G$$

with coherence constraint given by the system of 2*-cells* $\tau^\vee_\bullet$.

(ii) $H^\vee_F = \mathbf{1}_F$.

(iii) *Let* $\mu : H_{\mathscr{A}} \Rightarrow H_{\mathscr{B}}(F,G)$ *be another pseudo-natural transformations, and* $\Theta : \lambda \rightsquigarrow \mu$ *any modification. Then we have a modification* $\Theta^\vee : \lambda^\vee \rightsquigarrow \mu^\vee$ *given by the rule :*

$$A \mapsto (\Theta^\vee_A := \Theta_{(A,A),\mathbf{1}_A} : \lambda^\vee_A \Rightarrow \mu^\vee_A) \qquad \textit{for every } A \in \mathrm{Ob}(\mathscr{A}).$$

Proof. (i): Let $f, f' : A \to A'$ be two 1-cells in $\mathscr{A}$; the naturality of $\tau^\vee_\bullet$ amounts to the commutativity of the diagram

$$\begin{array}{ccccc} Gf \circ \lambda^\vee_A & \xRightarrow{\tau_{(\mathbf{1}_A,f),\mathbf{1}_A}} & \lambda_{(A,A')}(f) & \xLeftarrow{\tau_{(f,\mathbf{1}_{A'}),\mathbf{1}_{A'}}} & \lambda^\vee_{A'} \circ Ff \\ {\scriptstyle G\alpha * \lambda^\vee_A}\Downarrow & & \Downarrow{\scriptstyle \lambda_{(A,A')}(\alpha)} & & \Downarrow{\scriptstyle \lambda^\vee_{A'} * F\alpha} \\ Gf' \circ \lambda^\vee_A & \xRightarrow{\tau_{(\mathbf{1}_A,f'),\mathbf{1}_A}} & \lambda_{(A,A')}(f') & \xLeftarrow{\tau_{(f',\mathbf{1}_{A'}),\mathbf{1}_{A'}}} & \lambda^\vee_{A'} \circ Ff' \end{array}$$

for every 2-cell $\alpha : f \Rightarrow f'$ in $\mathscr{A}$. However, the commutativity of the two square subdiagrams follows by applying the naturality of τ to the 2-cells (i_A, α) and $(\alpha, i_{A'})$ of $\mathscr{A}^o \times \mathscr{A}$.

Let us check the coherence axioms for $\tau^\vee_\bullet$. First, since F and G are strict, we need to show :

$$\tau^\vee_{\mathbf{1}_A} = \mathbf{1}_{\lambda^\vee_A} \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A})$$

which follows by a simple inspection. Next, let $A \xrightarrow{f} A' \xrightarrow{g} A''$ be a composable pair of 1-cell of $\mathscr{A}$; we need to show that

$$(\tau^\vee_g * Ff) \odot (Gg * \tau^\vee_f) = \tau^\vee_{g \circ f}.$$

Now, the coherence axiom for $\tau_\bullet$ yields the identity

$$\tau_{(\mathbf{1}_A,g),f} \odot (Gg * \tau_{(\mathbf{1}_A,f),\mathbf{1}_A}) = \tau_{(\mathbf{1}_A,g\circ f),\mathbf{1}_A}.$$

Hence we are reduced to showing that

$$(\tau^\vee_g * Ff) \odot (Gg * \tau^{-1}_{(f,\mathbf{1}_{A'}),\mathbf{1}_{A'}}) = \tau^{-1}_{(g\circ f,\mathbf{1}_{A''}),\mathbf{1}_{A''}} \odot \tau_{(\mathbf{1}_A,g),f}.$$

Next, again by the coherence axiom for $\tau_\bullet$ we see that

$$\tau_{(g\circ f,\mathbf{1}_{A''}),\mathbf{1}_{A''}} = \tau_{(f,\mathbf{1}_{A''}),g} \odot (\tau_{(g,\mathbf{1}_{A''}),\mathbf{1}_{A''}} * Ff).$$

Hence we are further reduced to checking the identity :

$$\tau_{(f,\mathbf{1}_{A''}),g} \odot (\tau_{(\mathbf{1}_{A'},g),\mathbf{1}_{A'}} * Ff) = \tau_{(\mathbf{1}_A,g),f} \odot (Gg * \tau_{(f,\mathbf{1}_{A'}),\mathbf{1}_{A'}}). \tag{2.4.21}$$

However, applying twice the coherence axiom for $\tau_\bullet$ to the identities in $\mathscr{A}^o \times \mathscr{A}$:

$$(f, \mathbf{1}_{A''}) \circ (\mathbf{1}_{A'}, g) = (f, g) = (\mathbf{1}_A, g) \circ (f, \mathbf{1}_{A'})$$

we see that both sides of (2.4.21) equal $\tau_{(f,g),\mathbf{1}_{A'}}$.

(ii) follows by a direct inspection of the definitions.

(iii): The assertion follows from the commutativity of the diagram :

$$\begin{array}{ccccc} Gf\circ\lambda^\vee_A & \xrightarrow{\tau^\lambda_{(\mathbf{1}_A,f),\mathbf{1}_A}} & \lambda_{(A,A')}(f) & \xleftarrow{\tau^\lambda_{(f,\mathbf{1}_{A'}),\mathbf{1}_{A'}}} & \lambda^\vee_{A'}\circ Ff. \\ {\scriptstyle Gf*\Theta^\vee_A}\Downarrow & & {\scriptstyle \Theta_{(A,A'),f}}\Downarrow & & \Downarrow{\scriptstyle \Theta^\vee_{A'}*Ff} \\ Gf\circ\mu^\vee_A & \xrightarrow{\tau^\mu_{(\mathbf{1}_A,f),\mathbf{1}_A}} & \mu_{(A,A')}(f) & \xleftarrow{\tau^\mu_{(f,\mathbf{1}_{A'}),\mathbf{1}_{A'}}} & \mu^\vee_{A'}\circ Ff \end{array}$$

which in turn follows directly from the definition of Θ. □

2.4.22. Let now $F:\mathscr{A}\to\mathscr{B}$ be a pseudo-functor, and $G:\mathscr{B}\to\mathscr{A}$ a right 2-adjoint for F, and ϑ a 2-adjunction for the pair (F,G) as in definition 2.4.15. We suppose moreover that F and G are strict; by lemma 2.1.13(i) we may find a pseudo-natural equivalence

$$\psi : H_{\mathscr{A}}(\mathbf{1}_{\mathscr{A}},G)\Rightarrow H_{\mathscr{B}}(F,\mathbf{1}_{\mathscr{B}})$$

as well as invertible modifications

$$\Xi:\mathbf{1}_{H_{\mathscr{B}}(F,\mathbf{1}_{\mathscr{B}})}\rightsquigarrow\psi\odot\vartheta \qquad \Theta:\vartheta\odot\psi\rightsquigarrow\mathbf{1}_{H_{\mathscr{A}}(\mathbf{1}_{\mathscr{A}},G)}$$

such that

$$(\psi*\Theta)\odot(\Xi*\psi)=\mathbf{1}_\psi \qquad\text{and}\qquad (\Theta*\vartheta)\odot(\vartheta*\Xi)=\mathbf{1}_\vartheta.$$

To ease notation, we shall drop the subscripts when referring to $\vartheta_{AB}(h)$ or $\vartheta_{AB}(\mu)$ for any 1-cell $h:FA\to B$ or 2-cell $\mu:h\Rightarrow h'$ in $\mathscr{B}$, and write simply $\vartheta(h)$ and $\vartheta(\mu)$. Likewise, we shall write simply $\psi(k)$ and $\psi(\nu)$ for any 1-cell $k:A\to GB$ and any 2-cell $\nu:k\Rightarrow k'$ in $\mathscr{A}$. Now, for every $A\in\mathrm{Ob}(\mathscr{A})$ and $B\in\mathrm{Ob}(\mathscr{B})$ let us set

$$\eta_A:=\vartheta(\mathbf{1}_{FA}):A\to GFA \qquad \varepsilon_B:=\psi(\mathbf{1}_{GB}):FGB\to B.$$

For every 1-cell $f:A\to A'$ in $\mathscr{A}$, and every 1-cell $g:B\to B'$ in $\mathscr{B}$ we let

$$\tau^\eta_f:GFf\circ\eta_A\Rightarrow\eta_{A'}\circ f \qquad\text{and}\qquad \tau^\varepsilon_g:g\circ\varepsilon_B\Rightarrow\varepsilon_{B'}\circ FGg$$

be the unique 2-cells in $\mathscr{A}$ and respectively in $\mathscr{B}$ that make commute the diagrams :

$$\begin{array}{ccc} GFf\circ\eta_A & \xRightarrow{\tau^\eta_f} & \eta_{A'}\circ f \\ {\scriptstyle\tau^\vartheta_{(\mathbf{1}_A,Ff),\mathbf{1}_{FA}}}\searrow & & \swarrow{\scriptstyle\tau^\vartheta_{(f,\mathbf{1}_{FA'}),\mathbf{1}_{FA'}}} \\ & \vartheta(Ff) & \end{array} \qquad \begin{array}{ccc} g\circ\varepsilon_B & \xRightarrow{\tau^\varepsilon_g} & \varepsilon_{B'}\circ FGg \\ {\scriptstyle\tau^\psi_{(\mathbf{1}_{GB},g),\mathbf{1}_{GB}}}\searrow & & \swarrow{\scriptstyle\tau^\psi_{(Gg,\mathbf{1}_{B'}),\mathbf{1}_{GB'}}} \\ & \psi(Gg) & \end{array}$$

where, as usual, τ^ψ denotes the coherence constraint of ψ.

Lemma 2.4.23. *With the notation of* (2.4.22)*, we have :*

(i) *The system* $(\eta_A\mid A\in\mathrm{Ob}(\mathscr{A}))$ *defines a pseudo-natural transformation*

$$\eta:\mathbf{1}_{\mathscr{A}}\Rightarrow GF$$

whose coherence constraint is given by the system of 2*-cells* $\tau^\eta_\bullet$.

(ii) *The system* $(\varepsilon_B\mid B\in\mathrm{Ob}(\mathscr{B}))$ *defines a pseudo-natural transformation*

$$\varepsilon:FG\Rightarrow\mathbf{1}_{\mathscr{B}}$$

whose coherence constraint is given by the system of 2*-cells* $\tau^\varepsilon_\bullet$.

Proof. (i): Define the pseudo-natural transformation $H_F:H_{\mathscr{A}}\Rightarrow H_{\mathscr{B}}(F,F)$ as in lemma 2.4.18(i), and set

$$\lambda:=(\vartheta*(\mathbf{1}_{\mathscr{A}^o}\times F))\odot H_F:H_{\mathscr{A}}\Rightarrow H_{\mathscr{A}}(\mathbf{1}_{\mathscr{A}},G\circ F).$$

Lemma 2.4.20(i) yields a pseudo-natural transformation

$$\lambda^\vee:\mathbf{1}_{\mathscr{A}}\Rightarrow G\circ F$$

and it is easily seen that $\lambda^\vee_A = \eta_A$ for every $A \in \mathrm{Ob}(\mathscr{A})$. It remains to check that τ^η agrees with the coherence constraint $\tau^{\lambda^\vee}$ of $\lambda^\vee$. However, denote by τ^λ, τ^{H_F} and $\tau^{\vartheta*(\mathbf{1}_\mathscr{A}\times F)}$ the coherence constraints of respectively λ, H_F and $\vartheta * (\mathbf{1}_\mathscr{A} \times F)$; by inspecting the definitions we find that

$$\tau^\lambda_{(\mathbf{1}_A,f),\mathbf{1}_A} = (\vartheta * (\mathbf{1}_\mathscr{A} \times F))_{A,A'}(\tau^{H_F}_{(\mathbf{1}_A,f),\mathbf{1}_A}) \odot \tau^{\vartheta*(\mathbf{1}_\mathscr{A}\times F)}_{(\mathbf{1}_A,f),\mathbf{1}_{FA}} = \tau^\vartheta_{(\mathbf{1}_A,Ff),\mathbf{1}_{FA}}$$

and likewise : $\tau^\lambda_{(f,\mathbf{1}_{A'}),\mathbf{1}_{A'}} = \tau^\vartheta_{(f,\mathbf{1}_{FA'}),\mathbf{1}_{FA'}}$. The assertion follows.

(ii): A similar calculation shows that $\varepsilon = ((\psi * (G \times \mathbf{1}_\mathscr{B})) \odot H_G)^\vee$. □

We now turn to the case of an arbitrary 2-adjoint pair of pseudo-functors :

Theorem 2.4.24. *Let $F : \mathscr{A} \to \mathscr{B}$ and $G : \mathscr{B} \to \mathscr{A}$ be two pseudo-functors. We have :*

(i) *If (F, G) is a 2-adjoint pair, there exist pseudo-natural transformations*

$$\eta : \mathbf{1}_\mathscr{A} \Rightarrow GF \qquad \varepsilon : FG \Rightarrow \mathbf{1}_\mathscr{B}$$

related by a pair of invertible modifications

$$\Sigma : (G * \varepsilon) \odot (\eta * G) \rightsquigarrow \mathbf{1}_G \qquad \Sigma' : (\varepsilon * F) \odot (F * \eta) \rightsquigarrow \mathbf{1}_F.$$

We call η a unit *and ε a* counit *for the 2-adjunction ϑ, and Σ and Σ' the* triangular modifications *associated with (η, ε).*

(ii) *Conversely, the existence of pseudo-natural transformations ε, η and invertible modifications Σ, Σ' as in* (i)*, implies that G is right 2-adjoint to F.*

Proof. After replacing U by a larger universe, we may assume that $\mathscr{A}$ and $\mathscr{B}$ are small; in this case, let us remark that the existence of pseudo-natural transformations η and ε related by triangular modifications as in (i) means precisely that (F, G) is an adjoint pair of 1-cells of the 2-category $\overline{2\text{-}\mathbf{Cat}}$ of remark 2.2.16.

Claim 2.4.25. We may assume that F and G are unital pseudo-functors.

Proof of the claim. Let F^u and G^u be the unital pseudo-functors associated with F and G, with pseudo-natural isomorphisms $\alpha^F : F \Rightarrow F^u$ and $\alpha^G : G \Rightarrow G^u$, as in proposition 2.4.3. If ϑ is a 2-adjunction for (F, G), we get a unique pseudo-natural equivalence ϑ^* fitting into the commutative diagram :

$$\begin{array}{ccc} H_\mathscr{B}(F, \mathbf{1}_\mathscr{B}) & \stackrel{\vartheta}{\Longrightarrow} & H_\mathscr{A}(\mathbf{1}_\mathscr{A}, G) \\ {\scriptstyle H_\mathscr{B}(\alpha^F, i_\mathscr{B})}\Downarrow & & \Downarrow{\scriptstyle H_\mathscr{A}(i_\mathscr{A}, \alpha^G)} \\ H_\mathscr{B}(F^u, \mathbf{1}_\mathscr{B}) & \stackrel{\vartheta^*}{\Longrightarrow} & H_\mathscr{A}(\mathbf{1}_\mathscr{A}, G^u) \end{array}$$

(notation of example 2.2.7(ii); here $i_\mathscr{A}$ is the identity transformation of the pseudo-functor $\mathbf{1}_\mathscr{A}$, and likewise for $i_\mathscr{B}$). Then ϑ^* is a 2-adjunction for the pair (F^u, G^u). By the same token, from a given 2-adjunction for the pair (F^u, G^u) we easily deduce a 2-adjunction for (F, G). Also, (F, G) is an adjoint pair of 1-cells in $\overline{2\text{-}\mathbf{Cat}}$ if and only if the same holds for the pair (F^u, G^u) (remark 2.1.4(iv)). Thus, it suffices to show the theorem for F^u and G^u. ◊

Thus, henceforth we assume that F and G are unital. Next we consider the 2-categories $\mathscr{A}^{F,G}$ and $\mathscr{B}^{G,F}$ of proposition 2.4.7, as well as the strict pseudo-functors $F^\flat, G^\flat, \pi^{F,G}$ and $\pi^{G,F}$, the pseudo-functors $\sigma^{F,G}$ and $\sigma^{G,F}$, and the isomorphisms of pseudo-functors

$$\psi^{F,G} : \sigma^{F,G} \circ \pi^{F,G} \xrightarrow{\sim} \mathbf{1}_{\mathscr{A}^{F,G}} \qquad \psi^{G,F} : \sigma^{G,F} \circ \pi^{G,F} \xrightarrow{\sim} \mathbf{1}_{\mathscr{B}^{G,F}}.$$

Claim 2.4.26. $\pi^{F,G}$ and $\pi^{G,F}$ are 2-equivalences.

Proof of the claim. Since $\pi^{F,G}$ is the identity on objects, it suffices to check that it is fully faithful. The latter is clear, since $\pi^{F,G} \circ \sigma^{F,G} = \mathbf{1}_\mathscr{A}$ and $\sigma^{F,G} \circ \pi^{F,G}$ is isomorphic to $\mathbf{1}_{\mathscr{A}^{F,G}}$ (details left to the reader). The same argument applies to $\pi^{G,F}$. ◊

Claim 2.4.27. We may assume that F and G are strict pseudo-functors.

Proof of the claim. Let $\vartheta : H_{\mathscr{B}}(F, \mathbf{1}_{\mathscr{B}}) \stackrel{\sim}{\to} H_{\mathscr{A}}(\mathbf{1}_{\mathscr{A}}, G)$ be a 2-adjunction for the pair (F, G). By claim 2.4.26 and lemma 2.4.18(iii), $\pi^{F,G}$ and $\pi^{G,F}$ induce pseudo-natural equivalences

$$H_{\pi^{F,G}} : H_{\mathscr{A}^{F,G}} \stackrel{\sim}{\to} H_{\mathscr{A}}(\pi^{F,G}, \pi^{F,G}) \qquad \text{and} \qquad H_{\pi^{G,F}} : H_{\mathscr{B}^{G,F}} \stackrel{\sim}{\to} H_{\mathscr{B}}(\pi^{G,F}, \pi^{G,F}).$$

Then we may find a pseudo-natural equivalence $\vartheta^\flat : H_{\mathscr{B}^{G,F}}(F^\flat, \mathbf{1}_{\mathscr{B}^{G,F}}) \stackrel{\sim}{\to} H_{\mathscr{A}^{F,G}}(\mathbf{1}_{\mathscr{A}^{F,G}}, G^\flat)$ fitting into the essentially commutative diagram of pseudo-functors :

$$\begin{array}{ccc}
H_{\mathscr{B}^{G,F}}(F^\flat, \mathbf{1}_{\mathscr{B}^{G,F}}) & \xrightarrow{\quad \vartheta^\flat \quad} & H_{\mathscr{A}^{F,G}}(\mathbf{1}_{\mathscr{A}^{F,G}}, G^\flat) \\
{\scriptstyle H_{\pi^{G,F}}*(F^{\flat o} \times \mathbf{1}_{\mathscr{B}^{G,F}})}\downarrow & & \downarrow{\scriptstyle H_{\pi^{F,G}}*(\mathbf{1}_{\mathscr{A}^{F,G}} \times G^\flat)} \\
H_{\mathscr{B}}(\pi^{G,F} \circ F^\flat, \pi^{G,F}) & & H_{\mathscr{A}}(\pi^{F,G}, \pi^{F,G} \circ G^\flat) \\
{\scriptstyle H_{\mathscr{B}}*(\omega^{F,G} \times \mathbf{1}_{\pi^{G,F}})}\downarrow & & \uparrow{\scriptstyle H_{\mathscr{A}}*(\mathbf{1}_{\pi^{F,G}} \times \omega^{G,F})} \\
H_{\mathscr{B}}(F \circ \pi^{F,G}, \pi^{G,F}) & \xrightarrow{\vartheta*(\pi^{F,G} \times \pi^{G,F})} & H_{\mathscr{A}}(\pi^{F,G}, G \circ \pi^{G,F}).
\end{array}$$

Conversely, if $\vartheta^\flat$ is a given 2-adjunction for the pair $(F^\flat, G^\flat)$, then we deduce a pseudo-natural equivalence ϑ fitting into the essentially commutative diagram :

$$\begin{array}{ccc}
H_{\mathscr{B}}(F, \mathbf{1}_{\mathscr{B}}) & \xrightarrow{\quad \vartheta \quad} & H_{\mathscr{A}}(\mathbf{1}_{\mathscr{A}}, G) \\
{\scriptstyle H_{\pi^{G,F}}*((\sigma^{G,F} \circ F)^o \times \sigma^{G,F})}\uparrow & & \uparrow{\scriptstyle H_{\pi^{F,G}}*(\sigma^{F,G} \times (\sigma^{F,G} \circ G))} \\
H_{\mathscr{B}^{G,F}}(\sigma^{G,F} \circ F, \sigma^{G,F}) & & H_{\mathscr{A}^{F,G}}(\sigma^{F,G}, \sigma^{F,G} \circ G) \\
\| & & \| \\
H_{\mathscr{B}^{G,F}}(F^\flat \circ \sigma^{F,G}, \sigma^{G,F}) & \xrightarrow{\vartheta^\flat*(\sigma^{F,G} \times \sigma^{G,F})} & H_{\mathscr{A}^{F,G}}(\sigma^{F,G}, G^\flat \circ \sigma^{G,F}).
\end{array}$$

Thus (F, G) is a 2-adjoint pair if and only if the same holds for $(F^\flat, G^\flat)$.

Likewise, if $\eta : \mathbf{1}_{\mathscr{A}} \Rightarrow GF$ and $\eta : FG \Rightarrow \mathbf{1}_{\mathscr{B}}$ are given pseudo-natural transformations fulfilling the triangular identities $(G * \varepsilon) \odot (\eta * G) = \mathbf{1}_G$ and $(\varepsilon * F) \odot (F * \eta) = \mathbf{1}_F$ in $\overline{\mathbf{2\text{-}Cat}}$, there follow pseudo-natural transformations :

$$\begin{array}{ccccc}
\eta^\flat : \mathbf{1}_{\mathscr{A}^{F,G}} & \xRightarrow{\psi^{F,G\,-1}} & \sigma^{F,G} \circ \pi^{F,G} & \xRightarrow{\sigma^{F,G}*\eta*\pi^{F,G}} & \sigma^{F,G} \circ GF \circ \pi^{F,G} \\
 & & & & \| \\
G^\flat F^\flat & \xLeftarrow{G^\flat F^\flat * \psi^{F,G}} & G^\flat F^\flat \circ \sigma^{F,G} \circ \pi^{F,G} & = & G^\flat \circ \sigma^{G,F} \circ F \circ \pi^{F,G} \\
\varepsilon^\flat : F^\flat G^\flat & \xRightarrow{F^\flat G^\flat * \psi^{G,F\,-1}} & F^\flat G^\flat \circ \sigma^{G,F} \circ \pi^{G,F} & = & F^\flat \circ \sigma^{F,G} \circ G \circ \pi^{G,F} \\
 & & & & \| \\
\mathbf{1}_{\mathscr{B}^{F,G}} & \xLeftarrow[\psi^{G,F}]{} & \sigma^{G,F} \circ \pi^{G,F} & \xLeftarrow[\sigma^{G,F}*\varepsilon*\pi^{G,F}]{} & \sigma^{G,F} \circ FG \circ \pi^{G,F}
\end{array}$$

Set $X := G^\flat * \psi^{G,F}$ and $Y := \psi^{F,G} * G^\flat$. By proposition 2.4.7(ii) we have :

$$Z := G^\flat F^\flat * ((G^\flat * \psi^{G,F})^{-1} \odot (\psi^{F,G} * G^\flat)) = (G^\flat F^\flat \sigma^{F,G} * \omega^{G,F})^{-1} = (\sigma^{F,G} GF * \omega^{G,F})^{-1}$$

whence : $Z \odot (\sigma^{F,G} * \eta * \pi^{F,G} * G^\flat) = \sigma^{F,G} * ((\eta * G\pi^{G,F}) \odot \omega^{G,F\,-1})$. We deduce :

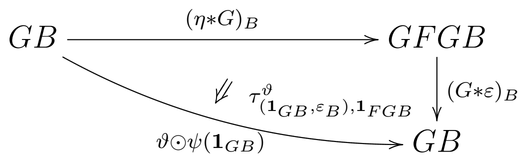
$$\begin{aligned}
(G^\flat * \varepsilon^\flat) \odot (\eta^\flat * G^\flat) &= X \odot (G^\flat \sigma^{G,F} * \varepsilon * \pi^{G,F}) \odot Z \odot (\sigma^{F,G} * \eta * \pi^{F,G} * G^\flat) \odot Y^{-1} \\
&= X \odot (G^\flat \sigma^{G,F} * \varepsilon * \pi^{G,F}) \odot (\sigma^{F,G} * ((\eta * G\pi^{G,F}) \odot \omega^{G,F\,-1})) \odot Y^{-1} \\
&= X \odot (\sigma^{F,G} G * \varepsilon * \pi^{G,F}) \odot (\sigma^{F,G} * ((\eta * G\pi^{G,F}) \odot \omega^{G,F\,-1})) \odot Y^{-1} \\
&= X \odot (\sigma^{F,G} * \omega^{G,F\,-1}) \odot Y^{-1} \\
&= \mathbf{1}_{G^\flat}
\end{aligned}$$

where the last identity follows again from proposition 2.4.7(ii). A similar computation that we leave to the reader shows that $(\varepsilon^\flat * F^\flat) \odot (F^\flat * \eta^\flat) = \mathbf{1}_{F^\flat}$ in $\overline{2\text{-}\mathbf{Cat}}$. Conversely, if given pseudo-natural transformations $\eta^\flat : \mathbf{1}_{\mathscr{A}^{F,G}} \Rightarrow G^\flat F^\flat$ and $\varepsilon^\flat : F^\flat G^\flat \Rightarrow \mathbf{1}_{\mathscr{B}^{G,F}}$ satisfy the triangular identities, then we get pseudo-natural transformations

$$\eta := \pi^{F,G} * \eta^\flat * \sigma^{F,G} : \mathbf{1}_{\mathscr{A}} \Rightarrow GF \qquad \varepsilon := \pi^{G,F} * \varepsilon^\flat * \sigma^{G,F} : FG \Rightarrow \mathbf{1}_{\mathscr{B}}$$

that also fulfill the corresponding triangular identities (details left to the reader). Thus, it suffices to prove the theorem for $F^\flat$ and $G^\flat$. $\Diamond$

Thus, henceforth we assume that F and G are strict. In order to exhibit Σ, we mimick the discussion of (1.1.13) : first, for every $B \in \mathrm{Ob}(\mathscr{B})$ we have an invertible 2-cell



where τ^ϑ denotes the coherence constraint of ϑ, and ψ is the pseudo-natural equivalence as in (2.4.22) used to define ε. Then, with the notation of (2.4.22), we set

$$\Sigma_B := \Theta_{GB,B} \odot \tau^{\vartheta}_{(\mathbf{1}_{FGB},\varepsilon_B),\mathbf{1}_{FGB}} \qquad \text{for every } B \in \mathrm{Ob}(\mathscr{B}).$$

We have to check that the system $(\Sigma_B \mid B \in \mathrm{Ob}(\mathscr{B}))$ is a modification $(G * \varepsilon) \odot (\eta * G) \rightsquigarrow \mathbf{1}_G$. However, set (notation of remark 2.2.10(iv,v) and lemma 2.4.18(i))

$$\mu := ((\vartheta \odot \psi) * (G \times \mathbf{1}_{\mathscr{B}})) \odot H_G \qquad \text{and} \qquad \Theta' := (\Theta \circ (G \times \mathbf{1}_{\mathscr{B}})) * H_G : \mu \rightsquigarrow H_G.$$

Unwinding the definitions, we see that $\Theta'_{B,B'} = \Theta_{GB,B'} * G_{BB'}$ for every $(B, B') \in \mathrm{Ob}(\mathscr{B}^o \times \mathscr{B})$; according to lemma 2.4.20(ii,iii) we then obtain an invertible modification

$$\Theta'^\vee : \mu^\vee \rightsquigarrow \mathbf{1}_G \qquad B \mapsto \Theta_{GB,B}.$$

We are thus reduced to showing that the system $(\tau^{\vartheta}_{(\mathbf{1}_{GB},\varepsilon_B),\mathbf{1}_{FGB}} \mid B \in \mathrm{Ob}(\mathscr{B}))$ yields an invertible modification

$$\Theta'' : (G * \varepsilon) \odot (\eta * G) \rightsquigarrow \mu^\vee$$

since in this case we shall have $\Sigma = \Theta'^\vee \odot \Theta''$. However, by unwinding the definitions we see that the coherence constraint of $\mu^\vee$ is the system of 2-cells

$$\tau^\mu_g := (\tau^{\vartheta}_{(Gg,\mathbf{1}_{B'}),\varepsilon_{B'}})^{-1} \odot \vartheta(\tau^\varepsilon_g) \odot \tau^{\vartheta}_{(\mathbf{1}_{GB},g),\varepsilon_B} \qquad \text{for every 1-cell } g : B \to B' \text{ of } \mathscr{B}$$

whereas that of $(G * \varepsilon) \odot (\eta * G)$ is given by the system of 2-cells

$$\tau^{(G*\varepsilon)\odot(\eta*G)}_g := (G(\varepsilon_{B'}) * \tau^\eta_{Gg}) \odot (G(\tau^\varepsilon_g) * \eta_{GB}) \qquad \text{for every } g : B \to B'$$

and we need to show the identities :

$$(\tau^{\vartheta}_{(\mathbf{1}_{GB'},\varepsilon_{B'}),\mathbf{1}_{FGB'}} * Gg) \odot \tau^{(G*\varepsilon)\odot(\eta*G)}_g = X := \tau^\mu_g \odot (Gg * \tau^{\vartheta}_{(\mathbf{1}_{FGB},\varepsilon_B),\mathbf{1}_{FGB}})$$

for every 1-cell $g : B \to B'$ of $\mathscr{B}$. We compute :

$$\begin{aligned} X &= (\tau^{\vartheta}_{(Gg,\mathbf{1}_{B'}),\varepsilon_{B'}})^{-1} \odot \vartheta(\tau^\varepsilon_g) \odot \tau^{\vartheta}_{(\mathbf{1}_{GB},g\circ\varepsilon_B),\mathbf{1}_{FGB}} \\ &= (\tau^{\vartheta}_{(Gg,\mathbf{1}_{B'}),\varepsilon_{B'}})^{-1} \odot \tau^{\vartheta}_{(\mathbf{1}_{GB},\varepsilon_{B'}\circ FGg),\mathbf{1}_{FGB}} \odot (G(\tau^\varepsilon_g) * \eta_{GB}) \end{aligned}$$

where the first equality follows from the coherence axioms for τ^ϑ, and the second follows from (2.4.17). So, we are further reduced to checking the identities :

$$\tau^{\vartheta}_{(Gg,\mathbf{1}_{B'}),\varepsilon_{B'}} \odot (\tau^{\vartheta}_{(\mathbf{1}_{GB'},\varepsilon_{B'}),\mathbf{1}_{FGB'}} * Gg) \odot (G(\varepsilon_{B'}) * \tau^\eta_{Gg}) = \tau^{\vartheta}_{(\mathbf{1}_{GB},\varepsilon_{B'}\circ FGg),\mathbf{1}_{FGB}}.$$

However, by applying again the coherence axiom for τ^ϑ we see that

$$\tau^\vartheta_{(\mathbf{1}_{GB},\varepsilon_{B'}\circ FGg),\mathbf{1}_{FGB}} = \tau^\vartheta_{\mathbf{1}_{GB},\varepsilon_{B'},FGg} \odot (G(\varepsilon_{B'}) * \tau^\vartheta_{(\mathbf{1}_{GB},FGg),\mathbf{1}_{FGB}})$$
$$\tau^\vartheta_{(Gg,\mathbf{1}_{B'}),\varepsilon_{B'}} \odot (\tau^\vartheta_{(\mathbf{1}_{GB'},\varepsilon_{B'}),\mathbf{1}_{FGB'}} * Gg) = \tau^\vartheta_{(Gg,\varepsilon_{B'}),\mathbf{1}_{FGB'}}$$

so we are further reduced to showing :

$$\tau^\vartheta_{(Gg,\varepsilon_{B'}),\mathbf{1}_{FGB'}} = \tau^\vartheta_{\mathbf{1}_{GB},\varepsilon_{B'},FGg} \odot (G(\varepsilon_{B'}) * \tau^\vartheta_{(Gg,\mathbf{1}_{FGB'}),\mathbf{1}_{FGB'}}).$$

But the latter follows by yet another application of the coherence axioms for τ^ϑ. This concludes the construction of Σ. Concerning Σ', notice that for every $A \in \mathrm{Ob}(\mathscr{A})$ and $B \in \mathrm{Ob}(\mathscr{B})$

$$\mathscr{A}^o(G^oB^o, A^o) = \mathscr{A}(A, GB) \qquad \text{and} \qquad \mathscr{B}^o(B^o, F^oA^o) = \mathscr{B}(FA, B)$$

and ψ can thus be regarded as a system of equivalences of categories $\psi^o_{B^oA^o} : \mathscr{A}^o(G^oB^o, A^o) \to \mathscr{B}^o(B^o, F^oA^o)$. The latter amounts then to a pseudo-natural equivalence

$$\psi^o : \mathscr{A}^o(G^o, \mathbf{1}_{\mathscr{A}^o}) \Rightarrow \mathscr{B}^o(\mathbf{1}_{\mathscr{B}^o}, F^o)$$

with coherence constraint given by the system of isomorphisms of functors $\tau^{\psi^o}_{(g^o,f^o)} := \tau^\psi_{(f,g)}$, for every 2-cell f of $\mathscr{A}$ and g of $\mathscr{B}$. Likewise, we may define the 2-adjunction ϑ^o for the pair (G^o, F^o), and a simple inspection shows that performing the foregoing constructions on this new pair of pseudo-natural equivalences amounts to swapping the roles of ε and η; then the modification Σ^o for the new pair of unit and counit will give the sought Σ' for the original pair.

(ii): Given such η and ε, we set

$$\vartheta := H_{\mathscr{A}}(\eta, \mathbf{1}_G) \odot (H_G * (F^o \times \mathbf{1}_{\mathscr{B}})) : H_{\mathscr{B}}(F, \mathbf{1}_{\mathscr{B}}) \Rightarrow H_{\mathscr{A}}(\mathbf{1}_{\mathscr{A}}, G)$$
$$\psi := H_{\mathscr{B}}(\mathbf{1}_F, \varepsilon) \odot (H_F * (\mathbf{1}^o_{\mathscr{A}} \times G)) : H_{\mathscr{A}}(\mathbf{1}_{\mathscr{A}}, G) \Rightarrow H_{\mathscr{B}}(F, \mathbf{1}_{\mathscr{B}}).$$

Now, example 2.2.15(ii) yields the following identity in $\overline{2\text{-}\mathbf{Cat}}$:

$$\Xi : (H_F * (\mathbf{1}^o_{\mathscr{A}} \times G)) \odot H_{\mathscr{A}}(\eta, \mathbf{1}_G) = (H_{\mathscr{B}}(F, F) * (\eta^o \times \mathbf{1}_G)) \odot (H_F * ((GF)^o \times G))$$

and on the other hand, it is easily seen that

$$(H_F*((GF)^o \times G)) \odot (H_G*(F^o \times \mathbf{1}_{\mathscr{B}})) = H_{FG}*(F^o \times \mathbf{1}_{\mathscr{B}}) : H_{\mathscr{B}}(F, \mathbf{1}_{\mathscr{B}}) \Rightarrow H_{\mathscr{B}}(FGF, FG)$$
$$(H_{\mathscr{B}}(\mathbf{1}_F, \varepsilon) \odot (H_{\mathscr{B}}(F, F) * (\eta^o \times \mathbf{1}_G)) = H_{\mathscr{B}}(F * \eta, \varepsilon) : H_{\mathscr{B}}(FGF, FG) \Rightarrow H_{\mathscr{B}}(F, \mathbf{1}_{\mathscr{B}})$$

whence the identity in $\overline{2\text{-}\mathbf{Cat}}$:

$$\psi \odot \vartheta = H_{\mathscr{B}}(F*\eta, \varepsilon) \odot (H_{FG}*(F^o \times \mathbf{1}_{\mathscr{B}})) = H_{\mathscr{B}}(F*\eta, i_{\mathscr{B}}) \odot ((H_{\mathscr{B}}(\mathbf{1}_{FG}, \varepsilon) \odot H_{FG})*(F^o \times \mathbf{1}_{\mathscr{B}})).$$

But we have $H_{\mathscr{B}}(\mathbf{1}_{FG}, \varepsilon) \odot H_{FG} = H_{\mathscr{B}}(\varepsilon, i_{\mathscr{B}})$ in $\overline{2\text{-}\mathbf{Cat}}$, by lemma 2.4.18(ii), so that :

$$\begin{aligned}
\psi \odot \vartheta &= H_{\mathscr{B}}(F * \eta, i_{\mathscr{B}}) \odot (H_{\mathscr{B}}(\varepsilon, i_{\mathscr{B}}) * (F^o \times \mathbf{1}_{\mathscr{B}})) \\
&= H_{\mathscr{B}}(F * \eta, i_{\mathscr{B}}) \odot H_{\mathscr{B}}(\varepsilon * F, i_{\mathscr{B}}) \\
&= H_{\mathscr{B}}((\varepsilon * F) \odot (F * \eta), i_{\mathscr{B}}) \\
&= H_{\mathscr{B}}(\mathbf{1}_F, i_{\mathscr{B}}) \\
&= \mathbf{1}_{H_{\mathscr{B}}(F, \mathbf{1}_{\mathscr{B}})}.
\end{aligned}$$

Arguing likewise, we obtain as well the identity $\vartheta \odot \psi = \mathbf{1}_{H_{\mathscr{A}}(\mathbf{1}_{\mathscr{A}}, G)}$ in $\overline{2\text{-}\mathbf{Cat}}$: the details shall be left to the reader. Summing up, we have shown that ϑ is an equivalence in the 2-category $\mathsf{PsFun}(\mathscr{A}^o \times \mathscr{B}, \mathbf{Cat})$ with quasi-inverse ψ, and the proof of the theorem is concluded. □

Remark 2.4.28. (i) Let $(F : \mathscr{A} \to \mathscr{B}, G : \mathscr{B} \to \mathscr{A})$ be a 2-adjoint pair of pseudo-functors, and denote by η and ε the unit and the counit of a 2-adjunction for this pair, and Σ,Σ' the associated triangular modifications as in theorem 2.4.24. There follow pseudo-natural transformations

$$\eta^o : G^oF^o \Rightarrow \mathbf{1}_{\mathscr{A}^o} \qquad \varepsilon^o : \mathbf{1}_{\mathscr{B}^o} \Rightarrow F^oG^o$$

and invertible modifications :

$$\Sigma^o : (\eta^o * G^o) \odot (G^o * \varepsilon^o) \rightsquigarrow \mathbf{1}_{G^o} \qquad \Sigma'^o : (F^o * \eta^o) \odot (\varepsilon^o * F^o) \rightsquigarrow \mathbf{1}_{F^o}.$$

In light of theorem 2.4.24, it follows that (G^o, F^o) is a 2-adjoint pair of pseudo-functors, and ε^o and η^o are respectively a unit and a counit of a 2-adjunction for this pair.

(ii) Likewise, we see that $({}^oF, {}^oG)$ is a 2-adjoint pair of pseudo-functors, and ${}^o\eta$ and ${}^o\varepsilon$ are the unit and respectively the counit of a 2-adjunction for this pair.

(iii) Moreover, the right 2-adjoint G of F is unique up to pseudo-natural equivalence of pseudo-functors. Indeed, we have already observed that the pair (F, G) is 2-adjoint if and only if it is an adjoint pair of 1-cells of the 2-category $\mathsf{U}'\text{-}\overline{2\text{-}\mathbf{Cat}}$ (for a suitable universe U'); on the other hand, the pseudo-natural equivalences of pseudo-functors are precisely the invertible 2-cells of $\mathsf{U}'\text{-}\overline{2\text{-}\mathbf{Cat}}$, hence the assertion follows from remark 2.1.4(v).

Corollary 2.4.29. *Let $F : \mathscr{A} \to \mathscr{B}$ be a pseudo-functor and $G : \mathscr{B} \to \mathscr{A}$ a right 2-adjoint for F. Let also $\eta : \mathbf{1}_{\mathscr{A}} \Rightarrow GF$ and $\varepsilon : FG \Rightarrow \mathbf{1}_{\mathscr{B}}$ be the unit and counit of a 2-adjunction ϑ for the pair (F, G). Then the following conditions are equivalent :*

(a) *F (resp. G) is fully faithful.*

(b) *η (resp. ε) is a pseudo-natural equivalence.*

(c) *There exists a pseudo-natural equivalence $\eta' : \mathbf{1}_{\mathscr{A}} \xrightarrow{\sim} GF$ (resp. $\varepsilon' : FG \xrightarrow{\sim} \mathbf{1}_{\mathscr{B}}$).*

Moreover, if (c) *holds, there exists a pseudo-natural transformation ε' (resp. η') with invertible modifications $(G * \varepsilon') \odot (\eta' * G) \rightsquigarrow \mathbf{1}_G$ and $(\varepsilon' * F) \odot (F * \eta') \rightsquigarrow \mathbf{1}_F$.*

Proof. By inspecting the construction of η and ε, we are easily reduced to the case where $\mathscr{A}$ and $\mathscr{B}$ are small and F and G are strict. Also, by remark 2.4.28(i) it suffices to check the assertions for F, η and η'. Suppose now that (a) holds for F. Then the composition

$$\lambda_{A'A} : \mathscr{A}(A', A) \xrightarrow{F_{A'A}} \mathscr{B}(FA', FA) \xrightarrow{\vartheta_{A',FA}} \mathscr{A}(A', GFA) \qquad \text{for every } A, A' \in \mathrm{Ob}(\mathscr{A})$$

is an equivalence of categories, and $\eta_A = \lambda_{AA}(\mathbf{1}_A)$ for every $A \in \mathrm{Ob}(\mathscr{A})$. Taking $A' := GFA$, we find a 1-cell $f : GFA \to A$ with an invertible 2-cell $\lambda_{GFA,A}(f) \xrightarrow{\sim} \mathbf{1}_{GFA}$. Moreover, as explained in the proof of lemma 2.4.23(i), the rule : $(A', A) \mapsto \lambda_{A'A}$ is pseudo-natural in both A and A'; thus, for every 1-cell $h : A' \to A$ of $\mathscr{A}$, the coherence constraint τ^λ of λ yields an isomorphism of functors :

$$\tau^\lambda_{(h,\mathbf{1}_A)} : \mathscr{A}(h, \mathbf{1}_{GFA}) \circ \lambda_{AA} \xrightarrow{\sim} \lambda_{GFA,A} \circ \mathscr{A}(h, \mathbf{1}_A)$$

and especially, we get as well an invertible 2-cell $\eta_A \circ f \xrightarrow{\sim} \lambda_{GFA,A}(f)$; summing up, we get an invertible 2-cell $\eta_A \circ f \xrightarrow{\sim} \mathbf{1}_{GFA}$. On the other hand, the invertible modification $(\varepsilon * F) \odot (F * \eta) \rightsquigarrow \mathbf{1}_F$ provided by theorem 2.4.24(i) yields an invertible 2-cell $\varepsilon_{FA} \circ F\eta_A \xrightarrow{\sim} \mathbf{1}_{FA}$. We conclude that $F\eta_A$ is an equivalence, and then the same holds for η_A, by virtue of lemma 2.4.11(iii). Combining with theorem 2.4.12, we see that (b) holds for η.

Next, obviously (b)⇒(c). Suppose then that $\eta' : \mathbf{1}_{\mathscr{A}} \xrightarrow{\sim} GF$ is a pseudo-natural equivalence, and denote also by $i_{\mathscr{A}^o}$ the identity automorphism of $\mathbf{1}_{\mathscr{A}^o}$; we choose a pseudo-natural equivalence $\psi : H_{\mathscr{A}}(\mathbf{1}_{\mathscr{A}}, G) \xrightarrow{\sim} H_{\mathscr{B}}(F, \mathbf{1}_{\mathscr{B}})$ and we set

$$\xi := (\psi * (\mathbf{1}_{\mathscr{A}^o} \times F)) \odot (H_{\mathscr{A}} * (i_{\mathscr{A}^o} \times \eta')) : H_{\mathscr{A}} \xrightarrow{\sim} H_{\mathscr{B}}(F, F).$$

Since ξ is pseudo-natural, for every 1-cell $f : A' \to A$ in $\mathscr{A}$, the coherence constraint τ^ξ of ξ yields invertible 2-cells :

$$Ff \circ \xi_{A'A'}(\mathbf{1}_{A'}) \xrightarrow{\tau^\xi_{(f,\mathbf{1}_A),\mathbf{1}_{A'}}} \xi_{A'A}(f) \xleftarrow{\tau^\xi_{(\mathbf{1}_{A'},f),\mathbf{1}_A}} \xi_{AA}(\mathbf{1}_A) \circ Ff. \tag{2.4.30}$$

Moreover, since $\xi_{AA} : \mathscr{A}(A, A) \xrightarrow{\sim} \mathscr{B}(FA, FA)$ is an equivalence for every $A \in \mathrm{Ob}(\mathscr{A})$, there exists a 1-cell $h : A \to A$ with an isomorphism $\xi_{AA}(h) \xrightarrow{\sim} \mathbf{1}_A$. Taking $A' = A$ and

$f := h$ in (2.4.30), we conclude that the 1-cell $g_A := \xi_{AA}(\mathbf{1}_A)$ is an equivalence in $\mathscr{A}$ for every $A \in \mathrm{Ob}(\mathscr{A})$. On the other hand, the naturality of τ^ξ easily implies that the rule :

$$(f : A' \to A) \mapsto \tau^\xi_{(f,\mathbf{1}_A),\mathbf{1}_A} : g_A \circ Ff \stackrel{\sim}{\to} \xi_{A'A}(f)$$

defines an isomorphism of functors $\mathscr{A}(\mathbf{1}_A, g_A) \stackrel{\sim}{\to} \xi_{A'A}$. But since g_A is an equivalence, $\mathscr{A}(\mathbf{1}_A, g_A)$ is an equivalence of categories, and the same holds for $\xi_{A'A}$. It follows that the rule : $f \mapsto Ff$ yields an equivalence $F_{A'A} : \mathscr{A}(A', A) \stackrel{\sim}{\to} \mathscr{B}(FA', FA)$, *i.e.* (a) holds for F.

Lastly, for a given η' as in (c), there exists a pseudo-natural equivalence $\omega : \mathbf{1}_\mathscr{A} \stackrel{\sim}{\to} \mathbf{1}_\mathscr{A}$ such that $\eta \odot \omega = \eta'$ in $\overline{2\text{-}\mathbf{Cat}}$. We set $\varepsilon' := \varepsilon \odot (F * \omega^{-1} * G) : FG \Rightarrow \mathbf{1}_\mathscr{B}$. We compute in $\overline{2\text{-}\mathbf{Cat}}$:

$$\begin{aligned}
(G * \varepsilon') \odot (\eta' * G) &= (G * \varepsilon) \odot (GF * \omega^{-1} * G) \odot (\eta' * G) \\
&= (G * \varepsilon) \odot (GF * \omega^{-1} * G) \odot (\eta * G) \odot (\omega * G) \\
&= (G * \varepsilon) \odot (\eta * G) \odot (\omega^{-1} * G) \odot (\omega * G) \\
&= (G * \varepsilon) \odot (\eta * G) \\
&= \mathbf{1}_G.
\end{aligned}$$

Likewise we get $(\varepsilon' * F) \odot (F * \eta') = \mathbf{1}_F$ in $\overline{2\text{-}\mathbf{Cat}}$: the details shall be left to the reader. □

Remark 2.4.31. Let $F : \mathscr{A} \to \mathscr{B}$ be a strict and strong 2-equivalence between two 2-categories. Then there exists a strict and strong 2-equivalence $G : \mathscr{B} \to \mathscr{A}$ with strict pseudo-natural isomorphisms $\eta : \mathbf{1}_\mathscr{B} \stackrel{\sim}{\to} F \circ G$ and $\varepsilon : G \circ F \stackrel{\sim}{\to} \mathbf{1}_\mathscr{A}$. Indeed, for every $B \in \mathrm{Ob}(\mathscr{B})$ let us pick $GB \in \mathrm{Ob}(\mathscr{A})$ with an isomorphism $\eta_B : B \stackrel{\sim}{\to} FGB$; for every $B, B' \in \mathrm{Ob}(\mathscr{B})$ we then get an isomorphism of categories

$$\mathscr{A}(GB, GB') \xrightarrow{F_{GB,GB'}} \mathscr{B}(FGB, FGB') \xrightarrow{\mathscr{B}(\eta_B, \eta^{-1}_{B'})} \mathscr{B}(B, B')$$

where $\mathscr{B}(\eta_B, \eta^{-1}_{B'})$ denotes the functor given by the rule : $\varphi \mapsto \eta^{-1}_{B'} \circ \varphi \circ \eta_B$ for every 1-cell $\varphi : FGB \to FGB'$ of $\mathscr{B}$, and $\beta \mapsto \eta^{-1}_{B'} * \beta * \eta_B$ for every 2-cell β between 1-cells $\varphi, \varphi' : FGB \to FGB'$. We let $G_{B,B'} : \mathscr{B}(B, B') \to \mathscr{A}(GB, GB')$ be the inverse of this isomorphism. Then the sought G is given by the rules : $B \mapsto GB$ for every $B \in \mathrm{Ob}(\mathscr{B})$, and $(B, B') \mapsto G_{B,B'}$ for every pair (B, B') of objects of $\mathscr{B}$: the straightforward verification is left to the reader. It is also clear that the rule : $B \mapsto \eta_B$ for every $B \in \mathrm{Ob}(\mathscr{B})$ defines a strict pseudo-natural isomorphism η. Lastly, we define ε by the rule : $A \mapsto F^{-1}_{GFA,A}(\eta^{-1}_{FA})$ for every $A \in \mathrm{Ob}(\mathscr{A})$. The following corollary extends this simple observation to every 2-equivalence.

Corollary 2.4.32. *Let $\mathscr{A}, \mathscr{B}$ be two 2-categories, $F : \mathscr{A} \to \mathscr{B}$ a pseudo-functor. We have :*

(i) *The following conditions are equivalent :*
  (a) *F is a 2-equivalence.*
  (b) *There exists a pseudo-functor $L : \mathscr{B} \to \mathscr{A}$ with two pseudo-natural equivalences*

$$\eta^* : \mathbf{1}_\mathscr{B} \Rightarrow F \circ L \qquad \text{and} \qquad \varepsilon^* : L \circ F \Rightarrow \mathbf{1}_\mathscr{A}.$$

We say that L is a pseudo-inverse *for F.*

(ii) *Suppose that F is a 2-equivalence. Then, for every L and η^* as in* (i) *there exist a pseudo-natural equivalence $\varepsilon^* : L \circ F \Rightarrow \mathbf{1}_\mathscr{A}$ and invertible modifications*

$$\Theta : (F * \varepsilon^*) \odot (\eta^* * F) \rightsquigarrow \mathbf{1}_F \qquad \Theta' : (\varepsilon^* * L) \odot (L * \eta^*) \rightsquigarrow \mathbf{1}_L.$$

Proof. (i.b)⇒(i.a): The coherence constraint of ε^* gives an isomorphism of functors

$$H_\mathscr{A}(\mathbf{1}_{LFA}, \varepsilon^*_{A'}) \circ L_{FA,FA'} \circ F_{AA'} \Rightarrow H_\mathscr{A}(\varepsilon^*_A, \mathbf{1}_{A'}) \qquad \text{for every } A, A' \in \mathrm{Ob}(\mathscr{A}).$$

However, it is easily seen that both $H_\mathscr{A}(\mathbf{1}_{LFA}, \varepsilon_{A'})$ and $H_\mathscr{A}(\varepsilon_A, \mathbf{1}_{A'})$ are equivalences of categories (cp. the proof of lemma 2.1.13), hence the same holds for $L_{FA,FA'} \circ F_{AA'}$. Arguing likewise with the coherence constraint for η^*, we see as well that $F_{LB,LB'} \circ L_{BB'}$ is an equivalence for every $B, B' \in \mathrm{Ob}(\mathscr{B})$. It follows easily that $F_{AA'}$ and $L_{BB'}$ are faithful for every such A, A' and B, B'; especially, $L_{FA,FA'}$ and $F_{LB,LB'}$ are both faithful, and therefore $F_{AA'}$ and $L_{BB'}$ must also be full. Lastly, let $f : FA \to FA'$ be any 1-cell of $\mathscr{B}$; by the foregoing there exists a 1-cell $g : A \to A'$ with an invertible 2-cell $b : LFg \Rightarrow Lf$, and since $L_{FA,FA'}$ is fully faithful, we have $b = Lc$ for an invertible 2-cell $c : Fg \Rightarrow f$, which shows that $F_{AA'}$ is essentially surjective, so it is an equivalence of categories. Furthermore, theorem 2.4.12 says that the 1-cell $\eta^*_B : B \to FLB$ is an equivalence for every $B \in \mathrm{Ob}(\mathscr{B})$, so (i.a) holds.

(i.b)⇒(i.a): Without loss of generality, we may assume that both $\mathscr{A}$ and $\mathscr{B}$ are small 2-categories. Now, consider the category $\mathscr{A}^F$ and the pseudo-functors $F^\flat : \mathscr{A}^F \to \mathscr{B}$, $\pi^F : \mathscr{A}^F \to \mathscr{A}$ and $\sigma^F : \mathscr{A} \to \mathscr{A}^F$ provided by proposition 2.4.6; we remark that π^F is a 2-equivalence, and σ^F is its pseudo-inverse : indeed, we have $\pi^F \circ \sigma^F = \mathbf{1}_{\mathscr{A}}$, and a pseudo-natural equivalence $\mu^F : \sigma^F \circ \pi^F \xrightarrow{\sim} \mathbf{1}_{\mathscr{A}}$, so the assertion follows from the foregoing. It is then clear that F is a 2-equivalence if and only if the same holds for $F \circ \pi^F$, if and only if the same holds for $F^\flat$. Now, suppose we have found a pseudo-functor $L' : \mathscr{B} \to \mathscr{A}^F$, and pseudo-natural equivalences $\eta^{**} : \mathbf{1}_{\mathscr{B}} \xrightarrow{\sim} F^\flat \circ L'$, $\varepsilon^{**} : L' \circ F^\flat \xrightarrow{\sim} \mathbf{1}_{\mathscr{A}^F}$; then set $L := \pi^F \circ L'$, and notice that we get pseudo-natural equivalences

$$(F^\flat * \mu^F * L')^{-1} \odot \eta^{**} : \mathbf{1}_{\mathscr{B}} \xrightarrow{\sim} F \circ L \qquad \pi^F * \varepsilon^{**} * \sigma^F : L \circ F \xrightarrow{\sim} \mathbf{1}_{\mathscr{A}}.$$

We may thus replace F by $F^\flat$, and assume from start that F is strict. Next, consider the pseudo-natural transformation $H_F : H_{\mathscr{A}} \Rightarrow H_{\mathscr{B}}(F, F)$ assigned to $\mathbf{1}_F : F \Rightarrow F$, as in lemma 2.4.18(i). Notice that our assumption on F means that $H_{F,(A,A')}$ is an equivalence in $\mathbf{Cat}$, for every object (A, A') of $\mathscr{A}^o \times \mathscr{A}$, so theorem 2.4.12 implies that H_F is a pseudo-natural equivalence of pseudo-functors. We may therefore find a pseudo-natural equivalence $G : H_{\mathscr{B}}(F, F) \Rightarrow H_{\mathscr{A}}$, with coherence constraint τ^G, and an adjunction :

$$\eta : \mathbf{1}_{H_{\mathscr{A}}} \rightsquigarrow G \odot H_F \qquad \varepsilon : H_F \odot G \rightsquigarrow \mathbf{1}_{H_{\mathscr{B}} \circ (F,F)}$$

for the pair (H_F, G). Explicitly, G attaches to every $A, A' \in \mathrm{Ob}(\mathscr{A})$ a functor

$$G_{AA'} : \mathscr{B}(FA, FA') \to \mathscr{A}(A, A')$$

which is an equivalence of categories, and η and ε are given by natural isomorphisms of functors

$$\eta_{AA'} : \mathbf{1}_{\mathscr{A}(A,A')} \Rightarrow G_{AA'} \circ F_{AA'} \qquad \varepsilon_{AA'} : F_{AA'} \circ G_{AA'} \Rightarrow \mathbf{1}_{\mathscr{B}(FA,FA')}.$$

On the other hand, by assumption, for every $B \in \mathrm{Ob}(\mathscr{B})$ we may find $LB \in \mathrm{Ob}(\mathscr{A})$ with an equivalence $f_B : B \to FLB$; then lemma 2.1.13(i) says that we may also find a 1-cell $g_B : FLB \to B$ and invertible 2-cells

$$\eta'_B : \mathbf{1}_{FLB} \Rightarrow f_B \circ g_B \qquad \varepsilon'_B : g_B \circ f_B \Rightarrow \mathbf{1}_B$$

that form an adjunction for the pair (g_B, f_B). To ease notation, we set $T_{BB'} := \mathscr{B}(g_B, f_{B'})$ for every $B, B' \in \mathrm{Ob}(\mathscr{B})$ and we define

$$L_{BB'} := G_{LB,LB'} \circ T_{BB'} : \mathscr{B}(B, B') \to \mathscr{A}(LB, LB').$$

We shall henceforth drop the subscripts from the notation for F, G, L, T, η and ε. We claim that L is a pseudo-functor $\mathscr{B} \to \mathscr{A}$, with coherence constraint given by the system of 2-cells in $\mathscr{A}$

$$\gamma^L_{h,k} := L(k * \varepsilon'_{B'} * h) \odot G(\varepsilon_{Tk} * \varepsilon_{Th}) \odot \eta_{Lk \circ Lh} : Lk \circ Lh \Rightarrow L(k \circ h)$$
$$\delta^L_B := G(\eta'_B) \odot \eta_{\mathbf{1}_{LB}} : \mathbf{1}_{LB} \Rightarrow L(\mathbf{1}_B)$$

for every $B, B', B'' \in \mathrm{Ob}(\mathscr{B})$ and every pair of 1-cells $h : B \to B'$ and $k : B' \to B''$ in $\mathscr{B}$. Indeed, the naturality of the rule $(h, k) \mapsto \gamma^L_{h,k}$ is clear from the definition; to check the composition axiom, we consider another 1-cell $l : B'' \to B'''$ in $\mathscr{B}$, and we need to show that

$$\gamma^L_{k \circ h, l} \odot (Ll * \gamma^L_{h,k}) = \gamma^L_{h, l \circ k} \odot (\gamma^L_{l,k} * Lh).$$

However, the naturality of η yields the identities :

$$\eta_{Ll\circ L(k\circ h)} \odot (Ll * \gamma^L_{h,k}) = GF(Ll * \gamma^L_{h,k}) \odot \eta_{Ll\circ Lk\circ Lh}$$
$$\eta_{L(l\circ k)\circ Lh} \odot (\gamma^L_{k,l} * Lh) = GF(\gamma^L_{k,l} * Lh) \odot \eta_{Ll\circ Lk\circ Lh}.$$

To ease notation, set

$$X := (\varepsilon_{T(l\circ k)} * \varepsilon_{Th}) \odot F(\gamma^L_{k,l} * Lh) \qquad Y := (\varepsilon_{Tl} * \varepsilon_{T(k\circ h)}) \odot F(Ll * \gamma^L_{h,k}).$$

We may compute :

$$\begin{aligned} X &= (\varepsilon_{T(l\circ k)} * \varepsilon_{Th}) \odot (F(L(l * \varepsilon'_{B''} * k) \odot G(\varepsilon_{Tl} * \varepsilon_{Tk}) \odot \eta_{Ll\circ Lk}) * FLh) \\ &= (\varepsilon_{T(l\circ k)} * \varepsilon_{Th}) \odot (F(L(l * \varepsilon'_{B''} * k) \odot G(\varepsilon_{Tl} * \varepsilon_{Tk})) * FLh) \odot F(\eta_{Ll\circ Lk} * Lh) \\ &= (\varepsilon_{T(l\circ k)} * \varepsilon_{Th}) \odot (FG(T(l * \varepsilon'_{B''} * k) \odot (\varepsilon_{Tl} * \varepsilon_{Tk})) * FLh) \odot F(\eta_{Ll\circ Lk} * Lh) \\ &= ((T(l * \varepsilon'_{B''} * k) \odot (\varepsilon_{Tl} * \varepsilon_{Tk})) * Th) \odot (\varepsilon_{F(Ll\circ Lk)} * \varepsilon_{Th}) \odot F(\eta_{Ll\circ Lk} * Lh) \\ &= ((T(l * \varepsilon'_{B''} * k) \odot (\varepsilon_{Tl} * \varepsilon_{Tk})) * Th) \odot (F(Ll \circ Lk) * \varepsilon_{Th}) \\ &= ((T(l * \varepsilon'_{B''} * k) \odot (\varepsilon_{Tl} * \varepsilon_{Tk})) * Th) \odot (FLl * FLk * \varepsilon_{Th}) \\ &= (T(l * \varepsilon'_{B''} * k) * Th) \odot (\varepsilon_{Tl} * \varepsilon_{Tk} * \varepsilon_{Th}) \end{aligned}$$

where the fourth equality follows from the naturality of ε, the fifth follows from the triangular identities (1.1.13) for the adjunction (η, ε), and the sixth and seventh follow from remark 2.1.1(i). Likewise, a similar calculation gives :

$$Y = (Tl * T(k * \varepsilon'_{B'} * h)) \odot (\varepsilon_{Tl} * \varepsilon_{Tk} * \varepsilon_{Th}).$$

To conclude, it suffices to notice the identity :

$$T(l * k * \varepsilon'_{B'} * h) \odot (T(l * \varepsilon'_{B''} * k) * Th) = T(l * \varepsilon'_{B''} * k * h) \odot (Tl * T(k * \varepsilon'_{B'} * h)).$$

Next, let us show the unit axiom : we come down to checking the identity

$$\gamma^L_{\mathbf{1}_B,f} \odot (Lf * \delta^L_B) = \mathbf{1}_{Lf} \qquad \text{for every 1-cell } f : B \to B' \text{ in } \mathscr{B}.$$

However,

$$\begin{aligned} \gamma^L_{\mathbf{1}_B,f} \odot (Lf * \delta^L_B) &= L(f * \varepsilon'_B) \odot G(\varepsilon_{Tf} * \varepsilon_{T\mathbf{1}_B}) \odot \eta_{Lf\circ L\mathbf{1}_B} \odot (Lf * \delta^L_B) \\ &= L(f * \varepsilon'_B) \odot G(\varepsilon_{Tf} * \varepsilon_{T\mathbf{1}_B}) \odot GF(Lf * \delta^L_B) \odot \eta_{Lf} \end{aligned}$$

by the naturality of η; taking into account the triangularity identities (1.1.13) for the adjunction (η, ε), we are then reduced to showing that

$$Z := T(f * \varepsilon'_B) \odot (\varepsilon_{Tf} * \varepsilon_{T\mathbf{1}_B}) \odot F(Lf * \delta^L_B) = \varepsilon_{Tf}.$$

However, from the triangular identities for the adjunction $(\eta'_B, \varepsilon'_B)$, we easily obtain :

$$T(f * \varepsilon'_B) = Tf * \eta'^{-1}_B$$

and on the other hand, the naturality of ε yields

$$\eta'^{-1}_B \odot \varepsilon_{T\mathbf{1}_B} = \varepsilon_{\mathbf{1}_{FLB}} \odot FG\eta'^{-1}_B$$

whence :

$$\begin{aligned} Z &= (\varepsilon_{Tf} * (\varepsilon_{\mathbf{1}_{FLB}} \odot FG\eta'^{-1}_B)) \odot (FLf * F\delta^L_B) \\ &= (\varepsilon_{Tf} * (\varepsilon_{\mathbf{1}_{FLB}} \odot FG\eta'^{-1}_B)) \odot (FLf * FG\eta'_B) \odot (FLf * F\eta_{\mathbf{1}_{LB}}) \\ &= (\varepsilon_{Tf} * \varepsilon_{\mathbf{1}_{FLB}}) \odot (FLf * F\eta_{\mathbf{1}_{LB}}). \end{aligned}$$

From the triangular identities for (η, ε) we also see that $F(\eta_{\mathbf{1}_{LB}}) = \varepsilon^{-1}_{F\mathbf{1}_{LB}} = \varepsilon^{-1}_{\mathbf{1}_{FLB}}$, so finally :

$$Z = (\varepsilon_{Tf} * \varepsilon_{\mathbf{1}_{FLB}}) \odot (FLf * \varepsilon^{-1}_{\mathbf{1}_{FLB}}) = \varepsilon_{Tf}$$

as required. A similar computation establishes the second identity for the unit axiom of L. This completes the construction of the pseudo-functor L. Next we set, for every $B, B' \in \mathrm{Ob}(\mathscr{B})$ and every 1-cell $h : B \to B'$ in $\mathscr{B}$

$$\eta^*_B := f_B : B \to FLB$$
$$\tau^*_h := (f_{B'} * h * \varepsilon'_B) \odot (\varepsilon_{Th} * f_B) : FL(h) \circ f_B \Rightarrow f_{B'} \circ h.$$

Claim 2.4.33. The system of 1-cells $\eta^*_\bullet$ defines a pseudo-natural equivalence $\eta^* : \mathbf{1}_{\mathscr{B}} \Rightarrow FL$ with coherence constraint given by the system of 2-cells $\tau^*_\bullet$.

Proof of the claim. By remark 2.2.5(i), the naturality of τ^* amounts to the identity

$$(f_{B'} * \beta) \odot (f_{B'} * h_1 * \varepsilon'_B) \odot (\varepsilon_{Th_1} * f_B) = (f_{B'} * h_2 * \varepsilon'_B) \odot (\varepsilon_{Th_2} * f_B) \odot (FL(\beta) * f_B)$$

for every pair of 1-cells $h_1, h_2 : B \to B'$ and every 2-cell $\beta : h_1 \Rightarrow h_2$. However, a simple inspection shows that

$$(f_{B'} * \beta) \odot (f_{B'} * h_1 * \varepsilon'_B) = (f_{B'} * h_2 * \varepsilon'_B) \odot (T(\beta) * f_B)$$

so we are reduced to checking that

$$T(\beta) \odot \varepsilon_{Th_1} = \varepsilon_{Th_2} \odot FL\beta$$

which in turns follows from the naturality of ε. Next, let us check the coherence axioms for τ^*. Denote by $(\delta^{FL}, \gamma^{FL})$ the coherence constraint of FL (see remark 2.1.17(v)); for given 1-cells $h : B \to B'$ and $h' : B' \to B''$ of $\mathscr{B}$ we have to verify the identities

$$(2.4.34) \qquad \tau^*_{\mathbf{1}_B} \odot (\delta^{FL}_B * f_B) = \mathbf{1}_{f_B} \qquad (\tau^*_{h'} * h) \odot (FLh' * \tau^*_h) = \tau^*_{h' \circ h} \odot (\gamma^{FL}_{h,h'} * f_B).$$

However, a direct inspection gives the identity

$$(\tau^*_{h'} * h) \odot (FLh' * \tau^*_h) = (f_{B''} * h' * \varepsilon'_{B'} * h * \varepsilon'_B) \odot (\varepsilon_{Th'} * \varepsilon_{Th} * f_B)$$

so we are reduced to showing that

$$T(h' * \varepsilon'_{B'} * h) \odot (\varepsilon_{Th'} * \varepsilon_{Th}) = \varepsilon_{T(h' \circ h)} \odot \gamma^{FL}_{h,h'}.$$

Now, we compute :

$$\begin{aligned}\varepsilon_{T(h'\circ h)} \odot \gamma^{FL}_{h,h'} &= \varepsilon_{T(h'\circ h)} \odot F(\gamma^{L}_{h,h'}) \\ &= \varepsilon_{T(h'\circ h)} \odot FG(T(h' * \varepsilon'_{B'} * h) \odot (\varepsilon_{Th'} * \varepsilon_{Th})) \odot F(\eta_{Lh'\circ Lh}) \\ &= T(h' * \varepsilon'_{B'} * h) \odot (\varepsilon_{Th'} * \varepsilon_{Th}) \odot \varepsilon_{F(Lh'\circ Lh)} \odot F(\eta_{Lh'\circ Lh}) \\ &= T(h' * \varepsilon'_{B'} * h) \odot (\varepsilon_{Th'} * \varepsilon_{Th})\end{aligned}$$

where the third identity follows from the naturality of ε, and the fourth follows from the triangular identities (1.1.13) for the pair (η, ε). For the first identity (2.4.34), we notice that

$$\tau^*_{\mathbf{1}_B} = (f_B * \varepsilon'_B) \odot (\varepsilon_{T\mathbf{1}_B} * f_B) = (\eta'^{-1}_B * f_B) \odot (\varepsilon_{T\mathbf{1}_B} * f_B)$$

due to the triangular identities for the pair (η', ε'), so we are reduced to checking that

$$\varepsilon_{T\mathbf{1}_B} \odot \delta^{FL}_B = \eta'_B.$$

We compute :

$$\varepsilon_{T\mathbf{1}_B} \odot \delta^{FL}_B = \varepsilon_{T\mathbf{1}_B} \odot F\delta^L_B = \varepsilon_{T\mathbf{1}_B} \odot F(G(\eta'_B) \odot \eta_{\mathbf{1}_{LB}}) = \eta'_B \odot \varepsilon_{\mathbf{1}_{FLB}} \odot F(\eta_{\mathbf{1}_{LB}}) = \eta'_B$$

which concludes the verification of the pseudo-naturality of η^*. Lastly, η^*_B is an equivalence for every $B \in \mathrm{Ob}(\mathscr{B})$, so η^* is a pseudo-natural equivalence, by theorem 2.4.12. ◊

Claim 2.4.35. For every $A \in \mathrm{Ob}(\mathscr{A})$, the 1-cell $G(g_{FA}) : LFA \to A$ is an equivalence in $\mathscr{A}$.

Proof of the claim. We have an invertible 2-cell $\varepsilon_{g_{FA}} : FG(g_{FA}) \Rightarrow g_{FA}$, and since g_{FA} is an equivalence, it follows that the same holds for $FG(g_{FA})$. Then the assertion follows from lemma 2.4.11(iii). ◊

A simple inspection shows that $L_{BB'}$ is equivalence of categories, for every $B, B' \in \mathrm{Ob}(\mathscr{B})$. Taking into account claim 2.4.35, we deduce that L is a 2-equivalence; therefore, the foregoing discussion applies as well with F replaced by L, and yields another 2-equivalence $M : \mathscr{A} \to \mathscr{B}$ with a pseudo-natural equivalence $\eta^{**} : \mathbf{1}_{\mathscr{A}} \Rightarrow LM$. Pick also pseudo-natural equivalences

$$\mu^* : FL \Rightarrow \mathbf{1}_{\mathscr{B}} \qquad \text{and} \qquad \mu^{**} : LM \Rightarrow \mathbf{1}_{\mathscr{A}}$$

representing the inverses of the 2-cells η^*, η^{**} in $\overline{2\text{-}\mathbf{Cat}}$. We get a pseudo-natural equivalence

$$\beta := (\mu^* * M) \odot (F * \eta^{**}) : F \Rightarrow M$$

(corollary 2.4.14), whence the sought pseudo-natural equivalence

$$\varepsilon^* := \mu^{**} \odot (L * \beta) : LF \Rightarrow \mathbf{1}_{\mathscr{A}}.$$

(ii): Assertion (i) says that F is a 2-equivalence if and only if it is an equivalence in the 2-category $\overline{2\text{-}\mathbf{Cat}}$. Then the assertion follows immediately from lemma 2.1.13(i). □

2.5. **2-Limits and 2-colimits.** Consider 2-categories $\mathscr{A}$, $\mathscr{B}$. For every object B of $\mathscr{B}$, one may define the *constant pseudo-functor* with value B : this is the pseudo-functor

$$\mathsf{F}_B : \mathscr{A} \to \mathscr{B} \qquad \text{such that} \qquad \mathsf{F}_B(A) := B \qquad \mathsf{F}_B(f) := \mathbf{1}_B \qquad \mathsf{F}_B(\alpha) := i_B$$

for every $A \in \mathrm{Ob}(\mathscr{A})$, every 1-cell f, and every 2-cell α of $\mathscr{A}$. The coherence constraint for F_B consists of identities. Given a pseudo-functor $F : \mathscr{A} \to \mathscr{B}$, a *pseudo-cone on F with vertex B* is a pseudo-natural transformation $\mathsf{F}_B \Rightarrow F$. Dually, a *pseudo-cocone on F with vertex B* is a pseudo-natural transformation $F \Rightarrow \mathsf{F}_B$. Especially, every 1-cell $f : B \to B'$ induces a pseudo-cone with vertex B :

$$\mathsf{F}_f : \mathsf{F}_B \Rightarrow \mathsf{F}_{B'} \quad : \quad (\mathsf{F}_f)_A := f \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A})$$

whose coherence constraint consists of identities. Notice that F_f can also be viewed as a pseudo-cocone with vertex B'. Also, every 2-cell $\beta : f \Rightarrow f'$ induces a modification

$$\mathsf{F}_\beta : \mathsf{F}_f \rightsquigarrow \mathsf{F}_{f'} \quad : \quad A \mapsto \beta \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A}).$$

Definition 2.5.1. Let I and $\mathscr{B}$ be two 2-categories, $F : I \to \mathscr{B}$ a pseudo-functor.

(i) A *2-limit* (resp. a *strong 2-limit*) of F is a pair :

$$2\text{-}\lim_I F := (L, \pi)$$

consisting of an object L of $\mathscr{B}$ and a pseudo-cone $\pi : \mathsf{F}_L \Rightarrow F$, such that the functor :

$$\mathscr{B}(B, L) \to \mathsf{PsNat}(\mathsf{F}_B, F) \quad : \quad f \mapsto \pi \odot \mathsf{F}_f \qquad (\beta : f \Rightarrow f') \mapsto (\pi * \mathsf{F}_\beta : \mathsf{F}_f \rightsquigarrow \mathsf{F}_{f'})$$

is an equivalence (resp. an isomorphism) of categories, for every $B \in \mathrm{Ob}(\mathscr{B})$. In this case, we also say that π is a *universal pseudo-cone* (resp. a *strong universal pseudo-cone*).

(ii) Dually, a *2-colimit* (resp. a *strong 2-colimit*) of F is a pair :

$$2\text{-}\operatorname{colim}_I F := (L, \pi)$$

consisting of an object L of $\mathscr{B}$ and a pseudo-cocone $\pi : F \Rightarrow \mathsf{F}_L$, such that the functor:

$$\mathscr{B}(L, B) \to \mathsf{PsNat}(F, \mathsf{F}_B) \quad : \quad f \mapsto \mathsf{F}_f \odot \pi \qquad (\beta : f \Rightarrow f') \mapsto (\mathsf{F}_\beta * \pi : \mathsf{F}_f \rightsquigarrow \mathsf{F}_{f'})$$

is an equivalence (resp. an isomorphism) of categories, for every $B \in \mathrm{Ob}(\mathscr{B})$. In this case, we also say that π is a *universal pseudo-cocone* (resp. a *strong universal pseudo-cocone*).

(iii) We say that $\mathscr{B}$ is 2-*complete* (resp. 2-*cocomplete*, resp. *strongly* 2-*complete*, resp. *strongly* 2-*cocomplete*) if, for every small 2-category I, every pseudo-functor $I \to \mathscr{B}$ admits a 2-limit (resp. a 2-colimit, resp. a strong 2-limit, resp. a strong 2-colimit).

(iv) Let $\mathscr{C}$ be any other 2-category, $G : \mathscr{B} \to \mathscr{C}$ any pseudo-functor, and (L, π) a 2-limit (resp. a 2-colimit) for F. We say that G *commutes with the* 2-*limit of* F (resp. that G *commutes with the* 2-*colimit of* F) if the pseudo-cone $G * \pi : \mathsf{F}_{GL} \Rightarrow G \circ F$ (resp. the pseudo-cocone $G * \pi : G \circ F \Rightarrow \mathsf{F}_{GL}$) is universal.

Remark 2.5.2. (i) As usual, if the 2-limit of a pseudo-functor exists, it is unique up to (non-unique) equivalence : if (L', π') is another 2-limit, there exist an equivalence $h : L \to L'$ and an isomorphism $\beta : \pi' \odot \mathsf{F}_h \stackrel{\sim}{\to} \pi$; moreover, the pair (h, β) is unique up to unique isomorphism, in a suitable sense, that the reader may spell out, as an exercise. A similar remark holds for 2-colimits.

(ii) Likewise, in the situation of definition 2.5.1(iv), the commutation of G with the 2-limit or 2-colimit of F is an intrinsic property of G, *i.e.* is independent of the choice of a 2-limit or 2-colimit for F.

(iii) To be in keeping with the terminology of [28, Ch.VII], we should write pseudo-bilimit instead of 2-limit (and likewise for 2-colimit). The term “2-limit” denotes in *loc.cit.* a related notion, which is unique up to isomorphism, not just up to equivalence. However, the notion introduced in definition 2.5.1 occurs more frequently in applications.

(iv) Let $A_\bullet := (A_i \mid i \in I)$ be any family of objects of the 2-category $\mathscr{A}$, indexed by a small set I. We may regard $A_\bullet$ as a strict pseudo-functor from the discrete category I to $\mathscr{A}$. Then a 2-limit (resp. a 2-colimit) of this pseudo-functor shall also be called a 2-*product* (resp. a 2-coproduct) of $A_\bullet$.

(v) Let L be the small category with $\mathrm{Ob}(L) := \{0, 1, 2\}$, and whose set of arrows consists of the identity morphisms, and two more arrows $1 \to 0$ and $2 \to 0$. An essentially commutative square (2.1.6) can be regarded as a pseudo-cone π with vertex A, on the functor $F : L \to \mathscr{A}$ such that $F(0) := D$, $F(1) := B$, $F(2) := C$, $F(1 \to 0) := h$ and $F(2 \to 0) := k$. We say that (2.1.6) is 2-*cartesian* if (A, π) is a 2-limit of the functor F. This 2-limit shall be called the 2-*fibre product* of k and h, and shall be denoted

$$B \overset{2}{\underset{(h,k)}{\times}} C$$

or sometimes, just $B \overset{2}{\times}_D C$, if there is no danger of ambiguity.

(vi) In view of (2.2.13), it is easily seen that a pair (L, π) is a 2-colimit for the pseudo-functor $F : I \to \mathscr{B}$ if and only if the pair (L^o, π^o) is a 2-limit for the pseudo-functor $F^o : I^o \to \mathscr{B}^o$, and if and only if $({}^oL, {}^o\pi)$ is a 2-limit for the pseudo-functor ${}^oF : {}^oI \to {}^o\mathscr{B}$. Especially, $\mathscr{B}$ is 2-cocomplete if and only if $\mathscr{B}^o$ is 2-complete, and if and only if ${}^o\mathscr{B}$ is 2-cocomplete.

(vii) Let I and $\mathscr{B}$ be two categories, which we regard as 2-categories with trivial 2-cells. Then every pseudo-functor $F : I \to \mathscr{B}$ is a functor, every pseudo-natural transformation $F \Rightarrow G$ of functors $F, G : I \to \mathscr{B}$ is a natural transformation, and the category $\mathsf{PsNat}(F, G)$ is discrete. It follows easily that a 2-limit (L, π) of any such functor $F : I \to \mathscr{B}$ is a strong 2-limit, it represents also the (usual) limit of F, and the universal pseudo-cone π is also a universal cone. Likewise, any 2-colimit of F represents the colimit of F, and every universal pseudo-cocone is a universal cocone.

The following lemma 2.5.3 indicates that the framework of 2-categories does indeed provide an adequate answer to the issues raised in the introduction of this chapter.

Lemma 2.5.3. *Let I be a* 2*-category, $F, G : I \to \mathscr{B}$ two pseudo-functors, $\omega : F \Rightarrow G$ a pseudo-natural equivalence, and suppose that the* 2*-limit of F exists. Then the same holds for* *the* 2*-limit of* G*, and there is a natural equivalence in* $\mathscr{B}$ *:*

$$2\text{-}\lim_I F \stackrel{\sim}{\to} 2\text{-}\lim_I G.$$

More precisely, if (L,π) *is a pair with* $L \in \mathrm{Ob}(\mathscr{B})$ *and a pseudo-cone* $\pi : \mathsf{F}_L \Rightarrow F$ *representing the* 2*-limit of* F*, then the pair* $(L, \omega \odot \pi)$ *represents the* 2*-limit of* G*.*

A dual assertion holds for 2*-colimits.*

Proof. It is easily seen that the rule $\alpha \mapsto \omega \odot \alpha$ induces an equivalence of categories :

$$\mathsf{PsNat}(\mathsf{F}_B, F) \to \mathsf{PsNat}(\mathsf{F}_B, G) \qquad \text{for every } B \in \mathrm{Ob}(\mathscr{B}).$$

The claim is an immediate consequence. □

2.5.4. Let $\mathscr{C}$ be any 2-category with small Hom-categories. To every object X of $\mathscr{C}$ we attach the strict pseudo-functor

$$h_X : \mathscr{C}^o \to \mathbf{Cat} \qquad Y \mapsto \mathscr{C}(Y,X) \subset Y/\mathscr{C}$$

that assigns to every 1-cell $Y' \xrightarrow{f} Y$ of $\mathscr{C}$ the restriction $\mathscr{C}(Y,X) \to \mathscr{C}(Y',X)$ of the strict pseudo-functor $f^* : Y/\mathscr{C} \to Y'/\mathscr{C}$, and to every 2-cell $\beta : f \Rightarrow f'$ the restriction of the strict pseudo-natural transformation $\beta^* : f^* \Rightarrow f'^*$ (notation of example 2.2.8(i)).

Notice that $h_{X^o} : \mathscr{C} \to \mathbf{Cat}$ is the strict pseudo-functor given by the rule : $Y \mapsto \mathscr{C}(X,Y)$ for every $Y \in \mathrm{Ob}(\mathscr{C})$, and which assigns to the 1-cell f as in the foregoing the restriction of the strict pseudo-functor $f_* : \mathscr{C}/Y \to \mathscr{C}/Y'$, and to the 2-cell β the restriction of $\beta_* : f_* \Rightarrow f'_*$ (again, with the notation of example 2.2.8(i)).

Proposition 2.5.5. *With the notation of* (2.5.4)*, let* I *be another* 2*-category,* $F : I \to \mathscr{C}$ *a pseudo-functor, and* $L \in \mathrm{Ob}(\mathscr{C})$ *any object. We have :*

- (i) *For every pseudo-cone* $\pi : \mathsf{F}_L \Rightarrow F$*, the following conditions are equivalent :*
  - (a) *The pseudo-cone* π *is universal.*
  - (b) *For every* $X \in \mathrm{Ob}(\mathscr{C})$ *the pseudo-cone* $h_{X^o} * \pi : \mathsf{F}_{\mathscr{C}(X,L)} \Rightarrow h_{X^o} \circ F$ *is universal.*
- (ii) *For every pseudo-cocone* $\pi : F \Rightarrow \mathsf{F}_L$*, the following conditions are equivalent :*
  - (a) *The pseudo-cocone* π *is universal.*
  - (b) *For every* $X \in \mathrm{Ob}(\mathscr{C})$ *the pseudo-cone* $h_X * \pi : \mathsf{F}_{\mathscr{C}(L,X)} \Rightarrow h_X \circ F$ *is universal.*

Proof. (i.a)⇒(i.b): We have to check that for every small category $\mathscr{B}$, the functor

$$T : \mathsf{Fun}(\mathscr{B}, \mathscr{C}(X,L)) \to \mathsf{PsNat}(\mathsf{F}_{\mathscr{B}}, h_{X^o} * \pi) \qquad (G : \mathscr{B} \to \mathscr{C}(X,L)) \mapsto (h_{X^o} * \pi) \odot \mathsf{F}_G$$

is an equivalence. To this aim, consider any pseudo-cone $\lambda : \mathsf{F}_{\mathscr{B}} \Rightarrow h_{X^o} * \pi$. Explicitly, λ is the datum of a system of functors $(\lambda_i : \mathscr{B} \to \mathscr{C}(X, Fi) \mid i \in \mathrm{Ob}(I))$ and a system of natural isomorphisms of functors $(\tau^\lambda_\varphi : h_{X^o}(F\varphi) \circ \lambda_i \Rightarrow \lambda_j \mid (i \xrightarrow{\varphi} j) \in \mathrm{Morph}(I))$ fulfilling the usual coherence axioms. To every $B \in \mathrm{Ob}(\mathscr{B})$ we attach the system

$$\lambda_\bullet(B) := (\lambda_i(B) : X \to Fi \mid i \in \mathrm{Ob}((I)).$$

It is easily seen that $\lambda_\bullet(B) : \mathsf{F}_X \Rightarrow F$ is a pseudo-cone with coherence constraint given by the system $(\tau^\lambda_{\varphi,B} : F(\varphi) \circ \lambda_i(B) \Rightarrow \lambda_j(B) \mid (i \xrightarrow{\varphi} j) \in \mathrm{Morph}(I))$. Since (L,π) is universal, we may then find a 1-cell $\lambda^\dagger_B : X \to L$ and an isomorphism of pseudo-cones

$$\Omega^\lambda_B : \pi \odot \mathsf{F}_{\lambda^\dagger_B} \rightsquigarrow \lambda_\bullet(B) \qquad \text{for every } B \in \mathrm{Ob}(\mathscr{B}).$$

Moreover, for every morphism $f : B \to B'$ in $\mathscr{B}$, the system $(\lambda_i(f) : \lambda_i(B) \Rightarrow \lambda_i(B') \mid i \in \mathrm{Ob}(I))$ yields a modification $\lambda_\bullet(f) : \lambda_\bullet(B) \rightsquigarrow \lambda_\bullet(B')$. Then, there exists a unique 2-cell in $\mathscr{C}$

$$\lambda^\dagger_f : \lambda^\dagger_B \Rightarrow \lambda^\dagger_{B'} \qquad \text{such that} \qquad \Omega^\lambda_{B'} \odot (\pi * \mathsf{F}_{\lambda^\dagger_f}) = \lambda_\bullet(f) \odot \Omega^\lambda_B. \tag{2.5.6}$$

Clearly $\lambda_\bullet(g) \odot \lambda_\bullet(f) = \lambda_\bullet(g \circ f)$ for every composable pair of morphisms $B \xrightarrow{f} B' \xrightarrow{g} B''$ of $\mathscr{B}$, whence $\lambda^\dagger_g \odot \lambda^\dagger_f = \lambda^\dagger_{g\circ f}$. We have thus associated with λ a well defined functor $\lambda^\dagger : \mathscr{B} \to \mathscr{C}(X, L)$, together with an isomorphism

$$\Omega^\lambda_\bullet : (h_{X^o} * \pi) \odot \mathsf{F}_{\lambda^\dagger} \xrightarrow{\sim} \lambda \qquad \text{in } \mathsf{PsNat}(\mathsf{F}_{\mathscr{B}}, h_{X^o} \circ F).$$

This proves that T is essentially surjective. Next, let us check that T is faithful : indeed, consider two functors $G, H : \mathscr{B} \to \mathscr{C}(X, L)$ and two natural transformations $\alpha, \beta : G \Rightarrow H$ such that $(h_{X^o} * \pi) \odot \mathsf{F}_\alpha = (h_{X^o} * \pi) \odot \mathsf{F}_\beta$; the latter identity means that

$$\pi_i * \alpha_B = \pi_i * \beta_B : \pi_i \circ GB \Rightarrow \pi_i \circ HB \qquad \text{for every } i \in \mathrm{Ob}(I) \text{ and every } B \in \mathrm{Ob}(\mathscr{B}).$$

In other words, for every $B \in \mathrm{Ob}(\mathscr{B})$, the morphisms of pseudo-cones $\pi * \mathsf{F}_{\alpha_B}, \pi * \mathsf{F}_{\beta_B} : \pi \odot \mathsf{F}_{GB} \Rightarrow \pi \odot \mathsf{F}_{HB}$ coincide; then the universality of π implies that $\alpha_B = \beta_B$ for every $B \in \mathrm{Ob}(\mathscr{B})$, whence the assertion. Lastly, to check that T is full we consider, for G and H as in the foregoing, any modification $\Xi : (h_{X^o} * \pi) \odot \mathsf{F}_G \rightsquigarrow (h_{X^o} * \pi) \odot \mathsf{F}_H$; hence, Ξ amounts to a system of natural transformations $(\Xi_i : \pi_{i,*} \circ G \Rightarrow \pi_{i,*} \circ H \mid i \in \mathrm{Ob}(I))$ related by the compatibility conditions :

$$\Xi_j = (\tau^\pi_{\varphi *} * H) \odot ((F\varphi)_* * \Xi_i) \qquad \text{for every 1-cell } \varphi : i \to j \text{ of } I$$

where $\pi_{i,*} : \mathscr{C}(X, L) \to \mathscr{C}(X, Fi)$ and $(F\varphi)_* : \mathscr{C}(X, Fi) \to \mathscr{C}(X, Fj)$ are the functors induced by $\pi_i : L \to Fi$ and respectively $F\varphi : Fi \to Fj$, and where $\tau^\pi_{\varphi*} : (F\varphi)_* \circ \pi_{i*} \xrightarrow{\sim} \pi_{j*}$ denotes the isomorphism of functors induced by the coherence constraint τ^π of π. Then it is easily seen that for every $B \in \mathrm{Ob}(\mathscr{B})$ the system

$$(\Xi_{i,B} : \pi_i \circ GB \Rightarrow \pi_i \circ HB \mid i \in \mathrm{Ob}(I))$$

yields a morphism of pseudo-cones $\Xi_{\bullet,B} : \pi * \mathsf{F}_{GB} \rightsquigarrow \pi * \mathsf{F}_{HB}$, and the naturality of Ξ_i gives the identities

(2.5.7) $$(\pi * \mathsf{F}_{Hf}) \odot \Xi_{\bullet,B} = \Xi_{\bullet,B'} \odot (\pi * \mathsf{F}_{Gf}) \qquad \text{for every morphism } f : B \to B' \text{ of } \mathscr{B}.$$

By the universality of π, the morphisms $\Xi_{\bullet,B}$ corresponds to a unique 2-cell $\Xi^*_B : GB \Rightarrow HB$, and (2.5.7) implies that $(\Xi^*_B \mid B \in \mathrm{Ob}(\mathscr{B}))$ is a well defined natural transformation $\Xi^* : G \Rightarrow H$. By direct inspection, we see that $(h_{X^o} * \pi) * \mathsf{F}_{\Xi^*} = \Xi$, whence the contention.

(i.b)⇒(i.a): To any $X \in \mathrm{Ob}(\mathscr{C})$ and any pseudo-cone $\varphi : \mathsf{F}_X \Rightarrow F$ we attach the pseudo-cone

$$\varphi_* : \mathsf{F}_{\mathscr{C}(X,X)} \Rightarrow h_{X^o} \circ F \qquad i \mapsto (\varphi_{i*} : \mathscr{C}(X, X) \to \mathscr{C}(X, Fi))$$

with coherence constraint given by the system of isomorphisms of functors

$$(\tau^\varphi_{\psi*} : (F\psi)_* \circ \varphi_{i*} \Rightarrow \varphi_{j*} \mid (i \xrightarrow{\psi} j) \in \mathrm{Morph}(I))$$

where $\tau^\varphi_\bullet$ denotes the coherence constraint of φ. By assumption, there exist a functor $\varphi^\dagger : \mathscr{C}(X, X) \to \mathscr{C}(X, L)$ and an isomorphism of pseudo-cones $\omega : \varphi_* \xrightarrow{\sim} (h_{X^o} * \pi) \odot \mathsf{F}_{\varphi^\dagger}$. Then it is easily seen that the system

$$(\omega_{i,\mathbf{1}_X} : \varphi_i \Rightarrow \pi_i \circ \varphi^\dagger(\mathbf{1}_X) \mid i \in \mathrm{Ob}(I))$$

yields an isomorphism of pseudo-cones $\varphi \xrightarrow{\sim} \pi \odot \mathsf{F}_{\varphi^\dagger(\mathbf{1}_X)}$. This shows that the functor

(2.5.8) $$\mathscr{C}(X, L) \to \mathsf{PsNat}(\mathsf{F}_X, F)$$

as in definition 2.5.1(i) is essentially surjective. Next, in order to check that (2.5.8) is faithful, consider two 1-cells $g, h : X \to L$ in $\mathscr{C}$ and two 2-cells $\alpha, \beta : g \Rightarrow h$ such that $\pi_i * \alpha = \pi_i * \beta$ for every $i \in \mathrm{Ob}(I)$; let also $\mathscr{B}$ be the initial object of $\mathbf{Cat}$, *i.e.* $\mathscr{B}$ is a category with a unique object b and a unique morphism $\mathbf{1}_b$. We let $G, H : \mathscr{B} \to \mathscr{C}(X, L)$ be the functors such that $Gb := g$ and $Hb := h$; then α and β correspond to natural transformations $\alpha', \beta' : G \Rightarrow H$ such that $(h_{X^o} * \pi) \odot \mathsf{F}_{\alpha'} = (h_{X^o} * \pi) \odot \mathsf{F}_{\beta'}$, and the universality of $h_{X^o} * \pi$ implies that $\alpha' = \beta'$, whence

$\alpha = \beta$, as required. Lastly, for g, h, $\mathscr{B}$, G and H as in the foregoing, let $\Xi : \pi \odot \mathsf{F}_g \rightsquigarrow \pi \odot \mathsf{F}_h$ be any modification; we deduce a modification $\Xi' : (h_{X^o} * \pi) \odot \mathsf{F}_G \rightsquigarrow (h_{X^o} * \pi) \odot \mathsf{F}_H$, whence – by the universality of $(h_{X^o} * \pi)$ – a unique natural transformation $\beta' : G \Rightarrow H$ such that $\Xi' = (h_{X^o} * \pi) \odot \mathsf{F}_\beta$. Then β' is the datum of a 2-cell $\beta : g \Rightarrow h$ such that $\Xi = \pi * \mathsf{F}_\beta$, which shows that the functor (2.5.8) is also full.

Assertion (ii) is easily deduced from (i), by considering the pseudo-cone $\pi^\circ : \mathsf{F}_{L^\circ} \Rightarrow F^\circ$ (details left to the reader). □

Proposition 2.5.9. *Let I, $\mathscr{B}$ and $\mathscr{C}$ be three 2-categories, $G : \mathscr{B} \to \mathscr{C}$, and $H : \mathscr{C} \to \mathscr{B}$ two pseudo-functors, and suppose that (H, G) is a 2-adjoint pair. We have :*

(i) *The pseudo-functor G commutes with the 2-limit of every pseudo-functor $F : I \to \mathscr{B}$.*

(ii) *Dually, H commutes with the 2-colimit of every pseudo-functor $F' : I \to \mathscr{C}$.*

Proof. (i): Let $F : I \to \mathscr{B}$ be any pseudo-functor, and (L, π) any 2-limit for F. We fix a unit and a counit (η, ε) for the 2-adjoint pair (H, G), and a pair of invertible modifications

$$\Sigma : (G * \varepsilon) \odot (\eta * G) \rightsquigarrow \mathbf{1}_G \qquad \Sigma' : (\varepsilon * H) \odot (H * \eta) \rightsquigarrow \mathbf{1}_H .$$

For every $Y \in \mathrm{Ob}(\mathscr{C})$ we consider the diagram of functors :

$$\mathscr{D} \quad : \quad \begin{array}{ccc} \mathscr{C}(Y, GL) & \xrightarrow{\ \vartheta\ } & \mathscr{B}(HY, L) \\ \big\downarrow & & \big\downarrow \\ \mathsf{PsNat}(\mathsf{F}_Y, GF) & \xrightarrow{\ \vartheta^\dagger\ } & \mathsf{PsNat}(\mathsf{F}_{HY}, F) \end{array}$$

where ϑ is given by the rules :

$$(f : Y \to GL) \mapsto (\varepsilon_L \circ Hf : HY \to HGL) \qquad \text{and} \qquad (\beta : f \Rightarrow f') \mapsto \varepsilon_L * H\beta$$

for every 1-cell f and every 2-cell β of $\mathscr{C}(Y, GL)$. The functor $\vartheta^\dagger$ assigns to every pseudo-natural transformation $\psi : \mathsf{F}_Y \Rightarrow GF$ the pseudo-natural transformation $(\varepsilon * F) \odot (H * \psi) : \mathsf{F}_{HY} \Rightarrow F$, and to every modification $\Xi : \psi \rightsquigarrow \psi'$ the modification $(\varepsilon * F) * (H \circ \Xi)$ (notation of remark 2.2.10(vi)). The left (resp. right) vertical arrow is the functor associated with the pseudo-cone $G * \pi$ (resp. π) as in definition 2.2.10(i). By inspecting the proof of theorem 2.2.10(ii), it is easily seen that ϑ is an equivalence, and by assumption, the same holds for the right vertical arrow. We notice :

Claim 2.5.10. Diagram $\mathscr{D}$ is essentially commutative.

Proof of the claim. The composition of ϑ with the right vertical arrow assigns to every 1-cell $f : Y \to GL$ the pseudo-natural transformation $\pi \odot \mathsf{F}_{\varepsilon_L \circ Hf} = \pi \odot \mathsf{F}_{\varepsilon_L} \odot \mathsf{F}_{Hf} = \pi \odot (\varepsilon * \mathsf{F}_L) \odot \mathsf{F}_{Hf}$. On the other hand, the composition of $\vartheta^\dagger$ with the left vertical arrow assigns to f the pseudo-natural transformation $(\varepsilon * F) \odot (H * ((G * \pi) \odot \mathsf{F}_f))$. However, we have invertible modifications:

$$\Theta_f : (\varepsilon * F) \odot (H * ((G * \pi) \odot \mathsf{F}_f)) \rightsquigarrow (\varepsilon * F) \odot (HG * \pi) \odot (H * \mathsf{F}_f) \rightsquigarrow \pi \odot (\varepsilon * \mathsf{F}_L) \odot \mathsf{F}_{Hf}$$

for every such f (example 2.2.15(i,ii)). We need to check that the rule : $f \mapsto \Theta_f$ yields a natural transformation; by unwinding the definitions, we come down to showing the commutativity of the diagram :

$$\begin{array}{ccc} \varepsilon_{Fi} \circ H(G\pi_i \circ f) & \xRightarrow{\ \varepsilon_{Fi} * H(G\pi_i * \beta)\ } & \varepsilon_{Fi} \circ H(G\pi_i \circ f') \\ {\scriptstyle \varepsilon_{Fi} * \gamma^H_{f, G\pi_i}} \Big\Downarrow & & \Big\Downarrow {\scriptstyle \varepsilon_{Fi} * \gamma^H_{f', G\pi_i}} \\ \varepsilon_{Fi} \circ HG\pi_i \circ Hf & \xRightarrow{\ \varepsilon_{Fi} * HG\pi_i * H\beta\ } & \varepsilon_{Fi} \circ HG\pi_i \circ Hf' \\ {\scriptstyle (\tau^\varepsilon_{\pi_i})^{-1} * Hf} \Big\Downarrow & & \Big\Downarrow {\scriptstyle (\tau^\varepsilon_{\pi_i})^{-1} * Hf'} \\ \pi_i \circ \varepsilon_L \circ Hf & \xRightarrow{\ (\pi_i \circ \varepsilon_L) * H\beta\ } & \pi_i \circ \varepsilon_L \circ Hf' \end{array}$$

where (δ^H, γ^H) is the coherence constraint of H and τ^ε is the coherence constraint of ε. However, the commutativity of the top square subdiagram follows from the naturality of γ^H (remark 2.1.17(ii)). The commutativity of the bottom square subdiagram is obvious, since the compositions of both pairs of arrows equal $(\tau^\varepsilon_{\pi_i})^{-1} * H\beta$ (remark 2.1.1(i)). $\diamondsuit$

In view of claim 2.5.10, we are reduced to checking that $\vartheta^\dagger$ is an equivalence of categories. To this aim, let us consider the functor

$$\mu : \mathsf{PsNat}(\mathsf{F}_{HY}, F) \to \mathsf{PsNat}(\mathsf{F}_Y, GF) \qquad (\varphi : \mathsf{F}_{HY} \Rightarrow F) \mapsto (G * \varphi) \odot \mathsf{F}_{\eta_Y}$$

that assigns to every modification $\Theta : \varphi \rightsquigarrow \varphi'$ between pseudo-cones $\varphi, \varphi' : \mathsf{F}_{HY} \Rightarrow F$ the modification $(G \circ \Theta) * \mathsf{F}_{\eta_Y}$. We claim that μ is a quasi-inverse for $\vartheta^\dagger$. Indeed, for every pseudo-cone $\psi : \mathsf{F}_Y \Rightarrow GF$ we have $\mu \circ \vartheta^\dagger(\psi) = (G * ((\varepsilon * F) \odot (H * \psi))) \odot \mathsf{F}_{\eta_Y}$, and example 2.2.15(i) and remark 2.2.10(iv) yield an invertible modification

$$\gamma^G_{\varepsilon * F, H * \psi} * \mathsf{F}_{\eta_Y} : \mu \circ \vartheta^\dagger(\psi) \rightsquigarrow (G * \varepsilon * F) \odot (GH * \psi) \odot \mathsf{F}_{\eta_Y}.$$

Moreover, example 2.2.15(ii) and remark 2.2.10(iv) yield an invertible modification

$$(G * \varepsilon * F) * \tau^\eta_\psi : (G * \varepsilon * F) \odot (GH * \psi) \odot \mathsf{F}_{\eta_Y} \rightsquigarrow (G * \varepsilon * F) \odot (\eta * GF) \odot \psi$$

which we may compose with the invertible modification

$$(\Sigma \circ F) * \psi : (G * \varepsilon * F) \odot (\eta * GF) \odot \psi \rightsquigarrow \mathbf{1}_{GF} \odot \psi = \psi.$$

Summing up, we obtain an invertible modification

$$\Lambda_\psi : \mu \circ \vartheta^\dagger(\psi) \rightsquigarrow \psi \qquad i \mapsto (\Sigma_{Fi} * \psi_i) \odot (G(\varepsilon_{Fi}) * \tau^\eta_{\psi_i}) \odot (\gamma^G_{\varepsilon_{Fi}, H\psi_i} * \eta_Y)$$

and we need to check that the rule $\psi \mapsto \Lambda_\psi$ yields a natural transformation

$$\Lambda : \mu \circ \vartheta^\dagger \Rightarrow \mathbf{1}_{\mathsf{PsNat}(\mathsf{F}_Y, GF)}.$$

Thus, let $\Xi : \psi \rightsquigarrow \psi'$ be any modification, and notice that $\mu \circ \vartheta^\dagger(\Xi)_i = G(\varepsilon_{Fi} * H(\Xi_i)) * \eta_Y$ for every $i \in \mathrm{Ob}(I)$; we compute :

$$\begin{aligned}
\Xi_i \odot \Lambda_{\psi,i} &= (\Sigma_{Fi} * \psi'_i) \odot (G(\varepsilon_{Fi}) * \eta_{GFi} * \Xi_i) \odot (G(\varepsilon_{Fi}) * \tau^\eta_{\psi_i}) \odot (\gamma^G_{\varepsilon_{Fi}, H\psi_i} * \eta_Y) \\
&= (\Sigma_{Fi} * \psi'_i) \odot (G(\varepsilon_{Fi}) * \tau^\eta_{\psi'_i}) \odot (G(\varepsilon_{Fi}) * GH(\Xi_i) * \eta_Y) \odot (\gamma^G_{\varepsilon_{Fi}, H\psi_i} * \eta_Y) \\
&= (\Sigma_{Fi} * \psi'_i) \odot (G(\varepsilon_{Fi}) * \tau^\eta_{\psi'_i}) \odot (\gamma^G_{\varepsilon_{Fi}, H\psi'_i} * \eta_Y) \odot (G(\varepsilon_{Fi} * H(\Xi_i)) * \eta_Y) \\
&= \Lambda_{\psi',i} \odot \mu \circ \vartheta^\dagger(\Xi)_i
\end{aligned}$$

where the first identity follows from remark 2.1.1(i), the second one from remark 2.2.5(i), and the third one from remark 2.1.17(ii). The assertion follows.

Lastly, we have $\vartheta^\dagger \circ \mu(\varphi) = (\varepsilon * F) \odot H * ((G * \varphi) \odot \mathsf{F}_{\eta_Y})$ for every pseudo-cone $\varphi : \mathsf{F}_{HY} \Rightarrow F$, and we get an invertible modification

$$\Lambda'_\varphi : \vartheta^\dagger \circ \mu(\varphi) \rightsquigarrow (\varepsilon * F) \odot (HG * \varphi) \odot \mathsf{F}_{H\eta_Y} \rightsquigarrow \varphi \odot \mathsf{F}_{\varepsilon_{HY}} \odot \mathsf{F}_{H\eta_Y} \rightsquigarrow \varphi$$

as the composition of $(\varepsilon * F) * (\gamma^H_{\mathsf{F}_{\eta_Y}, G * \varphi})^{-1}$ from example 2.2.15(i), together with $(\tau^\varepsilon_\varphi)^{-1} * \mathsf{F}_{H\eta_Y}$ from example 2.2.15(ii) and $\varphi * \mathsf{F}_{\Sigma'_Y}$. An explicit calculation as in the foregoing shows that the rule $\varphi \mapsto \Lambda'_\varphi$ yields a natural transformation $\Lambda : \vartheta^\dagger \circ \mu \Rightarrow \mathbf{1}_{\mathsf{PsNat}(\mathsf{F}_{HY}, F)}$ (details left to the reader), and concludes the proof of (i).

Assertion (ii) follows from (i), by considering the opposite 2-categories : details left to the reader. $\square$

Proposition 2.5.11. *Let $\mathscr{A}$, $\mathscr{B}$ be two 2-categories, $F : \mathscr{A} \to \mathscr{B}$ a fully faithful pseudo-functor that admits a left 2-adjoint $G : \mathscr{B} \to \mathscr{A}$. The following holds :*

(i) *For every small 2-category I and every pseudo-functor $\varphi : I \to \mathscr{A}$, if $F \circ \varphi : I \to \mathscr{B}$ admits a 2-limit (L, π^L), then φ admits a 2-limit (M, π^M).*

(ii) *In the situation of* (i)*, we have equivalences* $L \xrightarrow{\sim} FM$ *in* $\mathscr{B}$ *and* $M \xrightarrow{\sim} GL$ *in* $\mathscr{A}$*.*

Proof. Let $\eta : \mathbf{1}_{\mathscr{B}} \Rightarrow FG$ and $\varepsilon : GF \Rightarrow \mathbf{1}_{\mathscr{A}}$ be a unit and a counit for the 2-adjoint pair (G, F), and set $\pi^{GL} := (\varepsilon * \varphi) \odot (G * \pi^L) : \mathsf{F}_{GL} \Rightarrow \varphi$. By the universality of π^L, there exist a 1-cell $f : FGL \to L$ in $\mathscr{B}$ and an isomorphism of pseudo-cones $\pi^L \odot \mathsf{F}_f \xrightarrow{\sim} F * \pi^{GL}$. Invoking example 2.2.15(i,ii) we deduce isomorphisms of pseudo-cones :

$$\pi^L \odot \mathsf{F}_{f \circ \eta_L} = \pi^L \odot \mathsf{F}_f \odot \mathsf{F}_{\eta_L} \xrightarrow{\sim} (F * \pi^{GL}) \odot (\eta * \mathsf{F}_L) \xrightarrow{\sim} (F * \varepsilon * \varphi) \odot (FG * \pi^L) \odot (\eta * \mathsf{F}_L)$$
$$\xrightarrow{\sim} (F * \varepsilon * \varphi) \odot (\eta * F\varphi) \circ \pi^L \xrightarrow{\sim} \pi^L$$

whence an isomorphism $f \circ \eta_L \xrightarrow{\sim} \mathbf{1}_L$ in $\mathscr{B}$, by universality of π^L. On the other hand, since F is fully faithful, there exists a 1-cell $h : GL \to GL$ in $\mathscr{A}$ with an isomorphism $Fh \xrightarrow{\sim} \eta_L \circ f : FGL \to FGL$. Notice the isomorphisms :

(2.5.12) $$Fh \circ \eta_L \xrightarrow{\sim} \eta_L \circ f \circ \eta_L \xrightarrow{\sim} \eta_L \xrightarrow{\sim} F\mathbf{1}_{GL} \circ \eta_L.$$

On the other hand, using the pseudo-naturality of ε and the triangular modifications for the pair (η, ε) we get isomorphisms :

$$\varepsilon_{GL} \circ G(Fh \circ \eta_L) \xrightarrow{\sim} \varepsilon_{GL} \circ GFh \circ G\eta_L \xrightarrow{\sim} h \circ \varepsilon_{GL} \circ G\eta_L \xrightarrow{\sim} h$$

and similarly : $\varepsilon_{GL} \circ G(F\mathbf{1}_{GL} \circ \eta_L) \xrightarrow{\sim} \mathbf{1}_{GL}$. Combining with (2.5.12), we deduce an isomorphism $h \xrightarrow{\sim} \mathbf{1}_{GL}$, whence $\eta_L \circ f \xrightarrow{\sim} F\mathbf{1}_{GL} \xrightarrow{\sim} \mathbf{1}_{FGL}$, which shows that f is an equivalence in $\mathscr{B}$. Especially, (ii) holds with $M := GL$, and it also follows that $(FGL, F * \pi^{GL})$ is a 2-limit of $F \circ \varphi$. It remains to check that (GL, π^{GL}) is a 2-limit of φ. To this aim, we consider for every $A \in \mathrm{Ob}(\mathscr{A})$ the essentially commutative diagram of categories :

$$\begin{array}{ccc}
\mathscr{A}(A, GL) & \longrightarrow & \mathsf{PsNat}(\mathsf{F}_A, \varphi) \\
{\scriptstyle F_{A,GL}} \big\downarrow & & \big\downarrow {\scriptstyle U} \\
\mathscr{B}(FA, FGL) & \longrightarrow & \mathsf{PsNat}(\mathsf{F}_{FA}, F \circ \varphi)
\end{array}$$

whose top (resp. bottom) horizontal arrow is the pseudo-functor induced by the pseudo-cone π^{GL} (resp. $F * \pi^{GL}$) as in definition 2.5.1(i). The pseudo-functor U is given by the rules : $\beta \mapsto F * \beta$ and $\Theta \mapsto F * \Theta$ for every pseudo-cone $\beta : \mathsf{F}_A \Rightarrow \varphi$ and every modification of pseudo-cones $\Theta : \beta \rightsquigarrow \beta'$. Since F is fully faithful, the functor $F_{A,GL}$ is an equivalence, and the same holds for the bottom horizontal arrow. We are then reduced to checking that U is an equivalence. To this aim, recall that ε is a pseudo-natural equivalence (corollary 2.4.29) and fix a 1-cell $\omega_A : A \to GFA$ in $\mathscr{A}$ and an isomorphism

$$\rho_A : \varepsilon_A \circ \omega_A \xrightarrow{\sim} \mathbf{1}_A.$$

There follows an isomorphism $F\varepsilon_A \circ F\omega_A \xrightarrow{\sim} \mathbf{1}_{FA}$; on the other hand, the triangular modifications for (η, ε) give an isomorphism $F\varepsilon_A \circ \eta_{FA} \xrightarrow{\sim} \mathbf{1}_{FA}$, so we get as well an isomorphism

$$\rho'_A : F\omega_A \xrightarrow{\sim} \eta_{FA}.$$

We consider the pseudo-functor

$$V : \mathsf{PsNat}(\mathsf{F}_{FA}, F \circ \varphi) \to \mathsf{PsNat}(\mathsf{F}_A, \varphi) \qquad \beta \mapsto (\varepsilon * \varphi) \odot (G * \beta) \odot \mathsf{F}_{\omega_A}$$

that assigns to every modification $\Theta : \beta \rightsquigarrow \beta'$ of pseudo-cones $\beta, \beta' : \mathsf{F}_{FA} \Rightarrow F \circ \varphi$ the modification $(\varepsilon * \varphi) * (G * \Theta) * \mathsf{F}_{\omega_A}$. We construct as follows isomorphisms of functors

$$\Lambda : VU \xrightarrow{\sim} \mathbf{1}_{\mathsf{PsNat}(\mathsf{F}_A, \varphi)} \qquad \Lambda' : UV \xrightarrow{\sim} \mathbf{1}_{\mathsf{PsNat}(\mathsf{F}_{FA}, F \circ \varphi)}.$$

For every pseudo-cone $\beta : \mathsf{F}_A \Rightarrow \varphi$ we have $VU(\beta) = (\varepsilon * \varphi) \odot (GF * \beta) \odot \mathsf{F}_{\omega_A}$. By example 2.2.15(ii), we have an invertible modification

$$\Xi_\beta : \beta \odot (\varepsilon * \mathsf{F}_A) \rightsquigarrow (\varepsilon * \varphi) \odot (GF * \beta) \qquad i \mapsto \tau^\varepsilon_{\beta_i}$$

where τ^ε denotes the coherence constraint of ε. There follows an isomorphism $\Xi^{-1}_\beta * \mathsf{F}_{\omega_A}$: $VU(\beta) \xrightarrow{\sim} \beta \odot (\varepsilon * \mathsf{F}_A) \odot \mathsf{F}_{\omega_A} = \beta \odot \mathsf{F}_{\varepsilon_A \circ \omega_A}$. We compose the latter with the isomorphism $\beta * \mathsf{F}_{\rho_A} : \beta \odot \mathsf{F}_{\varepsilon_A \circ \omega_A} \xrightarrow{\sim} \beta$ to obtain the isomorphism $\Lambda_\beta : VU(\beta) \xrightarrow{\sim} \beta$. In order to check the naturality of the rule : $\beta \mapsto \Lambda_\beta$, we come down to verifying the identity :

$$((\varepsilon * \varphi) * (GF * \Theta)) \odot \Xi_\beta = \Xi_{\beta'} \odot (\Theta * (\varepsilon * \mathsf{F}_A))$$

for every morphism of pseudo-cones $\Theta : \beta \rightsquigarrow \beta'$. This follows from the naturality of τ^ε, applied to the system of 2-cells $\Theta_i : \beta_i \Rightarrow \beta'_i$: details left to the reader. Lastly, for every pseudo-cone $\beta : \mathsf{F}_{FA} \Rightarrow F \circ \varphi$ we have $UV(\beta) = F * ((\varepsilon * \varphi) \odot (G * \beta) \odot \mathsf{F}_{\omega_A})$. By example 2.2.15(i) we have the invertible modification

$$\Gamma_\beta : (F * \varepsilon * \varphi) \odot (FG * \beta) \odot \mathsf{F}_{F\omega_A} \rightsquigarrow F * ((\varepsilon * \varphi) \odot (G * \beta) \odot \mathsf{F}_{\omega_A}) \qquad i \mapsto \gamma^F_{\omega_A, G\beta_i, \varepsilon_{\varphi(i)}}$$

where $\gamma^F_{\bullet\bullet\bullet}$ is coherence constraint of F (for compositions of three 1-cells). We compose Γ^{-1}_β with the invertible modification $((F * \varepsilon * \varphi) \odot (FG * \beta)) * \mathsf{F}_{\rho'_A}$ to get an isomorphism $UV(\beta) \xrightarrow{\sim} (F * \varepsilon * \varphi) \odot (FG * \beta) \odot (\eta * \mathsf{F}_A)$. Then, example 2.2.15(ii) yields the invertible modification

$$\Xi'_\beta : (FG * \beta) \odot (\eta * \mathsf{F}_A) \rightsquigarrow (\eta * F * \varphi) \odot \beta \qquad i \mapsto \tau^\eta_{\beta_i}$$

where τ^η denotes the coherence constraint of η. On the other hand we have the triangular modification $\Sigma : (F * \varepsilon) \odot (\eta * F) \rightsquigarrow \mathbf{1}_F$, so we can compose further with

$$((\Sigma * \varphi) * \beta) \odot ((F * \varepsilon * \varphi) * \Xi'_\beta) : (F * \varepsilon * \varphi) \odot (FG * \beta) \odot (\eta * \mathsf{F}_A) \xrightarrow{\sim} \beta$$

to get the sought isomorphism $\Lambda'_\beta : UV(\beta) \xrightarrow{\sim} \beta$. Again, the naturality of the rule : $\beta \mapsto \Lambda'_\beta$ follows easily from the naturality of $\gamma^F_{\bullet\bullet\bullet}$ and τ^η. □

2.5.13. Let I, J be two small 2-categories, $\mathscr{C}$ another 2-category, and $\varphi : J \to I$, $F : I \to \mathscr{C}$ two pseudo-functors. Let also (L, π) and (L', π') be 2-limits for F and respectively $F \circ \varphi$. Then there exist a 1-cell $f : L \to L'$ of $\mathscr{C}$ and an invertible modification

$$\Theta : \pi * \varphi \rightsquigarrow \pi' \odot \mathsf{F}_f.$$

Moreover, if $f' : L \to L'$ is another such 1-cell with an invertible modification $\Theta' : \pi * \varphi \rightsquigarrow \pi' \odot \mathsf{F}_{f'}$, there exists a unique invertible 2-cell in $\mathscr{C}$:

$$\beta : f \xrightarrow{\sim} f' \qquad \text{such that} \qquad \mathsf{F}_\beta \odot \Theta = \Theta'.$$

In particular, f shall be an equivalence in $\mathscr{C}$ if and only if the same holds for f' (remark 2.1.4(iii)), so the property that f is an equivalence is an intrinsic feature of the pair (φ, F). Furthermore, Θ induces an essentially commutative diagram of categories :

$$\begin{array}{ccc} \mathscr{C}(X, L) & \xrightarrow{T} & \mathsf{PsNat}(\mathsf{F}_X, F) \\ {\scriptstyle f^X_*} \downarrow & & \downarrow {\scriptstyle S^X} \\ \mathscr{C}(X, L') & \xrightarrow{T'} & \mathsf{PsNat}(\mathsf{F}_X, F \circ \varphi) \end{array} \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C})$$

whose horizontal arrows are the equivalences of definition 2.5.1(i), where f^X_* is defined as in example 2.1.11(iii), and S^X is given by the rules : $(\beta : \mathsf{F}_X \Rightarrow F) \mapsto \beta * \varphi$ and $(\Xi : \beta \rightsquigarrow \beta') \mapsto \Xi \circ \varphi$. Then the required isomorphism of functors $S^X \circ T \xrightarrow{\sim} T' \circ f^X_*$ is given by the rule : $(g : X \to L) \mapsto \Theta * \mathsf{F}_g$. Hence, f is an equivalence in $\mathscr{C}$ if and only if S^X is an equivalence of categories for every $X \in \mathrm{Ob}(\mathscr{C})$.

Definition 2.5.14. Let I, J be two small 2-categories. We say that a pseudo-functor $\varphi : J \to I$ is 2-*coinitial* if for every 2-complete 2-category $\mathscr{C}$ and every pseudo-functor $F : I \to \mathscr{C}$ the induced 1-cell $f : L \to L'$ as in (2.5.13) is an equivalence. Likewise, we say that φ is 2-*cofinal* if $\varphi^o : J^o \to I^o$ is 2-coinitial.

Remark 2.5.15. Unlike as in the case for usual category, we do not provide a general characterization of 2-coinitial or 2-cofinal pseudo-functors, but we shall point out at least two simple, though useful, classes of such pseudo-functors. Such a characterization – in terms of simple connectivity of comma categories – can be found in [146, Prop.A.2.2], though under slightly different assumptions.

For our first example, let $\mathbb{1}$ be a final object of $\mathbf{Cat}$, *i.e.* a category with a unique object and a unique morphism (then the unique morphism is the identity of the unique object); let likewise $\mathbb{I}$ be a final object of 2-$\mathbf{Cat}$, *i.e.* a 2-category with a unique object, a unique 1-cell and a unique 2-cell. We say that a given object i_0 of I is *pseudo-initial* (resp. *pseudo-final*) if the category $I(i_0, i)$ (resp. $I(i, i_0)$) is equivalent to $\mathbb{1}$, for every $i \in \mathrm{Ob}(I)$.

Proposition 2.5.16. *Let i_0 be a pseudo-initial (resp. pseudo-final) object of I, and $\varphi : \mathbb{I} \to I$ the strict pseudo-functor that maps the object of $\mathbb{I}$ to i_0. Then φ is 2-coinitial (resp. 2-cofinal).*

Proof. Let i_0 be pseudo-initial; we need to check that for every 2-complete 2-category $\mathscr{C}$, every pseudo-functor $F : I \to \mathscr{C}$ and every 2-limit (L, π) of F, the pair $(L, \pi * \varphi)$ is a 2-limit of $F \circ \varphi$, and notice that the latter condition means that $\pi_{i_0} : L \to L' := Fi_0$ is an equivalence. To this aim, it suffices to construct a universal pseudo-cone $\pi' : \mathsf{F}_{L'} \Rightarrow F$ with $\pi'_{i_0} = \mathbf{1}_{L'}$. We may also assume that F is unital, by lemma 2.5.3 and proposition 2.4.3. Thus, let $i \in \mathrm{Ob}(I)$ be any object; by assumption, there exists a 1-cell $f_i : i_0 \to i$ in I, and we set $\pi'_i := Ff_i : L' \to Fi$. Naturally, we take $f_{i_0} := \mathbf{1}_{i_0}$, so that $\pi'_{i_0} = \mathbf{1}_{L'}$, since F is unital. Next, for every one-cell $g : i \to i'$ in I we have by assumption a unique 2-cell $\beta_g : g \circ f_i \Rightarrow f_{i'}$ in I, and it is easily seen that β_g must then be invertible (details left to the reader); we set $\tau_g := (F\beta_g) \odot \gamma^F_{f_i,g} : Ff \circ \pi_i \Rightarrow \pi'_{i'}$, where γ^F denotes the coherence constraint of F.

Claim 2.5.17. The rule : $i \mapsto \pi'_i$ defines a pseudo-cone $\pi' : \mathsf{F}_{L'} \Rightarrow F$ with coherence constraint given by the system of 2-cells $\tau_\bullet$.

Proof of the claim. The uniqueness of β_g implies that $\beta_{\mathbf{1}_i} = \mathbf{1}_{f_i}$ for every $i \in \mathrm{Ob}(I)$ and

$$\beta_h \odot (h * \beta_g) = \beta_{h \circ g} \qquad \text{for every pair of 1-cells } i \xrightarrow{g} i' \xrightarrow{h} i''.$$

Since F is unital, it follows already that $\tau_{\mathbf{1}_i} = \mathbf{1}_{\pi'_i}$ for every $i \in \mathrm{Ob}(I)$. It remains to check that

$$\tau_h \odot (Fh * \tau_g) = \tau_{h \circ g} \odot (\gamma^F_{g,h} * \pi'_i)$$

for every pair of 1-cells (g, h) as in the foregoing. We compute :

$$\begin{aligned} \tau_h \odot (Fh * \tau_g) &= F\beta_h \odot \gamma^F_{f_{i'},h} \odot (Fh * F\beta_g) \odot (Fh * \gamma^F_{f_i,g}) \\ &= F\beta_h \odot F(h * \beta_g) \odot \gamma^F_{g \circ f_i,h} \odot (Fh * \gamma^F_{f_i,g}) \\ &= F\beta_{h \circ g} \odot \gamma^F_{g \circ f_i,h} \odot (Fh * \gamma^F_{f_i,g}) \end{aligned}$$

whereas $\tau_{h \circ g} \odot (\gamma^F_{g,h} * \pi'_i) = F\beta_{g \circ h} \odot \gamma^F_{f_i,g} \odot (\gamma^F_{g,h} * Ff_i)$, so the sought identity follows from the composition axiom for γ^F. ◊

To conclude, we need to check that functor

$$\mathscr{C}(X, L) \to \mathsf{PsNat}(c_X, F) \qquad t \mapsto \pi' \odot \mathsf{F}_t$$

is an equivalence for every $X \in \mathrm{Ob}(\mathscr{C})$. The faithfulness is clear, since $\pi'_{i_0} = \mathbf{1}_{L'}$. To check that the functor is full, consider two 1-cells $t, t' : X \to L$ and a modification $\Xi : \pi' \odot \mathsf{F}_t \rightsquigarrow \pi' \odot \mathsf{F}_{t'}$;

we set $\mu := \Xi_{i_0} : t \Rightarrow t'$. Now, notice that $\beta_{f_i} = \mathbf{1}_{f_i}$ for every $i \in \mathrm{Ob}(I)$, so that $\tau_{f_i} = \mathbf{1}_{Ff_i}$, since F is unital; then the compatibility condition for Ξ, relative to the 1-cell $f_i : i_0 \to i$ yields:

$$\Xi_i = Ff_i * \mu \qquad \text{for every } i \in \mathrm{Ob}(I)$$

which shows that $\Xi = \pi' * \mathsf{F}_\mu$, as required. Lastly, let $\alpha : \mathsf{F}_X \Rightarrow F$ be any pseudo-cone; set $t := \alpha_{i_0} : X \to L'$, and $\Xi_i := \tau^\alpha_{f_i} : Ff_i \circ t \Rightarrow \alpha_i$ for every $i \in \mathrm{Ob}(I)$, where τ^α is the coherence constraint of α. To conclude, it suffices to check that the rule : $i \mapsto \Xi_i$ yields an invertible modification $\Xi : \pi' \odot \mathsf{F}_t \rightsquigarrow \alpha$. This comes down to showing :

$$\tau^\alpha_g \odot (Fg * \tau^\alpha_{f_i}) = \tau^\alpha_{f_{i'}} \odot (\tau_g * \alpha_{i_0}) \qquad \text{for every 1-cell } g : i \to i' \text{ of } I.$$

However, the left-hand side of the latter identity equals $\tau^\alpha_{g \circ f_i} \odot (\gamma^F_{f_i,g} * \alpha_{i_0})$, by the coherence axiom for τ^α, so we are reduced to checking the identity :

$$\tau^\alpha_{g \circ f_i} = \tau^\alpha_{f_{i'}} \odot (F\beta_g * \alpha_{i_0})$$

which holds by naturality of τ^α. $\square$

2.5.18. For our second example, consider a small category I (which we regard as a 2-category with trivial 2-cells, as usual), and a full subcategory J of I, such that the inclusion functor $\varphi : J \to I$ admits a left adjoint $\sigma : I \to J$ with $\sigma \circ \varphi = \mathbf{1}_J$.

Proposition 2.5.19. *In the situation of* (2.5.18)*, the pseudo-functor* $\varphi : J \to I$ *is* 2*-cofinal.*

Proof. For every pseudo-functor $F : I \to \mathscr{C}$, every pseudo-cocone $\pi : F \Rightarrow \mathsf{F}_L$, and every $C \in \mathrm{Ob}(\mathscr{C})$ we have a commutative diagram of categories :

$$\begin{array}{ccc} & \mathscr{C}(L,C) & \\ \swarrow & & \searrow \\ \mathsf{PsNat}(F, \mathsf{F}_C) & \xrightarrow{\ S_C\ } & \mathsf{PsNat}(F \circ \varphi, \mathsf{F}_C) \end{array}$$

whose downward arrows are the functors $f \mapsto \pi \odot \mathsf{F}_f$ and $f \mapsto (\pi * \varphi) \odot \mathsf{F}_f$ of definition 2.5.1(ii), and where S_C is given by the rules : $(\beta : F \Rightarrow \mathsf{F}_C) \mapsto \beta * \varphi$ and $(\Xi : \beta \rightsquigarrow \beta') \mapsto \Xi \circ \varphi$. We come down to checking that S_C is an equivalence, for every such F. To this aim, notice first that the adjoint pair (σ, φ) admits an adjunction whose counit $\sigma \circ \varphi \Rightarrow \mathbf{1}_J$ is the identity natural transformation (proposition 1.1.20(iii)); in view of the triangular identities of (1.1.13), it follows that the unit $\eta : \mathbf{1}_I \Rightarrow \varphi \circ \sigma$ fulfills as well the condition :

$$\eta * \varphi = \mathbf{1}_\varphi.$$

We consider for every $C \in \mathrm{Ob}(\mathscr{C})$ the functor

$$S'_C : \mathsf{PsNat}(F \circ \varphi, \mathsf{F}_C) \to \mathsf{PsNat}(F, \mathsf{F}_C) \qquad (\beta : F \circ \varphi \Rightarrow \mathsf{F}_C) \mapsto (\beta * \sigma) \odot (F * \eta)$$

that assigns to every modification $\Xi : \beta \rightsquigarrow \beta'$ the modification $(\Xi \circ \sigma) * (F * \eta) : S'_C(\beta) \rightsquigarrow S'_C(\beta')$. Notice that for every pseudo-natural transformation $\beta : F \circ \varphi \Rightarrow \mathsf{F}_C$ we have

$$S_C \circ S'_C(\beta) = ((\beta * \sigma) \odot (F * \eta)) * \varphi = (\beta * \sigma * \varphi) \odot (F * \eta * \varphi) = \beta$$

and likewise, if $\beta' : F \circ \varphi \Rightarrow \mathsf{F}_C$ is another such pseudo-natural transformation, and $\Xi : \beta \rightsquigarrow \beta'$ is any modification, we get $S_C \circ S'_C(\Xi) = \Xi$. On the other hand, for every pseudo-natural transformation $\beta : F \Rightarrow \mathsf{F}_C$, example 2.2.15(ii) yields an invertible modification

$$\tau^\beta_\eta : \beta = (\mathsf{F}_C * \eta) \odot (\beta * \mathbf{1}_I) \rightsquigarrow (\beta * \varphi * \sigma) \odot (F * \eta) = S'_C \circ S_C(\beta).$$

To conclude the proof, it suffices to check that the rule $\beta \mapsto \tau_\eta^\beta$ yields a natural transformation $\mathbf{1}_{\mathsf{PsNat}(F,\mathsf{F}_C)} \Rightarrow S'_C \circ S_C$. The latter comes down to the commutativity of the diagram of modifications :

$$\begin{array}{ccc} \beta & \overset{\tau_\eta^\beta}{\rightsquigarrow} & (\beta * \varphi * \sigma) \odot (F * \eta) \\ {\scriptstyle\Xi}\big\wr\downarrow & & \big\wr\downarrow{\scriptstyle (\Xi\circ\varphi\circ\sigma)*(F*\eta)} \\ \beta' & \overset{\tau_\eta^{\beta'}}{\rightsquigarrow} & (\beta' * \varphi * \sigma) \odot (F * \eta) \end{array}$$

for every modification $\Xi : \beta \rightsquigarrow \beta'$. This in turn amounts to the compatibility condition for Ξ, relative to the 1-cell $\eta_i : i \to \varphi \circ \sigma(i)$, for every $i \in \mathrm{Ob}(I)$. □

2.6. **2-Categorical Kan extensions.** Let $I, J, \mathscr{C}$ be three 2-categories, $\varphi : I \to J$ a *unital* pseudo-functor, and suppose that $\mathscr{C}$ is 2-complete, I is small and J has small Hom-categories. We define as follows a pseudo-functor

$$2\text{-}\!\int_\varphi : \mathsf{PsFun}(I, \mathscr{C}) \to \mathsf{PsFun}(J, \mathscr{C}).$$

For every *unital* pseudo-functor $F : I \to \mathscr{C}$ and every $j \in \mathrm{Ob}(J)$, notice that the 2-category $j/\varphi I$ is small under our assumptions, and choose a 2-limit $(L_{F,j}, \pi^{F,j})$ of $F \circ \mathsf{t}_j : j/\varphi I \to \mathscr{C}$ (notation of example 2.2.8(ii)). Then, for every 1-cell $g : j \to j'$ in J there exist a 1-cell $L_{F,g} : L_{F,j} \to L_{F,j'}$ in $\mathscr{C}$ and an invertible modification

$$\Omega^{F,g} : \pi^{F,j} * g^* \rightsquigarrow \pi^{F,j'} \odot \mathsf{F}_{L_{F,g}}$$

with the strict pseudo-functor $g^* : j'/\varphi I \to j/\varphi I$ defined as in example 2.2.8(ii), and we set

$$(2.6.1) \qquad 2\text{-}\!\int_\varphi F(j) := L_{F,j} \qquad 2\text{-}\!\int_\varphi F(g) := L_{F,g}.$$

Obviously, for $g = \mathbf{1}_j$, we take $L_{F,g}$ to be the identity 1-cell of $L_{F,j}$, and $\Omega^{F,g}$ the identity modification of $\pi^{F,j}$. If $h : j' \to j''$ is another 1-cell in J, there exists a unique invertible 2-cell $L_{F,g,h} : L_{F,h} \circ L_{F,g} \Rightarrow L_{F,h\circ g}$ in $\mathscr{C}$ such that

$$(2.6.2) \qquad (\pi^{F,j''} * \mathsf{F}_{L_{F,g,h}}) \odot (\Omega^{F,h} * \mathsf{F}_{L_{F,g}}) \odot (\Omega^{F,g} \circ h^*) = \Omega^{F,h\circ g}.$$

Moreover, if $g, g' : j \to j'$ are two 1-cells of J, and $\beta : g \Rightarrow g'$ is a 2-cell, we set

$$\pi_f^{F,\beta} := \tau_{\beta^*(f)}^{F,j} \qquad \text{for every } (f : j' \to \varphi(i)) \in \mathrm{Ob}(j'/\varphi I)$$

where $\tau^{F,j}$ denotes the coherence constraint of $\pi^{F,j}$, and $\beta^* : g^* \Rightarrow g'^*$ is the strict pseudo-natural transformation associated with β as in example 2.2.8(ii). Since F is unital, $\pi_f^{F,\beta}$ is a 2-cell $\pi_{g^*(f)}^{F,j} \Rightarrow \pi_{g'^*(f)}^{F,j}$ in $\mathscr{C}$, between two 1-cells $L_{F,j} \to Fi$. We claim that the rule : $(f : j' \to \varphi(i)) \mapsto \pi_f^{F,\beta}$ defines an invertible modification $\pi^{F,\beta} : \pi^{F,j} * g \rightsquigarrow \pi^{F,j} * g'$. Indeed, notice first that for every pair of 1-cells $(i_1, g_1) \xrightarrow{(f,\alpha)} (i_2, g_2) \xrightarrow{(f',\alpha')} (i_3, g_3)$ of $j/\varphi(I)$ we have by definition :

$$(2.6.3) \qquad (f', \alpha') \circ (f, \alpha) = \alpha' \odot (\varphi(f') * \alpha) \odot ((\gamma_{f,f'}^\varphi)^{-1} * g_1) \qquad \text{in } j/\varphi(I).$$

Now, again using the unital assumption for F, the assertion comes down to the identity :

$$\tau_{g'^*(h,\alpha)}^{F,j} \odot (Fh * \tau_{\beta^*(f)}^{F,j}) = \tau_{\beta^*(f')}^{F,j} \odot \tau_{g^*(h,\alpha)}^{F,j}$$

for every 1-cell $(h, \alpha) : (f : j' \to \varphi(i)) \to (f' : j' \to \varphi(i'))$ of $j'/\varphi I$. Let us also remark that $\beta^*(f') \circ g^*(\alpha, f) = g'^*(\alpha, f) \circ \beta^*(f)$, and $\beta^*(f) = (\mathbf{1}_i, f * \beta)$ and likewise for $\beta^*(f')$; since also φ is unital, we then have $\gamma_{\mathbf{1}_i,h}^\varphi = \mathbf{1}_h = \gamma_{h,\mathbf{1}_{i'}}^\varphi$, and the sought identity follows from (2.6.3) and the coherence axiom for $\tau^{F,j}$. Consequently, there exists a unique 2-cell $L_{F,\beta} : L_{F,g} \Rightarrow L_{F,g'}$ in $\mathscr{C}$ such that

$$\Omega^{F,g'} \odot \pi^{F,\beta} = (\pi^{F,j'} * \mathsf{F}_{L_{F,\beta}}) \odot \Omega^{F,g} \tag{2.6.4}$$

and we set

$$2\text{-}\!\!\int_\varphi F(\beta) := L_{F,\beta}. \tag{2.6.5}$$

Lemma 2.6.6. *In the situation of* (2.6)*, the system of invertible* 2*-cells* $L_{F,\bullet\bullet}$ *yields a coherence constraint for a unital pseudo-functor* $2\text{-}\!\int_\varphi F : J \to \mathscr{C}$ *defined on objects and* 1*-cells by* (2.6.1)*, and on* 2*-cells by* (2.6.5).

Proof. Let $\beta : g \Rightarrow g'$ and $\beta' : g' \Rightarrow g''$ be two 2-cells of J; a simple inspection shows that

$$\beta'^*(f) \circ \beta^*(f) = (\beta' \odot \beta)^*(f) \qquad \text{for every } (f : j' \to \varphi(i)) \in \mathrm{Ob}(j'/\varphi I)$$

whence $\pi^{F,\beta'} \odot \pi^{F,\beta} = \pi^{F,\beta'\odot\beta}$. On the other hand, we have

$$\begin{aligned}(\pi^{F,j'} * \mathsf{F}_{L_{F,\beta'}}) \odot (\pi^{F,j'} * \mathsf{F}_{L_{F,\beta}}) \odot \Omega^{F,g} &= (\pi^{F,j'} * \mathsf{F}_{L_{F,\beta'}}) \odot \Omega^{F,g'} \odot \pi^{F,\beta} \\ &= \Omega^{F,g''} \odot \pi^{F,\beta'} \odot \pi^{F,\beta}.\end{aligned}$$

Summing up, we already see that $2\text{-}\!\int_\varphi F(\beta') \odot 2\text{-}\!\int_\varphi F(\beta) = 2\text{-}\!\int_\varphi F(\beta' \odot \beta)$. Moreover, notice that $\pi^{F,\mathbf{1}_g}$ is the identity automorphism of $\pi^{F,j} * g$ (remark 2.4.2(ii)), whence

$$2\text{-}\!\!\int_\varphi F(\mathbf{1}_g) = \mathbf{1}_{L_{F,g}} \qquad \text{for every 1-cell } g \text{ of } J.$$

Next, let $g, g' : j \to j'$ and $h, h' : j' \to j''$ be four 1-cells of J and $\beta : g \Rightarrow g'$, $\beta : h \Rightarrow h'$ two 2-cells; we need to check that

$$\Big(2\text{-}\!\!\int_\varphi F(\beta' * \beta)\Big) \odot L_{F,g,h} = L_{F,g',h'} \odot \Big(2\text{-}\!\!\int_\varphi F(\beta') * 2\text{-}\!\!\int_\varphi F(\beta)\Big)$$

and in light of the foregoing, we may assume that either $\beta = \mathbf{1}_g$ or $\beta' = \mathbf{1}_h$. In these cases, the assertion comes down to the identities :

$$\begin{aligned}L_{F,h*\beta} \odot L_{F,g,h} &= L_{F,g',h} \odot (L_{F,h} * L_{F,\beta}) \\ L_{F,\beta'*g} \odot L_{F,g,h} &= L_{F,g,h'} \odot (L_{F,\beta'} * L_{F,g}).\end{aligned}$$

However, set $X := (\Omega^{F,h} * \mathsf{F}_{L_{F,g}}) \odot (\Omega^{F,g} \circ h^*)$. It suffices to show that

$$\begin{aligned}Y := (\pi^{F,j''} * (\mathsf{F}_{L_{F,g',h}} \odot (\mathsf{F}_{L_{F,h}} * \mathsf{F}_{L_{F,\beta}})) \odot X \ &= Z := (\pi^{F,j''} * (\mathsf{F}_{L_{F,h*\beta}} \odot \mathsf{F}_{L_{F,g,h}})) \odot X \\ Y' := (\pi^{F,j''} * (\mathsf{F}_{L_{F,g,h'}} \odot (\mathsf{F}_{L_{F,\beta'}} * \mathsf{F}_{L_{F,g}})) \odot X \ &= Z' := (\pi^{F,j''} * (\mathsf{F}_{L_{F,\beta'*g}} \odot \mathsf{F}_{L_{F,g,h}})) \odot X.\end{aligned}$$

We compute :

$$\begin{aligned}Y &= (\pi^{F,j''} * \mathsf{F}_{L_{F,g',h}}) \odot (\Omega^{F,h} * \mathsf{F}_{L_{F,g'}}) \odot ((\pi^{F,j'} * h^*) * \mathsf{F}_{L_{F,\beta}}) \odot (\Omega^{F,g} \circ h^*) \\ &= (\pi^{F,j''} * \mathsf{F}_{L_{F,g',h}}) \odot (\Omega^{F,h} * \mathsf{F}_{L_{F,g'}}) \odot (\Omega^{F,g'} \circ h^*) \odot (\pi^{F,\beta} \circ h^*) \\ &= \Omega^{F,h\circ g'} \odot (\pi^{F,\beta} \circ h^*).\end{aligned}$$

and on the other hand, $Z = (\pi^{F,j''} * \mathsf{F}_{L_{F,h*\beta}}) \odot \Omega^{F,h\circ g} = \Omega^{F,h\circ g'} \odot \pi^{F,\mathbf{1}_h*\beta}$. So, for the first identity we are reduced to showing that $\pi^{F,\beta} \circ h^* = \pi^{F,\mathbf{1}_h*\beta}$. The latter follows by direct inspection. Next, we compute :

$$\begin{aligned}Y' &= (\pi^{F,j''} * \mathsf{F}_{L_{F,g,h'}}) \odot (\Omega^{F,h'} * \mathsf{F}_{L_{F,g}}) \odot (\pi^{F,\beta'} * \mathsf{F}_{L_{F,g}}) \odot (\Omega^{F,g} \circ h^*) \\ &= (\Omega^{F,h'\circ g}) \odot (\Omega^{F,g} * h'^*)^{-1} \odot (\pi^{F,\beta'} * \mathsf{F}_{L_{F,g}}) \odot (\Omega^{F,g} \circ h^*)\end{aligned}$$

and on the other hand, $Z' = (\pi^{F,j''} * \mathsf{F}_{L_{F,\beta'*\mathbf{1}_g}}) \odot \Omega^{F,h\circ g} = \Omega^{F,h'\circ g} \odot \pi^{F,\beta'*g}$. So, for the second identity we are reduced to checking that

$$(\Omega^{F,g} * h'^*) \odot \pi^{F,\beta'*g} = (\pi^{F,\beta'} * \mathsf{F}_{L_{F,g}}) \odot (\Omega^{F,g} \circ h^*).$$

But this identity follows from the compatibility condition for $\Omega^{F,g}$. Lastly, let us check the composition and unit axioms for $2\text{-}\int_\varphi F$. Hence, let $j \xrightarrow{g} j' \xrightarrow{h} j'' \xrightarrow{k} j'''$ be three 1-cells of J; we need to prove that

$$L_{F,h\circ g,k} \odot (L_{F,k} * L_{F,g,h}) = L_{F,g,k\circ h} \odot (L_{F,h,k} * L_{F,g}) \qquad \text{and} \qquad L_{F,h,\mathbf{1}_{j'}} = \mathbf{1}_{L_{F,h}} = L_{F,\mathbf{1}_j,h}.$$

The two identities that express the unit axiom follow by a simple inspection. For the composition axiom, set $X := (\Omega^{F,k} * \mathsf{F}_{L_{F,h}} * \mathsf{F}_{L_{F,g}}) \odot ((\Omega^{F,h} \circ k^*) * \mathsf{F}_{L_{F,g}}) \odot (\Omega^{F,g} \circ h^* \circ k^*)$. It suffices to show that

$$Y := (\pi^{F,j'''} * (\mathsf{F}_{L_{F,h\circ g,k}} \odot (\mathsf{F}_{L_{F,k}} * \mathsf{F}_{L_{F,g,h}}))) \odot X = Z := (\pi^{F,j'''} * (\mathsf{F}_{L_{F,g,k\circ h}} \odot (\mathsf{F}_{L_{F,h,k}} * \mathsf{F}_{L_{F,g}}))) \odot X.$$

We compute :

$$\begin{aligned} Y &= (\pi^{F,j'''} * \mathsf{F}_{L_{F,h\circ g,k}}) \odot (\Omega^{F,k} * \mathsf{F}_{L_{F,h\circ g}}) \odot ((\pi^{F,j''} * k^*) * \mathsf{F}_{L_{F,g,h}}) \odot ((\Omega^{F,h} \circ k^*) * \mathsf{F}_{L_{F,g}}) \odot (\Omega^{F,g} \circ h^* \circ k^*) \\ &= (\pi^{F,j'''} * \mathsf{F}_{L_{F,h\circ g,k}}) \odot (\Omega^{F,k} * \mathsf{F}_{L_{F,h\circ g}}) \odot (\Omega^{F,h\circ g} \circ k^*) \\ &= \Omega^{F,k\circ h\circ g} \end{aligned}$$

and a similar calculation yields as well $Z = \Omega^{F,k\circ h\circ g}$: details left to the reader. □

Remark 2.6.7. In the situation of (2.6), suppose moreover that $\mathscr{C}$ is strongly 2-complete. In this case we can choose for $(L_{F,j}, \pi^{F,j})$ a strong 2-limit of $F \circ \mathsf{t}_j$, for every $j \in \mathrm{Ob}(J)$. Then, we may also choose $L_{F,g}$ for every 1-cell $g : j \to j'$ in J such that $\pi^{F,j} * g^* = \pi^{F,j'} \odot \mathsf{F}_{L_{F,g}}$, and take $\Omega^{F,g}$ to be the identity modification. With these choices, it follows easily that $L_{F,g,h}$ is an identity 2-cell, for every composable pair of 1-cells g, h of J. We conclude that, in this situation, the pseudo-functor $2\text{-}\int_\varphi F$ of lemma 2.6.6 shall be *strict*.

2.6.8. Keep the notation of (2.6), and let $F, F' : I \to \mathscr{C}$ be two unital pseudo-functors, and $\beta : F \Rightarrow F'$ a pseudo-natural transformation. Then, for every $j \in \mathrm{Ob}(J)$ there exist a 1-cell $L_{\beta,j} : L_{F,j} \to L_{F',j}$ and an invertible modification

$$\Omega^{\beta,j} : (\beta * \mathsf{t}_j) \odot \pi^{F,j} \rightsquigarrow \pi^{F',j} \odot \mathsf{F}_{L_{\beta,j}}.$$

Evidently, we take $L_{\mathbf{1}_F,j} := \mathbf{1}_{L_{F,j}}$ and $\Omega^{\mathbf{1}_F,j} := \mathbf{1}_{\pi^{F,j}}$ for every such F and j. If $g : j \to j'$ is any 1-cell of J, there exists a unique invertible 2-cell $L_{\beta,g} : L_{F',g} \circ L_{\beta,j} \Rightarrow L_{\beta,j'} \circ L_{F,g}$ such that

$$(2.6.9) \quad (\pi^{F',j'} * \mathsf{F}_{L_{\beta,g}}) \odot (\Omega^{F',g} * \mathsf{F}_{L_{\beta,j}}) \odot (\Omega^{\beta,j} \circ g^*) = (\Omega^{\beta,j'} * \mathsf{F}_{L_{F,g}}) \odot ((\beta * \mathsf{t}_{j'}) * \Omega^{F,g}).$$

A direct inspection shows that $L_{\mathbf{1}_F,g} = \mathbf{1}_{L_{F,g}}$ for every such F and g.

If $\beta' : F' \Rightarrow F''$ is another pseudo-natural transformation of unital pseudo-functors, there exists a unique invertible 2-cell $L_{\beta,\beta',j} : L_{\beta',j} \circ L_{\beta,j} \Rightarrow L_{\beta'\odot\beta,j}$ such that

$$(2.6.10) \qquad (\pi^{F'',j} * \mathsf{F}_{L_{\beta,\beta',j}}) \odot (\Omega^{\beta',j} * \mathsf{F}_{L_{\beta,j}}) \odot ((\beta' * \mathsf{t}_j) * \Omega^{\beta,j}) = \Omega^{\beta'\odot\beta,j}.$$

Lemma 2.6.11. *In the situation of* (2.6.8)*, the system of* 2*-cells* $(L_{\beta,g} \mid g : j \to j')$ *yields a coherence constraint for a pseudo-natural transformation*

$$2\text{-}\int_\varphi \beta : 2\text{-}\int_\varphi F \Rightarrow 2\text{-}\int_\varphi F' \qquad j \mapsto L_{\beta,j}.$$

Proof. Clearly $L_{\beta,\mathbf{1}_j} = \mathbf{1}_{L_{\beta,j}}$ for every $j \in \mathrm{Ob}(J)$. Next, let $j \xrightarrow{g} j' \xrightarrow{g'} j''$ be two 1-cells of J; we need to check the identity :

$$(L_{\beta,j''} * L_{F,g,g'}) \odot (L_{\beta,g'} * L_{F,g}) \odot (L_{F',g'} * L_{\beta,g}) = L_{\beta,g'\circ g} \odot (L_{F',g,g'} * L_{\beta,j}).$$

To this aim, set

$$\begin{aligned} X &:= (\Omega^{F',g'} * \mathsf{F}_{L_{F',g}} * \mathsf{F}_{L_{\beta,j}}) \odot ((\Omega^{F',g} \circ g'^*) * \mathsf{F}_{L_{\beta,j}}) \odot (\Omega^{\beta,j} \circ g^* \circ g'^*) \\ Y &:= \pi^{F',j''} * ((\mathsf{F}_{L_{\beta,j''}} * \mathsf{F}_{L_{F,g,g'}}) \odot (\mathsf{F}_{L_{\beta,g'}} * \mathsf{F}_{L_{F,g}})) \\ Z &:= Y \odot (\pi^{F',j''} * \mathsf{F}_{L_{F',g'}} * \mathsf{F}_{L_{\beta,g}}) \odot X \\ U &:= (\pi^{F',j''} * (\mathsf{F}_{L_{\beta,g'\circ g}} \odot (\mathsf{F}_{L_{F',g,g'}} * \mathsf{F}_{L_{\beta,j}}))) \odot X. \end{aligned}$$

It suffices to show that $U = Z$. We compute :

$$\begin{aligned} Z &= Y \odot (\Omega^{F',g'} * \mathsf{F}_{L_{\beta,j'}} * \mathsf{F}_{L_{F,g}}) \odot ((\pi^{F',j'} * g'^*) * \mathsf{F}_{L_{\beta,g}}) \odot ((\Omega^{F',g} \circ g'^*) * \mathsf{F}_{L_{\beta,j}}) \odot (\Omega^{\beta,j} \circ g^* \circ g'^*) \\ &= Y \odot (\Omega^{F',g'} * \mathsf{F}_{L_{\beta,j'}} * \mathsf{F}_{L_{F,g}}) \odot ((\Omega^{\beta,j'} \circ g'^*) * \mathsf{F}_{L_{F,g}}) \odot ((\beta * \mathsf{t}_{j''}) * (\Omega^{F,g} \circ g'^*)) \\ &= (\pi^{F',j''} * \mathsf{F}_{L_{\beta,j''} * L_{F,g,g'}}) \odot (\Omega^{\beta,j''} * \mathsf{F}_{L_{F,g'} * L_{F,g}}) \odot ((\beta * \mathsf{t}_{j''}) * \Omega^{F,g'} * \mathsf{F}_{L_{F,g}}) \odot ((\beta * \mathsf{t}_{j''}) * (\Omega^{F,g} \circ g'^*)) \\ &= (\Omega^{\beta,j''} * \mathsf{F}_{L_{F,g'\circ g}}) \odot ((\beta * \mathsf{t}_{j''}) * \pi^{F,j''} * \mathsf{F}_{L_{F,g,g'}}) \odot ((\beta * \mathsf{t}_{j''}) * \Omega^{F,g'} * \mathsf{F}_{L_{F,g}}) \odot ((\beta * \mathsf{t}_{j''}) * (\Omega^{F,g} \circ g'^*)) \\ &= (\Omega^{\beta,j''} * \mathsf{F}_{L_{F,g'\circ g}}) \odot ((\beta * \mathsf{t}_{j''}) * \Omega^{F,g'\circ g}) \end{aligned}$$

and on the other hand $U = (\pi^{F',j''} * \mathsf{F}_{L_{\beta,g'\circ g}}) \odot (\Omega^{F',g'\circ g} * \mathsf{F}_{L_{\beta,j}}) \odot (\Omega^{\beta,j} \circ g^* \circ g'^*)$, whence the contention. Lastly, we check the naturality condition for $L_{\beta,g}$: let $f, g : j \to j'$ be two 1-cells of J and $\alpha : f \Rightarrow g$ a 2-cell; we need to check the identity :

$$L_{\beta,g} \odot (L_{F',\alpha} * L_{\beta,j}) = (L_{\beta,j'} * L_{F,\alpha}) \odot L_{\beta,f}.$$

To this aim, set $X := (\Omega^{F',f} * \mathsf{F}_{L_{\beta,j}}) \odot (\Omega^{\beta,j} \circ f^*)$; it suffices to show that

$$Y' := (\pi^{F',j'} * (\mathsf{F}_{L_{\beta,g}} \odot (\mathsf{F}_{L_{F',\alpha}} * \mathsf{F}_{L_{\beta,j}}))) \odot X = Z' := (\pi^{F',j'} * ((\mathsf{F}_{L_{\beta,j'}} * \mathsf{F}_{L_{F,\alpha}}) \odot \mathsf{F}_{L_{\beta,f}})) \odot X.$$

Claim 2.6.12. $(\pi^{F',\alpha} * \mathsf{F}_{L_{\beta,j}}) \odot (\Omega^{\beta,j} \circ f^*) = (\Omega^{\beta,j} \circ g^*) \odot ((\beta * \mathsf{t}_{j'}) * \pi^{F,\alpha})$.

Proof of the claim. Recall that α induces a pseudo-natural transformation $\alpha^* : f^* \Rightarrow g^*$, and $\alpha^*(h) = (\mathbf{1}_i, \alpha) : h \circ f \to h \circ g$ for every $(h : j' \to \varphi(i)) \in \mathrm{Ob}(j'/\varphi I)$. The compatibility condition of $\Omega^{\beta,j}$ then yields a commutative diagram

$$\begin{array}{ccc} \beta_i \circ \pi^{F,j}_{f^*(h)} & \xrightarrow{\Omega^{\beta,j}_{f^*(h)}} & \pi^{F',j}_{f^*(h)} \circ L_{\beta,j} \\ {\scriptstyle \beta_i * \pi^{F,\alpha}_h} \Big\Downarrow & & \Big\Downarrow {\scriptstyle \pi^{F',\alpha}_h} \\ \beta_i \circ \pi^{F,j}_{g^*(h)} & \xrightarrow{\Omega^{\beta,j}_{g^*(h)}} & \pi^{F',j}_{g^*(h)} \circ L_{\beta,j}. \end{array}$$

The claim is an immediate consequence. ◊

Using claim 2.6.12, we may compute :

$$\begin{aligned} Y' &= (\pi^{F',j'} * \mathsf{F}_{L_{\beta,g}}) \odot (\Omega^{F',g} * \mathsf{F}_{L_{\beta,j}}) \odot (\pi^{F',\alpha} * \mathsf{F}_{L_{\beta,j}}) \odot (\Omega^{\beta,j} \circ f^*) \\ &= (\pi^{F',j'} * \mathsf{F}_{L_{\beta,g}}) \odot (\Omega^{F',g} * \mathsf{F}_{L_{\beta,j}}) \odot (\Omega^{\beta,j} \circ g^*) \odot ((\beta * \mathsf{t}_{j'}) * \pi^{F,\alpha}) \\ &= (\Omega^{\beta,j'} * \mathsf{F}_{L_{F,g}}) \odot ((\beta * \mathsf{t}_{j'}) * \Omega^{F,g}) \odot ((\beta * \mathsf{t}_{j'}) * \pi^{F,\alpha}) \\ &= (\Omega^{\beta,j'} * \mathsf{F}_{L_{F,g}}) \odot (\beta * \mathsf{t}_{j'} * ((\pi^{F,j'} * \mathsf{F}_{L_{F,\alpha}}) \odot \Omega^{F,f})) \end{aligned}$$

and on the other hand $Z' = (\pi^{F',j'} * (\mathsf{F}_{L_{\beta,j'}} * \mathsf{F}_{L_{F,\alpha}})) \odot (\Omega^{\beta,j'} * \mathsf{F}_{L_{F,f}}) \odot ((\beta * \mathsf{t}_{j'}) * \Omega^{F,f})$. So, we are reduced to proving that

$$(\Omega^{\beta,j'} * \mathsf{F}_{L_{F,g}}) \odot (\beta * \mathsf{t}_{j'} * \pi^{F,j'} * \mathsf{F}_{L_{F,\alpha}}) = (\pi^{F',j'} * (\mathsf{F}_{L_{\beta,j'}} * \mathsf{F}_{L_{F,\alpha}})) \odot (\Omega^{\beta,j'} * \mathsf{F}_{L_{F,f}}).$$

But the latter follows as usual from remark 2.1.1(i). □

Lemma 2.6.13. *In the situation of* (2.6.8)*, the system of* 2*-cells* $(L_{\beta,\beta',j} \mid j \in \mathrm{Ob}(J))$ *yields an invertible modification*

$$L_{\beta,\beta'} : 2\text{-}\!\int_\varphi \beta' \odot 2\text{-}\!\int_\varphi \beta \rightsquigarrow 2\text{-}\!\int_\varphi \beta' \odot \beta.$$

Proof. Let $g : j \to j'$ be any 1-cell of J; we need to show the identity

$$(L_{\beta,\beta',j'} * L_{F,g}) \odot (L_{\beta',j'} * L_{\beta,g}) \odot (L_{\beta',g} * L_{\beta,j}) = L_{\beta'\odot\beta,g} \odot (L_{F'',g} * L_{\beta,\beta',j}).$$

To this aim, let us set $X := ((\beta' * \mathsf{t}_{j'}) * \Omega^{\beta,j'} * \mathsf{F}_{L_{F,g}})^{-1} \odot (\Omega^{\beta',j'} * \mathsf{F}_{L_{\beta,j'}} * \mathsf{F}_{L_{F,g}})^{-1}$ and

$$\begin{aligned} Y_1 &:= X \odot (\pi^{F'',j'} * \mathsf{F}_{L_{\beta',j'}} * \mathsf{F}_{L_{\beta,g}}) \\ Y_2 &:= \pi^{F'',j'} * ((\mathsf{F}_{L_{\beta',g}} * \mathsf{F}_{L_{\beta,j}}) \odot (\mathsf{F}_{L_{F'',g}} * \mathsf{F}_{L_{\beta,\beta',j}})^{-1}) \\ Z &:= X \odot (\pi^{F'',j'} * ((\mathsf{F}_{L_{\beta,\beta',j'}} * \mathsf{F}_{L_{F,g}})^{-1} \odot \mathsf{F}_{L_{\beta'\odot\beta,g}})). \end{aligned}$$

It suffices to check that $Y := Y_1 \odot Y_2 = Z$. Set as well $U := (((\beta' \odot \beta) * \mathsf{t}_{j'}) * \Omega^{F,g})$; we compute :

$$\begin{aligned} Z &= (\Omega^{\beta'\odot\beta,j'} * \mathsf{F}_{L_{F,g}})^{-1} \odot (\pi^{F'',j'} * \mathsf{F}_{L_{\beta'\odot\beta,g}}) \\ &= U \odot (\Omega^{\beta'\odot\beta,j} \circ g^*)^{-1} \odot (\Omega^{F'',g} * \mathsf{F}_{L_{\beta'\odot\beta,j}})^{-1}. \end{aligned}$$

On the other hand, set $U' := (\Omega^{F'',g} * \mathsf{F}_{L_{\beta',j}})^{-1} \odot (\pi^{F'',j'} * \mathsf{F}_{L_{\beta',g}})^{-1}) * \mathsf{F}_{L_{\beta,j}}$; then

$$\begin{aligned} Y &= ((\beta' * \mathsf{t}_{j'}) * \Omega^{\beta,j'} * \mathsf{F}_{L_{F,g}})^{-1} \odot ((\beta' * \mathsf{t}_{j'}) * \pi^{F',j'} * \mathsf{F}_{L_{\beta,g}}) \odot (\Omega^{\beta',j'} * \mathsf{F}_{L_{F',g}} * \mathsf{F}_{L_{\beta,j}})^{-1} \odot Y_2 \\ &= U \odot ((\beta' * \mathsf{t}_{j'}) * ((\Omega^{\beta,j} \circ g^*)^{-1} \odot (\Omega^{F',g} * \mathsf{F}_{L_{\beta,j}})^{-1}) \odot (\Omega^{\beta',j'} * \mathsf{F}_{L_{F',g}} * \mathsf{F}_{L_{\beta,j}})^{-1} \odot Y_2 \\ &= U \odot ((\beta' * \mathsf{t}_{j'}) * (\Omega^{\beta,j} \circ g^*)^{-1}) \odot ((\Omega^{\beta',j} \circ g^*)^{-1} * \mathsf{F}_{L_{\beta,j}}) \odot U' \odot Y_2. \end{aligned}$$

Therefore, we are reduced to checking the identity :

$$((\pi^{F'',j} * g^*) * \mathsf{F}_{\beta,\beta',j})^{-1} \odot (\Omega^{F'',g} * \mathsf{F}_{L_{\beta'\odot\beta,j}})^{-1} = U' \odot Y_2.$$

However, we have :

$$((\pi^{F'',j} * g^*) * \mathsf{F}_{\beta,\beta',j})^{-1} \odot (\Omega^{F'',g} * \mathsf{F}_{L_{\beta'\odot\beta,j}})^{-1} = (\Omega^{F'',g} * \mathsf{F}_{L_{\beta',j} * L_{\beta,j}})^{-1} \odot (\pi^{F'',j'} * \mathsf{F}_{L_{F'',g}} * \mathsf{F}_{\beta,\beta',j})^{-1}$$

so we are further reduced to showing that :

$$(\pi^{F'',j'} * \mathsf{F}_{L_{F'',g}} * \mathsf{F}_{\beta,\beta',j})^{-1} = (\pi^{F'',j'} * \mathsf{F}_{L_{\beta',g}} * \mathsf{F}_{L_{\beta,j}})^{-1} \odot Y_2$$

which is obvious. □

2.6.14. Let $F, F' : I \to \mathscr{C}$ be two unital pseudo-functors, $\beta, \beta' : F \Rightarrow F'$ two pseudo-natural transformations, and $\Xi : \beta \rightsquigarrow \beta'$ a modification. Then for every $j \in \mathrm{Ob}(J)$ there exists a unique modification $L_{\Xi,j} : L_{\beta,j} \rightsquigarrow L_{\beta',j}$ such that

$$\Omega^{\beta',j} \odot ((\Xi \circ \mathsf{t}_j) * \pi^{F,j}) = (\pi^{F',j} * \mathsf{F}_{L_{\Xi,j}}) \odot \Omega^{\beta,j}.$$

Lemma 2.6.15. *In the situation of* (2.6.14)*, the rule* $j \mapsto L_{\Xi,j}$ *defines a modification*

$$2\text{-}\!\int_\varphi \Xi : 2\text{-}\!\int_\varphi \beta \rightsquigarrow 2\text{-}\!\int_\varphi \beta'.$$

Proof. Let $g : j \to j'$ be any 1-cell of J; we need to check the identity :

$$(L_{\Xi,j'} * L_{F,g}) \odot L_{\beta,g} = L_{\beta',g} \odot (L_{F',g} * L_{\Xi,j})$$

and as usual, it suffices to show that

$$Y := \pi^{F',j'} * ((\mathsf{F}_{L_{\Xi,j'}} * \mathsf{F}_{L_{F,g}}) \odot \mathsf{F}_{L_{\beta,g}}) = Z := \pi^{F',j'} * (\mathsf{F}_{L_{\beta',g}} \odot (\mathsf{F}_{L_{F',g}} * \mathsf{F}_{L_{\Xi,j}})).$$

We compute :

$$\begin{aligned}
Y &= ((\Omega^{\beta',j'} \odot ((\Xi \circ \mathsf{t}_{j'}) * \pi^{F,j'}) \odot (\Omega^{\beta,j'})^{-1}) * \mathsf{F}_{L_{F,g}}) \odot (\pi^{F',j'} * \mathsf{F}_{L_{\beta,g}}) \\
&= ((\Omega^{\beta',j'} \odot ((\Xi \circ \mathsf{t}_{j'}) * \pi^{F,j'})) * \mathsf{F}_{L_{F,g}}) \odot ((\beta * \mathsf{t}_{j'}) * \Omega^{F,g}) \odot (\Omega^{\beta,j} \circ g^*)^{-1} \odot (\Omega^{F',g} * \mathsf{F}_{L_{\beta,j}})^{-1} \\
&= (\Omega^{\beta',j'} * \mathsf{F}_{L_{F,g}}) \odot ((\beta' * \mathsf{t}_{j'}) * \Omega^{F,g}) \odot ((\Xi \circ \mathsf{t}_{j'}) * (\pi^{F,j} * g^*)) \odot (\Omega^{\beta,j} \circ g^*)^{-1} \odot (\Omega^{F',g} * \mathsf{F}_{L_{\beta,j}})^{-1} \\
&= (\Omega^{\beta',j'} * \mathsf{F}_{L_{F,g}}) \odot ((\beta' * \mathsf{t}_{j'}) * \Omega^{F,g}) \odot (\Omega^{\beta',j} \circ g^*)^{-1} \odot ((\pi^{F',j} * g^*) * \mathsf{F}_{L_{\Xi,j}}) \odot (\Omega^{F',g} * \mathsf{F}_{L_{\beta,j}})^{-1} \\
&= (\pi^{F',j'} * \mathsf{F}_{L_{\beta',g}}) \odot (\Omega^{F',g} * \mathsf{F}_{L_{\beta',j}}) \odot ((\pi^{F',j} * g^*) * \mathsf{F}_{L_{\Xi,j}}) \odot (\Omega^{F',g} * \mathsf{F}_{L_{\beta,j}})^{-1} \\
&= (\pi^{F',j'} * \mathsf{F}_{L_{\beta',g}}) \odot (\Omega^{F',g} * \mathsf{F}_{L_{\beta',j}}) \odot (\Omega^{F',g} * \mathsf{F}_{\beta',j})^{-1} \odot (\pi^{F',j'} * \mathsf{F}_{L_{F,g}} * \mathsf{F}_{\Xi,j}) \\
&= (\pi^{F',j'} * \mathsf{F}_{L_{\beta',g}}) \odot (\pi^{F',j'} * \mathsf{F}_{L_{F,g}} * \mathsf{F}_{\Xi,j})
\end{aligned}$$

whence the contention. □

Proposition 2.6.16. *Let $I, J, \mathscr{C}$ be as in* (2.6)*, and $\varphi : I \to J$ any pseudo-functor. The rules:*

$$F \mapsto 2\text{-}\int_{\varphi^u} F^u \qquad \beta \mapsto 2\text{-}\int_{\varphi^u} \beta^u \qquad \Xi \mapsto 2\text{-}\int_{\varphi^u} \Xi^u$$

for every pseudo-functor $F : I \to \mathscr{C}$, every pseudo-natural transformation β between pseudo-functors $F, F' : I \to \mathscr{C}$, and every modification Ξ of such pseudo-natural transformations (notation of remark 2.4.4(i)*) define a unital pseudo-functor*

$$2\text{-}\int_{\varphi} : \mathsf{PsFun}(I, \mathscr{C}) \to \mathsf{PsFun}(J, \mathscr{C})$$

with coherence constraint given by the system of invertible modifications $L_{\beta,\beta'}$ of lemma 2.6.13*. We call this pseudo-functor the* right 2-Kan extension along φ.

Proof. The sought functor shall be the composition of the strict 2-equivalence of remark 2.4.4(i) and a similar pseudo-functor $\mathsf{uniPsFun}(I, \mathscr{C}) \to \mathsf{uniPsFun}(J, \mathscr{C})$ given by the foregoing rules; we are therefore reduced to prove the existence of the latter. Now, a direct inspection shows that $L_{\mathbf{1}_F,\beta,j} = \mathbf{1}_{L_{\beta,j}} = L_{\beta,\mathbf{1}_{F'},j}$ for every pair of unital pseudo-functors $F, F' : I \to \mathscr{C}$, every $\beta : F \Rightarrow F'$ and every $j \in \mathrm{Ob}(J)$, whence the unit axiom for the system of modifications $L_{\beta,\beta'}$. In order to check the composition axiom, we need to show the identity :

$$L_{\beta' \odot \beta, \beta'', j} \odot (L_{\beta'',j} * L_{\beta,\beta',j}) = L_{\beta, \beta'' \odot \beta', j} \odot (L_{\beta',\beta'',j} * L_{\beta,j})$$

for every $j \in \mathrm{Ob}(J)$ and every three pseudo-natural transformations of unital pseudo-functors $\beta : F \Rightarrow F'$, $\beta' : F' \Rightarrow F''$, $\beta'' : F'' \Rightarrow F'''$. To this aim, set $X := \Omega^{\beta'' \odot \beta' \odot \beta, j}$, as well as :

$$\begin{aligned}
Y &:= (\pi^{F''',j} * ((\mathsf{F}_{L_{\beta'',j}} * \mathsf{F}_{L_{\beta,\beta',j}})^{-1} \odot \mathsf{F}^{-1}_{L_{\beta' \odot \beta, \beta'', j}})) \odot X \\
Z &:= (\pi^{F''',j} * ((\mathsf{F}_{L_{\beta',\beta'',j}} * \mathsf{F}_{L_{\beta,j}})^{-1} \odot \mathsf{F}^{-1}_{L_{\beta, \beta'' \odot \beta', j}})) \odot X.
\end{aligned}$$

It suffices to prove that $Y = Z$. We compute :

$$\begin{aligned}
Y &= (\pi^{F''',j} * \mathsf{F}_{L_{\beta'',j}} * \mathsf{F}_{L_{\beta,\beta',j}})^{-1} \odot (\Omega^{\beta'',j} * \mathsf{F}_{L_{\beta' \odot \beta, j}}) \odot ((\beta'' * \mathsf{t}_j) * \Omega^{\beta' \odot \beta, j}) \\
&= (\Omega^{\beta'',j} * \mathsf{F}_{L_{\beta',j}} * \mathsf{F}_{L_{\beta,j}}) \odot ((\beta'' * \mathsf{t}_j) * \pi^{F'',j} * \mathsf{F}_{L_{\beta,\beta',j}})^{-1} \odot ((\beta'' * \mathsf{t}_j) * \Omega^{\beta' \odot \beta, j}) \\
&= (\Omega^{\beta'',j} * \mathsf{F}_{L_{\beta',j}} * \mathsf{F}_{L_{\beta,j}}) \odot ((\beta'' * \mathsf{t}_j) * ((\Omega^{\beta',j} * \mathsf{F}_{L_{\beta,j}}) \odot ((\beta' * \mathsf{t}_j) * \Omega^{\beta,j})))
\end{aligned}$$

and likewise :

$$\begin{aligned} Z &= (\pi^{F''',j} * \mathsf{F}_{L_{\beta',\beta'',j}} * \mathsf{F}_{L_{\beta,j}})^{-1} \odot (\Omega^{\beta''\odot\beta',j} * \mathsf{F}_{L_{\beta,j}}) \odot ((\beta'' \odot \beta' * \mathsf{t}_j) * \Omega^{\beta,j}) \\ &= (((\Omega^{\beta'',j} * \mathsf{F}_{L_{\beta',j}}) \odot ((\beta'' * \mathsf{t}_j) * \Omega^{\beta',j})) * \mathsf{F}_{L_{\beta,j}}) \odot ((\beta'' \odot \beta' * \mathsf{t}_j) * \Omega^{\beta,j}) \end{aligned}$$

whence the contention. Next, consider three pseudo-natural transformations $\beta, \beta', \beta'' : F \Rightarrow F'$ and two modifications $\Xi : \beta \rightsquigarrow \beta'$ and $\Xi' : \beta' \rightsquigarrow \beta''$. For every $j \in \mathrm{Ob}(J)$ we have :

$$\Omega^{\beta'',j} \odot (((\Xi' \odot \Xi) \circ \mathsf{t}_j) * \pi^{F,j}) = (\pi^{F',j} * \mathsf{F}_{L_{\Xi',j}}) \odot \Omega^{\beta',j} \odot ((\Xi \circ \mathsf{t}_j) * \pi^{F,j}) = (\pi^{F',j} * \mathsf{F}_{L_{\Xi',j}} * \mathsf{F}_{L_{\Xi,j}}) \odot \Omega^{\beta,j}$$

whence $L_{\Xi'\odot\Xi,j} = L_{\Xi',j} \odot L_{\Xi,j}$. This shows that $2\text{-}\int_\varphi(\Xi' \odot \Xi) = 2\text{-}\int_\varphi \Xi' \odot 2\text{-}\int_\varphi \Xi$. Moreover, a simple inspection shows that $L_{\mathbf{1}_\beta,j} = \mathbf{1}_{L_{\beta,j}}$ for every pseudo-natural transformation β and every $j \in \mathrm{Ob}(J)$, so $2\text{-}\int_\varphi(\mathbf{1}_\beta)$ is the identity modification of $2\text{-}\int_\varphi \beta$.

Lastly, let $F, F', F'' : I \to \mathscr{C}$ be three unital pseudo-functors, $\beta, \beta : F \Rightarrow F'$ and $\alpha, \alpha' : F' \Rightarrow F''$ four pseudo-natural transformations, and $\Xi : \beta \rightsquigarrow \beta'$, $\Theta : \alpha \rightsquigarrow \alpha'$ two modifications; we need to show that

$$L_{\Theta*\Xi,j} \odot L_{\beta,\alpha,j} = L_{\beta',\alpha',j} \odot (L_{\Theta,j} * L_{\Xi,j}) \qquad \text{for every } j \in \mathrm{Ob}(J)$$

and by the foregoing, we may assume that either $\Xi = \mathbf{1}_\beta$ or $\Theta = \mathbf{1}_\alpha$. Suppose first that $\Theta = \mathbf{1}_\alpha$, and let $X := (\Omega^{\alpha,j} * \mathsf{F}_{\beta,j}) \odot ((\alpha * \mathsf{t}_j) * \Omega^{\beta,j})$; it suffices to prove that

$$Y := (\pi^{F'',j} * (\mathsf{F}_{L_{\alpha*\Xi,j}} \odot \mathsf{F}_{L_{\beta,\alpha,j}})) \odot X = Z := (\pi^{F'',j} * (\mathsf{F}_{L_{\beta',\alpha,j}} \odot (\mathsf{F}_{L_{\alpha,j}} * \mathsf{F}_{L_{\Xi,j}}))) \odot X.$$

We compute :

$$\begin{aligned} Z &= (\pi^{F'',j} * \mathsf{F}_{L_{\beta',\alpha,j}}) \odot (\Omega^{\alpha,j} * \mathsf{F}_{\beta',j}) \odot ((\alpha * \mathsf{t}_j) * \pi^{F',j} * \mathsf{F}_{L_{\Xi,j}}) \odot ((\alpha * \mathsf{t}_j) * \Omega^{\beta,j}) \\ &= (\pi^{F'',j} * \mathsf{F}_{L_{\beta',\alpha,j}}) \odot (\Omega^{\alpha,j} * \mathsf{F}_{\beta',j}) \odot ((\alpha * \mathsf{t}_j) * (\Omega^{\beta',j} \odot ((\Xi \circ \mathsf{t}_j) * \pi^{F,j}))) \\ &= \Omega^{\alpha\odot\beta',j} \odot ((\alpha * \mathsf{t}_j) * ((\Xi \circ \mathsf{t}_j) * \pi^{F,j}))) \end{aligned}$$

and on the other hand, $Y = (\pi^{F'',j} * \mathsf{F}_{L_{\alpha*\Xi,j}}) \odot \Omega^{\alpha\odot\beta}$, whence the contention. A similar calculation, left to the reader, settles the case where $\Xi = \mathbf{1}_\beta$, and concludes the proof. □

2.6.17. On the other hand, if $\mathscr{C}$ is 2-cocomplete, then $\mathscr{C}^o$ is 2-complete (remark 2.5.2(vi)), and in view of the strict isomorphisms of (2.2.13), we get a *left 2-Kan extension along* φ :

$$2\text{-}\int^\varphi : \mathsf{PsFun}(I, \mathscr{C}) \to \mathsf{PsFun}(J, \mathscr{C}) \qquad F \mapsto \Big(2\text{-}\int_{\varphi^o} F^o\Big)^o.$$

Explicitly, for every $j \in \mathrm{Ob}(J)$, the object $(2\text{-}\int^\varphi F)(j)$ represents the 2-colimit of the pseudo-functor $F \circ {}^o\mathsf{s}_{{}^oj} : {}^o({}^o\varphi({}^oI)/{}^oj) \to \mathscr{C}$.

Remark 2.6.18. (i) In the situation of (2.6.8), suppose that $\mathscr{C}$ is strongly 2-complete, and choose strong 2-limits $(L_{F,j}, \pi^{F,j})$, identity modifications $\Omega^{F,g}$, and 1-cells $L_{F,g}$ as in remark 2.6.7. Then we may further choose $L_{\beta,j}$ such that $(\beta * \mathsf{t}_j) \odot \pi^{F,j} = \pi^{F',j} \odot \mathsf{F}_{L_{\beta,j}}$, and let $\Omega^{\beta,j}$ as well be the corresponding identity modification. With such choices, it follows easily that $L_{\beta,g}$ shall be an identity 2-cell, for every 1-cell g of J, and the same for $L_{\beta,\beta'}$. Therefore, in this situation the pseudo-natural transformation $2\text{-}\int_\varphi \beta$ of lemma 2.6.11 shall be *strict* as well, and moreover $(2\text{-}\int_\varphi \beta') \odot (2\text{-}\int_\varphi \beta) = 2\text{-}\int_\varphi(\beta' \odot \beta)$.

(ii) We conclude that, with these choices, the pseudo-functor $2\text{-}\int_\varphi$ of proposition 2.6.16 factors through a *strict* pseudo-functor called the *strong right 2-Kan extension along* φ :

$$\mathsf{PsFun}(I, \mathscr{C}) \to \mathsf{stPsFun}(J, \mathscr{C})$$

(notation of definition 2.2.12(iii)). Likewise, if $\mathscr{C}$ is strongly 2-cocomplete, we obtain as in (2.6.17), a *strong left 2-Kan extension along* φ which is another strict pseudo-functors with values in $\mathsf{stPsFun}(J, \mathscr{C})$, namely the opposite of the strong right 2-Kan extension along φ^o.

2.6.19. Keep the notation of (2.6), and suppose now that *all the* 2*-cells of* J *are invertible*. Under this assumption, we easily see that the rule : $(i, f : j \to \varphi(i)) \mapsto f$ yields a pseudo-cone

$$\varphi_j^* : \mathsf{F}_j \Rightarrow \varphi \circ \mathsf{t}_j \qquad \text{for every } j \in \mathrm{Ob}(J)$$

whose coherence constraint is given by the rule : $(h, \alpha) \mapsto \alpha$ (notation of example 2.2.8(ii); notice that this would not be a coherence constraint, if α were not invertible : details left to the reader). Moreover, we have :

$$\varphi_{j'}^* \odot \mathsf{F}_g = \varphi_j^* * g^* \qquad \text{for every 1-cell } g : j \to j' \text{ of } J. \tag{2.6.20}$$

Furthermore, for every pair of 1-cells $g, g' : j \to j'$ and every 2-cell $\alpha : g \Rightarrow g'$ we get a modification

$$\varphi_j^* * \alpha^* : \varphi_j^* * g^* \rightsquigarrow \varphi_j^* * g'^* \qquad (f : j' \to \varphi(i)) \mapsto (\alpha * f : g^*(f) \Rightarrow g'^*(f)).$$

Let $F : I \to \mathscr{C}$ and $G : J \to \mathscr{C}$ be two *unital* pseudo-functors, and $\beta : G \circ \varphi \Rightarrow F$ a pseudo-natural transformation; there exist a 1-cell $\beta_j^\dagger : Gj \to L_{F,j}$ and an invertible modification

$$\Theta^{\beta,j} : (\beta * \mathsf{t}_j) \odot (G * \varphi_j^*) \rightsquigarrow \pi^{F,j} \odot \mathsf{F}_{\beta_j^\dagger} \qquad \text{for every } j \in \mathrm{Ob}(J).$$

Next, let $g : j \to j'$ be any 1-cell of J, and notice that $G * \varphi_j^* * g^* = G * (\varphi_{j'}^* \odot \mathsf{F}_g)$, due to (2.6.20); according to example 2.2.15(i) the coherence constraint γ^G of G induces an invertible modification

$$\Gamma^{G,g} : (G * \varphi_{j'}^*) \odot \mathsf{F}_{Gg} \rightsquigarrow G * \varphi_j^* * g^* \qquad (f : j' \to \varphi(i)) \mapsto \gamma_{g,f}^G.$$

Then there exists a unique invertible 2-cell $\tau_g^{\beta^\dagger} : L_{F,g} \circ \beta_j^\dagger \Rightarrow \beta_{j'}^\dagger \circ Gg$ such that :

$$(\pi^{F,j'} * \mathsf{F}_{\tau_g^{\beta^\dagger}}) \odot (\Omega^{F,g} * \mathsf{F}_{\beta_j^\dagger}) \odot (\Theta^{\beta,j} \circ g^*) \odot ((\beta * \mathsf{t}_{j'}) * \Gamma^{G,g}) = \Theta^{\beta,j'} * \mathsf{F}_{Gg}. \tag{2.6.21}$$

Lemma 2.6.22. *With the notation of* (2.6.19)*, the rule :* $j \mapsto \beta_j^\dagger$ *yields a pseudo-natural transformation*

$$\beta^\dagger : G \Rightarrow 2\text{-}\!\int_\varphi F$$

with coherence constraint given by the system of 2*-cells* $\tau_\bullet^{\beta^\dagger}$.

Proof. A simple inspection shows that $\tau_{\mathbf{1}_j}^{\beta^\dagger} = \mathbf{1}_{\beta_j^\dagger}$ for every $j \in \mathrm{Ob}(J)$. Next, let $g : j \to g'$ and $g' : j' \to j''$ be two 1-cells of J; we have to check the identity :

$$(\beta_{j''}^\dagger * \gamma_{g,g'}^G) \odot (\tau_{g'}^{\beta^\dagger} * Gg) \odot (L_{F,g'} * \tau_g^{\beta^\dagger}) = \tau_{g' \circ g}^{\beta^\dagger} \odot (L_{F,g,g'} * \beta_j^\dagger).$$

To this aim, set

$$\begin{aligned}
X &:= (\Theta^{\beta,j} \circ g^* \circ g'^*) \odot ((\beta * \mathsf{t}_{j''}) * (\Gamma^{G,g} \circ g'^*)) \odot ((\beta * \mathsf{t}_{j''}) * \Gamma^{G,g'} * \mathsf{F}_{Gg}) \\
X' &:= (\Omega^{F,g'} * \mathsf{F}_{L_{F,g}} * \mathsf{F}_{\beta_j^\dagger}) \odot ((\Omega^{F,g} \circ g'^*) * \mathsf{F}_{\beta_j^\dagger}) \odot X \\
Y &:= (\pi^{F,j''} * ((\mathsf{F}_{\beta_{j''}^\dagger} * \mathsf{F}_{\gamma_{g,g'}^G}) \odot (\mathsf{F}_{\tau_{g'}^{\beta^\dagger}} * \mathsf{F}_{Gg}) \odot (\mathsf{F}_{L_{F,g'}} * \mathsf{F}_{\tau_g^{\beta^\dagger}}))) \odot X' \\
Z &:= (\pi^{F,j''} * (\mathsf{F}_{\tau_{g' \circ g}^{\beta^\dagger}} \odot (\mathsf{F}_{L_{F,g,g'}} * \mathsf{F}_{\beta_j^\dagger}))) \odot X'.
\end{aligned}$$

It suffices to show that $Y = Z$. Set as well $Y' := \pi^{F,j''} * ((\mathsf{F}_{\beta^\dagger_{j''}} * \mathsf{F}_{\gamma^G_{g,g'}}) \odot (\mathsf{F}_{\tau^{\beta\dagger}_{g'}} * \mathsf{F}_{Gg}))$; we compute :

$$\begin{aligned} Y &= Y' \odot (\Omega^{F,g'} * \mathsf{F}_{\beta^\dagger_{j'}} * \mathsf{F}_{Gg}) \odot ((\pi^{F,j'} * g'^*) * \mathsf{F}_{\tau^{\beta\dagger}_{g}}) \odot ((\Omega^{F,g} \circ g'^*) * \mathsf{F}_{\beta^\dagger_j}) \odot X' \\ &= Y' \odot (\Omega^{F,g'} * \mathsf{F}_{\beta^\dagger_{j'}} * \mathsf{F}_{Gg}) \odot ((\Theta^{\beta,j'} \circ g'^*) * \mathsf{F}_{Gg}) \odot ((\beta * \mathsf{t}_{j''}) * \Gamma^{G,g'} * \mathsf{F}_{Gg}) \\ &= (\pi^{F,j''} * \mathsf{F}_{\beta^\dagger_{j''}} * \mathsf{F}_{\gamma^G_{g,g'}}) \odot (\Theta^{\beta,j''} * \mathsf{F}_{Gg'} * \mathsf{F}_{Gg}) \\ &= (\Theta^{\beta,j''} * \mathsf{F}_{G(g'\circ g)}) \odot ((\beta * \mathsf{t}_{j''}) * (G * \varphi^*_{j''}) * \mathsf{F}_{\gamma^G_{g,g'}}) \end{aligned}$$

whereas : $Z = (\pi^{F,j''} * \mathsf{F}_{\tau^{\beta\dagger}_{g'\circ g}}) \odot (\Omega^{F,g'\circ g} * \mathsf{F}_{\beta^\dagger_j}) \odot X$. So, we are reduced to checking that

$$(\Gamma^{G,g} \circ g'^*) \odot (\Gamma^{G,g'} * \mathsf{F}_{Gg}) = \Gamma^{G,g'\circ g} \odot ((G * \varphi^*_{j''}) * \mathsf{F}_{\gamma^G_{g,g'}}).$$

The latter follows from the composition axiom for γ^G. Lastly, the naturality of $\tau^{\beta^\dagger}$ amounts to the identity :

$$\tau^{\beta\dagger}_{g'} \odot (L_{F,\alpha} * \beta^\dagger_j) = (\beta^\dagger_{j'} * G\alpha) \odot \tau^{\beta\dagger}_g \qquad \text{for every 2-cell } \alpha : g \Rightarrow g' \text{ of } J.$$

To prove the latter, set $X := (\Omega^{F,g} * \mathsf{F}_{\beta^\dagger_j}) \odot (\Theta^{\beta,j} \circ g^*) \odot ((\beta * \mathsf{t}_{j'}) * \Gamma^{G,g})$; it suffices to show:

$$Y := (\pi^{F,j'} * (\mathsf{F}_{\tau^{\beta\dagger}_{g'}} \odot (\mathsf{F}_{L_{F,\alpha}} * \mathsf{F}_{\beta^\dagger_j}))) \odot X = Z := (\pi^{F,j'} * ((\mathsf{F}_{\beta^\dagger_{j'}} * \mathsf{F}_{G\alpha}) \odot \mathsf{F}_{\tau^{\beta\dagger}_g})) \odot X.$$

To this aim, we remark :

Claim 2.6.23. $(\pi^{F,\alpha} * \mathsf{F}_{\beta^\dagger_j}) \odot (\Theta^{\beta,j} \circ g^*) = (\Theta^{\beta,j} \circ g'^*) \odot ((\beta * \mathsf{t}_{j'}) * (G \circ (\varphi^*_j * \alpha^*))$.

Proof of the claim. We have $\alpha^*(f) = (\mathbf{1}_i, \alpha) : g \circ f \to g' \circ f$ for every $(f : j' \to \varphi(i)) \in \mathrm{Ob}(j'/\varphi I)$. Now, let $\tau^{G*\varphi^*_j}$ be the coherence constraint of $G * \varphi^*_j$; since φ is unital, it is easily seen that $\tau^{G*\varphi^*_j}_{\alpha^*(f)} = G(f * \alpha)$ (details left to the reader). Then the compatibility condition of $\Theta^{\beta,j}$ yields the commutative diagram :

$$\begin{array}{ccc} \beta_i \circ G(f \circ g) & \xrightarrow{\ \Theta^{\beta,j}_{g^*(f)}\ } & \pi^{F,j}_{g^*(f)} \circ \beta^\dagger_j \\ {\scriptstyle \beta_i * G(f*\alpha)} \Downarrow & & \Downarrow {\scriptstyle \pi^{F,\alpha}} \\ \beta_i \circ G(f \circ g') & \xrightarrow{\ \Theta^{\beta,j}_{g'^*(f)}\ } & \pi^{F,j}_{g'^*(f)} \odot \beta^\dagger_j \end{array}$$

whence the claim. ◊

Using claim 2.6.23 we compute :

$$\begin{aligned} Y &= (\pi^{F,j'} * \mathsf{F}_{\tau^{\beta\dagger}_{g'}}) \odot ((\Omega^{F,g'} \odot \pi^{F,\alpha}) * \mathsf{F}_{\beta^\dagger_j}) \odot (\Theta^{\beta,j} \circ g^*) \odot ((\beta * \mathsf{t}_{j'}) * \Gamma^{G,g}) \\ &= (\pi^{F,j'} * \mathsf{F}_{\tau^{\beta\dagger}_{g'}}) \odot (\Omega^{F,g'} * \mathsf{F}_{\beta^\dagger_j}) \odot (\Theta^{\beta,j} \circ g'^*) \odot ((\beta * \mathsf{t}_{j'}) * (G \circ (\varphi^*_j * \alpha^*)) \odot ((\beta * \mathsf{t}_{j'}) * \Gamma^{G,g}) \\ &= (\Theta^{\beta,j'} * \mathsf{F}_{Gg'}) \odot ((\beta * \mathsf{t}_{j'}) * \Gamma^{G,g'})^{-1} \odot ((\beta * \mathsf{t}_{j'}) * (G \circ (\varphi^*_j * \alpha^*)) \odot ((\beta * \mathsf{t}_{j'}) * \Gamma^{G,g}) \end{aligned}$$

and on the other hand

$$Z = (\pi^{F,j'} * \mathsf{F}_{\beta^\dagger_{j'}} * \mathsf{F}_{G\alpha}) \odot (\Theta^{\beta,j'} * \mathsf{F}_{Gg}) = (\Theta^{\beta,j'} * \mathsf{F}_{Gg'}) \odot ((\beta * \mathsf{t}_{j'}) * (G * \varphi^*_{j'}) * \mathsf{F}_{G\alpha})$$

so we are reduced to showing that :

$$(G \circ (\varphi^*_j * \alpha^*)) \odot \Gamma^{G,g} = \Gamma^{G,g'} \odot ((G * \varphi^*_{j'}) * \mathsf{F}_{G\alpha}).$$

But the latter follows from the naturality condition for γ^G. □

Remark 2.6.24. In the situation of (2.6.19), suppose that $\mathscr{C}$ is strongly 2-complete, so that we may take for 2-$\int_\varphi$ the strong 2-right Kan extension of remark 2.6.18(ii). Then we may also choose $\beta^\dagger_j$ such that $(\beta * \mathsf{t}_j) \odot (G * \varphi^*_j) = \pi^{F,j} \odot \mathsf{F}_{\beta^\dagger_j}$, and we may let $\Theta^{\beta,j}$ be the corresponding identity modification. Suppose now additionally that G is a strict pseudo-functor; by inspecting (2.6.21), we deduce that with such choices, $\beta^\dagger$ is then a *strict* pseudo-natural transformation.

2.6.25. Keep the notation of (2.6.19), and let $\beta, \beta' : G \circ \varphi \Rightarrow F$ be two pseudo-natural transformations and $\Xi : \beta \rightsquigarrow \beta'$ a modification. Then there exists for every $j \in \mathrm{Ob}(J)$ a unique 2-cell $\Xi^\dagger_j : \beta^\dagger_j \Rightarrow \beta'^\dagger_j$ such that

$$(2.6.26) \qquad (\pi^{F,j} * \mathsf{F}_{\Xi^\dagger_j}) \odot \Theta^{\beta,j} = \Theta^{\beta',j} \odot ((\Xi \circ \mathsf{t}_j) * (G * \varphi^*_j)).$$

Lemma 2.6.27. *In the situation of* (2.6.25)*, the rule :* $j \mapsto \Xi^\dagger_j$ *defines a modification*

$$\Xi^\dagger : \beta^\dagger \rightsquigarrow \beta'^\dagger.$$

Proof. Let $g : j \to j'$ be any 1-cell of J; we need to show the identity :

$$\tau^{\beta'^\dagger}_g \odot (L_{F,g} * \Xi^\dagger_j) = (\Xi^\dagger_{j'} * Gg) \odot \tau^{\beta^\dagger}_g.$$

To this aim, set $X := (\Omega^{F,g} * \mathsf{F}_{\beta^\dagger_j}) \odot (\Theta^{\beta,j} \circ g^*) \odot ((\beta * \mathsf{t}_{j'}) * \Gamma^{G,g})$; it suffices to show that

$$Y := (\pi^{F,j'} * (\mathsf{F}_{\tau^{\beta'\dagger}_g} \odot (\mathsf{F}_{L_{F,g}} * \mathsf{F}_{\Xi^\dagger_j}))) \odot X = Z := (\pi^{F,j'} * ((\mathsf{F}_{\Xi^\dagger_{j'}} * \mathsf{F}_{Gg}) \odot \mathsf{F}_{\tau^{\beta\dagger}_g})) \odot X.$$

We compute :

$$\begin{aligned}
Y &= (\pi^{F,j'} * \mathsf{F}_{\tau^{\beta'\dagger}_g}) \odot (\Omega^{F,g} * \mathsf{F}_{\beta'^\dagger_j}) \odot ((\pi^{F,j} * g^*) * \mathsf{F}_{\Xi^\dagger_j}) \odot (\Theta^{\beta,j} \circ g^*) \odot ((\beta * \mathsf{t}_{j'}) * \Gamma^{G,g}) \\
&= (\pi^{F,j'} * \mathsf{F}_{\tau^{\beta'\dagger}_g}) \odot (\Omega^{F,g} * \mathsf{F}_{\beta'^\dagger_j}) \odot (\Theta^{\beta',j} \circ g^*) \odot ((\Xi \circ \mathsf{t}_{j'}) * (G * \varphi^*_j * g^*)) \odot ((\beta * \mathsf{t}_{j'}) * \Gamma^{G,g}) \\
&= (\pi^{F,j'} * \mathsf{F}_{\tau^{\beta'\dagger}_g}) \odot (\Omega^{F,g} * \mathsf{F}_{\beta'^\dagger_j}) \odot (\Theta^{\beta',j} \circ g^*) \odot ((\beta' * \mathsf{t}_{j'}) * \Gamma^{G,g}) \odot ((\Xi \circ \mathsf{t}_{j'}) * (G * \varphi^*_{j'}) * \mathsf{F}_{Gg}) \\
&= (\Theta^{\beta',j'} * \mathsf{F}_{Gg}) \odot ((\Xi \circ \mathsf{t}_{j'}) * (G * \varphi^*_{j'}) * \mathsf{F}_{Gg}).
\end{aligned}$$

whereas : $Z = (\pi^{F,j'} * \mathsf{F}_{\Xi^\dagger_{j'}} * \mathsf{F}_{Gg}) \odot (\Theta^{\beta,j'} * \mathsf{F}_{Gg})$, whence the contention. □

Proposition 2.6.28. *With the notation of lemmata* 2.6.22 *and* 2.6.27*, the rules :* $\beta \mapsto \beta^\dagger$ *and* $\Xi \mapsto \Xi^\dagger$ *define a functor*

$$(-)^\dagger_{F,G} : \mathsf{PsNat}(G \circ \varphi, F) \to \mathsf{PsNat}\Big(G, 2\text{-}\int_\varphi F\Big).$$

Proof. A simple inspection shows that $(\mathbf{1}_\beta)^\dagger = \mathbf{1}_{\beta^\dagger}$ for every pseudo-natural transformation $\beta : G \circ \varphi \Rightarrow F$. It remains to check that $(\Xi' \odot \Xi)^\dagger = \Xi'^\dagger \odot \Xi$ for every three pseudo-natural transformations $\beta, \beta', \beta'' : G \circ \varphi \Rightarrow F$ and every pair of modifications $\Xi : \beta \rightsquigarrow \beta'$ and $\Xi' : \beta' \rightsquigarrow \beta''$. However, we have :

$$\begin{aligned}
(\pi^{F,j} * \mathsf{F}_{\Xi'^\dagger_j} * \mathsf{F}_{\Xi^\dagger_j}) \odot \Theta^{\beta,j} &= (\pi^{F,j} * \mathsf{F}_{\Xi'^\dagger_j}) \odot \Theta^{\beta',j} \odot ((\Xi \circ \mathsf{t}_j) * (G * \varphi^*_j)) \\
&= \Theta^{\beta'',j} \odot ((\Xi' \circ \mathsf{t}_j) * (G * \varphi^*_j)) \odot ((\Xi \circ \mathsf{t}_j) * (G * \varphi^*_j)) \\
&= \Theta^{\beta'',j} \odot (((\Xi' \odot \Xi) \circ \mathsf{t}_j) * (G * \varphi^*_j))
\end{aligned}$$

whence the contention. □

2.6.29. Keep the notation of (2.6.19). We set

$$\omega_i^F := \pi^{F,\varphi(i)}_{(i,\mathbf{1}_{\varphi(i)})} : L_{F,\varphi(i)} \to Fi \qquad \text{for every } i \in \mathrm{Ob}(I)$$

$$\tau_f^{\omega^F} := \Omega^{F,\varphi(f)}_{(i',\mathbf{1}_{\varphi(i')})} \odot \tau^{F,\varphi(i)}_{(f,\mathbf{1}_{\varphi(f)})} : Ff \circ \omega_i^F \Rightarrow \omega_{i'}^F \circ L_{F,\varphi(f)} \quad \text{for every 1-cell } f : i \to i' \text{ of } I$$

where $\tau^{F,\varphi(i)}$ denotes the coherence constraint of $\pi^{F,\varphi(i)}$.

Lemma 2.6.30. *The rule : $i \mapsto \omega_i^F$ for every $i \in \mathrm{Ob}(I)$ defines a pseudo-natural transformation*

$$\omega^F : \Big(2\text{-}\!\int_\varphi F\Big) \circ \varphi \Rightarrow F$$

whose coherence constraint is given by the system of 2*-cells* $\tau_\bullet^{\omega^F}$.

Proof. Let $f, f' : i \to i'$ be two 1-cells of I and $\alpha : f \Rightarrow f'$ a 2-cell; for the naturality of τ^{ω^F} we need to check the identity :

$$\tau_{f'}^{\omega^F} \odot (F\alpha * \omega_i^F) = (\omega_{i'}^F * L_{F,\varphi(\alpha)}) \odot \tau_f^{\omega^F}.$$

However, notice that α induces two 1-cells $(f, \varphi(\alpha)), (f', \mathbf{1}_{\varphi(f')}) : (i, \mathbf{1}_{\varphi(i)}) \to (i', \varphi(f'))$ and a 2-cell $\alpha : (f, \varphi(\alpha)) \Rightarrow (f', \mathbf{1}_{\varphi(f')})$ of $\varphi(i)/\varphi I$. By naturality of $\tau^{F,\varphi(i)}$ we deduce the identity :

$$\tau^{F,\varphi(i)}_{(f,\varphi(\alpha))} = \pi^{F,\varphi(i)}_{(f',\mathbf{1}_{\varphi(f')})} \odot (F\alpha * \pi^{F,\varphi(i)}_{(i,\mathbf{1}_{\varphi(i)})})$$

whence :

$$\tau_{f'}^{\omega^F} \odot (F\alpha * \omega_i^F) = \Omega^{F,\varphi(f')}_{(i',\mathbf{1}_{\varphi(i')})} \odot \tau^{F,\varphi(i)}_{(f,\varphi(\alpha))}.$$

On the other hand, from (2.6.4) we get :

$$(\omega_{i'}^F * L_{F,\varphi(\alpha)}) \odot \tau_f^{\omega^F} = \Omega^{F,\varphi(f')}_{(i',\mathbf{1}_{\varphi(i')})} \odot \pi^{F,\varphi(\alpha)}_{(i',\mathbf{1}_{\varphi(i')})} \odot \tau^{F,\varphi(i)}_{(f,\mathbf{1}_{\varphi(f)})}.$$

So we are reduced to checking the identity : $\tau^{F,\varphi(i)}_{(f,\varphi(\alpha))} = \tau^{F,\varphi(i)}_{(\mathbf{1}_{i'},\varphi(\alpha))} \odot \tau^{F,\varphi(i)}_{(f,\mathbf{1}_{\varphi(f)})}$. The latter follows from the coherence axiom for $\tau^{F,\varphi(i)}$. Next, we check the coherence axioms for ω^F. To this aim, notice that for every $i \in \mathrm{Ob}(I)$ and $f := \mathbf{1}_i$, the two-cell $\tau^{F,\varphi(i)}_{(f,\mathbf{1}_{\varphi(f)})}$ is the identity of the 1-cell $\pi^{F,\varphi(i)}_{(i,\mathbf{1}_{\varphi(i)})}$ (remark 2.4.2(ii)); it follows easily that $\tau_{\mathbf{1}_i}^{\omega^F} = \mathbf{1}_{\omega_i^F}$. Lastly, consider two 1-cells $f : i \to i'$, $f' : i' \to i''$ of I, and set $X := \omega_{i''}^F * (L_{F,\gamma^\varphi_{f,f'}} \odot L_{F,\varphi(f),\varphi(f')})$; we need to show that

$$Y := X \odot (\tau_{f'}^{\omega^F} * L_{F,\varphi(f)}) \odot (Ff' * \tau_f^{\omega^F}) = Z := \tau_{f'\circ f}^{\omega^F} \odot (\gamma^F_{f,f'} * \omega_i^F)$$

where γ^φ and γ^F are the coherence constraints of φ and F. We compute :

$$\begin{aligned}
Y &= X \odot ((\Omega^{F,\varphi(f')}_{(i'',\mathbf{1}_{\varphi(i'')})} \odot \tau^{F,\varphi(i')}_{(f',\mathbf{1}_{\varphi(f')})}) * L_{F,\varphi(f)}) \odot (Ff' * (\Omega^{F,\varphi(f)}_{(i',\mathbf{1}_{\varphi(i')})} \odot \tau^{F,\varphi(i)}_{(f,\mathbf{1}_{\varphi(f)})})) \\
&= X \odot (\Omega^{F,\varphi(f')}_{(i'',\mathbf{1}_{\varphi(i'')})} * L_{F,\varphi(f)}) \odot \Omega^{F,\varphi(f)}_{(i',\varphi(f'))} \odot \tau^{F,\varphi(i)}_{(f',\mathbf{1}_{\varphi(f')\circ\varphi(f)})} \odot (Ff' * \tau^{F,\varphi(i)}_{(f,\mathbf{1}_{\varphi(f)})}) \\
&= (\omega_{i''}^F * L_{F,\gamma^\varphi_{f,f'}}) \odot \Omega^{F,\varphi(f')\circ\varphi(f)}_{(i'',\mathbf{1}_{\varphi(i'')})} \odot \tau^{F,\varphi(i)}_{(f',\mathbf{1}_{\varphi(f')\circ\varphi(f)})} \odot (Ff' * \tau^{F,\varphi(i)}_{(f,\mathbf{1}_{\varphi(f)})}) \\
&= \Omega^{F,\varphi(f'\circ f)}_{(i'',\mathbf{1}_{\varphi(i'')})} \odot \pi^{F,\gamma^\varphi_{f,f'}}_{(i'',\mathbf{1}_{\varphi(i'')})} \odot \tau^{F,\varphi(i)}_{(f',\mathbf{1}_{\varphi(f')\circ\varphi(f)})} \odot (Ff' * \tau^{F,\varphi(i)}_{(f,\mathbf{1}_{\varphi(f)})}) \\
&= \Omega^{F,\varphi(f'\circ f)}_{(i'',\mathbf{1}_{\varphi(i'')})} \odot \pi^{F,\gamma^\varphi_{f,f'}}_{(i'',\mathbf{1}_{\varphi(i'')})} \odot \tau^{F,\varphi(i)}_{(f'\circ f,(\gamma^\varphi_{f,f'})^{-1})} \odot (\gamma^F_{f,f'} * \pi^{F,\varphi(i)}_{i,\mathbf{1}_{\varphi(i)}})
\end{aligned}$$

where the second equality follows from the compatibility condition for $\Omega^{F,\varphi(f)}$, the third follows from (2.6.2), the fourth follows from (2.6.4), and the fifth holds by virtue of the coherence axiom for $\tau^{F,\varphi(i)}$, taking into account (2.6.3). So, we are reduced to checking that

$$\pi^{F,\gamma^\varphi_{f,f'}}_{(i'',\mathbf{1}_{\varphi(i'')})} \odot \tau^{F,\varphi(i)}_{(f'\circ f,(\gamma^\varphi_{f,f'})^{-1}))} = \tau^{F,\varphi(i)}_{(f'\circ f,\mathbf{1}_{\varphi(f'\circ f)})}$$

which follows again from (2.6.3) and the coherence axiom for $\tau^{F,\varphi(i)}$. □

2.6.31. In view of lemma 2.6.30 we may define a functor :

$$(-)^{\ddagger}_{F,G} : \mathsf{PsNat}\Big(G, 2\text{-}\int_{\varphi} F\Big) \to \mathsf{PsNat}(G \circ \varphi, F) \qquad \beta \mapsto \beta^{\ddagger} := \omega^F \odot (\beta * \varphi)$$

attaching to every modification $\Xi : \beta \rightsquigarrow \beta'$ of pseudo-natural transformations $\beta, \beta' : G \Rightarrow 2\text{-}\int_{\varphi} F$, the modification $\omega^F * (\Xi \circ \varphi)$. For any pseudo-natural transformation $\beta : G \circ \varphi \Rightarrow F$ we set

$$\Lambda^{\beta}_i := \Theta^{\beta,\varphi(i)}_{(i,\mathbf{1}_{\varphi(i)})} : \beta_i \Rightarrow (\beta^{\dagger})^{\ddagger}_i \qquad \text{for every } i \in \mathrm{Ob}(I).$$

Lemma 2.6.32. *The rule : $i \mapsto \Lambda^{\beta}_i$ defines an invertible modification*

$$\Lambda^{\beta} : \beta \rightsquigarrow (\beta^{\dagger})^{\ddagger}$$

and the rule : $\beta \mapsto \Lambda^{\beta}$ defines an isomorphism of functors :

$$\Lambda : \mathbf{1}_{\mathsf{PsNat}(G\circ\varphi,F)} \xrightarrow{\sim} (-)^{\ddagger}_{F,G} \circ (-)^{\dagger}_{F,G}.$$

Proof. Let $f : i \to i'$ be any 1-cell of I; we need to check the identity :

$$Y := (\pi^{F,\varphi(i')}_{(i',\mathbf{1}_{\varphi(i')})} * \tau^{\beta^{\dagger}}_{\varphi(f)}) \odot (\tau^{\omega^F}_f * \beta^{\dagger}_{\varphi(i)}) \odot (Ff * \Theta^{\beta,\varphi(i)}_{(i,\mathbf{1}_{\varphi(i)})}) = Z := (\Theta^{\beta,\varphi(i')}_{i',\mathbf{1}_{\varphi(i')}} * G\varphi(f)) \odot \tau^{\beta}_f$$

where τ^{β} denotes the coherence constraint of β. Let also $\tau^{(\beta*\mathsf{t}_{\varphi(i)})\odot(G*\varphi^*_{\varphi(i)})}$ be the coherence constraint of $(\beta * \mathsf{t}_{\varphi(i)}) \odot (G * \varphi^*_{\varphi(i)})$, and notice that $\tau^{(\beta*\mathsf{t}_{\varphi(i)})\odot(G*\varphi^*_{\varphi(i)})}_{(f,\mathbf{1}_{\varphi(f)})} = \tau^{\beta}_f$. Combining with the compatibility condition for $\Theta^{\beta,\varphi(i)}$ relative to the 1-cell $(f, \mathbf{1}_{\varphi(f)})$ of $\varphi(i)/\varphi I$, we get :

$$Y = (\pi^{F,\varphi(i')}_{(i',\mathbf{1}_{\varphi(i')})} * \tau^{\beta^{\dagger}}_{\varphi(f)}) \odot (\Omega^{F,\varphi(f)}_{(i',\mathbf{1}_{\varphi(i')})} * \beta^{\dagger}_{\varphi(i)}) \odot (\Theta^{\beta,\varphi(i)}_{(i',\varphi(f))} * G\varphi(i)) \odot \tau^{\beta}_f.$$

Then the sought identity follows from (2.6.21), applied with $g := (f, \mathbf{1}_{\varphi(i)})$, after noticing that $\Gamma^{G,g}_{(i',\mathbf{1}_{\varphi(i')})} = \mathbf{1}_{G\varphi(f)}$, since G is unital. Lastly, let $\beta, \beta' : G \Rightarrow 2\text{-}\int_{\varphi} F$ be two pseudo-natural transformations, and $\Xi : \beta \rightsquigarrow \beta'$ a modification; the naturality of Λ amounts to the identity :

$$(\omega^F_i * \Xi^{\dagger}_{\varphi(i)}) \odot \Lambda^{\beta}_i = \Lambda^{\beta'}_i \odot \Xi_i \qquad \text{for every } i \in \mathrm{Ob}(I)$$

which follows directly from (2.6.26). □

Lemma 2.6.33. *In the situation of* (2.6.19)*, for every $j \in \mathrm{Ob}(J)$ the rule*

$$(i, j \xrightarrow{g} \varphi(i)) \mapsto \Delta^{F,j}_{(i,g)} := \Omega^{F,g}_{(i,\mathbf{1}_{\varphi(i)})} \qquad \textit{for every } (i,g) \in \mathrm{Ob}(j/\varphi I)$$

defines an invertible modification

$$\Delta^{F,j} : \pi^{F,j} \rightsquigarrow (\omega^F * \mathsf{t}_j) \odot \Big(\Big(2\text{-}\int_{\varphi} F\Big) * \varphi^*_j\Big).$$

Proof. Let $(f, \alpha) : (i, g) \to (i', g')$ be any 1-cell of $j/\varphi I$; we need to check the identity :

$$\Omega^{F,g'}_{(i',\mathbf{1}_{\varphi(i')})} \odot \tau^{F,j}_{(f,\alpha)} = Y := (\pi^{F,\varphi(i')}_{(i',\mathbf{1}_{\varphi(i')})} * (L_{F,\alpha} \odot L_{F,g,\varphi(f)})) \odot (\tau^{\omega^F}_f * L_{F,g}) \odot (Ff * \Omega^{F,g}_{(i,\mathbf{1}_{\varphi(i)})}).$$

We compute :

$$\begin{aligned}
Y &= (\pi^{F,\varphi(i')}_{(i',\mathbf{1}_{\varphi(i')})} * (L_{F,\alpha} \odot L_{F,g,\varphi(f)})) \odot ((\Omega^{F,\varphi(f)}_{(i',\mathbf{1}_{\varphi(i')})} \odot \tau^{F,\varphi(i)}_{(f,\mathbf{1}_{\varphi(f)})}) * L_{F,g}) \odot (Ff * \Omega^{F,g}_{(i,\mathbf{1}_{\varphi(i)})}) \\
&= (\pi^{F,\varphi(i')}_{(i',\mathbf{1}_{\varphi(i')})} * (L_{F,\alpha} \odot L_{F,g,\varphi(f)})) \odot (\Omega^{F,\varphi(f)}_{(i',\mathbf{1}_{\varphi(i')})} * L_{F,g}) \odot \Omega^{F,g}_{(i',\varphi(f))} \odot \tau^{F,j}_{(f,g^*(\mathbf{1}_{\varphi(f)}))} \\
&= (\pi^{F,\varphi(i')}_{(i',\mathbf{1}_{\varphi(i')})} * L_{F,\alpha}) \odot \Omega^{F,\varphi(f)\circ g}_{(i',\mathbf{1}_{\varphi(i')})} \odot \tau^{F,j}_{(f,g^*(\mathbf{1}_{\varphi(f)}))} \\
&= \Omega^{F,g'}_{(i',\mathbf{1}_{\varphi(i')})} \odot \pi^{F,\alpha}_{(i',\mathbf{1}_{\varphi(i')})} \odot \tau^{F,j}_{(f,g^*(\mathbf{1}_{\varphi(f)}))}
\end{aligned}$$

where the second equality holds by the compatibility condition of $\Omega^{F,g}$, applied to the 1-cell $(f,\mathbf{1}_{\varphi(f)}):(i,\mathbf{1}_{\varphi(i)})\to(i',\varphi(f))$ of $\varphi(i)/\varphi I$, the third equality follows from (2.6.2), and the fourth equality follows from (2.6.4). So we are reduced to checking that

$$\tau^{F,j}_{(f,\alpha)}=\pi^{F,\alpha}_{(i',\mathbf{1}_{\varphi(i')})}\odot\tau^{F,j}_{(f,g^*(\mathbf{1}_{\varphi(f)}))}$$

which follows from the coherence condition for $\tau^{F,j}$, relative to the composition of 1-cells $(i,g)\xrightarrow{(f,\mathbf{1}_{\varphi(f)\circ g})}(i',\varphi(f)\circ g)\xrightarrow{(\mathbf{1}_{i'},\alpha)}(i',g')$. □

2.6.34. Now, let $\beta:G\Rightarrow 2\text{-}\int_\varphi F$ be a pseudo-natural transformation. For every $j\in\mathrm{Ob}(J)$ we get the 1-cell $(\beta^\ddagger)^\dagger_j:Gj\to L_{F,j}$, as well as the invertible modification

$$\Theta^{\beta^\ddagger,j}:(\omega^F*\mathsf{t}_j)\odot(\beta*(\varphi\circ\mathsf{t}_j))\odot(G*\varphi^*_j)\rightsquigarrow\pi^{F,j}\odot\mathsf{F}_{(\beta^\ddagger)^\dagger_j}.$$

On the other hand, by example 2.2.15(ii) we have the invertible modification

$$\Upsilon^{\beta,j}:\left(\left(2\text{-}\int_\varphi F\right)*\varphi^*_j\right)\odot(\beta*\mathsf{F}_j)\rightsquigarrow(\beta*(\varphi\circ\mathsf{t}_j))\odot(G*\varphi^*_j)\qquad(i,f:j\to\varphi(i))\mapsto\tau^\beta_{\varphi^*_{j,(i,f)}}$$

where τ^β is the coherence constraint of β, and notice that $\beta*\mathsf{F}_j=\mathsf{F}_{\beta_j}$. We set

$$\Delta^{\beta,j}:=\Theta^{\beta^\ddagger,j}\odot((\omega^F*\mathsf{t}_j)*\Upsilon^{\beta,j})\odot(\Delta^{F,j}*\mathsf{F}_{\beta_j}):\pi^{F,j}\odot\mathsf{F}_{\beta_j}\rightsquigarrow\pi^{F,j}\odot\mathsf{F}_{(\beta^\ddagger)^\dagger_j}.$$

There exists then a unique invertible 2-cell

$$\Psi^\beta_j:\beta_j\Rightarrow(\beta^\ddagger)^\dagger_j\qquad\text{such that}\qquad\pi^{F,j}*\mathsf{F}_{\Psi^\beta_j}=\Delta^{\beta,j}.$$

Lemma 2.6.35. *The rule : $j\mapsto\Psi^\beta_j$ for every $j\in\mathrm{Ob}(J)$ yields an invertible modification*

$$\Psi^\beta:\beta\rightsquigarrow(\beta^\ddagger)^\dagger.$$

Proof. Let $g:j\to j'$ be any 1-cell of J; we need to show that

$$\tau^{(\beta^\ddagger)^\dagger}_g\odot(L_{F,g}*\Psi^\beta_j)=(\Psi^\beta_{j'}*Gg)\odot\tau^\beta_g$$

and recall that the coherence constraint $\tau^{(\beta^\ddagger)^\dagger}_g$ of $(\beta^\ddagger)^\dagger$ is characterized by the identity :

$$(\pi^{F,j'}*\mathsf{F}_{\tau^{(\beta^\ddagger)^\dagger}_g})\odot(\Omega^{F,g}*\mathsf{F}_{(\beta^\ddagger)^\dagger_j})\odot(\Theta^{\beta^\ddagger,j}\circ g^*)\odot((\beta^\ddagger*\mathsf{t}_{j'})*\Gamma^{G,g})=\Theta^{\beta^\ddagger,j'}*\mathsf{F}_{Gg}.$$

As usual, we reduce to checking the identity :

$$Y:=\pi^{F,j'}*(\mathsf{F}_{\tau^{(\beta^\ddagger)^\dagger}_g}\odot(\mathsf{F}_{L_{F,g}}*\mathsf{F}_{\Psi^\beta_j}))=Z:=\pi^{F,j'}*((\mathsf{F}_{\Psi^\beta_{j'}}*\mathsf{F}_{Gg})\odot\mathsf{F}_{\tau^\beta_g}).$$

To ease notation, set $H:=2\text{-}\int_\varphi F$; we remark :

Claim 2.6.36. $((\beta*\varphi*\mathsf{t}_{j'})*\Gamma^{G,g})^{-1}\odot(\Upsilon^{\beta,j}\circ g^*)=(\Upsilon^{\beta,j'}*\mathsf{F}_{Gg})\odot((H*\varphi^*_{j'})*\mathsf{F}_{\tau^\beta_g})\odot(\Gamma^{H,g}*\mathsf{F}_{\beta_j})^{-1}$.

Proof of the claim. The left-hand side is the modification

$$(H*\varphi^*_j*g^*)\odot\mathsf{F}_{\beta_j}\rightsquigarrow(\beta*(\varphi\circ\mathsf{t}_{j'}))\odot(G*\varphi^*_{j'})\odot\mathsf{F}_{Gg}\qquad(i,h:j'\to\varphi(i))\mapsto\tau^\beta_{h\circ g}\odot(\beta_{\varphi(i)}*\gamma^G_{g,h})^{-1}$$

and the coherence axiom for τ^β gives :

$$(\beta_{\varphi(i)}*\gamma^G_{g,h})^{-1}\odot\tau^\beta_{h\circ g}=(\tau^\beta_h*Gg)\odot(L_{F,h}*\tau^\beta_g)\odot(L_{F,g,h}*\beta_j)^{-1}$$

where γ^G is the coherence constraint of G. The claim translates the latter identity. ◊

Now, let $X := \Theta^{\beta^\ddagger,j'} * \mathsf{F}_{Gg}$ and $X' := X \odot (\omega^F * \mathsf{t}_{j'}) * \Upsilon^{\beta',j} * \mathsf{F}_{Gg}$. We compute :

$$\begin{aligned} Y &= X \odot ((\beta^\ddagger * \mathsf{t}_{j'}) * \Gamma^{G,g})^{-1} \odot (\Theta^{\beta^\ddagger,j} \circ g^*)^{-1} \odot (\Omega^{F,g} * \mathsf{F}_{(\beta^\ddagger)^\dagger_j})^{-1} \odot (\pi^{F,j'} * \mathsf{F}_{L_{F,g}} * \mathsf{F}_{\Psi^\beta_j}) \\ &= X \odot ((\beta^\ddagger * \mathsf{t}_{j'}) * \Gamma^{G,g})^{-1} \odot (\Theta^{\beta^\ddagger,j} \circ g^*)^{-1} \odot ((\pi^{F,j} * g^*) * \mathsf{F}_{\psi^\beta_j}) \odot (\Omega^{F,g} * \mathsf{F}_{\beta_j})^{-1} \\ &= X \odot ((\beta^\ddagger * \mathsf{t}_{j'}) * \Gamma^{G,g})^{-1} \odot (\Theta^{\beta^\ddagger,j} \circ g^*)^{-1} \odot (\Delta^{\beta,j} \circ g^*) \odot (\Omega^{F,g} * \mathsf{F}_{\beta_j})^{-1} \\ &= X \odot ((\beta^\ddagger * \mathsf{t}_{j'}) * \Gamma^{G,g})^{-1} \odot ((\omega^F * \mathsf{t}_{j'}) * (\Upsilon^{\beta,j} \circ g^*)) \odot ((\Delta^{F,j} \circ g^*) * \mathsf{F}_{\beta_j}) \odot (\Omega^{F,g} * \mathsf{F}_{\beta_j})^{-1} \\ &= X' \odot ((\omega^F * \mathsf{t}_{j'}) * (((H * \varphi^*_{j'}) * \mathsf{F}_{\tau^\beta_g}) \odot (\Gamma^{H,g} * \mathsf{F}_{\beta_j})^{-1})) \odot ((\Delta^{F,j} \circ g^*) * \mathsf{F}_{\beta_j}) \odot (\Omega^{F,g} * \mathsf{F}_{\beta_j})^{-1} \end{aligned}$$

where the last equality follows from claim 2.6.36. On the other hand :

$$Z = X' \odot (\Delta^{F,j'} * \mathsf{F}_{\beta_{j'}} * \mathsf{F}_{Gg}) \odot (\pi^{F,j'} * \mathsf{F}_{\tau^\beta_g}) = X' \odot ((\omega^F * \mathsf{t}_{j'}) * (H * \varphi^*_{j'}) * \mathsf{F}_{\tau^\beta_g}) \odot (\Delta^{F,j'} * \mathsf{F}_{Hg} * \mathsf{F}_{\beta_j})$$

so we are reduced to showing that

$$\Delta^{F,j} \circ g^* = ((\omega^F * \mathsf{t}_{j'}) * \Gamma^{H,g}) \odot (\Delta^{F,j'} * \mathsf{F}_{Hg}) \odot \Omega^{F,g}$$

which follows from (2.6.2). □

Proposition 2.6.37. *For every unital pseudo-functors $F : I \to \mathscr{C}$ and $G : J \to \mathscr{C}$, the functors $(-)^\dagger_{F,G}$ of proposition 2.6.28 and $(-)^\ddagger_{F,G}$ of (2.6.31) are equivalences.*

Proof. In view of lemmata 2.6.32 and 2.6.35, it suffices to prove that the rule : $\beta \mapsto \Psi^\beta$ defines a natural transformation

$$\Psi : \mathbf{1}_{\mathsf{PsNat}(G,2\text{-}\int_\varphi F)} \Rightarrow (-)^\dagger_{F,G} \circ (-)^\ddagger_{F,G}.$$

Thus, let $\alpha, \beta : G \Rightarrow 2\text{-}\int_\varphi F$ be two pseudo-natural transformations, and $\Xi : \alpha \rightsquigarrow \beta$ a modification; we need to check the identity :

$$\Psi^\beta_j \odot \Xi_j = (\omega^F * (\Xi \circ \varphi))^\dagger_j \odot \Psi^\alpha_j \qquad \text{for every } j \in \mathrm{Ob}(J)$$

and as usual, it suffices to show that

$$Y := \pi^{F,j} * (\mathsf{F}_{\Psi^\beta_j} \odot \mathsf{F}_{\Xi_j}) = Z := \pi^{F,j} * (\mathsf{F}_{(\omega^F * (\Xi \circ \varphi))^\dagger_j} \odot \mathsf{F}_{\Psi^\alpha_j}).$$

To ease notation, set $H := 2\text{-}\int_\varphi F$; we remark :

Claim 2.6.38. $((\Xi \circ \varphi \circ \mathsf{t}_j) * (G * \varphi^*_j)) \odot \Upsilon^{\alpha,j} = \Upsilon^{\beta,j} \odot ((H * \varphi^*_j) * (\Xi \circ \mathsf{F}_j))$.

Proof of the claim. The left-hand side is the modification :

$$(H * \varphi^*_j) \odot (\alpha * \mathsf{F}_j) \rightsquigarrow (\beta * (\varphi \circ \mathsf{t}_j)) \odot (G * \varphi^*_j) \qquad (j, g \mapsto \varphi(i)) \mapsto (\Xi_{\varphi(i)} * Gg) \odot \tau^\alpha_g$$

where τ^α is the coherence constraint of α; then the compatibility condition for Ξ gives :

$$(\Xi_{\varphi(i)} * Gg) \odot \tau^\alpha_g = \tau^\beta_g \odot (Hg * \Xi_j)$$

and the claim translates the latter identity. ◊

We have : $Y = \Delta^{\beta,j} \odot (\pi^{F,j} * \mathsf{F}_{\Xi_j}) = \Theta^{\beta^\ddagger,j} \odot ((\omega^F * \mathsf{t}_j) * \Upsilon^{\beta,j}) \odot (\Delta^{F,j} * \mathsf{F}_{\beta_j}) \odot (\pi^{F,j} * \mathsf{F}_{\Xi_j})$, and

$$\begin{aligned} Z &= (\pi^{F,j} * \mathsf{F}_{(\omega^F * (\Xi \circ \varphi))^\dagger_j}) \odot \Delta^\alpha_j \\ &= (\pi^{F,j} * \mathsf{F}_{(\omega^F * (\Xi \circ \varphi))^\dagger_j}) \odot \Theta^{\alpha^\ddagger,j} \odot ((\omega^F * \mathsf{t}_j) * \Upsilon^{\alpha,j}) \odot (\Delta^{F,j} * \mathsf{F}_{\alpha_j}) \\ &= \Theta^{\beta^\ddagger,j} \odot (((\omega^F * (\Xi \circ \varphi)) \circ \mathsf{t}_j) * (G * \varphi^*_j)) \odot ((\omega^F * \mathsf{t}_j) * \Upsilon^{\alpha,j}) \odot (\Delta^{F,j} * \mathsf{F}_{\alpha_j}) \\ &= \Theta^{\beta^\ddagger,j} \odot ((\omega^F * \mathsf{t}_j) * (\Xi \circ \varphi \circ \mathsf{t}_j) * (G * \varphi^*_j)) \odot ((\omega^F * \mathsf{t}_j) * \Upsilon^{\alpha,j}) \odot (\Delta^{F,j} * \mathsf{F}_{\alpha_j}) \\ &= \Theta^{\beta^\ddagger,j} \odot ((\omega^F * \mathsf{t}_j) * (\Upsilon^{\beta,j} \odot ((H * \varphi^*_j) * (\Xi \circ \mathsf{F}_j)))) \odot (\Delta^{F,j} * \mathsf{F}_{\alpha_j}) \end{aligned}$$

where the last equality holds by claim 2.6.38. Thus, we are reduced to checking the identity :

$$\Delta^{F,j} * \mathsf{F}_{\beta_j} \odot (\pi^{F,j} * \mathsf{F}_{\Xi_j}) = ((\omega^F * \mathsf{t}_j) * (H * \varphi_j^*) * (\Xi \circ \mathsf{F}_j)) \odot (\Delta^{F,j} * \mathsf{F}_{\alpha_j})$$

which follows as usual from remark 2.1.1(i). □

Theorem 2.6.39. *Let I be a small 2-category, J a 2-category with small* Hom*-categories, $\varphi : I \to J$ any pseudo-functor, and suppose that all the 2-cells of J are invertible. Then for every 2-complete (resp. 2-cocomplete) 2-category $\mathscr{C}$ the right (resp. left) 2-Kan extension along φ is a right (resp. left) 2-adjoint for the pseudo-functor*

$$\mathsf{PsFun}(\varphi, \mathscr{C}) : \mathsf{PsFun}(J, \mathscr{C}) \to \mathsf{PsFun}(I, \mathscr{C}).$$

Proof. Let us show first that the rule : $(F, G) \mapsto (-)^\ddagger_{F,G}$ yields a pseudo-natural equivalence :

$$(-)^\ddagger : \mathsf{PsNat}\Big(\mathbf{1}_{\mathsf{uniPsFun}(J,\mathscr{C})}, 2\text{-}\!\int_\varphi\Big) \xrightarrow{\sim} \mathsf{PsNat}(\mathsf{uniPsFun}(\varphi^u, \mathscr{C}), \mathbf{1}_{\mathsf{uniPsFun}(I,\mathscr{C})})$$

(notation of remark 2.4.4(i)). To this aim let us remark :

Claim 2.6.40. Let $F, F' : I \to \mathscr{C}$ be two unital pseudo-functors. Every pseudo-natural transformation $\mu : F \Rightarrow F'$ induces an invertible modification :

$$\Sigma^\mu : \mu \odot \omega^F \rightsquigarrow \omega^{F'} \odot \Big(\Big(2\text{-}\!\int_\varphi \mu\Big) * \varphi\Big) \qquad i \mapsto \Omega^{\mu,\varphi(i)}_{(i,\mathbf{1}_{\varphi(i)})}.$$

Proof of the claim. Let $f : i \to i'$ be any 1-cell of I, and τ^μ the coherence constraint of μ; set :

$$Y := (\pi^{F',\varphi(i')}_{(i',\mathbf{1}_{\varphi(i')})} * L_{\mu,\varphi(f)}) \odot (\tau^{\omega^{F'}}_f * L_{\mu,\varphi(i)}) \odot (F'f * \Omega^{\mu,\varphi(i)}_{(i,\mathbf{1}_{\varphi(i)})})$$
$$Z := (\Omega^{\mu,\varphi(i')}_{(i',\mathbf{1}_{\varphi(i')})} * L_{F,\varphi(f)}) \odot (\mu_{i'} * \tau^{\omega^F}_f) \odot (\tau^\mu_f * \pi^{F,\varphi(i)}_{(i,\mathbf{1}_{\varphi(i)})})$$

so that we need to check the identity $Y = Z$. We compute :

$$\begin{aligned} Y &= (\pi^{F',\varphi(i')}_{(i',\mathbf{1}_{\varphi(i')})} * L_{\mu,\varphi(f)}) \odot ((\Omega^{F',\varphi(f)}_{(i',\mathbf{1}_{\varphi(i')})} \odot \tau^{F',\varphi(i)}_{(f,\mathbf{1}_{\varphi(f)})}) * L_{\mu,\varphi(i)}) \odot (F'f * \Omega^{\mu,\varphi(i)}_{(i,\mathbf{1}_{\varphi(i)})}) \\ &= (\pi^{F',\varphi(i')}_{(i',\mathbf{1}_{\varphi(i')})} * L_{\mu,\varphi(f)}) \odot (\Omega^{F',\varphi(f)}_{(i',\mathbf{1}_{\varphi(i')})} * L_{\mu,\varphi(i)}) \odot \Omega^{\mu,\varphi(i)}_{(i',\varphi(f))} \odot (\mu_{i'} * \tau^{F,\varphi(i)}_{(f,\mathbf{1}_{\varphi(f)})}) \odot (\tau^\mu_f * \pi^{F,\varphi(i)}_{(i,\mathbf{1}_{\varphi(i)})}) \end{aligned}$$

where the second equality follows from the compatibility condition of $\Omega^{\mu,\varphi(i)}$, relative to the 1-cell $(f, \mathbf{1}_{\varphi(f)}) : (i, \mathbf{1}_{\varphi(i)}) \to (i', \varphi(f))$ of $\varphi(i)/\varphi I$. We are thus reduced to showing that :

$$(\pi^{F',\varphi(i')}_{(i',\mathbf{1}_{\varphi(i')})} * L_{\mu,\varphi(f)}) \odot (\Omega^{F',\varphi(f)}_{(i',\mathbf{1}_{\varphi(i')})} * L_{\mu,\varphi(i)}) \odot \Omega^{\mu,\varphi(i)}_{(i',\varphi(f))} = (\Omega^{\mu,\varphi(i')}_{(i',\mathbf{1}_{\varphi(i')})} * L_{F,\varphi(f)}) \odot (\mu_{i'} * \Omega^{F,\varphi(f)}_{(i',\mathbf{1}_{\varphi(i')})})$$

which follows from (2.6.9). ♢

Claim 2.6.41. Let $F, F' : I \to \mathscr{C}$ and $G, G' : J \to \mathscr{C}$ be four unital pseudo-functors, $\lambda : G' \Rightarrow G$ and $\mu : F \Rightarrow F'$ two pseudo-natural transformations. The rule

$$\beta \mapsto \tau^\ddagger_{(\lambda,\mu),\beta} := \Sigma^\mu * ((\beta \odot \lambda) * \varphi)$$

yields the orientation for an essentially commutative square diagram of functors :

$$\begin{array}{ccc} \mathsf{PsNat}(G, 2\text{-}\!\int_\varphi F) & \xrightarrow{(-)^\ddagger_{F,G}} & \mathsf{PsNat}(G \circ \varphi, F) \\ {\scriptstyle \mathsf{PsNat}(\lambda, 2\text{-}\!\int_\varphi \mu)} \downarrow & \swarrow \tau^\ddagger_{(\lambda,\mu)} & \downarrow {\scriptstyle \mathsf{PsNat}(\lambda * \varphi, \mu)} \\ \mathsf{PsNat}(G', 2\text{-}\!\int_\varphi F') & \xrightarrow[(-)^\ddagger_{F',G'}]{} & \mathsf{PsNat}(G' \circ \varphi, F'). \end{array}$$

Proof of the claim. Let $\beta, \beta' : G \to 2\text{-}\int_\varphi F$ be two pseudo-natural transformations, and $\Xi : \beta \rightsquigarrow \beta'$ a modification; we need to check the identity :

$$\tau^\ddagger_{(\lambda,\mu),\beta'} \odot (\mu * \omega^F * (\Xi \circ \varphi) * (\lambda * \varphi)) = \Big(\omega^{F'} * \Big(\Big(\Big(2\text{-}\int_\varphi \mu\Big) * \Xi * \lambda\Big) \circ \varphi\Big)\Big) \odot \tau^\ddagger_{(\lambda,\mu),\beta}$$

and we come down to showing that :

$$(\Sigma^\mu * (\beta' * \varphi)) \odot (\mu * \omega^F * (\Xi \circ \varphi)) = \Big(\omega^{F'} * \Big(\Big(2\text{-}\int_\varphi \mu\Big) * \varphi\Big) * (\Xi \circ \varphi)\Big) \odot (\Sigma^\mu * (\beta * \varphi))$$

which follows from remark 2.1.1(i). $\Diamond$

To conclude the proof, it remains to check that the rule $(\lambda, \mu) \mapsto \tau^\ddagger_{(\lambda,\mu)}$ yields a coherence constraint for the sought pseudo-functor $(-)^\ddagger$. For the first coherence axiom, notice that both the source and target of $(-)^\ddagger$ are themselves unital pseudo-functors, hence it suffices to check that $\tau^\ddagger_{(\mathbf{1}_G,\mathbf{1}_F)}$ is the identity automorphism of $(-)^\ddagger_{F,G}$, for every pair of unital pseudo-functors $F : I \to \mathscr{C}$ and $G : J \to \mathscr{C}$ (remark 2.4.2(ii)). We then come down to checking that $\Sigma^{\mathbf{1}_F} = \mathbf{1}_{\omega^F}$ for every such F; the latter identity follows by a direct inspection of the definitions.

Next, consider unital pseudo-functors $F, F', F'' : I \to \mathscr{C}$, $G, G', G'' : J \to \mathscr{C}$ and two pairs of pseudo-natural transformations $(\lambda' : G'' \Rightarrow G', \mu' : F' \Rightarrow F'')$ and $(\lambda : G' \Rightarrow G, \mu : F \Rightarrow F')$; we need to check the identity :

$$((-)^\ddagger_{F'',G''} * \mathsf{PsNat}(G'', L_{\mu,\mu'})) \odot \Big(\tau^\ddagger_{(\lambda',\mu')} * \mathsf{PsNat}\Big(\lambda, 2\text{-}\int_\varphi \mu\Big)\Big) \odot (\mathsf{PsNat}(\lambda' * \varphi, \mu') * \tau^\ddagger_{(\lambda,\mu)}) = \tau^\ddagger_{(\lambda'\odot\lambda,\mu'\odot\mu)}.$$

Thus, let $\beta : G \Rightarrow 2\text{-}\int_\varphi F$ be any pseudo-natural transformation, and set $\rho := (\beta \odot \lambda \odot \lambda') * \varphi$; the assertion comes down to the identity :

$$(\omega^F * (L_{\mu,\mu'} \circ \varphi) * \rho) \odot \Big(\Sigma^{\mu'} * \Big(\Big(\Big(2\text{-}\int_\varphi \mu\Big) * \varphi\Big) \odot \rho\Big)\Big) \odot (\mu' * \Sigma^\mu * \rho) = \Sigma^{\mu'\odot\mu} * \rho$$

so it suffices to show that :

$$(\omega^F * (L_{\mu,\mu'} \circ \varphi)) \odot \Big(\Sigma^{\mu'} * \Big(\Big(2\text{-}\int_\varphi \mu\Big) * \varphi\Big)\Big) \odot (\mu' * \Sigma^\mu) = \Sigma^{\mu'\odot\mu}$$

which holds by (2.6.10). Lastly, the source and target of $(-)^\ddagger$ are pseudo-functors

$$\mathsf{uniPsFun}(J, \mathscr{C})^o \times \mathsf{uniPsFun}(I, \mathscr{C}) \to \mathbf{Cat}.$$

On the other hand, the strict 2-equivalences $(-)^u$ of remark 2.4.4(i) yield a strict 2-equivalence

$$U : \mathsf{PsFun}(J, \mathscr{C})^o \times \mathsf{PsFun}(I, \mathscr{C}) \xrightarrow{\sim} \mathsf{uniPsFun}(J, \mathscr{C})^o \times \mathsf{uniPsFun}(I, \mathscr{C})$$

and the strict isomorphisms of pseudo-functors (2.4.5) yield pseudo-natural isomorphisms

$$\mathsf{PsNat}\Big(\mathbf{1}_{\mathsf{uniPsFun}(J,\mathscr{C})}, 2\text{-}\int_\varphi\Big) \circ U \xrightarrow{\sim} \mathsf{PsNat}\Big(\mathbf{1}_{\mathsf{PsFun}(J,\mathscr{C})}, 2\text{-}\int_\varphi\Big)$$

$$\mathsf{PsNat}(\mathsf{uniPsFun}(\varphi^u, \mathscr{C}), \mathbf{1}_{\mathsf{uniPsFun}(I,\mathscr{C})}) \circ U \xrightarrow{\sim} \mathsf{PsNat}(\mathsf{PsFun}(\varphi, \mathscr{C}), \mathbf{1}_{\mathsf{PsFun}(I,\mathscr{C})}).$$

Summing up, we deduce the sought 2-adjunction between $\mathsf{PsFun}(\varphi, \mathscr{C})$ and $2\text{-}\int_\varphi$.

The assertion concerning the left 2-Kan extension along φ is an immediate consequence, in view of remark 2.4.28(i). $\square$

Corollary 2.6.42. *In the situation of theorem* 2.6.39*, suppose that φ is fully faithful. Then the same holds for the pseudo-functor* $2\text{-}\int_\varphi$ *(resp. for* $2\text{-}\int^\varphi$*).*

Proof. As usual, it suffices to check the assertion concerning right 2-Kan extensions. To this aim, we notice :

Claim 2.6.43. Suppose that $\varphi : I \to J$ is fully faithful and that all the 2-cells of J are invertible. Then for every $i \in \mathrm{Ob}(I)$, the object $(i, \mathbf{1}_{\varphi(i)})$ is pseudo-initial in $\varphi(i)/\varphi I$.

Proof of the claim. Let (i', f) be any othe object of $\varphi(i)/\varphi I$; by assumption, there exist a 1-cell $g : i \to i'$ in I and an invertible 2-cell $\alpha : \varphi(g) \xrightarrow{\sim} f$ in J. Then we get the 1-cell

$$(i, \mathbf{1}_{\varphi(i)}) \xrightarrow{(g,\mathbf{1}_{\varphi(g)})} (i', \varphi(g)) \xrightarrow{(\mathbf{1}_{i'},\alpha)} (i', f).$$

Next, let $(t, \alpha), (s, \beta) : (i, \mathbf{1}_{\varphi(i)}) \to (i', f)$ be two 1-cells in $\varphi(i)/\varphi I$; by assumption β and α are invertible, hence we get the invertible 2-cell $\beta^{-1} \odot \alpha : \varphi(t) \xrightarrow{\sim} \varphi(s)$, and since φ is fully faithful, there exists a unique invertible 2-cell $\lambda : t \xrightarrow{\sim} s$ in I such that $\varphi(\lambda) = \beta^{-1} \odot \alpha$. We deduce an invertible 2-cell $\lambda : (t, \alpha) \xrightarrow{\sim} (s, \beta)$ in $\varphi(i)/\varphi I$, and it is easily seen that this is the unique 2-cell from (t, α) to (s, β). The claim follows. ◊

Let now $F : I \to \mathscr{C}$ be any pseudo-functor, and for every $j \in \mathrm{Ob}(J)$, let $(L_{F,j}, \pi^{F,j})$ be a 2-limit of $F \circ \mathrm{t}_j$, as in (2.6); in view of claim 2.6.43 and proposition 2.5.16, we deduce that the 1-cell $\pi^{F,\varphi(i)}_{(i,\mathbf{1}_{\varphi(i)})} : L_{F,j} \to Fi$ is an equivalence for every $i \in \mathrm{Ob}(I)$, and therefore the pseudo-natural transformation ω^F of lemma 2.6.30 is a pseudo-natural equivalence. To conclude, it suffices now to invoke corollary 2.4.29. □

3. Special categories

3.1. **Fibrations.** Let $\varphi : \mathscr{A} \to \mathscr{B}$ be a functor, $f : A' \to A$ a morphism in $\mathscr{A}$. We say that f is *φ-cartesian*, or – slightly abusively – that f is *$\mathscr{B}$-cartesian*, if the induced commutative diagram of sets (notation of (1.1.25)) :

$$\begin{array}{ccc} \mathrm{Hom}_{\mathscr{A}}(X, A') & \xrightarrow{f_*} & \mathrm{Hom}_{\mathscr{A}}(X, A) \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\varphi} \\ \mathrm{Hom}_{\mathscr{B}}(\varphi X, \varphi A') & \xrightarrow{(\varphi f)_*} & \mathrm{Hom}_{\mathscr{B}}(\varphi X, \varphi A) \end{array}$$

is cartesian for every $X \in \mathrm{Ob}(\mathscr{A})$. In this case, one also says that f *is an inverse image of* A over φf, or – slightly abusively – that A' *is an inverse image of* A over φf.

Remark 3.1.1. Keep the notation of (3.1).

(i) It is easily seen that the composition of two $\mathscr{B}$-cartesian morphisms is $\mathscr{B}$-cartesian.

(ii) Let $g : B' \to B$ and $g' : B'' \to B'$ be two morphisms of $\mathscr{B}$, and $f : A' \to A$ and $f'' : A'' \to A$ two $\mathscr{B}$-cartesian morphisms of $\mathscr{A}$ such that $\varphi f = g$ and $\varphi f'' = g \circ g'$. Then there exists a unique morphism $f' : A'' \to A'$ of $\mathscr{A}$ such that $\varphi f' = g'$ and $f'' = f \circ f'$, and this morphism is $\mathscr{B}$-cartesian : the detailed verification shall be left to the reader.

Definition 3.1.2. Let $\varphi : \mathscr{A} \to \mathscr{B}$ be a functor, and B any object of $\mathscr{B}$.

(i) The *fibre of φ over B* is the category whose objects are all the $A \in \mathrm{Ob}(\mathscr{A})$ such that $\varphi A = B$, and whose morphisms $f : A' \to A$ are the elements of $\mathrm{Hom}_{\mathscr{A}}(A', A)$ such that $\varphi f = \mathbf{1}_B$. We denote this category by

$$\varphi^{-1}B \qquad \text{or more simply by} \qquad \mathscr{A}_B$$

in the contexts where the latter notation does not give rise to ambiguities. We denote the natural faithful embedding of $\mathscr{A}_B$ into $\mathscr{A}$ by :

$$\iota_B : \mathscr{A}_B \to \mathscr{A}.$$

(ii) We say that φ is a *fibration* if, for every morphism $g : B' \to B$ in $\mathscr{B}$, and every $A \in \mathrm{Ob}(\mathscr{A}_B)$, there exists an inverse image $f : A' \to A$ of A over g. In this case, we also say that $(\mathscr{A}, \varphi)$ is a *fibred $\mathscr{B}$-category*, and φ is called the *structure functor* of $\mathscr{A}$.

Example 3.1.3. Let $\mathscr{B}, \mathscr{C}$ be any two categories, $F : \mathscr{C} \to \mathscr{B}$ a functor, X any object of $\mathscr{B}$.

(i) The source functor $\mathsf{s}_X : F\mathscr{C}/X \to \mathscr{C}$ of (1.1.27) is a fibration, and all the morphisms in $F\mathscr{C}/X$ are $\mathscr{C}$-cartesian. The easy verification shall be left to the reader.

(ii) The source functor $\mathsf{s} : \mathscr{B}/F\mathscr{C} \to \mathscr{B}$ of (1.1.28) is a fibration. Namely, the s-cartesian morphisms are the commutative diagrams

$$\begin{array}{ccc} B & \xrightarrow{f} & FC \\ {\scriptstyle g}\downarrow & & \downarrow{\scriptstyle Fg'} \\ B' & \xrightarrow{f'} & FC' \end{array}$$

such that g' is an isomorphism in $\mathscr{C}$. The fibre $\mathsf{s}^{-1}X$ is the category $X/F\mathscr{C}$. As a special case, the source functor $\mathsf{s} : \mathsf{Morph}(\mathscr{B}) \to \mathscr{B}$ of (1.1.30) is a fibration.

(iii) Suppose that all fibre products are representable in $\mathscr{B}$. Then also the target functor $\mathsf{t} : \mathsf{Morph}(\mathscr{B}) \to \mathscr{B}$ is a fibration; more precisely, the t-cartesian morphisms are the square diagrams as in (ii) (with $F := \mathbf{1}_{\mathscr{B}}$) which are cartesian (*i.e.* fibred). We have $\mathsf{t}^{-1}X = \mathscr{B}/X$.

Definition 3.1.4. Let $\mathscr{A}$, $\mathscr{A}'$, and $\mathscr{B}$ be three categories, $\varphi : \mathscr{A} \to \mathscr{B}$ and $\varphi' : \mathscr{A}' \to \mathscr{B}$ two functors, and $F : \mathscr{A} \to \mathscr{A}'$ a *$\mathscr{B}$-functor*, *i.e.* F verifies the identity $\varphi' \circ F = \varphi$.

(i) We say that F is *cartesian* if it sends $\mathscr{B}$-cartesian morphisms of $\mathscr{A}$ to $\mathscr{B}$-cartesian morphisms in $\mathscr{A}'$. We denote by :

$$\mathsf{Cart}_{\mathscr{B}}(\mathscr{A}, \mathscr{A}')$$

the category whose objects are the cartesian $\mathscr{B}$-functors $F : \mathscr{A} \to \mathscr{A}'$, and whose morphisms are the *natural $\mathscr{B}$-transformations*, *i.e.* the natural transformations such that :

$$\alpha : F \Rightarrow G \qquad \text{such that} \qquad \varphi' * \alpha = \mathbf{1}_\varphi.$$

The composition law is the usual composition of natural transformations : $(\beta, \alpha) \mapsto \alpha \odot \beta$. Notice that if $\mathscr{A}$ and $\mathscr{A}'$ are small, the same holds for $\mathsf{Cart}_{\mathscr{B}}(\mathscr{A}, \mathscr{A}')$: details left to the reader.

(ii) For any two other $\mathscr{B}$-categories $\mathscr{C} \to \mathscr{B}$ and $\mathscr{C}' \to \mathscr{B}$, every pair of cartesian $\mathscr{B}$-functors $H : \mathscr{C} \to \mathscr{A}$ and $K : \mathscr{A}' \to \mathscr{C}'$ induces a functor :

$$\mathsf{Cart}_{\mathscr{B}}(H, K) : \mathsf{Cart}_{\mathscr{A}}(\mathscr{A}, \mathscr{A}') \to \mathsf{Cart}_{\mathscr{B}}(\mathscr{C}, \mathscr{C}') \qquad G \mapsto K \circ G \circ H.$$

To any morphism $\alpha : G \Rightarrow G'$ in $\mathsf{Cart}_{\mathscr{B}}(\mathscr{A}, \mathscr{A}')$, the functor $\mathsf{Cart}_{\mathscr{B}}(H, K)$ assigns the natural transformation $K * \alpha * H : K \circ G \circ H \Rightarrow K \circ G' \circ H$. In case $H = \mathbf{1}_{\mathscr{A}}$ (resp. $K = \mathbf{1}_{\mathscr{A}'}$) we also denote this functor by $\mathsf{Cart}_{\mathscr{B}}(\mathscr{A}, K)$ (resp. by $\mathsf{Cart}_{\mathscr{B}}(H, \mathscr{A}')$).

Likewise, if $H, H' : \mathscr{C} \to \mathscr{A}$ and $K, K' : \mathscr{A}' \to \mathscr{C}'$ are four $\mathscr{B}$-cartesian functors, every pair of natural $\mathscr{B}$-transformations $\beta : H \Rightarrow H'$ and $\gamma : K \Rightarrow K'$ induces a natural transformation :

$$\mathsf{Cart}_{\mathscr{B}}(\beta, \gamma) : \mathsf{Cart}_{\mathscr{B}}(H, K) \Rightarrow \mathsf{Cart}_{\mathscr{B}}(H', K') \qquad G \mapsto \gamma * G * \beta$$

and again, if $\beta = \mathbf{1}_H$ (resp. $\gamma = \mathbf{1}_K$) we also denote this natural transformation by $\mathsf{Cart}_{\mathscr{B}}(H, \gamma)$ (resp. $\mathsf{Cart}_{\mathscr{B}}(\alpha, K)$).

(iii) Let U, V be two universes, with $\mathsf{U} \subset \mathsf{V}$, and such that $\mathscr{B}$ is V-small; we say that the fibration φ has *essentially* U*-small fibres* if $\varphi^{-1}B$ is an essentially U-small category for every $B \in \mathrm{Ob}(\mathscr{B})$. The V-small fibrations over $\mathscr{B}$ with essentially U-small fibres form a 2-category

$$(\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B})$$

with Hom-category $\mathsf{Cart}_{\mathscr{B}}(\mathscr{C}, \mathscr{C}')$, for every pair of fibrations $\mathscr{C} \to \mathscr{B} \leftarrow \mathscr{C}'$, and with composition functors given by (ii). When there is no danger of ambiguities, we shall often write U-$\mathsf{Fib}(\mathscr{B})$, or even just $\mathsf{Fib}(\mathscr{B})$ for this 2-category. Notice that if $\mathscr{B}$ is essentially U-small, then (U, V)-$\mathsf{Fib}(\mathscr{B})$ has essentially U-small Hom-categories.

Remark 3.1.5. Let $\mathscr{B}$ and $\mathscr{B}'$ be two categories and $\psi : \mathscr{B}' \to \mathscr{B}$ any functor.

(i) For every category $\mathscr{A}$ and every functor $\varphi : \mathscr{A} \to \mathscr{B}$, the cartesian morphisms of the projection $\varphi' : \mathscr{A} \times_{(\varphi,\psi)} \mathscr{B}' \to \mathscr{B}'$ are the pairs (f, f') where f is a cartesian morphism of $\mathscr{A}$, f' is a morphism of $\mathscr{B}'$, and $\varphi f = \psi f'$ (see example 1.2.25(i)). Moreover, the projection $\mathscr{A} \times_{(\varphi,\psi)} \mathscr{B}' \to \mathscr{A}$ restricts to a natural isomorphism of fibre categories

$$\varphi'^{-1}B' \xrightarrow{\sim} \varphi^{-1}(\psi B') \qquad \text{for every } B' \in \mathrm{Ob}(\mathscr{B}').$$

If φ is a fibration, the same then holds for φ'. Therefore, for every pair of universes $\mathsf{U} \subset \mathsf{V}$ such that $\mathscr{B}$ and $\mathscr{B}'$ are V-small, we get a well defined strict pseudo-functor

$$(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\psi)^* : (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}) \to (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}') \qquad (\mathscr{A} \xrightarrow{\varphi} \mathscr{B}) \mapsto (\mathscr{A} \times_{(\varphi,\psi)} \mathscr{B}' \xrightarrow{\varphi'} \mathscr{B}')$$

which assigns to every $\mathscr{B}$-cartesian functor $F : \mathscr{A}_1 \to \mathscr{A}_2$ the $\mathscr{B}'$-cartesian functor $F \times_{\mathscr{B}} \mathscr{B}' : \mathscr{A}_1 \times_{\mathscr{B}} \mathscr{B}' \to \mathscr{A}_2 \times_{\mathscr{B}} \mathscr{B}'$, and to any natural $\mathscr{B}$-transformation $\alpha : F_1 \Rightarrow F_2$ between $\mathscr{B}$-cartesian functors $F_1, F_2 : \mathscr{A}_1 \to \mathscr{A}_2$ the induced $\mathscr{B}'$-transformation $\alpha \times_{\mathscr{B}} \mathscr{B}' : F_1 \times_{\mathscr{B}} \mathscr{B}' \Rightarrow F_2 \times_{\mathscr{B}} \mathscr{B}'$. As usual, we often write $\mathsf{U}\text{-}\mathsf{Fib}(\psi)^*$, or just $\mathsf{Fib}(\psi)^*$ instead of $(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\psi)^*$.

(ii) Suppose that ψ is a fibration with essentially U-small fibres; then for every fibration $F' : \mathscr{A}' \to \mathscr{B}'$ with essentially U-small fibres, the composition $\psi \circ F' : \mathscr{A}' \to \mathscr{B}$ is also a fibration with essentially U-small fibres, and in this case we get therefore also a well defined strict pseudo-functor

$$(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}') \to (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}) \qquad (F' : \mathscr{A}' \to \mathscr{B}') \mapsto (\psi \circ F : \mathscr{A}' \to \mathscr{B}).$$

(iii) For $i = 1, 2$, let $\mathscr{A}_i \to \mathscr{B}$ be two fibrations; combining (i) and (ii) we see that the induced functor $\mathscr{A}_1 \times_{\mathscr{B}} \mathscr{A}_2 \to \mathscr{B}$ is also a fibration.

(iv) In the situation of (i), it is easily seen that $\mathsf{Cart}_{\mathscr{B}'}(\mathscr{B}', \mathscr{A} \times_{(\varphi,\psi)} \mathscr{B}')$ is naturally identified with the full subcategory of $\mathsf{Cart}_{\mathscr{B}}(\mathscr{B}', \mathscr{A})$ whose objects are the $\mathscr{B}$-functors $\mathscr{B}' \to \mathscr{A}$ that send *every* morphism of $\mathscr{B}'$ to a $\mathscr{B}$-cartesian morphism of $\mathscr{A}$: the detailed verification shall be left to the reader.

(v) Suppose that $F : \mathscr{A} \to \mathscr{A}'$ is a *$\mathscr{B}$-equivalence*, *i.e.* an equivalence in the 2-category $\mathsf{V}\text{-}\mathbf{Cat}/\mathscr{B}$ (in the sense of definition 2.1.3(iii)). Then it is easily seen that F is $\mathscr{B}$-cartesian.

(vi) In the situation of (i), let $\psi' : \mathscr{B}'' \to \mathscr{B}'$ be another functor between V-small categories; then we have a natural isomorphism of categories :

$$(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\psi')^* \circ (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\psi)^*(\mathscr{A}) \xrightarrow{\sim} (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\psi \circ \psi')^*(\mathscr{A})$$

that assigns to every object (A, B', B'') of $(\mathscr{A} \times_{(\varphi,\psi)} \mathscr{B}') \times_{(\varphi',\psi')} \mathscr{B}''$ the object (A, B'') of $\mathscr{A} \times_{(\varphi,\psi\circ\psi')} \mathscr{B}''$, and it is likewise defined on morphisms. Clearly this isomorphism is strictly pseudo-natural with respect to $\mathscr{A}$, so we get a strict pseudo-natural isomorphism of strict pseudo-functors :

$$\gamma^{(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}}_{\psi',\psi} : (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\psi')^* \circ (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\psi)^* \xrightarrow{\sim} (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\psi \circ \psi')^*.$$

3.1.6. *Cleavages.* Let $\varphi : \mathscr{A} \to \mathscr{B}$ be a fibration, and for every object $(A, g : B \to FA)$ of $\mathscr{B}/\varphi\mathscr{A}$ let us choose an inverse image of A over g :

$$g_A : g^*A \to A.$$

Then we claim that the rule $(A, g) \mapsto g_A$ extends uniquely to a functor

$$\boldsymbol{\lambda} : \mathscr{B}/\varphi\mathscr{A} \to \mathsf{Morph}(\mathscr{A})$$

that makes commute the resulting diagram (notation of (1.1.30)) :

(3.1.7)
$$\begin{array}{ccc} \mathscr{B}/\varphi\mathscr{A} & \xrightarrow{\ \boldsymbol{\lambda}\ } & \mathsf{Morph}(\mathscr{A}) \\ & {\scriptstyle \mathsf{S}}\searrow \quad \swarrow{\scriptstyle \mathsf{Morph}(\varphi)} & \\ & \mathsf{Morph}(\mathscr{B}). & \end{array}$$

Indeed, since g_A is φ-cartesian, for every morphism $(h,k) : (A', B' \xrightarrow{g'} \varphi A') \to (A, B \xrightarrow{g} \varphi A)$ of $\mathscr{B}/\varphi\mathscr{A}$ there exists a unique morphism $f : g'^*A' \to g^*A$ that makes commute the diagram

(3.1.8)
$$\begin{array}{ccc} g'^*A' & \xrightarrow{g'_{A'}} & A' \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle h} \\ g^*A & \xrightarrow{g_A} & A \end{array} \qquad \text{and such that} \qquad \varphi(f) = k$$

and this square diagram can be regarded as a morphism $(f,h) : g'_{A'} \to g_A$ in $\mathsf{Morph}(\mathscr{A})$ such that $\mathsf{Morph}(\varphi)(f,h) = (k, \varphi(h)) = \mathsf{S}(h,k)$. The uniqueness of f easily implies that the rule $(h,k) \mapsto (f,h)$ yields a well defined functor as sought. We call a *cleavage* for φ any such functor (*"clivage"* in french); hence, the cleavages for φ are characterized as the functors $\boldsymbol{\lambda}$ that make commute (3.1.7) and that map every object of $\mathscr{B}/\varphi\mathscr{A}$ to a φ-cartesian morphism.

Notice that we may always choose a cleavage such that $\boldsymbol{\lambda}(A, \mathbf{1}_{FA}) = \mathbf{1}_A$ for every $A \in \mathrm{Ob}(\mathscr{A})$. We call *unital* a cleavage fulfilling this condition.

Example 3.1.9. Let $\varphi : \mathscr{A} \to \mathscr{B}$ be any fibration. Then $\mathsf{Morph}(\varphi) : \mathsf{Morph}(\mathscr{A}) \to \mathsf{Morph}(\mathscr{B})$ is a fibration as well (notation of (1.1.30)). Indeed, pick a cleavage $\boldsymbol{\lambda}$ for φ; consider any object $(A' \xrightarrow{h} A)$ of $\mathsf{Morph}(\mathscr{A})$ and a morphism $(g', g) : (B' \xrightarrow{k} B) \to (\varphi A' \xrightarrow{\varphi(h)} \varphi A)$ of $\mathsf{Morph}(\mathscr{B})$. By definition, $g : B \to \varphi A$ and $g' : B' \to \varphi A'$ are morphisms of $\mathscr{B}$ such that $\varphi(h) \circ g' = g \circ k$, hence $(h,k) : (A', B' \xrightarrow{g'} \varphi A') \to (A, B \xrightarrow{g} \varphi A)$ is a morphism of $\mathscr{B}/\varphi\mathscr{A}$, and $(f,h) := \boldsymbol{\lambda}(h,k)$ is a commutative square (3.1.8). With this notation, it is easily seen that $(g'^*A' \xrightarrow{f} g^*A)$ is an inverse image of $(A' \xrightarrow{h} A)$ over (g', g) : the details are left to the reader.

3.1.10. *The pseudo-functor associated with a cleavage.* Let now $\boldsymbol{\lambda}$ be any cleavage for a given fibration $\varphi : \mathscr{A} \to \mathscr{B}$; to any morphism $g : B' \to B$ in $\mathscr{B}$ we attach a functor

$$\mathsf{c}_g : \varphi^{-1}B \to \varphi^{-1}B'$$

as follows. First, we consider the functor

$$(-, g) : \varphi^{-1}B \to B'/\varphi\mathscr{A} \qquad A \mapsto (A, g) \qquad (A_1 \xrightarrow{h} A_2) \mapsto ((A_1, g) \xrightarrow{(h, \mathbf{1}_{B'})} (A_2, g)).$$

Let also $\mathsf{s} : \mathsf{Morph}(\mathscr{A}) \to \mathscr{A}$ be the source functor (see (1.1.30)), and notice that the composition $\mathsf{s} \circ \boldsymbol{\lambda} \circ (-, g)$ factors through $\varphi^{-1}B'$, and yields therefore the sought functor c_g. Moreover, the commutativity of the diagram (3.1.8) also means that the rule : $A \mapsto \boldsymbol{\lambda}(A, g)$ defines a natural transformation

(3.1.11)
$$g_\bullet : \iota_{B'} \circ \mathsf{c}_g \Rightarrow \iota_B$$

(notation of definition 3.1.2(i)). Notice especially the natural isomorphism of functors

$$\delta_B : \mathbf{1}_{\varphi^{-1}B} \Rightarrow \mathsf{c}_{\mathbf{1}_B} \qquad A \mapsto ((\mathbf{1}_B)_A^{-1} : A \xrightarrow{\sim} (\mathbf{1}_B)^*A) \qquad \text{for every } B \in \mathrm{Ob}(\mathscr{B}).$$

Furthermore, let $B'' \xrightarrow{h} B' \xrightarrow{g} B$ be two morphisms in $\mathscr{B}$, so we get the functors

$$\mathsf{c}_g : \varphi^{-1}B \to \varphi^{-1}B' \qquad \mathsf{c}_h : \varphi^{-1}B' \to \varphi^{-1}B'' \qquad \mathsf{c}_{g \circ h} : \varphi^{-1}B \to \varphi^{-1}B''$$

as well as the natural transformations :

$$g_\bullet : \iota_{B'} \circ \mathsf{c}_g \Rightarrow \iota_B \qquad h_\bullet : \iota_{B''} \circ \mathsf{c}_h \Rightarrow \iota_{B'} \qquad (g \circ h)_\bullet : \iota_{B''} \circ \mathsf{c}_{g \circ h} \Rightarrow \iota_B.$$

By inspecting the constructions, one easily finds a unique natural isomorphism :

$$\gamma_{(h,g)} : \mathsf{c}_h \circ \mathsf{c}_g \Rightarrow \mathsf{c}_{g \circ h}$$

which fits into a commutative diagram :

$$\begin{array}{ccc} \iota_{B''} \circ \mathsf{c}_h \circ \mathsf{c}_g & \xRightarrow{h_\bullet * \mathsf{c}_g} & \iota_{B'} \circ \mathsf{c}_g \\ {\scriptstyle \iota_{B''} * \gamma_{(h,g)}} \Downarrow & & \Downarrow {\scriptstyle g_\bullet} \\ \iota_{B''} \circ \mathsf{c}_{g \circ h} & \xRightarrow{(g \circ h)_\bullet} & \iota_B. \end{array}$$

Moreover, if $k : B''' \to B''$ is a third morphism of $\mathscr{B}$, we can compute :

$$\begin{aligned} (g \circ h \circ k)_A \circ \gamma_{(k,g \circ h),A} \circ \mathsf{c}_k(\gamma_{(h,g),A}) &= (g \circ h)_A \circ k_{\mathsf{c}_{g \circ h} A} \circ \mathsf{c}_k(\gamma_{(h,g),A}) \\ &= (g \circ h)_A \circ \gamma_{(h,g),A} \circ k_{\mathsf{c}_h \mathsf{c}_g A} \\ &= g_A \circ h_{\mathsf{c}_g A} \circ k_{\mathsf{c}_h \mathsf{c}_g A} \\ &= g_A \circ (h \circ k)_{\mathsf{c}_g A} \circ \gamma_{(k,h),\mathsf{c}_g A} \\ &= (g \circ h \circ k)_A \circ \gamma_{(h \circ k, g),A} \circ \gamma_{(k,h),\mathsf{c}_g A} \end{aligned}$$

for every $A \in \mathrm{Ob}(\mathscr{A})$, and since $(g \circ h \circ k)_A$ is $\mathscr{B}$-cartesian, we deduce :

$$\gamma_{(k,g \circ h),A} \circ \mathsf{c}_k(\gamma_{(h,g),A}) = \gamma_{(h \circ k,g),A} \circ \gamma_{(k,h),\mathsf{c}_g A}. \tag{3.1.12}$$

Likewise, for every morphism $f : B' \to B$ of $\mathscr{B}$ and every $A \in \mathrm{Ob}(\varphi^{-1}B)$ we have the commutative diagram :

$$\begin{array}{ccccc} f^* \mathbf{1}_B^* A & \xrightarrow{\mathsf{c}_f(\mathbf{1}_B)_A} & f^* A & \xleftarrow{(\mathbf{1}_{B'})_{f^* A}} & \mathbf{1}_{B'}^* f^* A \\ {\scriptstyle f_{\mathbf{1}_B^* A}} \downarrow & & \downarrow {\scriptstyle f_A} & & \downarrow {\scriptstyle \gamma_{(\mathbf{1}_{B'},f),A}} \\ \mathbf{1}_B^* A & \xrightarrow{(\mathbf{1}_B)_A} & A & \xleftarrow{f_A} & f^* A \end{array}$$

which implies :

$$\gamma_{(f,\mathbf{1}_B),A} = \mathsf{c}_f((\mathbf{1}_B)_A) \qquad \gamma_{(\mathbf{1}_{B'},f),A} = (\mathbf{1}_{B'})_{\mathsf{c}_f A}. \tag{3.1.13}$$

Suppose now that φ is an object of (U,V)-Fib, for some universe V, and denote by

$$(\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$$

the strong sub-2-category of V-$\mathbf{Cat}$ whose objects are the essentially U-small categories (see definition 2.4.9(iii)). Then the identities (3.1.12) and (3.1.13) mean that the rule which assigns to each $B \in \mathrm{Ob}(\mathscr{B})$ the small category $\varphi^{-1}B$ and to each morphism g in $\mathscr{B}$ the functor c_g defines a pseudo-functor

$$\mathsf{c} : \mathscr{B}^o \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$$

whose coherence constraint is the system of natural isomorphisms $(\delta_\bullet, \gamma_\bullet)$. Moreover, the system of inclusion functors $(\iota_B \mid B \in \mathrm{Ob}(\mathscr{B}))$ amounts to a pseudo-cocone

$$\iota : \mathsf{c} \Rightarrow \mathsf{F}_{\mathscr{A}}$$

whose coherence constraint is given by the system of natural transformations (3.1.11). Notice that if $\boldsymbol{\lambda}$ is a unital cleavage, c will be a unital pseudo-functor. (Here we view $\mathscr{B}^o$ as a 2-category, as explained in example 2.2.4(i); also, the 2-category structure on V-$\mathbf{Cat}$ is the one of remark 2.1.1(ii)). We call c and ι respectively *the pseudo-functor and the pseudo-cocone associated with the cleavage* $\boldsymbol{\lambda}$.

Example 3.1.14. As an application, we may generalize example 1.5.15 as follows. Let I, J be two small categories, $\varphi : I \to J$ a fibration, fix a cleavage $\boldsymbol{\lambda}$ for φ, and denote by c the associated pseudo-functor.

(i) First, we claim that for every $j \in \mathrm{Ob}(J)$ the functor $(-, \mathbf{1}_j) : \varphi^{-1}j \to j/\varphi I$ is coinitial (notation of (3.1.10)). Indeed, for any $(i_0, f : j \to \varphi i_0) \in \mathrm{Ob}(j/\varphi I)$ we have the cartesian morphism $\boldsymbol{\lambda}(i_0, f) : \mathsf{c}_f(i_0) \to i_0$, and it is easily seen that the category $(-, \mathbf{1}_j)(\varphi^{-1}j)/(i_o, f)$ is isomorphic to $(\varphi^{-1}j)/\mathsf{c}_f(i_0)$, which is obviously connected, whence the claim.

(ii) Notice that the composition $\mathsf{t}_j \circ (-, \mathbf{1}_j) : \varphi^{-1}j \to I$ equals the inclusion functor ι_j (here $\mathsf{t}_j : j/\varphi I \to I$ is the target functor). Moreover, for every morphism $f : j \to j'$ in J, the natural transformation $f_\bullet : \iota_j \circ \mathsf{c}_f \Rightarrow \iota_{j'}$ associated with $\boldsymbol{\lambda}$ induces a morphism

$$\omega_F^f : \lim_{\varphi^{-1}j} F \circ \iota_j \xrightarrow{\lim_{\mathsf{c}_f} \mathbf{1}_{F\circ\iota_j}} \lim_{\varphi^{-1}j'} F \circ \iota_j \circ \mathsf{c}_f \xrightarrow{\lim_{\varphi^{-1}j'} F * f_\bullet} \lim_{\varphi^{-1}j'} F \circ \iota_{j'}$$

for every functor $F : I \to \mathscr{C}$, fitting into a commutative diagram

$$\begin{array}{ccc}
\int_\varphi^\wedge F(j) & \xrightarrow{\int_\varphi^\wedge F(f)} & \int_\varphi^\wedge F(j') \\
\downarrow & & \downarrow \\
\lim\limits_{\varphi^{-1}j} F \circ \iota_j & \xrightarrow{\omega_F^f} & \lim\limits_{\varphi^{-1}j'} F \circ \iota_{j'}
\end{array}$$

whose vertical arrows are the natural isomorphisms provided by (i) and remark 1.5.5(ii). In other words, $\int_\varphi^\wedge$ is naturally isomorphic to the functor that assigns to every such F the functor

$$\int_{\boldsymbol{\lambda}}^\wedge F : J \to \mathscr{C}^\wedge \qquad j \mapsto \lim_{\varphi^{-1}j} F \circ \iota_j \qquad (f : j \to j') \mapsto \omega_F^f.$$

(iii) Furthermore, in this situation, proposition 1.3.2 says that there is a natural isomorphism

$$\lim_I F \xrightarrow{\sim} \operatorname*{Lim}_J \int_{\boldsymbol{\lambda}}^\wedge F \qquad \text{in } \mathscr{C}^\wedge$$

for every functor $F : I \to \mathscr{C}$. If $\mathscr{C}$ is complete, the functor $\int_{\boldsymbol{\lambda}}^\wedge$ is isomorphic, by remark 1.5.16, to the composition of $\mathsf{Fun}(J, h_{\mathscr{C}})$ and a functor well defined up to isomorphism

$$\int_{\boldsymbol{\lambda}} : \mathsf{Fun}(I, \mathscr{C}) \to \mathsf{Fun}(J, \mathscr{C}) \qquad F \mapsto (j \mapsto \operatorname*{Lim}_{\varphi^{-1}j} F \circ \iota_j)$$

and we can restate the foregoing "Fubini" isomorphism in terms of this latter functor.

(iv) Lastly, let $G : I^o \to \mathscr{C}$ be any functor. It follows from (ii) that the functor $\int_\wedge^{\varphi^o} G$ is naturally isomorphic to the functor

$$\int_\wedge^{\boldsymbol{\lambda}} G : J^o \to \mathscr{C}^{o\wedge o} \qquad j^o \mapsto \operatorname*{colim}_{(\varphi^{-1}j)^o} G \circ \iota_j^o \qquad (f^o : j'^o \to j^o) \mapsto \omega_{G^o}^f$$

and we have a natural isomorphism

$$\operatorname*{colim}_{I^o} G \xrightarrow{\sim} \operatorname*{colim}_{J^o} \int_\wedge^{\boldsymbol{\lambda}} G \qquad \text{in } \mathscr{C}^{o\wedge o}.$$

Again, if $\mathscr{C}$ is cocomplete, the functor $\int_\wedge^{\boldsymbol{\lambda}}$ is the composition of $\mathsf{Fun}(J^o, h_{\mathscr{C}^o}^o)$ and a functor

$$\int^{\boldsymbol{\lambda}} : \mathsf{Fun}(I^o, \mathscr{C}) \to \mathsf{Fun}(J^o, \mathscr{C}) \qquad G \mapsto (j^o \mapsto \operatorname*{Colim}_{(\varphi^{-1}j)^o} G \circ \iota_j^o)$$

and we may state the foregoing "Fubini" isomorphism for colimits in terms of this latter functor.

3.1.15. *Fibration associated with a presheaf.* Let $\mathscr{B}$ be a category, F a presheaf on $\mathscr{B}$. As in (1.4.7), we let $\mathscr{F}ib(F)$ be the category of elements of F, and we notice that the source functor

$$\mathsf{s}_F : \mathscr{F}ib(F) \to \mathscr{B}$$

is a fibration. For every $X \in \mathrm{Ob}(\mathscr{B})$, the fibre $\mathsf{s}_F^{-1}(X)$ is (naturally isomorphic to) the discrete category FX (see example 1.1.6(ii)). Notice also that every morphism in $\mathscr{F}ib(F)$ is cartesian, and for every $\mathscr{B}$-category $\mathscr{C}$, the category $\mathsf{Cart}_{\mathscr{B}}(\mathscr{C}, \mathscr{F}ib(F))$ is discrete.

For every pair of presheaves F, G on $\mathscr{B}$, we have a natural bijection:

$$\mathrm{Hom}_{\mathscr{C}^\wedge}(F, G) \stackrel{\sim}{\to} \mathrm{Ob}(\mathsf{Cart}_{\mathscr{B}}(\mathscr{F}ib(F), \mathscr{F}ib(G)))$$

(which we can view as an isomorphism of discrete categories). Namely, to a morphism $\psi : F \to G$ one assigns the functor

$$\mathscr{F}ib(\psi) : \mathscr{F}ib(F) \to \mathscr{F}ib(G) \qquad (X, s) \mapsto (X, \psi_X(s)) \quad \text{for every } (X, s) \in \mathrm{Ob}(\mathscr{F}ib(F)).$$

Example 3.1.16. Let U be a universe, and $\mathscr{C}$ a category with U-small Hom-sets.

(i) We have already remarked in example 1.4.9(ii) the identification of $\mathscr{C}$-fibrations

$$\mathscr{F}ib(h_X) = \mathscr{C}/X \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C})$$

where h_X is the presheaf represented by X (see (1.2.4)), and $\mathscr{C}/X$ is regarded as a $\mathscr{C}$-fibration as in example 3.1.3(i). Moreover, every morphism $f : X \to Y$ of $\mathscr{C}$ induces a morphism of presheaves $h_f : h_Y \to h_X$, and under the foregoing identification, $\mathscr{F}ib(h_f)$ corresponds to the functor $f_* : \mathscr{C}/X \to \mathscr{C}/Y$ of (1.1.25).

(ii) In the situation of (i), let $u : \mathscr{C}' \to \mathscr{C}$ be any functor; as in example 1.4.9(iii), by direct inspection we get a natural isomorphism of categories

$$\mathsf{Fib}(u)^*(\mathscr{C}/X) \stackrel{\sim}{\to} \mathscr{F}ib(h_X \circ u) = u\mathscr{C}'/X \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C})$$

(notation of remark 3.1.5(i)) which identifies the fibration $\mathsf{Fib}(u)^*(\mathscr{C}/X) \to \mathscr{C}'$ with the source functor $\mathsf{s}_X : u\mathscr{C}'/X \to \mathscr{C}'$ of (1.1.27). Likewise, for every morphism $f : X \to Y$ in $\mathscr{C}$, the cartesian functor $\mathsf{Fib}(u)^*(f_*) : \mathsf{Fib}(u)^*(\mathscr{C}/X) \to \mathsf{Fib}(u)^*(\mathscr{C}/Y)$ is identified with the functor $u\mathscr{C}'/f : u\mathscr{C}'/X \to u\mathscr{C}'/Y$ as in (1.1.27).

(iii) As a special case, let $h_{\mathscr{C}} : \mathscr{C} \to \mathscr{C}^\wedge_{\mathsf{U}}$ be the Yoneda embedding, and F any U-presheaf on $\mathscr{C}$. As noted in (1.4.7), we have a natural isomorphism of categories $h_{\mathscr{C}}\mathscr{C}/F \stackrel{\sim}{\to} \mathscr{F}ib(F)$, so (i) generalizes to a natural isomorphism of $\mathscr{C}$-fibrations :

$$\mathscr{F}ib(F) \stackrel{\sim}{\to} (\mathsf{V}, \mathsf{V})\text{-}\mathsf{Fib}(h_{\mathscr{C}})^*(\mathscr{C}^\wedge_{\mathsf{U}}/F)$$

for any universe V with $\mathsf{U} \subset \mathsf{V}$, and such that $\mathscr{C}$ is V-small.

3.1.17. Conversely, let $\varphi : \mathscr{A} \to \mathscr{B}$ be a fibration *with discrete fibres*, *i.e.* such that $\varphi^{-1}B$ is a discrete small category for every $B \in \mathrm{Ob}(\mathscr{B})$. Then it is easily seen that for every morphism $g : B' \to B$ of $\mathscr{B}$, every $A \in \varphi^{-1}B$ admits a unique inverse image over g. It follows that φ admits a unique cleavage. Moreover the associated pseudo-functor $\mathsf{c} : \mathscr{B}^o \to \mathbf{Cat}$ is strict, hence it may be regarded as a functor with values in the subcategory $\mathbf{Set}$ of $\mathbf{Cat}$; *i.e.* c is a presheaf on $\mathscr{B}$, and a simple inspection shows that the fibration $\mathscr{F}ib(\mathsf{c})$ is naturally isomorphic to φ. Summing up, we have obtained a fully faithful functor

$$\mathscr{F}ib : \mathscr{B}^\wedge \to \mathsf{Fib}(\mathscr{B})$$

whose essential image is the full subcategory of $\mathsf{Fib}(\mathscr{B})$ whose objects are the fibrations with discrete fibres. We shall show next how to extend this equivalence to the whole of $\mathsf{Fib}(\mathscr{B})$.

3.1.18. *Fibration associated with a pseudo-functor.* Let $\mathscr{B}$ be any V-small category, and $\mathsf{c} : \mathscr{B}^o \to (\mathsf{U},\mathsf{V})\mathbf{Cat}$ any pseudo-functor, with coherence constraint $(\delta^{\mathsf{c}}, \gamma^{\mathsf{c}})$. We attach to c the $\mathscr{B}$-category

$$\pi^{\mathsf{c}} : \mathscr{F}ib(\mathsf{c}) \to \mathscr{B}$$

such that $\mathrm{Ob}(\mathscr{F}ib(\mathsf{c})) := \{(B,X) \mid B \in \mathrm{Ob}(\mathscr{B}),\ X \in \mathrm{Ob}(\mathsf{c}_B)\}$, and where

$$\mathrm{Hom}_{\mathscr{F}ib(\mathsf{c})}((B,X),(B',Y)) := \{(\varphi,f) \mid \varphi \in \mathrm{Hom}_{\mathscr{B}}(B,B'),\ f \in \mathrm{Hom}_{\mathsf{c}_B}(X,\mathsf{c}_\varphi Y)\}$$

for every two objects $(B,X),(B',Y)$. The composition of two morphisms $f : X \to \mathsf{c}_\varphi Y$ and $g : Y \to \mathsf{c}_\psi Z$ is the pair $(\psi\circ\varphi, t)$, where t is the composition

$$X \xrightarrow{\ f\ } \mathsf{c}_\varphi Y \xrightarrow{\mathsf{c}_\varphi(g)} \mathsf{c}_\varphi\mathsf{c}_\psi Z \xrightarrow{\gamma^{\mathsf{c}}_{(\varphi,\psi),Z}} \mathsf{c}_{\psi\circ\varphi} Z.$$

The unit axiom for δ^{c} implies easily that for every object (B,X) the morphism

$$(\mathbf{1}_B, \delta^{\mathsf{c}}_{B,X} : X \to \mathsf{c}_{\mathbf{1}_B} X)$$

is neutral for left and right composition with any other morphism of $\mathscr{F}ib(\mathsf{c})$. Let us show the associativity : if $h : Z \to \mathsf{c}_\lambda W$ is a third morphism, we need to verify the identity

$$\gamma^{\mathsf{c}}_{(\psi\circ\varphi,\lambda),W} \circ \mathsf{c}_{\psi\circ\varphi}(h) \circ \gamma^{\mathsf{c}}_{(\varphi,\psi),Z} \circ \mathsf{c}_\varphi(g) \circ f = \gamma^{\mathsf{c}}_{(\varphi,\lambda\circ\psi),W} \circ \mathsf{c}_\varphi(\gamma^{\mathsf{c}}_{(\psi,\lambda),W}) \circ \mathsf{c}_\varphi\mathsf{c}_\psi(h) \circ \mathsf{c}_\varphi(g) \circ f.$$

But we have $\mathsf{c}_{\psi\circ\varphi}(h) \circ \gamma^{\mathsf{c}}_{(\varphi,\psi),Z} = \gamma^{\mathsf{c}}_{(\varphi,\psi),\mathsf{c}_\lambda W} \circ \mathsf{c}_\varphi\mathsf{c}_\psi(h)$ by the naturality of $\gamma^{\mathsf{c}}_{(\varphi,\psi)}$, hence we are reduced to checking that

$$\gamma^{\mathsf{c}}_{(\psi\circ\varphi,\lambda),W} \circ \gamma^{\mathsf{c}}_{(\varphi,\psi),\mathsf{c}_\lambda W} = \gamma^{\mathsf{c}}_{(\varphi,\lambda\circ\psi),W} \circ \mathsf{c}_\varphi(\gamma^{\mathsf{c}}_{(\psi,\lambda),W})$$

which follows from the composition axioms for γ^{c}. The functor π^{c} is given by the rules : $(B,X) \mapsto B$ and $(\varphi,f) \mapsto \varphi$ for every object (B,X) and every morphism (φ,f) of $\mathscr{F}ib(\mathsf{c})$.

3.1.19. Let $\mathsf{d} : \mathscr{B}^o \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$ be another pseudo-functor, with coherence constraint $(\delta^{\mathsf{d}}, \gamma^{\mathsf{d}})$, and

$$\omega : \mathsf{c} \Rightarrow \mathsf{d}$$

any pseudo-natural transformation, with coherence constraint τ^ω. We define a $\mathscr{B}$-functor

$$\mathscr{F}ib(\omega) : \mathscr{F}ib(\mathsf{c}) \to \mathscr{F}ib(\mathsf{d})$$

by assigning to every object (B,X) of $\mathscr{F}ib(\mathsf{c})$ the object $(B,\omega_B X)$ of $\mathscr{F}ib(\mathsf{d})$, and to every morphism $(\varphi,f) : (B,X) \to (B',Y)$ the morphism (φ,t), where t is the composition

$$\omega_B X \xrightarrow{\omega_B f} \omega_B \circ \mathsf{c}_\varphi Y \xrightarrow{(\tau^\omega_{\varphi,Y})^{-1}} \mathsf{d}_\varphi \circ \omega_{B'} Y.$$

To check that these rules do yield a functor, consider any other morphism $(\psi,g) : (B',Y) \to (B'',Z)$ of $\mathscr{F}ib(\mathsf{c})$; we need to show that

$$\tau^{\omega\ -1}_{\psi\circ\varphi,Z} \circ \omega_B(\gamma^{\mathsf{c}}_{(\varphi,\psi),Z} \circ \mathsf{c}_\varphi(g) \circ f) = \gamma^{\mathsf{d}}_{(\varphi,\psi),\omega_{B''}Z} \circ \mathsf{d}_\varphi(\tau^{\omega\ -1}_{\psi,Z} \circ \omega_{B'}(g)) \circ \tau^{\omega\ -1}_{\varphi,Y} \circ \omega_B(f).$$

However, the naturality of τ^ω_φ implies that $\tau^{\omega\ -1}_{\varphi,\mathsf{c}_\psi Z} \circ \omega_B(\mathsf{c}_\varphi g) = \mathsf{d}_\varphi(\omega_{B'} g) \circ \tau^{\omega\ -1}_{\varphi,Y}$, so we are reduced to checking that :

$$\tau^{\omega\ -1}_{\psi\circ\varphi,Z} \circ \omega_B(\gamma^{\mathsf{c}}_{(\varphi,\psi),Z}) = \gamma^{\mathsf{d}}_{(\varphi,\psi),\omega_{B''}Z} \circ \mathsf{d}_\varphi(\tau^{\omega\ -1}_{\psi,Z}) \circ \tau^{\omega\ -1}_{\varphi,\mathsf{c}_\psi Z}.$$

But the latter follows directly from the coherence axioms for τ^ω. Likewise, the assertion that $\mathscr{F}ib(\omega)$ respects identity morphisms comes down to the equalities :

$$\tau^{\omega\ -1}_{\mathbf{1}_B,X} \circ \omega_B(\delta^{\mathsf{c}}_{B,X}) = \delta^{\mathsf{d}}_{B,\omega_B X}$$

which again follows from the coherence axioms for τ^ω. Moreover, if $\mathsf{e} : \mathscr{B}^o \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$ is a third pseudo-functor, and

$$\mu : \mathsf{d} \Rightarrow \mathsf{e}$$

a second pseudo-natural transformation, we have

$$\mathscr{F}ib(\mu) \circ \mathscr{F}ib(\omega) = \mathscr{F}ib(\mu \odot \omega).$$

Indeed, if τ^{μ} and $\tau^{\mu\odot\omega}$ are the coherence constraints for μ and $\mu \odot \omega$, the assertion amounts to :

$$\tau^{\mu\ -1}_{\varphi,\omega_{B'}Y} \circ \mu_B(\tau^{\omega}_{\varphi,Y})^{-1} \circ \mu_B(\omega_B f) = \tau^{\mu\odot\omega\ -1}_{B,Y} \circ \mu_B(\omega_B f)$$

for every morphism $(\varphi, f) : (B, X) \to (B', Y)$ in $\mathscr{F}ib(\mathsf{c})$, which is clear from the definition of $\mu \odot \omega$.

Lemma 3.1.20. *With the notation of* (3.1.19)*, the following holds :*

(i) *A morphism* $(\varphi, f) : (B, X) \to (B', Y)$ *of* $\mathscr{F}ib(\mathsf{c})$ *is* π^{c}*-cartesian if and only if* $f : X \to \mathsf{c}_{\varphi}Y$ *is an isomorphism in* c_B*.*

(ii) *The functor* π^{c} *is a fibration, and is endowed with a distinguished cleavage*

$$\boldsymbol{\lambda}^* : \mathscr{B}/\pi^{\mathsf{c}}\mathscr{F}ib(\mathsf{c}) \to \mathsf{Morph}(\mathscr{F}ib(\mathsf{c})) \qquad (X, \varphi) \mapsto (\varphi, \mathbf{1}_{\mathsf{c}_{\varphi}X}).$$

(iii) *The functor* $\mathscr{F}ib(\omega)$ *is* $\mathscr{B}$*-cartesian.*

Proof. (i): In view of proposition 2.4.3 and the discussion of (3.1.19), we may assume that $\boldsymbol{\lambda}$ is unital (details left to the reader). Now, suppose first that (φ, f) is $\mathscr{B}$-cartesian; then there exists a unique morphism $(\mathbf{1}_B, g) : (B, \mathsf{c}_{\varphi}Y) \to (B, X)$ such that $(\varphi, f) \circ (\mathbf{1}_{\mathbb{B}}, g) = (\varphi, \mathbf{1}_{\mathsf{c}_{\varphi}Y})$. Since c is unital, we easily deduce that $f \circ g = \mathbf{1}_{\mathsf{c}_{\varphi}Y}$. Moreover, $(\mathbf{1}_B, g \circ f) : (B, X) \to (B, X)$ is a morphism of $\mathscr{F}ib(\mathsf{c})$ such that $(\varphi, f) \circ (\mathbf{1}_B, g \circ f) = (\varphi, f) = (\varphi, f) \circ (\mathbf{1}_B, \mathbf{1}_X)$, whence $g \circ f = \mathbf{1}_X$. Conversely, suppose that f is an isomorphism, and let $\psi : C \to B$ any morphism in $\mathscr{B}$, $Z \in \mathrm{Ob}(\mathsf{c}_C)$ any object, and $(\varphi \circ \psi, h) : (C, Z) \to (B', Y)$ any morphism of $\mathscr{F}ib(\mathsf{c})$; we let $k : Z \to \mathsf{c}_{\psi}X$ be the composition

$$Z \xrightarrow{h} \mathsf{c}_{\varphi\circ\psi}Y \xrightarrow{\gamma^{\mathsf{c}\ -1}_{(\psi,\varphi),Y}} \mathsf{c}_{\psi}\mathsf{c}_{\varphi}Y \xrightarrow{\mathsf{c}_{\varphi}(f^{-1})} \mathsf{c}_{\psi}X.$$

Then $(\psi, k) : (C, Z) \to (B, X)$ is the unique morphism of $\mathscr{F}ib(\mathsf{c})$ such that $(\varphi, f) \circ (\psi, k) = (\varphi \circ \psi, h)$; this shows that (φ, f) is $\mathscr{B}$-cartesian.

(ii) and (iii) are immediate consequences of (i). □

3.1.21. Lastly, consider pseudo-natural transformations

$$\omega, \omega' : \mathsf{c} \Rightarrow \mathsf{d} \qquad \text{and a modification} \qquad \Xi : \omega \rightsquigarrow \omega'.$$

We attach to Ξ the natural transformation of functors

$$\mathscr{F}ib(\Xi) : \mathscr{F}ib(\omega) \Rightarrow \mathscr{F}ib(\omega')$$

assigning to every object (B, X) of $\mathscr{F}ib(\mathsf{c})$ the morphism $(\mathbf{1}_B, t)$ of $\mathscr{F}ib(\mathsf{d})$, where t is the composition

$$\omega_B X \xrightarrow{\Xi_{B,X}} \omega'_B X \xrightarrow{\delta^{\mathsf{d}}_{B,\omega'_B X}} \mathsf{d}_{\mathbf{1}_B}(\omega'_B X).$$

In order to verify the naturality of $\mathscr{F}ib(\Xi)$, it suffices to check the commutativity of the diagram:

$$\begin{array}{ccccc}
\omega_B X & \xrightarrow{\Xi_{B,X}} & \omega'_B X & \xrightarrow{\delta^{\mathsf{d}}_{B,\omega'_B X}} & \mathsf{d}_{\mathbf{1}_B}(\omega'_B X) \\
{\scriptstyle \omega_B f}\downarrow & & {\scriptstyle \omega'_B f}\downarrow & & \downarrow{\scriptstyle \mathsf{d}_{\mathbf{1}_B}(\omega'_B f)} \\
\omega_B \mathsf{c}_{\varphi} Y & \xrightarrow{\Xi_{B,\mathsf{c}_{\varphi}Y}} & \omega'_B \mathsf{c}_{\varphi} Y & \xrightarrow{\delta^{\mathsf{d}}_{B,\omega'_B \mathsf{c}_{\varphi}Y}} & \mathsf{d}_{\mathbf{1}_B}(\omega'_B \mathsf{c}_{\varphi} Y) \\
{\scriptstyle \tau^{\omega\ -1}_{\varphi,Y}}\downarrow & & {\scriptstyle \tau^{\omega'\ -1}_{\varphi,Y}}\downarrow & & \downarrow{\scriptstyle \gamma^{\mathsf{d}}_{(\mathbf{1}_B,\varphi),\omega'_{B'}Y} \circ \mathsf{d}_{\mathbf{1}_B}(\tau^{\omega'\ -1}_{\varphi,Y})} \\
\mathsf{d}_{\varphi}\omega_{B'} Y & \xrightarrow{\mathsf{d}_{\varphi}(\Xi_{B',Y})} & \mathsf{d}_{\varphi}\omega'_{B'} Y & \xrightarrow{\gamma^{\mathsf{d}}_{(\varphi,\mathbf{1}_B),\omega'_{B'}Y} \circ \mathsf{d}_{\varphi}(\delta^{\mathsf{d}}_{B',\omega'_{B'}Y})} & \mathsf{d}_{\varphi}\omega'_{B'} Y
\end{array}$$

for every morphism $(\varphi, f) : (B, X) \to (B', Y)$ of $\mathscr{F}ib(\mathsf{c})$. However, the commutativity of the two top squares follows from the naturality of Ξ_B and δ^{d}_B, and that of the left bottom square translates the compatibility condition for Ξ. Then, since

$$\gamma^{\mathsf{d}}_{(\mathbf{1}_B,\varphi),\omega'_{B'}Y} = \delta^{\mathsf{d}\ -1}_{B',\mathsf{d}_\varphi\omega'_{B'}Y} \qquad \text{and} \qquad \gamma^{\mathsf{d}}_{(\varphi,\mathbf{1}_B),\omega'_{B'}Y} \circ \mathsf{d}_\varphi(\delta^{\mathsf{d}}_{B',\omega'_{B'}Y}) = \mathbf{1}_{\mathsf{d}_\varphi\omega'_{B'}Y}$$

we are reduced to checking the identity

$$\mathsf{d}_{\mathbf{1}_B}(\tau^{\omega'}_{\varphi,Y}) \circ \delta^{\mathsf{d}}_{B',\mathsf{d}_\varphi\omega'_{B'}Y} = \delta^{\mathsf{d}}_{B,\omega'_B\mathsf{c}_\varphi Y} \circ \tau^{\omega'}_{\varphi,Y}$$

which follows from the naturality of δ^{d}_B. Furthermore, suppose we have a third pseudo-natural transformation

$$\omega'' : \mathsf{c} \Rightarrow \mathsf{d} \qquad \text{and a modification} \qquad \Xi' : \omega' \rightsquigarrow \omega''.$$

Then we have as well

$$\mathscr{F}ib(\Xi' \odot \Xi) = \mathscr{F}ib(\Xi') \odot \mathscr{F}ib(\Xi). \tag{3.1.22}$$

Indeed, the assertion amounts to checking, for every object (B, X) of $\mathscr{F}ib(\mathsf{c})$, the identity

$$\gamma^{\mathsf{d}}_{(\mathbf{1}_B,\mathbf{1}_B),\omega''_BX} \circ \mathsf{d}_{\mathbf{1}_B}(\delta^{\mathsf{d}}_{B,\omega''_BX}) \circ \mathsf{d}_{\mathbf{1}_B}(\Xi'_{B,X}) \circ \delta^{\mathsf{d}}_{B,\omega'_BX} \circ \Xi_{B,X} = \delta^{\mathsf{d}}_{B,\omega''_BX} \circ \Xi'_{B,X} \circ \Xi_{B,X}$$

which is clear, since $\gamma^{\mathsf{d}}_{(\mathbf{1}_B,\mathbf{1}_B),\omega''_BX} \circ \mathsf{d}_{\mathbf{1}_B}(\delta^{\mathsf{d}}_{B,\omega''_BX}) = \mathbf{1}_{\mathsf{d}_{\mathbf{1}_B}\omega''_BX}$ by the unit axiom for δ^{d}, and $\mathsf{d}_{\mathbf{1}_B}(\Xi'_{B,X}) \circ \delta^{\mathsf{d}}_{B,\omega'_BX} = \delta^{\mathsf{d}}_{B,\omega''_BX} \circ \Xi'_{B,X}$, by the naturality of δ^{d}_B. Likewise, suppose we have two pseudo-natural transformations

$$\mu, \mu' : \mathsf{d} \Rightarrow \mathsf{e} \qquad \text{and a modification} \qquad \Theta : \mu \rightsquigarrow \mu'.$$

Then we have as well

$$\mathscr{F}ib(\Theta) * \mathscr{F}ib(\Xi) = \mathscr{F}ib(\Theta * \Xi).$$

For the proof, in light of (3.1.22) we may assume that either $\Theta = \mathbf{1}_\mu$ or $\Xi = \mathbf{1}_\omega$. In the first case, the assertion comes down to the identity

$$(\tau^{\mu}_{\mathbf{1}_B,\omega'_BX})^{-1} \circ \mu_B(\delta^{\mathsf{d}}_{B,\omega'_BX} \circ \Xi_{B,X}) = \delta^{\mathsf{d}}_{B,\mu_B\omega'_BX} \circ \mu_B(\Xi_{B,X})$$

which is equivalent to : $\mu_B(\delta^{\mathsf{d}}_{B,\omega'_BX}) = \tau^{\mu}_{\mathbf{1}_B,\omega'_BX} \circ \delta^{\mathsf{d}}_{B,\mu_B\omega'_BX}$, which in turns follows from the coherence axioms for τ^μ. The case where $\Xi = \mathbf{1}_\omega$ is clear by a simple inspection. Summing up, for every universe V, and every V-small category $\mathscr{B}$, we have obtained a strict pseudo-functor

$$\mathscr{F}ib_{\mathscr{B}} : \mathsf{PsFun}(\mathscr{B}^o, (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}) \to (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}).$$

Remark 3.1.23. (i) Notice that the discussion of (3.1.19) requires the invertibility of the coherence constraint τ^ω, and therefore it does not apply to general lax-natural transformations $\omega : \mathsf{c} \Rightarrow \mathsf{d}$. However, with the obvious changes, it does apply to lax-natural transformations $\omega : {}^o\mathsf{c} \Rightarrow {}^o\mathsf{d}$ (see example 2.2.6(ii)) : the details shall be left to the reader. From lemma 3.1.20 and its proof, we then easily see that the resulting functor $\mathscr{F}ib(\omega) : \mathscr{F}ib(\mathsf{c}) \to \mathscr{F}ib(\mathsf{d})$ will be cartesian if and only if ω is pseudo-natural.

(ii) Likewise, the discussion of (3.1.21) applies more generally to a modification $\Xi : \omega' \rightsquigarrow \omega$ between any pair of lax-natural transformations $\omega, \omega' : {}^o\mathsf{c} \Rightarrow {}^o\mathsf{d}$; namely, any such modification induces a natural transformation $\mathscr{F}ib(\Xi) : \mathscr{F}ib(\omega) \Rightarrow \mathscr{F}ib(\omega')$.

Theorem 3.1.24. *For every category $\mathscr{B}$, the pseudo-functor $\mathscr{F}ib_{\mathscr{B}}$ is a strong 2-equivalence.*

Proof. Let $\varphi : \mathscr{A} \to \mathscr{B}$ be any fibration with essentially small fibres; pick a unital cleavage $\boldsymbol{\lambda}$ for φ, and let $\mathsf{c} : \mathscr{B}^o \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$ be the pseudo-functor associated with $\boldsymbol{\lambda}$.

Claim 3.1.25. There exists an isomorphism of $\mathscr{B}$-categories

$$\psi^{\boldsymbol{\lambda}} : \mathscr{F}ib(\mathsf{c}) \xrightarrow{\sim} \mathscr{A} \qquad (B, X) \mapsto X \qquad ((B, X) \xrightarrow{(g,f)} (B', X')) \mapsto \boldsymbol{\lambda}(X', g) \circ f.$$

Proof of the claim. Indeed, since c is unital, it is clear that $\psi^{\boldsymbol{\lambda}}(\mathbf{1}_{(B,X)}) = \mathbf{1}_{\psi(B,X)}$ for every $(B,X) \in \mathrm{Ob}(\mathscr{F}ib(\mathsf{c}))$. Next, let $(g,f) : (B,X) \to (B',X')$ and $(g',f') : (B',X') \to (B'',X'')$ be two morphisms; then $(g',f') \circ (g,f) = (g' \circ g, \gamma^{\mathsf{c}}_{(g,g'),X''} \circ \mathsf{c}_g(f') \circ f)$, and on the other hand, we may compute

$$\begin{aligned}\psi^{\boldsymbol{\lambda}}(g',f') \circ \psi^{\boldsymbol{\lambda}}(g,f) &= \boldsymbol{\lambda}(X'',g') \circ f' \circ \boldsymbol{\lambda}(X',g) \circ f \\ &= \boldsymbol{\lambda}(X'',g') \circ \boldsymbol{\lambda}(\mathsf{c}_{g'}X'',g) \circ \mathsf{c}_g(f') \circ f \\ &= \boldsymbol{\lambda}(X'',g'g) \circ \gamma^{\mathsf{c}}_{(g,g'),X''} \circ \mathsf{c}_g(f') \circ f \\ &= \psi^{\boldsymbol{\lambda}}((g',f') \circ (g,f))\end{aligned}$$

as required. Clearly $\psi^{\boldsymbol{\lambda}}$ is bijective on objects, and since $\boldsymbol{\lambda}(A,g)$ is a φ-cartesian morphism for every object (A,g) of $\mathscr{B}/\varphi\mathscr{A}$, it is easily seen that $\psi^{\boldsymbol{\lambda}}$ is fully faithful, hence it is an isomorphism of $\mathscr{B}$-categories. ◊

In view of claim 3.1.25, it remains only to check that for every pair of pseudo-functors $\mathsf{c}, \mathsf{d} : \mathscr{B}^o \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$ the induced functor

$$\mathsf{PsNat}(\mathsf{c},\mathsf{d}) \to \mathsf{Cart}_{\mathscr{B}}(\mathscr{F}ib(\mathsf{c}), \mathscr{F}ib(\mathsf{d})) \tag{3.1.26}$$

is an isomorphism of categories, and due to proposition 2.4.3 and the discussion of (3.1.19), we may assume that c and d are unital. Thus, let $\omega, \omega' : \mathsf{c} \Rightarrow \mathsf{d}$ be two pseudo-natural transformations, with respective coherence constraints τ^ω and $\tau^{\omega'}$, and suppose that $\mathscr{F}ib(\omega) = \mathscr{F}ib(\omega')$; then clearly $\omega_B X = \omega'_B X$ for every object (B,X) of $\mathscr{F}ib(\mathsf{c})$. Likewise, in light of remark 2.4.2(ii) we see that $\tau^\omega_{\mathbf{1}_B,X} = \tau^{\omega'}_{\mathbf{1}_B,X} = \mathbf{1}_{\omega_B X}$ for every such (B,X), whence $\omega_B f = \omega'_B f$ for every $B \in \mathrm{Ob}(\mathscr{B})$ and every morphism f of c_B. Then it is also clear that $\tau^\omega_{\varphi,Y} = \tau^{\omega'}_{\varphi,Y}$ for every morphism $\varphi : B \to B'$ of $\mathscr{B}$ and every $Y \in \mathrm{Ob}(\mathsf{c}_{B'})$, *i.e.* $\omega = \omega'$.

Next, let $F : \mathscr{F}ib(\mathsf{c}) \to \mathscr{F}ib(\mathsf{d})$ be any $\mathscr{B}$-cartesian functor; for every object (B,X) of $\mathscr{F}ib(\mathsf{c})$ we define $\omega_B X$ as the unique object of d_B such that $F(B,X) = (B, \omega_B X)$. Likewise – and since d is unital – for every morphism of $\mathscr{F}ib(\mathsf{c})$ of the form $(\mathbf{1}_B, f) : (B,X) \to (B,Y)$ we may define $\omega_B f : \omega_B X \to \omega_B Y$ so that $F(\mathbf{1}_B, f) = (\mathbf{1}_B, \omega_B f)$. Since both c and d are unital, it is easily seen that these rules yield a well defined functor $\omega_B : \mathsf{c}_B \to \mathsf{d}_B$. To define a coherence constraint τ^ω for this system $(\omega_B \mid B \in \mathrm{Ob}(\mathscr{B}))$, notice that for every morphism $\varphi : B \to B'$ of $\mathscr{B}$ and every $Y \in \mathrm{Ob}(\mathsf{c}_{B'})$ we have the $\mathscr{B}$-cartesian morphism $(\varphi, \mathbf{1}_{\mathsf{c}_\varphi Y}) : (B, \mathsf{c}_\varphi Y) \to (B', Y)$ of $\mathscr{F}ib(\mathsf{c})$, and let $t : \mathsf{d}_\varphi \circ \omega_{B'} Y \to \omega_B \circ \mathsf{c}_\varphi Y$ be the unique morphism of d_B such that $F(\varphi, \mathbf{1}_{\mathsf{c}_\varphi Y}) = (\varphi, t) : (B, \omega_B \mathsf{c}_\varphi Y) \to (B', \omega_{B'} Y)$; in light of lemma 3.1.20(i) we see that t is an isomorphism of d_B, and we set $\tau^\omega_{\varphi,Y} := t^{-1} : \mathsf{d}_\varphi \circ \omega_{B'} Y \to \omega_B \circ \mathsf{c}_\varphi Y$. To check the naturality of the rule $Y \mapsto \tau^\omega_{\varphi,Y}$, notice that every morphism $f : X \to Y$ in $\mathsf{c}_{B'}$ yields a commutative diagram :

$$\begin{array}{ccc} (B, \mathsf{c}_\varphi X) & \xrightarrow{(\mathbf{1}_B, \mathsf{c}_\varphi f)} & (B, \mathsf{c}_\varphi Y) \\ {\scriptstyle (\varphi, \mathbf{1}_{\mathsf{c}_\varphi X})}\downarrow & & \downarrow{\scriptstyle (\varphi, \mathbf{1}_{\mathsf{c}_\varphi Y})} \\ (B', X) & \xrightarrow{(\mathbf{1}_{B'}, f)} & (B', Y) \end{array}$$

in $\mathscr{F}ib(\mathsf{c})$, whence the identity :

$$(\varphi, \tau^{\omega\,-1}_{\varphi,Y}) \circ (\mathbf{1}_B, \omega_B \mathsf{c}_\varphi f) = (\mathbf{1}_{B'}, \omega_{B'} f) \circ (\varphi, \tau^{\omega\,-1}_{\varphi,X}) \qquad \text{in } \mathscr{F}ib(\mathsf{d})$$

which in turn translates as the identity $\tau^{\omega\,-1}_{\varphi,Y} \circ \omega_B \mathsf{c}_\varphi(f) = \mathsf{d}_\varphi \omega_{B'}(f) \circ \tau^{\omega\,-1}_{\varphi,X}$ in d_B, as required. Lastly, we need to verify the coherence axioms for τ^ω. However, since c and d are unital, the first coherence axiom amounts to the identity

$$\tau^\omega_{\mathbf{1}_B} = \mathbf{1}_{\omega_B} \qquad \text{for every } B \in \mathrm{Ob}(\mathscr{B})$$

which is immediate from the construction of τ^ω. Next, let $\varphi : B \to B'$ and $\psi : B' \to B''$ be two morphisms of $\mathscr{B}$, and X any object of $\mathsf{c}_{B''}$; we notice the commutative diagram :

$$\begin{array}{ccc} (B, \mathsf{c}_\varphi \mathsf{c}_\psi X) & \xrightarrow{(\varphi, \mathbf{1}_{\mathsf{c}_\varphi \mathsf{c}_\psi X})} & (B', \mathsf{c}_\psi X) \\ {\scriptstyle (\mathbf{1}_B, \gamma^{\mathsf{c}}_{(\varphi,\psi),X})}\downarrow & & \downarrow{\scriptstyle (\psi, \mathbf{1}_{\mathsf{c}_\psi X})} \\ (B, \mathsf{c}_{\psi\varphi} X) & \xrightarrow{(\psi\varphi, \mathbf{1}_{\mathsf{c}_{\psi\varphi} X})} & (B'', X). \end{array} \qquad \text{in } \mathscr{F}ib(\mathsf{c})$$

which, after applying the functor F, yields the identity in $\mathscr{F}ib(\mathsf{d})$:

$$(\psi, \tau^{\omega\ -1}_{\psi,X}) \circ (\varphi, \tau^{\omega\ -1}_{\varphi,\mathsf{c}_\psi X}) = (\psi\varphi, \tau^{\omega\ -1}_{\psi\varphi,X}) \circ (\mathbf{1}_B, \omega_B(\gamma^{\mathsf{c}}_{(\varphi,\psi),X})).$$

which in turn translates as the second coherence axiom. A direct inspection now gives :

$$\mathscr{F}ib(\omega) = F.$$

Summing up, we have shown that (3.1.26) is bijective on objects. A simple inspection shows that (3.1.26) is also injective on morphisms. To conclude, consider therefore two pseudo-natural transformations $\omega, \omega' : \mathsf{c} \to \mathsf{d}$ and a natural transformation $\xi : \mathscr{F}ib(\omega) \Rightarrow \mathscr{F}ib(\omega')$ such that $\pi^{\mathsf{d}} * \xi = \mathbf{1}_{\pi^{\mathsf{c}}}$, and for every object (B, X) of $\mathscr{F}ib(\mathsf{c})$, let $\Xi_{B,X} : \omega_B X \to \omega'_B X$ be the unique morphism of d_B such that $\xi_{(B,X)} = (\mathbf{1}_B, \Xi_{B,X})$. We need to check that the rule: $(B, X) \mapsto \Xi_{B,X}$ yields a well defined modification $\omega \rightsquigarrow \omega'$, in which case we shall have $\mathscr{F}ib(\Xi) = \xi$, by inspection. However, for every $B \in \mathrm{Ob}(\mathscr{B})$, the naturality of the rule : $X \mapsto \Xi_{B,X}$ follows from a simple inspection. It remains thus only to verify the compatibility condition for Ξ. To this aim, let $\varphi : B \to B'$ be any morphism of $\mathscr{B}$, and Y any object of $\mathsf{c}_{B'}$; the morphism $(\varphi, \mathbf{1}_{\mathsf{c}_\varphi Y}) : (B, \mathsf{c}_\varphi Y) \to (B', Y)$ of $\mathscr{F}ib(\mathsf{c})$ yields a commutative diagram

$$\begin{array}{ccc} (B, \omega_B \mathsf{c}_\varphi Y) & \xrightarrow{\xi_{(B,\mathsf{c}_\varphi Y)}} & (B, \omega'_B \mathsf{c}_\varphi Y) \\ {\scriptstyle (\varphi, \tau^{\omega\ -1}_{\varphi,Y})}\downarrow & & \downarrow{\scriptstyle (\varphi, \tau^{\omega'\ -1}_{\varphi,Y})} \\ (B', \omega_{B'} Y) & \xrightarrow{\xi_{(B',Y)}} & (B', \omega'_{B'} Y) \end{array} \qquad \text{in } \mathscr{F}ib(\mathsf{d})$$

which in turn is equivalent to the required identity : we leave the details to the reader. □

Remark 3.1.27. (i) Let $\varphi : \mathscr{A} \to \mathscr{B}$ be any fibration, and c the pseudo-functor associated with a given cleavage $\boldsymbol{\lambda}$ for φ. Claim 3.1.25 exhibits a natural isomorphism $\psi^{\boldsymbol{\lambda}} : \mathscr{F}ib(\mathsf{c}) \xrightarrow{\sim} \mathscr{A}$ and the fibration $\pi^{\mathsf{c}} : \mathscr{F}ib(\mathsf{c}) \to \mathscr{B}$ carries the distinguished cleavage $\boldsymbol{\lambda}^*$ provided by lemma 3.1.20(ii). By inspecting the constructions, we find

$$\psi^{\boldsymbol{\lambda}}(\boldsymbol{\lambda}^*(X, g)) = \psi^{\boldsymbol{\lambda}}(g, \mathbf{1}_{\mathsf{c}_\varphi X}) = \boldsymbol{\lambda}(X, g)$$

for every morphism $g : B' \to B$ of $\mathscr{B}$ and every object X of $\varphi^{-1}B$, whence :

$$\psi^{\boldsymbol{\lambda}} \circ \boldsymbol{\lambda}^* = \boldsymbol{\lambda}.$$

Denote by c^* the pseudo-functor associated with $\boldsymbol{\lambda}^*$; it follows that the restrictions of $\psi^{\boldsymbol{\lambda}}$

$$\psi^{\boldsymbol{\lambda}}_{|B} : \mathscr{F}ib(\mathsf{c})_B \xrightarrow{\sim} \mathscr{A}_B \qquad \text{for every } B \in \mathrm{Ob}(\mathscr{B})$$

define a strict pseudo-natural isomorphism of pseudo-functors

$$\psi^{\boldsymbol{\lambda}}_{|\bullet} : \mathsf{c}^* \xrightarrow{\sim} \mathsf{c}.$$

(ii) Let $\mathscr{B}, \mathscr{C}$ be two V-small categories (for some universe V containing U), $\rho : \mathscr{C} \to \mathscr{B}$ a functor, and $\mathsf{c} : \mathscr{B}^o \to (\mathsf{U}, \mathsf{V})\text{-}\mathbf{Cat}$ a pseudo-functor. We have a natural commutative diagram

$$\begin{array}{ccc} \mathscr{F}ib(\mathsf{c} \circ \rho^o) & \xrightarrow{\mathscr{F}ib(\rho)} & \mathscr{F}ib(\mathsf{c}) \\ {\scriptstyle \pi^{\mathsf{c}\circ\rho^o}} \downarrow & & \downarrow {\scriptstyle \pi^{\mathsf{c}}} \\ \mathscr{C} & \xrightarrow{\quad \rho \quad} & \mathscr{B} \end{array}$$

where $\mathscr{F}ib(\rho)$ is the functor given by the rules : $(C, X) \mapsto (\rho(C), X)$ and $(g, f) \mapsto (\rho(g), f)$ for every object (C, X) and morphism (g, f) of $\mathscr{F}ib(\mathsf{c} \circ \rho)$. This diagram induces a natural identification of fibrations over $\mathscr{C}$:

$$\mathsf{T}^\rho_{\mathsf{c}} : \mathscr{F}ib(\mathsf{c} \circ \rho^o) \xrightarrow{\sim} \mathsf{Fib}(\rho)^*(\mathscr{F}ib(\mathsf{c})) \qquad (C, X) \mapsto (C, (\rho(C), X))$$

(notation of remark 3.1.5(i)). Especially, via this identification, $\mathsf{c} \circ \rho^o$ is the pseudo-functor associated with a cleavage for $\mathsf{Fib}(\rho)^*(\mathscr{F}ib(\mathsf{c}))$. By a simple inspection, it is easily seen that the rule : $\mathsf{c} \mapsto \mathsf{T}^\rho_{\mathsf{c}}$ yields a strict pseudo-natural isomorphism of strict pseudo-functors :

$$\begin{array}{ccc} \mathsf{PsFun}(\mathscr{B}^o, (\mathsf{U}, \mathsf{V})\text{-}\mathbf{Cat}) & \xrightarrow{\mathscr{F}ib_{\mathscr{B}}} & (\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}) \\ {\scriptstyle \mathsf{PsFun}(\rho^o, \mathbf{Cat})} \downarrow & \mathsf{T}^\rho \nearrow & \downarrow {\scriptstyle \mathsf{Fib}(\rho)^*} \\ \mathsf{PsFun}(\mathscr{C}^o, (\mathsf{U}, \mathsf{V})\text{-}\mathbf{Cat}) & \xrightarrow[\mathscr{F}ib_{\mathscr{C}}]{} & (\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}(\mathscr{C}). \end{array}$$

(iii) Let $\mathscr{A} \xrightarrow{\varphi} \mathscr{B} \xleftarrow{\varphi'} \mathscr{A}'$ be two fibrations, and $G : \mathscr{A} \to \mathscr{A}'$ a $\mathscr{B}$-cartesian functor; let us fix cleavages $\boldsymbol{\lambda}$ for $\mathscr{A}$ and $\boldsymbol{\lambda}'$ for $\mathscr{A}'$, and let c and c' be the respective associated pseudo-functors. By theorem 3.1.24, there exists a unique pseudo-natural transformation

$$\mathsf{c}^G : \mathsf{c} \Rightarrow \mathsf{c}'$$

that makes commute the diagram

$$\begin{array}{ccc} \mathscr{F}ib(\mathsf{c}) & \xrightarrow{\psi^{\boldsymbol{\lambda}}} & \mathscr{A} \\ {\scriptstyle \mathscr{F}ib(\mathsf{c}^G)} \downarrow & & \downarrow {\scriptstyle G} \\ \mathscr{F}ib(\mathsf{c}') & \xrightarrow{\psi^{\boldsymbol{\lambda}'}} & \mathscr{A}'. \end{array}$$

By inspecting the constructions, we can extract the following explicit description of c^G :

- for every $B \in \mathrm{Ob}(\mathscr{B})$, the functor $\mathsf{c}^G_B : \mathscr{A}_B \to \mathscr{A}'_B$ is the restriction of G
- for every morphism $g : B \to B'$ in $\mathscr{B}$, the coherence constraint of c^G is the isomorphism of functors $\tau_g : \mathsf{c}'_g \circ \mathsf{c}^G_B \Rightarrow \mathsf{c}^G_{B'} \circ \mathsf{c}_g$ that assigns to every $A \in \mathrm{Ob}(\mathscr{A}_{B'})$ the unique isomorphism of $\mathscr{A}'_B$

$$\tau_{g,A} : \mathsf{c}'_g(GA) \xrightarrow{\sim} G(\mathsf{c}_g A) \qquad \text{such that} \qquad G(\boldsymbol{\lambda}(A, g)) \circ \tau_{g,A} = \boldsymbol{\lambda}'(GA, g).$$

Corollary 3.1.28. *Let $\varphi : \mathscr{A} \to \mathscr{B}$ and $\varphi' : \mathscr{A}' \to \mathscr{B}$ be two fibrations, $F : \mathscr{A} \to \mathscr{A}'$ a cartesian $\mathscr{B}$-functor, and $i \leq 2$ an integer. We have :*

(i) *The following conditions are equivalent :*
  (a) *F is* fibrewise i-faithful, i.e. *the restriction $\mathscr{A}_B \to \mathscr{A}'_B$ of the functor F is i-faithful for every $B \in \mathrm{Ob}(\mathscr{B})$ (see remark* 1.1.5*).*
  (b) *F is i-faithful, and in case $i = 2$, it is even a $\mathscr{B}$-equivalence (see remark* 3.1.5(v)*).*

(ii) *Let $\mathscr{C} \to \mathscr{B}$ be any fibration, and suppose that the conditions of* (i) *hold. Then :*
  (a) *The functor* $\mathsf{Cart}_{\mathscr{B}}(\mathscr{C}, F)$ *is i-faithful.*
  (b) *If $i = 2$, also* $\mathsf{Cart}_{\mathscr{B}}(F, \mathscr{C})$ *is i-faithful.*

Proof. (i): The implication (i.b)⇒(i.a) is trivial. For the converse, we consider first the case where $i = 2$: by theorem 3.1.24 we may assume that $\mathscr{A} = \mathscr{F}ib(\mathsf{c})$ and $\mathscr{A}' = \mathscr{F}ib(\mathsf{c}')$ for (unital) pseudo-functors $\mathsf{c}, \mathsf{c}' : \mathscr{B}^o \to (\mathsf{U}, \mathsf{V})\text{-}\mathbf{Cat}$ (with suitable universes U and V), and $F = \mathscr{F}ib(\omega)$ for a pseudo-natural transformation $\omega : \mathsf{c} \Rightarrow \mathsf{c}'$. Then condition (a) means that $\omega_B : \mathsf{c}_B \to \mathsf{c}'_B$ is an equivalence of categories for every $B \in \mathrm{Ob}(\mathscr{B})$. By theorem 2.4.12, the latter holds if and only if ω is a pseudo-natural equivalence, in which case (i.b) follows.

Next, if $i = 0$, let $A, A' \in \mathrm{Ob}(\mathscr{A})$ and $f_1, f_2 : A \to A'$ be two morphisms of $\mathscr{A}$ such that $Ff_1 = Ff_2$; set $B := \varphi A$ and $t := \varphi(f_1)$, and notice that $\varphi(f_2) = \varphi'(Ff_2) = \varphi'(Ff_1) = t$ as well. Pick any cartesian morphism $h : A'' \to A'$ with $\varphi(h) = t$; then there exist unique morphisms $g_1, g_2 : A \to A''$ in $\varphi^{-1}B$ with $h \circ g_i = f_i$ for $i = 1, 2$. Therefore $Fh \circ Fg_1 = Fh \circ Fg_2$, and since F is cartesian we deduce that $Fg_1 = Fg_2$; by assumption, it follows that $g_1 = g_2$, whence $f_1 = f_2$, as required.

The case where $i = 1$ is similar : let A, A' and B as in the foregoing, and $f' : FA \to FA'$ a morphism of $\mathscr{A}'$; set $t := \varphi'(f')$, and pick a cartesian morphism $h : A'' \to A'$ with $\varphi(h) = t$; then Fh is still cartesian, so there exists a unique morphism $g' : FA \to FA''$ in $\varphi'^{-1}B$ with $Fh \circ g' = f'$. By assumption, $g' = Fg$ for some morphism $g : A \to A''$ in $\varphi^{-1}B$, so that $F(h \circ g) = f'$, as required.

(ii): we consider again first the case where $i = 2$: then, notice that every $\mathscr{B}$-functor $G : \mathscr{A}' \to \mathscr{A}$ that is quasi-inverse to F is also $\mathscr{B}$-cartesian (remark 3.1.5(v)); both assertions (ii.a) and (ii.b) are immediate consequences.

Next, suppose that $i = 0$, and let $G, G' : \mathscr{C} \to \mathscr{A}$ be two functors, $\alpha, \beta : G \Rightarrow G'$ two natural transformations with $F * \alpha = F * \beta$. The latter means that $F(\alpha_C) = F(\beta_C)$ for every $C \in \mathrm{Ob}(\mathscr{C})$; by assumption, we then have $\alpha_C = \beta_C$ for every such C, as required.

Lastly, suppose that $i = 1$, and let $\alpha' : F \circ G \Rightarrow F \circ G'$ be a natural transformation; by assumption, there exists for every $C \in \mathrm{Ob}(\mathscr{C})$ a morphism $\alpha_C : GC \to G'C$ such that $F(\alpha_C) = \alpha'_C$. We claim that the rule : $C \mapsto \alpha_C$ yields a natural transformation $\alpha : G \Rightarrow G'$; indeed, the assertion amounts to the identity $G'f \circ \alpha_C = \alpha_{C'} \circ Gf$ for every morphism $f : C \to C'$ of $\mathscr{C}$. The latter can be checked after composition with F, where it is clear. □

3.1.29. By remark 2.2.17(v), for every universe V with $\mathsf{U} \in \mathsf{V}$, we get a strict pseudo-functor

$$\mathsf{PsFun}((-)^o, \mathbf{Cat}) : {}^o\mathsf{V}\text{-}\mathbf{Cat}^o \to \mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}}.$$

We wish now to show how, likewise, the rule $\mathscr{B} \mapsto (\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B})$ yields a well defined pseudo-functor. Indeed, remark 3.1.5 already says that every functor $\rho : \mathscr{B}' \to \mathscr{B}$ between V-small categories induces a strict pseudo-functor $(\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}(\rho)^* : (\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}) \to (\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}')$, and we have an obvious strict pseudo-natural isomorphism

$$\delta^{(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}}_{\mathscr{B}} : \mathbf{1}_{(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B})} \xrightarrow{\sim} (\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}(\mathbf{1}_{\mathscr{B}})^* \qquad \text{for every small category } \mathscr{B}.$$

Hence, let V′ be yet another universe, with $\mathsf{V} \in \mathsf{V}'$; combining with the strict pseudo-natural isomorphisms of remark 3.1.5(vi), we have a datum $(\delta^{(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}}_{\bullet}, \gamma^{(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}}_{\bullet,\bullet})$ fulfilling the unit and associativity axioms for a pseudo-functor

$$(\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib} : {}^o\mathsf{V}\text{-}\mathbf{Cat}^o \to \mathsf{V}'\text{-}\overline{2\text{-}\mathbf{Cat}}$$

for which we must however still assign the rule prescribing its action on natural transformations. To this aim, we choose for every $\mathscr{B} \in \mathrm{Ob}(\mathsf{V}\text{-}\mathbf{Cat})$ and every V-small fibration $F : \mathscr{A} \to \mathscr{B}$ with essentially U-small fibres, a cleavage $\boldsymbol{\lambda}^F$, and we denote by $\mathsf{c}^F : \mathscr{B}^o \to (\mathsf{U}, \mathsf{V})\text{-}\mathbf{Cat}$ the corresponding pseudo-functor. With the notation of remark 3.1.27, we deduce for every functor $\rho : \mathscr{B}' \to \mathscr{B}$ between V-small categories, a cartesian isomorphism of $\mathscr{B}'$-fibrations

$$\mathsf{T}^\rho_F := (\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}(\rho)^*(\psi^{\boldsymbol{\lambda}^F}) \circ \mathsf{T}^\rho_{\mathsf{c}^F} : \mathscr{F}ib(\mathsf{c}^F \circ \rho^o) \xrightarrow{\sim} (\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}(\rho)^*(\mathscr{A}).$$

Let now $\rho, \rho' : \mathscr{B}' \to \mathscr{B}$ be two functors, and $\alpha : \rho \Rightarrow \rho'$ a natural transformation. There exists a unique $\mathscr{B}'$-cartesian functor $(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\alpha)^*_{\mathscr{A}}$ making commute the diagram :

$$\begin{array}{ccc} \mathscr{F}ib(\mathsf{c}^F \circ \rho'^o) & \xrightarrow{\mathscr{F}ib(\mathsf{c}^F * \alpha^o)} & \mathscr{F}ib(\mathsf{c}^F \circ \rho^o) \\ {\scriptstyle \mathsf{T}^{\rho'}_F}\downarrow & & \downarrow{\scriptstyle \mathsf{T}^{\rho}_F} \\ (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\rho')^*\mathscr{A} & \xrightarrow{(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\alpha)^*_{\mathscr{A}}} & (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\rho)^*\mathscr{A}. \end{array}$$

To ease notation, throughout the rest of this section we shall write Fib *instead of* $(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}$. Next, let $F' : \mathscr{A}' \to \mathscr{B}$ be another fibration with essentially U-small fibres, $G : \mathscr{A} \to \mathscr{A}'$ a cartesian functor between $\mathscr{B}$-fibrations, and define $\mathsf{c}^G : \mathsf{c}^F \Rightarrow \mathsf{c}^{F'}$ as in remark 3.1.27(iii); by example 2.2.15(ii), the coherence constraint τ^G of c^G defines an invertible modification :

$$\tau^G_\alpha : (\mathsf{c}^{F'} * \alpha^o) \odot (\mathsf{c}^G * \rho'^o) \rightsquigarrow (\mathsf{c}^G * \rho^o) \odot (\mathsf{c}^F * \alpha^o).$$

We consider the induced diagram of $\mathscr{B}'$-cartesian functors :

$$\begin{array}{ccccccc} \mathscr{F}ib(\mathsf{c}^{F'} \circ \rho'^o) & & & \xrightarrow{\mathscr{F}ib(\mathsf{c}^{F'} * \alpha^o)} & & & \mathscr{F}ib(\mathsf{c}^{F'} \circ \rho^o) \\ & \nwarrow^{\mathscr{F}ib(\mathsf{c}^G * \rho'^o)} & & & & \nearrow^{\mathscr{F}ib(\mathsf{c}^G * \rho^o)} & \\ & & \mathscr{F}ib(\mathsf{c}^F \circ \rho'^o) & \xrightarrow{\mathscr{F}ib(\mathsf{c}^F * \alpha^o)} & \mathscr{F}ib(\mathsf{c}^F \circ \rho^o) & & \\ {\scriptstyle \mathsf{T}^{\rho'}_{F'}}\downarrow & & {\scriptstyle \mathsf{T}^{\rho'}_F}\downarrow & & \downarrow{\scriptstyle \mathsf{T}^{\rho}_F} & & \downarrow{\scriptstyle \mathsf{T}^{\rho}_{F'}} \\ & & \mathsf{Fib}(\rho')^*\mathscr{A} & \xrightarrow{\mathsf{Fib}(\alpha)^*_{\mathscr{A}}} & \mathsf{Fib}(\rho)^*\mathscr{A} & & \\ & \swarrow_{\mathsf{Fib}(\rho')^*(G)} & & & & \searrow_{\mathsf{Fib}(\rho)^*(G)} & \\ \mathsf{Fib}(\rho')^*\mathscr{A}' & & & \xrightarrow{\mathsf{Fib}(\alpha)^*_{\mathscr{A}'}} & & & \mathsf{Fib}(\rho)^*\mathscr{A}' \end{array}$$

whose inner and outer rectangular subdiagrams commute by definition, and whose left and right trapezoidal subdiagrams commute by the strict pseudo-naturality of T^ρ and $\mathsf{T}^{\rho'}$. If we orient the upper trapezoidal subdiagram with the natural transformation $\mathscr{F}ib(\tau^G_\alpha)^{-1}$, there exists therefore a unique natural transformation

$$\tau^\alpha_G : \mathsf{Fib}(\alpha)^*_{\mathscr{A}'} \circ \mathsf{Fib}(\rho')^*(G) \Rightarrow \mathsf{Fib}(\rho)^*(G) \circ \mathsf{Fib}(\alpha)^*_{\mathscr{A}}$$

orienting the lower trapezoidal subdiagram, such that the resulting oriented cubical diagram (whose other four faces are oriented by identities) commutes on 2-cells, in the sense of (2.3.21); the latter means that :

$$\mathsf{T}^\rho_{F'} * \mathscr{F}ib(\tau^G_\alpha)^{-1} = \tau^\alpha_G * \mathsf{T}^{\rho'}_F.$$

Lemma 3.1.30. *With the notation of* (3.1.29)*, the rule :* $\mathscr{A} \mapsto \mathsf{Fib}(\alpha)^*_{\mathscr{A}}$ *defines a pseudo-natural transformation* $\mathsf{Fib}(\alpha)^* : \mathsf{Fib}(\rho')^* \Rightarrow \mathsf{Fib}(\rho)^*$ *whose coherence constraint is given by the system of natural transformations* $\tau^\alpha_\bullet$.

Proof. By inspecting the construction, we are easily reduced to checking that $\tau^{G'}_\alpha \boxminus \tau^G_\alpha = \tau^{G' \circ G}_\alpha$ for every pair of cartesian functors of $\mathscr{B}$-fibrations $\mathscr{A} \xrightarrow{G} \mathscr{A}' \xrightarrow{G'} \mathscr{A}''$. But this is clear, since $\mathsf{c}^{G' \circ G} = \mathsf{c}^{G'} \odot \mathsf{c}^G$. □

3.1.31. Next, let $\rho'' : \mathscr{B}' \to \mathscr{B}$ be another functor, and $\alpha' : \rho' \Rightarrow \rho''$ a second natural transformation. According to example 2.2.15(i), we have an invertible modification

$$\gamma^F_{\alpha,\alpha'} : (\mathsf{c}^F * \alpha^o) \odot (\mathsf{c}^F * \alpha'^o) \rightsquigarrow \mathsf{c}^F * (\alpha' \odot \alpha)^o$$

induced by the coherence constraint $\gamma^F_{\bullet\bullet}$ of c^F. Whence, a unique natural transformation

$$\Xi^{\alpha,\alpha'}_{\mathscr{A}} : \mathsf{Fib}(\alpha)^*_{\mathscr{A}} \circ \mathsf{Fib}(\alpha')^*_{\mathscr{A}} \Rightarrow \mathsf{Fib}(\alpha' \odot \alpha)^*_{\mathscr{A}} \quad \text{such that} \quad \mathsf{T}^\rho_F * \mathscr{F}ib(\gamma^F_{\alpha,\alpha'}) = \Xi^{\alpha,\alpha'}_{\mathscr{A}} * \mathsf{T}^{\rho''}_F.$$

Lemma 3.1.32. *With the notation of* (3.1.31)*, the following holds :*

(i) *The rule :* $\mathscr{A} \mapsto \Xi^{\alpha,\alpha'}_{\mathscr{A}}$ *is a modification* $\Xi^{\alpha,\alpha'} : \mathsf{Fib}(\alpha)^* \odot \mathsf{Fib}(\alpha')^* \rightsquigarrow \mathsf{Fib}(\alpha' \odot \alpha)^*$.
(ii) *Especially, we have* $\mathsf{Fib}(\alpha)^* \odot \mathsf{Fib}(\alpha')^* = \mathsf{Fib}(\alpha' \odot \alpha)^*$ *in* $\mathsf{V}'\text{-}\overline{2\text{-}\mathbf{Cat}}$.

Proof. Recall that the coherence constraint of $\mathsf{Fib}(\alpha)^* \odot \mathsf{Fib}(\alpha')^*$ assigns to every cartesian functor $G : \mathscr{A} \to \mathscr{A}'$ of $\mathscr{B}$-fibrations the natural transformation

$$\beta := (\mathsf{Fib}(\alpha)^*_{\mathscr{A}'} * \tau^{\alpha'}_G) \odot (\tau^{\alpha}_G * \mathsf{Fib}(\alpha')^*_{\mathscr{A}})$$

and we need to check the identity :

$$X := (\Xi^{\alpha,\alpha'}_{\mathscr{A}'} * \mathsf{Fib}(\rho'')^*(G)) \odot \beta = Y := \tau^{\alpha'\odot\alpha}_G \odot (\mathsf{Fib}(\rho)^*(G) * \Xi^{\alpha,\alpha'}_{\mathscr{A}}).$$

To this aim, it suffices to check that $X * \mathsf{T}^{\rho''}_F = Y * \mathsf{T}^{\rho''}_F$. We compute :

$$\begin{aligned} X*\mathsf{T}^{\rho''}_F &= (\Xi^{\alpha,\alpha'}_{\mathscr{A}'} * \mathsf{Fib}(\rho'')^*(G) * \mathsf{T}^{\rho''}_F) \odot (\beta * \mathsf{T}^{\rho''}_F) \\ &= (\Xi^{\alpha,\alpha'}_{\mathscr{A}'} * \mathsf{T}^{\rho''}_{F'} * \mathscr{F}ib(\mathsf{c}^G * \rho''^o)) \odot (\mathsf{Fib}(\alpha)^*_{\mathscr{A}'} * \mathsf{T}^{\rho'}_{F'} * \mathscr{F}ib(\tau^G_{\alpha'})^{-1}) \odot (\tau^\alpha_G * \mathsf{T}^{\rho'}_F * \mathscr{F}ib(\mathsf{c}^F * \alpha'^o)) \\ &= \mathsf{T}^\rho_{F'} * (\mathscr{F}ib(\gamma^{F'}_{\alpha,\alpha'} * (\mathsf{c}^G * \rho''^o)) \odot \mathscr{F}ib((\mathsf{c}^{F'} * \alpha^o) * \tau^G_{\alpha'})^{-1} \odot \mathscr{F}ib(\tau^G_\alpha * (\mathsf{c}^F * \alpha'^o))^{-1}) \end{aligned}$$

and :

$$\begin{aligned} Y * \mathsf{T}^{\rho''}_F &= (\mathsf{T}^\rho_{F'} * \mathscr{F}ib(\tau^G_{\alpha'\odot\alpha})^{-1}) \odot (\mathsf{Fib}(\rho)^*(G) * \mathsf{T}^\rho_F * \mathscr{F}ib(\gamma^F_{\alpha,\alpha'})) \\ &= (\mathsf{T}^\rho_{F'} * \mathscr{F}ib(\tau^G_{\alpha'\odot\alpha})^{-1}) \odot (\mathsf{T}^\rho_{F'} * \mathscr{F}ib((\mathsf{c}^G * \rho^o) * \gamma^F_{\alpha,\alpha'}). \end{aligned}$$

Thus, we are reduced to showing the identity :

$$\tau^G_{\alpha'\odot\alpha} \odot (\gamma^{F'}_{\alpha,\alpha'} * (\mathsf{c}^G * \rho''^o)) = ((\mathsf{c}^G * \rho^o) * \gamma^F_{\alpha,\alpha'}) \odot (\tau^G_\alpha * (\mathsf{c}^F * \alpha'^o)) \odot ((\mathsf{c}^{F'} * \alpha^o) * \tau^G_{\alpha'}).$$

which follows directly from the coherence axiom for τ^G. ◻

In light of lemma 3.1.32(ii), the construction of the pseudo-functor (U,V)-Fib of (3.1.29) shall be complete, once we have shown :

Lemma 3.1.33. *Let* $\mu, \mu' : \mathscr{B}'' \to \mathscr{B}'$ *and* $\rho, \rho' : \mathscr{B}' \to \mathscr{B}$ *be four functors, and* $\alpha : \rho \Rightarrow \rho'$, $\beta : \mu \Rightarrow \mu'$ *two natural transformations. Then the following diagram commutes in* $\mathsf{V}'\text{-}\overline{2\text{-}\mathbf{Cat}}$ *:*

$$\begin{array}{ccc} \mathsf{Fib}(\mu')^* \circ \mathsf{Fib}(\rho')^* & \xRightarrow{\mathsf{Fib}(\beta)^* * \mathsf{Fib}(\alpha)^*} & \mathsf{Fib}(\mu)^* \circ \mathsf{Fib}(\rho)^* \\ {\scriptstyle \gamma^{\mathsf{Fib}}_{\mu',\rho'}} \Downarrow & & \Downarrow {\scriptstyle \gamma^{\mathsf{Fib}}_{\mu,\rho}} \\ \mathsf{Fib}(\rho' \circ \mu')^* & \xRightarrow{\mathsf{Fib}(\alpha * \beta)^*} & \mathsf{Fib}(\rho \circ \mu)^*. \end{array}$$

Proof. In view of lemma 3.1.32(ii), it suffices to consider separately the cases where $\mu = \mu'$ and $\beta = \mathbf{1}_\mu$, and where $\rho = \rho'$ and $\alpha = \mathbf{1}_\rho$. In the first case, we have to check the identities :

$$\begin{aligned} \gamma^{\mathsf{Fib}}_{(\mu,\rho),\mathscr{A}} \circ \mathsf{Fib}(\mu)^*(\mathsf{Fib}(\alpha)^*_{\mathscr{A}}) &= \mathsf{Fib}(\alpha * \mu)^*_{\mathscr{A}} \circ \gamma^{\mathsf{Fib}}_{(\mu,\rho'),\mathscr{A}} \\ X := \tau^{\alpha*\mu}_G * \gamma^{\mathsf{Fib}}_{(\mu,\rho'),\mathscr{A}} &= Y := \gamma^{\mathsf{Fib}}_{(\mu,\rho),\mathscr{A}'} * \mathsf{Fib}(\mu)^*(\tau^\alpha_G) \end{aligned}$$

for every fibration $F : \mathscr{A} \to \mathscr{B}$ and every cartesian functor of $\mathscr{B}$-fibrations $G : \mathscr{A} \to \mathscr{A}'$. For the first identity, we consider the diagram :

$$\begin{array}{ccc}
\mathscr{F}ib(\mathsf{c}^F \circ \rho'^o \circ \mu^o) & \xrightarrow{\mathscr{F}ib(\mathsf{c}^F * \alpha^o * \mu^o)} & \mathscr{F}ib(\mathsf{c}^F \circ \rho^o \circ \mu^o) \\
{\scriptstyle \mathsf{T}^\mu_{\mathsf{c}^F \circ \rho'^o}} \downarrow & & \downarrow {\scriptstyle \mathsf{T}^\mu_{\mathsf{c}^F \circ \rho^o}} \\
\mathsf{Fib}(\mu)^* \mathscr{F}ib(\mathsf{c}^F \circ \rho'^o) & \xrightarrow{\mathsf{Fib}(\mu)^* \mathscr{F}ib(\mathsf{c}^F * \alpha^o)} & \mathsf{Fib}(\mu)^* \mathscr{F}ib(\mathsf{c}^F \circ \rho^o) \\
{\scriptstyle \mathsf{Fib}(\mu)^*(\mathsf{T}^{\rho'}_F)} \downarrow & & \downarrow {\scriptstyle \mathsf{Fib}(\mu)^*(\mathsf{T}^{\rho}_F)} \\
\mathsf{Fib}(\mu)^* \mathsf{Fib}(\rho')^* \mathscr{A} & \xrightarrow{\mathsf{Fib}(\mu)^* \mathsf{Fib}(\alpha)^*_{\mathscr{A}}} & \mathsf{Fib}(\mu)^* \mathsf{Fib}(\rho)^* \mathscr{A} \\
{\scriptstyle \gamma^{\mathsf{Fib}}_{(\mu,\rho'),\mathscr{A}}} \downarrow & & \downarrow {\scriptstyle \gamma^{\mathsf{Fib}}_{(\mu,\rho),\mathscr{A}}} \\
\mathsf{Fib}(\rho' \circ \mu)^* \mathscr{A} & \xrightarrow{\mathsf{Fib}(\alpha * \mu)^*_{\mathscr{A}}} & \mathsf{Fib}(\rho \circ \mu)^* \mathscr{A}
\end{array}$$

whose central square subdiagrams commutes by construction, and whose upper square subdiagram commutes by strict naturality of T^μ. Notice that the composition of the three left (resp. right) vertical arrows equals $\mathsf{T}^{\rho'\circ\mu}_F$ (resp. $\mathsf{T}^{\rho\circ\mu}_F$); it then follows that also the external square diagram commutes. We conclude that the bottom square subdiagram commutes as well, whence the sought identity. For the second identity, set $Z := \mathsf{Fib}(\mu)^*(\mathsf{T}^{\rho'}_F) \circ \mathsf{T}^\mu_{\mathsf{c}^F \circ \rho'^o}$; it suffices to check that $X * Z = Y * Z$. We compute :

$$\begin{aligned}
X * Z &= \tau^{\alpha*\mu}_G * \mathsf{T}^{\rho'\circ\mu}_F = \mathsf{T}^{\rho\circ\mu}_{F'} * \mathscr{F}ib(\tau^G_{\alpha*\mu})^{-1} \\
Y * Z &= \gamma^{\mathsf{Fib}}_{(\mu,\rho),\mathscr{A}'} * \mathsf{Fib}(\mu)^*(\tau^\alpha_G * \mathsf{T}^{\rho'}_F) * \mathsf{T}^\mu_{\mathsf{c}^F \circ \rho'^o} \\
&= \gamma^{\mathsf{Fib}}_{(\mu,\rho),\mathscr{A}'} * \mathsf{Fib}(\mu)^*(\mathsf{T}^\rho_{F'} * \mathscr{F}ib(\tau^G_\alpha)^{-1}) * \mathsf{T}^\mu_{\mathsf{c}^F \circ \rho'^o} \\
&= \mathsf{T}^{\rho\circ\mu}_{F'} * \mathsf{T}^{\mu\,-1}_{\mathsf{c}^{F'} \circ \rho^o} * \mathsf{Fib}(\mu)^* \mathscr{F}ib(\tau^G_\alpha)^{-1} * \mathsf{T}^\mu_{\mathsf{c}^F \circ \rho'^o} \\
&= \mathsf{T}^{\rho\circ\mu}_{F'} * \mathscr{F}ib(\tau^G_\alpha * \mu^o)
\end{aligned}$$

where the last equality holds by the strict pseudo-naturality of T^μ. So we are reduced to checking that $\tau^G_{\alpha*\mu} = \tau^G_\alpha * \mu^o$. The latter follows by direct inspection.

For the case where $\alpha = \mathbf{1}_\rho$, let $F : \mathscr{A} \to \mathscr{B}$ be any fibration, set $\rho^*\mathscr{A} := \mathsf{Fib}(\rho)^*\mathscr{A}$, and let $\rho^*F : \rho^*\mathscr{A} \to \mathscr{B}'$ be the induced functor. There exists a unique pseudo-natural isomorphism

$$\omega_{F,\rho} : \mathsf{c}^F \circ \rho^o \xrightarrow{\sim} \mathsf{c}^{\rho^* F}$$

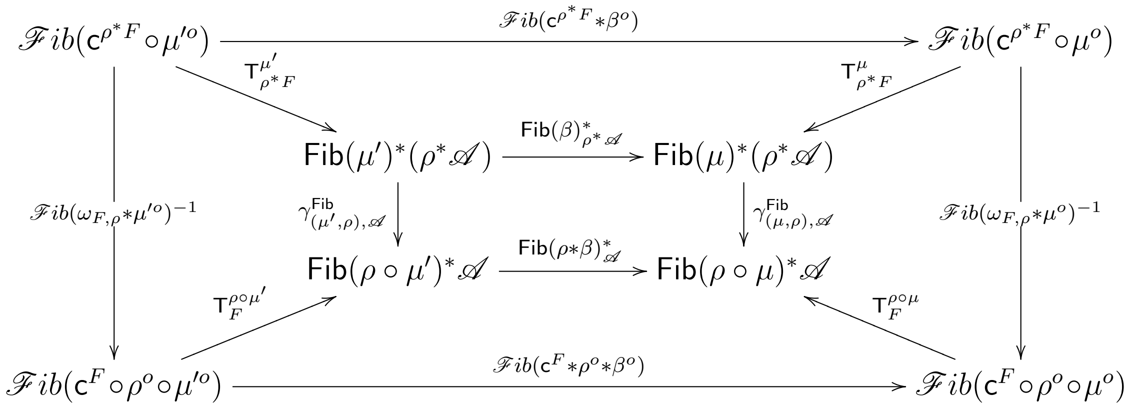
that makes commute the diagram :

$$\begin{array}{ccc}
\mathscr{F}ib(\mathsf{c}^F \circ \rho^o) & \xrightarrow{\mathscr{F}ib(\omega_{F,\rho})} & \mathscr{F}ib(\mathsf{c}^{\rho^* F}) \\
& {\scriptstyle \mathsf{T}^\rho_F} \searrow \quad \swarrow {\scriptstyle \psi\lambda^{\rho^* F}} & \\
& \rho^* \mathscr{A}. &
\end{array}$$

It follows easily that for every cartesian functor $G : \mathscr{A} \to \mathscr{A}'$ we have :

$$\mathsf{c}^{\mathsf{Fib}(\rho)^* G} = \omega_{F',\rho} \odot (\mathsf{c}^G * \rho) \odot \omega^{-1}_{F,\rho} \qquad (3.1.34)$$

(details left to the reader). We consider the diagram :



whose upper and lower trapezoidal subdiagrams commute by construction; it is easily seen that the same holds for the right and left trapezoidal subdiagrams (details left to the reader). Moreover, by example 2.2.15(ii) there exists an invertible modification

$$\tau^{\omega^{-1}_{F,\rho}}_{\beta^o} : (\omega^{-1}_{F,\rho} * \mu^o) \odot (\mathsf{c}^{\rho^*F} * \beta^o) \rightsquigarrow ((\mathsf{c}^F \circ \rho^o) * \beta^o) \odot (\omega^{-1}_{F,\rho} * \mu'^o).$$

Hence, there exists a unique orientation

$$\Xi_{\mathscr{A}} : \gamma^{\mathsf{Fib}}_{(\mu,\rho),\mathscr{A}} \circ \mathsf{Fib}(\beta)^*_{\rho^*\mathscr{A}} \Rightarrow \mathsf{Fib}(\beta*\rho)^*_{\mathscr{A}} \circ \gamma^{\mathsf{Fib}}_{(\mu',\rho),\mathscr{A}}$$

for the inner square subdiagram, such that :

$$\Xi_{\mathscr{A}} * \mathsf{T}^{\mu'}_{\rho^*F} = \mathsf{T}^{\rho\circ\mu}_{F} * \mathscr{F}ib(\tau^{\omega^{-1}_{F,\rho}}_{\beta^o}).$$

To conclude the proof, it suffices then to show :

Claim 3.1.35. The rule : $\mathscr{A} \mapsto \Xi_{\mathscr{A}}$ defines an invertible modification

$$\Xi : \gamma^{\mathsf{Fib}}_{\mu,\rho} \odot (\mathsf{Fib}(\beta)^* * \mathsf{Fib}(\rho)^*) \rightsquigarrow \mathsf{Fib}(\beta*\rho)^* \odot \gamma^{\mathsf{Fib}}_{\mu',\rho}.$$

Proof of the claim. Notice that the coherence constraint of $\gamma^{\mathsf{Fib}}_{\mu,\rho} \odot (\mathsf{Fib}(\beta)^* * \mathsf{Fib}(\rho)^*)$ assigns to every cartesian functor $G : \mathscr{A} \to \mathscr{A}'$ of $\mathscr{B}$-fibrations the natural transformation $X := \gamma^{\mathsf{Fib}}_{(\mu,\rho),\mathscr{A}'} * \tau^{\beta}_{\mathsf{Fib}(\rho)^*(G)}$, and the coherence constraint of $\mathsf{Fib}(\beta*\rho)^* \odot \gamma^{\mathsf{Fib}}_{\mu',\rho}$ assigns to G the natural transformation $Y := \tau^{\rho*\beta}_{G} * \gamma^{\mathsf{Fib}}_{(\mu',\rho),\mathscr{A}}$. Then the assertion comes down to the identity:

$$X' := (\Xi_{\mathscr{A}'} * (\mathsf{Fib}(\mu')^*\mathsf{Fib}(\rho)^*G)) \odot X = Y' := Y \odot ((\mathsf{Fib}(\rho\circ\mu)^*G) * \Xi_{\mathscr{A}})$$

and it suffices to check that $X' * \mathsf{T}^{\mu'}_{\rho^*F} = Y' * \mathsf{T}^{\mu'}_{\rho^*(F)}$. We compute :

$$\begin{aligned}
Y' * \mathsf{T}^{\mu'}_{\rho^*F} &= (\tau^{\rho*\beta}_{G} * \mathsf{T}^{\rho\circ\mu'}_{F} * \mathscr{F}ib(\omega_{F,\rho} * \mu'^o)^{-1}) \odot ((\mathsf{Fib}(\rho\circ\mu)^*G) * \mathsf{T}^{\rho\circ\mu}_{F} * \mathscr{F}ib(\tau^{\omega^{-1}_{F,\rho}}_{\beta^o})) \\
&= (\mathsf{T}^{\rho\circ\mu}_{F'} * \mathscr{F}ib(\tau^{G\,-1}_{\rho*\beta} * (\omega_{F,\rho} * \mu'^o)^{-1})) \odot ((\mathsf{Fib}(\rho\circ\mu)^*G) * \mathsf{T}^{\rho\circ\mu}_{F} * \mathscr{F}ib(\tau^{\omega^{-1}_{F,\rho}}_{\beta^o})) \\
&= (\mathsf{T}^{\rho\circ\mu}_{F'} * \mathscr{F}ib(\tau^{G\,-1}_{\rho*\beta} * (\omega_{F,\rho} * \mu'^o)^{-1})) \odot (\mathsf{T}^{\rho\circ\mu}_{F'} * \mathscr{F}ib(\mathsf{c}^G * \rho^o * \mu^o) * \mathscr{F}ib(\tau^{\omega^{-1}_{F,\rho}}_{\beta^o})) \\
&= \mathsf{T}^{\rho\circ\mu}_{F'} * \mathscr{F}ib((\tau^{G\,-1}_{\rho*\beta} * (\omega_{F,\rho} * \mu'^o)^{-1}) \odot ((\mathsf{c}^G * \rho^o * \mu^o) * \tau^{\omega^{-1}_{F,\rho}}_{\beta^o})) \\
X * \mathsf{T}^{\mu'}_{\rho^*F} &= \gamma^{\mathsf{Fib}}_{(\mu,\rho),\mathscr{A}'} * \mathsf{T}^{\mu}_{\rho^*F'} * \mathscr{F}ib(\tau^{\mathsf{Fib}(\rho)^*G}_{\beta})^{-1} \\
&= \mathsf{T}^{\rho\circ\mu}_{F'} * \mathscr{F}ib((\omega_{F',\rho} * \mu^o)^{-1} * (\tau^{\mathsf{Fib}(\rho)^*G}_{\beta})^{-1})
\end{aligned}$$

and :

$$\begin{aligned}
\Xi_{\mathscr{A}'} * (\mathsf{Fib}(\mu')^*\mathsf{Fib}(\rho)^*G) * \mathsf{T}^{\mu'}_{\rho^*F} &= \Xi_{\mathscr{A}'} * \mathsf{T}^{\mu'}_{\rho^*F'} * \mathscr{F}ib(\mathsf{c}^{\mathsf{Fib}(\rho)^*G} * \mu'^o) \\
&= \mathsf{T}^{\rho\circ\mu}_{F'} * \mathscr{F}ib(\tau^{\omega^{-1}_{F',\rho}}_{\beta^o} * (\mathsf{c}^{\mathsf{Fib}(\rho)^*G} * \mu'^o))
\end{aligned}$$

so that $X' * Z = \mathsf{T}^{\rho\circ\mu}_{F'} * \mathscr{F}ib((\tau_{\beta^o}^{\omega^{-1}_{F',\rho}} * (\mathsf{c}^{\mathsf{Fib}(\rho)^*G} * \mu'^o)) \odot ((\omega_{F',\rho} * \mu^o)^{-1} * (\tau_\beta^{\mathsf{Fib}(\rho)^*G})^{-1}))$. We are thus reduced to checking that :

$$((\mathsf{c}^G * \rho^o * \mu^o) * \tau_{\beta^o}^{\omega^{-1}_{F,\rho}}) \odot ((\omega^{-1}_{F',\rho} * \mu^o) * \tau_\beta^{\mathsf{Fib}(\rho)^*G}) = (\tau^G_{\rho*\beta} * (\omega^{-1}_{F,\rho} * \mu'^o)) \odot (\tau_{\beta^o}^{\omega^{-1}_{F',\rho}} * (\mathsf{c}^{\mathsf{Fib}(\rho)^*G} * \mu'^o)).$$

The latter follows easily from (3.1.34) : details left to the reader. $\square$

Corollary 3.1.36. *We have a pseudo-natural equivalence*

$$\mathscr{F}ib_\bullet : \mathsf{PsFun}((-)^o, \mathbf{Cat}) \Rightarrow (\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib} \qquad \mathscr{C} \mapsto \mathscr{F}ib_{\mathscr{C}}$$

whose coherence constraint attaches to every functor ρ of small categories the strict pseudo-natural isomorphism $(\mathsf{T}^\rho)^{-1}$.

Proof. The required coherence axioms for the rule $\rho \mapsto (\mathsf{T}^\rho)^{-1}$ hold by direct inspection (details left to the reader). There remains therefore only to check the naturality of this rule, relative to natural transformations $\beta : \rho \Rightarrow \rho'$ between functors $\rho, \rho' : \mathscr{B}' \to \mathscr{B}$ of V-small categories. The assertion amounts to checking the following identity in the 2-category $\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}}$:

$$(\mathsf{T}^\rho)^{-1} \odot (\mathsf{Fib}(\beta)^* * \mathscr{F}ib_{\mathscr{B}}) = (\mathscr{F}ib_{\mathscr{B}'} * \mathsf{PsFun}(\beta^o, \mathbf{Cat})) \odot (\mathsf{T}^{\rho'})^{-1}. \tag{3.1.37}$$

Thus, let $\mathsf{d} : \mathscr{B}^o \to \mathbf{Cat}$ be any pseudo-functor, and denote by $F_\mathsf{d} : \mathscr{F}ib(\mathsf{d}) \to \mathscr{B}$ the induced fibration. With the notation of (3.1.29), there exists a unique pseudo-natural isomorphism

$$\omega^\mathsf{d} : \mathsf{c}^{F_\mathsf{d}} \xrightarrow{\sim} \mathsf{d} \qquad \text{such that} \qquad \mathscr{F}ib(\omega^\mathsf{d}) = \psi^{\lambda^{F_\mathsf{d}}}.$$

We consider the diagram :

$$\begin{array}{ccccc}
\mathscr{F}ib(\mathsf{c}^{F_\mathsf{d}} \circ \rho'^o) & \xrightarrow{\mathsf{T}^{\rho'}_{F_\mathsf{d}}} & \mathsf{Fib}(\rho')^*\mathscr{F}ib(\mathsf{d}) & \xrightarrow{(\mathsf{T}^{\rho'}_\mathsf{d})^{-1}} & \mathscr{F}ib(\mathsf{d} \circ \rho'^o) \\
\Big\downarrow{\scriptstyle \mathscr{F}ib(\mathsf{c}^{F_\mathsf{d}} * \beta^o)} & & \Big\downarrow{\scriptstyle \mathsf{Fib}(\beta)^*\mathscr{F}ib(\mathsf{d})} & & \Big\downarrow{\scriptstyle \mathscr{F}ib(\mathsf{d} * \beta^o)} \\
\mathscr{F}ib(\mathsf{c}^{F_\mathsf{d}} \circ \rho^o) & \xrightarrow[\mathsf{T}^{\rho}_{F_\mathsf{d}}]{} & \mathsf{Fib}(\rho)^*\mathscr{F}ib(\mathsf{d}) & \xrightarrow[(\mathsf{T}^{\rho}_\mathsf{d})^{-1}]{} & \mathscr{F}ib(\mathsf{d} \circ \rho'^o)
\end{array}$$

whose left square subdiagram commutes by construction. Invoking the strict pseudo-naturality of T^ρ, it is easily seen that the composition of the two bottom horizontal arrows agrees with $\mathscr{F}ib(\omega^\mathsf{d} * \rho^o)$; likewise, the composition of the two top horizontal arrows yields $\mathscr{F}ib(\omega^\mathsf{d} * \rho'^o)$. Now, according to example 2.2.15(ii), there exists an invertible modification :

$$\tau^{\omega^\mathsf{d}}_\beta : (\mathsf{d} * \beta^o) \odot (\omega^\mathsf{d} * \rho'^o) \rightsquigarrow (\omega^\mathsf{d} * \rho^o) \odot (\mathsf{c}^{F_\mathsf{d}} * \beta^o).$$

Hence, there exists a unique isomorphism of functors

$$\vartheta^\beta_\mathsf{d} : \mathscr{F}ib(\mathsf{d} * \beta^o) \circ (\mathsf{T}^{\rho'}_\mathsf{d})^{-1} \xrightarrow{\sim} (\mathsf{T}^\rho_\mathsf{d})^{-1} \circ \mathsf{Fib}(\rho)^*\mathscr{F}ib(\mathsf{d}) \quad \text{such that} \quad \vartheta^\beta_\mathsf{d} * \mathsf{T}^{\rho'}_{F_\mathsf{d}} = \mathscr{F}ib(\tau^{\omega^\mathsf{d}}_\beta)$$

and we are reduced to checking that the rule : $\mathsf{d} \mapsto \vartheta^\beta_\mathsf{d}$ defines an invertible modification from the right to the left side of (3.1.37). Hence, let $\alpha : \mathsf{d} \Rightarrow \mathsf{d}'$ be a pseudo-natural transformation, and define $\mathsf{c}^{\mathscr{F}ib(\alpha)} : \mathsf{c}^{F_\mathsf{d}} \Rightarrow \mathsf{c}^{F_{\mathsf{d}'}}$ as in remark 3.1.27(iii); it is easily seen that

$$\mathsf{c}^{\mathscr{F}ib(\alpha)} = \omega^{\mathsf{d}'\,-1} \odot \alpha \odot \omega^\mathsf{d}.$$

Now, the coherence constraint of the left-hand side of (3.1.37) assigns to α the natural transformation $X := (\mathsf{T}^\rho_{\mathsf{d}'})^{-1} * \tau^\beta_{\mathscr{F}ib(\alpha)}$, where $\tau^\beta_{\mathscr{F}ib(\alpha)}$ is characterized by the identity :

$$\tau^\beta_{\mathscr{F}ib(\alpha)} * \mathsf{T}^{\rho'}_{F_\mathsf{d}} = \mathsf{T}^\rho_{F_{\mathsf{d}'}} * \mathscr{F}ib(\tau_\beta^{\mathscr{F}ib(\alpha)})^{-1}$$

and $\tau_\beta^{\mathscr{F}ib(\alpha)} : (\mathsf{c}^{F_{\mathsf{d}'}} * \beta^o) \odot (\mathsf{c}^{\mathscr{F}ib(\alpha)} * \rho'^o) \rightsquigarrow (\mathsf{c}^{\mathscr{F}ib(\alpha)} * \rho^o) \odot (\mathsf{c}^{F_\mathsf{d}} * \beta^o)$ is given as well by example 2.2.15(ii). According to remark 2.2.17(ii), the right-hand side of (3.1.37) assigns to α

the natural transformation $Y := \mathscr{F}ib(\tau^{\alpha}_{\beta})^{-1} * (\mathsf{T}^{\rho'}_{\mathsf{d}})^{-1}$, where again $\tau^{\alpha}_{\beta} : (\mathsf{d}' * \beta^o) \odot (\alpha * \rho'^o) \Rightarrow (\alpha * \rho^o) \odot (\mathsf{d} * \beta^o)$ is given by example 2.2.15(ii). We need then to check that :

$$Y' := (\vartheta^{\beta}_{\mathsf{d}'} * \mathsf{Fib}(\rho')^* \mathscr{F}ib(\alpha)) \odot Y = X' := X \odot (\mathscr{F}ib(\alpha * \rho^o) * \vartheta^{\beta}_{\mathsf{d}})$$

and it suffices to check that $Y' * \mathsf{T}^{\rho'}_{F_{\mathsf{d}}} = X' * \mathsf{T}^{\rho'}_{F_{\mathsf{d}}}$. We compute :

$$\begin{aligned} Y' * \mathsf{T}^{\rho'}_{F_{\mathsf{d}}} &= (\vartheta^{\beta}_{\mathsf{d}'} * \mathsf{T}^{\rho'}_{F'_{\mathsf{d}}} * \mathscr{F}ib(\mathsf{c}^{\mathscr{F}ib(\alpha)} * \rho'^o)) \odot \mathscr{F}ib(\tau^{\alpha}_{\beta} * (\omega^{\mathsf{d}} * \rho'^o))^{-1} \\ &= (\mathscr{F}ib(\tau^{\omega^{\mathsf{d}'}}_{\beta}) * \mathscr{F}ib(\mathsf{c}^{\mathscr{F}ib(\alpha)} * \rho'^o)) \odot \mathscr{F}ib(\tau^{\alpha}_{\beta} * (\omega^{\mathsf{d}} * \rho'^o))^{-1} \\ X' * \mathsf{T}^{\rho'}_{F_{\mathsf{d}}} &= ((\mathsf{T}^{\rho}_{\mathsf{d}'})^{-1} * \mathsf{T}^{\rho}_{F_{\mathsf{d}'}} * \mathscr{F}ib(\tau^{\mathscr{F}ib(\alpha)}_{\beta})^{-1}) \odot (\mathscr{F}ib(\alpha * \rho^o) * \mathscr{F}ib(\tau^{\omega^{\mathsf{d}}}_{\beta})) \\ &= (\mathscr{F}ib(\omega^{\mathsf{d}'} * \rho^o) * \mathscr{F}ib(\tau^{\mathscr{F}ib(\alpha)}_{\beta})^{-1}) \odot (\mathscr{F}ib(\alpha * \rho^o) * \mathscr{F}ib(\tau^{\omega^{\mathsf{d}}}_{\beta})) \end{aligned}$$

hence we are further reduced to showing that :

$$((\omega^{\mathsf{d}'} * \rho^o) * \tau^{\mathscr{F}ib(\alpha)}_{\beta}) \odot (\tau^{\omega^{\mathsf{d}'}}_{\beta} * (\mathsf{c}^{\mathscr{F}ib(\alpha)} * \rho'^o)) = ((\alpha * \rho^o) * \tau^{\omega^{\mathsf{d}}}_{\beta}) \odot (\tau^{\alpha}_{\beta} * (\omega^{\mathsf{d}} * \rho'^o))$$

but this is clear, since both sides agree with $\tau^{\alpha\odot\omega^{\mathsf{d}}}_{\beta}$, where $\tau^{\alpha\odot\omega^{\mathsf{d}}}$ denotes as usual the coherence constraint of $\alpha \odot \omega^{\mathsf{d}}$. ☐

3.2. **Split fibrations and cartesian sections.** As usual, we fix a universe U, but some of the constructions in this section shall produce fibrations whose fibre categories will be *equivalent, though not necessarily isomorphic* to a U-small category.

Definition 3.2.1. Let $\mathscr{B}$ be any category.

(i) A *split fibration* over $\mathscr{B}$ is a pair $(\varphi, \boldsymbol{\lambda})$ where $\varphi : \mathscr{A} \to \mathscr{B}$ is a fibration and $\boldsymbol{\lambda}$ a cleavage for φ whose associated pseudo-functor is strict, in which case we also say that $\boldsymbol{\lambda}$ is *split*.

(ii) For $i = 1, 2$, let $(\varphi_i : \mathscr{A}_i \to \mathscr{B}, \boldsymbol{\lambda}_i)$ be two split fibrations, and $F : \mathscr{A}_1 \to \mathscr{A}_2$ a cartesian functor. Let also c_i be the pseudo-functor associated with $\boldsymbol{\lambda}_i$, for $i = 1, 2$. For every $B \in \mathrm{Ob}(\mathscr{B})$, let $F_B : \varphi_1^{-1}B \to \varphi_2^{-1}B$ denote the restriction of F. We say that F is *a split cartesian functor* $(\varphi_1, \mathsf{c}_1) \to (\varphi_2, \mathsf{c}_2)$ if the rule : $B \mapsto F_B$ defines a strict pseudo-natural transformation $\mathsf{c}_1 \Rightarrow \mathsf{c}_2$.

Remark 3.2.2. (i) With the notation of definition 3.2.1(i), it is easily seen that $\boldsymbol{\lambda}$ is split if and only if for every $B \in \mathrm{Ob}(\mathscr{B})$ we have $\mathsf{c}_{\mathbf{1}_B} = \mathbf{1}_{\mathsf{c}_B}$, and for every pair of morphisms $B'' \xrightarrow{h} B' \xrightarrow{g} B$ of $\mathscr{B}$ we have $\mathsf{c}_{g\circ h} = \mathsf{c}_g \mathsf{c}_h$ and the following diagram commutes :

$$\begin{array}{ccc} \mathsf{c}_{g\circ h}A & \xrightarrow{\boldsymbol{\lambda}(\mathsf{c}_g A, h)} & \mathsf{c}_g A \\ & {\scriptstyle \boldsymbol{\lambda}(A, g\circ h)} \searrow \quad \swarrow {\scriptstyle \boldsymbol{\lambda}(A,g)} & \\ & A & \end{array} \qquad \text{for every } A \in \mathrm{Ob}(\varphi^{-1}B).$$

(ii) Likewise, with the notation of definition 3.2.1(ii), and in light of remark 3.1.27(iii), we see that the $\mathscr{B}$-cartesian functor $F : \mathscr{A}_1 \to \mathscr{A}_2$ is split if and only if for every morphism $g : B' \to B$ of $\mathscr{B}$ and every $A \in \mathrm{Ob}(\varphi_1^{-1}B)$ we have

$$\mathsf{c}'_g(FA) = F(\mathsf{c}_g A) \qquad \text{and} \qquad F(\boldsymbol{\lambda}(A, g)) = \boldsymbol{\lambda}'(FA, g).$$

(details left to the reader).

Example 3.2.3. The fibration $\mathsf{s} : \mathscr{B}/F\mathscr{C} \to \mathscr{B}$ associated with any functor $F : \mathscr{C} \to \mathscr{B}$ (see example 3.1.3(ii)) is split. Indeed, we have a natural cleavage, defined as follows. An object of

$\mathscr{B}/\mathsf{s}(\mathscr{B}/F\mathscr{C})$ is the datum of objects $B \in \mathrm{Ob}(\mathscr{B})$ and $(f : B' \to FC') \in \mathrm{Ob}(\mathscr{B}/F\mathscr{C})$, and a morphism $g : B \to B'$ in $\mathscr{B}$; to such a datum we assign the commutative diagram

$$\begin{array}{ccc} B & \xrightarrow{f\circ g} & FC' \\ {\scriptstyle g}\downarrow & & \downarrow{\scriptstyle F\mathbf{1}_{C'}} \\ B' & \xrightarrow{f} & FC' \end{array}$$

which is an object $\boldsymbol{\lambda}(B, f, g)$ of $\mathsf{Morph}(\mathscr{B}/F\mathscr{C})$. Since this object is a $\mathscr{B}$-cartesian morphism of $\mathscr{B}/F\mathscr{C}$, the rule $(B, f, g) \mapsto \boldsymbol{\lambda}(B, f, g)$ extends uniquely to a cleavage for s. By a simple inspection, we find that the corresponding pseudo-functor c associates with every morphism $g : B \to B'$ of $\mathscr{B}$ the functor $g/F\mathscr{C} : B'/F\mathscr{C} \to B/F\mathscr{C}$ (notation of (1.1.27)). Then it is clear that c is strict.

3.2.4. *Cartesian sections of a fibration.* Let $\mathscr{B}$ be a category, V a universe such that $\mathsf{U} \subset \mathsf{V}$ and $\mathscr{B}$ is V-small. The V-small split fibrations over $\mathscr{B}$ with essentially U-small fibres are the objects of a 2-category

$$(\mathsf{U}, \mathsf{V})\text{-}\mathsf{Split}(\mathscr{B})$$

whose 1-cells are given by the split cartesian functors, and whose 2-cells are the natural $\mathscr{B}$-transformations. As usual, we also often write $\mathsf{U}\text{-}\mathsf{Split}(\mathscr{B})$ or just $\mathsf{Split}(\mathscr{B})$ for this 2-category. Furthermore, we have an obvious forgetful strict pseudo-functor :

$$\mathsf{F} : (\mathsf{U}, \mathsf{V})\text{-}\mathsf{Split}(\mathscr{B}) \to (\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}) \qquad (\varphi, \boldsymbol{\lambda}) \mapsto \varphi.$$

On the other hand, *if $\mathscr{B}$ is U-small*, we have as well a natural strict pseudo-functor

$$\mathsf{C} : (\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}) \to (\mathsf{U}, \mathsf{V})\text{-}\mathsf{Split}(\mathscr{B}).$$

Namely, for a fibration $\varphi : \mathscr{A} \to \mathscr{B}$ with essentially U-small fibres, we consider the strict pseudo-functor

$$\mathscr{A}(-) : \mathscr{B}^o \to (\mathsf{U}, \mathsf{V})\text{-}\mathbf{Cat} \qquad B \mapsto \mathscr{A}(B) := \mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/B, \mathscr{A})$$

that assigns to every morphism $f : B \to B'$ of $\mathscr{B}$ the functor $\mathsf{Cart}(f_*, \mathscr{A})$ for (recall that $\mathscr{B}/B$ is fibred over $\mathscr{B}$, by example 3.1.3(i); also $f_* : \mathscr{B}/B \to \mathscr{B}/B'$ is the $\mathscr{B}$-cartesian functor as in (1.1.25)). The objects of $\mathscr{A}(B)$ are called the *cartesian sections* of $\mathscr{A}$ over B, and the morphisms of $\mathscr{A}(B)$ are also called *morphisms of cartesian sections*. Then we set

$$\mathsf{C}(\mathscr{A}) := \mathscr{F}ib(\mathscr{A}(-))$$

and we let $\mathsf{C}(\varphi) : \mathsf{C}(\mathscr{A}) \to \mathscr{B}$ be the resulting fibration; recall that the fibre category $\mathsf{C}(\varphi)^{-1}B$ is naturally isomorphic to $\mathscr{A}(B)$ for every $B \in \mathrm{Ob}(\mathscr{B})$, and $\mathsf{C}(\mathscr{A})$ carries a distinguished cleavage whose associated pseudo-functor corresponds – under this identification – to the strict pseudo-functor $\mathscr{A}(-)$ (remark 3.1.27(i)).

Every $\mathscr{B}$-cartesian functor $F : \mathscr{A}_1 \to \mathscr{A}_2$ induces a strict pseudo-natural transformation

$$\mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/-, F) : \mathscr{A}_1(-) \Rightarrow \mathscr{A}_2(-) \qquad B \mapsto \mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/B, F)$$

whence a $\mathscr{B}$-cartesian functor

$$\mathsf{C}(F) := \mathscr{F}ib(\mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/-, F)) : \mathsf{C}(\mathscr{A}_1) \to \mathsf{C}(\mathscr{A}_2)$$

and every natural $\mathscr{B}$-transformation $\alpha : F_1 \Rightarrow F_2$ of $\mathscr{B}$-cartesian functors $F_1, F_2 : \mathscr{A}_1 \to \mathscr{A}_2$ induces a modification

$$\mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/-, \alpha) : \mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/-, F_1) \rightsquigarrow \mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/-, F_2) \qquad B \mapsto \mathsf{Cart}_{\mathscr{B}}(\mathbf{1}_{\mathscr{B}/B}, \alpha)$$

whence a natural $\mathscr{B}$-transformation

$$\mathsf{C}(\alpha) := \mathscr{F}ib(\mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/-, \alpha)) : \mathsf{C}(F_1) \Rightarrow \mathsf{C}(F_2).$$

Taking into account the discussion of (3.1.18)-(3.1.21) we easily conclude that the foregoing rules yield a well defined strict pseudo-functor C as sought.

3.2.5. *The evaluation functor of a fibration.* Let $\mathscr{B}$ be a category, and $\varphi : \mathscr{A} \to \mathscr{B}$ a fibration; we claim that there exists a $\mathscr{B}$-cartesian functor

$$\mathsf{ev}^{\mathscr{A}} : \mathsf{C}(\mathscr{A}) \to \mathscr{A}$$

that assigns to every object $(B, G : \mathscr{B}/B \to \mathscr{A})$ of $\mathsf{C}(\mathscr{A})$ its evaluation $G\mathbf{1}_B \in \mathrm{Ob}(\mathscr{A}_B)$, and to any morphism $(f, \alpha : G \Rightarrow G' \circ f_*) : (B, G) \to (B', G')$, the composition

$$G\mathbf{1}_B \xrightarrow{\alpha_{\mathbf{1}_B}} G'f \xrightarrow{G'(f/B')} G'\mathbf{1}_{B'}$$

where $f/B' : f \to \mathbf{1}_{B'}$ is the morphism of $\mathscr{B}/B'$ determined by f. In order to check that these rules define a functor, let $(g, \beta : G' \Rightarrow G'' \circ g_*) : (B', G') \to (B'', G'')$ be any other morphism; then $(g, \beta) \circ (f, \alpha) = (g \circ f, (\beta * f_*) \odot \alpha)$, and the assertion comes down to the identity

$$G''(g/B'') \circ \beta_{\mathbf{1}_{B'}} \circ G'(f/B') \circ \alpha_{\mathbf{1}_B} = G''(g \circ f/B'') \circ ((\beta * f_*) \odot \alpha)_{\mathbf{1}_B}.$$

But we have

$$\beta_{\mathbf{1}_{B'}} \circ G'(f/B') = G''(g_*(f/B')) \circ \beta_f \quad \text{and} \quad G''(g/B'') \circ G''(g_*(f/B')) = G''(g \circ f/B'')$$

whence the contention. Moreover, a simple inspection shows that every cartesian functor $F : \mathscr{A}_1 \to \mathscr{A}_2$ of fibred $\mathscr{B}$-categories yields a commutative diagram of $\mathscr{B}$-categories :

$$\begin{array}{ccc} \mathsf{C}(\mathscr{A}_1) & \xrightarrow{\mathsf{C}(F)} & \mathsf{C}(\mathscr{A}_2) \\ {\scriptstyle \mathsf{ev}^{\mathscr{A}_1}}\downarrow & & \downarrow{\scriptstyle \mathsf{ev}^{\mathscr{A}_2}} \\ \mathscr{A}_1 & \xrightarrow{F} & \mathscr{A}_2 \end{array}$$

and for every natural $\mathscr{B}$-transformation $\alpha : F_1 \Rightarrow F_2$ of $\mathscr{C}$-cartesian functors $F_1, F_2 : \mathscr{A}_1 \to \mathscr{A}_2$ we have the identity :

$$\mathsf{ev}^{\mathscr{A}_2} * \mathsf{C}(\alpha) = \alpha * \mathsf{ev}^{\mathscr{A}_1}.$$

Hence, *if* B *is* U*-small*, the rule $\mathscr{A} \mapsto \mathsf{ev}^{\mathscr{A}}$ defines a strict pseudo-natural transformation

$$\mathsf{ev}^\bullet : \mathsf{F} \circ \mathsf{C} \Rightarrow \mathbf{1}_{\mathsf{Fib}(\mathscr{B})}.$$

Remark 3.2.6. With the notation of (3.2.5), let $G, G' \in \mathscr{A}(B)$ be two cartesian sections over an object $B \in \mathrm{Ob}(\mathscr{B})$, and $\alpha : G \Rightarrow G'$ a natural $\mathscr{B}$-transformation. Then it is easily seen that α is uniquely determined by its evaluation $\mathsf{ev}^{\mathscr{A}}(\mathbf{1}_B, \alpha) = \alpha_{\mathbf{1}_B} : G\mathbf{1}_B \to G'\mathbf{1}_B$. Indeed, every object $(f : B' \to B) \in \mathrm{Ob}(\mathscr{B}/B)$ yields a morphism $f/B : f \to \mathbf{1}_B$ in $\mathscr{B}/B$, whence a commutative diagram

$$\begin{array}{ccc} Gf & \xrightarrow{\alpha_f} & G'f \\ {\scriptstyle G(f/B)}\downarrow & & \downarrow{\scriptstyle G'(f/B)} \\ G\mathbf{1}_B & \xrightarrow{\alpha_{\mathbf{1}_B}} & G'\mathbf{1}_B \end{array}$$

which determines α_f uniquely, since $G'(f/B)$ is cartesian. By the same token, given any morphism $g : G\mathbf{1}_B \to G'\mathbf{1}_B$ in $\varphi^{-1}B$, let us define $\alpha^g_f : Gf \to G'f$ as the unique morphism in $\varphi^{-1}B'$ such that $G'(f/B) \circ \alpha^g_f = g \circ G(f/B)$. Then it is easily seen that the rule $f \mapsto \alpha^g_f$ defines a natural $\mathscr{B}$-transformation $\alpha^g : G \Rightarrow G'$ such that $\alpha^g_{\mathbf{1}_B} = g$. If $G'' : \mathscr{B}/B \to \mathscr{A}$ is another cartesian functor, and $g' : G'\mathbf{1}_B \to G''\mathbf{1}_B$ is any morphism in $\varphi^{-1}B$, clearly we have :

$$\alpha^{g'} \odot \alpha^g = \alpha^{g' \circ g}.$$

Theorem 3.2.7. *The pseudo-functor* C *is a strong right* 2*-adjoint for* F*, and is fully faithful.*

Proof. According to proposition 1.1.15(i) and theorem 2.4.24(i), in order to prove the first assertion it suffices to exhibit a unit and a counit fulfilling the triangular identities (1.1.13). Our candidate counit shall be the pseudo-natural transformation $\mathsf{ev}^\bullet$. Taking into account remark 3.1.5(v) and corollary 2.4.29, in order to see that $\mathsf{ev}^{\mathscr{A}}$ is $\mathscr{B}$-cartesian for every fibration $\varphi : \mathscr{A} \to \mathscr{B}$, and to prove the second assertion of the theorem, it then suffices to notice :

Claim 3.2.8. The functor $\mathsf{ev}^{\mathscr{A}}$ is a $\mathscr{B}$-equivalence.

Proof of the claim. It suffices to show that $\mathsf{ev}^{\mathscr{A}}$ is a fibrewise equivalence (corollary 3.1.28(i)). However, from remark 3.2.6 we see already that for every $B \in \mathrm{Ob}(\mathscr{B})$ the restriction

$$\mathsf{ev}^{\mathscr{A}}_{|B} : \mathscr{A}(B) \to \mathscr{A}_B$$

of $\mathsf{ev}^{\mathscr{A}}$ is fully faithful. To show that $\mathsf{ev}^{\mathscr{A}}_{|B}$ is essentially surjective, let $\boldsymbol{\lambda}$ be a unital cleavage for φ, and c its associated unital pseudo-functor. For every $A \in \mathrm{Ob}(\mathscr{A}_B)$ consider the functor

$$i_A : \mathscr{B}/B \to \mathscr{B}/\varphi\mathscr{A} \qquad (g : B' \to B) \mapsto (A, B, g)$$

that assigns to every morphism $(h/B) : g \to g'$ of $\mathscr{B}/B$ the morphism $(A, B, (h/A)) : (A, B, g) \to (A, B, g')$ of $\mathscr{B}/\varphi\mathscr{A}$. Let also $\mathsf{s} : \mathsf{Morph}(\mathscr{A}) \to \mathscr{A}$ be the source functor (notation of (1.1.30)); it suffices to notice that

$$\beta^{\boldsymbol{\lambda}}_{B,A} := \mathsf{s} \circ \boldsymbol{\lambda} \circ i_A : \mathscr{B}/B \to \mathscr{A}.$$

is a cartesian section with $\beta^{\boldsymbol{\lambda}}_{B,A}(\mathbf{1}_B) = A$. ◊

Next, let $(\varphi : \mathscr{A} \to \mathscr{B}, \boldsymbol{\lambda})$ be any split fibration with small fibres, and c the strict pseudo-functor associated with $\boldsymbol{\lambda}$; denote also by $\boldsymbol{\lambda}^*$ the distinguished cleavage of $\mathsf{C}(\mathscr{A})$, whose associated pseudo-functor is $\mathscr{A}(-)$ (see (3.2.4)). To define a unit for our adjunction, we need to exhibit a natural split cartesian functor :

$$(\varphi, \boldsymbol{\lambda}) \to (\mathsf{C}(\mathscr{A}), \boldsymbol{\lambda}^*).$$

Now, for every $B \in \mathrm{Ob}(\mathscr{B})$ any $A \in \mathrm{Ob}(\mathscr{A}_B)$ define $\beta^{\boldsymbol{\lambda}}_{B,A} \in \mathscr{A}(B)$ as in the proof of claim 3.2.8; by virtue of remark 3.2.6, for every morphism $f : A' \to A$ in $\mathscr{A}_B$ there exists a unique natural $\mathscr{C}$-transformation $\beta^{\boldsymbol{\lambda}}_{B,f} : \beta^{\boldsymbol{\lambda}}_{B,A'} \Rightarrow \beta^{\boldsymbol{\lambda}}_{B,A}$ such that $(\beta^{\boldsymbol{\lambda}}_{B,f})_{\mathbf{1}_B} = f$, and the rules $A \mapsto \beta^{\boldsymbol{\lambda}}_{B,A}$, $f \mapsto \beta^{\boldsymbol{\lambda}}_{B,f}$ yield a well defined functor

$$\beta^{\boldsymbol{\lambda}}_B : \mathscr{A}_B \to \mathscr{A}(B).$$

According to theorem 3.1.24, it then suffices to show that the rule : $B \mapsto \beta^{\boldsymbol{\lambda}}_B$ defines a strict pseudo-natural transformation

$$\beta^{\boldsymbol{\lambda}} : \mathsf{c} \Rightarrow \mathscr{A}(-).$$

The assertion amounts to checking the identities

$$\beta^{\boldsymbol{\lambda}}_{B,A} \circ g_* = \beta^{\boldsymbol{\lambda}}_{B',\mathsf{c}_g A} \qquad \text{for every } (B' \xrightarrow{g} B) \in \mathrm{Ob}(\mathscr{B}/B) \text{ and every } A \in \mathrm{Ob}(\mathscr{A}_B).$$

However, we have :

$$\beta^{\boldsymbol{\lambda}}_{B',\mathsf{c}_g A}(g') = \mathsf{c}_{g'}(\mathsf{c}_g A) = \mathsf{c}_{g\circ g'} A = \beta^{\boldsymbol{\lambda}}_{B,A}(g \circ g') \qquad \text{for every object } g' : B'' \to B' \text{ of } \mathscr{B}/B'$$

which shows that $\beta^{\boldsymbol{\lambda}}_{B,A} \circ g_*$ and $\beta^{\boldsymbol{\lambda}}_{B',\mathsf{c}_g A}$ agree on objects; to see that they also agree on morphisms, we consider two objects $f : C \to B'$ and $f' : C' \to B'$ of $\mathscr{B}/B'$ and a morphism $h/B' : f \to f'$ of $\mathscr{B}/B'$ (notation as in the proof of claim 3.2.8), and we notice that, due to remark 3.2.2(i), the three subdiagrams of the following diagram commute

$$\begin{array}{ccccc} \mathsf{c}_{gf}A & & \xrightarrow{\quad\beta^{\boldsymbol{\lambda}}_{B',\mathsf{c}_gA}(h/B')\quad} & & \mathsf{c}_{gf'}A \\ & \searrow^{\boldsymbol{\lambda}(\mathsf{c}_gA,f)} & & {}^{\boldsymbol{\lambda}(\mathsf{c}_gA,f')}\swarrow & \\ & & \mathsf{c}_gA & & \\ & & \downarrow{\scriptstyle \boldsymbol{\lambda}(A,g)} & & \\ & {\scriptstyle\boldsymbol{\lambda}(A,gf)}\searrow & A & \swarrow{\scriptstyle\boldsymbol{\lambda}(A,gf')} & \end{array}$$

The assertion is an immediate consequence. We need to verify that the rule $(\varphi,\boldsymbol{\lambda}) \mapsto \beta^{\boldsymbol{\lambda}}$ yields a strict pseudo-natural transformation

$$\beta^{\bullet} : \mathbf{1}_{\mathsf{Split}(\mathscr{B})} \Rightarrow \mathsf{C} \circ \mathsf{F}.$$

To this aim, let $G : (\varphi : \mathscr{A} \to \mathscr{B}, \boldsymbol{\lambda}) \to (\varphi' : \mathscr{A}' \to \mathscr{B}, \boldsymbol{\lambda}')$ be any split $\mathscr{B}$-cartesian functor, and let c and c' be the pseudo-functors associated with $\boldsymbol{\lambda}$ and respectively $\boldsymbol{\lambda}'$; we come down to showing the commutativity of the diagram

$$\begin{array}{ccc} \mathscr{A}_B & \xrightarrow{\beta^{\boldsymbol{\lambda}}_B} & \mathscr{A}(B) \\ {\scriptstyle G_B}\downarrow & & \downarrow{\scriptstyle \mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/B,G)} \\ \mathscr{A}'_B & \xrightarrow{\beta^{\boldsymbol{\lambda}'}_B} & \mathscr{A}'(B) \end{array} \qquad \text{for every } B \in \mathrm{Ob}(\mathscr{B}).$$

However, the composition $\mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/B, G) \circ \beta^{\boldsymbol{\lambda}}_B$ assigns to every $A \in \mathrm{Ob}(\mathscr{A}_B)$ the cartesian section $\mathscr{B}/B \to \mathscr{A}'$ given by the rule : $(B' \xrightarrow{g} B) \mapsto G(\mathsf{c}_gA)$, whereas $\beta^{\boldsymbol{\lambda}'}_B \circ G$ assigns to the same object the cartesian section given by the rule : $(B' \xrightarrow{g} B) \mapsto \mathsf{c}'_g(GA)$; moreover, if $B'' \xrightarrow{g'} B$ is any other object of $\mathscr{B}/B$ and $h/B : g \to g'$ is any morphism, we get two commutative diagrams :

$$\begin{array}{ccc} G(\mathsf{c}_gA) & \xrightarrow{G(\beta^{\boldsymbol{\lambda}}_{B,A}(h/B))} & G(\mathsf{c}_{g'}A) \\ & {\scriptstyle G(\boldsymbol{\lambda}(A,g))}\searrow \quad \swarrow{\scriptstyle G(\boldsymbol{\lambda}(A,g'))} & \\ & GA & \end{array} \qquad \begin{array}{ccc} \mathsf{c}'_g(GA) & \xrightarrow{\beta^{\boldsymbol{\lambda}'}_{B,GA}(h/B)} & \mathsf{c}'_{g'}(GA) \\ & {\scriptstyle \boldsymbol{\lambda}'(GA,g)}\searrow \quad \swarrow{\scriptstyle \boldsymbol{\lambda}'(GA,g')} & \\ & GA. & \end{array}$$

Since G is split, remark 3.2.2(ii) says that these two diagrams coincide, i.e. the functors $\mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/B, G) \circ \beta^{\boldsymbol{\lambda}}_B$ and $\beta^{\boldsymbol{\lambda}'}_B \circ G$ agree on all objects of $\varphi^{-1}B$. To see that they agree also on morphisms, let $f : A \to A'$ be any morphism of $\varphi^{-1}B$; we have to show that $G * \beta^{\boldsymbol{\lambda}}_{B,f} = \beta^{\boldsymbol{\lambda}'}_{B,Gf}$. By remark 3.2.6, it suffices then to compare the evaluations at $\mathbf{1}_B$ of both of these natural $\mathscr{B}$-transformation; but by definition we have $(G * \beta^{\boldsymbol{\lambda}}_{B,f})_{\mathbf{1}_B} = Gf = (\beta^{\boldsymbol{\lambda}'}_{B,Gf})_{\mathbf{1}_B}$, as required.

Lastly, let $G, G' : (\varphi : \mathscr{A} \to \mathscr{B}, \boldsymbol{\lambda}) \to (\varphi' : \mathscr{A}' \to \mathscr{B}, \boldsymbol{\lambda}')$ be two split $\mathscr{B}$-cartesian functors, and $\gamma : G \Rightarrow G'$ a natural $\mathscr{B}$-transformation; we need to show :

$$\mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/B, \gamma) * \beta^{\boldsymbol{\lambda}}_B = \beta^{\boldsymbol{\lambda}'}_B * (\gamma_{|\mathscr{A}_B}) \qquad \text{for every } B \in \mathrm{Ob}(\mathscr{B})$$

which translates as the identity : $\gamma_{\mathsf{c}_gA} = \mathsf{c}'_g(\gamma_A)$ for every $g \in \mathrm{Ob}(\mathscr{B}/B)$ and $A \in \mathrm{Ob}(\mathscr{A}_B)$. However, again by virtue of remark 3.2.2(ii), the following commutative diagrams coincide :

$$\begin{array}{ccc} G(\mathsf{c}_gA) & \xrightarrow{\gamma_{\mathsf{c}_gA}} & G'(\mathsf{c}_gA) \\ {\scriptstyle G(\boldsymbol{\lambda}(A,g))}\downarrow & & \downarrow{\scriptstyle G'(\boldsymbol{\lambda}(A,g))} \\ GA & \xrightarrow{\gamma_A} & G'A \end{array} \qquad \begin{array}{ccc} \mathsf{c}'_g(GA) & \xrightarrow{\mathsf{c}'_g(\gamma_A)} & \mathsf{c}'_g(G'A) \\ {\scriptstyle \boldsymbol{\lambda}'(GA,g)}\downarrow & & \downarrow{\scriptstyle \boldsymbol{\lambda}'(G'A,g)} \\ GA & \xrightarrow{\gamma_A} & G'A \end{array}$$

whence the contention.

It remains to show that the unit and counit thus defined fulfill the triangular identities. Now, let $\varphi : \mathscr{A} \to \mathscr{B}$ be any fibration, $(\varphi' : \mathscr{A}' \to \mathscr{B}, \boldsymbol{\lambda}')$ any split fibration, and c' the pseudo-functor associated with $\boldsymbol{\lambda}'$. Denote by $\boldsymbol{\lambda}^*$ the distinguished cleavage of $\mathsf{C}(\mathscr{A})$ as in (3.2.4), whose associated pseudo-functor is (naturally identified with) $\mathscr{A}(-)$; then, in view of theorem 3.1.24, the triangular identities come down to the commutativity of the diagrams

$$\begin{array}{ccc} \mathscr{A}(B) & \xrightarrow{\beta_B^{\boldsymbol{\lambda}^*}} & \mathsf{C}(\mathscr{A})(B) \\ & \diagdown\!\!\diagdown & \downarrow{\scriptstyle \mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/B,\mathsf{ev}^{\mathscr{A}})} \\ & & \mathscr{A}(B) \end{array} \qquad\qquad \begin{array}{ccc} \mathsf{c}'_B & \xrightarrow{\beta_B^{\boldsymbol{\lambda}'}} & \mathscr{A}'(B) \\ & \diagdown\!\!\diagdown & \downarrow{\scriptstyle \mathsf{ev}^{\mathscr{A}'}_{|B}} \\ & & \mathsf{c}'_B \end{array}$$

for every $B \in \mathrm{Ob}(\mathscr{B})$. The latter follows by a direct inspection. $\square$

Remark 3.2.9. (i) Let $\varphi : \mathscr{A} \to \mathscr{B}$ be a fibration, and c the pseudo-functor associated with a given cleavage $\boldsymbol{\lambda}$ for φ. The proof of theorem 3.2.7 furnishes a pseudo-natural equivalence

$$\mathsf{ev}^{\mathscr{A}}_{|\bullet} : \mathscr{A}(-) \Rightarrow \mathsf{c}.$$

In case $\boldsymbol{\lambda}$ is split, it also furnishes a quasi-inverse for $\mathsf{ev}^{\mathscr{A}}_{|\bullet}$ which is a *strict* pseudo-natural equivalence $\beta^{\boldsymbol{\lambda}} : \mathsf{c} \Rightarrow \mathscr{A}(-)$. However, we cannot deduce from this that the unit of the 2-adjunction of theorem 3.2.7 is an equivalence, since we cannot ensure the existence of a *strict* quasi-inverse for $\beta^{\boldsymbol{\lambda}}$. (Especially, $\mathsf{ev}^{\mathscr{A}}_{|\bullet}$ is not strict, in general.)

(ii) On the other hand, denote by $\mathsf{spFib}(\mathscr{B})$ the full 2-subcategory of $\mathsf{Fib}(\mathscr{B})$ whose objects are the fibrations that admit a split cleavage. Then claim 3.2.8 implies that the inclusion functor

$$\mathsf{spFib}(\mathscr{B}) \to \mathsf{Fib}(\mathscr{B})$$

is a 2-equivalence which admits a pseudo-inverse given by the rule : $(\varphi : \mathscr{A} \to \mathscr{B}) \mapsto \mathsf{C}(\mathscr{A})$ for every fibration φ.

3.2.10. For every pair of universes U, V with $\mathsf{U} \subset \mathsf{V}$, and every $\mathscr{C} \in \mathrm{Ob}((\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat})$, the set of connected components $\pi_0(\mathscr{C})$ is essentially U-small (see remark 1.2.21(ii)); hence, after replacing $\pi_0(\mathscr{C})$ by a U-small set of the same cardinality, we get a well defined functor

$$\pi_0 : (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat} \to \mathbf{Set}$$

that is left adjoint to the fully faithful imbedding $\mathbf{Set} \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$ which assigns to every U-small set the associated discrete category (see example 1.1.6(ii)). Moreover, π_0 is also a well defined strict pseudo-functor, for the natural 2-category structure on $(\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$ (and here we regard $\mathbf{Set}$ as a 2-category whose only 2-cells are identities : see example 2.2.4(i)).

Now, if $\mathscr{B}$ is any V-small category, and $\mathsf{c} : \mathscr{B}^o \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$ any pseudo-functor, it follows that the composition $\pi_0 \circ \mathsf{c} : \mathscr{B}^o \to \mathbf{Set}$ is a strict pseudo-functor, *i.e.* it is a presheaf on $\mathscr{B}$. Also, every pseudo-natural transformation $\omega : \mathsf{c} \Rightarrow \mathsf{d}$ of pseudo-functors $\mathsf{c}, \mathsf{d} : \mathscr{B}^o \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$ induces a morphism of presheaves $\pi_0 * \omega : \pi_0 \circ \mathsf{c} \to \pi_0 \circ \mathsf{d}$, and notice that if $\Xi : \omega \rightsquigarrow \omega'$ is any modification of such pseudo-natural transformations, then $\pi_0 * \omega = \pi_0 * \omega'$ and the induced modification $\pi_0 \circ \Xi : \pi_0 * \omega \rightsquigarrow \pi_0 * \omega$ is just the identity. In view of theorem 3.1.24, it then follows that the rule $\mathsf{c} \mapsto \pi_0 \circ \mathsf{c}$ yields a well defined strict pseudo-functor

$$\pi_0^{\mathscr{B}} : (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}) \to \mathscr{B}^\wedge_{\mathsf{U}}$$

Explicitly, for every fibration $\varphi : \mathscr{A} \to \mathscr{B}$, the presheaf $\pi_0^{\mathscr{B}}(\mathscr{A})$ is given by the rule : $X \mapsto \pi_0(\varphi^{-1}X)$ for every $X \in \mathrm{Ob}(\mathscr{B})$. It is then easily seen that $\pi_0^{\mathscr{B}}$ is a strong left 2-adjoint to the strict pseudo-functor $\mathscr{F}ib$ of (3.1.17).

Remark 3.2.11. The functor $\mathscr{F}ib$ of (3.1.17) also admits a right adjoint. Indeed, notice that $\mathscr{F}ib$ factors uniquely as the composition of a strict pseudo-functor

$$sp\mathscr{F}ib : \mathscr{B}^\wedge \to \mathsf{Split}(\mathscr{B})$$

and the forgetful strict pseudo-functor F (notation of (3.2.4)). In light of theorem 3.2.7, it then suffices to find a right adjoint for $sp\mathscr{F}ib$. Now, if $(\varphi : \mathscr{A} \to \mathscr{B}, \boldsymbol{\lambda})$ is any split fibration, and $\mathsf{c} : \mathscr{B}^o \to \mathbf{Cat}$ the associated pseudo-functor, notice that the composition

$$\mathrm{Ob} \circ \mathsf{c} : \mathscr{B}^o \to \mathbf{Cat} \to \mathbf{Set} \qquad B \mapsto \mathrm{Ob}(\mathscr{A}_B)$$

is a presheaf. It is easily seen that the resulting functor

$$\mathrm{Ob}^{\mathscr{B}} : \mathsf{Split}(\mathscr{B}) \to \mathscr{B}^o \qquad (\varphi : \mathscr{A} \to \mathscr{B}, \boldsymbol{\lambda}) \mapsto \mathrm{Ob} \circ \mathsf{c}$$

is a right adjoint for $sp\mathscr{F}ib$. However, we do not get a right 2-adjoint by this rule.

3.3. 2**-Fibrations.** We wish now to consider the generalization of (3.1.18) where $\mathscr{B}$ is an arbitrary V-small 2-category. In this case, for every pseudo-functor $\mathsf{c} : \mathscr{B}^o \to (\mathsf{U}, \mathsf{V})\text{-}\mathbf{Cat}$ we get a natural 2-category structure on $\mathscr{F}ib(\mathsf{c})$, such that the resulting functor $\pi^c : \mathscr{F}ib(\mathsf{c}) \to \mathscr{B}$ is a strict pseudo-functor. Indeed, for every two objects $(B, X), (B', Y)$ of $\mathscr{F}ib(\mathsf{c})$, and any two morphisms $(\varphi_1, f_1), (\varphi_2, f_2) : (B, X) \to (B', Y)$ of $\mathscr{F}ib(\mathsf{c})$, we declare that the 2-cells $(\varphi_1, f_1) \Rightarrow (\varphi_2, f_2)$ are the 2-cells $\alpha : \varphi_1 \Rightarrow \varphi_2$ that make commute the diagram

$$\xymatrix{ & X \ar[ld]_{f_1} \ar[rd]^{f_2} & \\ \mathsf{c}_{\varphi_1}Y \ar[rr]^{\mathsf{c}_{\alpha,Y}} & & \mathsf{c}_{\varphi_2}Y. }$$

If $(\varphi_3, f_3) : (B, X) \to (B', Y)$ is another morphism and $\beta : (\varphi_2, f_2) \Rightarrow (\varphi_3, f_3)$ another 2-cell, the composition $\beta \odot \alpha : (\varphi_1, f_1) \Rightarrow (\varphi_3, f_3)$ is given by the composition law for 2-cells of $\mathscr{B}(B, B')$. Since $\mathsf{c}_{\beta\odot\alpha,Y} = \mathsf{c}_{\beta,Y} \circ \mathsf{c}_{\alpha,Y}$, it is easily seen that this composition rule is well defined. Likewise, if (B'', Z) is any other object of $\mathscr{F}ib(\mathsf{c})$, $(\psi_1, g_1), (\psi_2, g_2) : (B', Y) \to (B'', Z)$ any two morphisms and $\alpha' : (\psi_1, g_1) \Rightarrow (\psi_2, g_2)$ any 2-cell, we let $\alpha' * \alpha : (\psi_1, g_1) \circ (\varphi_1, f_1) \Rightarrow (\psi_2, g_2) \circ (\varphi_2, f_2)$ be defined by the corresponding composition law for 2-cells in $\mathscr{B}$. In order to check that this rule is well defined, it suffices to show the commutativity of the diagram :

$$\xymatrix{ X \ar[r]^{f_1} \ar[rd]_{f_2} & \mathsf{c}_{\varphi_1}Y \ar[r]^{\mathsf{c}_{\varphi_1}(g_1)} \ar[d]^{\mathsf{c}_{\alpha,Y}} & \mathsf{c}_{\varphi_1}\mathsf{c}_{\psi_1}Z \ar[r]^{\gamma^{\mathsf{c}}_{(\varphi_1,\psi_1),Z}} \ar[d]^{\mathsf{c}_{\alpha,\mathsf{c}_{\psi_1}Z}} & \mathsf{c}_{\psi_1\circ\varphi_1}Z \ar[dd]^{\mathsf{c}_{\alpha'*\alpha,Z}} \\ & \mathsf{c}_{\varphi_2}Y \ar[r]^{\mathsf{c}_{\varphi_2}(g_1)} \ar[rd]_{\mathsf{c}_{\varphi_2}(g_2)} & \mathsf{c}_{\varphi_2}\mathsf{c}_{\psi_1}Z \ar[d]^{\mathsf{c}_{\varphi_2}(\mathsf{c}_{\alpha',Z})} & \\ & & \mathsf{c}_{\varphi_2}\mathsf{c}_{\psi_2}Z \ar[r]_{\gamma^{\mathsf{c}}_{(\varphi_2,\psi_2),Z}} & \mathsf{c}_{\psi_2\circ\varphi_2}Z }$$

(where γ^{c} is the coherence constraint of c); the latter follows directly from remark 2.1.17(ii) and the identity : $\mathsf{c}_{\varphi_2}(\mathsf{c}_{\alpha',Z}) \circ \mathsf{c}_{\alpha,\mathsf{c}_{\psi_1}Z} = (\mathsf{c}_{\alpha'} * \mathsf{c}_\alpha)_Z$. It is then obvious that $\mathscr{F}ib(\mathsf{c})$ is a 2-category with these composition laws (and with the composition law for 1-cells given by (3.1.18)), since the required associativity and unit axioms hold already in $\mathscr{B}$.

In analogy with the case of usual categories, it is natural to make the following :

Definition 3.3.1. Let $\mathscr{A}$, $\mathscr{B}$ be two V-small 2-categories, $\pi : \mathscr{A} \to \mathscr{B}$ a strict pseudo-functor.

(i) We say that a 1-cell $f : A' \to A$ of $\mathscr{A}$ is *$\mathscr{B}$-cartesian* if for every $X \in \mathrm{Ob}(\mathscr{A})$ the following diagram is cartesian in the category $\mathsf{V}\text{-}\mathbf{Cat}$:

$$\begin{array}{ccc} \mathscr{A}(X, A') & \xrightarrow{f_*} & \mathscr{A}(X, A) \\ \downarrow{\scriptstyle \pi} & & \downarrow{\scriptstyle \pi} \\ \mathscr{B}(\pi X, \pi A') & \xrightarrow{(\pi f)_*} & \mathscr{B}(\pi X, \pi A). \end{array}$$

(ii) We say that π (or $\mathscr{A}$) is a 2-fibration over $\mathscr{B}$, if for every 1-cell $\varphi : B' \to B$ in $\mathscr{B}$ and every $A \in \pi^{-1}B$ there exists a $\mathscr{B}$-cartesian 1-cell $f : A' \to A$ in $\mathscr{A}$ such that $\pi(f) = \varphi$.

(iii) For every $B \in \mathrm{Ob}(\mathscr{B})$, the *fibre* $\pi^{-1}B$ is the 2-subcategory of $\mathscr{A}$ whose underlying category is the fibre over B of the functor underlying π, and whose 2-cells are the 2-cells α of $\mathscr{A}$ such that $\pi(\alpha) = i_B$. We say that π *has essentially* U*-small fibres* if $\pi^{-1}B$ is an essentially U-small 2-category for every $B \in \mathrm{Ob}(\mathscr{B})$.

Remark 3.3.2. (i) With the notation of definition 3.3.1, notice that a $\mathscr{B}$-cartesian 1-cell of $\mathscr{A}$ is also a cartesian morphism of the underlying category, since the forgetful functor $\mathsf{V}\text{-}\mathbf{Cat} \to \mathsf{V}\text{-}\mathbf{Set}$ commutes with fibre products.

(ii) It is easily seen that a composition of cartesian 1-cells is cartesian, and every invertible 1-cell is cartesian (details left to the reader).

(iii) It follows from (i) that if π is a 2-fibration, then it is also a (usual) fibration on the underlying categories. Moreover, in this case a 1-cell of $\mathscr{A}$ is cartesian if and only if it is a cartesian morphism of the underlying category : indeed, the necessity has already been remarked in (i). Conversely, let $f : A' \to A$ be a 1-cell which is a cartesian morphism in the underlying category, and pick any 1-cell $g : A'' \to A$ of $\mathscr{A}$ which is cartesian in the sense of definition 3.3.1(i), and with $\pi(g) = \pi(f)$; then there exists an isomorphism $h : A' \xrightarrow{\sim} A''$ in the underlying category of $\mathscr{A}$ such that $f = g \circ h$. By (ii), we deduce that f is a cartesian 1-cell.

(iv) Notice that our definition of 2-fibrations (which follows [81, pp.35–36]) does not include any condition on the existence of cartesian liftings of 2-cells of $\mathscr{B}$. This is somewhat inadequate, and thus our definition should be regarded as provisional. A much more comprehensive treatment of 2-fibrations (including the relevant condition of cartesian liftings of 2-cells) can be found in the paper [44].

Lemma 3.3.3. *Let $\mathscr{B}$ be a 2-category, and $\mathsf{c} : \mathscr{B}^o \to (\mathsf{U}, \mathsf{V})\text{-}\mathbf{Cat}$ a pseudo-functor. We have :*

(i) *The 2-category $\mathscr{F}ib(\mathsf{c})$ is a 2-fibration over $\mathscr{B}$.*

(ii) *A 1-cell $(\varphi, f) : (B', X) \to (B, Y)$ of $\mathscr{F}ib(\mathsf{c})$ is cartesian if and only if $f : X \to \mathsf{c}_\varphi Y$ is an isomorphism in $\mathsf{c}_{B'}$.*

Proof. It suffices to prove (ii). Now, notice that the condition of (ii) is necessary, due to lemma 3.1.20(i). Conversely, let (φ, f) be such a 1-cell with f an isomorphism; consider any object (B'', Z) of $\mathscr{F}ib(\mathsf{c})$, any two 1-cells $\psi_1, \psi_2 : B'' \to B'$ in $\mathscr{B}$, a 2-cell $\alpha : \psi_1 \Rightarrow \psi_2$ in $\mathscr{B}$, and any 2-cell $\beta : (\varphi \circ \psi_1, g_1) \Rightarrow (\varphi \circ \psi_2, g_2)$ in $\mathscr{F}ib(\mathsf{c})$ such that $\beta = \varphi_* * \alpha$. We know already by lemma 3.1.20(i) that for $i = 1, 2$ there exists a unique 1-cell $(\psi_i, g'_i) : (B'', Z) \to (B', X)$ of $\mathscr{F}ib(\mathsf{c})$ such that $(\varphi, f) \circ (\psi_i, g'_i) = (\varphi \circ \psi_i, g_i)$, and it remains to check that α yields a 2-cell $(\psi_1, g'_1) \Rightarrow (\psi_2, g'_2)$. To this aim, we consider the diagram :

$$\begin{array}{ccccccc} Z & \xrightarrow{g'_1} & \mathsf{c}_{\psi_1} X & \xrightarrow{\mathsf{c}_{\psi_1}(f)} & \mathsf{c}_{\psi_1}\mathsf{c}_\varphi Y & \xrightarrow{\gamma^{\mathsf{c}}_{(\psi_1,\varphi),Y}} & \mathsf{c}_{\varphi\circ\psi_1} Y \\ & \searrow^{g'_2} & \downarrow{\scriptstyle \mathsf{c}_{\alpha,X}} & & \downarrow{\scriptstyle \mathsf{c}_{\alpha,\mathsf{c}_\varphi Y}} & & \downarrow{\scriptstyle \mathsf{c}_{\varphi*\alpha,Y}} \\ & & \mathsf{c}_{\psi_2} X & \xrightarrow{\mathsf{c}_{\psi_2}(f)} & \mathsf{c}_{\psi_2}\mathsf{c}_\varphi Y & \xrightarrow{\gamma^{\mathsf{c}}_{(\psi_2,\varphi),Y}} & \mathsf{c}_{\varphi\circ\psi_2} Y \end{array}$$

(where γ^{c} is the coherence constraint of c). By assumption, the subdiagram obtained after removing the two middle vertical arrows commutes, and we need to check that the triangular subdiagram on the left commutes as well. However, the square subdiagram on the right commutes by remark 2.1.17(ii), and the central square subdiagram commutes by naturality oc c_α. Moreover, since f is an isomorphism, the two bottom horizontal arrows are both isomorphisms. The contention follows straightforwardly. □

Example 3.3.4. Let $\mathscr{B}$ be any 2-category.

(i) Denote by $\mathbb{1}$ a chosen final object of $\mathbf{Cat}$, *i.e.* a category with only one object and one morphism, and consider the constant pseudo-functor $\mathsf{F}_{\mathbb{1}} : \mathscr{B}^o \to \mathbf{Cat}$ with value $\mathbb{1}$ (notation of (2.5)). It is easily seen that the induced projection :

$$\mathscr{F}ib(\mathsf{F}_{\mathbb{1}}) \to \mathscr{B}$$

is an isomorphism of 2-categories.

(ii) If $\mathscr{B}$ has small Hom-categories, fix $B \in \mathscr{B}$ and consider the strict pseudo-functor

$$h_B : \mathscr{B}^o \to \mathbf{Cat} \qquad B' \mapsto \mathscr{B}(B', B)$$

that assigns to every 1-cell $f : B' \to B''$ the functor $f^* : \mathscr{B}(B'', B) \to \mathscr{B}(B', B)$, and to every 2-cell $\beta : f \Rightarrow f'$ between 1-cells $f, f' : B' \to B''$ the natural transformation $\beta^* : f^* \Rightarrow f'^*$ (see example 2.2.8(i)). Then we have a natural isomorphism of 2-categories

$$\mathscr{F}ib(h_B) \xrightarrow{\sim} \mathscr{B}/B$$

(notation of example 2.1.11(ii)) which identifies the natural projection $\mathscr{F}ib(h_B) \to \mathscr{B}$ with the source strict pseudo-functor $\mathsf{s}_B : \mathscr{B}/B \to \mathscr{B}$.

3.3.5. For any pair of 2-fibrations $\mathscr{A}, \mathscr{A}'$ over $\mathscr{B}$ we denote by

$$2\text{-}\mathsf{Cart}_{\mathscr{B}}(\mathscr{A}, \mathscr{A}')$$

the category whose objects are the *$\mathscr{B}$-cartesian strict pseudo-functors*, *i.e.* the strict pseudo-functors $\mathscr{A} \to \mathscr{A}'$ that are $\mathscr{B}$-cartesian functors on the underlying categories; the morphisms are the strict pseudo-natural transformations that are natural $\mathscr{B}$-transformations on the underlying categories. Notice that $2\text{-}\mathsf{Cart}_{\mathscr{B}}(\mathscr{A}, \mathscr{F}ib(\mathsf{c}))$ is a full subcategory of $\mathsf{Cart}_{\mathscr{B}}(\mathscr{A}, \mathscr{F}ib(\mathsf{c}))$, for every pseudo-functor $\mathsf{c} : \mathscr{B}^o \to \mathbf{Cat}$ and every 2-fibration $\mathscr{A}$.

Just as in definition 3.1.4(ii), every pair of $\mathscr{B}$-cartesian strict pseudo-functors $H : \mathscr{C} \to \mathscr{A}$ and $K : \mathscr{A}' \to \mathscr{C}'$ induces a functor

$$2\text{-}\mathsf{Cart}_{\mathscr{B}}(H, K) : 2\text{-}\mathsf{Cart}_{\mathscr{B}}(\mathscr{A}, \mathscr{A}') \to 2\text{-}\mathsf{Cart}_{\mathscr{B}}(\mathscr{C}, \mathscr{C}') \qquad G \mapsto K \circ G \circ H$$

which assigns to any morphism $\alpha : G \Rightarrow G'$ in $2\text{-}\mathsf{Cart}_{\mathscr{B}}(\mathscr{A}, \mathscr{A}')$, the natural transformation $K * \alpha * H : K \circ G \circ H \Rightarrow K \circ G' \circ H$. As usual, in case $H = \mathbf{1}_{\mathscr{A}}$ (resp. $K = \mathbf{1}_{\mathscr{A}'}$) we also denote this functor by $2\text{-}\mathsf{Cart}_{\mathscr{B}}(\mathscr{A}, K)$ (resp. by $2\text{-}\mathsf{Cart}_{\mathscr{B}}(H, \mathscr{A}')$).

Likewise, if $H, H' : \mathscr{C} \to \mathscr{A}$ and $K, K' : \mathscr{A}' \to \mathscr{C}'$ are four $\mathscr{B}$-cartesian strict pseudo-functors, every pair of strict pseudo-natural $\mathscr{B}$-transformations $\beta : H \Rightarrow H'$ and $\gamma : K \Rightarrow K'$ induces a natural transformation :

$$2\text{-}\mathsf{Cart}_{\mathscr{B}}(\beta, \gamma) : 2\text{-}\mathsf{Cart}_{\mathscr{B}}(H, K) \Rightarrow 2\text{-}\mathsf{Cart}_{\mathscr{B}}(H', K') \qquad G \mapsto \gamma * G * \beta$$

and again, if $\beta = \mathbf{1}_H$ (resp. $\gamma = \mathbf{1}_K$) we denote this natural transformation by $2\text{-}\mathsf{Cart}_{\mathscr{B}}(H, \gamma)$ (resp. $2\text{-}\mathsf{Cart}_{\mathscr{B}}(\alpha, K)$).

3.3.6. In the situation of (3.3), let $\mathsf{d} : \mathscr{B}^o \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$ be another pseudo-functor, and $\omega : \mathsf{c} \Rightarrow \mathsf{d}$ any pseudo-natural transformation. We claim that the functor $\mathscr{F}ib(\omega) : \mathscr{F}ib(\mathsf{c}) \to \mathscr{F}ib(\mathsf{d})$ defined as in (3.1.19) is a $\mathscr{B}$-cartesian strict pseudo-functor. The assertion amounts to saying that any 2-cell $\alpha : (\varphi_1, f_1) \Rightarrow (\varphi_2, f_2)$ as in (3.3) induces a 2-cell

$$\alpha : \mathscr{F}ib(\omega)(\varphi_1, f_1) \Rightarrow \mathscr{F}ib(\omega)(\varphi_2, f_2).$$

In turn, the latter boils down to the commutativity of the diagram :

$$\begin{array}{ccccc}
\omega_B \circ \mathsf{c}_{\varphi_1} Y & \xleftarrow{\omega_B f_1} & \omega_B X & \xrightarrow{\omega_B f_2} & \omega_B \circ \mathsf{c}_{\varphi_2} Y \\
\downarrow{\scriptstyle (\tau^\omega_{\varphi_1,Y})^{-1}} & & & & \downarrow{\scriptstyle (\tau^\omega_{\varphi_2,Y})^{-1}} \\
\mathsf{d}_{\varphi_1} \circ \omega_{B'} Y & & \xrightarrow{\quad \mathsf{d}_{\alpha,\omega_{B'}Y} \quad} & & \mathsf{d}_{\varphi_2} \circ \omega_{B'} Y.
\end{array}$$

However, since α is a 2-cell in $\mathscr{F}ib(\mathsf{c})$, we have the identity :

$$\omega_B f_2 = \omega_B(\mathsf{c}_{\alpha,Y}) \circ \omega_B f_1$$

and on the other hand, by remark 2.2.5(i), the naturality of τ^ω implies the identity

$$(\tau^\omega_{\varphi_2,Y})^{-1} \circ \omega_B(\mathsf{c}_{\alpha,Y}) = \mathsf{d}_{\alpha,\omega_{B'}Y} \circ (\tau^\omega_{\varphi_1,Y})^{-1}$$

whence the assertion. Lastly, for any two pseudo-natural transformations $\omega, \omega' : \mathsf{c} \Rightarrow \mathsf{d}$ and every modification $\Xi : \omega \rightsquigarrow \omega'$, a simple inspection shows that the natural transformation $\mathscr{F}ib(\Xi) : \mathscr{F}ib(\omega) \Rightarrow \mathscr{F}ib(\omega')$ of (3.1.21) is also a strict pseudo-natural transformation.

Lemma 3.3.7. (i) *For every two pseudo-functors* $\mathsf{c}, \mathsf{d} : \mathscr{B}^o \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$*, the induced functor:*

$$\mathscr{F}ib : \mathsf{PsNat}(\mathsf{c}, \mathsf{d}) \to 2\text{-}\mathsf{Cart}_{\mathscr{B}^o}(\mathscr{F}ib(\mathsf{c}), \mathscr{F}ib(\mathsf{d}))$$

is an isomorphism of categories.

(ii) (2-Yoneda's Lemma) *For every pseudo-functor* $\mathsf{c} : \mathscr{B}^o \to (\mathsf{U},\mathsf{V})\mathbf{Cat}$ *and every* $X \in \mathrm{Ob}(\mathscr{B})$*, we have an equivalence of categories pseudo-natural in both arguments :*

$$\mathsf{PsNat}(h_X, \mathsf{c}) \xrightarrow{\sim} \mathsf{c}_X.$$

Proof. (i): Notice that a $\mathscr{B}$-cartesian strict pseudo-functor $\mathscr{F}ib(\mathsf{c}) \to \mathscr{F}ib(\mathsf{d})$ is completely determined by its underlying cartesian functor of (usual) $\mathscr{B}$-fibrations. Then the assertion is already known from the proof of theorem 3.1.24.

(ii) follows from (i), example 3.3.4(ii) and claim 3.2.8. □

3.3.8. Clearly the 2-fibrations with V-small and essentially U-small fibres over a given V-small 2-category $\mathscr{B}$ form a 2-category

$$(\mathsf{U},\mathsf{V})\text{-}2\text{-}\mathsf{Fib}(\mathscr{B})$$

whose Hom-categories are given by the categories $2\text{-}\mathsf{Cart}_{\mathscr{B}}(-,-)$ as in (3.3.5). As usual, this 2-category shall be often just denoted $2\text{-}\mathsf{Fib}(\mathscr{B})$. We have a strict and strongly faithful pseudo-functor

$$\mathscr{F}ib_{\mathscr{B}} : \mathsf{PsFun}(\mathscr{B}^o, \mathbf{Cat}) \to 2\text{-}\mathsf{Fib}(\mathscr{B}) \qquad F \mapsto \mathscr{F}ib(F)$$

but unlike for usual fibrations, $\mathscr{F}ib_{\mathscr{B}}$ is not a 2-equivalence. As an application of these constructions, we deduce :

Theorem 3.3.9. *The* 2*-category* $(\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$ *is strongly* 2*-complete and strongly* 2*-cocomplete.*

Proof. Let $F : \mathscr{B} \to (\mathsf{U},\mathsf{V})\mathbf{Cat}$ be any pseudo-functor from a U-small 2-category $\mathscr{B}$; we set :

$$\mathscr{L}_F := 2\text{-}\mathsf{Cart}_{\mathscr{B}^o}(\mathscr{B}^o, \mathscr{F}ib(F))$$

and we define a pseudo-cone $\pi : \mathsf{F}_{\mathscr{L}_F} \Rightarrow F$ as follows. First, in light of lemma 3.3.7(i) and example 3.3.4, we have a natural isomorphism of categories

$$\omega : \mathscr{L}_F \xrightarrow{\sim} \mathsf{PsNat}(\mathsf{F}_{\mathbf{1}}, F)$$

where $\mathsf{F}_{\mathbf{1}} : \mathscr{B} \to \mathbf{Cat}$ is the constant pseudo-functor with value $\mathbf{1}$. Now, let $\beta : \mathsf{F}_{\mathbf{1}} \Rightarrow F$ be any pseudo-cone; for every $B \in \mathrm{Ob}(\mathscr{B})$ we have then the functor $\beta_B : \mathbf{1} \to FB$, which is identified with the object $\beta_B(\varnothing) \in \mathrm{Ob}(FB)$, under the isomorphism of categories :

$$\mathsf{Fun}(\mathbf{1}, FB) \xrightarrow{\sim} FB \qquad G \mapsto G(\varnothing) \qquad (\alpha : G \Rightarrow G') \mapsto \alpha_\varnothing : G(\varnothing) \to G'(\varnothing)$$

(here $\mathrm{Ob}(\mathbf{1}) = \{\varnothing\}$). Clearly, the rule $\beta \mapsto \beta_B$ yields a functor

$$\pi_B : \mathsf{PsNat}(\mathsf{F}_{\mathbf{1}}, F) \to FB$$

that assigns to every modification $\Xi : \beta \rightsquigarrow \beta'$ the natural transformation $\Xi_B : \beta_B \Rightarrow \beta'_B$, identified with the morphism $\Xi_{B,\varnothing} : \beta_B(\varnothing) \to \beta'_B(\varnothing)$ in FB. Lastly, it is easily seen that the rule $B \mapsto \pi_B \circ \omega$ yields a pseudo-cone as sought, with coherence constraint

$$\tau^\pi_f : Ff \circ \pi_B \Rightarrow \pi_{B'} \qquad \text{such that} \qquad \tau^\pi_{f,\beta} := \tau^\beta_{f,\varnothing}$$

for every pseudo-cone $\beta : \mathsf{F}_{\mathbf{1}} \to F$ with coherence constraint τ^β.

Explicitly, for every $B \in \mathrm{Ob}(\mathscr{B})$ the functor $\pi_B : \mathscr{L}_F \to FB$ is determined by the identity :

$$\varphi(B) = (B, \pi_B(\varphi)) \qquad \text{for every cartesian strict pseudo-functor } \varphi : \mathscr{B}^o \to \mathscr{F}ib(F)$$

and for every pair of cartesian strict pseudo-functors $\varphi, \varphi' : \mathscr{B}^o \to \mathscr{F}ib(F)$ and every strict pseudo-natural $\mathscr{B}^o$-transformation $\beta : \varphi \Rightarrow \varphi'$, we have $\beta_B = (\mathbf{1}_B, \pi_B(\beta))$.

We claim that $(\mathscr{L}_F, \pi)$ is a strong 2-limit of F, *i.e.* for every small category $\mathscr{C}$, the functor

$$\text{(3.3.10)} \qquad \mathsf{Fun}(\mathscr{C}, \mathscr{L}_F) \to \mathsf{PsNat}(\mathsf{F}_\mathscr{C}, F) \qquad (\varphi : \mathscr{C} \to \mathscr{L}_F) \mapsto \pi \odot \mathsf{F}_\varphi$$

is an isomorphism of categories (see definition 2.5.1(i)). Indeed, let $\alpha : \mathsf{F}_\mathscr{C} \Rightarrow F$ be any pseudo-cone with vertex $\mathscr{C}$ and basis F; there follows a $\mathscr{B}^o$-cartesian strict pseudo-functor $\mathscr{F}ib(\alpha) : \mathscr{F}ib(\mathsf{F}_\mathscr{C}) \to \mathscr{F}ib(F)$, whence a functor

$$\alpha^\dagger := 2\text{-}\mathsf{Cart}_{\mathscr{B}^o}(\mathscr{B}^o, \mathscr{F}ib(\alpha)) : 2\text{-}\mathsf{Cart}_{\mathscr{B}^o}(\mathscr{B}^o, \mathscr{F}ib(\mathsf{F}_\mathscr{C})) \to \mathscr{L}_F.$$

If $\Theta : \alpha \rightsquigarrow \beta$ is any modification, we set as well $\Theta^\dagger := 2\text{-}\mathsf{Cart}_{\mathscr{B}^o}(\mathscr{B}^o, \mathscr{F}ib(\Theta)) : \alpha^\dagger \to \beta^\dagger$. However, a simple inspection shows that $\mathscr{F}ib(\mathsf{F}_\mathscr{C}) = \mathscr{B}^o \times \mathscr{C}$, the product in the category of 2-categories (where $\mathscr{C}$ is regarded as a 2-category with trivial 2-cells), fibred over $\mathscr{B}^o$ via the natural projection $p : \mathscr{B}^o \times \mathscr{C} \to \mathscr{B}^o$. There is an obvious functor

$$c^\mathscr{C} : \mathscr{C} \to 2\text{-}\mathsf{Cart}_{\mathscr{B}^o}(\mathscr{B}^o, \mathscr{F}ib(\mathsf{F}_\mathscr{C})) \qquad X \mapsto c_X$$

that assigns to every object X of $\mathscr{C}$ the constant functor $c_X : \mathscr{B}^o \to \mathscr{C}$ with value X, naturally identified with a section $\mathscr{B}^o \to \mathscr{B}^o \times \mathscr{C}$ of the projection p. Then, a simple inspection shows that the functor

$$\mathsf{PsNat}(\mathsf{F}_\mathscr{C}, F) \to \mathsf{Fun}(\mathscr{C}, \mathscr{L}_F) \qquad \alpha \mapsto \alpha^\dagger \circ c^\mathscr{C} \qquad \Theta \mapsto \Theta^\dagger * c^\mathscr{C}$$

is inverse to the functor (3.3.10), whence the contention.

Next we consider the category $\overline{\mathscr{F}ib}(F)$ such that $\mathrm{Ob}(\overline{\mathscr{F}ib}(F)) := \mathrm{Ob}(\mathscr{F}ib(F))$ and

$$\mathrm{Hom}_{\overline{\mathscr{F}ib}(F)}(X, X') := \pi_0(\mathscr{F}ib(F)(X, X')) \qquad \text{for every } X, X' \in \mathrm{Ob}(\mathscr{F}ib(F))$$

(notation of (3.2.10)). The composition law for morphisms in $\overline{\mathscr{F}ib}(F)$ is induced in the obvious way by that of 1-cells of $\mathscr{F}ib(F)$. For every 1-cell f of $\mathscr{F}ib(F)$ we denote by $[f]$ the class of f in $\mathrm{Morph}(\overline{\mathscr{F}ib}(F))$ and we let $\Sigma := \{[f] \in \mathrm{Morph}(\overline{\mathscr{F}ib}(F)) \mid f \text{ is } \mathscr{B}\text{-cartesian}\}$. We set

$$\mathscr{L}'_F := \overline{\mathscr{F}ib}(F))[\Sigma^{-1}]$$

(notation of theorem 1.6.9). We have a natural functor

$$\mathscr{F}ib(F) \to \mathscr{L}'_F$$

namely, the composition of the obvious projection $\mathscr{F}ib(F) \to \overline{\mathscr{F}ib}(F)$ with the localization $\overline{\mathscr{F}ib}(F) \to \mathscr{L}'_F$. Recall that $\mathscr{F}ib(F)$ carries a distinguished cleavage $\boldsymbol{\lambda}^*$, whose associated pseudo-functor is naturally identified with F (remark 3.1.27(i)). Then, the pseudo-cocone $\iota : F \to \mathsf{F}_{\mathscr{F}ib(F)}$ associated with $\boldsymbol{\lambda}^*$ induces a a pseudo-cocone $\iota' : F \Rightarrow \mathsf{F}_{\mathscr{L}'_F}$. We claim that $(\mathscr{L}'_F, \iota')$ is a strong 2-colimit of F, *i.e.* for every small category $\mathscr{C}$, the induced functor

$$\mathsf{Fun}(\mathscr{L}'_F, \mathscr{C}) \to \mathsf{PsNat}(F, \mathsf{F}_{\mathscr{C}}) \qquad (\varphi : \mathscr{L}'_F \to \mathscr{C}) \mapsto \mathsf{F}_\varphi \odot \iota' \tag{3.3.11}$$

is an isomorphism of categories. Indeed, let $\alpha : F \Rightarrow \mathsf{F}_{\mathscr{C}}$ be any pseudo-cocone; there follows a $\mathscr{B}^o$-cartesian strict pseudo-functor $\mathscr{F}ib(\alpha) : \mathscr{F}ib(F) \to \mathscr{F}ib(\mathsf{F}_{\mathscr{C}}) \stackrel{\sim}{\to} \mathscr{B}^o \times \mathscr{C}$. After composing with the projection $p : \mathscr{B}^o \times \mathscr{C} \to \mathscr{C}$ we get a functor

$$\alpha^* : \mathscr{F}ib(F) \to \mathscr{C}.$$

Since $\mathscr{C}$ has trivial 2-cells, α^* factors through a unique functor $\overline{\alpha}^* : \overline{\mathscr{F}ib}(F) \to \mathscr{C}$. By lemma 3.3.3(ii), a 1-cell $(f, g) : (B, X) \to (B', X')$ of $\mathscr{F}ib(\mathsf{F}_{\mathscr{C}})$ is cartesian if and only if $g : X \to X'$ is an isomorphism of $\mathscr{C}$. It follows that $\overline{\alpha}^*$ in turn factors uniquely through a functor

$$\alpha^\ddagger : \mathscr{L}'_F \to \mathscr{C}.$$

On the other hand, notice that a functor $\mathscr{F}ib(F) \to \mathscr{C}$ factors through $\overline{\mathscr{F}ib}(F)$ if and only if it induces a strict pseudo-functor $\mathscr{F}ib(F) \to \mathscr{B}^o \times \mathscr{C}$, and the latter is $\mathscr{B}^o$-cartesian if and only if the resulting functor $\overline{\mathscr{F}ib}(F) \to \mathscr{C}$ factors through $\mathscr{L}'_F$.

If $\Theta : \alpha \rightsquigarrow \beta$ is any modification, we get a natural $\mathscr{B}$-transformation $\Theta^* := p * \mathscr{F}ib(\Theta) : \alpha^* \Rightarrow \beta^*$, which in turn induces a natural transformation

$$\Theta^\ddagger : \alpha^\ddagger \Rightarrow \beta^\ddagger.$$

By a direct inspection, we see that the functor

$$\mathsf{PsNat}(F, \mathsf{F}_{\mathscr{C}}) \to \mathsf{Fun}(\mathscr{L}'_F, \mathscr{C}) \qquad \alpha \mapsto \alpha^\ddagger \qquad \Theta \mapsto \Theta^\ddagger$$

is inverse to (3.3.11), whence the contention. □

Example 3.3.12. (i) For instance, let $\mathscr{C}_\bullet := (\mathscr{C}_i \mid i \in I)$ be any small family of small categories. By inspecting the proof of theorem 3.3.9, we see that the 2-product of $\mathscr{C}_\bullet$ is represented by the product $\mathscr{C} := \prod_{i \in I} \mathscr{C}_i$, as constructed in example 1.2.25(i), and the universal cone for $\mathscr{C}$ is also a universal pseudo-cone for the 2-product of $\mathscr{C}_\bullet$.

(ii) Let $F : \mathscr{C} \to \mathscr{B}$ and $F' : \mathscr{C}' \to \mathscr{B}$ be two functors between small categories; by inspecting the proof of theorem 3.3.9, we see that the 2-fibre product of F and F' (remark 2.5.2(v)) is represented by the category whose objects are all data of the form $X := (c, c', \xi)$, where $c \in \mathrm{Ob}(\mathscr{C})$, $c' \in \mathrm{Ob}(\mathscr{C}')$, and $\xi : F(c) \stackrel{\sim}{\to} F'(c')$ is an isomorphism in $\mathscr{B}$. If $X' := (d, d', \zeta)$ is another such datum, the morphisms $X \to X'$ are the pairs (φ, φ'), where $\varphi : c \to d$ (resp. $\varphi' : c' \to d'$) is a morphism in $\mathscr{C}$ (resp. in $\mathscr{C}'$), and $\zeta \circ F(\varphi) = F'(\varphi') \circ \xi$.

Example 3.3.13. (i) Consider a small category $\mathscr{B}$ and a pseudo-functor $F : \mathscr{B} \to (\mathsf{U}, \mathsf{V})$-$\mathbf{Cat}$. In this case, obviously $\overline{\mathscr{F}ib}(F) = \mathscr{F}ib(F)$, so the strong 2-colimit of F is represented by $\mathscr{F}ib(F)[\Sigma^{-1}]$, where $\Sigma \subset \mathrm{Morph}(\mathscr{F}ib(F))$ is the set of cartesian morphisms.

(ii) Suppose next that $\mathscr{B}$ is *filtered*. Then we claim that Σ admits a right calculus of fractions. Indeed, it is clear that Σ satisfies conditions (CF1) and (CF2) of definition 1.6.14(i). Next, let $(\varphi, f) : (B, X) \to (B', Y)$ and $(\psi, g) : (B'', Z) \to (B', Y)$ be two morphisms of $\mathscr{F}ib(F)$, with $(\psi, g) \in \Sigma$; hence $\varphi : B' \to B$ and $\psi : B' \to B''$ are morphisms of $\mathscr{B}$, so there exist morphisms $\varphi' : B \to B'''$ and $\psi' : B'' \to B'''$ in $\mathscr{B}$ with $\varphi' \circ \varphi = \psi' \circ \psi$. It follows that $(\varphi', \mathbf{1}_{F_{\varphi'}X}) : (B''', F_{\varphi'}X) \to (B, X)$ lies in Σ, and since (ψ, g) is cartesian there exists a unique morphism $(\psi',h) : (B''',F_{\varphi'}X) \to (B'',Y)$ such that $(\psi,g)\circ(\psi',h) = (\varphi,f)\circ(\varphi',\mathbf{1}_{F_{\varphi'}X})$. This proves that condition (CF3) holds as well for Σ. Lastly, let $(\varphi,f),(\varphi',f') : (B,X) \to (B',Y)$ and $(\psi,g) : (B',Y) \to (B'',Z)$ be three morphisms of $\mathscr{F}ib(F)$, with (ψ,g) cartesian, and suppose that $(\psi,g)\circ(\varphi,f) = (\psi,g)\circ(\varphi',f')$; hence $\varphi,\varphi' : B' \to B$ are two morphisms of $\mathscr{B}$, and by assumption there exists a morphism $\mu : B \to B'''$ such that $\mu\circ\varphi = \mu\circ\varphi'$. Then we have the cartesian morphism $(\mu,\mathbf{1}_{F_\mu X}) : (B''',F_\mu X) \to (B,X)$, and obviously $(\psi,g)\circ(\varphi,f)\circ(\mu,\mathbf{1}_{F_\mu X}) = (\psi,g)\circ(\varphi',f')\circ(\mu,\mathbf{1}_{F_\mu X})$. Since (ψ,g) is cartesian, it follows that $(\varphi,f)\circ(\mu,\mathbf{1}_{F_\mu X}) = (\varphi',f')\circ(\mu,\mathbf{1}_{F_\mu X})$. This shows that condition (CF4) holds for Σ.

(iii) In particular, in the situation of (ii), the morphisms in $\mathscr{F}ib(F)[\Sigma^{-1}]$ can be expressed as fractions with denominators in Σ, as detailed by proposition 1.6.16 (and remark 1.6.19).

(iv) Let I be a small filtered category, and $F : I \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$ any functor; let $\mathscr{L}$ be the colimit of F, as explicitly given by example 1.5.10. In particular, the objects of $\mathscr{L}$ are equivalence classes $[i,X]$ of pairs $(i,X) \in \mathrm{Ob}(\mathscr{F}ib(F))$, and the morphisms $[f] : [i,X] \to [i',X']$ are equivalence classes of morphisms $f : F_\varphi X \to F_{\varphi'}X'$, for all pairs of morphism $(i \xrightarrow{\varphi} j \xleftarrow{\varphi_2} i')$ of I. By direct inspection of the construction of $\mathscr{L}$, we get a well defined functor

$$\mathscr{F}ib(F) \to \mathscr{L} \qquad (i,X) \mapsto [i,X] \qquad ((i' \to i, f) : (i,X) \to (i',X')) \mapsto [f].$$

By the universal property of the localization, this functor extends uniquely to a well defined functor $\mathscr{F}ib(F)[\Sigma^{-1}] \to \mathscr{L}$, where Σ is as in (ii), and in view of (iii) and lemma 3.1.20(i), it is easily seen that the latter functor is an equivalence. In other words, the colimit of F represents as well the 2-colimit of the same functor, and more precisely, every universal cocone $F \Rightarrow c_{\mathscr{L}}$ is also a (strict) universal pseudo-cocone.

3.3.14. Let $\mathscr{C}$ a U-small category, $\mathscr{B}$ a V-small category with U-small Hom-sets, and $\rho : \mathscr{C} \to \mathscr{B}$ a functor; theorem 3.3.9 enables us to construct both right and left 2-adjoints for the strict pseudo-functor $\mathsf{V}\text{-}\mathsf{Fib}(\rho)^*$ of remark 3.1.5(i). Indeed, combining with theorem 2.6.39 and remark 2.6.18(ii) we see first that the strong left 2-Kan extension along ρ^o is a strict left 2-adjoint L for $\mathsf{P} := \mathsf{PsFun}(\rho^o,(\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat})$. On the other hand, by remark 2.4.31, the strict and strong 2-equivalence $\mathscr{F}ib_{\mathscr{B}}$ of theorem 3.1.24 admits a strict and strong pseudo-inverse

$$\mathsf{Q}_{\mathscr{B}} : (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}) \xrightarrow{\sim} \mathsf{PsFun}(\mathscr{B}^o,(\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}).$$

It follows that the strict pseudo-functor

$$(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\rho)_! := \mathscr{F}ib_{\mathscr{B}}\circ\mathsf{L}\circ\mathsf{Q}_{\mathscr{C}} : (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{C}) \to (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B})$$

is a left 2-adjoint for $\mathscr{F}ib_{\mathscr{C}}\circ\mathsf{P}\circ\mathsf{Q}_{\mathscr{B}}$. On the other hand, remark 3.1.27(ii) yields a pseudo-natural isomorphism $\mathscr{F}ib_{\mathscr{C}}\circ\mathsf{P} \xrightarrow{\sim} (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\rho)^*\circ\mathscr{F}ib_{\mathscr{B}}$, so $(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\rho)_!$ is also left 2-adjoint to $(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\rho)^*$. Likewise, from the strong right 2-Kan extension R along ρ^o we get a strict right 2-adjoint for $(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\rho)^*$, namely the pseudo-functor

$$(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\rho)_* := \mathscr{F}ib_{\mathscr{B}}\circ\mathsf{R}\circ\mathsf{Q}_{\mathscr{C}} : (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{C}) \to (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}).$$

As usual, we will omit mentioning V, when no ambiguities are likely to arise from the omission.

Remark 3.3.15. (i) Like all 2-adjoints, the pseudo-functors $\mathsf{Fib}(\rho)_!$ and $\mathsf{Fib}(\rho)_*$ are well defined up to pseudo-natural equivalence. However, our construction yields more canonical representatives, that are well defined up to pseudo-natural *isomorphisms*, since it relies on the strong 2-Kan extensions along ρ^o. Moreover, both these 2-adjoints factor naturally through pseudo-functors

$$\mathsf{Fib}(\mathscr{C}) \to \mathsf{Split}(\mathscr{B})$$

again because this is a feature of strong 2-Kan extensions : see remark 2.6.18(ii).

(ii) In the situation of (3.3.14), we can describe more explicitly the pseudo-functor $\mathsf{Fib}(\rho)_*$ as follows. Let $\mathscr{A} \to \mathscr{C}$ be any fibration with essentially small fibres; then $\mathsf{C}(\mathsf{Fib}(\rho)_*(\mathscr{A}))$ is the fibration associated with the strict pseudo-functor $\mathsf{Fib}(\rho)_*(\mathscr{A})(-) : \mathscr{B}^o \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$, and by example 3.1.16(ii), for every $B \in \mathrm{Ob}(\mathscr{B})$ we have an equivalence of categories :

$$\mathsf{Fib}(\rho)_*(\mathscr{A})(B) \stackrel{\sim}{\to} \mathsf{Cart}_{\mathscr{C}}(\rho\mathscr{C}/B,\mathscr{A})$$

that is pseudo-natural with respect to morphisms $B' \to B$ in $\mathscr{B}$. Thus, $\mathsf{Fib}(\rho)_*(\mathscr{A})$ is naturally equivalent to the fibration associated with the strict pseudo-functor

$$\mathsf{Cart}_{\mathscr{C}}(\rho\mathscr{C}/-,\mathscr{A}) : \mathscr{B}^o \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat} \qquad B \mapsto \mathsf{Cart}_{\mathscr{C}}(\rho\mathscr{C}/B,\mathscr{A})$$

that assigns to every morphism $f : B' \to B$ of $\mathscr{B}$ the functor $\mathsf{Cart}_{\mathscr{C}}(\rho\mathscr{C}/f,\mathscr{A})$.

(iii) Moreover, we have a pseudo-commutative diagram of 2-categories :

$$\begin{array}{ccc} \mathscr{C}^\wedge & \xrightarrow{\mathscr{F}ib_{\mathscr{C}}} & \mathsf{Fib}(\mathscr{C}) \\ {\scriptstyle\rho_*}\downarrow & & \downarrow{\scriptstyle\mathsf{Fib}(\rho)_*} \\ \mathscr{B}^\wedge & \xrightarrow{\mathscr{F}ib_{\mathscr{B}}} & \mathsf{Fib}(\mathscr{B}) \end{array}$$

(see remark 2.4.10). Indeed, let $j : \mathbf{Set} \to \mathbf{Cat}$ be the inclusion functor (that assigns to every set the associated discrete category); by inspecting the constructions of $\mathsf{Fib}(\rho)_*$ and ρ_* (see remark 1.3.6(i)), we come down to exhibiting an equivalence :

$$2\text{-}\!\!\int_{\rho^o} j \circ F \stackrel{\sim}{\to} j \circ \int_{\rho^o} F \qquad\qquad \text{for every presheaf } F : \mathscr{C}^o \to \mathbf{Set}$$

pseudo-natural with respect to F. Now, for every $B \in \mathrm{Ob}(\mathscr{B})$ the category $2\text{-}\!\int_{\rho^o} j \circ F(B)$ is the 2-limit of the functor $j \circ F \circ \mathsf{t}_{B^o} : B^o/\varphi^o\mathscr{C}^o \to \mathbf{Cat}$. But since j is fully faithful and admits a left 2-adjoint (see (3.2.10)), proposition 2.5.11 says that such 2-limit is the discrete category associated with the set representing the 2-limit of $F \circ \mathsf{t}_{B^o} : B^o/\varphi^o\mathscr{C}^o \to \mathbf{Set}$. By remark 2.5.2(vii), the latter is represented by the (usual) limit of the same functor. But this in turn is none else than the definition of $\int_\varphi F(B^o)$, whence the contention.

(iv) In view of corollary 2.6.42, we also see that if ρ is a fully faithful functor, then $\mathsf{Fib}(\rho)_*$ and $\mathsf{Fib}(\rho)_!$ are both fully faithful pseudo-functors.

(v) For every other universe V' with $\mathsf{V} \subset \mathsf{V}'$, we get a diagram of pseudo-functors :

$$\begin{array}{ccc} (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{C}) & \xrightarrow{(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\rho)_!} & (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}) \\ \downarrow & & \downarrow \\ (\mathsf{U},\mathsf{V}')\text{-}\mathsf{Fib}(\mathscr{C}) & \xrightarrow{(\mathsf{U},\mathsf{V}')\text{-}\mathsf{Fib}(\rho)_!} & (\mathsf{U},\mathsf{V}')\text{-}\mathsf{Fib}(\mathscr{B}) \end{array} \qquad \begin{array}{ccc} (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{C}) & \xrightarrow{(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\rho)_*} & (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}) \\ \downarrow & & \downarrow \\ (\mathsf{U},\mathsf{V}')\text{-}\mathsf{Fib}(\mathscr{C}) & \xrightarrow{(\mathsf{U},\mathsf{V}')\text{-}\mathsf{Fib}(\rho)_*} & (\mathsf{U},\mathsf{V}')\text{-}\mathsf{Fib}(\mathscr{B}) \end{array}$$

whose vertical arrows are the inclusions. A direct inspection of the constructions easily shows that both diagrams are commutative : the details shall be left to the reader.

(vi) Let $\mathscr{C}$ and $\mathscr{C}'$ be two small categories, $u : \mathscr{C} \to \mathscr{C}'$ and $v : \mathscr{C}' \to \mathscr{C}$ two functors, such that v is left adjoint to u. In light of (1.1.32), we get for every fibration $\mathscr{A} \to \mathscr{C}'$ and every $X \in \mathrm{Ob}(\mathscr{C})$ a natural isomorphism of categories :

$$\omega_X : \mathsf{Cart}_{\mathscr{C}'}(v\mathscr{C}'/X,\mathscr{A}) \stackrel{\sim}{\to} \mathscr{A}(uX)$$

and for every morphism $f : Y \to X$ in $\mathscr{C}$, a commutative diagram of categories :

$$\begin{array}{ccc} \mathsf{Cart}_{\mathscr{C}'}(v\mathscr{C}'/X,\mathscr{A}) & \xrightarrow{\omega_X} & \mathscr{A}(uX) \\ {\scriptstyle\mathsf{Cart}_{\mathscr{C}'}(v\mathscr{C}'/f,\mathscr{A})}\downarrow & & \downarrow{\scriptstyle\mathscr{A}(uf)} \\ \mathsf{Cart}_{\mathscr{C}'}(v\mathscr{C}'/Y,\mathscr{A}) & \xrightarrow{\omega_Y} & \mathscr{A}(uY). \end{array}$$

Combining with (i) and claim 3.2.8, we deduce a natural equivalence of fibrations over $\mathscr{C}$:

$$\mathsf{Fib}(v)_*(\mathscr{A}) \stackrel{\sim}{\to} \mathsf{Fib}(u)^*(\mathscr{A})$$

and it is easily seen that the system of such equivalences amounts to a pseudo-natural equivalence of pseudo-functors :

$$\mathsf{Fib}(v)_* \stackrel{\sim}{\to} \mathsf{Fib}(u)^*.$$

3.3.16. For every small category $\mathscr{C}$ we have a natural functor

$$\mathscr{C}/- : \mathscr{C} \to \mathsf{Fib}(\mathscr{C}) \qquad X \mapsto (\mathsf{s}_X : \mathscr{C}/X \to \mathscr{C})$$

that assigns to every morphism $f : X \to Y$ of $\mathscr{C}$ the (cartesian) functor $f_* : \mathscr{C}/X \to \mathscr{C}/Y$ as in (1.1.25). The following proposition upgrades remark 1.3.6(ii) from presheaves to fibrations :

Proposition 3.3.17. *Let $u : \mathscr{C} \to \mathscr{B}$ be any functor between small categories. With the notation of* (3.3.16)*, we have a pseudo-commutative diagram of 2-categories :*

$$\begin{array}{ccc} \mathscr{C} & \xrightarrow{\ u\ } & \mathscr{B} \\ {\scriptstyle \mathscr{C}/-}\downarrow & & \downarrow{\scriptstyle \mathscr{B}/-} \\ \mathsf{Fib}(\mathscr{C}) & \xrightarrow{\mathsf{Fib}(u)_!} & \mathsf{Fib}(\mathscr{B}). \end{array}$$

Proof. Set $\mathsf{Fib}(u)_!(\mathscr{C}/-) := \mathsf{Fib}(u)_! \circ (\mathscr{C}/-) : \mathscr{C} \to \mathsf{Fib}(\mathscr{B})$ and let $\mathscr{B}/u- : \mathscr{C} \to \mathsf{Fib}(\mathscr{B})$ be the composition of u with the pseudo-funtor $\mathscr{B}/-$. To ease notation, we set :

$$F := \mathsf{Cart}_{\mathscr{B}}(\mathsf{Fib}(u)_!(\mathscr{C}/-), -) : \mathscr{C}^o \times \mathsf{Fib}(\mathscr{B}) \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$$
$$G := \mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/u-, -) : \mathscr{C}^o \times \mathsf{Fib}(\mathscr{B}) \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$$

(notation of example 2.2.7(ii)). Let ϑ be the 2-adjunction for the pair $(\mathsf{Fib}(u)_!, \mathsf{Fib}(u)^*)$; we deduce a pseudo-natural equivalence

$$\omega := \vartheta * ((\mathscr{C}/-)^o \times \mathbf{1}_{\mathsf{Fib}(\mathscr{B})}) : F \Rightarrow \mathsf{Cart}_{\mathscr{C}}(\mathscr{C}/-, \mathsf{Fib}(u)^*).$$

On the other hand, we have a strict pseudo-natural equivalence :

$$\lambda : G \Rightarrow \mathsf{Cart}_{\mathscr{C}}(\mathscr{C}/-, \mathsf{Fib}(u)^*).$$

Namely, for every $X \in \mathrm{Ob}(\mathscr{C})$ and every $\mathscr{B}$-fibration $\mathscr{A}$, the functor

$$\lambda_{X,\mathscr{A}} : \mathscr{A}(uX) \to \mathsf{Fib}(u)^*\mathscr{A}(X)$$

assigns to every cartesian section $\varphi \in \mathscr{A}(uX)$ the unique cartesian section $\varphi^* \in \mathscr{A} \times_{\mathscr{B}} \mathscr{C}(X)$ whose composition with the projection $\pi : \mathscr{A} \times_{\mathscr{B}} \mathscr{C} \to \mathscr{A}$ equals $\varphi \circ u_{|X}$. To every natural $\mathscr{B}$-transformation $\alpha : \varphi \Rightarrow \varphi'$ between such functors, $\lambda_{X,\mathscr{A}}$ assigns the unique natural $\mathscr{C}$-transformation α^* such that $\pi * \alpha^* = \alpha * u_{|X}$. We may then pick a quasi-inverse μ for λ, and consider the pseudo-natural equivalence

$$\gamma := \mu \odot \omega : F \stackrel{\sim}{\to} G.$$

For every $X \in \mathrm{Ob}(\mathscr{C})$, let $i_X : \mathsf{Fib}(\mathscr{B}) \to \mathscr{C}^o \times \mathsf{Fib}(\mathscr{B})$ be the unique strict pseudo-functor whose composition with the projection $\mathscr{C}^o \times \mathsf{Fib}(\mathscr{B}) \to \mathsf{Fib}(\mathscr{B})$ equals $\mathbf{1}_{\mathsf{Fib}(\mathscr{B})}$, and whose composition with the projection $\mathscr{C}^o \times \mathsf{Fib}(\mathscr{B}) \to \mathscr{C}^o$ is the constant pseudo-functor F_{X^o} (notation of (2.5)); we deduce the pseudo-natural equivalence

$$\gamma * i_X : \mathsf{Cart}_{\mathscr{B}}(\mathsf{Fib}(u)_!(\mathscr{C}/X), -) \stackrel{\sim}{\to} \mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/uX, -).$$

We show more generally :

Claim 3.3.18. Let $\mathscr{F}$ and $\mathscr{G}$ be two $\mathscr{B}$-fibrations, and $\beta_\bullet : \mathsf{Cart}_{\mathscr{B}}(\mathscr{F}, -) \stackrel{\sim}{\to} \mathsf{Cart}_{\mathscr{B}}(\mathscr{G}, -)$ a pseudo-natural equivalence. Then $\beta^* := \beta_{\mathscr{F}}(\mathbf{1}_{\mathscr{F}})$ is a $\mathscr{B}$-equivalence of categories $\mathscr{G} \stackrel{\sim}{\to} \mathscr{F}$.

Proof of the claim. Let $\alpha_\bullet : \mathsf{Cart}_{\mathscr{B}}(\mathscr{G},-) \to \mathsf{Cart}_{\mathscr{B}}(\mathscr{F},-)$ be a quasi-inverse of $\beta_\bullet$, and set $\alpha^* := \alpha_{\mathscr{G}}(\mathbf{1}_{\mathscr{G}}) : \mathscr{F} \to \mathscr{G}$. There follow essentially commutative diagrams :

$$\begin{array}{ccc} \mathsf{Cart}_{\mathscr{B}}(\mathscr{F},\mathscr{F}) & \xrightarrow{\mathsf{Cart}_{\mathscr{B}}(\mathscr{F},\alpha^*)} & \mathsf{Cart}_{\mathscr{B}}(\mathscr{F},\mathscr{G}) \\ {\scriptstyle\beta_{\mathscr{F}}}\downarrow & & \downarrow{\scriptstyle\beta_{\mathscr{G}}} \\ \mathsf{Cart}_{\mathscr{B}}(\mathscr{G},\mathscr{F}) & \xrightarrow{\mathsf{Cart}_{\mathscr{B}}(\mathscr{G},\alpha^*)} & \mathsf{Cart}_{\mathscr{B}}(\mathscr{G},\mathscr{G}) \end{array} \qquad \begin{array}{ccc} \mathsf{Cart}_{\mathscr{B}}(\mathscr{G},\mathscr{G}) & \xrightarrow{\mathsf{Cart}_{\mathscr{B}}(\mathscr{G},\beta^*)} & \mathsf{Cart}_{\mathscr{B}}(\mathscr{G},\mathscr{F}) \\ {\scriptstyle\alpha_{\mathscr{G}}}\downarrow & & \downarrow{\scriptstyle\alpha_{\mathscr{F}}} \\ \mathsf{Cart}_{\mathscr{B}}(\mathscr{F},\mathscr{G}) & \xrightarrow{\mathsf{Cart}_{\mathscr{B}}(\mathscr{F},\beta^*)} & \mathsf{Cart}_{\mathscr{B}}(\mathscr{F},\mathscr{F}). \end{array}$$

From the left diagram we get isomorphisms : $\alpha^* \circ \beta^* \xrightarrow{\sim} \beta_{\mathscr{G}}(\alpha^*) = \beta_{\mathscr{G}} \circ \alpha(\mathbf{1}_{\mathscr{G}}) \xrightarrow{\sim} \mathbf{1}_{\mathscr{G}}$. Likewise, from the right diagram we get an isomorphism $\beta^* \circ \alpha^* \xrightarrow{\sim} \mathbf{1}_{\mathscr{F}}$, whence the contention. ◊

To ease notation, for every $X \in \mathrm{Ob}(\mathscr{C})$ and every morphism $f : X \to Y$ of $\mathscr{C}$ set

$$[X] := \mathsf{Fib}(u)_!(\mathscr{C}/X) \qquad \text{and} \qquad [f] := \mathsf{Fib}(u)_!(f_*) : [X] \to [Y]$$

According to claim 3.3.18, for every $X \in \mathrm{Ob}(\mathscr{C})$ we get an equivalence of $\mathscr{B}$-categories :

$$\Gamma_X := \gamma_{X,[X]}(\mathbf{1}_{[X]}) : \mathscr{B}/uX \xrightarrow{\sim} [X].$$

To conclude, it remains to show that the rule : $X \mapsto \Gamma_X$ yields a pseudo-natural equivalence as sought. To this aim, we need to exhibit a coherence constraint for Γ. Now, notice that, after possibly replacing it by a pseudo-naturally isomorphic pseudo-functor, we may assume that $\mathsf{Fib}(u)_!$ is unital (proposition 2.4.3); then, for every morphism $f : X \to Y$ in $\mathscr{C}$ consider the diagram of oriented squares :

$$\begin{array}{ccc} F(Y,[Y]) & \xrightarrow{\gamma_{Y,[Y]}} & G(Y,[Y]) \\ {\scriptstyle F(f,\mathbf{1}_{[Y]})}\downarrow & \Downarrow \tau^{\gamma}_{f,\mathbf{1}_{[Y]}} & \downarrow{\scriptstyle G(f,\mathbf{1}_{[Y]})} \\ F(X,[Y]) & \xrightarrow{\gamma_{X,[Y]}} & G(X,[Y]) \\ {\scriptstyle F(\mathbf{1}_X,[f])}\uparrow & \Uparrow \tau^{\gamma}_{\mathbf{1}_X,[f]} & \uparrow{\scriptstyle G(\mathbf{1}_X,[f])} \\ F(X,[X]) & \xrightarrow[\gamma_{X,[X]}]{} & G(X,[X]). \end{array}$$

where $\tau^{\gamma}_{\bullet,\bullet}$ is the coherence constraint of γ. We deduce isomorphisms of $\mathscr{B}$-cartesian functors :

$$[f] \circ \Gamma_X \xrightarrow{(\tau^{\gamma}_{\mathbf{1}_X,[f]})_{\mathbf{1}_{[X]}}} \gamma_{X,[Y]}([f]) \xleftarrow{(\tau^{\gamma}_{f,\mathbf{1}_{[Y]}})_{\mathbf{1}_{[Y]}}} \Gamma_Y \circ (uf)_*$$

so our candidate coherence constraint is :

$$\tau^{\Gamma}_f := (\tau^{\gamma}_{f,\mathbf{1}_{[Y]}})^{-1}_{\mathbf{1}_{[Y]}} \odot (\tau^{\gamma}_{\mathbf{1}_X,[f]})_{\mathbf{1}_{[X]}} : [f] \circ \Gamma_X \xrightarrow{\sim} \Gamma_Y \circ (uf)_*.$$

With this definition, it is already clear that $\tau^{\Gamma}_{\mathbf{1}_X} = \mathbf{1}_{\Gamma_X}$ for every $X \in \mathrm{Ob}(\mathscr{C})$. Next, let $f : X \to Y$ and $g : Y \to Z$ be two morphisms of $\mathscr{C}$; we need to check that :

$$(\tau^{\Gamma}_g * (uf)_*) \odot ([g] * \tau^{\Gamma}_f) = \tau^{\Gamma}_{g\circ f} \odot (\gamma^{\mathsf{Fib}(u)_!}_{f_*,g_*} * \Gamma_X)$$

where $\gamma^{\mathsf{Fib}(u)_!}$ denotes the coherence constraint of $\mathsf{Fib}(u)_!$ But the coherence condition for τ^{γ}, relative to the composition of 1-cells $(\mathbf{1}_{X^o},[g]) \circ (f^o,\mathbf{1}_{[Y]}) = (f^o,[g]) = (f^o,\mathbf{1}_{[Z]}) \circ (\mathbf{1}_{Y^o},[g])$ yields the identities :

$$(\tau^{\gamma}_{\mathbf{1}_X,[g]})_{[f]} \odot ([g] * (\tau^{\gamma}_{f,\mathbf{1}_{[Y]}})) = (\tau^{\gamma}_{f,[g]})_{\mathbf{1}_{[Y]}} = (\tau^{\gamma}_{f,\mathbf{1}_{[Z]}})_{[g]} \odot (\tau^{\gamma}_{\mathbf{1}_Y,[g]} * (uf)_*)$$

By the same token, from the identity : $(f^o,\mathbf{1}_{[Z]}) \circ (g^o,\mathbf{1}_{[Z]}) = ((g\circ f)^o,\mathbf{1}_{[Z]})$ we get :

$$\gamma_{X,[Z]}(\gamma^{\mathsf{Fib}(u)_!}_{f_*,g_*}) \odot (\tau^{\gamma}_{f,\mathbf{1}_{[Z]}})_{[g]} \odot ((\tau^{\gamma}_{g,\mathbf{1}_{[Z]}})_{\mathbf{1}_{[Z]}} * (uf)_*) = (\tau^{\gamma}_{g\circ f,\mathbf{1}_{[Z]}})_{\mathbf{1}_{[Z]}}$$

whence :

$$(\tau^\Gamma_g * (uf)_*)\odot([g] * \tau^\Gamma_f) = ((\tau^\gamma_{g,\mathbf{1}_{[Z]}})^{-1}_{\mathbf{1}_{[Z]}} * (uf)_*)\odot(\tau^\gamma_{f,\mathbf{1}_{[Z]}})^{-1}_{[g]}\odot(\tau^\gamma_{\mathbf{1}_X,[g]})_{[f]}\odot([g]*(\tau^\gamma_{\mathbf{1}_X,[f]})_{\mathbf{1}_{[X]}})$$
$$= (\tau^\gamma_{g\circ f,\mathbf{1}_{[Z]}})^{-1}_{\mathbf{1}_{[Z]}} \odot \gamma_{X,[Z]}(\gamma^{\mathsf{Fib}(u)_!}_{f_*,g_*})\odot(\tau^\gamma_{\mathbf{1}_X,[g]})_{[f]}\odot([g]*(\tau^\gamma_{\mathbf{1}_X,[f]})_{\mathbf{1}_{[X]}}).$$

Thus, we are reduced to checking that :

$$(\tau^\gamma_{\mathbf{1}_X,[g\circ f]})_{\mathbf{1}_{[X]}} \odot (\gamma^{\mathsf{Fib}(u)_!}_{f_*,g_*} * \Gamma_X) = \gamma_{X,[Z]}(\gamma^{\mathsf{Fib}(u)_!}_{f_*,g_*}) \odot (\tau^\gamma_{\mathbf{1}_X,[g]})_{[f]} \odot ([g] * (\tau^\gamma_{\mathbf{1}_X,[f]})_{\mathbf{1}_{[X]}}).$$

But the latter follows once again from the coherence condition for τ^γ, applied to the identity : $(\mathbf{1}_X, [g]) \circ (\mathbf{1}_X, [f]) = (\mathbf{1}_X, [g \circ f])$. □

In the same vein, we point out the following :

Proposition 3.3.19. *Let $\mathscr{C}$, $\mathscr{C}'$ be two small categories, $u : \mathscr{C} \to \mathscr{C}'$ a functor, and V a universe such that $\mathscr{C}^\wedge$ and $\mathscr{C}'^\wedge$ are V-small. We have a pseudo-commutative diagram of 2-categories :*

$$\begin{array}{ccc} (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{C}'^\wedge_\mathsf{U}) & \xrightarrow{(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(u^\wedge_\mathsf{U})_!} & (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{C}^\wedge_\mathsf{U}) \\ \downarrow{\scriptstyle (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(h_{\mathscr{C}'})^*} & & \downarrow{\scriptstyle (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(h_{\mathscr{C}})^*} \\ (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{C}') & \xrightarrow{(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(u)^*} & (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{C}). \end{array}$$

Proof. Let $\mathscr{E}'$ be any fibration with V-small fibres over $\mathscr{C}'^\wedge$; pick a unital cleavage for $\mathscr{E}'$ and let c' be its associated pseudo-functor. Set $\mathscr{E} := (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(u^\wedge_\mathsf{U})_!\mathscr{E}'$; by inspecting (3.3.14) we see that for every $F \in \mathrm{Ob}(\mathscr{C}^\wedge)$ the fibre category $\mathscr{E}_F$ represents the strong 2-colimit of

$$\mathsf{c}' \circ \mathsf{t}^o_F : (F/u^\wedge\mathscr{C}'^\wedge) \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat}$$

where $\mathsf{t}_F : (F/u^\wedge\mathscr{C}'^\wedge) \to \mathscr{C}'^\wedge$ denotes the target functor. Fix a universal pseudo-cocone

$$e^F_\bullet : \mathsf{c}' \circ \mathsf{t}^o_F \Rightarrow \mathsf{F}_{\mathscr{E}_F} \qquad (F \xrightarrow{\varphi} u^\wedge G) \mapsto (\mathscr{E}'_G \xrightarrow{e^F_\varphi} \mathscr{E}_F)$$

and let $\tau^F_\bullet$ be the coherence constraint of $e^F_\bullet$. Then $\mathscr{E}$ admits a split cleavage d, that assigns to every morphism $\psi : F' \to F$ of $\mathscr{C}^\wedge$ the unique functor $\mathscr{E}_\psi : \mathscr{E}_F \to \mathscr{E}_{F'}$ such that

$$\mathsf{F}_{\mathscr{E}_\psi} \odot e^F = e^{F'} * \psi^{*o}$$

where $\psi^* : F/u^\wedge\mathscr{C}'^\wedge \to F'/u^\wedge\mathscr{C}'^\wedge$ is defined as in (1.1.25). Hence, $\mathsf{V}\text{-}\mathsf{Fib}(h_\mathscr{C})^*$ admits the split cleavage $\mathsf{d} \circ h^o_\mathscr{C}$. For every $X \in \mathrm{Ob}(\mathscr{C})$, let $\eta_X : h_X \to u^\wedge h_{uX}$ be the morphism given by the rule : $\varphi \mapsto u(\varphi) \in h_{uX}(uY)$ for every $Y \in \mathrm{Ob}(\mathscr{C})$ and every $\varphi \in h_X(Y)$. We notice :

Claim 3.3.20. For every $X \in \mathrm{Ob}(\mathscr{C})$, the morphism $\eta_\mathscr{E}$ is an initial object of $h_X/u^\wedge\mathscr{C}'^\wedge$.

Proof of the claim. Indeed, In light of remark 1.3.6(ii,iii), we may regard η_X as the unit of the natural adjunction for the adjoint pair $(u_!, u^\wedge)$. Hence, for every $G \in \mathrm{Ob}(\mathscr{C}'^\wedge)$ and every morphism of presheaves $\beta : h_X \to u^\wedge G$ there exists a unique morphism of presheaves $\beta' : h_{uX} \to G$ on $\mathscr{C}'$ such that $\beta = u^\wedge(\beta') \circ \eta_X$ (explicitly, under the canonical bijection provided by Yoneda's lemma, β corresponds to a unique section $s_\beta \in (u^\wedge G)X$, and β' corresponds then to the same s_β, regarded as an element of $G(uX)$). The claim is an immediate consequence. ◊

From claim 3.3.20 and proposition 2.5.16, we get an equivalence of categories

$$\varepsilon_X := e^{h_X}_{\eta_X} : \mathscr{E}'_{h_{uX}} \to \mathscr{E}_{h_X} \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C}).$$

Claim 3.3.21. The rule : $X \mapsto \varepsilon_X$ yields a pseudo-natural equivalence $\varepsilon : \mathsf{c}'\circ(h_{\mathscr{C}'}\circ u)^o \xrightarrow{\sim} \mathsf{d}\circ h^o_\mathscr{C}$.

Proof of the claim. For every morphism $f : Y \to X$ in $\mathscr{C}$ we have a natural isomorphism :

$$\tau^{\varepsilon}_f : \mathsf{d}_{h_f} \circ \varepsilon_X = e^{h_Y}_{\eta_X \circ h_f} = e^{h_Y}_{u^\wedge(h_{uf}) \circ \eta_Y} \xrightarrow{\tau^{h_Y}_{h_{uf}}} \varepsilon_Y \circ \mathsf{c}'_{h_{uf}}$$

and we check that the system $(\tau^{\varepsilon}_f \mid f \in \mathrm{Morph}(\mathscr{C}))$ yields a coherence constraint for ε. First, we get $\tau^{\varepsilon}_{\mathbf{1}_X} = \mathbf{1}_{\varepsilon_X}$ for every $X \in \mathrm{Ob}(\mathscr{C})$, by remark 2.4.2(ii). Next, notice that for every morphism $\psi : F' \to F$ in $\mathscr{C}^\wedge$ we have :

$\mathscr{E}_\psi * \tau^F_\mu = \tau^{F'}_\mu$ for every morphism $F'/\mu : (F' \to u^\wedge G_1) \to (F' \to u^\wedge G_2)$ in $F'/u^\wedge \mathscr{C}'^\wedge$.

Thus, let $f : X \to Y$ and $g : Y \to Z$ be two morphisms in $\mathscr{C}$; we deduce :

$$\begin{aligned}(\varepsilon_Z * \gamma^{\mathsf{c}'}_{h_{uf},h_{ug}}) \odot (\tau^{\varepsilon}_g * \mathsf{c}'_{uf}) \odot (\mathsf{d}_{h_g} * \tau^{\varepsilon}_f) &= (\varepsilon_Z * \gamma^{\mathsf{c}'}_{h_{uf},h_{ug}}) \odot (\tau^{h_Z}_{h_{ug}} * \mathsf{c}'_{uf}) \odot \tau^{h_Z}_{h_{uf}} \\ &= (\varepsilon_Z * \gamma^{\mathsf{c}'}_{h_{uf},h_{ug}}) \odot \tau^{h_Z}_{h_{u(g\circ f)}} \\ &= \tau^{\varepsilon}_{g\circ f}\end{aligned}$$

whence the contention. ◊

From claim 3.3.21 we deduce an equivalence of fibrations over $\mathscr{C}$:

$$\Omega_{\mathscr{E}'} : \mathsf{Fib}(h_{\mathscr{C}'} \circ u)^* \mathscr{E}' \xrightarrow{\sim} \mathsf{Fib}(h_{\mathscr{C}})^* \circ \mathsf{Fib}(u^\wedge_{\mathsf{U}})_! \mathscr{E}'.$$

Next, let $\varphi' : \mathscr{E}'_1 \to \mathscr{E}'_2$ be a cartesian functor of fibrations over $\mathscr{C}'^\wedge$; let $\mathscr{E}_i := \mathsf{Fib}(u^\wedge)_! \mathscr{E}'_i$ for $i = 1, 2$, and set $\varphi := \mathsf{Fib}(u^\wedge_{\mathsf{U}})_! \varphi' : \mathscr{E}_1 \to \mathscr{E}_2$. For $i = 1, 2$, pick also unital a cleavage c'_i for $\mathscr{E}'$, so that φ' corresponds to a pseudo-natural transformation $\omega' : \mathsf{c}'_1 \Rightarrow \mathsf{c}'_2$. For every $F \in \mathrm{Ob}(\mathscr{C}^\wedge)$ we pick universal cocones $e^F_{1,\bullet} : \mathsf{c}'_i \circ \mathsf{t}^o_F \Rightarrow \mathsf{F}_{\mathscr{E}_{i,F}}$, and denote by d_1 and d_2 the natural split cleavages for $\mathscr{E}_1$ and $\mathscr{E}_2$ described in the foregoing. Then φ corresponds to the strict pseudo-natural transformation $\omega : \mathsf{d}_1 \Rightarrow \mathsf{d}_2$ that assigns to every $F \in \mathrm{Ob}(\mathscr{C}^\wedge)$ the unique functor $\omega_F : \mathscr{E}_{1,F} \to \mathscr{E}_{2,F}$ such that

$$e^F_{2,\bullet} \odot (\omega' * \mathsf{t}^o_F) = \mathsf{F}_{\omega_F} \odot e^F_{1,\bullet}. \tag{3.3.22}$$

Let $\varepsilon_i : \mathsf{c}'_i \circ (h_{\mathscr{C}'} \circ u)^o \xrightarrow{\sim} \mathsf{d}_i \circ h^o_{\mathscr{C}}$ be the pseudo-natural equivalence of claim 3.3.21, for $i = 1, 2$.

Claim 3.3.23. $(\omega * h^o_{\mathscr{C}}) \odot \varepsilon_1 = \varepsilon_2 \odot (\omega' * (h_{\mathscr{C}'} \circ u)^o)$.

Proof of the claim. Directly from (3.3.22) we see that the two sides of the identity of the claim agree on every $X \in \mathrm{Ob}(\mathscr{C})$. It remains to check that the respective coherence constraints agree as well. However, for every $F \in \mathrm{Ob}(\mathscr{C}^\wedge)$ denote by $\tau^F_{i,\bullet}$ the coherence constraint of $e^F_{i,\bullet}$, for $i = 1, 2$; the coherence constraint of $(\omega * h^o_{\mathscr{C}}) \odot \varepsilon_1$ assigns to every morphism $f : X \to Y$ of $\mathscr{C}$ the natural isomorphism of functors $\omega_{h_X} * \tau^{h_Y}_{1,h_{uf}}$, whereas the coherence constraint of $\varepsilon_2 \odot (\omega' * (h_{\mathscr{C}'} \circ u)^o)$ assigns to f the natural isomorphism $\tau^{h_Y}_{2,h_{uf}} * \omega'_{h_{uY}}$. Then again the required identity follows directly from (3.3.22). ◊

From claim 3.3.23 we deduce a commutative diagram of cartesian functors :

$$\begin{array}{ccc} \mathsf{Fib}(h_{\mathscr{C}'} \circ u)^* \mathscr{E}'_1 & \xrightarrow{\Omega_{\mathscr{E}'_1}} & \mathsf{Fib}(h_{\mathscr{C}})^* \mathscr{E}_1 \\ {\scriptstyle \mathsf{Fib}(h_{\mathscr{C}'} \circ u)^* \varphi'} \downarrow & & \downarrow {\scriptstyle \mathsf{Fib}(h_{\mathscr{C}})^* \varphi} \\ \mathsf{Fib}(h_{\mathscr{C}'} \circ u)^* \mathscr{E}'_2 & \xrightarrow{\Omega_{\mathscr{E}'_2}} & \mathsf{Fib}(h_{\mathscr{C}})^* \mathscr{E}_2. \end{array}$$

Lastly, for $\mathscr{E}'_1, \mathscr{E}'_2$ as in the foregoing, let $\varphi'_1, \varphi'_2 : \mathscr{E}' \to \mathscr{E}'_2$ be two cartesian functors, $\beta' : \varphi'_1 \Rightarrow \varphi'_2$ a natural $\mathscr{C}'^\wedge$-transformation, and set $\varphi_i := \mathsf{Fib}(u^\wedge_{\mathsf{U}})_! \varphi'_i$ for $i = 1, 2$ and $\beta := \mathsf{Fib}(u^\wedge_{\mathsf{U}})_! \beta' : \varphi_1 \Rightarrow \varphi_2$. Say that φ'_1 and φ'_2 correspond to pseudo-natural transformations $\omega'_1, \omega'_2 : \mathsf{c}'_1 \Rightarrow \mathsf{c}'_2$, and β' corresponds to a modification $\Xi' : \omega'_1 \rightsquigarrow \omega'_2$; then φ_1 and φ_2 correspond to strict pseudo-natural transformations $\omega_1, \omega_2 : \mathsf{d}_1 \Rightarrow \mathsf{d}_2$ described as in the foregoing, and β corresponds to the modification $\Xi : \omega_1 \rightsquigarrow \omega_2$ assigning to every $F \in \mathrm{Ob}(\mathscr{C}^\wedge)$ the unique natural transformation $\Xi_F : \omega_{1,F} \Rightarrow \omega_{2,F}$ with :

$$e^F_{2,\bullet} * (\Xi' \circ \mathsf{t}^o_F) = \mathsf{F}_{\Xi_F} * e^F_{1,\bullet}$$

which specializes to the identity : $\Xi_{h_X} \odot e^{h_X}_{1,\eta_X} = e^{h_X}_{2,\eta_X} \odot \Xi'_{h_{uX}}$ for every $X \in \mathrm{Ob}(\mathscr{C})$. The latter in turns yields the identity :

$$(\Xi \circ h^o_{\mathscr{C}}) * \varepsilon_1 = \varepsilon_2 * (\Xi' \circ (h_{\mathscr{C}'} \circ u)^o)$$

which finally shows that :

$$\mathsf{Fib}(h_{\mathscr{C}})^*(\beta) * \Omega_{\mathscr{E}'_1} = \Omega_{\mathscr{E}'_2} * \mathsf{Fib}(h_{\mathscr{C}'} \circ u)^*(\beta').$$

Summing up, this shows that the system of equivalences $\Omega_\bullet$ yields a strict pseudo-natural equivalence of strict pseudo-functors $\mathsf{Fib}(h_{\mathscr{C}'} \circ u)^* \stackrel{\sim}{\to} \mathsf{Fib}(h_{\mathscr{C}})^* \circ \mathsf{Fib}(u^\wedge_{\mathsf{U}})_!$, as stated. □

3.3.24. We conclude this section by showing that the 2-limits and 2-colimits are computed fibrewise in the 2-category (U,V)-$\mathsf{Fib}(\mathscr{B})$, a result that extends the corresponding assertion for the category of presheaves (corollary 1.4.3(ii)). To begin with, let $\mathscr{B}$ be any V-small category; with every $B \in \mathrm{Ob}(\mathscr{B})$ we associate a strict pseudo-functor

$$\mathsf{fib}_B : (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(\mathscr{B}) \to (\mathsf{U},\mathsf{V})\text{-}\mathbf{Cat} \qquad \mathscr{A} \mapsto \mathscr{A}_B.$$

If $\mathscr{A}$ and $\mathscr{A}'$ are two $\mathscr{B}$-fibrations, $\psi, \psi' : \mathscr{A} \to \mathscr{A}'$ two $\mathscr{B}$-cartesian functors, and $\beta : \psi \Rightarrow \psi'$ a natural $\mathscr{B}$-transformation, then $\mathsf{fib}_B(\psi) : \mathscr{A}_B \to \mathscr{A}'_B$ is the restriction of ψ, and $\mathsf{fib}_B(\beta) : \mathsf{fib}_B(\psi) \Rightarrow \mathsf{fib}_B(\psi')$ is the restriction of β. We may then state :

Theorem 3.3.25. *With the notation of* (3.3.24)*, we have :*

(i) *The* 2*-category* (U,V)-$\mathsf{Fib}(\mathscr{B})$ *is strongly* 2*-complete and strongly* 2*-cocomplete.*
(ii) *For every* $B \in \mathrm{Ob}(\mathscr{B})$ *and any small* 2*-category* I*, the pseudo-functor* fib_B *commutes with the strong* 2*-limit and strong* 2*-colimit of any pseudo-functor* $I \to (\mathsf{U},\mathsf{V})$-$\mathsf{Fib}(\mathscr{B})$.

Proof. We prove the 2-completeness of $\mathsf{Fib}(\mathscr{B})$; the 2-cocompleteness follows by the same argument, considering the opposite 2-categories : the details shall be left to the reader. In view of theorem 3.1.24, it suffices to show the corresponding assertions for the 2-category $\mathsf{PsFun}(\mathscr{B}^o, \mathbf{Cat})$ and the similar strict pseudo-functors that we denote as well by

$$\mathsf{fib}_B : \mathsf{PsFun}(\mathscr{B}^o, \mathbf{Cat}) \to \mathbf{Cat} \qquad \mathsf{c} \mapsto \mathsf{c}_B.$$

Notice that every morphism $g : B' \to B$ of $\mathscr{B}$ induces a pseudo-natural transformation

$$\mathsf{fib}_g : \mathsf{fib}_B \Rightarrow \mathsf{fib}_{B'} \qquad \mathsf{c} \mapsto (\mathsf{c}_g : \mathsf{c}_B \to \mathsf{c}_{B'})$$

with coherence constraint given by the rule :

$$\tau^{\mathsf{fib}_g}_\beta := (\tau^\beta_g)^{-1}$$

for every pair of pseudo-natural functors $\mathsf{c}, \mathsf{d} : \mathscr{B}^o \to \mathbf{Cat}$ and every pseudo-natural transformation $\beta : \mathsf{c} \Rightarrow \mathsf{d}$ with coherence constraint τ^β. Moreover, if $h : B'' \to B'$ is any other morphism of $\mathscr{B}$, we get the invertible modification

$$\Gamma_{h,g} : \mathsf{fib}_h \odot \mathsf{fib}_g \rightsquigarrow \mathsf{fib}_{g \circ h} \qquad \mathsf{c} \mapsto \gamma^{\mathsf{c}}_{h,g}$$

where $(\delta^{\mathsf{c}}, \gamma^{\mathsf{c}})$ denotes the coherence constraint of c. Indeed, it is easily seen that the compatibility condition for $(\Gamma_{h,g})_\beta$ corresponding to a pseudo-natural transformation $\beta : \mathsf{c} \Rightarrow \mathsf{d}$ is equivalent to the coherence axiom for τ^β : details left to the reader. Likewise, for every third morphism $k : B''' \to B''$ of $\mathscr{B}$, the composition axiom for pseudo-functors translates as :

$$\Gamma_{k,g\circ h} \odot (\mathsf{fib}_k * \Gamma_{h,g}) = \Gamma_{h\circ k,g} \odot (\Gamma_{k,h} * \mathsf{fib}_g). \tag{3.3.26}$$

Let now $F : I \to \mathsf{PsFun}(\mathscr{B}^o, \mathbf{Cat})$ be any pseudo-functor; we need to exhibit a 2-limit for F, and by virtue of proposition 2.4.3, we may assume that $Fi : \mathscr{B}^o \to \mathbf{Cat}$ is unital for every

$i \in \mathrm{Ob}(I)$. Then, for every $B \in \mathrm{Ob}(\mathscr{B})$ choose a strong 2-limit $(L(B), \pi^B)$ of the pseudo-functor $\mathsf{fib}_B \circ F$ (theorem 3.3.9), and let τ^B be the coherence constraint of the pseudo-cone $\pi^B : \mathsf{F}_{L(B)} \Rightarrow \mathsf{fib}_B \circ F$. Let $g : B' \to B$ be any morphism of $\mathscr{B}$; by the (strong) universality of $\pi^{B'}$, we find a unique functor $L(g) : L(B) \to L(B')$ such that

$$\pi^{B'} \odot \mathsf{F}_{L(g)} = (\mathsf{fib}_g * F) \odot \pi^B. \tag{3.3.27}$$

Notice that $\mathsf{fib}_{\mathbf{1}_B} * F = \mathbf{1}_{\mathsf{fib}_B \circ F}$, since Fi is unital for every $i \in \mathrm{Ob}(I)$; therefore :

$$L(\mathbf{1}_B) = \mathbf{1}_{L(B)} \qquad \text{for every } B \in \mathrm{Ob}(\mathscr{B}).$$

Moreover, if $h : B'' \to B'$ is another morphism of $\mathscr{B}$, we have identities :

$$\begin{aligned}
\pi^{B''} \odot \mathsf{F}_{L(h)\circ L(g)} &= (\mathsf{fib}_h * F) \odot (\mathsf{fib}_g * F) \odot \pi^B = ((\mathsf{fib}_h \odot \mathsf{fib}_g) * F) \odot \pi^B \\
\pi^{B''} \odot \mathsf{F}_{L(h\circ g)} &= (\mathsf{fib}_{h\circ g}) \odot \pi^B
\end{aligned}$$

so there exists a unique natural transformation $\gamma^L_{h,g} : L(h) \circ L(g) \Rightarrow L(g \circ h)$ such that

$$\pi^{B''} * \mathsf{F}_{\gamma^L_{h,g}} = (\Gamma_{h,g} \circ F) * \pi^B.$$

Claim 3.3.28. The rules $B \mapsto L(B)$ and $(g : B' \to B) \mapsto L(g)$ for every $B \in \mathrm{Ob}(\mathscr{B})$ and every morphism g of $\mathscr{B}$ define a unital pseudo-functor $L : \mathscr{B}^o \to \mathbf{Cat}$ with coherence constraint given by the system of natural transformations $\gamma^L_{\bullet,\bullet}$.

Proof of the claim. The unit axiom for γ^L is clear from the construction. To check the composition axiom, let g and h be as in the foregoing, and consider as well a third morphism $k : B''' \to B''$ of $\mathscr{B}$. Since $\pi^{B'''}$ is a universal pseudo-cone, it suffices to show that

$$X := \pi^{B'''} * (\mathsf{F}_{\gamma^L_{k,g\circ h}} \odot \mathsf{F}_{L(k)*\gamma^L_{h,g}}) = Y := \pi^{B'''} * (\mathsf{F}_{\gamma^L_{h\circ k,g}} \odot \mathsf{F}_{\gamma^L_{k,h}*L(g)}).$$

However, by unwinding the definitions we find :

$$\begin{aligned}
X &= ((\Gamma_{k,g\circ h} \circ F) * \pi^B) \odot (\pi^{B'''} * \mathsf{F}_{L(k)} * \mathsf{F}_{\gamma^L_{h,g}}) \\
&= ((\Gamma_{k,g\circ h} \circ F) * \pi^B) \odot ((\mathsf{fib}_k * F) * \pi^{B''} * \mathsf{F}_{\gamma^L_{h,g}}) \\
&= ((\Gamma_{k,g\circ h} \circ F) * \pi^B) \odot ((\mathsf{fib}_k * F) * (\Gamma_{h,g} \circ F) * \pi^B) \\
&= ((\Gamma_{k,g\circ h} \circ F) * \pi^B) \odot (((\mathsf{fib}_k * \Gamma_{h,g}) \circ F) * \pi^B) \\
Y &= ((\Gamma_{h\circ k,g} \circ F) * \pi^B) \odot (\pi^{B'''} * \mathsf{F}_{\gamma^L_{k,h}} * \mathsf{F}_{L(g)}) \\
&= ((\Gamma_{h\circ k,g} \circ F) * \pi^B) \odot ((\Gamma_{k,h} \circ F) * \pi^{B'} * \mathsf{F}_{L(g)}) \\
&= ((\Gamma_{h\circ k,g} \circ F) * \pi^B) \odot ((\Gamma_{k,h} \circ F) * (\mathsf{fib}_g * F) * \pi^B) \\
&= ((\Gamma_{h\circ k,g} \circ F) * \pi^B) \odot ((\Gamma_{k,h} * \mathsf{fib}_g) \circ F) \odot \pi^B
\end{aligned}$$

so it suffices to show:

$$(\Gamma_{h\circ k,g} \circ F) \odot ((\Gamma_{k,h} * \mathsf{fib}_g) \circ F) = (\Gamma_{k,g\circ h} \circ F) \odot ((\mathsf{fib}_k * \Gamma_{h,g}) \circ F)$$

which follows straightforwardly from (3.3.26). ◊

Next, we notice that for every $i \in \mathrm{Ob}(I)$ the rule : $B \mapsto (\pi^B_i : L(B) \to Fi(B))$ defines a strict pseudo-natural transformation

$$\pi_i : L \Rightarrow Fi.$$

Indeed, the first coherence axiom for π_i is easily checked, recalling that both L and Fi are unital, and the second one follows directly from the definition of γ^L : details left to the reader.

Claim 3.3.29. (i) For every 1-cell $\varphi : i \to j$ in I, the rule :

$$B \mapsto \tau_\varphi^B$$

defines an invertible modification $\Xi^\varphi : F(\varphi) \odot \pi_i \rightsquigarrow \pi_j$.

(ii) The system $(\pi_i \mid i \in \mathrm{Ob}(I))$ defines a pseudo-cone

$$\pi : \mathsf{F}_L \Rightarrow F$$

with coherence constraint given by the invertible modifications $\Xi^\bullet$.

Proof of the claim. (i): Let $\tau^{F\varphi}$ and $\tau^{\mathsf{fib}_g * F}$ be the coherence constraints of $F\varphi$ and respectively $\mathsf{fib}_g * F$. We need to verify the compatibility condition :

$$Fj(g) * \tau_\varphi^B = (\tau_j^{B'} * L(g)) \odot (\tau_g^{F\varphi} * \pi_i^B)$$

for every morphism $g : B' \to B$ of $\mathscr{B}$. However, comparing the coherence constraints of the two sides of (3.3.27) we get :

$$(Fj(g) * \tau_\varphi^B) \odot (\tau_\varphi^{\mathsf{fib}_g * F} * \pi_i^B) = \tau_\varphi^{B'} * L(g).$$

Since $\tau_\varphi^{\mathsf{fib}_g * F} = (\tau_g^{F\varphi})^{-1}$, the assertion follows.

(ii): Denote by (δ^F, γ^F) the coherence constraint of F; we need to check the identities

$$\Xi^{\mathbf{1}_i} \odot (\delta_i^F * \pi_i) = \mathbf{1}_{\pi_i} \qquad \Xi^\psi \odot (F\psi * \Xi^\varphi) = \Xi^{\psi\circ\varphi} \odot (\gamma_{\varphi,\psi}^F * \pi_i)$$

for every $i, j, k \in \mathrm{Ob}(I)$ and every pair of 1-cells $\varphi : i \to j$ and $\psi : j \to k$ of I. However, the latter are none else than a rephrasing of the coherence axioms for the pseudo-cones π^B, for B ranging over all the objects of $\mathscr{B}$. ◊

It remains to check that the pseudo-cone $\pi : \mathsf{F}_L \Rightarrow F$ of claim 3.3.29(ii) is universal. To this aim, let $X : \mathscr{B}^o \to \mathbf{Cat}$ be any pseudo-functor, and $\beta : \mathsf{F}_X \Rightarrow F$ any pseudo-cone; we need to exhibit a pseudo-natural trasformation $t : X \Rightarrow L$ such that $\pi \odot \mathsf{F}_t = \beta$. Let $\omega : X \stackrel{\sim}{\to} X^u$ be the isomorphism furnished by proposition 2.4.3, with X^u a unital pseudo-functor; we get a commutative diagram of categories :

$$\begin{array}{ccc} \mathsf{PsNat}(X^u, L) & \longrightarrow & \mathsf{PsNat}(\mathsf{F}_{X^u}, F) \\ {\scriptstyle \mathsf{PsNat}(\omega, L)}\downarrow & & \downarrow{\scriptstyle \mathsf{PsNat}(\mathsf{F}_\omega, F)} \\ \mathsf{PsNat}(X, L) & \longrightarrow & \mathsf{PsNat}(\mathsf{F}_X, F) \end{array}$$

whose vertical arrows are isomorphisms. We need to check that the bottom horizontal arrow is an isomorphism, so it suffices to show that the same holds for the top horizontal arrow; we may thus assume that X is unital. Now, $\mathsf{fib}_B * \beta$ is a pseudo-cone with vertex $X(B)$ and basis $\mathsf{fib}_B \circ F : I \to \mathbf{Cat}$; then there exists a unique functor $t_B : X(B) \to L(B)$ such that

$$\pi^B \odot \mathsf{F}_{t_B} = \mathsf{fib}_B * \beta \qquad \text{for every } B \in \mathrm{Ob}(\mathscr{B}).$$

Denote by τ^β the coherence constraint of β, and by τ^{β_i} the coherence constraint of the pseudo-natural transformation $\beta_i : X \Rightarrow Fi$, for every $i \in \mathrm{Ob}(I)$; we remark :

Claim 3.3.30. For every morphism $g : B' \to B$ of $\mathscr{B}$, the rule :

$$i \mapsto \tau_g^{\beta_i} \qquad \text{for every } i \in \mathrm{Ob}(I)$$

defines an invertible modification $\Lambda^g : (\mathsf{fib}_g * F) \odot (\mathsf{fib}_B * \beta) \rightsquigarrow (\mathsf{fib}_{B'} * \beta) \odot \mathsf{F}_{X(g)}$.

Proof of the claim. The coherence constraint of $(\mathsf{fib}_g * F) \odot (\mathsf{fib}_B * \beta)$ assigns to every 1-cell $\varphi : i \to j$ of I the composition of oriented squares :

$$\begin{array}{ccccc} X(B) & \xrightarrow{\beta_{i,B}} & Fi(B) & \xrightarrow{Fi(g)} & Fi(B') \\ \| & \Downarrow \tau^{\beta}_{\varphi,B} & \downarrow F\varphi(B) & \Downarrow (\tau^{F\varphi}_g)^{-1} & \downarrow F\varphi(B') \\ X(B) & \xrightarrow[\beta_{j,B}]{} & Fj(B) & \xrightarrow[Fj(g)]{} & Fj(B') \end{array}$$

whereas the coherence constraint of $(\mathsf{fib}_{B'} * \beta) \odot \mathsf{F}_{X(g)}$ assigns to φ the natural transformation

$$\tau^{\beta}_{\varphi,B'} * X(g) : F\varphi(B') \circ \beta_{i,B'} \circ X(g) \Rightarrow \beta_{j,B'} \circ X(g).$$

Thus, for every such φ we need to show the identity :

$$\tau^{\beta_j}_g \odot (Fj(g) * \tau^{\beta}_{\varphi,B}) \odot ((\tau^{F\varphi}_g)^{-1} * \beta_{i,B}) = \tau^{\beta}_{\varphi,B'} \odot (F\varphi(B') * \tau^{\beta_i}_g).$$

But the latter is equivalent to the compatibility condition for the invertible modification $\tau^{\beta}_{\varphi} : F\varphi \odot \beta_i \rightsquigarrow \beta_j$, corresponding to the morphism g. $\Diamond$

Notice now that $(\mathsf{fib}_g * F) \odot (\mathsf{fib}_B * \beta) = \pi^{B'} \odot \mathsf{F}_{L(g)\circ t_B}$ and $(\mathsf{fib}_{B'} * \beta) \odot \mathsf{F}_{X(g)} = \pi^{B'} \odot \mathsf{F}_{t_{B'}\circ X(g)}$ for every morphism $g : B' \to B$ of $\mathscr{B}$. In view of claim 3.3.30, and since $\pi^{B'}$ is universal, there exists therefore a unique natural isomorphism of functors

$$\tau^t_g : L(g) \circ t_B \Rightarrow t_{B'} \circ X(g) \qquad \text{such that} \qquad \pi^{B'} * \mathsf{F}_{\tau^t_g} = \Lambda^g.$$

Notice that, by virtue of remark 2.4.2(ii), we have $\Lambda^{\mathbf{1}_B} = \mathbf{1}_{\mathsf{fib}_B * \beta}$ for every $B \in \mathrm{Ob}(\mathscr{B})$, and therefore $\tau^t_{\mathbf{1}_B} = \mathbf{1}_{t_B}$ for every such B. Let us check that the system $(t_B \mid B \in \mathrm{Ob}(\mathscr{B}))$ yields the sought pseudo-natural transformation, with coherence constraint given by the system of isomorphisms of functors $\tau^t_\bullet$. Indeed, the first coherence axiom follows easily from the foregoing; it remains therefore only to show that for every pair of morphisms $g : B' \to B$ and $h : B'' \to B'$ of $\mathscr{B}$ we have :

$$(t_{B''} * \gamma^X_{h,g}) \odot (\tau^t_h * X(g)) \odot (L(h) * \tau^t_g) = \tau^t_{g\circ h} \odot (\gamma^L_{g,h} * t_B)$$

where γ^X denotes the coherence constraint of X. Using the universality of $\pi^{B''}$, we are then reduced to showing the identity :

$$U := (\pi^{B''} * \mathsf{F}_{t_{B''}} * \mathsf{F}_{\gamma^X_{h,g}}) \odot (\Lambda^h * \mathsf{F}_{X(g)}) \odot (\pi^{B''} * \mathsf{F}_{L(h)} * \mathsf{F}_{\tau^t_g}) = V := \Lambda^{g\circ h} \odot (\pi^{B''} * \mathsf{F}_{\gamma^L_{g,h}} * \mathsf{F}_{t_B}).$$

However, we have :

$$\begin{aligned} U &= (\pi^{B''} * \mathsf{F}_{t_{B''}} * \mathsf{F}_{\gamma^X_{h,g}}) \odot (\Lambda^h * \mathsf{F}_{X(g)}) \odot ((\mathsf{fib}_h * F) * \pi^{B'} * \mathsf{F}_{\tau^t_g}) \\ &= ((\mathsf{fib}_{B''} * \beta) * \mathsf{F}_{\gamma^X_{h,g}}) \odot (\Lambda^h * \mathsf{F}_{X(g)}) \odot ((\mathsf{fib}_h * F) * \pi^{B'} * \mathsf{F}_{\tau^t_g}) \\ &= ((\mathsf{fib}_{B''} * \beta) * \mathsf{F}_{\gamma^X_{h,g}}) \odot (\Lambda^h * \mathsf{F}_{X(g)}) \odot ((\mathsf{fib}_h * F) * \Lambda^g) \\ V &= \Lambda^{g\circ h} \odot ((\Gamma_{h,g} \circ F) * \pi^B * \mathsf{F}_{t_B}). \end{aligned}$$

Thus, it suffices to show :

$$((\mathsf{fib}_{B''} * \beta) * \mathsf{F}_{\gamma^X_{h,g}}) \odot (\Lambda^h * \mathsf{F}_{X(g)}) \odot ((\mathsf{fib}_h * F) * \Lambda^g) = \Lambda^{g\circ h} \odot ((\Gamma_{h,g} \circ F) * (\mathsf{fib}_B * \beta)).$$

But a simple inspection shows that the latter identity translates the coherence axiom for β_i, relative to the pair of 1-cells (h, g), and for i ranging over all the objects of I.

Claim 3.3.31. (i) $\pi_i \odot t = \beta_i$ for every $i \in \mathrm{Ob}(I)$.
(ii) $\pi \odot \mathsf{F}_t = \beta$.

Proof of the claim. We need to check that the coherence constraint $\tau^{\pi_i \odot t}$ of $\pi_i \odot t$ equals τ^{β_i}. But for every morphism $g : B' \to B$ of $\mathscr{B}$ we have $\tau_g^{\pi_i \odot t} = \pi_i^{B'} * \tau_g^t = \Lambda_i^g$, whence the contention.

(ii): In view of (i), it suffices to check that β and $\pi \odot \mathsf{F}_t$ have the same coherence constraints. But the coherence constraint of $\pi \odot \mathsf{F}_t$ assigns to every 1-cell $\varphi : i \to j$ in I the invertible modification $\Xi^\varphi * t$, so the assertion follows by a direct inspection of the definitions. ◊

Claim 3.3.31(ii) shows that the functor

$$\mathsf{PsNat}(X, L) \to \mathsf{PsNat}(\mathsf{F}_X, F) \qquad t \mapsto \pi \odot \mathsf{F}_t \tag{3.3.32}$$

is surjective on objects. To check injectivity on objects, consider two pseudo-natural transformations $t, t' : X \Rightarrow L$ such that $\pi \odot \mathsf{F}_t = \pi \odot \mathsf{F}_{t'}$. Then we have

$$\pi^B \odot \mathsf{F}_{t_B} = \mathsf{fib}_B * (\pi \odot \mathsf{F}_t) = \mathsf{fib}_B * (\pi \odot \mathsf{F}_{t'}) = \pi^B \odot \mathsf{F}_{t'_B} \qquad \text{for every } B \in \mathrm{Ob}(\mathscr{B}).$$

By strong universality of π^B, we deduce that $t_B = t'_B$ for every such B. Moreover, recall that we have attached to $\pi \odot \mathsf{F}_t$ and every morphism $g : B' \to B$ an invertible modification $\Lambda^g : \pi^{B'} \odot \mathsf{F}_{L(g) \circ t_B} \rightsquigarrow \pi^{B'} \odot \mathsf{F}_{t_{B'} \circ X(g)}$. Let τ^t and $\tau^{t'}$ be the coherence constraint of t and t'; by inspecting the definition, we find that

$$\Lambda_i^g = (\tau_g^B * t_B) \odot (\pi_i^{B'} * \tau_g^t) \qquad \text{for every } i \in \mathrm{Ob}(I).$$

Since $\pi \odot \mathsf{F}_t = \pi \odot \mathsf{F}_{t'}$ and $t_B = t'_B$, we get $\pi_i^{B'} * \tau_g^t = \pi_i^{B'} * \tau_g^{t'}$ for every $i \in \mathrm{Ob}(I)$, *i.e.* $\pi^{B'} * \mathsf{F}_{\tau_g^t} = \pi^{B'} * \mathsf{F}_{\tau_g^{t'}}$, whence $\tau_g^t = \tau_g^{t'}$, by the universality of $\pi^{B'}$. Thus, $t = t'$ as required.

To check that (3.3.32) is faithful, consider pseudo-natural transformations $t, t' : X \Rightarrow L$ and modifications $\Delta, \Delta' : t \rightsquigarrow t'$ with $\pi * \mathsf{F}_\Delta = \pi * \mathsf{F}_{\Delta'}$; we deduce:

$$\pi^B * (\mathsf{fib}_B \circ \mathsf{F}_\Delta) = \mathsf{fib}_B \circ (\pi * \mathsf{F}_\Delta) = \mathsf{fib}_B \circ (\pi * \mathsf{F}_{\Delta'}) = \pi^B * (\mathsf{fib}_B \circ \mathsf{F}_{\Delta'}) \qquad \text{for every } B \in \mathrm{Ob}(\mathscr{B})$$

and clearly $\mathsf{fib}_B \circ \mathsf{F}_\Delta$ and $\mathsf{fib}_B \circ \mathsf{F}_{\Delta'}$ are the constant modifications $\mathsf{F}_{t_B} \rightsquigarrow \mathsf{F}_{t'_B}$ associated with Δ and Δ'. By the universality of π^B, it follows that $\mathsf{fib}_B \circ \mathsf{F}_\Delta = \mathsf{fib}_B \circ \mathsf{F}_{\Delta'}$ for every $B \in \mathrm{Ob}(\mathscr{B})$, whence $\Delta = \Delta'$, as required.

Lastly, let $\Delta : \pi \odot \mathsf{F}_t \rightsquigarrow \pi \odot \mathsf{F}_{t'}$ be any modification; for every $B \in \mathrm{Ob}(\mathscr{B})$ we obtain the modification $\mathsf{fib}_B \circ \Delta : \pi^B \odot \mathsf{F}_{t_B} \rightsquigarrow \pi^B \odot \mathsf{F}_{t'_B}$, and since π^B is universal, there exists a unique natural transformation $\delta^B : t_B \Rightarrow t'_B$ such that $\mathsf{fib}_B \circ \Delta = \pi^B * \mathsf{F}_{\delta^B}$. It remains to check that the rule : $B \mapsto \delta^B$ yields a modification $\delta : t \rightsquigarrow t'$, since in this case we get $\Delta = \pi * \mathsf{F}_\delta$, which will prove that (3.3.32) is also full, thus concluding the proof of the theorem. However, Δ is the datum of a modification $\Delta_i : \pi_i \odot t \rightsquigarrow \pi_i \odot t'$ for every $i \in \mathrm{Ob}(I)$; the compatibility condition for Δ_i asserts that the following two compositions of oriented squares coincide for every morphism $g : B' \to B$ of $\mathscr{B}$:

$$\begin{array}{ccccc} X(B) & \xrightarrow{t_B} & L(B) & \xrightarrow{\pi_i^B} & Fi(B) \\ \| & \Swarrow_{\delta^B} & \| & \Swarrow_{\mathbf{1}_{\pi_i^B}} & \| \\ X(B) & \xrightarrow{t'_B} & L(B) & \xrightarrow{\pi_i^B} & Fi(B) \\ {\scriptstyle X(g)}\downarrow & \Swarrow_{\tau_g^{t'}} & \downarrow{\scriptstyle L(g)} & \Swarrow_{\tau_g^{\pi_i}} & \downarrow{\scriptstyle Fi(g)} \\ X(B') & \xrightarrow[t'_{B'}]{} & L(B') & \xrightarrow[\pi_i^{B'}]{} & Fi(B') \end{array} \qquad \begin{array}{ccccc} X(B) & \xrightarrow{t_B} & L(B) & \xrightarrow{\pi_i^B} & Fi(B) \\ {\scriptstyle X(g)}\downarrow & \Swarrow_{\tau_g^{t}} & \downarrow{\scriptstyle L(g)} & \Swarrow_{\tau_g^{\pi_i}} & \downarrow{\scriptstyle Fi(g)} \\ X(B') & \xrightarrow{t_{B'}} & L(B') & \xrightarrow{\pi_i^{B'}} & Fi(B') \\ \| & \Swarrow_{\delta^{B'}} & \| & \Swarrow_{\mathbf{1}_{\pi_i^{B'}}} & \| \\ X(B') & \xrightarrow[t'_{B'}]{} & L(B') & \xrightarrow[\pi_i^{B'}]{} & Fi(B') \end{array}$$

where τ_g^t, $\tau_g^{t'}$ and $\tau_g^{\pi_i}$ are the coherent constraints of respectively t, t' and π_i. We deduce that

$$\pi_i^{B'} * (\tau_g^{t'} \odot (L(g) * \delta^B)) = \pi_i^{B'} * ((\delta^{B'} * X(g)) \odot \tau_g^t) \qquad \text{for every } i \in \mathrm{Ob}(I)$$

and invoking again the universality of $\pi^{B'}$ we conclude that $\tau_g^{t'} \odot (L(g) * \delta^B) = (\delta^{B'} * X(g)) \odot \tau_g^t$, which is the required compatibility condition for δ. □

3.4. **Fibrations in groupoids.** Recall that a *groupoid* is a category all whose morphisms are invertible. To every category $\mathscr{B}$, we may attach the groupoid $\mathscr{B}^\times$ such that $\mathrm{Ob}(\mathscr{B}^\times) = \mathrm{Ob}(\mathscr{B})$, and whose morphisms are the isomorphisms of $\mathscr{B}$; the composition law for morphisms in $\mathscr{B}^\times$ is the same as that of $\mathscr{B}$, so $\mathscr{B}^\times$ is a subcategory of $\mathscr{B}$. Then clearly every functor $G : \mathscr{A} \to \mathscr{B}$ restricts to a functor $G^\times : \mathscr{A}^\times \to \mathscr{B}^\times$, and for every universe U, the rules : $\mathscr{C} \mapsto \mathscr{C}^\times$ and $(F : \mathscr{A} \to \mathscr{B}) \mapsto F^\times$ yield a right adjoint $(-)^\times : \mathsf{U}\text{-}\mathbf{Cat} \to \mathsf{U}\text{-}\mathsf{Gpd}$ for the inclusion functor

$$\mathsf{U}\text{-}\mathsf{Gpd} \to \mathsf{U}\text{-}\mathbf{Cat}$$

of the full subcategory $\mathsf{U}\text{-}\mathsf{Gpd}$ of $\mathsf{U}\text{-}\mathbf{Cat}$ whose objects are the U-small groupoids.

Remark 3.4.1. (i) Notice that every isomorphism of functors $\alpha : G \xrightarrow{\sim} H$ restricts to an isomorphism of functors $\alpha^\times : G^\times \xrightarrow{\sim} H^\times$.

(ii) Let $\mathscr{A}$ and $\mathscr{B}$ be any two categories, and $G : \mathscr{A} \to \mathscr{B}$ any functor. Then it is easily seen that G is essentially surjective if and only if the same holds for $G^\times$. Moreover, if G is i-faithful for some $i \in \{0, 1, 2\}$, then the same holds for $G^\times$. The verification in case $i = 0$ shall be left to the reader. Next, let $f : GX \to GY$ be a morphism in $\mathscr{B}^\times$; if G is fully faithful, there exists $g : X \to Y$ in $\mathscr{A}$ such that $Gg = f$. But f is invertible, so by the same token there exists $h : Y \to X$ in $\mathscr{A}$ such that $Gh = f^{-1}$; since $G(f \circ g) = G\mathbf{1}_Y$ and $G(g \circ f) = G\mathbf{1}_X$, we deduce $f \circ g = \mathbf{1}_Y$ and $g \circ f = \mathbf{1}_X$, since G is faithful. This shows that g is a morphism in $\mathscr{A}^\times$, and proves the assertion for $i = 1$. For $i = 2$, the functor G is an equivalence, so we know already that $G^\times$ is fully faithful; but we have also already noticed that $G^\times$ is essentially surjective, whence the assertion for $i = 2$.

(iii) Since $(-)^\times$ is a right adjoint, it commutes with all limits of $\mathsf{V}\text{-}\mathbf{Cat}$ (see proposition 1.3.25(iii)). Moreover, by inspecting the construction of example 1.5.10, it is easily seen that $(-)^\times$ also commutes with all filtered (small) colimits : details left to the reader.

3.4.2. We wish now to upgrade the associated groupoid construction to the 2-category of $\mathscr{C}$-fibrations, for any given base category $\mathscr{C}$. Indeed, let $F : \mathscr{A} \to \mathscr{C}$ be any fibration; we associate with $\mathscr{A}$ the category

$$\mathscr{A}^\times$$

with $\mathrm{Ob}(\mathscr{A}^\times) = \mathscr{A}$, and whose morphisms are the cartesian morphisms of $\mathscr{A}$. The composition law for morphisms in $\mathscr{A}^\times$ is the restriction of that of $\mathscr{A}$, hence $\mathscr{A}^\times$ is a subcategory of $\mathscr{A}$, and we denote by $F^\times : \mathscr{A}^\times \to \mathscr{C}$ the restriction of F. Then it is easily seen that $F^\times$ is also a fibration, and all morphisms of $\mathscr{A}^\times$ are cartesian for this fibration; moreover, for every $X \in \mathrm{Ob}(\mathscr{C})$ the fibre category $(F^\times)^{-1}X$ is a groupoid. The latter assertion can be easily checked directly, and it follows also straightforwardly from lemma 3.1.20(i). We call $F^\times$ the *fibration in groupoids associated with* F. We say that F is a *fibration in groupoids* if $\mathscr{A} = \mathscr{A}^\times$. Clearly every cartesian functor $G : \mathscr{A} \to \mathscr{B}$ of $\mathscr{C}$-fibrations restricts to a (cartesian) functor

$$G^\times : \mathscr{A}^\times \to \mathscr{B}^\times.$$

On the other hand, a given natural $\mathscr{C}$-transformation $\beta : G \Rightarrow H$ between $\mathscr{C}$-cartesian functors $G, H : \mathscr{A} \to \mathscr{B}$ induces a natural $\mathscr{C}$-transformation $\beta^\times : G^\times \Rightarrow H^\times$ if and only if β is an isomorphism of functors, *i.e.* if and only if β is a morphism of the groupoid $\mathsf{Cart}_\mathscr{C}(\mathscr{A}, \mathscr{B})^\times$ associated with $\mathsf{Cart}_\mathscr{C}(\mathscr{A}, \mathscr{B})$ as in (3.4). Thus, we get a natural functor

$$\mathsf{Cart}_\mathscr{C}(\mathscr{A}, \mathscr{B})^\times \to \mathsf{Cart}_\mathscr{C}(\mathscr{A}^\times, \mathscr{B}^\times) \qquad G \mapsto G^\times \qquad (\beta : G \Rightarrow H) \mapsto \beta^\times \tag{3.4.3}$$

3.4.4. Let U, V be universes such that $\mathsf{U} \subset \mathsf{V}$, and $\mathscr{C}$ a V-small category; we denote by

$$(\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}^\times(\mathscr{C}) \qquad \text{and} \qquad (\mathsf{U}, \mathsf{V})\text{-}\mathsf{Gpd}(\mathscr{C})$$

respectively : the sub-2-category of $(\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}(\mathscr{C})$ whose objects are the same as those of $(\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}(\mathscr{C})$, and whose Hom-category is $\mathsf{Cart}_\mathscr{C}(\mathscr{A}, \mathscr{B})^\times$ for every pair $(\mathscr{A}, \mathscr{B})$ of such $\mathscr{C}$-fibrations, and : the strong sub-2-category of $(\mathsf{U}, \mathsf{V})\text{-}\mathsf{Fib}(\mathscr{C})$ whose objects are the fibrations in groupoids. With this notation, clearly we get as well a strict pseudo-functor

$$(-)^{\times}_{\mathscr{C}} : (\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}^{\times}(\mathscr{C}) \to (\mathsf{U},\mathsf{V})\text{-}\mathsf{Gpd}(\mathscr{C}) \qquad \mathscr{A} \mapsto \mathscr{A}^{\times}$$

which is given on Hom-categories by the foregoing system of functors (3.4.3). As usual, we may omit mentioning the universes in the above notation, if no ambiguities are likely to arise.

3.4.5. Moreover, every functor $u : \mathscr{C} \to \mathscr{C}'$ induces strict pseudo-functors

$$(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}^{\times}(u)^* : \mathsf{Fib}^{\times}(\mathscr{C}') \to \mathsf{Fib}^{\times}(\mathscr{C}) \qquad (\mathsf{U},\mathsf{V})\text{-}\mathsf{Gpd}(u)^* : \mathsf{Gpd}(\mathscr{C}') \to \mathsf{Gpd}(\mathscr{C})$$

defined as the restrictions of $\mathsf{Fib}(u)^* : \mathsf{Fib}(\mathscr{C}') \to \mathsf{Fib}(\mathscr{C})$. As usual, these functors will be sometimes just denoted $\mathsf{Fib}^{\times}(u)^*$ and respectively $\mathsf{Gpd}(u)^*$. By simple inspection we get a commutative diagram of 2-categories :

$$\begin{array}{ccc} \mathsf{Fib}^{\times}(\mathscr{C}') & \xrightarrow{\mathsf{Fib}^{\times}(u)^*} & \mathsf{Fib}^{\times}(\mathscr{C}) \\ {\scriptstyle (-)^{\times}_{\mathscr{C}'}}\downarrow & & \downarrow{\scriptstyle (-)^{\times}_{\mathscr{C}}} \\ \mathsf{Gpd}(\mathscr{C}') & \xrightarrow{\mathsf{Gpd}(u)^*} & \mathsf{Gpd}(\mathscr{C}). \end{array}$$

3.4.6. Let $u : \mathscr{C} \to \mathscr{C}'$ be a functor from a U-small category $\mathscr{C}$ to a V-small category $\mathscr{C}'$ with U-small Hom-sets. Recall that the source functor $\mathsf{s}_X : u\mathscr{C}/X \to \mathscr{C}$ is a fibration in groupoids for every $X \in \mathrm{Ob}(\mathscr{C}')$ (example 3.1.3(i)); taking into account remark 3.3.15(ii) we deduce for every $\mathscr{C}$-fibration $\mathscr{A}$ with V-small fibres and every such X, natural equivalences of categories :

$$(\mathsf{Fib}(u)_*\mathscr{A}(X))^{\times} \xrightarrow{\sim} \mathsf{Cart}_{\mathscr{C}}(u\mathscr{C}/X, \mathscr{A})^{\times} \xrightarrow{\sim} \mathsf{Cart}_{\mathscr{C}}(u\mathscr{C}/X, \mathscr{A}^{\times}) \xrightarrow{\sim} (\mathsf{Fib}(u)_*(\mathscr{A}^{\times}))(X).$$

There follows a pseudo-commutative diagram of 2-categories :

$$\begin{array}{ccc} \mathsf{Fib}^{\times}(\mathscr{C}) & \xrightarrow{(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}^{\times}(u)_*} & \mathsf{Fib}^{\times}(\mathscr{C}') \\ {\scriptstyle (-)^{\times}_{\mathscr{C}}}\downarrow & & \downarrow{\scriptstyle (-)^{\times}_{\mathscr{C}'}} \\ \mathsf{Gpd}(\mathscr{C}) & \xrightarrow{(\mathsf{U},\mathsf{V})\text{-}\mathsf{Gpd}(u)_*} & \mathsf{Gpd}(\mathscr{C}') \end{array}$$

where $(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}^{\times}(u)_*$ and $(\mathsf{U},\mathsf{V})\text{-}\mathsf{Gpd}(u)_*$ are the restrictions of $(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(u)_*$. *Suppose moreover that the category $X/u\mathscr{C}$ is cofiltered for every $X \in \mathrm{Ob}(\mathscr{C}')$*; then, in view of remarks 3.4.1(iii) and 5.5.14(iii), for every such X we have as well a natural equivalence of categories :

$$(\mathsf{Fib}(u)_!\mathscr{A}(X))^{\times} \xrightarrow{\sim} \operatorname*{colim}_{X \to uY} \mathscr{A}(Y)^{\times} \xrightarrow{\sim} \mathsf{Fib}(u)_!(\mathscr{A}^{\times})(X)$$

where the colimit ranges over the small filtered category $(X/u\mathscr{C})^o$. We get therefore a pseudo-commutative diagram of 2-categories :

$$\begin{array}{ccc} \mathsf{Fib}^{\times}(\mathscr{C}) & \xrightarrow{(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}^{\times}(u)_!} & \mathsf{Fib}^{\times}(\mathscr{C}') \\ {\scriptstyle (-)^{\times}_{\mathscr{C}}}\downarrow & & \downarrow{\scriptstyle (-)^{\times}_{\mathscr{C}'}} \\ \mathsf{Gpd}(\mathscr{C}) & \xrightarrow{(\mathsf{U},\mathsf{V})\text{-}\mathsf{Gpd}(u)_!} & \mathsf{Gpd}(\mathscr{C}) \end{array} \tag{3.4.7}$$

where $(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}^{\times}(u)_!$ and $(\mathsf{U},\mathsf{V})\text{-}\mathsf{Gpd}(u)_!$ denote the restrictions of $(\mathsf{U},\mathsf{V})\text{-}\mathsf{Fib}(u)_!$.

Remark 3.4.8. Let $\mathscr{C}$, U and V be as in (3.4.4).

(i) It is easily seen that the pseudo-functor $(-)^{\times}_{\mathscr{C}}$ is a strong right 2-adjoint for the inclusion pseudo-functor $\mathsf{Gpd}(\mathscr{C}) \to \mathsf{Fib}^{\times}(\mathscr{C})$, and the counit of the resulting 2-adjunction assigns to every fibration $\mathscr{A} \to \mathscr{C}$ the inclusion functor $\mathscr{A}^{\times} \to \mathscr{A}$: details left to the reader.

(ii) Notice that a fibration $\pi : \mathscr{A} \to \mathscr{C}$ is a fibration in groupoids if and only if $\pi^{-1}X$ is a groupoid for every $X \in \mathrm{Ob}(\mathscr{C})$. Indeed, the condition is obviously necessary. Conversely, recall that every morphism f of $\mathscr{A}$ is the composition of a cartesian morphism and a morphism g such that $\pi(g) = \mathbf{1}_X$ for some $X \in \mathrm{Ob}(\mathscr{C})$; but if $\pi^{-1}X$ is a groupoid, then g is an isomorphism in $\mathscr{A}$, in particular it is cartesian, so the same holds for f, which shows that $\mathscr{A} = \mathscr{A}^\times$.

(iii) By the same token, to every pseudo-functor $F : \mathscr{C}^o \to \mathbf{Cat}$ we attach the pseudo-functor

$$F^\times : \mathscr{C}^o \to \mathbf{Cat} \qquad X \mapsto (FX)^\times$$

(whose coherence constraints are the same as those of F). Then we easily see that :

$$\mathscr{F}ib(F)^\times = \mathscr{F}ib(F^\times).$$

3.4.9. With the notation of (3.4.4), notice that for every presheaf $F \in \mathrm{Ob}(\mathscr{C}^\wedge_{\mathsf{U}})$, the fibration $\mathscr{F}ib_{\mathscr{C}}(F)$ is a fibration in groupoid, so we get a well defined strict pseudo-functor

$$\mathscr{F}ib_{\mathscr{C}} : \mathscr{C}^\wedge_{\mathsf{U}} \to (\mathsf{U},\mathsf{V})\text{-}\mathsf{Gpd}(\mathscr{C})$$

and by restriction, the pseudo-functor $\pi_0^{\mathscr{C}}$ (see (3.2.10)) yields a strong left 2-adjoint

$$\pi_0^{\mathscr{C}} : (\mathsf{U},\mathsf{V})\text{-}\mathsf{Gpd}(\mathscr{C}) \to \mathscr{C}^\wedge_{\mathsf{U}}.$$

Moreover, for every functor $u : \mathscr{C} \to \mathscr{C}'$, a simple inspection yields an essentially commutative diagram

$$\begin{array}{ccc}
\mathsf{Gpd}(\mathscr{C}') & \xrightarrow{\mathsf{Gpd}(u)^*} & \mathsf{Gpd}(\mathscr{C}) \\
{\scriptstyle \pi_0^{\mathscr{C}'}}\downarrow & & \downarrow{\scriptstyle \pi_0^{\mathscr{C}}} \\
\mathscr{C}'^\wedge_{\mathsf{U}} & \xrightarrow{u^\wedge_{\mathsf{U}}} & \mathscr{C}^\wedge_{\mathsf{U}}.
\end{array}$$

Furthermore, if $\mathscr{C}$ is U-small and $\mathscr{C}'$ is V-small with U-small Hom-sets, we also get the essentially commutative diagram :

$$(3.4.10) \qquad \begin{array}{ccc}
\mathsf{Gpd}(\mathscr{C}) & \xrightarrow{\mathsf{Gpd}(u)_!} & \mathsf{Gpd}(\mathscr{C}') \\
{\scriptstyle \pi_0^{\mathscr{C}}}\downarrow & & \downarrow{\scriptstyle \pi_0^{\mathscr{C}'}} \\
\mathscr{C}^\wedge_{\mathsf{U}} & \xrightarrow{u_{\mathsf{U}!}} & \mathscr{C}'^\wedge_{\mathsf{U}}.
\end{array}$$

Indeed, for every $X \in \mathrm{Ob}(\mathscr{C}')$ and every fibration $\mathscr{A}$ with essentially U-small fibres we have natural equivalences of categories :

$$(\pi_0^{\mathscr{C}'}\mathsf{Gpd}(u)_!\mathscr{A})(X) \xrightarrow{\sim} \pi_0((\mathsf{Fib}(u)_!\mathscr{A})(X)) \xrightarrow{\sim} \pi_0(\underset{X\to uY}{2\text{-colim}}\,\mathscr{A}(Y)) \xrightarrow{\sim} \underset{X\to uY}{2\text{-colim}}\,\pi_0(\mathscr{A}(Y))$$

since π_0 is a 2-left adjoint pseudo-functor (proposition 2.5.9(ii)). However, remark 2.5.2(vii) says that the 2-colimit of the (strict) pseudo-functor given by the rule $(X \to uY) \mapsto \pi_0(\mathscr{A}(Y))$ also represents the colimit of the same functor, in the category of U-small sets; on the other hand, the latter colimit is represented by $u_{\mathsf{U}!}(\pi_0^{\mathscr{C}}\mathscr{A})(X)$, whence the contention.

3.5. **Sieves and descent theory.** This section develops the basics of descent theory, in the general framework of fibred categories.

Definition 3.5.1. Let $\mathscr{B}$ and $\mathscr{C}$ be two categories, $F : \mathscr{B} \to \mathscr{C}$ a functor.

(i) A *sieve* of $\mathscr{C}$ is a full subcategory $\mathscr{S}$ of $\mathscr{C}$ such that the following holds. If $A \in \mathrm{Ob}(\mathscr{S})$, and $B \to A$ is any morphism in $\mathscr{C}$, then $B \in \mathrm{Ob}(\mathscr{S})$.

(ii) If $S \subset \mathrm{Ob}(\mathscr{C})$ is any subset, there is a smallest sieve $\mathscr{S}_S$ of $\mathscr{C}$ such that $S \subset \mathrm{Ob}(\mathscr{S}_S)$; we call $\mathscr{S}_S$ the *sieve generated by* S. If $S' \subset \mathrm{Ob}(\mathscr{C})$ is another subset and $\mathscr{S}_{S'} \subset \mathscr{S}_S$, we say that S' is a *refinement* of S.

(iii) If $\mathscr{S}$ is a sieve of $\mathscr{C}$, the *inverse image of* $\mathscr{S}$ *under* F is the full subcategory $F^{-1}\mathscr{S}$ of $\mathscr{B}$ with $\mathrm{Ob}(F^{-1}\mathscr{S}) = \{B \in \mathrm{Ob}(\mathscr{B}) \mid FB \in \mathrm{Ob}(\mathscr{S})\}$ (notice that $F^{-1}\mathscr{S}$ is a sieve).

(iv) If $f : X \to Y$ is any morphism in $\mathscr{C}$, and $\mathscr{S}$ is any sieve of $\mathscr{C}/Y$, we shall write $\mathscr{S} \times_Y f$ for the inverse image of $\mathscr{S}$ under the functor f_* (notation of (1.1.25)).

Remark 3.5.2. Let $\mathscr{C}$ be a category with small Hom-sets and X an object of $\mathscr{C}$.

(i) Every sieve $\mathscr{T}$ of $\mathscr{C}$ yields a subobject $F_{\mathscr{T}}$ of the final object $\mathbb{1}_{\mathscr{C}}$ of $\mathscr{C}^\wedge$, by declaring that $F_{\mathscr{T}}(Y) \neq \varnothing$ if and only if $Y \in \mathrm{Ob}(\mathscr{T})$; hence $F_{\mathscr{T}}(Y)$ is a set with one element for every $Y \in \mathrm{Ob}(\mathscr{T})$, and is empty for $Y \in \mathrm{Ob}(\mathscr{C}) \setminus \mathrm{Ob}(\mathscr{T})$. It is easily seen that the rule $\mathscr{T} \mapsto F_{\mathscr{T}}$ establishes a bijection between the set of sieves of $\mathscr{C}$ and the set of subobjects of $\mathbb{1}_{\mathscr{C}}$. The inverse mapping is given by the rule :

$$(F \subset \mathbb{1}_{\mathscr{C}}) \mapsto (\mathscr{F}ib(F) \subset \mathscr{F}ib(\mathbb{1}_{\mathscr{C}}) = \mathscr{C}).$$

(ii) For every sieve $\mathscr{S}$ of the category $\mathscr{C}/X$ we may then also consider the presheaf on $\mathscr{C}$

$$h_{\mathscr{S}} := \mathsf{s}_{X!}(F_{\mathscr{S}})$$

where $F_{\mathscr{S}}$ is the presheaf on $\mathscr{C}/X$ defined as in (i), and $\mathsf{s}_{X!} : (\mathscr{C}/X)^\wedge \to \mathscr{C}^\wedge$ is the left adjoint to the functor $\mathsf{s}_X^\wedge$ induced by the source functor $\mathsf{s}_X : \mathscr{C}/X \to \mathscr{C}$ (proposition 1.4.13(vi.a)). By proposition 1.4.13(vi.b,c), the presheaf $h_{\mathscr{S}}$ is a subobject of h_X (notation of (1.2.4)), and by inspecting (1.4.11) we see that

$$h_{\mathscr{S}}(Y) = \{f \in \mathrm{Hom}_{\mathscr{C}}(Y, X) \mid (Y, f) \in \mathrm{Ob}(\mathscr{S})\} \qquad \text{for every } Y \in \mathrm{Ob}(\mathscr{C}).$$

For a given morphism $f : Y' \to Y$ in $\mathscr{C}$, the map $h_{\mathscr{S}}(f)$ is just the restriction of $\mathrm{Hom}_{\mathscr{C}}(f, X)$. By the same token, it also follows that the rule $\mathscr{S} \mapsto h_{\mathscr{S}}$ sets up a natural bijection between the subobjects of h_X in $\mathscr{C}^\wedge$ and the sieves of $\mathscr{C}/X$. The inverse mapping is given by the rule :

$$(F \subset h_X) \mapsto (\mathscr{F}ib(F) \subset \mathscr{F}ib(h_X) = \mathscr{C}/X)$$

(see example 3.1.16(i)). Especially, the restriction $\mathscr{S} \to \mathscr{C}$ of the source functor $\mathsf{s}_X : \mathscr{C}/X \to \mathscr{C}$ is a fibration, and example 3.1.16(i) generalizes to a natural isomorphism of $\mathscr{C}$-fibrations :

$$\mathscr{F}ib(h_{\mathscr{S}}) \xrightarrow{\sim} \mathscr{S}.$$

Combining with lemma 1.4.8, we also deduce a natural isomorphism in $\mathscr{C}^\wedge$:

$$\operatorname*{colim}_{\mathscr{S}} h_{\mathscr{C}} \circ \mathsf{s}_{\mathscr{S}} \xrightarrow{\sim} h_{\mathscr{S}} \tag{3.5.3}$$

where $\mathsf{s}_{\mathscr{S}} : \mathscr{S} \to \mathscr{C}$ is the restriction of the source functor s_X of (1.1.24).

(iii) Let $S := \{X_i \to X \mid i \in I\}$ be any family of morphisms of $\mathscr{C}$. Then S generates a given sieve $\mathscr{S}$ of $\mathscr{C}/X$ if and only if :

$$h_{\mathscr{S}} = \bigcup_{i \in I} \mathrm{Im}(h_{X_i} \to h_X).$$

(Notice that the above union is well defined even in case I is not small.)

(iv) Moreover, if S as in (iii) generates $\mathscr{S}$ and $f : Y \to X$ is any morphism such that the fibre product $Y_i := Y \times_X X_i$ is representable in $\mathscr{C}$ for every $i \in I$, then $\mathscr{S} \times_X f$ is the sieve generated by the family of induced projections $\{Y_i \to Y \mid i \in I\} \subset \mathrm{Ob}(\mathscr{C}/Y)$.

(v) Furthermore, let $f : Y \to X$ be any morphism of $\mathscr{C}$; it is easily seen that the correspondence of (ii) induces a natural identification of subobjects of h_Y:

$$h_{\mathscr{S} \times_X f} = h_{\mathscr{S}} \times_{h_X} h_Y \qquad \text{for every sieve } \mathscr{S} \text{ of } \mathscr{C}/X.$$

Since the Yoneda embedding is fully faithful, we may sometimes abuse notation, to identify X with the corresponding representable presheaf h_X; then we may write $h_{\mathscr{S} \times_X f} = h_{\mathscr{S}} \times_X Y$. In view of (ii) we deduce an isomorphism of fibred $\mathscr{C}$-categories $\mathscr{F}ib(h_{\mathscr{S}} \times_X Y) \xrightarrow{\sim} \mathscr{S} \times_X f$. On the other hand, let $\pi : h_{\mathscr{S}} \times_X Y \to h_{\mathscr{S}}$ be the natural projection; a direct inspection shows that the foregoing isomorphisms fit into the commutative diagram :

$$\begin{array}{ccc} \mathscr{F}ib(h_{\mathscr{S}} \times_X Y) & \xrightarrow{\sim} & \mathscr{S} \times_X f \\ {\scriptstyle \mathscr{F}ib(\pi)} \downarrow & & \downarrow {\scriptstyle f_{*|\mathscr{S}}} \\ \mathscr{F}ib(h_{\mathscr{S}}) & \xrightarrow{\sim} & \mathscr{S} \end{array}$$

where the right vertical arrow is the restriction of the functor $f_* : \mathscr{C}/Y \to \mathscr{C}/X$ (details left to the reader). (Especially, $f_{*|\mathscr{S}}$ is a $\mathscr{C}$-cartesian functor, but this assertion is trivial, since every morphism of $\mathscr{C}/X$ is $\mathscr{C}$-cartesian).

3.5.4. Let $\mathscr{C}$ be a small category, and $\mathscr{S}$ the sieve of $\mathscr{C}$ generated by a subset $S \subset \mathrm{Ob}(\mathscr{C})$. Say that $S = \{S_i \mid i \in I\}$ for a small set I; for every $i \in I$ there is a faithful embedding $\varepsilon_i : \mathscr{C}/S_i \to \mathscr{S}$, and for every pair $(i, j) \in I \times I$, we define

$$\mathscr{C}/S_{ij} := \mathscr{C}/S_i \times_{(\varepsilon_i,\varepsilon_j)} \mathscr{C}/S_j$$

(notation of example 1.2.25(i)). Hence, the objects of $\mathscr{C}/S_{ij}$ are all the triples (X, g_i, g_j), where $X \in \mathrm{Ob}(\mathscr{C})$ and $g_l \in \mathrm{Hom}_{\mathscr{C}}(X, S_l)$ for $l = i, j$. The natural projections :

$$\pi^1_{ij*} : \mathscr{C}/S_{ij} \to \mathscr{C}/S_i \qquad \pi^0_{ij*} : \mathscr{C}/S_{ij} \to \mathscr{C}/S_j$$

are faithful embeddings. We deduce a natural diagram of categories :

$$\coprod_{(i,j)\in I\times I} \mathscr{C}/S_{ij} \overset{\partial_0}{\underset{\partial_1}{\rightrightarrows}} \coprod_{i\in I} \mathscr{C}/S_i \xrightarrow{\varepsilon} \mathscr{S}$$

where :

$$\partial_0 := \coprod_{(i,j)\in I\times I} \pi^0_{ij*} \qquad \partial_1 := \coprod_{(i,j)\in I\times I} \pi^1_{ij*} \qquad \varepsilon := \coprod_{i\in I} \varepsilon_i.$$

Remark 3.5.5. Notice that, under the current assumptions, the product $S_{ij} := S_i \times S_j$ is not necessarily representable in $\mathscr{C}$. In case it is, we may consider another category, also denoted $\mathscr{C}/S_{ij}$, namely the category of S_{ij}-objects of $\mathscr{C}$ (as in (1.1.24)). The latter is naturally isomorphic to the category with the same name introduced in (3.5.4). Moreover, under this natural isomorphism, the projections π^0_{ij*} and π^1_{ij*} are identified with the functors induced by the natural morphisms $\pi^0_{ij} : S_{ij} \to S_j$ and respectively $\pi^1_{ij} : S_{ij} \to S_i$. Hence, in this case, the notation of (3.5.4) is compatible with (1.1.25).

Lemma 3.5.6. *With the notation of* (3.5.4)*, the functor* ε *induces an isomorphism between* $\mathscr{S}$ *and the coequalizer (in the category* $\mathbf{Cat}$*) of the pair of functors* (∂_0, ∂_1)*.*

Proof. Let $\mathscr{A}$ be any other object of $\mathbf{Cat}$, and $F : \coprod_{i\in I} \mathscr{C}/S_i \to \mathscr{A}$ a functor such that $F \circ \partial_0 = F \circ \partial_1$. We have to show that F factors uniquely through ε. To this aim, we construct explicitly a functor $G : \mathscr{S} \to \mathscr{A}$ such that $G \circ \varepsilon = F$. First of all, by the universal property of the coproduct, F is the same as a family of functors $(F_i : \mathscr{C}/S_i \to \mathscr{A} \mid i \in I)$, and the assumption on F amounts to the system of identities :

$$F_i \circ \pi^1_{ij*} = F_j \circ \pi^0_{ij*} \qquad \text{for every } i, j \in I. \tag{3.5.7}$$

Hence, let $X \in \mathrm{Ob}(\mathscr{S})$; by assumption there exist $i \in I$ and a morphism $f : X \to S_i$ in $\mathscr{C}$, so we may set $GX := F_i f$. In case $g : X \to S_j$ is another morphism in $\mathscr{C}$, we deduce an object $h := (X, f, g) \in \mathrm{Ob}(\mathscr{C}/S_{ij})$, so $f = \pi^1_{ij*}h$ and $g = \pi^0_{ij*}h$; then (3.5.7) shows that $F_i f = F_j g$, *i.e.* GX is well-defined.

Next, let $\varphi : X \to Y$ be any morphism in $\mathscr{S}$; choose $i \in I$ and a morphism $f_Y : Y \to S_i$, and set $f_X := f_Y \circ \varphi$. We let $G\varphi := F_i(\varphi : f_X \to f_Y)$. Arguing as in the foregoing, one verifies easily that $G\varphi$ is independent of all the choices, and then it follows easily that $G(\psi \circ \varphi) = G\psi \circ G\varphi$ for every other morphism $\psi : Y \to Z$ in $\mathscr{S}$. It is also clear that $G\mathbf{1}_X = \mathbf{1}_{GX}$, whence the contention. □

3.5.8. In the situation of (3.5.4), suppose that the set of generators S is the whole of $\mathrm{Ob}(\mathscr{S})$; in this case, the augmentation ε can also be used to produce the following 2-categorical presentation of $\mathscr{S}$, which upgrades the isomorphism (3.5.3). Consider the strict pseudo-functor

$$G_{\mathscr{S}} : \mathscr{S} \to \mathsf{Fib}(\mathscr{C}) \quad : \quad Y \mapsto \mathscr{C}/Y \qquad (Z \xrightarrow{f} Y) \mapsto (\mathscr{C}/Z \xrightarrow{f_*} \mathscr{C}/Y).$$

We have a natural strict pseudo-cocone

$$\widehat{\varepsilon} : G_{\mathscr{S}} \Rightarrow \mathsf{F}_{\mathscr{S}}$$

where $\mathsf{F}_{\mathscr{S}}$ is the constant pseudo-functor $\mathscr{S} \to \mathsf{Fib}(\mathscr{C})$ with value $\mathscr{S}$, and $\widehat{\varepsilon}_X : \mathscr{C}/X \to \mathscr{S}$ is the faithful embedding as in (3.5.4), for every $X \in \mathrm{Ob}(\mathscr{S})$. We may then state :

Lemma 3.5.9. *The pseudo-cocone $\widehat{\varepsilon}$ induces an equivalence of fibrations over $\mathscr{C}$:*

$$2\text{-}\operatorname*{colim}_{\mathscr{S}} G_{\mathscr{S}} \xrightarrow{\sim} \mathscr{S}.$$

Proof. By theorem 3.3.25(ii), the 2-colimits are computed fibrewise in the 2-category $\mathsf{Fib}(\mathscr{C})$, so we are reduced to checking that $\widehat{\varepsilon}$ induces an equivalence of categories

$$2\text{-}\operatorname*{colim}_{\mathscr{S}} G_{\mathscr{S},X} \xrightarrow{\sim} \mathscr{S}_X \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C})$$

where $\mathscr{S}_X$ is the fibre category over X of the fibration $\mathscr{S} \to \mathscr{C}$, and $G_{\mathscr{S},X} : \mathscr{S} \to \mathbf{Cat}$ is the strict pseudo-functor that assigns to every $Y \in \mathrm{Ob}(\mathscr{S})$ the fibre category $(\mathscr{C}/Y)_X$ of the fibration $\mathscr{C}/Y \to \mathscr{C}$ (for every morphism $f : Z \to Y$ in $\mathscr{S}$, the corresponding functor $G_{\mathscr{S},X}(f)$ is the restriction of $G_{\mathscr{S}}(f) = f_*$). However, if $X \notin \mathrm{Ob}(\mathscr{S})$, the category $\mathscr{S}_X$ is empty, and $G_{\mathscr{S},X}$ is the constant pseudo-functor with value equal to the empty category, so the assertion is clear in this case. Suppose then that $X \in \mathrm{Ob}(\mathscr{S})$, in which case $\mathscr{S}_X$ is the category whose unique object is X and whose unique morphism is $\mathbf{1}_X$. Also, for every $Y \in \mathrm{Ob}(\mathscr{S})$, the category $(\mathscr{C}/Y)_X$ is discrete, with set of objects given by $\mathrm{Hom}_{\mathscr{C}}(X, Y)$. According to example 3.3.13(i), the strong 2-colimit of $G_{\mathscr{S},X}$ is represented by the category $\mathscr{F}ib(G_{\mathscr{S},X})[\Sigma^{-1}]$, where Σ is the set of cartesian morphisms of the fibration $\mathscr{F}ib(G_{\mathscr{S},X}) \to \mathscr{S}^o$. Now, it is easily seen that $\mathscr{F}ib(G_{\mathscr{S},X}) = (X/\mathscr{S})^o = \mathscr{S}^o/X^o$, with structure functor given by the usual source functor $\mathscr{S}^o/X^o \to \mathscr{S}^o$. Hence, Σ is the set of all morphisms of $\mathscr{C}^o/X^o$, and since $\mathscr{C}^o/X^o$ has the final object $\mathbf{1}_{X^o}$, the assertion follows easily from example 1.6.12. □

Definition 3.5.10. Let $\varphi : \mathscr{A} \to \mathscr{B}$ be a fibration, $B \in \mathrm{Ob}(\mathscr{B})$ an object, $\mathscr{S} \subset \mathscr{B}/B$ a sieve, $i \in \{0, 1, 2\}$, and denote by $\iota_{\mathscr{S}} : \mathscr{S} \to \mathscr{B}/B$ the fully faithful embedding.

(i) We say that $\mathscr{S}$ is a *sieve of φ-i-descent*, if the restriction functor :

$$\mathsf{Cart}_{\mathscr{B}}(\iota_{\mathscr{S}}, \mathscr{A}) : \mathscr{A}(B) \to \mathsf{Cart}_{\mathscr{B}}(\mathscr{S}, \mathscr{A})$$

is i-faithful (see remark 1.1.5).

(ii) We say that $\mathscr{S}$ is a *sieve of universal φ-i-descent* if the sieve $\mathscr{S} \times_B f$ is of φ-i-descent for every morphism $f : B' \to B$ of $\mathscr{B}$ (notation of definition 3.5.1(iv)).

(iii) Let $f : B' \to B$ be a morphism in $\mathscr{B}$. We say that f is a *morphism of φ-i-descent* (resp. a *morphism of universal φ-i-descent*), if the sieve generated by $\{f\}$ is of φ-i-descent (resp. of universal φ-i-descent).

Remark 3.5.11. In the situation of definition 3.5.10, suppose that $\mathscr{S}$ is the sieve generated by a set of objects $\{S_i \to B \mid i \in I\} \subset \mathrm{Ob}(\mathscr{B}/B)$. There follows a natural diagram of categories (notation of (3.5.4)) :

$$\mathsf{Cart}_{\mathscr{B}}(\mathscr{S},\mathscr{A}) \xrightarrow{\varepsilon^*} \prod_{i\in I} \mathscr{A}(S_i) \underset{\partial_1^*}{\overset{\partial_0^*}{\rightrightarrows}} \prod_{(i,j)\in I\times I} \mathsf{Cart}_{\mathscr{B}}(\mathscr{B}/S_{ij},\mathscr{A})$$

where $\varepsilon^* := \mathsf{Cart}_{\mathscr{B}}(\varepsilon,\mathscr{A})$ and $\partial_i^* := \mathsf{Cart}_{\mathscr{B}}(\partial_i,\mathscr{A})$, for $i = 0, 1$. With this notation, lemma 3.5.6 easily implies that ε^* induces an isomorphism between $\mathsf{Cart}_{\mathscr{B}}(\mathscr{S},\mathscr{A})$ and the equalizer (in the category $\mathbf{Cat}$) of the pair of functors $(\partial_0^*, \partial_1^*)$.

3.5.12. We would like to exploit the presentation of $\mathsf{Cart}_{\mathscr{B}}(\mathscr{S},\mathscr{A})$ in remark 3.5.11, in order to translate definition 3.5.10 in terms of the fibre categories $\mathscr{A}_{S_i}$ and $\mathscr{A}_{S_{ij}}$. The problem is that such a translation must be carried out via a pseudo-natural equivalence (namely ev), and such equivalences do not respect a presentation as above in terms of equalizers in the category $\mathbf{Cat}$. What we need is to upgrade our presentation of $\mathscr{S}$ to a new one, which is preserved by pseudo-natural transformations. This is achieved as follows. Resume the general situation of (3.5.4). For every $i, j, k \in I$, set $\mathscr{C}/S_{ijk} := \mathscr{C}/S_{ij} \times_{\mathscr{C}} \mathscr{C}/S_k$. We have a natural diagram of categories :

$$\coprod_{(i,j,k)\in I^3} \mathscr{C}/S_{ijk} \overset{\partial_0'}{\underset{\partial_2'}{\overset{\partial_1'}{\rightrightarrows\!\!\!\to}}} \coprod_{(i,j)\in I^2} \mathscr{C}/S_{ij} \underset{\partial_1}{\overset{\partial_0}{\rightrightarrows}} \coprod_{i\in I} \mathscr{C}/S_i \xrightarrow{\varepsilon} \mathscr{S} \qquad (3.5.13)$$

where ∂_0' is the coproduct of the natural projections $\pi^0_{ijk*} : \mathscr{C}/S_{ijk} \to \mathscr{C}/S_{jk}$ for every $i, j, k \in I$, and likewise ∂_1' (resp. ∂_2') is the coproduct of the projections $\pi^1_{ijk*} : \mathscr{C}/S_{ijk} \to \mathscr{C}/S_{ik}$ (resp. $\pi^2_{ijk*} : \mathscr{C}/S_{ijk} \to \mathscr{C}/S_{ij}$). We can view (3.5.13) as an *augmented* 2*-truncated semi-simplicial object* in $\mathsf{Fib}(\mathscr{C})$, *i.e.* a functor :

$$F_{\mathscr{S}} : \Sigma_2^{+o} \to \mathsf{Fib}(\mathscr{C})$$

from the opposite of the category Σ_2^+ whose objects are the ordered sets $[-1]$, $[0]$, $[1]$ and $[2]$, and whose morphisms are the non-decreasing injective maps (this is a subcategory of the category $\Delta_2^\wedge$ of definition 7.4.1(iii)).

Remark 3.5.14. Suppose that finite products are representable in $\mathscr{B}$, and for every $i, j, k \in I$, set $S_{ij} := S_i \times S_j$, and $S_{ijk} := S_{ij} \times S_k$. Just as in remark 3.5.5, the category $\mathscr{C}/S_{ijk}$ of S_{ijk}-objects of $\mathscr{C}$ is naturally isomorphic to the category with the same name introduced in (3.5.12), and under this isomorphism, the functors π^0_{ijk*} are identified with the functors arising from the natural projections $\pi^0_{ijk} : S_{ijk} \to S_{jk}$ (and likewise for π^1_{ijk*} and π^2_{ijk*}).

With this notation, denote by Σ_2 the full subcategory of Σ_2^+ whose objects are the non-empty sets; we have the following 2-category analogue of lemma 3.5.6 :

Proposition 3.5.15. *The augmentation ε induces an equivalence of categories :*

$$2\text{-}\operatorname*{colim}_{\Sigma_2^o} F_{\mathscr{S}} \xrightarrow{\sim} \mathscr{S}.$$

Proof. By theorem 3.3.25(ii), the 2-colimits are computed fibrewise in the 2-category $\mathsf{Fib}(\mathscr{C})$, so we are reduced to checking that ε induces an equivalence of categories

$$2\text{-}\operatorname*{colim}_{\Sigma_2^o} F_{\mathscr{S},X} \xrightarrow{\sim} \mathscr{S}_X \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C})$$

where $\mathscr{S}_X$ is the fibre category over X of the fibration $\mathscr{S} \to \mathscr{C}$, and $F_{\mathscr{S},X} := \mathsf{fib}_X \circ F_{\mathscr{S}}$, where $\mathsf{fib}_X : \mathsf{Fib}(\mathscr{C}) \to \mathbf{Cat}$ is defined as in (3.3.24). Now, if $X \notin \mathrm{Ob}(\mathscr{S})$, the category $\mathscr{S}_X$ is empty, and $\mathsf{fib}_X \circ F_{\mathscr{S}}$ is the constant pseudo-functor with value equal to the empty category, so the assertion trivially holds in this case. Suppose then that $X \in \mathrm{Ob}(\mathscr{S})$, in which case $\mathscr{S}_X$ is the category whose unique object is X and whose unique morphism is $\mathbf{1}_X$. Set

$$T := \coprod_{i\in I} \mathrm{Hom}_{\mathscr{C}}(X, S_i)$$

and notice that $F_{\mathscr{S},J}[0], F_{\mathscr{S},J}[1]$ and $F_{\mathscr{S},J}[2]$ are the discrete categories whose sets of objects are respectively T, $T\times T$ and $T\times T\times T$. Moreover, the strict pseudo-functor $F_{\mathscr{S},X}$ corresponds to the 2-truncated semi-simplicial diagram of sets :

$$T\times T\times T \underset{\partial'_2}{\overset{\partial'_0}{\rightrightarrows}}\!\!\xrightarrow{\partial'_1} T\times T \underset{\partial_1}{\overset{\partial_0}{\rightrightarrows}} T \tag{3.5.16}$$

whose maps ∂_i and ∂'_i are the natural projections. To conclude, it therefore suffices to show :

Claim 3.5.17. For every set $T\neq\varnothing$, the 2-colimit in the 2-category $\mathbf{Cat}$ of the system of discrete categories (3.5.16) is represented by the discrete category with one object.

Proof of the claim. The diagram (3.5.16) can be regarded as a presheaf $T_\bullet$ on the category Σ_2, and according to example 3.3.13(i), the strong 2-colimit of $T_\bullet$ is represented by the category $\mathscr{T} := \mathscr{F}ib(T_\bullet)[\Lambda^{-1}]$, where Λ is the set of cartesian morphisms of the fibration $\mathscr{F}ib(T_\bullet)\to\Sigma_2$; but every morphism of $\mathscr{F}ib(T_\bullet)$ is cartesian (see (3.1.15)). Denote by $\mathscr{T}_0$ the category with $\mathrm{Ob}(\mathscr{T}_0) = T$, and such that $\mathrm{Hom}_{\mathscr{T}_0}(t,t')$ contains a unique element $\tau_{t,t'}$, for every $t,t'\in T$. We define a functor $q:\mathscr{T}_0\to\mathscr{T}$ as follows. Recall that the objects of $\mathscr{F}ib(T_\bullet)$ are the pairs $(j,\underline{t})$, where $j\in\{0,1,2\}$ and $\underline{t}\in T^{j+1}$. For every $\underline{t} := (t_0,t_1)\in T\times T$ we have morphisms $(0,t_1)\xleftarrow{\delta_{0,\underline{t}}}(1,\underline{t})\xrightarrow{\delta_{1,\underline{t}}}(0,t_0)$ in $\mathscr{F}ib(T_\bullet)$, and we set

$$q(t_0) := (0,t_0) \quad\text{and}\quad q(\tau_{t_0,t_1}) := [\delta_{0,(t_0,t_1)}]\circ[\delta_{1,(t_0,t_1)}]^{-1} \qquad \text{for every } t_0,t_1\in T$$

where we denote by $[f]$ the image in $\mathscr{T}$ of every morphism f of $\mathscr{F}ib(T_\bullet)$. Indeed, for every $\underline{t} := (t_0,t_1,t_2)\in T^3$ and $j = 0,1,2$, we have as well morphisms $\delta'_{j,\underline{t}} : (2,\underline{t})\to(1,\partial'_j(\underline{t}))$ in $\mathscr{F}ib(T_\bullet)$, and we may compute :

$$\begin{aligned} q(\tau_{t_1,t_2})\circ q(\tau_{t_0,t_1}) &= [\delta_{0,\partial'_0\underline{t}}]\circ[\delta_{1,\partial'_0\underline{t}}]^{-1}\circ[\delta_{0,\partial'_2\underline{t}}]\circ[\delta_{1,\partial'_2\underline{t}}]^{-1} \\ &= [\delta_{0,\partial'_0\underline{t}}]\circ[\delta'_{0,\underline{t}}]\circ[\delta'_{0,\underline{t}}]^{-1}\circ[\delta_{1,\partial'_0\underline{t}}]^{-1}\circ[\delta_{0,\partial'_2\underline{t}}]\circ[\delta'_{2,\underline{t}}]\circ[\delta'_{2,\underline{t}}]^{-1}\circ[\delta_{1,\partial'_2\underline{t}}]^{-1} \\ &= [\delta_{0,\partial'_0\underline{t}}]\circ[\delta'_{0,\underline{t}}]\circ[\delta'_{0,\underline{t}}]^{-1}\circ[\delta_{1,\partial'_0\underline{t}}]^{-1}\circ[\delta_{1,\partial'_0\underline{t}}]\circ[\delta'_{0,\underline{t}}]\circ[\delta'_{1,\underline{t}}]^{-1}\circ[\delta_{1,\partial'_1\underline{t}}]^{-1} \\ &= [\delta_{0,\partial'_0\underline{t}}]\circ[\delta'_{0,\underline{t}}]\circ[\delta'_{1,\underline{t}}]^{-1}\circ[\delta_{1,\partial'_1\underline{t}}]^{-1} \\ &= [\delta_{0,\partial'_1\underline{t}}]\circ[\delta'_{1,\underline{t}}]\circ[\delta'_{1,\underline{t}}]^{-1}\circ[\delta_{1,\partial'_1\underline{t}}]^{-1} \\ &= q(\tau_{t_0,t_2}) \end{aligned}$$

as required. Next, let also $q':\mathscr{T}\to\mathscr{T}_0$ be the unique functor given by the rules :

$$(0,t_0)\mapsto t_0 \qquad (1,(t_0,t_1))\mapsto t_0 \qquad (2,(t_0,t_1,t_2))\mapsto t_0 \qquad \text{for every } t_0,t_1,t_2\in T.$$

Obviously $q'\circ q = \mathbf{1}_{\mathscr{T}_0}$. Let $L:\mathscr{F}ib(T_\bullet)\to\mathscr{T}$ be the localization; to conclude, it suffices to exhibit an isomorphism of functors $\mathbf{1}_{\mathscr{T}}\xrightarrow{\sim} q\circ q'$, and corollary 1.6.11 further reduces to exhibiting an isomorphism $\omega : L\xrightarrow{\sim} q\circ q'\circ L$. We define ω by the rules :

$$(0,t_0)\mapsto\mathbf{1}_{(0,t_0)} \qquad (1,(t_0,t_1))\mapsto[\delta_{1,(t_0,t_1)}] \qquad (2,(t_0,t_1,t_2))\mapsto[\delta_{1,(t_0,t_2)}\circ\delta'_{2,(t_0,t_1,t_2)}]$$

for every $t_0,t_1,t_2\in T$. The naturality of ω follows by a straightforward verification. □

3.5.18. Resume the situation of remark 3.5.11, and notice that all the categories appearing in (3.5.13) are fibred over $\mathscr{B}$: indeed, every morphism in each of these categories is cartesian, hence all the functors appearing in (3.5.13) are cartesian. Let us consider now the functor :

$$\mathsf{Cart}_{\mathscr{B}}(-,\mathscr{A}) : (\mathbf{Cat}/\mathscr{B})^o \to \mathbf{Cat}$$

that assigns to every $\mathscr{B}$-category $\mathscr{C}$ the category $\mathsf{Cart}_{\mathscr{B}}(\mathscr{C},\mathscr{A})$. With the notation of remark 3.5.11, we deduce a functor :

$$\mathsf{Cart}_{\mathscr{B}}(F_{\mathscr{S}},\mathscr{A}) : \Sigma_2^+ \to \mathbf{Cat}$$

and in light of the foregoing observations, proposition 3.5.15 easily implies that $\mathsf{Cart}_{\mathscr{B}}(\varepsilon,\mathscr{A})$ induces an equivalence of categories :

$$2\text{-}\lim_{\Sigma_2} \mathsf{Cart}_{\mathscr{B}}(F_{\mathscr{S}},\mathscr{A}) \xrightarrow{\sim} \mathsf{Cart}_{\mathscr{B}}(\mathscr{S},\mathscr{A}). \qquad (3.5.19)$$

Next, suppose that the fibre products $S_{ij} := S_i \times S_j$ and $S_{ijk} := S_{ij} \times S_k$ are representable in $\mathscr{B}$ (see remark 3.5.14); in this case, we may compose with the pseudo-equivalence $\mathsf{ev}^{\mathscr{A}}_{|\bullet}$ of remark 3.2.9(i) : combining with lemma 2.5.3 we finally obtain an equivalence between the category $\mathsf{Cart}_{\mathscr{B}}(\mathscr{S},\mathscr{A})$, and the 2-limit of the pseudo-functor $\mathsf{d} := \mathsf{ev} \circ \mathsf{Cart}_{\mathscr{B}}(F_{\mathscr{S}},\mathscr{A}) : \Sigma_2 \to \mathbf{Cat}$:

$$\prod_{i\in I} \mathscr{A}_{S_i} \overset{\partial^0}{\underset{\partial^1}{\rightrightarrows}} \prod_{(i,j)\in I^2} \mathscr{A}_{S_{ij}} \overset{\partial^0,\ \partial^1}{\underset{\partial^2}{\rightrightarrows}} \prod_{(i,j,k)\in I^3} \mathscr{A}_{S_{ijk}}.$$

Of course, the coface operators ∂^s on $\prod_{i\in I} \mathscr{A}_{S_i}$ decompose as products of pull-back functors:

$$\pi^{0*}_{ij} : \mathscr{A}_{S_j} \to \mathscr{A}_{S_{ij}} \qquad \pi^{1*}_{ij} : \mathscr{A}_{S_i} \to \mathscr{A}_{S_{ij}}$$

attached – via the chosen cleavage c of φ – to the projections $\pi^0_{ij} : S_{ij} \to S_j$ and $\pi^1_{ij} : S_{ij} \to S_i$ (and likewise for the components π^{t*}_{ijk} of the other coface operators).

3.5.20. By inspecting the proof of theorem 3.3.9, we may give the following explicit description of this 2-limit. Namely, it is the category whose objects are the data

$$\underline{X} := (X_i, X_{ij}, X_{ijk}, \xi^u_i, \xi^s_{ij}, \xi^t_{ijk} \mid i,j,k \in I; s \in \{0,1\}; u,t \in \{0,1,2\})$$

where :

$$X_i \in \mathrm{Ob}(\mathscr{A}_{S_i}) \quad X_{ij} \in \mathrm{Ob}(\mathscr{A}_{S_{ij}}) \quad X_{ijk} \in \mathrm{Ob}(\mathscr{A}_{S_{ijk}}) \qquad \text{for every } i,j,k \in I$$

and for every $i,j,k \in I$:

$$\begin{array}{lll} \xi^0_i : (\pi^1_{ik}\pi^1_{ijk})^* X_i \xrightarrow{\sim} X_{ijk} & \xi^0_{ij} : \pi^{0*}_{ij} X_j \xrightarrow{\sim} X_{ij} & \xi^0_{ijk} : \pi^{0*}_{ijk} X_{jk} \xrightarrow{\sim} X_{ijk} \\ \xi^1_j : (\pi^1_{jk}\pi^0_{ijk})^* X_j \xrightarrow{\sim} X_{ijk} & \xi^1_{ij} : \pi^{1*}_{ij} X_i \xrightarrow{\sim} X_{ij} & \xi^1_{ijk} : \pi^{1*}_{ijk} X_{ik} \xrightarrow{\sim} X_{ijk} \\ \xi^2_k : (\pi^0_{jk}\pi^0_{ijk})^* X_k \xrightarrow{\sim} X_{ijk} & & \xi^2_{ijk} : \pi^{2*}_{ijk} X_{ij} \xrightarrow{\sim} X_{ijk} \end{array}$$

are isomorphisms related by the cosimplicial identities :

$$\begin{array}{ll} \xi^0_{ijk} \circ \pi^{0*}_{ijk}\xi^0_{jk} = \xi^2_k \circ \gamma^{00}_X & \xi^1_{ijk} \circ \pi^{1*}_{ijk}\xi^0_{ik} = \xi^2_k \circ \gamma^{01}_X \\ \xi^2_{ijk} \circ \pi^{2*}_{ijk}\xi^0_{ij} = \xi^1_j \circ \gamma^{02}_X & \xi^0_{ijk} \circ \pi^{0*}_{ijk}\xi^1_{jk} = \xi^1_j \circ \gamma^{10}_X \\ \xi^2_{ijk} \circ \pi^{2*}_{ijk}\xi^1_{ij} = \xi^0_i \circ \gamma^{12}_X & \xi^1_{ijk} \circ \pi^{1*}_{ijk}\xi^1_{ik} = \xi^0_i \circ \gamma^{11}_X \end{array}$$

where $\gamma^{st} := \gamma_{\mathsf{d}(\partial^s),\mathsf{d}(\partial^t)} : \mathsf{d}(\partial^s) \circ \mathsf{d}(\partial^t) \Rightarrow \mathsf{d}(\partial^s \circ \partial^t)$ denotes the coherence constraint of the cleavage c, for any pair of arrows (∂^s, ∂^t) in the category Σ_2. The morphisms $\underline{X} \to \underline{Y}$ in this category are the systems of morphisms :

$$(X_i \to Y_i, X_{ij} \to Y_{ij}, X_{ijk} \to Y_{ijk} \mid i,j,k \in I)$$

that are compatible in the obvious way with the various isomorphisms. However, one may argue as in the proof of proposition 3.5.15, to replace this category by an equivalent one which admits a handier description : given a datum $\underline{X}$, one can make up an isomorphic datum $\underline{X}^* := (X_i, X^*_{ij}, X^*_{ijk}, \eta_i, \eta_{ij}, \eta_{ijk})$, by the rule :

$$X^*_{ij} := \pi^{1*}_{ij} X_i \qquad X^*_{ijk} := (\pi^1_{ik} \circ \pi^1_{ijk})^* X_i$$

$$\begin{array}{lll} \eta^0_i := \mathbf{1} & \eta^1_{ij} := \mathbf{1} & \eta^0_{ijk} := \eta^1_j \circ \gamma^{10}_X \\ \eta^1_j := (\xi^0_i)^{-1} \circ \xi^1_j & \eta^0_{ij} := (\xi^1_{ij})^{-1} \circ \xi^0_{ij} & \eta^1_{ijk} := \gamma^{11}_X \\ \eta^2_k := (\xi^0_i)^{-1} \circ \xi^2_k & & \eta^2_{ijk} := \gamma^{12}_X. \end{array}$$

The cosimplicial identities for this new object are subsumed into a single cocycle identity for $\omega_{ij} := \eta^0_{ij}$. Summing up, we arrive at the following description of our 2-limit :

- The objects are all the systems $\underline{X} := (X_i, \omega^X_{ij} \mid i, j \in I)$ where $X_i \in \mathrm{Ob}(\mathscr{A}_{S_i})$ for every $i \in I$, and
$$\omega^X_{ij} : \pi^{0*}_{ij} X_j \xrightarrow{\sim} \pi^{1*}_{ij} X_i$$
is an isomorphism in $\mathscr{A}_{S_{ij}}$, for every $i, j \in I$, fulfilling the cocycle identity :
$$p^{2*}_{ijk}\omega^X_{ij} \circ p^{0*}_{ijk}\omega^X_{jk} = p^{1*}_{ijk}\omega^X_{ik} \qquad \text{for every } i, j, k \in I$$
where, for every $i, j, k \in I$, and $t = 0, 1, 2$ we have set :
$$p^{t*}_{ijk}\omega^X_{\bullet\bullet} := \gamma^{1t}_X \circ \pi^{t*}_{ijk}\omega^X_{\bullet\bullet} \circ (\gamma^{0t}_X)^{-1}.$$
- The morphisms $\underline{X} \to \underline{Y}$ are the systems of morphisms $(f_i : X_i \to Y_i \mid i \in I)$ with :

(3.5.21) $$\omega^Y_{ij} \circ \pi^{0*}_{ij} f_j = \pi^{1*}_{ij} f_i \circ \omega^X_{ij} \qquad \text{for every } i, j \in I.$$

3.5.22. We shall call any pair $(X_\bullet, \omega_\bullet)$ of the above form, a *descent datum for the fibration* φ, *relative to the family* $\underline{S} := (\pi_i : S_i \to B \mid i \in I)$ *and the cleavage* c. The category of such descent data shall be denoted:

$$\mathsf{Desc}(\varphi, \underline{S}, \mathsf{c}).$$

Sometimes we may also denote it by $\mathsf{Desc}(\mathscr{A}, \underline{S}, \mathsf{c})$, if the notation is not ambiguous. Of course, two different choices of cleavage lead to equivalent categories of descent data, so usually we omit mentioning explicitly c, and write simply $\mathsf{Desc}(\varphi, \underline{S})$ or $\mathsf{Desc}(\mathscr{A}, \underline{S})$. The foregoing discussion can be summarized, by saying that there is a commutative diagram of categories :

(3.5.23) $$\begin{array}{ccc} \mathscr{A}(B) & \xrightarrow{\mathsf{Cart}_{\mathscr{B}}(\iota_{\mathscr{S}}, \mathscr{A})} & \mathsf{Cart}_{\mathscr{B}}(\mathscr{S}, \mathscr{A}) \\ {\scriptstyle \mathsf{ev}_B}\downarrow & & \downarrow{\scriptstyle \delta_{\underline{S}}} \\ \mathscr{A}_B & \xrightarrow{\rho_{\underline{S}}} & \mathsf{Desc}(\varphi, \underline{S}, \mathsf{c}) \end{array}$$

whose vertical arrows are equivalences, and where $\rho_{\underline{S}}$ is determined by c. Explicitly, $\rho_{\underline{S}}$ assigns to every $C \in \mathrm{Ob}(\mathscr{A}_B)$ the pair $(C_\bullet, \omega^C_\bullet)$ where $C_i := \pi^*_i C$, and ω^C_{ij} is the composition :

$$\pi^{0*}_{ij} \circ \pi^*_j C \xrightarrow[\sim]{\gamma_{(\pi^0_{ij}, \pi_j)}} (\pi_j \circ \pi^0_{ij})^* C = (\pi_i \circ \pi^1_{ij})^* C \xrightarrow[\sim]{\gamma^{-1}_{(\pi^1_{ij}, \pi_i)}} \pi^{1*}_{ij} \circ \pi^*_i C$$

where $\gamma_{(\pi^1_{ij}, \pi_i)}$ and $\gamma_{(\pi^0_{ij}, \pi_j)}$ are the coherence constraints for the cleavage c (see (3.1.6)). The descent datum $(X_\bullet, \omega_\bullet)$ is said to be *effective*, if it lies in the essential image of $\rho_{\underline{S}}$.

We also have an obvious functor :

$$\mathsf{p}_{\underline{S}} : \mathsf{Desc}(\varphi, \underline{S}) \to \prod_{i \in I} \mathscr{A}_{S_i} \qquad (X_i, \omega_{ij} \mid i, j \in I) \mapsto (X_i \mid i \in I)$$

such that :

$$\mathsf{p}_{\underline{S}} \circ \rho_{\underline{S}} = \prod_{i \in I} \pi^*_i : \mathscr{A}_B \to \prod_{i \in I} \mathscr{A}_{S_i}.$$

3.5.24. Furthermore, for every morphism $f : B' \to B$ in $\mathscr{B}$, set

$$\underline{S} \times_B f := (\pi_i \times_B B' : S_i \times_B B' \to B' \mid i \in I)$$

which is a generating family for the sieve $\mathscr{S} \times_B f$ (notation of (1.1.24)); then we deduce a pseudo-natural transformation of pseudo-functors $(\mathscr{B}/B)^o \to \mathbf{Cat}$:

$$\rho : \mathsf{c} \circ i_B^o \Rightarrow \mathsf{Desc}(\varphi, \underline{S} \times_B -, \mathsf{c}) \qquad (f : B' \to B) \mapsto \rho_{\underline{S}\times_B f}$$

(where $\mathsf{s}_B : \mathscr{B}/B \to \mathscr{B}$ is the source functor of (1.1.24)) fitting into a commutative diagram :

$$\begin{array}{ccc} \mathscr{A}(-) \circ \mathsf{s}_B^o & \stackrel{\mathsf{Cart}_{\mathscr{B}}(\iota_{\mathscr{S}\times_B -}, \mathscr{A})}{\Longrightarrow} & \mathsf{Cart}_{\mathscr{B}}(\mathscr{S} \times_B -, \mathscr{A}) \\ {\scriptstyle \mathsf{ev}*\mathsf{s}_B^o}\Downarrow & & \Downarrow{\scriptstyle \delta_{\underline{S}\times_B -}} \\ \mathsf{c} \circ \mathsf{s}_B^o & \stackrel{\rho}{\Longrightarrow} & \mathsf{Desc}(\varphi, \underline{S} \times_B -, \mathsf{c}) \end{array}$$

using which, one can figure out the pseudo-functoriality of the rule : $f \mapsto \mathsf{Desc}(\varphi, \underline{S} \times_B f, \mathsf{c})$. Namely, every pair of objects $f : C \to B$ and $f' : C' \to B$, and any morphism $h : C' \to C$ in $\mathscr{B}/B$, yield a commutative diagram :

$$\begin{array}{ccccccc} S_j \times_B C' & \xleftarrow{\widetilde{\pi}^0_{ij}} & S_{ij} \times_B C' & \xrightarrow{\widetilde{\pi}^1_{ij}} & S_i \times_B C' & \xrightarrow{\widetilde{\pi}_i} & C' \\ {\scriptstyle h_j := S_j \times_B h}\downarrow & & {\scriptstyle h_{ij} := S_{ij} \times_B h}\downarrow & & \downarrow{\scriptstyle h_i := S_i \times_B h} & & \downarrow{\scriptstyle h} \\ S_j \times_B C & \xleftarrow[\pi^0_{ij}]{} & S_{ij} \times_B C & \xrightarrow[\pi^1_{ij}]{} & S_i \times_B C & \xrightarrow[\pi_i]{} & C. \end{array}$$

Hence one obtains a functor :

$$\mathsf{Desc}(\varphi, h, \mathsf{c}) : \mathsf{Desc}(\varphi, \underline{S} \times_B f, \mathsf{c}) \to \mathsf{Desc}(\varphi, \underline{S} \times_B f', \mathsf{c})$$

by the rule :

$$(X_i, \omega^X_{ij} \mid i, j \in I) \mapsto (h_i^* X_i, \widetilde{\omega}^X_{ij} \mid i, j \in I)$$

where $\widetilde{\omega}^X_{ij}$ is the isomorphism that makes commute the diagram :

$$\begin{array}{ccccc} h_{ij}^* \pi^{0*}_{ij} X_j & \xrightarrow{\gamma_{(h_{ij}, \pi^0_{ij})}} & (\pi^0_{ij} \circ h_{ij})^* X_j & \xleftarrow{\gamma_{(\widetilde{\pi}^0_{ij}, h_j)}} & \widetilde{\pi}^{0*}_{ij} \circ h_j^* X_j \\ {\scriptstyle h_{ij}^* \omega_{ij}}\downarrow & & & & \downarrow{\scriptstyle \widetilde{\omega}^X_{ij}} \\ h_{ij}^* \pi^{1*}_{ij} X_i & \xrightarrow{\gamma_{(h_{ij}, \pi^1_{ij})}} & (\pi^1_{ij} \circ h_{ij})^* X_i & \xleftarrow{\gamma_{(\widetilde{\pi}^1_{ij}, h_i)}} & \widetilde{\pi}^{1*}_{ij} \circ h_i^* X_i \end{array}$$

and if $f'' : C'' \to B$ is a third object, with a morphism $g : C'' \to C'$, we have a natural isomorphism of functors :

$$\mathsf{Desc}(\varphi, g, \mathsf{c}) \circ \mathsf{Desc}(\varphi, h, \mathsf{c}) \Rightarrow \mathsf{Desc}(\varphi, h \circ g, \mathsf{c})$$

which is induced by the cleavage c, in the obvious fashion.

Theorem 3.5.25. *For $i = 1, 2$, let $\varphi_i : \mathscr{A}_i \to \mathscr{B}$ be two fibrations, $F : \mathscr{A}_1 \to \mathscr{A}_2$ a cartesian functor of $\mathscr{B}$-categories, B an object of $\mathscr{B}$ and $\mathscr{S}$ a sieve of $\mathscr{B}/B$ generated by the family $(S_i \to B \mid i \in I)$. We assume that S_{ij} and S_{ijk} are representable in $\mathscr{B}$, for every $i, j, k \in I$ (see remark* 3.5.14*); then we have :*

(i) *For $n \in \{0, 1, 2\}$ and every $i, j, k \in I$, suppose that*
  (a) *$\mathscr{S}$ is a sieve both of φ_1-n-descent and of φ_2-$(n-1)$-descent.*
  (b) *The restriction $F_i : \varphi_1^{-1} S_i \to \varphi_2^{-1} S_i$ of F is n-faithful.*
  (c) *The restriction $F_{ij} : \varphi_1^{-1} S_{ij} \to \varphi_2^{-1} S_{ij}$ of F is $(n-1)$-faithful.*
  (d) *The restriction $F_{ijk} : \varphi_1^{-1} S_{ijk} \to \varphi_2^{-1} S_{ijk}$ of F is $(n-2)$-faithful.*

Then the restriction $F_B : \varphi_1^{-1} B \to \varphi_2^{-1} B$ of F is n-faithful.

(ii) *Suppose that the functors F_{ij} are fully faithful, and the functors F_{ijk} are faithful, for every $i, j, k \in I$. Then the natural commutative diagram*

$$\begin{array}{ccc} \mathsf{Cart}_{\mathscr{B}}(\mathscr{S}, \mathscr{A}_1) & \xrightarrow{\mathsf{Cart}_{\mathscr{B}}(\mathscr{S}, F)} & \mathsf{Cart}_{\mathscr{B}}(\mathscr{S}, \mathscr{A}_2) \\ \downarrow & & \downarrow \\ \prod_{i \in I} \varphi_1^{-1} S_i & \xrightarrow{\prod_{i \in I} F_i} & \prod_{i \in I} \varphi_2^{-1} S_i \end{array}$$

is 2*-cartesian.*

Proof. (i): In view of theorem 3.2.7, we may assume that both $\mathscr{A}_1$ and $\mathscr{A}_2$ are split fibrations (with a suitable choice of cleavages), and F is a split cartesian functor. Recall that the latter condition means the following. For every morphism $g : X \to Y$ in $\mathscr{B}$, the induced diagram

$$\begin{array}{ccc} \varphi_1^{-1} Y & \xrightarrow{g^*} & \varphi_1^{-1} X \\ {\scriptstyle F}\downarrow & & \downarrow{\scriptstyle F} \\ \varphi_2^{-1} Y & \xrightarrow{g^*} & \varphi_2^{-1} X \end{array}$$

commutes (where the horizontal arrows are the pull-back functor given by the chosen cleavages). In this situation, we have a commutative diagram

$$(3.5.26) \qquad \begin{array}{ccc} \varphi_1^{-1} B & \xrightarrow{\rho_{\underline{S}}} & \mathsf{Desc}(\varphi_1, \underline{S}) \\ {\scriptstyle F_B}\downarrow & & \downarrow{\scriptstyle \underline{F}} \\ \varphi_2^{-1} B & \xrightarrow{\rho_{\underline{S}}} & \mathsf{Desc}(\varphi_2, \underline{S}) \end{array}$$

whose right vertical arrow is the functor given by the rule :

$$\underline{X} := (X_i, \omega_{ij} \mid i, j \in I) \mapsto \underline{F}(\underline{X}) := (F_i X_i, F_{ij} \omega_{ij} \mid i, j \in I).$$

for every object $\underline{X}$ of $\mathsf{Desc}(\varphi_1, \underline{S})$. By assumption, the top horizontal arrow of (3.5.26) is n-faithful, and the bottom horizontal arrow is $(n-1)$-faithful. We need to prove that the left vertical arrow is n-faithful, and it is easily seen that this will follow, once we have shown that the same holds for the right vertical arrow.

Suppose first that $n = 0$; we have to show that $\underline{F}$ is faithful. However, let $\underline{X}$ and $\underline{Y}$ be two objects of $\mathsf{Desc}(\varphi_1, \underline{S})$, and $\underline{h}_1, \underline{h}_2 : \underline{X} \to \underline{Y}$ two morphisms. By definition, $\underline{h}_t$ (for $t = 1, 2$) is a compatible system $(h_{t,i} : X_i \to Y_i \mid i \in I)$, where each $h_{t,i}$ is a morphism in $\varphi_1^{-1} S_i$. Then, $\underline{F}(\underline{h}_t)$ is the compatible system $(F_i h_{t,i} \mid i \in I)$. Thus, the condition $\underline{F}(\underline{h}_1) = \underline{F}(\underline{h}_2)$ translates the system of identities $F_i h_{1,i} = F_i h_{2,i}$ for every $i \in I$. By assumption, each F_i is faithful, therefore $\underline{h}_1 = \underline{h}_2$, as stated.

For $n = 1$, assumption (d) is empty, (b) means that F_i is fully faithful, and (c) means that F_{ij} is faithful for every $i, j \in I$. In light of the previous case, we have only to show that $\underline{F}$ is full. Hence, let $\underline{X}, \underline{Y}$ be as in the foregoing, and $(h_i : F_i X_i \to F_i Y_i \mid i \in I)$ a morphism $\underline{F}(\underline{X}) \to \underline{F}(\underline{Y})$ in $\mathsf{Desc}(\varphi_2, \underline{S})$. By assumption, for every $i \in I$ we may find a unique morphism $f_i : X_i \to Y_i$ such that $F_i f_i = h_i$. It remains only to check that the system $(f_i \mid i \in I)$ fulfills condition (3.5.21), and since the functors F_{ij} are faithful, it suffices to verify that F_{ij}(3.5.21) holds. However, since F is split cartesian, we have :

$$F_{ij} \circ \pi_{ij}^{0*} f_j = \pi_{ij}^{0*} \circ F_j f_j \qquad F_{ij} \circ \pi_{ij}^{1*} f_i = \pi_{ij}^{1*} \circ F_i f_i$$

hence we reduce to showing that $(F_{ij} \omega_{ij}^Y) \circ \pi_{ij}^{0*} h_j = \pi_{ij}^{1*} h_i \circ (F_{ij} \omega_{ij}^X)$, which holds by assumption.

Next, we consider assertion (ii) : the contention is that the functors $\underline{F}$ and :

$$\mathsf{p}_{1,\underline{S}} : \mathsf{Desc}(\varphi_1, \underline{S}) \to \prod_{i\in I} \varphi_1^{-1} S_i$$

as in (3.5.22), induce an equivalence $(\mathsf{p}_{1,\underline{S}}, \underline{F})$ between $\mathsf{Desc}(\varphi_1, \underline{S})$ and the category $\mathscr{C}$ consisting of all data of the form $\underline{G} := (G_i, H_i, \alpha_i, \omega_{ij}^H \mid i, j \in I)$, where $G_i \in \mathrm{Ob}(\varphi_1^{-1} S_i)$, $H_i \in \mathrm{Ob}(\varphi_2^{-1} S_i)$, $\alpha_i : F_i G_i \xrightarrow{\sim} H_i$ are isomorphisms in $\varphi_2^{-1} S_i$, and $\underline{H} := (H_i, \omega_{ij}^H \mid i, j \in I)$ is an object of $\mathsf{Desc}(\varphi_2, \underline{S})$. However, given an object as above, set :

$$\omega_{ij}^{H'} := (\pi_{ij}^{1*} \alpha_i^{-1}) \circ \omega_{ij}^H \circ (\pi_{ij}^{0*} \alpha_j).$$

Since φ_2 is a split fibration, one verifies easily that the datum $\underline{H}' := (H'_i := F_i G_i, \omega_{ij}^{H'} \mid i, j \in I)$ is an object of $\mathsf{Desc}(\varphi_2, \underline{S})$ isomorphic to $\underline{H}$, and the new datum $(F_i, H'_i, \mathbf{1}_{H'_i}, \omega_{ij}^{H'} \mid i, j \in I)$ is isomorphic to $\underline{G}$; hence $\mathscr{C}$ is equivalent to the category $\mathscr{C}'$ whose objects are all data of the form $(G_i, \omega_{ij} \mid i, j \in I)$ where $G_i \in \mathrm{Ob}(\varphi_1^{-1} S_i)$, and $(F_i G_i, \omega_{ij} \mid i, j \in I)$ is an object of $\mathsf{Desc}(\varphi_2, \underline{S})$. By assumption F_{ij} is fully faithful, and F is a split cartesian functor; hence we may find unique isomorphisms $\widetilde{\omega}_{ij}^G : \pi_{ij}^{0*} G_j \xrightarrow{\sim} \pi_{ij}^{1*} G_i$ such that $\widetilde{\omega}_{ij} = F_{ij} \widetilde{\omega}_{ij}^G$. We claim that the datum $(G_i, \omega_{ij}^G \mid i, j \in I)$ is an object of $\mathsf{Desc}(\varphi_1, \underline{S})$, *i.e.* the isomorphisms ω_{ij}^G satisfy the cocycle condition

$$\pi_{ijk}^{2*} \omega_{ij}^G \circ \pi_{ijk}^{0*} \omega_{jk}^G = \pi_{ijk}^{1*} \omega_{ik}^G \qquad \text{for every } i, j, k \in I. \tag{3.5.27}$$

To check this identity, since by assumption the functors F_{ijk} are faithful, it suffices to see that F_{ijk}(3.5.27) holds, which is clear, since the cocycle condition holds for the isomorphisms ω_{ij} (and since F is split cartesian). This shows that $(\mathsf{p}_{1,\underline{S}}, \underline{F})$ is essentially surjective. Next, since the functor $\mathsf{p}_{1,\underline{S}}$ is faithful, the same holds for $(\mathsf{p}_{1,\underline{S}}, \underline{F})$. Finally, let

$$\underline{G} := (G_i, \omega_{ij} \mid i, j \in I) \qquad \underline{G}' := (G'_i, \omega'_{ij} \mid i, j \in I)$$

be two objects of $\mathscr{C}'$. A morphism $\underline{G} \to \underline{G}'$ consists of a system $(\alpha_i : G_i \to G'_i \mid i \in I)$ of morphisms such that $(F_i \alpha_i \mid i \in I)$ is a morphism

$$(F_i G_i, \omega_{ij} \mid i, j \in I) \to (F_i G'_i, \omega'_{ij} \mid i, j \in I)$$

in $\mathsf{Desc}(\varphi_2, \underline{S})$. To show that $(\mathsf{p}_{1\underline{S}}, \underline{F})$ is full, and since we know already that this functor is essentially surjective, we may assume that there exist $(G_i, \omega_{ij}^G \mid i, j \in I)$, $(G'_i, \omega_{ij}^{G'} \mid i, j \in I)$ in $\mathsf{Desc}(\varphi_1, \underline{S})$ such that $\omega_{ij} = F_{ij} \omega_{ij}^G$ and $\omega'_{ij} = F_{ij} \omega_{ij}^{G'}$ for every $i, j \in I$; in this case, it suffices to verify the identity

$$\omega_{ij}^{G'} \circ \pi_{ij}^{0*} \alpha_j = \pi_{ij}^{1*} \alpha_i \circ \omega_{ij}^G \qquad \text{for every } i, j \in I. \tag{3.5.28}$$

Again, the faithfulness of F_{ij} reduces to checking that F_{ij}(3.5.28) holds, which is clear, since F is split cartesian.

Lastly, notice that the case $n = 2$ of assertion (i) is a formal consequence of (ii). □

3.5.29. In the situation of (3.5.22), let $\mathscr{S}$ be the sieve generated by the family $\underline{S}$, and $g : B' \to B$ any morphism in $\mathscr{B}$. We let :

$$B'_i := B' \times_B S_i \quad B'_{ij} := B' \times_B S_{ij} \quad B'_{ijk} := B' \times_B S_{ijk} \qquad \text{for every } i, j, k \in I$$

and denote $g_i : B'_i \to S_i$, $g_{ij} : B'_{ij} \to S_{ij}$ and $g_{ijk} : B'_{ijk} \to S_{ijk}$ the induced projections.

Corollary 3.5.30. *With the notation of* (3.5.29)*, let* $n \in \{0, 1, 2\}$. *The following holds :*

(i) *$\mathscr{S}$ is a sieve of φ-n-descent, if and only if $\rho_{\underline{S}}$ is n-faithful (see* (3.5.23)*).*

(ii) *Suppose that :*

  (a) *$\mathscr{S}$ is a sieve of universal φ-n-descent.*

  (b) *The pull-back functors $g_i^* : \varphi^{-1} S_i \to \varphi^{-1} B'_i$ are n-faithful.*

(c) *The pull-back functors* $g^*_{ij} : \varphi^{-1}S_{ij} \to \varphi^{-1}B'_{ij}$ *are* $(n-1)$*-faithful.*
(d) *The pull-back functors* $g^*_{ijk} : \varphi^{-1}S_{ijk} \to \varphi^{-1}B'_{ijk}$ *are* $(n-2)$*-faithful.*
Then the pull-back functor g^* *is* n*-faithful.*

(iii) *Suppose that the functors* g^*_{ij} *are fully faithful, and the functors* g^*_{ijk} *are faithful, for every* $i, j, k \in I$*. Then the natural essentially commutative diagram :*

$$\begin{array}{ccc} \mathsf{Desc}(\varphi, \underline{S}) & \xrightarrow{\mathsf{Desc}(\varphi,g)} & \mathsf{Desc}(\varphi, \underline{S} \times_B B') \\ {\scriptstyle \mathsf{p}_{\underline{S}}}\downarrow & & \downarrow{\scriptstyle \mathsf{p}_{\underline{S}\times_B B'}} \\ \prod_{i\in I} \varphi^{-1}S_i & \xrightarrow{\prod_{i\in I} g^*_i} & \prod_{i\in I} \varphi^{-1}B'_i \end{array}$$

is 2*-cartesian (see remark* 2.5.2(v) *and example* 3.3.12(ii)*).*

Proof. (i) follows by inspecting (3.5.23).

(ii): Thanks to theorem 3.2.7, we may assume that φ is a split fibration. Now, set

$$\mathscr{C} := \mathsf{Morph}(\mathscr{B}) \qquad \mathscr{A}_1 := \mathscr{C} \times_{(\mathsf{t},\varphi)} \mathscr{A} \qquad \mathscr{A}_2 := \mathscr{C} \times_{(\mathsf{s},\varphi)} \mathscr{A}$$

where $\mathsf{s}, \mathsf{t} : \mathscr{C} \to \mathscr{B}$ are the source and target functors (see (1.1.30)). The natural projections $\varphi_i : \mathscr{A}_i \to \mathscr{C}$ (for $i = 1, 2$) are two fibrations (see remark 3.1.5(i)). Moreover, t induces a functor $\mathsf{t}_{|g} : \mathscr{C}/g \to \mathscr{B}/B$ (notation of (1.1.26)) and we let $\mathscr{S}/g := \mathsf{t}^{-1}_{|g}\mathscr{S}$, which is the sieve of $\mathscr{C}/g$ generated by the cartesian diagrams

$$D_i \quad : \quad \begin{array}{ccc} B'_i & \xrightarrow{g_i} & S_i \\ \downarrow & & \downarrow \\ B' & \xrightarrow{g} & B \end{array} \qquad \text{for every } i \in I.$$

Notice that the products $D_{ij} := D_i \times D_j$ are represented in $\mathscr{C}/g$ by the diagrams

$$\begin{array}{ccc} B'_{ij} & \xrightarrow{g_{ij}} & S_{ij} \\ \downarrow & & \downarrow \\ B' & \xrightarrow{g} & B \end{array} \qquad \text{for every } i, j \in I$$

and likewise one may represent the triple products $D_{ijk} := D_{ij} \times D_k$.

By definition, the objects of $\mathscr{A}_1$ (resp. $\mathscr{A}_2$) are the pairs $(h : X \to Y, a)$, where h is a morphism in $\mathscr{B}$ and $a \in \mathrm{Ob}(\varphi^{-1}Y)$ (resp. $a \in \mathrm{Ob}(\varphi^{-1}X)$). A morphism of $\mathscr{A}_1$ (resp. of $\mathscr{A}_2$)

$$(h : X \to Y, a) \to (h' : X' \to Y', a')$$

is a datum (f_1, f_2, t), where $f_1 : X \to X'$ and $f_2 : Y \to Y'$ are morphisms in $\mathscr{B}$ with $f_2 \circ h = h' \circ f_1$, and $t : a \to f^*_2 a'$ (resp. $t : a \to f^*_1 a'$) is a morphism in $\varphi^{-1}Y$ (resp. in $\varphi^{-1}X$). Now, we define a functor $F : \mathscr{A}_1 \to \mathscr{A}_2$ of $\mathscr{C}$-categories, by the rule :

- $(h, a) \mapsto (h, h^*a)$ for every $(h, a) \in \mathrm{Ob}(\mathscr{A}_1)$.
- $(f_1, f_2, t) \mapsto (f_1, f_2, h^*t)$ for every morphism (f_1, f_2, t) of $\mathscr{A}_1$ as above. Notice that if $t : a \to f^*_2 a'$ is a morphism in $\varphi^{-1}Y$, then $h^*t : h^*a \to h^* f^*_2 a' = f^*_1 h'^* a'$ is a morphism of $\varphi^{-1}Y'$, since φ is a split fibration.

Notice that a morphism (f_1, f_2, t) of either $\mathscr{A}_1$ or $\mathscr{A}_2$ is cartesian if and only if t is an isomorphism; especially, it is clear that F is a cartesian functor. Moreover, for every object $h : X \to Y$ of $\mathscr{C}$, the restriction $\varphi_1^{-1}h \to \varphi_2^{-1}h$ of F is isomorphic to the pull-back functor $h^* : \varphi^{-1}Y \to \varphi^{-1}h$. Especially, conditions (b)–(d) say that the restriction $F_i : \varphi_1^{-1}g_i \to \varphi_2^{-1}g_i$ (resp. $F_{ij} : \varphi_1^{-1}g_{ij} \to \varphi_2^{-1}g_{ij}$, resp. $F_{ijk} : \varphi_1^{-1}g_{ijk} \to \varphi_2^{-1}g_{ijk}$) are n-faithful (resp. $(n-1)$-faithful, resp. $(n-2)$-faithful). In light of theorem 3.5.25(i), we are then reduced to showing

Claim 3.5.31. $\mathscr{S}/g$ is a sieve both of φ_1-n-descent and of φ_2-n-descent.

Proof of the claim. Let $\mathscr{D}$ be any (small) category; we remark first that a functor $\mathscr{D} \to \mathscr{A}_1$ is the same as a pair of functors $(H : \mathscr{D} \to \mathscr{A}, K : \mathscr{D} \to \mathscr{C})$ such that $\varphi \circ H = \mathsf{t} \circ K$, and likewise one can describe the functors $\mathscr{D} \to \mathscr{A}_2$. Then, it is easily seen that the functors

$$\mathscr{A}(B) \to \mathsf{Cart}_{\mathscr{C}}(\mathscr{C}/g, \mathscr{A}_1) \qquad G \mapsto (G \circ \mathsf{t}, \mathsf{t})$$
$$\mathscr{A}(B') \to \mathsf{Cart}_{\mathscr{C}}(\mathscr{C}/g, \mathscr{A}_2) \qquad G \mapsto (G \circ \mathsf{s}, \mathsf{s})$$

are equivalences, and induce equivalences

$$\mathsf{Cart}_{\mathscr{B}}(\mathscr{S}, \mathscr{A}) \to \mathsf{Cart}_{\mathscr{C}}(\mathscr{S}/g, \mathscr{A}_1)$$
$$\mathsf{Cart}_{\mathscr{B}}(\mathscr{S} \times_B g, \mathscr{A}) \to \mathsf{Cart}_{\mathscr{C}}(\mathscr{S}/g, \mathscr{A}_2)$$

(details left to the reader). The claim follows immediately. □

3.5.32. Quite generally, if $\varphi : \mathscr{A} \to \mathscr{B}$ is a fibration over a category $\mathscr{B}$ that admits fibre products, the descent data for φ (relative to a fixed cleavage c) also form a fibration :

$$\mathsf{D}\varphi : \varphi\text{-}\mathsf{Desc} \to \mathsf{Morph}(\mathscr{B}).$$

Namely, for every morphism $f : T' \to T$ of $\mathscr{B}$, the fibre over f is the category $\mathsf{Desc}(\varphi, f)$ of all descent data (f, A, ξ) relative to the family $\{f\}$, and the cleavage c, so A is an object of $\varphi^{-1}T'$ and $\xi : p_1^*A \xrightarrow{\sim} p_2^*A$ is an isomorphism in the category $\varphi^{-1}(T' \times_T T')$ satisfying the usual cocycle condition (here $p_1, p_2 : T' \times_T T' \to T'$ denote the two natural morphisms). Given two objects $\underline{A} := (f : T' \to T, A, \xi)$, $\underline{A}' := (g : W' \to W, A', \zeta)$ of φ-Desc, the morphisms $\underline{A} \to \underline{A}'$ are the data (h, α) consisting of a commutative diagram :

$$\begin{array}{ccc} W' & \xrightarrow{h} & T' \\ {\scriptstyle g}\downarrow & & \downarrow{\scriptstyle f} \\ W & \longrightarrow & T \end{array}$$

and a morphism $\alpha : A \to A'$ such that $\varphi(\alpha) = h$ and $p_1^*(\alpha) \circ \xi = \zeta \circ p_2^*(\alpha)$.

We have a natural cartesian functor of fibrations :

$$\begin{array}{ccc} \mathscr{A} \times_{(\varphi,\mathsf{t})} \mathsf{Morph}(\mathscr{B}) & \xrightarrow{\quad \mathsf{d} \quad} & \varphi\text{-}\mathsf{Desc} \\ & {\scriptstyle \mathsf{p}} \searrow \quad \swarrow {\scriptstyle \mathsf{D}\varphi} & \\ & \mathsf{Morph}(\mathscr{B}) & \end{array}$$

where $\mathsf{t} : \mathsf{Morph}(\mathscr{B}) \to \mathscr{B}$ is the target functor (see (1.1.30) and example 1.2.25(i)). Namely, to any pair $(T, f : S \to \varphi T)$ with $T \in \mathrm{Ob}(\mathscr{A})$ and $f \in \mathrm{Ob}(\mathsf{Morph}(\mathscr{B}))$, one assigns the canonical descent datum $\mathsf{d}(T, f) := \rho_{\{f\}}(T)$ in $\mathsf{Desc}(\varphi, f)$ associated with the pair as in (3.5.23).

Corollary 3.5.33. *In the situation of* (3.5.32)*, let $f : B' \to B$ be a morphism of $\mathscr{B}$, and $\mathscr{S}$ a sieve of $\mathscr{B}/B$, generated by a family $(S_i \to B \mid i \in I)$. Let $n \in \{0, 1, 2\}$, and suppose that :*

(a) *$\mathscr{S}$ is a sieve of universal φ-n-descent.*
(b) *For every $i \in I$, the morphism $S_i \times_B f$ is of φ-n-descent.*
(c) *For every $i, j \in I$, the morphism $S_{ij} \times_B f$ is of φ-$(n-1)$-descent.*
(d) *For every $i, j, k \in I$, the morphism $S_{ijk} \times_B f$ is of φ-$(n-2)$-descent.*

Then f is a morphism of φ-n-descent.

Proof. In view of corollary 3.5.30(i), it is easily seen that a morphism $g : T' \to T$ in $\mathscr{B}$ is of φ-n-descent if and only if the restriction $\varphi^{-1}T \to \mathsf{D}\varphi^{-1}g$ of d is n-faithful. Set $\mathscr{C} := \mathsf{Morph}(\mathscr{B})$; as in the proof of corollary 3.5.30(ii), the functor t induces a functor $\mathsf{t}_{|f} : \mathscr{C}/f \to \mathscr{B}/B$, and we let $\mathscr{S}/f := \mathsf{t}_{|f}^{-1}\mathscr{S}$. With this notation, theorem 3.5.25(i) reduces to showing :

Claim 3.5.34. The sieve $\mathscr{S}/f$ is both of p-n-descent and of Dφ-n-descent.

Proof of the claim. By claim 3.5.31, it is already known that $\mathscr{S}/f$ is of p-n-descent. To show that $\mathscr{S}/f$ is of Dφ-n-descent, we consider the commutative diagram

$$\begin{array}{ccc} \mathscr{A}(B') & \longrightarrow & \mathsf{Cart}_{\mathscr{C}}(\mathscr{C}/f, \varphi\text{-}\mathsf{Desc}) \\ \downarrow & & \downarrow \\ \mathsf{Cart}_{\mathscr{B}}(\mathscr{S} \times_B f, \mathscr{A}) & \longrightarrow & \mathsf{Cart}_{\mathscr{C}}(\mathscr{S}/f, \varphi\text{-}\mathsf{Desc}) \end{array}$$

whose left (resp. right) vertical arrow is induced by the inclusion $\mathscr{S} \times_B f \to \mathscr{B}/B'$ (resp. $\mathscr{S}/f \to \mathscr{S} \times_B f$) and whose top horizontal arrow is defined as follows. Given a cartesian functor $G : \mathscr{B}/B' \to \mathscr{A}$, we let D$G : \mathscr{C}/f \to \varphi$-Desc be the unique cartesian functor determined on the objects of $\mathscr{C}/f$ by the rule :

$$\left(\begin{array}{ccc} T' & \xrightarrow{g} & T \\ {\scriptstyle h}\downarrow & & \downarrow \\ B' & \xrightarrow{f} & B \end{array}\right) \mapsto \mathsf{d}(G(h), g).$$

We leave to the reader the verification the rule $G \mapsto \mathrm{D}G$ extends to a well defined functor, and then there exists a unique (similarly defined) bottom horizontal arrow that makes commute the foregoing diagram. Moreover, both horizontal arrow thus obtained are equivalences of categories. The claim follows. ◻

Lemma 3.5.35. *Let $i \leq 2$ be an integer, $F : \mathscr{E} \to \mathscr{C}$ a fibration, $X \in \mathrm{Ob}(\mathscr{C})$, and $\mathscr{T} \subset \mathscr{S}$ two sieves of $\mathscr{C}/X$. The following holds :*

(i) *If $\mathscr{T} \times_X f$ is of F-i-descent for every $(Y \xrightarrow{f} X) \in \mathscr{S}$, then the induced functor*

$$j : \mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, \mathscr{E}) \to \mathsf{Cart}_{\mathscr{C}}(\mathscr{T}, \mathscr{E})$$

is i-faithful.

(ii) *If $\mathscr{T}$ is of universal F-i-descent, the same holds for $\mathscr{S}$.*

Proof. (i): The assertion is trivial for $i < 0$. We consider first the case where $i = 0$; thus, let $\varphi, \psi : \mathscr{S} \to \mathscr{E}$ be two $\mathscr{C}$-cartesian functors, and $\alpha, \beta : \varphi \Rightarrow \psi$ two natural $\mathscr{C}$-transformations such that $\alpha_{|\mathscr{T}} = \beta_{|\mathscr{T}}$. Let also $(Y \xrightarrow{f} X) \in \mathrm{Ob}(\mathscr{S})$ be any object and $f_* : \mathscr{C}/Y \to \mathscr{S}$ the induced functor; then $\mathscr{T}' := \mathscr{T} \times_X f \subset \mathscr{C}/Y$ is a sieve of F-0-descent and

$$(\alpha * f_*)_{|\mathscr{T}'} = (\beta * f_*)_{|\mathscr{T}'}.$$

We deduce that $\alpha * f_* = \beta * f_*$; especially $\alpha_f = \beta_f$, which shows that j is faithful.

Next, suppose that $i = 1$, and for φ and ψ as in the foregoing, let $\alpha : \varphi_{|\mathscr{T}} \Rightarrow \psi_{|\mathscr{T}}$ be a given natural $\mathscr{C}$-transformation, and $(Y \xrightarrow{f} X) \in \mathrm{Ob}(\mathscr{S})$; then the sieve $\mathscr{T}' := \mathscr{T} \times_X f \subset \mathscr{C}/Y$ is of F-1-descent, and f_* restricts to a functor $f_{*|\mathscr{T}'} : \mathscr{T}' \to \mathscr{T}$, so the natural $\mathscr{C}$-transformation

$$\alpha * (f_{*|\mathscr{T}'}) : (\varphi \circ f_*)_{|\mathscr{T}'} \Rightarrow (\psi \circ f_*)_{|\mathscr{T}'}$$

extends to a unique natural $\mathscr{C}$-transformation $\alpha^{(f)} : \varphi \circ f_* \Rightarrow \psi \circ f_*$. Now, let us define

$$\widetilde{\alpha}_f := \alpha^{(f)}_{\mathbf{1}_Y} \qquad \text{for every } (Y \xrightarrow{f} X) \in \mathrm{Ob}(\mathscr{S}).$$

Clearly, $\widetilde{\alpha}_f = \alpha_f$ whenever $f \in \mathrm{Ob}(\mathscr{T})$, and it remains to check that $\widetilde{\alpha}$ is a natural $\mathscr{C}$-transformation $\varphi \Rightarrow \psi$. Thus, let $h/X : (Y' \xrightarrow{f'} X) \to (Y \xrightarrow{f} X)$ be a morphism of $\mathscr{S}$; we need to show that

$$\psi(h/X) \circ \widetilde{\alpha}_f = \widetilde{\alpha}_{f'} \circ \varphi(h/X).$$

Considering the morphism $h/Y : (Y' \xrightarrow{h} Y) \to \mathbf{1}_Y$ of $\mathscr{C}/Y$, and noticing that $\varphi(h/X) = (\varphi \circ f_*)(h/Y)$ and $\psi(h/X) = (\psi \circ f_*)(h/Y)$, we come down to checking that $\alpha^{(f)}_h = \alpha^{(f')}_{\mathbf{1}_{Y'}}$. We show more precisely that $\alpha^{(f)} * h_* = \alpha^{(f')}$. Indeed, notice that

$$(\alpha^{(f)} * h_*)_{|\mathscr{T}\times_X f'} = \alpha * (f'_{*|\mathscr{T}\times_X f'}) = \alpha^{(f')}_{|\mathscr{T}\times_X f'}$$

and since $\mathscr{T} \times_X f'$ is of F-0-descent, the assertion follows.

Lastly, for $i = 2$, we know already that j is fully faithful, so it remains only to show that every cartesian functor $\varphi : \mathscr{T} \to \mathscr{E}$ is isomorphic to the restriction of a cartesian functor $\mathscr{S} \to \mathscr{E}$. Now, for every $(f : Y \to X) \in \mathrm{Ob}(\mathscr{S})$ set $\mathscr{T}^{(f)} := \mathscr{T} \times_X f$; by assumption there exists a $\mathscr{C}$-cartesian functor $\varphi^{(f)} : \mathscr{C}/Y \to \mathscr{E}$ with an isomorphism of functors :

$$\omega_f : \varphi^{(f)}_{|\mathscr{T}^{(f)}} \xrightarrow{\sim} \varphi \circ (f_{*|\mathscr{T}^{(f)}}).$$

Notice that if $f \in \mathrm{Ob}(\mathscr{T})$, we have $\mathscr{T}^{(f)} = \mathscr{C}/Y$, and in this case we take $\varphi^{(f)} := \varphi \circ f_*$ and $\omega_f := \mathbf{1}_{\varphi^{(f)}}$. Then, for every morphism $h/X : (Y' \xrightarrow{f'} X) \to (Y \xrightarrow{f'} X)$ in $\mathscr{S}$ we get the isomorphism :

$$\varphi^{(f')}_{|\mathscr{T}^{(f')}} \xrightarrow{\omega_{f'}} \varphi \circ f'_{*|\mathscr{T}^{(f')}} \xrightarrow{(\omega_f * h_*)^{-1}_{|\mathscr{T}^{(f')}}} (\varphi^{(f)} \circ h_*)_{*|\mathscr{T}^{(f')}}$$

which, as $\mathscr{T}^{(f')}$ is of F-1-descent, extends uniquely to an isomorphism of functors $\mathscr{C}/Y' \to \mathscr{E}$

$$\tau_{h/X} : \varphi^{(f')} \xrightarrow{\sim} \varphi^{(f)} \circ h_*.$$

Claim 3.5.36. The rule : $(f : Y \to X) \mapsto (\varphi^{(f)} : \mathscr{C}/Y \to \mathscr{E})$ for every $f \in \mathrm{Ob}(\mathscr{S})$ defines a pseudo-cocone

$$\varphi^{(\bullet)} : G_{\mathscr{S}} \Rightarrow \mathsf{F}_{\mathscr{E}}$$

whose coherence constraint is given by the system of isomorphisms $\tau_{\bullet/X}$, and where $G_{\mathscr{S}} : \mathscr{S} \to \mathbf{Cat}$ is the functor associated with $\mathscr{S}$ as in (3.5.8).

Proof of the claim. Clearly $(\tau_{\mathbf{1}_Y/Y})_{|\mathscr{T}^{(f)}} = \mathbf{1}_{\varphi^{(f)}_{|\mathscr{T}^{(f)}}}$ for every $(f : Y \to X) \in \mathrm{Ob}(\mathscr{S})$, whence $\tau_{\mathbf{1}_Y/Y} = \mathbf{1}_{\varphi^{(f)}}$ by the uniqueness of $\tau_{\mathbf{1}_Y/Y}$. Next, let $(Y'' \xrightarrow{f''} X) \xrightarrow{h'/X} (Y' \xrightarrow{f'} X) \xrightarrow{h/X} (Y \xrightarrow{f} X)$ be two morphism of $\mathscr{S}$; the coherence axiom for $\tau_{\bullet/X}$ comes down to the identity :

$$(\tau_{h/X} * h'_*) \circ \tau_{h'/X} = \tau_{(h\circ h')/X}.$$

But the latter can be checked after restriction to the sieve $\mathscr{T}^{(f'')}$, where it follows by a simple inspection : the details are left to the reader. ◊

From claim 3.5.36 it follows that there exists a functor

$$\widetilde{\varphi} : \mathscr{S} \to \mathscr{E} \qquad \text{and an invertible modification} \qquad \Xi : \mathsf{F}_{\widetilde{\varphi}} \odot \widehat{\varepsilon} \xrightarrow{\sim} \varphi^{(\bullet)}$$

where $\widehat{\varepsilon} : G_{\mathscr{S}} \Rightarrow \mathsf{F}_{\mathscr{E}}$ is the universal pseudo-cocone provided by lemma 3.5.9. Explicitly, Ξ is a system of isomorphisms of functors

$$\Xi_f : \widetilde{\varphi} \circ f_* \xrightarrow{\sim} \varphi^{(f)} \qquad \text{for every } (f : Y \to X) \in \mathrm{Ob}(\mathscr{S})$$

from which it follows easily that $\widetilde{\varphi}$ is $\mathscr{C}$-cartesian. The compatibility conditions for Ξ amount to the identities :

(3.5.37) $$\Xi_f * h_* = \tau_h \odot \Xi_{f'} \qquad \text{for every morphism } h/X : f \to f' \text{ in } \mathscr{S}.$$

To conclude, it suffices to exhibit an isomorphism of functors $\xi : \widetilde{\varphi}_{|\mathscr{T}} \xrightarrow{\sim} \varphi$. To this aim, we set

$$\xi_g := (\Xi_g)_{\mathbf{1}_Y} : \widetilde{\varphi}(g) \xrightarrow{\sim} \varphi^{(g)}(\mathbf{1}_Y) = \varphi(g) \qquad \text{for every } (g : Y \to X) \in \mathrm{Ob}(\mathscr{T}).$$

To check the naturality of ξ, let $h/X : (Y' \xrightarrow{g'} X) \to (Y \xrightarrow{g} X)$ be any morphism of $\mathscr{T}$; notice that $\tau_{h/X} = \mathbf{1}_{\varphi(g')}$, whence $\xi_{g'} = (\Xi_g)_h$, due to (3.5.37). On the other hand, the naturality of Ξ_g yields the commutative diagram

$$\begin{array}{ccc}
\widetilde{\varphi}(g') = \widetilde{\varphi} \circ g_*(h) & \xrightarrow{(\Xi_g)_h} & \varphi^{(g)}(h) = \varphi(g') \\
{\scriptstyle \widetilde{\varphi}\circ g_*(h/Y)}\downarrow & & \downarrow{\scriptstyle \varphi^{(g)}(h/Y)} \\
\widetilde{\varphi}(g) = \widetilde{\varphi} \circ g_*(\mathbf{1}_Y) & \xrightarrow{\xi_g} & \varphi^{(g)}(\mathbf{1}_Y) = \varphi(g)
\end{array}$$

where $\widetilde{\varphi} \circ g_*(h/Y) = \widetilde{\varphi}(h/x)$ and $\varphi^{(g)}(h/Y) = \varphi(h/X)$, whence the contention.

(ii): We consider the induced functors

$$\mathscr{E}(X) \xrightarrow{j'} \mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, \mathscr{E}) \xrightarrow{j''} \mathsf{Cart}_{\mathscr{C}}(\mathscr{T}, \mathscr{E})$$

and notice that j'' is i-faithful, by virtue of (i); the same holds for $j'' \circ j'$, by assumption. Then it follows easily that j' is i-faithful as well, whence the assertion. □

Proposition 3.5.38. *Let $i \leq 2$ be an integer, $F : \mathscr{E} \to \mathscr{C}$ a fibration, $X \in \mathrm{Ob}(\mathscr{C})$, and $\mathscr{T}, \mathscr{S}$ two sieves of $\mathscr{C}/X$, such that :*

(a) *$\mathscr{S}$ is of universal F-i-descent.*

(b) *$\mathscr{T} \times_X f$ is of universal F-i-descent for every $(Y \xrightarrow{f} X) \in \mathscr{S}$.*

Then $\mathscr{T}$ is of universal F-i-descent.

Proof. According to lemma 3.5.35(ii), the sieve $\mathscr{S}' := \mathscr{S} \bigcup \mathscr{T}$ is also of universal F-i-descent. It is also clear that $\mathscr{T} \times_X f$ is of F-i-descent for every $(Y \xrightarrow{f} X) \in \mathscr{S}'$. Thus, we may replace $\mathscr{S}$ by $\mathscr{S}'$ and assume that $\mathscr{T} \subset \mathscr{S}$. Next, let $f : Y \to X$ be any morphism of $\mathscr{C}$; we need to check that $\mathscr{T} \times_X f$ is a sieve of F-i-descent, and by assumption the same holds for $\mathscr{S} \times_X f$, so it suffices to show that the induced functor $\mathsf{Cart}_{\mathscr{C}}(\mathscr{S} \times_X f, \mathscr{E}) \to \mathsf{Cart}_{\mathscr{C}}(\mathscr{T} \times_X f, \mathscr{E})$ is i-faithful. In view of lemma 3.5.35(i), we are then reduced to checking that $(\mathscr{T} \times_X f) \times_Y g$ is a sieve of F-i-descent for every $g \in \mathrm{Ob}(\mathscr{S} \times_X f)$. But we have $(\mathscr{T} \times_X f) \times_Y g = \mathscr{T} \times_X (f \circ g)$, and $f \circ g \in \mathrm{Ob}(\mathscr{S})$, so the assertion follows from (b). □

3.6. **Profinite groups and Galois categories.** Quite generally, for any profinite group P, let P-$\mathbf{Set}$ denote the category of discrete finite sets, endowed with a continuous left action of P (the morphisms in P-$\mathbf{Set}$ are the P-equivariant maps). Any continuous group homomorphism $\omega : P \to Q$ of profinite groups induces a *restriction functor*

$$\mathrm{Res}(\omega) : Q\text{-}\mathbf{Set} \to P\text{-}\mathbf{Set}$$

in the obvious way. In case the notation is not ambiguous, one writes also Res^P_Q for this functor.

For any two profinite groups P and Q, we denote by

$$\mathrm{Hom}_{\mathrm{cont}}(P, Q)$$

the set of all continuous group homomorphisms $P \to Q$. If φ_1, φ_2 are two such group homomorphisms, we say that φ_1 is *conjugate* to φ_2, and we write $\varphi_1 \sim \varphi_2$, if there exists an inner automorphism ω of G, such that $\varphi_2 = \omega \circ \varphi_1$. Clearly the trivial map $\pi \to G$ (whose image is the neutral element of G), is the unique element of a distinguished conjugacy class.

3.6.1. Let P be any profinite group; for any (discrete) finite group G, consider the pointed set $\mathrm{Hom}_{\mathrm{cont}}(P, G)/\!\sim$ of conjugacy classes of continuous group homomorphisms $P \to G$. This is also denoted

$$H^1_{\mathrm{cont}}(P, G)$$

and called the first *non-abelian continuous cohomology group* of P with coefficients in G (so G is regarded as a P-module with trivial P-action). Clearly the formation of $H^1(P,G)$ is covariant on the argument G, and controvariant for continuous homomorphisms of profinite groups.

Lemma 3.6.2. *Let $\varphi : P \to P'$ be a continuous homomorphism of profinite groups, and suppose that the induced map of pointed sets :*

$$H^1_{\mathrm{cont}}(P',G) \to H^1_{\mathrm{cont}}(P,G) \quad : \quad f \mapsto f \circ \varphi$$

is bijective, for every finite group G. Then φ is an isomorphism of topological groups.

Proof. First we show that φ is injective. Indeed, let $x \in P$ be any element; we may find an open normal subgroup $H \subset P$ such that $x \notin H$; taking $G := P/H$, we deduce that the projection $P \to P/H$ factors through φ and a group homomorphism $f : P' \to P/H$, hence $x \notin \mathrm{Ker}\,\varphi$, as claimed. Moreover, let $H' := \mathrm{Ker}\, f$; clearly $H' \cap P = H$, so the topology of P is induced from that of P'. It remains only to show that φ is surjective; to this aim, we consider any continuous surjection $f' : P' \to G'$ onto a finite group, and it suffices to show that the restriction of f' to φP is still surjective. Indeed, let G be the image of φP in G', denote by $i : G \to G'$ the inclusion map, and let $f : P \to G$ be the unique continuous map such that $i \circ f = f' \circ \varphi$; by assumption, there exists a continuous group homomorphism $g : P' \to G$ such that $f = g \circ \varphi$. On the other hand, $(i \circ g) \circ \varphi = f' \circ \varphi$, hence the conjugacy class of $i \circ g$ equals the conjugacy class of f', especially $i \circ g$ is surjective, hence the same holds for i, as required. $\square$

3.6.3. Let G be a profinite group, and $H \subset G$ an open subgroup. It is easily seen that H is also a profinite group, with the topology induced from G. Moreover, the restriction functor

$$\mathrm{Res}^H_G : G\text{-}\mathbf{Set} \to H\text{-}\mathbf{Set}$$

admits a left adjoint

$$\mathrm{Ind}^G_H : H\text{-}\mathbf{Set} \to G\text{-}\mathbf{Set}.$$

Namely, to any finite set Σ with a continuous left action of H, one assigns the set $\mathrm{Ind}^G_H\Sigma := G \times \Sigma/\!\sim$, where $\sim$ is the equivalence relation such that

$$(gh, \sigma) \sim (g, h\sigma) \qquad \text{for every } g \in G,\ h \in H \text{ and } \sigma \in \Sigma.$$

The left G-action on $\mathrm{Ind}^G_H\Sigma$ is given by the rule : $(g', (g, \sigma)) \mapsto (g'g, \sigma)$ for every $g, g' \in G$ and $\sigma \in \Sigma$. It is easily seen that this action is continuous, and the reader may check that the functor Ind^G_H is indeed left adjoint to Res^H_G.

3.6.4. Moreover, let 1 denote the final object of H-$\mathbf{Set}$; notice that $\mathrm{Ind}^G_H 1 = G/H$, the set of orbits of G under its right translation action by H. Hence, for any finite set Σ with continuous H-action, the unique map $t_\Sigma : \Sigma \to 1$ yields a G-equivariant map

$$\mathrm{Ind}^G_H t_\Sigma : \mathrm{Ind}^G_H \to G/H$$

and therefore Ind^G_H factors through a functor

$$H\text{-}\mathbf{Set} \to G\text{-}\mathbf{Set}/(G/H). \tag{3.6.5}$$

It is easily seen that (3.6.5) is an equivalence. Indeed, one obtains a natural quasi-inverse, by the rule : $(f : \Sigma \to G/H) \mapsto f^{-1}(H)$. The detailed verification shall be left to the reader.

Definition 3.6.6. ([82, Exp.V, Def.5.1]) Let $\mathscr{C}$ be a category, and $F : \mathscr{C} \to \mathbf{Set}$ a functor.

(i) We say that $\mathscr{C}$ is a *Galois category*, if $\mathscr{C}$ is equivalent to P-$\mathbf{Set}$, for some profinite group P. We denote $\mathbf{Galois}$ the category whose objects are all the Galois categories, and whose morphisms are the exact functors between Galois categories.

(ii) We say that F is a *fibre functor*, if F is exact and conservative, and $F(X)$ is a finite set for every $X \in \mathrm{Ob}(\mathscr{C})$.

(iii) We denote $\mathbf{fibre.Fun}$ the 2-*category of fibre functors*, defined as follows :
  (a) The objects are all the pairs $(\mathscr{C}, F)$ consisting of a Galois category $\mathscr{C}$ and a fibre functor F for $\mathscr{C}$.
  (b) The 1-cells $(\mathscr{C}_1, F_1) \to (\mathscr{C}_2, F_2)$ are all the pairs (G, β) consisting of an exact functor $G : \mathscr{C}_1 \to \mathscr{C}_2$ and an isomorphism of functors $\beta : F_1 \stackrel{\sim}{\to} F_2 \circ G$.
  (c) And for every pair of 1-cells $(G', \beta'), (G, \beta) : (\mathscr{C}_1, F_1) \to (\mathscr{C}_2, F_2)$, the 2-cells $(G', \beta') \to (G, \beta)$ are the isomorphisms $\gamma : G' \stackrel{\sim}{\to} G$ such that $(F_2 * \gamma) \odot \beta' = \beta$.

Composition of 1-cells and 2-cells is defined in the obvious way. We shall also denote simply by G a 1-cell (G, β) as in (b), such that $F_1 = F_2 \circ G$ and β is the identity automorphism of F_1.

3.6.7. Notice that any Galois category $\mathscr{C}$ admits a fibre functor : indeed, if P is any profinite group, the forgetful functor

$$\mathsf{f}_P : P\text{-}\mathbf{Set} \to \mathbf{Set}$$

fulfills the conditions of definition 3.6.6(ii), therefore the same holds for the functor $\mathsf{f}_P \circ \beta$, if $\beta : \mathscr{C} \to P\text{-}\mathbf{Set}$ is any equivalence. For any Galois category $\mathscr{C}$ and any fibre functor $F : \mathscr{C} \to \mathbf{Set}$, we denote

$$\pi_1(\mathscr{C}, F)$$

the group of automorphisms of F, and we call it the *fundamental group of $\mathscr{C}$ pointed at F*. By definition, for every $X \in \mathrm{Ob}(\mathscr{C})$, the finite set $F(X)$ is endowed with a natural left action of $\pi_1(\mathscr{C}, F)$. For every $X \in \mathrm{Ob}(\mathscr{C})$ and every $\xi \in F(X)$, the stabilizer $H_{X,\xi} \subset \pi_1(\mathscr{C}, F)$ is a subgroup of finite index, and we endow $\pi_1(\mathscr{C}, F)$ with the coarsest group topology for which all such $H_{X,\xi}$ are open subgroups. The resulting topological group $\pi_1(\mathscr{C}, F)$ is profinite, and its natural left action on every $F(X)$ is continuous. Thus, F upgrades to a functor denoted

$$F^\dagger : \mathscr{C} \stackrel{\sim}{\to} \pi_1(\mathscr{C}, F)\text{-}\mathbf{Set}.$$

A basic result states that $F^\dagger$ is an equivalence ([82, Exp.V, Th.4.1]).

Example 3.6.8. Let P be any profinite group. Then there is an obvious injective map

$$P \to \pi_1(P\text{-}\mathbf{Set}, \mathsf{f}_P)$$

and [82, Exp.V, Th.4.1] implies that this map is an isomorphism of profinite groups. In other words, the group P can be recovered, up to unique isomorphism, from the category P-$\mathbf{Set}$ together with its forgetful functor f_P.

Remark 3.6.9. Let $\mathscr{C}, \mathscr{C}'$ be two Galois categories, and $F : \mathscr{C} \to \mathbf{Set}$ a fibre functor.
(i) Any exact functor $G : \mathscr{C}' \to \mathscr{C}$ induces a continuous group homomorphism :

$$\pi_1(G) : \pi_1(\mathscr{C}, F) \to \pi_1(\mathscr{C}', F \circ G) \qquad \omega \mapsto \omega * G.$$

(ii) Furthermore, any isomorphism $\beta : F' \stackrel{\sim}{\to} F$ of fibre functors of $\mathscr{C}$ induces an isomorphism of profinite groups :

$$\pi_1(\beta) : \pi_1(\mathscr{C}', F) \stackrel{\sim}{\to} \pi_1(\mathscr{C}', F) \qquad \omega \mapsto \beta^{-1} \odot \omega \odot \beta$$

(see [82, Exp.V, §4] for all these generalities).
(iii) Let now $(G, \beta) : (\mathscr{C}_1, F_1) \to (\mathscr{C}_2, F_2)$ be a 1-cell of $\mathbf{fibre.Fun}$. Combining (i) and (ii), we deduce a natural continuous group homomorphism

$$\pi_1(G, \beta) : \pi_1(\mathscr{C}_2, F_2) \xrightarrow{\pi_1(G)} \pi_1(\mathscr{C}_1, F_2 \circ G) \xrightarrow{\pi_1(\beta)} \pi_1(\mathscr{C}_1, F_1).$$

Proposition 3.6.10. *With the notation of remark* 3.6.9*, the rule that assigns :*
- *To any object $(\mathscr{C}, F)$ of* $\mathbf{fibre.Fun}$*, the profinite group $\pi_1(\mathscr{C}, F)$*
- *To any* 1*-cell (G, β) of* $\mathbf{fibre.Fun}$*, the continuous map $\pi_1(G, \beta)$*

defines a pseudo-functor

$$\pi_1 : \mathbf{fibre.Fun} \to \mathbf{pf.Grp}^o$$

from the 2*-category of fibre functors, to the opposite of the category of profinite groups (and continuous group homomorphisms).*

Proof. (Here we regard $\mathbf{pf.Grp}$ as a 2-category with trivial 2-cells : see example 2.2.4(i)). Let

$$(\mathscr{C}_1, F_1) \xrightarrow{(G,\beta_G)} (\mathscr{C}_2, F_2) \xrightarrow{(H,\beta_H)} (\mathscr{C}_3, F_3)$$

be any pair of (composable) 1-cells; functoriality on 1-cells amounts to the identity :

$$\pi_1(G, \beta_G) \circ \pi_1(H, \beta_H) = \pi_1(H \circ G, (\beta_H * G) \circ \beta_G)$$

whose detailed verification we leave to the reader. Next, let $\gamma : (G', \beta') \to (G, \beta)$ be a 2-cell between 1-cells $(G', \beta'), (G, \beta) : (\mathscr{C}_1, F_1) \to (\mathscr{C}_2, F_2)$; we have to check that $\pi_1(G, \beta) = \pi_1(G', \beta')$. This identity boils down to the commutativity of the diagram :

$$\begin{array}{ccc}
\pi_1(\mathscr{C}_2, F_2) & \xrightarrow{\pi_1(G')} & \pi_1(\mathscr{C}_1, F_2 \circ G') \\
{\scriptstyle \pi_1(G)}\downarrow & \nearrow{\scriptstyle \pi_1(F_2 * \gamma)} & \downarrow{\scriptstyle \pi_1(\beta')} \\
\pi_1(\mathscr{C}_2, F_2 \circ G) & \xrightarrow{\pi_1(\beta)} & \pi_1(\mathscr{C}_1, F_1).
\end{array}$$

However, the commutativity of the lower triangular subdiagram is clear, hence we are reduced to checking the commutativity of the upper triangular subdiagram; the latter is a special case of the following more general :

Claim 3.6.11. Let $\mathscr{C}$ and $\mathscr{C}'$ be two Galois categories, $G, G' : \mathscr{C}' \to \mathscr{C}$ two exact functors, $\beta : G' \stackrel{\sim}{\to} G$ an isomorphism, and $F : \mathscr{C} \to \mathbf{Set}$ a fibre functor. Then the induced diagram of profinite groups

$$\begin{array}{ccc}
 & \pi_1(\mathscr{C}, F) & \\
{\scriptstyle \pi_1(G)}\swarrow & & \searrow{\scriptstyle \pi_1(G')} \\
\pi_1(\mathscr{C}', F \circ G) & \xrightarrow{\pi_1(F * \beta)} & \pi_1(\mathscr{C}', F \circ G')
\end{array}$$

commutes.

Proof of the claim. Left to the reader. □

Example 3.6.12. Let $\omega : P \to Q$ be a continuous group homomorphism between profinite groups. Clearly $\mathsf{f}_P \circ \mathrm{Res}(\omega) = \mathsf{f}_Q$, and it is easily seen that the resulting diagram

$$\begin{array}{ccc}
P & \xrightarrow{\omega} & Q \\
\downarrow & & \downarrow \\
\pi_1(P\text{-}\mathbf{Set}, \mathsf{f}_P) & \xrightarrow{\pi_1(\mathrm{Res}(\omega))} & \pi_1(Q\text{-}\mathbf{Set}, \mathsf{f}_Q)
\end{array}$$

commutes, where the vertical arrows are the natural identifications given by example 3.6.8 : the verification is left as an exercise to the reader.

3.6.13. Let $\underline{P} := (P_i \mid i \in I)$ be a cofiltered system of profinite groups, with continuous transition maps, and denote by P the limit of this system, in the category of groups. Then P is naturally a closed subgroup of $Q := \prod_{i \in I} P_i$, and the topology $\mathscr{T}$ induced by the inclusion map $P \to Q$ makes it into a compact and complete topological group. Moreover, since the topology of Q is profinite, the same holds for the topology $\mathscr{T}$ (details left to the reader). It is then easily seen that the resulting topological group $(P, \mathscr{T})$ is the limit of the system $\underline{P}$ in the category of profinite groups.

Proposition 3.6.14. *In the situation of* (3.6.13)*, the natural functor*

$$\text{2-}\operatorname*{colim}_{i\in I} P_i\text{-}\mathbf{Set} \to P\text{-}\mathbf{Set}$$

is an equivalence.

Proof. The functor is obviously faithful; let us show that it is also full. Indeed, let $j \in I$ be any index, Σ, Σ' two objects of P_j-$\mathbf{Set}$, and $\varphi : \Sigma \to \Sigma'$ a P-equivariant map; we need to show that φ is already P_i-equivariant, for some index $i \in I$. To this aim, we may as usual replace I by I/j, and assume that j is the final element of I. We may also find an open normal subgroup $H_j \subset P_j$ that acts trivially on both Σ and Σ'. Then, for every $i \in I$, we let $H_i \subset P_i$ be the preimage of P_j, and we set $\overline{P}_i := P_i/H_i$. Let also $\overline{P} := P/H$, where $H \subset P$ is the preimage of H_j; by construction, φ is $\overline{P}$-equivariant. Clearly, we may find $i \in I$ such that the image of $\overline{P}$ in the finite group $\overline{P}_j$ equals the image of $\overline{P}_i$, and for such index i, the induced map $\overline{P} \to \overline{P}_i$ is an isomorphism. Especially, φ is P_i-equivariant, as sought.

Lastly, we show essential surjectivity. Indeed, let Σ be any object of P-$\mathbf{Set}$; we have to show that the P-action on Σ is the restriction of a continuous P_i-action, for a suitable $i \in I$. However, we may find a normal open subgroup $H \subset P$ that acts trivially on Σ. Then there exists a normal open subgroup $L \subset Q$ (notation of (3.6.13)) such that $P \cap L \subset H$. We may also assume that there exist a finite subset $J \subset I$ and for every $i \in J$ an open normal subgroup $L_i \subset P_i$ such that $L = \prod_{i\in J} L_i \times \prod_{i\in I\setminus J} P_i$. Pick an index $j \in I$ that admits morphisms $f_i : j \to i$ in I, for every $i \in J$, and let $L'_i \subset P_j$ denote the preimage of L_i under the corresponding map $P_j \to P_i$. Finally, set $H_j := \bigcap_{i\in J} L'_i$. By construction, H contains the preimage of H_j in P, and we may therefore assume that H is this preimage. We may replace as usual I by I/j, and assume that j is the final element of I. Then, for every $i \in I$, we let H_i denote the preimage of H_j in P_i, and we set $\overline{P}_i := P_i/H_i$. Set as well $\overline{P} := P/H$. Clearly, there exists $i \in I$ such that the image of the induced map $\overline{P} \to \overline{P}_j$ equals the image of $\overline{P}_i$; for such index i, the induced map $\overline{P} \to \overline{P}_i$ is an isomorphism. Thus, Σ the restriction of an object of P_i-$\mathbf{Set}$, as wished. □

3.6.15. We consider now a situation that generalizes slightly that of (3.6.13). Namely, let I be a small filtered category, and

$$(\mathscr{C}_\bullet, F_\bullet) : I \to \mathbf{fibre.Fun} \qquad i \mapsto (\mathscr{C}_i, F_i)$$

a pseudo-functor. By proposition 3.6.10, the composition of π_1 and $(\mathscr{C}_\bullet, F_\bullet)$ is a functor

$$\pi_1(\mathscr{C}_\bullet, F_\bullet) : I^o \to \mathbf{pf.Grp} \qquad i \mapsto P_i := \pi_1(\mathscr{C}_i, F_i).$$

Let P denote the limit (in $\mathbf{pf.Grp}$) of the cofiltered system $P_\bullet$, and set

$$\mathscr{C} := \text{2-}\operatorname*{colim}_I \mathscr{C}_\bullet$$

where the 2-colimit is formed in the 2-category of small categories. We may then state :

Corollary 3.6.16. *In the situation of* (3.6.15)*, there exists a natural equivalence :*

$$\mathscr{C} \xrightarrow{\sim} P\text{-}\mathbf{Set}.$$

Proof. Recall that $(\mathscr{C}_\bullet, F_\bullet)$ is the datum of isomorphisms

$$\beta_\varphi : F_j \xrightarrow{\sim} F_i \circ \mathscr{C}_\varphi \qquad \text{for every morphism } \varphi : j \to i \text{ in } I$$

and 2-cells :

$$\tau_{\psi,\varphi} : (\mathscr{C}_{\psi\circ\varphi}, \beta_{\psi\circ\varphi}) \xrightarrow{\sim} (\mathscr{C}_\psi, \beta_\psi) \circ (\mathscr{C}_\varphi, \beta_\varphi) \qquad \text{for every composition } j \xrightarrow{\varphi} i \xrightarrow{\psi} k$$

that – by definition – satisfy the identities :

$$(3.6.17) \qquad (\beta_\psi * \mathscr{C}_\varphi) \odot \beta_\varphi = (F_k * \tau_{\psi,\varphi}) \odot \beta_{\psi\circ\varphi} \qquad \text{for every composition } j \xrightarrow{\varphi} i \xrightarrow{\psi} k$$

as well as the composition identities :

$$((\mathscr{C}_\mu, \beta_\mu) * \tau_{\psi,\varphi}) \odot \tau_{\mu,\psi\circ\varphi} = (\tau_{\mu,\psi} * (\mathscr{C}_\varphi, \beta_\varphi)) \odot \tau_{\mu\circ\psi,\varphi} \qquad \text{for compositions } j \xrightarrow{\varphi} i \xrightarrow{\psi} k \xrightarrow{\mu} l.$$

Let $P_\bullet\text{-}\mathbf{Set} : I \to \mathbf{Cat}$ denote the functor given by the rule : $i \mapsto P_i\text{-}\mathbf{Set}$ for every $i \in \mathrm{Ob}(I)$, and $\varphi \mapsto \mathrm{Res}(P_\varphi)$, where $P_\varphi := \pi_1(\mathscr{C}_\varphi, \beta_\varphi)$ for every morphism φ of I. In view of proposition 3.6.14 and lemma 2.5.3, it suffices to show that the rule : $i \mapsto F_i^\dagger$ for every $i \in \mathrm{Ob}(I)$ (notation of (3.6.7)), extends to a pseudo-natural isomorphism

$$F_\bullet^\dagger : \mathscr{C}_\bullet \xrightarrow{\sim} P_\bullet\text{-}\mathbf{Set}.$$

Indeed, let $\varphi : j \to i$ be any morphism of I, and X any object of $\mathscr{C}_j$; we remark that the bijection

$$\beta_\varphi(X) : \mathrm{Res}(P_\varphi)(F_j^\dagger X) \xrightarrow{\sim} F_i^\dagger \circ \mathscr{C}_\varphi(X)$$

is P_i-equivariant; the proof amounts to unwinding the definitions, and shall be left to the reader. Hence we get an isomorphism of functors $\beta_\varphi^\dagger : \mathrm{Res}(P_\varphi) \circ F_j^\dagger \xrightarrow{\sim} F_i^\dagger \circ \mathscr{C}_\varphi$, and from (3.6.17) we deduce the identities :

$$(\beta_\psi^\dagger * \mathscr{C}_\varphi) \odot (\mathrm{Res}(P_\varphi) * \beta_\varphi^\dagger) = (F_k^\dagger * \tau_{\psi,\varphi}) \odot \beta_{\psi\circ\varphi}^\dagger \qquad \text{for every composition } j \xrightarrow{\varphi} i \xrightarrow{\psi} k.$$

The latter show that the system $\beta_\bullet^\dagger$ fulfills the coherence axiom for a pseudo-natural transformation, as required. □

Remark 3.6.18. (i) Keep the situation of (3.6.15), and let $a_\bullet : \mathscr{C}_\bullet \Rightarrow \mathscr{C}$ be the universal pseudo-cocone induced by the pseudo-functor $\mathscr{C}_\bullet$. We may regard the pseudo-functor $(\mathscr{C}_\bullet, F_\bullet)$ as a pseudo-cocone $F_\bullet : \mathscr{C}_\bullet \Rightarrow \mathbf{Set}$ whose vertex is the category $\mathbf{Set}$. Then, by the universal property of colimits, we get a functor $F : \mathscr{C} \to \mathbf{Set}$ and an isomorphism

$$\sigma_\bullet : F * a_\bullet \xrightarrow{\sim} F_\bullet.$$

On the other hand, let $r_\bullet : P_\bullet\text{-}\mathbf{Set} \Rightarrow P\text{-}\mathbf{Set}$ be the natural cocone (so r_i is the restriction functor corresponding to the natural map $P \to P_i$, for every $i \in \mathrm{Ob}(I)$); the equivalence G of corollary 3.6.16 is deduced from the pseudo-cocone $r_\bullet \circ F_\bullet^\dagger : \mathscr{C}_\bullet \to P\text{-}\mathbf{Set}$ (where $F_\bullet^\dagger$ is as in the proof of corollary 3.6.16), so we have an isomorphism of pseudo-functors

$$t_\bullet : G * a_\bullet \xrightarrow{\sim} r_\bullet \circ F_\bullet^\dagger$$

whence an isomorphism

$$\mathsf{f}_P * t_\bullet : (\mathsf{f}_P \circ G) * a_\bullet \xrightarrow{\sim} \mathsf{f}_P * (r_\bullet \circ F_\bullet^\dagger) = F_\bullet$$

(notation of (3.6.7)). There follows an isomorphism $F * a_\bullet \xrightarrow{\sim} (\mathsf{f}_P \circ G) * a_\bullet$; by the universal property of the 2-colimit, the latter must come from a unique isomorphism $\vartheta : F \xrightarrow{\sim} \mathsf{f}_P \circ G$. Especially, we see that F is also a fibre functor, and we get a pseudo-cocone

$$(a_\bullet, \sigma_\bullet) : (\mathscr{C}_\bullet, F_\bullet) \Rightarrow (\mathscr{C}, F).$$

It is now immediate that $(\mathscr{C}, F)$ is the 2-colimit (in the 2-category $\mathbf{fibre.Fun}$) of the pseudo-functor $(\mathscr{C}_\bullet, F_\bullet)$, and $(a_\bullet, \sigma_\bullet)$ is the corresponding universal pseudo-cocone.

(ii) Likewise, $r_\bullet$ may be regarded as a universal pseudo-cocone

$$r_\bullet : (P_\bullet\text{-}\mathbf{Set}, \mathsf{f}_{P_\bullet}) \Rightarrow (P\text{-}\mathbf{Set}, \mathsf{f}_P)$$

(with trivial coherence constraint), and the coherence constraint $\beta_\bullet^\dagger$ as in the proof of corollary 3.6.16 yields a pseudo-natural equivalence

$$F_\bullet^\dagger : (\mathscr{C}_\bullet, F_\bullet) \xrightarrow{\sim} (P_\bullet\text{-}\mathbf{Set}, \mathsf{f}_{P_\bullet})$$

as well as an isomorphism

$$(G, \vartheta) * (a_\bullet, \sigma_\bullet) \xrightarrow{\sim} r_\bullet \odot F_\bullet^\dagger.$$

Thus, for every $i \in \mathrm{Ob}(I)$ we get a 2-cell of $\mathbf{fibre.Fun}$:

$$(G, \vartheta) \circ (a_i, \sigma_i) \to r_i \circ F_i^\dagger$$

whence – by proposition 3.6.10 – a commutative diagram of profinite groups :

$$\begin{array}{ccc} P & \longrightarrow & P_i \\ {\scriptstyle \pi_1(G,\vartheta)} \downarrow & & \downarrow {\scriptstyle \pi_1(F_i^\dagger)} \\ \pi_1(\mathscr{C}, F) & \xrightarrow{\pi_1(a_i,\sigma_i)} & \pi_1(\mathscr{C}_i, F_i). \end{array}$$

3.6.19. Let $(\mathscr{C}, F)$ be a fibre functor, and X a connected object of $\mathscr{C}$ (example 1.2.16(iv)); pick any $\xi \in F(X)$, and let $H_\xi \subset \pi_1(\mathscr{C}, F)$ be the stabilizer of ξ for the natural left action of $\pi_1(\mathscr{C}, F)$ on $F(X)$. For every object $f : Y \to X$ of $\mathscr{C}/X$, we set

$$F_\xi(f) := F(f)^{-1}(\xi) \subset F(Y).$$

It is clear that the rule $f \mapsto F_\xi(f)$ yields a functor $F_\xi^\dagger : \mathscr{C}/X \to H_\xi\text{-}\mathbf{Set}$, which we call the *subfunctor of $F_{|X}$ selected by ξ*.

Proposition 3.6.20. *In the situation of* (3.6.19)*, we have :*

(i) *$\mathscr{C}/X$ is also a Galois category, and $F_\xi := \mathsf{f}_{H_\xi} \circ F_\xi^\dagger$ is a fibre functor for $\mathscr{C}/X$.*

(ii) *The functor $F_\xi^\dagger$ induces a natural isomorphism of profinite groups :*

$$\pi_1(F_\xi^\dagger) : H_\xi \xrightarrow{\sim} \pi_1(\mathscr{C}/X, F_\xi).$$

Proof. The fibre functor F induces an equivalence of categories

$$\mathscr{C}/X \xrightarrow{\sim} \pi_1(\mathscr{C}, F)\text{-}\mathbf{Set}/F(X).$$

On the other hand, since X is connected, there exists a unique isomorphism $\omega : F(X) \xrightarrow{\sim} G/H_\xi$ of G-sets such that $\omega(\xi) = H_\xi$, and then the discussion of (3.6.4) yields an equivalence

$$\pi_1(\mathscr{C}, F)\text{-}\mathbf{Set}/F(X) \xrightarrow{\sim} H_\xi\text{-}\mathbf{Set}.$$

A simple inspection shows that the resulting equivalence $\mathscr{C}/X \xrightarrow{\sim} H_\xi\text{-}\mathbf{Set}$ is none else than the functor $F_\xi^\dagger$, so the assertion follows from remark 3.6.9(i) and example 3.6.8. □

3.6.21. Let $(\mathscr{C}, F)$ be a fibre functor, and let us now fix a cleavage $\mathsf{c} : \mathscr{C}^o \to \mathbf{Cat}$ for the fibred category $\mathsf{t} : \mathsf{Morph}(\mathscr{C}) \to \mathscr{C}$ (see example 3.1.3(iii)). Also, let I be a small cofiltered category, and $X_\bullet : I \to \mathscr{C}$ a functor such that X_i is a connected object of $\mathscr{C}$, for every $i \in \mathrm{Ob}(I)$; we pick an element

$$\xi_\bullet \in \lim_I F \circ X_\bullet.$$

In other words, $\xi_\bullet := (\xi_i \in F(X_i) \mid i \in I)$ is a compatible system of elements such that

$$F(\varphi)(\xi_j) = \xi_i \qquad \text{for every morphism } \varphi : j \to i \text{ in } I.$$

For every $i \in I$, we denote by $H_i \subset \pi_1(\mathscr{C}, F)$ the stabilizer of ξ_i for the left action of $\pi_1(\mathscr{C}, F)$ on $F(X_i)$. Clearly, any morphism $j \to i$ induces an inclusion $H_j \subset H_i$. Furthermore, let

$$F_i^\dagger : \mathscr{C}/X_i \to H_i\text{-}\mathbf{Set} \qquad \text{for every } i \in I$$

be the subfunctor selected by ξ_i, and set $F_i := \mathsf{f}_{H_i} \circ F_i^\dagger$. Let $\varphi : j \to i$ be a morphism of I; to the corresponding morphism $X_\varphi : X_j \to X_i$, the cleavage c attaches a pull-back functor

$$X_\varphi^* : \mathscr{C}/X_i \to \mathscr{C}/X_j.$$

Especially, for any object $Y \in \mathrm{Ob}(\mathscr{C}/X_i)$ we have the cartesian diagram in $\mathscr{C}$:

$$\begin{array}{ccc} X_\varphi^*(Y) & \longrightarrow & Y \\ \downarrow & & \downarrow \\ X_j & \xrightarrow{X_\varphi} & X_i \end{array}$$

whence, since F is exact, a natural bijection :

$$F(X_\varphi^*(Y)) \stackrel{\sim}{\to} F(Y) \times_{F(X_i)} F(X_j)$$

which in turns yields a bijection :

$$F_j^\dagger(X_\varphi^*(Y)) \stackrel{\sim}{\to} F(Y) \times_{F(X_i)} \{\xi_j\} = F_i^\dagger(Y) \times \{\xi_j\}.$$

That is, we have a natural isomorphism of functors :

$$\alpha_\varphi^\dagger : F_j^\dagger \circ X_\varphi^* \stackrel{\sim}{\to} \mathrm{Res}_{H_i}^{H_j} \circ F_i^\dagger \tag{3.6.22}$$

and since the X_φ^* are exact functors, it is easily seen that the isomorphisms $\alpha_\varphi := \mathsf{f}_j * \alpha_\varphi^\dagger$ yield a pseudo-functor

$$I \to \mathbf{fibre.Fun} \qquad i \mapsto (\mathscr{C}/X_i, F_i) \qquad \varphi \mapsto (X_\varphi^*, \alpha_\varphi). \tag{3.6.23}$$

Moreover, $\alpha_\varphi^\dagger$ can be seen as a 2-cell of **fibre.Fun** : $F_j^\dagger \circ (X_\varphi^*, \alpha_\varphi) \stackrel{\sim}{\to} \mathrm{Res}_{H_j}^{H_i} \circ F_i^\dagger$, whence a commutative diagram of profinite groups :

$$\begin{array}{ccc} H_j & \longrightarrow & H_i \\ {\scriptstyle \pi_1(F_j^\dagger)}\downarrow & & \downarrow{\scriptstyle \pi_1(F_i^\dagger)} \\ \pi_1(\mathscr{C}/X_j, F_j) & \xrightarrow{\pi_1(X_\varphi^*, \alpha_\varphi)} & \pi_1(\mathscr{C}/X_i, F_i) \end{array}$$

whose top horizontal arrow is the inclusion map. Especially, notice that the map $\pi_1(X_\varphi^*, \alpha_\varphi)$ does not depend on the chosen cleavage; this can also be seen by remarking that any two cleavages c, c' are related by a pseudo-natural isomorphism $\mathsf{c} \stackrel{\sim}{\to} \mathsf{c}'$ (details left to the reader).

3.6.24. Let $(\mathscr{C}/X, F_\xi)$ be the 2-colimit of the pseudo-functor (3.6.23), as in remark 3.6.18(i), and fix a corresponding universal pseudo-cocone $(a_\bullet, \sigma_\bullet) : (\mathscr{C}/X_\bullet, F_\bullet) \Rightarrow (\mathscr{C}/X, F_\xi)$. We may then state :

Corollary 3.6.25. *In the situation of* (3.6.24)*, there exists a natural isomorphism of profinite groups :*

$$H := \bigcap_{i \in \mathrm{Ob}(I)} H_i \stackrel{\sim}{\to} \pi_1(\mathscr{C}/X, F_\xi)$$

which fits into a commutative diagram :

$$\begin{array}{ccc} H & \longrightarrow & H_i \\ \downarrow & & \downarrow{\scriptstyle \pi_1(F_i^\dagger)} \\ \pi_1(\mathscr{C}/X, F_\xi) & \xrightarrow{\pi_1(a_i, \sigma_i)} & \pi_1(\mathscr{C}/X_i, F_i) \end{array} \qquad \textit{for every } i \in \mathrm{Ob}(I) \tag{3.6.26}$$

whose top horizontal arrow is the inclusion map.

Proof. By corollary 3.6.16, we have an isomorphism of $\pi_1(\mathscr{C}/X, F_\xi)$ with the limit of the cofiltered system $(\pi_1(\mathscr{C}/X, F_i) \mid i \in \mathrm{Ob}(I))$; on the other hand, the discussion of (3.6.21) shows that the latter system is naturally isomorphic to the system $(H_i \mid i \in \mathrm{Ob}(I))$. Lastly, the commutativity of (3.6.26) follows from remark 3.6.18(ii). □

3.7. **Tensor categories and abelian categories.** In this section we assemble some basic definitions and results that pertain to abelian categories and other related classes of categories with extra structure.

Definition 3.7.1. A *tensor category* is a datum $\underline{\mathscr{C}} := (\mathscr{C}, \otimes, \Phi, \Psi)$ consisting of a category $\mathscr{C}$, a functor

$$\otimes : \mathscr{C} \times \mathscr{C} \to \mathscr{C} \quad : \quad (X, Y) \mapsto X \otimes Y$$

and natural isomorphisms :

$$\Phi_{X,Y,Z} : X \otimes (Y \otimes Z) \xrightarrow{\sim} (X \otimes Y) \otimes Z \qquad \Psi_{X,Y} : X \otimes Y \xrightarrow{\sim} Y \otimes X$$

for every $X, Y, Z \in \mathrm{Ob}(\mathscr{C})$, called respectively the *associativity* and *commutativity constraints* of $\underline{\mathscr{C}}$, that satisfy the following axioms.

(a) *Coherence axiom* : the diagram

$$\begin{array}{ccccc}
X \otimes (Y \otimes (Z \otimes T)) & \xrightarrow{\Phi_{X,Y,Z\otimes T}} & (X \otimes Y) \otimes (Z \otimes T) & \xrightarrow{\Phi_{X\otimes Y,Z,T}} & ((X \otimes Y) \otimes Z) \otimes T \\
{\scriptstyle X\otimes\Phi_{Y,Z,T}}\downarrow & & & & \uparrow{\scriptstyle \Phi_{X,Y,Z}\otimes T} \\
X \otimes ((Y \otimes Z) \otimes T) & & \xrightarrow{\qquad\qquad\Phi_{X,Y\otimes Z,T}\qquad\qquad} & & (X \otimes (Y \otimes Z)) \otimes T
\end{array}$$

commutes, for every $X, Y, Z, T \in \mathrm{Ob}(\mathscr{C})$.

(b) *Compatibility axiom* : the diagram

$$\begin{array}{ccccc}
X \otimes (Y \otimes Z) & \xrightarrow{\Phi_{X,Y,Z}} & (X \otimes Y) \otimes Z & \xrightarrow{\Psi_{X\otimes Y,Z}} & Z \otimes (X \otimes Y) \\
{\scriptstyle X\otimes\Psi_{Y,Z}}\downarrow & & & & \downarrow{\scriptstyle \Phi_{Z,X,Y}} \\
X \otimes (Z \otimes Y) & \xrightarrow{\Phi_{X,Z,Y}} & (X \otimes Z) \otimes Y & \xrightarrow{\Psi_{X,Z}\otimes Y} & (Z \otimes X) \otimes Y
\end{array}$$

commutes, for every $X, Y, Z \in \mathrm{Ob}(\mathscr{C})$.

(c) *Commutation axiom* : we have $\Psi_{Y,X} \circ \Psi_{X,Y} = \mathbf{1}_{X\otimes Y}$ for every $X, Y \in \mathrm{Ob}(\mathscr{C})$

(d) *Unit axiom* : there exist an object $U \in \mathrm{Ob}(\mathscr{C})$ and an isomorphism $u : U \xrightarrow{\sim} U \otimes U$ such that the functor

$$\mathscr{C} \to \mathscr{C} \quad : \quad X \mapsto U \otimes X \tag{3.7.2}$$

is an equivalence. One says that (U, u) is a *unit object* of $\underline{\mathscr{C}}$.

Lemma 3.7.3. *Let* $\underline{\mathscr{C}} := (\mathscr{C}, \otimes, \Phi, \Psi)$ *be any tensor category. The diagram*

$$\begin{array}{ccccc}
X \otimes (Y \otimes Z) & \xrightarrow{\Phi_{X,Y,z}} & (X \otimes Y) \otimes Z & \xrightarrow{\Psi_{X,Y}\otimes Z} & (Y \otimes X) \otimes Z \\
{\scriptstyle X\otimes\Psi_{Y,Z}}\downarrow & & & & \uparrow{\scriptstyle \Phi_{Y,X,Z}} \\
X \otimes (Z \otimes Y) & \xrightarrow{\Phi_{X,Z,Y}} & (X \otimes Z) \otimes Y & \xrightarrow{\Psi_{X\otimes Z,Y}} & Y \otimes (X \otimes Z)
\end{array}$$

commutes, for every $X, Y, Z \in \mathrm{Ob}(\mathscr{C})$.

Proof. To ease notation, we shall omit the tensor symbol $\otimes$ between objects, and we shall drop the subscript from Φ and Ψ when we display a diagram. It suffices to consider the diagram

$$\begin{tikzcd} & Y(XZ) \arrow[rrr, "\Phi"] \arrow[d, "Y\otimes\Psi"] & & & (YX)Z \arrow[d, "\Psi"] & \\ & Y(ZX) \arrow[r, "\Phi"] & (YZ)X \arrow[r, "\Psi\otimes X"] & (ZY)X & Z(YX) \arrow[l, "\Phi"'] & \\ (XZ)Y \arrow[ruu, "\Psi"] \arrow[r, "\Psi\otimes Y"] & (ZX)Y \arrow[u, "\Psi"] & & & Z(XY) \arrow[lll, "\Phi"'] \arrow[u, "Z\otimes\Psi"'] & (XY)Z \arrow[l, "\Psi"'] \arrow[luu, "\Psi\otimes Z"'] \\ X(ZY) \arrow[u, "\Phi"] & & & & & X(YZ) \arrow[lllll, "X\otimes\Psi"'] \arrow[u, "\Phi"'] \end{tikzcd}$$

whose two triangular subdiagrams commute by naturality of Ψ, and whose three rectangular subdiagrams commute by compatibility. $\square$

Definition 3.7.4. Let $\underline{\mathscr{C}} := (\mathscr{C}, \otimes, \Phi, \Psi)$ and $\underline{\mathscr{C}}' := (\mathscr{C}', \otimes', \Phi', \Psi')$ be two tensor categories. A *tensor functor* $\underline{\mathscr{C}} \to \underline{\mathscr{C}}'$ is a pair (F, c) consisting of a functor $F : \mathscr{C} \to \mathscr{C}'$ and a natural isomorphism

$$c_{X,Y} : FX \otimes FY \xrightarrow{\sim} F(X \otimes Y) \qquad \text{for all } X, Y \in \mathrm{Ob}(\mathscr{C})$$

such that the following holds.

(a) For every objects X, Y, Z of $\mathscr{C}$, the diagram

$$\begin{tikzcd} FX \otimes (FY \otimes FZ) \arrow[r, "FX\otimes c_{YZ}"] \arrow[d, "\Phi'_{FX,FY,FZ}"'] & FX \otimes F(Y \otimes Z) \arrow[r, "c_{X,Y\otimes Z}"] & F(X \otimes (Y \otimes Z)) \arrow[d, "F(\Phi_{X,Y,Z})"] \\ (FX \otimes FY) \otimes FZ \arrow[r, "c_{X,Y}\otimes FZ"] & F(X \otimes Y) \otimes FZ \arrow[r, "c_{X\otimes Y,Z}"] & F((X \otimes Y) \otimes Z) \end{tikzcd}$$

commutes.

(b) For all objects X, Y of $\mathscr{C}$, the diagram

$$\begin{tikzcd} FX \otimes FY \arrow[r, "c_{X,Y}"] \arrow[d, "\Psi_{FX,FY}"'] & F(X \otimes Y) \arrow[d, "F(\Psi_{X,Y})"] \\ FY \otimes FX \arrow[r, "c_{Y,X}"] & F(Y \otimes X) \end{tikzcd}$$

commutes.

(c) If (U, u) is a unit object of $\underline{\mathscr{C}}$, then $(FU, c^{-1}_{U,U} \circ Fu)$ is a unit object of $\underline{\mathscr{C}}'$.

Remark 3.7.5. (i) Lemma 3.7.3 illustrates a general principle valid in every tensor categor $\underline{\mathscr{C}}$: namely, say that $X_1, \dots, X_n$ is a sequence of *distinct* objects of $\mathscr{C}$, and X' and X'' are obtained from these two sequences by taking tensor products several times, and in any order, in which case we say that X' and X'' *have no repetitions*. Now, there will be usually various ways to combine the associativity and commutativity constraints, in order to exhibit some isomorphism $X' \xrightarrow{\sim} X''$. However, the resulting isomorphism shall be independent of the way in which it is expressed as such a combination. This follows from a theorem of Mac Lane. To formalize this result, one could observe that, for any set Σ, there exists a universal tensor category T_Σ "generated by Σ", *i.e.* such that – for any other tensor category $\underline{\mathscr{C}}$ – any mapping $\Sigma \to \mathrm{Ob}(\mathscr{C})$ extends uniquely, up to isomorphism, to a tensor functor $T_\Sigma \to \underline{\mathscr{C}}$. Then Mac Lane's theorem says that, for every set Σ, and every object $X \in \mathrm{Ob}(T_\Sigma)$ that has no repetitions, the group $\mathrm{Aut}_{T_\Sigma}(X)$ is trivial. Instead of relying on such a general result, we shall make *ad hoc* verifications, as in the proof of lemma 3.7.3 and of the forthcoming proposition 3.7.6. However, in view of this principle, in the following we shall often omit a detailed description of the isomorphism that we choose to connect two given objects that are thus related : the reader will be able in any case to produce one isomorphism, and the principle says that these choices cannot be source of ambiguities.

(ii) Let $\mathscr{D}$ be any category, and $\underline{\mathscr{C}}$ a tensor category. Then notice that $\mathsf{Fun}(\mathscr{D}, \mathscr{C})$ inherits from $\underline{\mathscr{C}}$ a natural tensor category structure : we leave to the reader the task of spelling out the details. Moreover notice that if $(F, c) : \underline{\mathscr{C}}_1 \to \underline{\mathscr{C}}_2$ and $(F', c') : \underline{\mathscr{C}}_2 \to \underline{\mathscr{C}}_3$ are any two tensor functors between tensor categories, then the composition

$$(F' \circ F, (F' * c) \odot (c' * (F \times F))) : \underline{\mathscr{C}}_1 \to \underline{\mathscr{C}}_3$$

is again a tensor functor.

Proposition 3.7.6. *Let (U, u) be a unit object of a tensor category $\underline{\mathscr{C}}$. Then there exists a unique natural isomorphism*

$$u_X : X \xrightarrow{\sim} U \otimes X \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C})$$

such that $u_U = u$, and such that the diagrams

$$\begin{array}{ccc} X \otimes Y & \xrightarrow{u_{X\otimes Y}} & U \otimes (X \otimes Y) \\ & \searrow^{u_X \otimes Y} & \downarrow{\scriptstyle \Phi_{U,X,Y}} \\ & & (U \otimes X) \otimes Y \end{array} \qquad \begin{array}{ccc} X \otimes Y & \xrightarrow{u_X \otimes Y} & (U \otimes X) \otimes Y \\ {\scriptstyle X \otimes u_Y}\downarrow & & \downarrow{\scriptstyle \Psi_{U,X} \otimes Y} \\ X \otimes (U \otimes Y) & \xrightarrow{\Phi_{X,U,Y}} & (X \otimes U) \otimes Y \end{array}$$

commute for every $X, Y \in \mathrm{Ob}(\mathscr{C})$.

Proof. Since (3.7.2) is an equivalence, there exists a unique isomorphism u_X fitting into the commutative diagram

$$\begin{array}{ccc} UX & \xrightarrow{u \otimes X} & (UU)X \\ & \searrow^{U \otimes u_X} & \uparrow{\scriptstyle \Phi} \\ & & U(UX). \end{array}$$

With this definition, the naturality of the rule : $X \mapsto u_X$ is clear. In order to check the commutativity of the first diagram, it suffices to show that

$$(U \otimes \Phi_{U,X,Y}) \circ (U \otimes u_{XY}) = U \otimes (u_X \otimes Y). \tag{3.7.7}$$

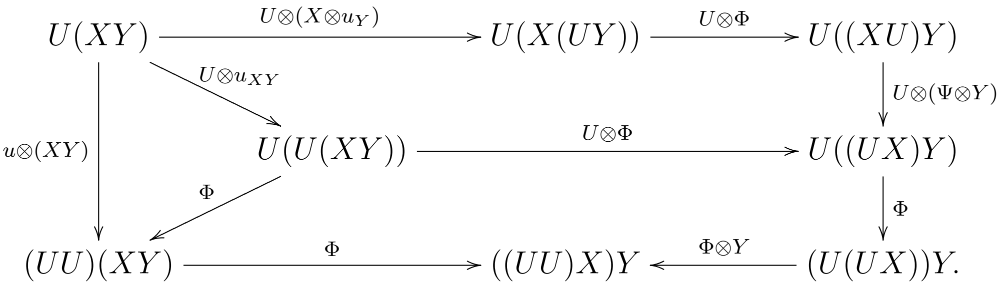
However, set $\Theta := (\Phi_{U,U,X} \otimes Y) \circ \Phi_{U,UX,Y}$; we have :

$$\begin{aligned} \Theta \circ (U \otimes (u_X \otimes Y)) &= (\Phi_{U,U,X} \otimes Y) \circ ((U \otimes u_X) \otimes Y) \circ \Phi_{U,X,Y} \\ &= ((u \otimes X) \otimes Y) \circ \Phi_{U,X,Y} \\ &= \Phi_{UU,X,Y} \circ (u \otimes (XY)) \\ &= \Phi_{UU,X,Y} \circ \Phi_{U,U,XY} \circ (U \otimes u_{XY}) \\ &= \Theta \circ (U \otimes \Phi_{U,X,Y}) \circ (U \otimes u_{XY}) \end{aligned}$$

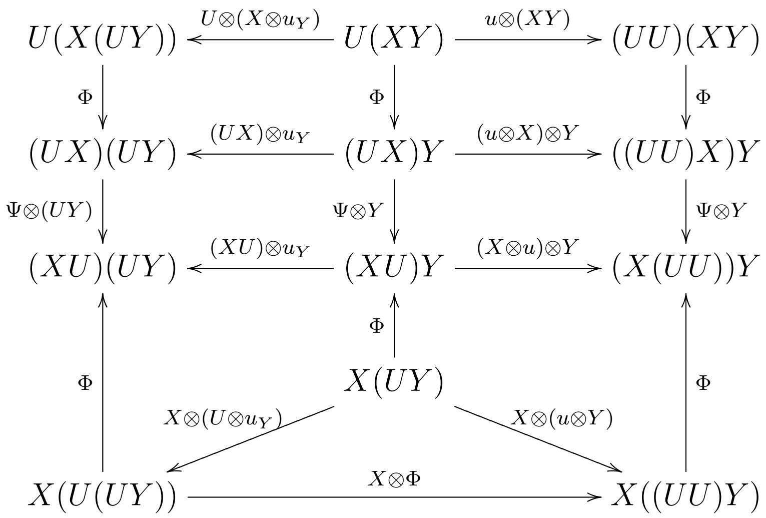
where the first and third identities hold by naturality of Φ, the second and fourth by the definition of u_X and respectively $u_{X \otimes Y}$, and the fifth by coherence. Since Θ is an isomorphism, we get (3.7.7). Next, in light of the foregoing, the second diagram commutes if and only if the diagram

$$\begin{array}{ccccc} XY & \xrightarrow{u_{XY}} & U(XY) & \xrightarrow{\Phi} & (UX)Y \\ & \searrow^{X \otimes u_Y} & & & \downarrow{\scriptstyle \Psi \otimes Y} \\ & & X(UY) & \xrightarrow{\Phi} & (XU)Y \end{array} \tag{3.7.8}$$

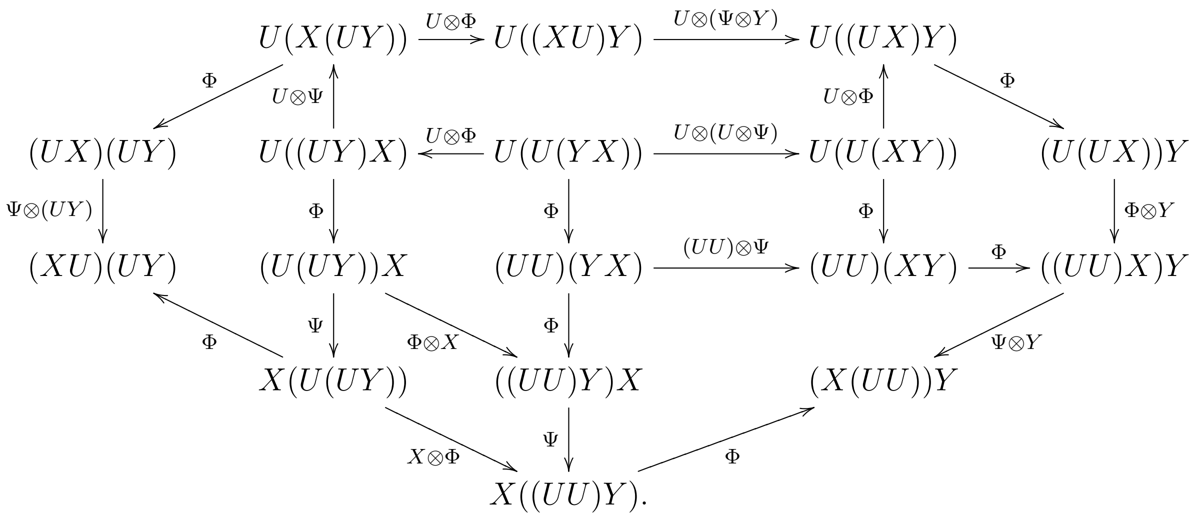
commutes, and it suffices to check that $U \otimes$ (3.7.8) commutes. To this aim, we consider the diagram



whose lower subdiagram commutes by the coherence axiom for (U, U, X, Y), whose upper subdiagram is equivalent to (3.7.8), since $\Psi_{U,X}^{-1} = \Psi_{X,U}$, and whose triangular subdiagram commutes by definition of u_{XY}. Hence, we are reduced to showing that the outer rectangular subdiagram of the above diagram commutes. However, we have a commutative diagram :



so we are further reduced to checking the commutativity of the diagram :



However, the leftmost and the lower triangular subdiagrams commute by compatibility, and the upper rightmost subdiagram commutes by coherence. The lower leftmost subdiagram commutes by naturality of Ψ, and the central square sudiagram commutes by naturality of Φ. The remaining central subdiagram commutes by coherence, and the top rectangular subdiagram is of the form $U \otimes D$, where D is a diagram that commutes by virtue of lemma 3.7.3.

The uniqueness of u_X is clear by inspecting the second diagram, with $Y = U$. □

Remark 3.7.9. (i) Keep the notation of proposition 3.7.6. As a consequence of the naturality of u_X, we get a commutative diagram

$$\begin{array}{ccc} X & \xrightarrow{u_X} & U \otimes X \\ {\scriptstyle u_X}\downarrow & & \downarrow{\scriptstyle u\otimes u_X} \\ U \otimes X & \xrightarrow{u_{U\otimes X}} & U \otimes (U \otimes X) \end{array}$$

for every object X of $\mathscr{C}$. In other words :

$$u_{U\otimes X} = U \otimes u_X \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C}).$$

(ii) Let $X = Y = U$ in the second diagram of proposition 3.7.6; we obtain a commutative diagram

$$\begin{array}{ccc} U \otimes U & \xrightarrow{u\otimes U} & (U \otimes U) \otimes U \\ {\scriptstyle U\otimes u}\downarrow & & \downarrow{\scriptstyle \Psi_{U,U}\otimes U} \\ U \otimes (U \otimes U) & \xrightarrow{\Phi_{U,U,U}} & (U \otimes U) \otimes U \end{array}$$

Since $u = u_U$, we may combine with (i), to deduce that $\Psi_{U,U} \otimes U = \mathbf{1}_{(U\otimes U)\otimes U} = \mathbf{1}_{U\otimes U} \otimes U$. By naturality of Ψ, it follows that $U \otimes \Psi_{U,U} = U \otimes \mathbf{1}_{U\otimes U}$, and since (3.7.2) is an equivalence, we conclude that

$$\Psi_{U,U} = \mathbf{1}_{U\otimes U}.$$

Example 3.7.10. Let $\mathscr{C}$ be any category with small Hom-sets, in which finite products are representable. For every pair (X, Y) of objects of $\mathscr{C}$, pick an object $X \otimes Y$ representing their product, and fix also two projections $p_{X,Y} : X \otimes Y \to X$, $q_{X,Y} : X \otimes Y \to Y$ inducing an isomorphism of functors

$$h_{X\otimes Y} \xrightarrow{\sim} h_X \times h_Y \quad : \quad \varphi \mapsto (p_{X,Y} \circ \varphi, q_{X,Y} \circ \varphi) \qquad \text{for every } Z \in \mathrm{Ob}(\mathscr{C}) \text{ and } \varphi \in h_{X\times Y}(Z)$$

(notation of (1.2.4)). If (X', Y') is another such pair, and $(g, h) : (X, Y) \to (X', Y')$ any morphism in $\mathscr{C} \times \mathscr{C}$, then there exists a unique morphism $f : X \otimes Y \to X' \otimes Y'$ such that

$$(p_{X',Y'} \circ f, q_{X',Y'} \circ f) = (g \circ p_{X,Y}, h \circ p_{X,Y})$$

and we set $g \otimes h := f$. These rules define a functor $\otimes : \mathscr{C} \times \mathscr{C} \to \mathscr{C}$. For every three objects X, Y, Z there is a natural isomorphism $X \otimes (Y \otimes Z) \xrightarrow{\sim} (X \otimes Y) \otimes Z$ that yields an associativity constraint for $\otimes$; namely, we let

$$\Phi_{X,Y,Z} := (p_{X,Y\otimes Z} \otimes (p_{Y,Z} \otimes q_{X,Y\otimes Z})) \otimes (q_{Y,Z} \circ q_{X,Y\otimes Z}).$$

Likewise, we get a commutativity constraint by setting

$$\Psi_{X,Y} := q_{X,Y} \otimes p_{X,Y} \qquad \text{for every } X, Y \in \mathrm{Ob}(\mathscr{C}).$$

The verifications of the axioms of definition 3.7.1 are lengthy but straightforward, and shall be left to the reader. If U is any final object of $\mathscr{C}$ (example 1.2.16(iv)), then there exists a unique morphism $u : U \to U \otimes U$ which is easily seen to be an isomorphism, and the pair (U, u) yields a unit for $\otimes$. In this way, any category with finite products and small Hom-sets is naturally endowed with a structure of tensor category. Notice that, for this tensor structure on $\mathscr{C}$ (and indeed, for most of the tensor categories that are found in applications), the existence of functorial isomorphisms u_X fulfilling the conditions of proposition 3.7.6, is self-evident.

Definition 3.7.11. Let $(\mathscr{C}, \otimes, \Phi, \Psi)$ be a tensor category, $X \in \mathrm{Ob}(\mathscr{C})$ any object, and suppose that the functor

$$- \otimes X : \mathscr{C} \to \mathscr{C} \qquad Y \mapsto Y \otimes X$$

admits a right adjoint :

$$\mathscr{H}om(X, -) : \mathscr{C} \to \mathscr{C} \qquad Y \mapsto \mathscr{H}om(X, Y).$$

Then, we call $\mathscr{H}om(X, -)$ the *internal* Hom *functor* for the object X.

Remark 3.7.12. (i) As usual, the internal Hom functor is determined up to unique isomorphism, if it exists. The counit of adjunction is a morphism of $\mathscr{C}$

$$\mathrm{ev}_{X,Y} : \mathscr{H}om(X, Y) \otimes X \to Y$$

called the *evaluation morphism*.

(ii) Suppose that every object of $\mathscr{C}$ admits an internal Hom functor; then we say briefly that $\mathscr{C}$ *admits an internal* Hom *functor*, and clearly we get a functor

$$\mathscr{C}^o \times \mathscr{C} \to \mathscr{C} \quad : \quad (X, Y) \mapsto \mathscr{H}om(X, Y) \qquad \text{for every } X, Y \in \mathrm{Ob}(\mathscr{C}).$$

Moreover, for every $X, Y, Z \in \mathrm{Ob}(\mathscr{C})$ the composition

$$\begin{array}{ccc} (\mathscr{H}om(X,Y) \otimes \mathscr{H}om(Y,Z)) \otimes X & \xrightarrow{\sim} & (\mathscr{H}om(X,Y) \otimes X) \otimes \mathscr{H}om(Y,Z) \\ & & \downarrow{\scriptstyle \mathrm{ev}_{X,Y} \otimes \mathscr{H}om(Y,Z)} \\ Z \xleftarrow{\mathrm{ev}_{Y,Z}} \mathscr{H}om(Y,Z) \otimes Y & \xleftarrow{\sim} & Y \otimes \mathscr{H}om(Y,Z) \end{array}$$

corresponds, by adjunction, to a unique *composition morphism*

$$\mathscr{H}om(X, Y) \otimes \mathscr{H}om(Y, Z) \to \mathscr{H}om(X, Z).$$

(iii) In the situation of (ii), notice that the functor $\mathscr{C} \to \mathscr{C}$ given by the rule : $Z \mapsto \mathscr{H}om(X, \mathscr{H}om(Y, Z))$, for every $Z \in \mathrm{Ob}(\mathscr{C})$, is right adjoint to the functor given by the rule : $Z \mapsto (Z \otimes X) \otimes Y \xrightarrow{\sim} Z \otimes (X \otimes Y)$. There follows a natural isomorphism

$$\mathscr{H}om(X, \mathscr{H}om(Y, Z)) \xrightarrow{\sim} \mathscr{H}om(X \otimes Y, Z) \qquad \text{for every } X, Y, Z \in \mathrm{Ob}(\mathscr{C}).$$

(iv) Moreover, for any unit (U, u) of $\underline{\mathscr{C}}$, we get natural bijections :

$$\mathrm{Hom}_{\mathscr{C}}(U, \mathscr{H}om(X, Y)) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{C}}(U \otimes X, Y) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{C}}(X, Y) \qquad \text{for every } X, Y \in \mathrm{Ob}(\mathscr{C}).$$

Also, for every object Y of $\mathscr{C}$, denote by $u_Y : Y \xrightarrow{\sim} U \otimes Y$ the isomorphism given by proposition 3.7.6; for every $X \in \mathrm{Ob}(X)$, it induces natural bijections

$$\mathrm{Hom}_{\mathscr{C}}(Y, \mathscr{H}om(U, X)) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{C}}(Y \otimes U, X) \xrightarrow{\mathrm{Hom}_{\mathscr{C}}(u_Y \circ \Psi_{U,Y}, X)} \mathrm{Hom}_{\mathscr{C}}(Y, X)$$

which correspond, via the Yoneda embedding, to a natural isomorphism

$$\mathscr{H}om(U, X) \xrightarrow{\sim} X \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C}).$$

(v) Let X, Y, Z be any three objects of $\mathscr{C}$; the natural transformation

$$\mathrm{Hom}_{\mathscr{C}}(W \otimes X, Y) \to \mathrm{Hom}_{\mathscr{C}}(W \otimes (X \otimes Z), Y \otimes Z) \qquad \varphi \mapsto (\varphi \otimes Z) \circ \Phi_{W,X,Z}$$

corresponds, via the Yoneda embedding, to a unique morphism

$$t_{X,Y,Z} : \mathscr{H}om(X, Y) \to \mathscr{H}om(X \otimes Z, Y \otimes Z).$$

The reader can check that $t_{X,Y,Z}$ also corresponds, by adjunction, to the morphism

$$(\mathrm{ev}_{X,Y} \otimes Z) \circ \Phi_{\mathscr{H}om(X,Y),X,Z} : \mathscr{H}om(X, Y) \otimes (X \otimes Z) \to Y \otimes Z.$$

(vi) In the situation of remark 3.7.5(ii), suppose that $\mathscr{C}$ admits an internal Hom functor; then it is easily seen that the resulting tensor category $\mathsf{Fun}(\mathscr{D},\mathscr{C})$ inherits as well an internal Hom functor, in the obvious way.

The formalism of tensor categories provides the language to deal uniformly with the notions of algebras and their modules that occur in various concrete settings.

Definition 3.7.13. Let $(\mathscr{C},\otimes,\Phi,\Psi)$ be a tensor category, A and B any two objects of $\mathscr{C}$.

(i) A *left A-module* (resp. a *right B-module*) is a datum (X,μ_X), consisting of an object X of $\mathscr{C}$, and a morphism in $\mathscr{C}$:

$$\mu_X : A\otimes X\to X \qquad \text{(resp. } \mu_X : X\otimes B\to X\text{)}$$

called the *scalar multiplication* of X.

(ii) A *morphism of left A-modules* $(X,\mu_X)\to(X',\mu_{X'})$ is a morphism $f:X\to X'$ in $\mathscr{C}$ which makes commute the diagram :

$$\begin{array}{ccc} A\otimes X & \xrightarrow{\mu_X} & X \\ {\scriptstyle \mathbf{1}_A\otimes f}\downarrow & & \downarrow{\scriptstyle f} \\ A\otimes X' & \xrightarrow{\mu_{X'}} & X'. \end{array}$$

One defines likewise morphisms of right B-modules.

(iii) An *(A,B)-bimodule* is a datum (X,μ^l_X,μ^r_X) such that (X,μ^l_X) is a left A-module, (X,μ^r_X) is a right B-module, and the scalar multiplications commute, *i.e.* the diagram

$$\begin{array}{ccccc} A\otimes(X\otimes B) & & \xrightarrow{\mathbf{1}_A\otimes\mu^r_X} & & A\otimes X \\ {\scriptstyle \Phi_{A,X,B}}\downarrow & & & & \downarrow{\scriptstyle \mu^l_X} \\ (A\otimes X)\otimes B & \xrightarrow{\mu^l_X\otimes\mathbf{1}_B} & X\otimes B & \xrightarrow{\mu^r_X} & X \end{array}$$

commutes. Of course, a morphism of (A,B)-bimodules must be compatible with both left and right multiplication.

We denote by $A\text{-}\mathbf{Mod}_l$ (resp. $B\text{-}\mathbf{Mod}_r$, resp. $(A,B)\text{-}\mathbf{Mod}$) the category of left A-modules (resp. right B-modules, resp. (A,B)-bimodules). For any two left A-modules (resp. right B-modules, resp. (A,B)-bimodules) X and X', we shall write

$$\mathrm{Hom}_{A_l}(X,X') \qquad (\text{ resp. } \mathrm{Hom}_{B_r}(X,X')\text{ }) \qquad (\text{ resp. } \mathrm{Hom}_{(A,B)}(X,X')\text{ })$$

for the set of morphisms of left A-modules (resp. of right B-modules, resp. of (A,B)-bimodules) $X\to X'$.

3.7.14. In the situation of definition 3.7.13, notice that

$$\mathrm{Hom}_{B_r}(X,X') = \mathrm{Equal}(\ \mathrm{Hom}_{\mathscr{C}}(X,X') \overset{\alpha}{\underset{\beta}{\rightrightarrows}} \mathrm{Hom}_{\mathscr{C}}(X\otimes B,X')\ )$$

where α (resp. β) is given by the rule :

$$f\mapsto f\circ\mu_X \qquad (\text{ resp. } f\mapsto\mu_{X'}\circ(f\otimes B)\text{ }) \qquad \text{for every } f\in\mathrm{Hom}_{\mathscr{C}}(X,X')$$

and similarly for left A-modules. Now, suppose that all equalizers in $\mathscr{C}$ are representable, and that $\mathscr{C}$ admits an internal Hom functor; then we may define

$$\mathscr{H}\!om_{B_r}(X,X') := \mathrm{Equal}(\ \mathscr{H}\!om(X,X') \overset{\alpha}{\underset{\beta}{\rightrightarrows}} \mathscr{H}\!om(X\otimes B,X')\ )$$

where $\alpha := \mathscr{H}om(\mu_X, X')$ and $\beta := \mathscr{H}om(X \otimes B, \mu_{X'}) \circ t_{X,X',B}$ (notation of remark 3.7.12(v)). Then, it is easily seen that the bijections of remark 3.7.12(iv) induce natural identifications

$$\mathrm{Hom}_{\mathscr{C}}(U, \mathscr{H}om_{B_r}(X, X')) \xrightarrow{\sim} \mathrm{Hom}_{B_r}(X, X') \qquad \text{for every } X, X' \in \mathrm{Ob}(B_r\text{-}\mathbf{Mod}).$$

Likewise we may represent in $\mathscr{C}$ the set of morphisms between two left A-modules, and two (A, B)-modules (details left to the reader).

3.7.15. Let $\underline{\mathscr{C}}$ be a tensor category as in (3.7.14) and A, B, C any three objects of $\mathscr{C}$; suppose that (X, μ^l_X, μ^r_X) is an (A, B)-bimodule, and $(X', \mu^l_{X'}, \mu^r_{X'})$ a (C, B)-bimodule. Then we claim that $\mathscr{H} := \mathscr{H}om_{B_r}((X, \mu^r_X), (X', \mu^r_{X'}))$ is naturally a (C, A)-bimodule. For this, we have to exhibit natural morphisms

$$C \otimes \mathscr{H} \xrightarrow{\mu_l} \mathscr{H} \xleftarrow{\mu_r} \mathscr{H} \otimes A$$

fulfilling the condition of definition 3.7.13(iii). However, by adjunction, the datum of μ_l is the same as that of a morphism $C \to \mathscr{H}om(\mathscr{H}, \mathscr{H})$, and since the functor $\mathscr{H}om(X, -)$ is left exact, the latter is the same as a morphism

$$C \to \mathrm{Equal}(\ \mathscr{H}om(\mathscr{H}, \mathscr{H}om(X, X')) \underset{\mathscr{H}om(\mathscr{H},\beta)}{\overset{\mathscr{H}om(\mathscr{H},\alpha)}{\rightrightarrows}} \mathscr{H}om(\mathscr{H}, \mathscr{H}om(X \otimes B, X'))$$

which in turn – by remark 3.7.12(iii) – corresponds to a morphism

$$C \to \mathrm{Equal}(\ \mathscr{H}om(\mathscr{H} \otimes X, X') \underset{\mathscr{H}om(\mathscr{H}\otimes\beta,X')}{\overset{\mathscr{H}om(\mathscr{H}\otimes\alpha,X')}{\rightrightarrows}} \mathscr{H}om(\mathscr{H} \otimes (X \otimes B), X')$$

and again, the latter is the same as an element of

$$\mathrm{Equal}(\ \mathrm{Hom}_{\mathscr{C}}(C \otimes (\mathscr{H} \otimes X), X') \underset{\mathrm{Hom}_{\mathscr{C}}(C\otimes(\mathscr{H}\otimes\beta),X')}{\overset{\mathrm{Hom}_{\mathscr{C}}(C\otimes(\mathscr{H}\otimes\alpha),X')}{\rightrightarrows}} \mathrm{Hom}_{\mathscr{C}}(C \otimes (\mathscr{H} \otimes (X \otimes B)), X').$$

By unwinding the definition, it is easily seen that the composition

$$\overline{\mu}_l : C \otimes (\mathscr{H} \otimes X) \xrightarrow{\mathrm{ev}_{X,X'}} C \otimes X' \xrightarrow{\mu^l_{X'}} X'$$

lies in the above equalizer, and it provides a left C-module structure for $\mathscr{H}$. Likewise, μ_r shall be the morphism corresponding to the composition

$$\overline{\mu}_r : (\mathscr{H} \otimes X) \otimes A \xrightarrow{\sim} \mathscr{H} \otimes (A \otimes X) \xrightarrow{\mathscr{H}\otimes\mu^l_X} \mathscr{H} \otimes X \xrightarrow{\mathrm{ev}_{X,X'}} X'.$$

Then, the condition that $(\mathscr{H}, \mu_l, \mu_r)$ is a bimodule, comes down to the commutativity of the diagram

$$\begin{array}{ccccc}
C \otimes ((\mathscr{H} \otimes X) \otimes A) & & \xrightarrow{\quad \mathbf{1}_C\otimes\overline{\mu}_r \quad} & & C \otimes X' \\
\Big\downarrow {\scriptstyle C\otimes\Phi_{\mathscr{H},X,A}} & & & & \Big\downarrow {\scriptstyle \mu^l_{X'}} \\
C \otimes (\mathscr{H} \otimes (X \otimes A)) & \xrightarrow{C\otimes(\mathscr{H}\otimes(\mu^l_X\circ\Psi_{X,A}))} & C \otimes (\mathscr{H} \otimes X) & \xrightarrow{\overline{\mu}_l} & X'
\end{array}$$

which is immediate (details left to the reader). We have thus obtained a bifunctor :

(3.7.16) $$\mathscr{H}om_{B_r}(-,-) : (A, B)\text{-}\mathbf{Mod}^o \times (C, B)\text{-}\mathbf{Mod} \to (C, A)\text{-}\mathbf{Mod}.$$

Likewise, we may define a bifunctor :

$$\mathscr{H}om_{A_l}(-,-) : (A, B)\text{-}\mathbf{Mod}^o \times (A, C)\text{-}\mathbf{Mod} \to (B, C)\text{-}\mathbf{Mod}.$$

3.7.17. Keep the situation of (3.7.15), and suppose moreover that all coequalizers in $\mathscr{C}$ are representable. Fix an (A, B)-bimodule (X, μ^l_X, μ^r_X); the functor

$$(C, B)\text{-}\mathbf{Mod} \to (C, A)\text{-}\mathbf{Mod} \quad : \quad X' \mapsto \mathscr{H}om_{B_r}(X, X')$$

admits a left adjoint, the *tensor product*

$$(C, A)\text{-}\mathbf{Mod} \to (C, B)\text{-}\mathbf{Mod} \quad : \quad (X', \mu^l_{X'}, \mu^l_{X'}) \mapsto (X', \mu^l_{X'}, \mu^r_{X'}) \otimes_A (X, \mu^l_X, \mu^r_X)$$

given by the coequalizer (in $\mathscr{C}$) of the morphisms :

$$X' \otimes (A \otimes X) \underset{(\mu^r_{X'} \otimes \mathbf{1}_X) \circ \Phi_{X', A, X}}{\overset{\mathbf{1}_{X'} \otimes \mu^l_X}{\rightrightarrows}} X' \otimes X$$

with scalar multiplications induced by μ^r_X and $\mu^l_{X'}$. Likewise, we have a functor :

$$(A, C)\text{-}\mathbf{Mod} \to (B, C)\text{-}\mathbf{Mod} \quad : \quad (X', \mu^l_{X'}, \mu^l_{X'}) \mapsto (X, \mu^l_X, \mu^r_X) \otimes_A (X', \mu^l_{X'}, \mu^l_{X'})$$

which admits a similar description, and is left adjoint to the functor $X' \mapsto \mathscr{H}om_{A_l}(X, X')$ (verifications left to the reader).

3.7.18. Let (U, u) be unit object for $\underline{\mathscr{C}}$. Notice that, for any object A of $\mathscr{C}$, the rule $(Y, \mu_Y) \mapsto (Y, u_Y^{-1}, \mu_Y)$ (where $u_Y : Y \to U \otimes Y$ is the natural isomorphism supplied by proposition 3.7.6), induces a faithful functor $A\text{-}\mathbf{Mod}_r \to (U, A)\text{-}\mathbf{Mod}$. Letting $C := U$ in (3.7.17), we see that any (A, B)-bimodule X also determines a functor :

$$A\text{-}\mathbf{Mod}_r \to B\text{-}\mathbf{Mod}_r \quad : \quad Y \mapsto Y \otimes_A X$$

and likewise for left A-modules.

Example 3.7.19. If $\mathscr{C} = \mathbf{Set}$ is the category of sets (regarded as a tensor category as in example 3.7.21), then a left A-module is just a set X' with a *left action* of A, *i.e.* a map of sets

$$A \times X' \to X' \quad : \quad (a, x) \mapsto a \cdot x.$$

An (A, A)-bimodule X is a set with both left and right actions of A, such that $(a \cdot x) \cdot a' = a \cdot (x \cdot a')$ for every $a, a' \in A$ and every $x \in X$. With this notation, the tensor product $X' \otimes_A X$ is the quotient $(X' \times X)/\!\sim$, where $\sim$ is the smallest equivalence relation such that $(x'a, x) \sim (x', ax)$ for every $x \in X$, $x' \in X'$ and $a \in A$.

Definition 3.7.20. Let $\underline{\mathscr{C}} := (\mathscr{C}, \otimes, \Phi, \Psi)$ be a tensor category, and (U, u) a unit for $\underline{\mathscr{C}}$.

(i) A $\underline{\mathscr{C}}$*-semigroup* is a datum (M, μ_M) consisting of an object M of $\mathscr{C}$ and a morphism $\mu_M : M \otimes M \to M$, the *multiplication law* of $\underline{M}$, such that (M, μ_M, μ_M) is a (M, M)-bimodule. A morphism of $\underline{\mathscr{C}}$-semigroups is a morphism $\varphi : M \to M'$ in $\mathscr{C}$, such that

$$\mu_{M'} \circ (\varphi \otimes \varphi) = \varphi \circ \mu_M.$$

(ii) A $\underline{\mathscr{C}}$*-monoid* is a datum $\underline{M} := (M, \mu_M, 1_M)$, where (M, μ_M) is a semigroup, and $1_M : U \to M$ is a morphism in $\mathscr{C}$, called the *unit* of $\underline{M}$, such that

$$\mu_M \circ (1_M \otimes \mathbf{1}_M) \circ u_M = \mathbf{1}_M = \mu_M \circ (\mathbf{1}_M \otimes 1_M) \circ u_M$$

where $u_M : M \xrightarrow{\sim} U \otimes M$ is the natural isomorphism provided by proposition 3.7.6. We say that $\underline{M}$ is *commutative*, if

$$\mu_M = \mu_M \circ \Psi_{M,M}.$$

A morphism of monoids $\underline{M} \to \underline{M}'$ is a morphism of semigroups $\varphi : M \to M'$ such that $\varphi \circ 1_M = 1_{M'}$.

Example 3.7.21. (i) Let $\mathscr{C}$ be any category with small Hom-sets, in which finite products are representable, endow $\mathscr{C}$ with the tensor category structure described in example 3.7.10, and pick a final object $1_\mathscr{C}$ of $\mathscr{C}$. Then, a $\underline{\mathscr{C}}$-monoid is a datum $\underline{M} := (M, \mu_M, 1_M)$, where $\mu_M : M \times M \to M$ and $1_M : 1_\mathscr{C} \to M$ are morphisms of $\mathscr{C}$, and the axioms for μ_M and 1_M can be rephrased as requiring that, for every object X of $\mathscr{C}$, the set $M(X) := \mathrm{Hom}_\mathscr{C}(X, M)$, endowed with the composition law :

$$M(X) \times M(X) \xrightarrow{\sim} \mathrm{Hom}_\mathscr{C}(X, M \times M) \xrightarrow{\mathrm{Hom}_\mathscr{C}(X,\mu_M)} M(X) \qquad (m, m') \mapsto m \cdot m'$$

is a (usual) monoid, with unit $\mathrm{Im}\, 1_M(X) \in M(X)$. Of course, $\underline{M}$ is commutative, if and only if $m \cdot m' = m' \cdot m$ for all objects X of $\mathscr{C}$ and every $m, m' \in M(X)$.

(ii) In the situation of (i), a $\underline{\mathscr{C}}$-monoid shall also be called simply a $\mathscr{C}$-monoid. The category of $\mathscr{C}$-monoids admits an initial object which is also a final object, namely $\underline{1}_\mathscr{C} := (1_\mathscr{C}, \mu_1, \mathbf{1}_1)$, where μ_1 is the (unique) morphism $1_\mathscr{C} \times 1_\mathscr{C} \to 1_\mathscr{C}$. (Most of the above can be repeated with the theory of semigroups replaced by any "algebraic theory" in the sense of [29, Def.3.3.1] : *e.g.* in this way one can define $\mathscr{C}$-groups, $\mathscr{C}$-rings, and so on.)

3.7.22. Let $\underline{\mathscr{C}}$ and U be as in definition 3.7.20, and $\underline{M} := (M, \mu_M, 1_M)$ a $\underline{\mathscr{C}}$-monoid; of course, we are especially interested in the M-modules which are compatible with the unit and multiplication law of M. Hence we define a *left $\underline{M}$-module* as a left M-module (S, μ_S) such that the following diagrams commute :

$$\begin{array}{ccc} U \otimes S & = & U \otimes S \\ {\scriptstyle 1_M \otimes \mathbf{1}_S}\downarrow & & \uparrow{\scriptstyle u_S} \\ M \otimes S & \xrightarrow{\mu_S} & S \end{array} \qquad \begin{array}{ccccc} M \otimes (M \otimes S) & & \xrightarrow{\mathbf{1}_M \otimes \mu_S} & & M \otimes S \\ {\scriptstyle \Phi_{M,M,S}}\downarrow & & & & \downarrow{\scriptstyle \mu_S} \\ (M \otimes M) \otimes S & \xrightarrow{\mu_M \otimes \mathbf{1}_S} & M \otimes S & \xrightarrow{\mu_S} & S \end{array}$$

where u_S is the isomorphism given by proposition 3.7.6. Likewise we define right $\underline{M}$-modules, and $(\underline{M}, \underline{N})$-bimodules, if $\underline{N}$ is a second $\underline{\mathscr{C}}$-monoid; especially, $(\underline{M}, \underline{M})$-bimodules shall also be called simply $\underline{M}$-bimodules.

A morphism of left $\underline{M}$-modules $(S, \mu_S) \to (S', \mu_{S'})$ is just a morphism of left M-modules, and likewise for right modules and bimodules. For instance, $\underline{M}$ is a $\underline{M}$-bimodule in a natural way, and an *ideal* of M is a sub-$\underline{M}$-bimodule I of $\underline{M}$. We denote by $\underline{M}$-$\mathbf{Mod}_l$ (resp. $\underline{M}$-$\mathbf{Mod}_r$, resp. $\underline{M}$-$\mathbf{Mod}$) the category of left (resp. right, resp. bi-) $\underline{M}$-modules; more generally, if $\underline{N}$ is a second $\underline{\mathscr{C}}$-monoid, we have the category $(\underline{M}, \underline{N})$-$\mathbf{Mod}$ of the corresponding bimodules.

Example 3.7.23. Take $\mathscr{C} := \mathbf{Set}$, regarded as a tensor category, as in example 3.7.10. Then a $\mathscr{C}$-monoid is just a usual monoid M, and a left M-module is a datum (S, μ_S) consisting of a set S and a *scalar multiplication* $M \times S \to S : (m, s) \mapsto m \cdot s$ such that

$$1 \cdot s = s \quad \text{and} \quad x \cdot (y \cdot s) = (x \cdot y) \cdot s \qquad \text{for every } x, y \in M \text{ and every } s \in S.$$

A morphism $\varphi : (S, \mu_S) \to (T, \mu_T)$ of M-modules is then a map of sets $S \to T$ such that

$$x \cdot \varphi(s) = \varphi(x \cdot s) \qquad \text{for every } x \in M \text{ and every } s \in S$$

Likewise, an ideal of M is a subset $I \subset M$ such that $a \cdot x, x \cdot a \in I$ whenever $a \in I$ and $x \in M$.

Remark 3.7.24. Let $\mathscr{C}$ be a complete and cocomplete category, whose colimits are universal (see example 1.4.17), and $\underline{M}$ a $\mathscr{C}$-monoid (see example 3.7.21(ii)).

(i) The categories $\underline{M}$-$\mathbf{Mod}_l$, $\underline{M}$-$\mathbf{Mod}_r$ and $(\underline{M}, \underline{N})$-$\mathbf{Mod}$ are complete and cocomplete, and the forgetful functor $\underline{M}$-$\mathbf{Mod}_l \to \mathscr{C}$ (resp. the same for right modules and bimodules) commutes with all limits and colimits.

(ii) Notice also that the forgetful functor $\underline{M}$-$\mathbf{Mod}_l \to \mathscr{C}$ is conservative. Together with (i) and propositions 1.3.18 and 1.3.21(i), this implies that a morphism of left $\underline{M}$-modules is a monomorphism (resp. an epimorphism) if and only if the same holds for the underlying morphism in $\mathscr{C}$ (and likewise for right modules and bimodules).

(iii) For each of these categories, the initial object is just the initial object $\varnothing_{\mathscr{C}}$ of $\mathscr{C}$, endowed with the trivial scalar multiplication. Likewise, the final object is the final object $1_{\mathscr{C}}$ of $\mathscr{C}$, with scalar multiplication given by the unique morphism $M \times 1_{\mathscr{C}} \to 1_{\mathscr{C}}$. Moreover, the forgetful functor $\underline{M}\text{-}\mathbf{Mod}_l \to \mathscr{C}$ admits a left adjoint, that assigns to any $\Sigma \in \mathrm{Ob}(\mathscr{C})$ the *free $\underline{M}$-module* $\underline{M}^{(\Sigma)}$ generated by Σ; as an object of $\mathscr{C}$, the latter is just $M \times \Sigma$, and the scalar multiplication is derived from the composition law of $\underline{M}$, in the obvious way.

For instance, for any $n \in \mathbb{N}$, and any left (or right or bi-) $\underline{M}$-module S, we denote as usual by $S^{\oplus n}$ the coproduct of n copies of S.

Remark 3.7.25. Let $\underline{\mathscr{C}}$ be a tensor category, $\underline{M}$, $\underline{N}$, $\underline{P}$, $\underline{Q}$ four $\underline{\mathscr{C}}$-monoids.

(i) Let S be a $(\underline{M},\underline{N})$-bimodule, S' a $(\underline{P},\underline{N})$-bimodule and S'' a $(\underline{P},\underline{M})$-bimodule. Then it is easily seen that the (P,M)-bimodule (resp. the (P,N)-bimodule) $\mathscr{H}om_{N_r}(S,S')$ (resp. $S'' \otimes_M S$) is actually a $(\underline{P},\underline{M})$-bimodule (resp. a $(\underline{P},\underline{N})$-bimodule) and the adjunction of (3.7.17) restricts to an adjunction between the corresponding categories of bimodules : the details shall be left to the reader.

(ii) We have as well the analogue of the usual associativity constraints. Namely, for every $(\underline{M},\underline{N})$-bimodule S, every $(\underline{N},\underline{P})$-bimodule S' and every $(\underline{P},\underline{Q})$-bimodule S'', there is a natural isomorphism

$$(S \otimes_N S') \otimes_P S'' \xrightarrow{\sim} S \otimes_N (S' \otimes_P S'') \qquad \text{in } (\underline{M},\underline{Q})\text{-}\mathbf{Mod}$$

and natural isomorphisms $M \otimes_M S \xrightarrow{\sim} S \xrightarrow{\sim} S \otimes_N N$ in $(\underline{M},\underline{N})\text{-}\mathbf{Mod}$.

(iii) Also, if $\underline{M}$ is commutative, every left (or right) $\underline{M}$-module is naturally a $(\underline{M},\underline{M})$-bimodule, and we have a commutative constraint

$$S \otimes_M S' \xrightarrow{\sim} S' \otimes_M S \qquad \text{for all left (or right) } \underline{M}\text{-modules.}$$

And taking into account (ii), it is easily seen that $(\underline{M}\text{-}\mathbf{Mod}_l, \otimes_M)$ is a tensor category.

3.7.26. Let $\varphi : \underline{M}_1 \to \underline{M}_2$ be a morphism of $\underline{\mathscr{C}}$-monoids; we have the $(\underline{M}_1,\underline{M}_2)$-bimodule :

$$M_{1,2} := (M_2, \mu_{M_2} \circ (\varphi \otimes \mathbf{1}_{M_2}), \mu_{M_2}).$$

Letting $X := M_{1,2}$ in (3.7.18), we obtain a *base change functor* for right modules :

$$\underline{M}_1\text{-}\mathbf{Mod}_r \to \underline{M}_2\text{-}\mathbf{Mod}_r \quad : \quad X \mapsto X \otimes_{M_1} M_2 := X \otimes_{M_1} M_{1,2}.$$

The base change is left adjoint to the *restrictions of scalars* associated with φ, *i.e.* the functor :

$$\underline{M}_2\text{-}\mathbf{Mod}_r \to \underline{M}_1\text{-}\mathbf{Mod}_l \quad : \quad (X,\mu_X) \mapsto (X,\mu_X)_{(\varphi)} := (X, \mu_X \circ (\mathbf{1}_X \otimes \varphi))$$

(verifications left to the reader). The same can be repeated, as usual, for left modules; for bimodules, one must take the tensor product on both sides : $X \mapsto M_2 \otimes_{M_1} X \otimes_{M_1} M_2$.

Example 3.7.27. Take $\mathscr{C} = \mathbf{Set}$, and let M be any monoid, Σ any set, and $M^{(\Sigma)}$ the free M-module generated by Σ. From the isomorphism

$$M^{(\Sigma)} \otimes_M \{1\} \xrightarrow{\sim} \{1\}^{(\Sigma)} = \Sigma$$

we see that the cardinality of Σ is an invariant, called the *rank* of the free M-module $M^{(\Sigma)}$, and which we denote $\mathrm{rk}_M M^{(\Sigma)}$.

Definition 3.7.28. (i) A *pre-additive category* is the datum of a category $\mathscr{A}$ and of an abelian group structure on $\mathrm{Hom}_{\mathscr{A}}(A,B)$ for every $A, B \in \mathrm{Ob}(\mathscr{A})$ (especially, the Hom-sets of $\mathscr{A}$ are not empty), such that the following holds. For every $A, B, C \in \mathrm{Ob}(\mathscr{A})$, the composition law

$$\mathrm{Hom}_{\mathscr{A}}(A,B) \times \mathrm{Hom}_{\mathscr{A}}(B,C) \to \mathrm{Hom}_{\mathscr{A}}(A,C)$$

is a bilinear pairing.

(ii) A functor $F : \mathscr{A} \to \mathscr{B}$ between pre-additive categories is *additive* if it induces group homomorphisms

$$\mathrm{Hom}_{\mathscr{A}}(X,Y) \to \mathrm{Hom}_{\mathscr{B}}(FX,FY) \quad : \quad \varphi \mapsto F\varphi \qquad \text{for every } X,Y \in \mathrm{Ob}(\mathscr{A}).$$

Remark 3.7.29. Let $\mathscr{A}$ be any pre-additive category, and choose a universe U such that $\mathscr{A}$ is U-small, so that all the finite limits and finite colimits of $\mathscr{A}$ are well defined as U-presheaves.

(i) If $A \in \mathrm{Ob}(\mathscr{A})$ is any object, denote by $\mathbf{0}_A$ the neutral element of the abelian group $\mathrm{End}_{\mathscr{A}}(A)$. Suppose that the equalizer of the pair of morphisms $\mathbf{1}_A, \mathbf{0}_A : A \to A$ is representable by an object 0 of $\mathscr{A}$ (see example 1.2.16(ii)). Then, the datum of a morphism $B \to 0$ is the same as that of a morphism $\varphi : B \to A$ such that $\varphi = \mathbf{0}_A \circ \varphi$. By the bilinearity of the Hom-pairing, the latter condition holds if and only if φ is the neutral element of $\mathrm{Hom}_{\mathscr{A}}(B,A)$. We conclude that 0 is a final object in $\mathscr{A}$. Dually, if the coequalizer of the pair $(\mathbf{1}_A, \mathbf{0}_A)$ is representable by some object $0'$ of $\mathscr{A}$, then $0'$ is initial in $\mathscr{A}$. Moreover, if $\mathscr{A}$ admits a final object 0, then it is easily seen that the unique morphism $A \to 0$ is also the coequalizer of the pair $(\mathbf{1}_A, \mathbf{0}_A)$, so 0 is also an initial object. Conversely, if $\mathscr{A}$ admits an initial object, then this object is also final in $\mathscr{A}$, and for any two objects A, B of $\mathscr{A}$, the neutral element $\mathbf{0}_{A,B}$ of $\mathrm{Hom}_{\mathscr{A}}(A,B)$ is the unique morphism that factors through 0. We say that 0 is a *zero object* for $\mathscr{A}$.

(ii) Suppose that the product $A_1 \times A_2$ is representable in $\mathscr{A}$ for given $A_1, A_2 \in \mathrm{Ob}(\mathscr{A})$. Denote by $p_i : A_1 \times A_2 \to A_i$ $(i = 1,2)$ the projections; then, there are unique morphisms $e_i : A_i \to A_1 \times A_2$ $(i = 1,2)$ such that

$$p_i \circ e_i = \mathbf{1}_{A_i} \qquad \text{for } i = 1,2 \qquad \text{and} \qquad p_i \circ e_j = \mathbf{0}_{A_j,A_i} \qquad \text{for } i \neq j. \tag{3.7.30}$$

Notice that

$$e_1 \circ p_1 + e_2 \circ p_2 = \mathbf{1}_{A_1 \times A_1}. \tag{3.7.31}$$

Indeed, we have

$$p_i \circ (e_1 \circ p_1 + e_2 \circ p_2) = (p_i \circ e_1 \circ p_1) + (p_i \circ e_2 \circ p_2) = p_i \qquad i = 1,2$$

by bilinearity of the Hom pairing, and $\mathbf{1}_{A_1 \times A_2}$ is the unique endomorphism φ of $A_1 \times A_2$ such that $p_i \circ \varphi = p_i$ for $i = 1,2$. It follows that $A_1 \times A_2$ also represents the coproduct $A_1 \amalg A_2$. Indeed, say that $f_i : A_i \to B$, for $i = 1,2$, are two morphisms to another object B of $\mathscr{A}$, and set $f := f_1 \circ p_1 + f_2 \circ p_2 : A_1 \times A_2 \to B$; it is easily seen that $f \circ e_i = f_i$ for $i = 1,2$, and by virtue of (3.7.31), the morphism f is the unique one that satisfies these identities. Conversely, if the coproduct of A_1 and A_2 is representable, a similar argument shows that also $A_1 \times A_2$ is representable. We say that $A_1 \times A_2$ is a *biproduct* of A_1 and A_2, and denote it by $A_1 \oplus A_2$.

(iii) Notice that the morphisms $(p_i, e_i \mid i = 1,2)$ with the identities (3.7.30) and (3.7.31) characterize $A_1 \oplus A_2$ up to unique isomorphism. Namely, say that B is another object of $\mathscr{A}$, for which exist morphisms $p'_i : B \to A_i$ and $e'_i : A_i \to B$ $(i = 1,2)$ such that $p'_i \circ e'_i = \mathbf{1}_{A_i}$ for $i = 1,2$, and $p'_i \circ e'_j = \mathbf{0}_{A_j A_i}$ for $i \neq j$, and moreover $e'_1 \circ p'_1 + e'_2 \circ p'_2 = \mathbf{1}_B$. Then the pair (e'_1, e'_2) (resp. (p'_1, p'_2)) induces a morphism $e' : A_1 \oplus A_2 \to B$ (resp. $p' : B \to A_1 \oplus A_2$) with

$$p_j \circ p' \circ e' \circ e_i = p'_j \circ e'_i = p_j \circ e_i \qquad \text{for } i,j = 1,2$$

which – by virtue of the universal properties of the biproduct – implies that $p' \circ e' = \mathbf{1}_{A_1 \oplus A_2}$. Likewise, we may compute

$$\begin{aligned} e' \circ p' &= (e' \circ e_1 \circ p_1 + e' \circ e_2 \circ p_2) \circ (e_1 \circ p_1 \circ p' + e_2 \circ p_2 \circ p') \\ &= e' \circ e_1 \circ p_1 \circ p' + e' \circ e_2 \circ p_2 \circ p' \\ &= e'_1 \circ p'_1 + e'_2 \circ p'_2 = \mathbf{1}_B \end{aligned}$$

whence the contention.

(iv) Suppose that B_1 and B_2 are any other two objects of $\mathscr{A}$ such that $B_1 \oplus B_2$ is also representable; given two morphisms $f_1 : A_1 \to B_1$ and $f_2 : A_2 \to B_2$, we denote by $f_1 \oplus f_2 : A_1 \oplus A_2 \to B_1 \oplus B_2$ the unique morphism such that

$$p_{B,i} \circ (f_1 \oplus f_2) \circ e_{A,i} = f_i \quad \text{for } i = 1,2, \text{ and} \quad p_{B,i} \circ (f_1 \oplus f_2) \circ e_{A,j} = \mathbf{0}_{A_j,B_i} \quad \text{for } i \neq j.$$

Notice that

$$f_1 \oplus f_2 = (f_1 \oplus \mathbf{0}_{A_2,B_2}) + (\mathbf{0}_{A_1,B_1} \oplus f_2) \tag{3.7.32}$$

(where the sum is taken in the abelian group $\mathrm{Hom}_{\mathscr{A}}(A_1 \oplus A_2, B_1 \oplus B_2)$); indeed, by bilinearity of the Hom pairing, it is easily seen that the right-hand side of (3.7.32) also satisfies the same identities above that define $f_1 \oplus f_2$.

(v) If $f : A \to B$ is any morphism of $\mathscr{A}$, then we define the *kernel* (resp. *cokernel*) of f as the equalizer (resp. coequalizer)

$$\mathrm{Ker}\, f := \mathrm{Equal}(f, \mathbf{0}_{A,B}) \qquad \mathrm{Coker}\, f := \mathrm{Coequal}(f, \mathbf{0}_{A,B}).$$

Suppose that all kernels and cokernels of $\mathscr{A}$ are representable in $\mathscr{A}$, and denote by

$$\iota_f : \mathrm{Ker}\, f \to A \qquad \pi_f : B \to \mathrm{Coker}\, f$$

the natural morphisms in $\mathscr{A}$. Notice that ι_f is a monomorphism, and π_f an epimorphism. Notice also that f factors uniquely in $\mathscr{A}$ as a composition

$$A \xrightarrow{\pi_{\iota_f}} \mathrm{Coker}\, \iota_f \xrightarrow{\beta_f} \mathrm{Ker}\, \pi_f \xrightarrow{\iota_{\pi_f}} B. \tag{3.7.33}$$

(vi) Suppose that $\mathscr{A}$ admits a zero object 0, and let $f : A \to B$ be any morphism; by definition $\mathrm{Ker}\, f$ is the presheaf such that

$$\mathrm{Ker}\, f(C) = \{g : B \to C \mid g \circ f = g \circ \mathbf{0}_{A,B} = \mathbf{0}_{A,C}\}.$$

If f is a monomorphism, the identity $g \circ f = \mathbf{0}_{A,C} = \mathbf{0}_{B,C} \circ f$ implies that $g = \mathbf{0}_{B,C}$, so $\mathrm{Ker}\, f$ is represented by 0. Dually, if f is an epimorphism, then $\mathrm{Coker}\, f$ is represented by 0.

Remark 3.7.34. Let $\mathscr{A}$, $\mathscr{B}$ be any two pre-additive categories that admit a zero object, and $F : \mathscr{A} \to \mathscr{B}$ a functor.

(i) If F is additive, remark 3.7.29(iii) immediately implies that F transforms representable biproducts into representable biproducts. The latter assertion still holds in case F is not necessarily additive, but is either left or right exact. Indeed, suppose that F is left exact, let $A_1 \oplus A_2$ be any biproduct, and let p_i, e_i be the morphisms described in remark 3.7.29(ii); by left exactness, $F(A_1 \oplus A_2)$ represents the product of FA_1 and FA_2, whence an isomorphism $FA_1 \oplus FA_2 \xrightarrow{\sim} F(A_1 \oplus A_2)$ which identifies Fp_1 and Fp_2 with the natural projections. Moreover, F transforms the final object of $\mathscr{A}$ into the final object of $\mathscr{B}$ (see example 1.2.16(iv)); then, by inspecting the argument in remark 3.7.29(ii), it is easily seen that F identifies as well Fe_i with the natural injections $FA_i \to FA_1 \oplus FA_2$, for $i = 1, 2$, so the assertion follows from remark 3.7.29(iii). A similar argument works in case F is right exact.

(ii) Suppose moreover, that all biproducts of $\mathscr{A}$ are representable. Then we claim that the abelian group structure on $\mathrm{Hom}_{\mathscr{A}}(A, B)$ is determined by the category $\mathscr{A}$, *i.e.* if $\mathscr{B}$ is any other pre-additive category, and $F : \mathscr{A} \to \mathscr{B}$ is any equivalence of categories, then F induces group isomorphisms (and not just bijections) on Hom sets. Indeed, let A and B be any two objects of $\mathscr{A}$, and denote by $\Delta_A : A \to A \oplus A$ (resp. $\mu_B : B \oplus B \to B$) the unique morphism such that $p_i \circ \Delta_A = \mathbf{1}_A$ (resp. $\mu_B \circ e_i = \mathbf{1}_B$) for $i = 1, 2$. Then we have

$$f_1 + f_2 = \mu_B \circ (f_1 \oplus f_2) \circ \Delta_A \qquad \text{for every } f_1, f_2 : A \to B$$

where $f_1 + f_2$ denotes the sum in the abelian group $\mathrm{Hom}_{\mathscr{A}}(A, B)$. Indeed, since clearly $\mathbf{0}_{A,B} \oplus \mathbf{0}_{A,B} = \mathbf{0}_{A \oplus A, B \oplus B}$, identity (3.7.32) reduces to checking that $f_1 = \mu_B \circ (f_1 \oplus \mathbf{0}_{A,B}) \circ \Delta_A$ (and likewise for f_2), which follows easily from (3.7.31) : details left to the reader.

(iii) Combining (i) and (ii) we see that if all biproducts of $\mathscr{A}$ are representable, and F is either left or right exact, then F is additive. More generally, we see that for F to be additive, it suffices that F sends the zero object of $\mathscr{A}$ to the zero object of $\mathscr{B}$, and that F commutes with the biproducts of the form $A \oplus A$, for every $A \in \mathrm{Ob}(\mathscr{A})$.

Definition 3.7.35. (i) An *additive category* is a pre-additive category which admits a zero object, and whose biproducts are representable.

(ii) An *abelian category* is an additive category $\mathscr{A}$ such that the following holds:

(a) All the kernels and cokernels of $\mathscr{A}$ are representable.

(b) For every morphism f of $\mathscr{A}$, the morphism β_f of (3.7.33) is an isomorphism.

Example 3.7.36. Let $\mathscr{A}$ be an additive category, A an object of $\mathscr{A}$, and $e : A \to A$ an endomorphism of A such that :

(a) $e = e \circ e$, *i.e.* e is an *idempotent* element of the ring $\mathrm{End}_{\mathscr{A}}(A)$.

(b) $\mathrm{Ker}\,(e)$ and $\mathrm{Ker}\,(\mathbf{1}_A - e)$ are representable in $\mathscr{A}$.

Then the morphisms $\iota_e : \mathrm{Ker}\,(e) \to A$ and $\iota_{\mathbf{1}_A - e} : \mathrm{Ker}\,(\mathbf{1}_A - e) \to A$ induce an isomorphism

$$\omega : \mathrm{Ker}\,(e) \oplus \mathrm{Ker}\,(\mathbf{1}_A - e) \stackrel{\sim}{\to} A.$$

Indeed, it is easily seen that the morphism $\varepsilon : A \to A \oplus A$ defined by the pair $(\mathbf{1}_A - e, e)$ factors as a composition

$$A \xrightarrow{\overline{\varepsilon}} \mathrm{Ker}\,(e) \oplus \mathrm{Ker}\,(\mathbf{1}_A - e) \xrightarrow{\iota_e \oplus \iota_{\mathbf{1}_A - e}} A \oplus A$$

for a unique morphism $\overline{\varepsilon}$ of $\mathscr{A}$. Then a direct computation shows that $\omega \circ \overline{\varepsilon} = \mathbf{1}_A$ and $\overline{\varepsilon} \circ \omega = \mathbf{1}_{\mathrm{Ker}\,(e) \oplus \mathrm{Ker}\,(\mathbf{1}_A - e)}$, whence the assertion (details left to the reader).

Remark 3.7.37. Let $\mathscr{A}$ be any pre-additive category.

(i) The category $\mathscr{A}^o$ is naturally pre-additive : namely, if $A, B \in \mathrm{Ob}(\mathscr{A}^o)$ are any two objects, one endows $\mathrm{Hom}_{\mathscr{A}^o}(A, B)$ with the group structure of $\mathrm{Hom}_{\mathscr{A}}(B, A)$. Likewise, if $F : \mathscr{A} \to \mathscr{B}$ is any additive functor between the pre-additive categories $\mathscr{A}$, $\mathscr{B}$, then also $F^o : \mathscr{A}^o \to \mathscr{B}^o$ is additive. Moreover, if $\mathscr{A}$ is additive the same holds for $\mathscr{A}^o$. Indeed, the zero object of $\mathscr{A}$ is obviously a zero object also in $\mathscr{A}^o$, and biproducts are representable in $\mathscr{A}^o$, since one can take

$$A^o \oplus B^o := (A \oplus B)^o \qquad \text{for every } A, B \in \mathrm{Ob}(\mathscr{A}).$$

Furthermore, if $\mathscr{A}$ is abelian, the same holds for $\mathscr{A}^o$. Indeed, we can take

$$\mathrm{Ker}\, f^o := (\mathrm{Coker}\, f)^o \qquad \mathrm{Coker}\, f^o := (\mathrm{Ker}\, f)^o \qquad \text{for every morphism } f \text{ in } \mathscr{A}$$

and with these choices we have :

$$\iota_{f^o} = (\pi_f)^o \qquad \pi_{f^o} = (\iota_f)^o \qquad \beta_{f^o} = (\beta_f)^o$$

so β_{f^o} is an isomorphism whenever the same holds for β_f.

(ii) Notice that for every category $\mathscr{C}$, the category $\mathsf{Fun}(\mathscr{C}, \mathscr{A})$ is pre-additive; indeed, if $\tau, \sigma : F \Rightarrow G$ are two natural transformations between functors $F, G : \mathscr{C} \to \mathscr{A}$, then we obtain a natural transformation $\tau + \sigma$ from F to G, by the rule : $(\tau + \sigma)_X := \tau_X + \sigma_X$ for every $X \in \mathrm{Ob}(\mathscr{C})$ (where the sum denotes the addition law of $\mathrm{Hom}_{\mathscr{A}}(FX, GX)$). Clearly, this rule yields an abelian group structure, and the composition of natural transformation defines a bilinear pairing $(\tau, \tau') \mapsto \tau \odot \tau'$ on the resulting groups of natural transformations (verification left to the reader).

Moreover, if $\mathscr{A}$ is an additive (resp. abelian) category, then the same holds for $\mathsf{Fun}(\mathscr{C}, \mathscr{A})$, for every category $\mathscr{C}$. Indeed, if 0 denotes a zero object of $\mathscr{A}$, it follows easily from remark 1.4.2(iii) that the constant functor $0_{\mathscr{C}} : \mathscr{C} \to \mathscr{A}$ with $0_{\mathscr{C}}(C) := 0$ for every $C \in \mathrm{Ob}(\mathscr{C})$ is a zero object for $\mathsf{Fun}(\mathscr{C}, \mathscr{A})$. By the same token, if $F, G : \mathscr{C} \to \mathscr{A}$ are any two functors, then the biproduct $F \oplus G$ is represented by the functor given by the rule : $C \mapsto FC \oplus GC$ for every $C \in \mathrm{Ob}(\mathscr{C})$ (where $FC \oplus GC$ denotes any fixed choice of an object of $\mathscr{A}$ representing the biproduct of FC and GC); then $(F \oplus G)(\varphi)$ is the induced morphism $F\varphi \oplus G\varphi : FC \oplus GC \to FC' \oplus GC'$ for every morphism $\varphi : C \to C'$ in $\mathscr{C}$ (details left to the reader). Likewise, for every natural transformation $\tau : F \Rightarrow G$, the kernel and cokernel of τ are computed argumentwise, and the same holds for the natural morphism β_τ of (3.7.33), so if all kernels and cokernels are representable in $\mathscr{A}$, the same holds for the kernels and cokernels in $\mathsf{Fun}(\mathscr{C}, \mathscr{A})$, and if β_{τ_C} is an isomorphism for every $C \in \mathrm{Ob}(\mathscr{C})$, then the same holds for β_τ, whence the contention.

(iii) For any other pre-additive category $\mathscr{B}$, let us denote by $\mathbf{Add}(\mathscr{B}, \mathscr{A})$ the full subcategory of $\mathsf{Fun}(\mathscr{B}, \mathscr{A})$ whose objects are the additive functors. It follows from (ii) that $\mathbf{Add}(\mathscr{B}, \mathscr{A})$ is a pre-additive category.

(iv) Suppose that $\mathscr{A}$ has small Hom-sets. By definition, for every $A, B \in \mathrm{Ob}(\mathscr{A})$, the set $h_A(B) := \mathrm{Hom}_{\mathscr{A}}(B, A)$ carries an abelian group structure, such that the presheaf h_A factors through an additive functor $h_A^\dagger : \mathscr{A}^o \to \mathbb{Z}\text{-}\mathbf{Mod}$ from $\mathscr{A}^o$ to the category of (small) abelian groups, and the forgetful functor $\mathbb{Z}\text{-}\mathbf{Mod} \to \mathbf{Set}$. Hence, the Yoneda embedding factors through a fully faithful *group-valued Yoneda embedding*

$$h^\dagger : \mathscr{A} \to \mathbf{Add}(\mathscr{A}^o, \mathbb{Z}\text{-}\mathbf{Mod}).$$

In view of (iii), we conclude that every pre-additive category is a full subcategory of an abelian category. Moreover, Yoneda's lemma extends *verbatim* to the group-valued case : namely, by inspecting the proof of proposition 1.2.6, we see that, for every $A \in \mathrm{Ob}(\mathscr{A})$ and every *additive* functor $F : \mathscr{A}^o \to \mathbb{Z}\text{-}\mathbf{Mod}$ there are natural isomorphisms of abelian groups

$$FA \xrightarrow{\sim} \mathrm{Hom}_{\mathbf{Add}(\mathscr{A}^o, \mathbb{Z}\text{-}\mathbf{Mod})}(h_A^\dagger, F). \tag{3.7.38}$$

(v) Let $f : \mathscr{A} \to \mathscr{B}$ be any functor between pre-additive categories; then the arguments of remark 1.3.6(i) extend *verbatim* to the present situation : after choosing a universe U large enough so that $\mathscr{A}$ and $\mathscr{B}$ are U-small, f induces functor

$$f^* : \mathsf{Fun}(\mathscr{B}^o, \mathbb{Z}\text{-}\mathbf{Mod}) \to \mathsf{Fun}(\mathscr{A}^o, \mathbb{Z}\text{-}\mathbf{Mod})$$

that admits both left and right adjoints, denoted respectively $f_!$ and f_*, and we have :

Proposition 3.7.39. *In the situation of remark* 3.7.37(v)*, suppose that f is additive and both $\mathscr{A}$ and $\mathscr{B}$ are additive categories. Then :*

(i) *Both f^*, $f_!$ and f_* are additive functors, and restrict to functors*

$$\mathbf{Add}(\mathscr{B}^o, \mathbb{Z}\text{-}\mathbf{Mod}) \underset{f_! \quad f_*}{\overset{f^*}{\rightleftarrows}} \mathbf{Add}(\mathscr{A}^o, \mathbb{Z}\text{-}\mathbf{Mod}).$$

(ii) *The resulting diagram of functors*

$$\begin{array}{ccc} \mathscr{A} & \xrightarrow{h^\dagger} & \mathbf{Add}(\mathscr{A}^o, \mathbb{Z}\text{-}\mathbf{Mod}) \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f_!} \\ \mathscr{B} & \xrightarrow{h^\dagger} & \mathbf{Add}(\mathscr{B}^o, \mathbb{Z}\text{-}\mathbf{Mod}) \end{array}$$

is essentially commutative.

Proof. (i): Since every left (resp. right) adjoint functor is right (resp. left) exact, remark 3.7.34(iii) says that f^*, f_* and $f_!$ are additive. Next, a simple inspection shows that f^* transforms additive functors into additive functors. Let now $F : \mathscr{A}^o \to \mathbb{Z}\text{-}\mathbf{Mod}$ be an additive functor, $B \in \mathrm{Ob}(\mathscr{B})$ any object, and $G := f_! F$; from the proof of theorem 1.3.4, we see that

$$GB = \operatorname*{colim}_{\psi : B \to fA} FA$$

where the colimit ranges over the small category $f\mathscr{A}^o/B$ of all pairs (A, ψ) consisting of an object A of $\mathscr{A}$, and a morphism $\psi : B \to fA$ in $\mathscr{B}$. Denote by $0_\mathscr{A}$ and $0_\mathscr{B}$ the zero objects of $\mathscr{A}$ and $\mathscr{B}$; we wish to show that G is additive, and according to remark 3.7.34(iii), it suffices to check that $G(0_\mathscr{B}) = 0$, and that the natural morphism $G(B \oplus B) \to GB \oplus GB$ (deduced from the projections $p_i : B \oplus B \to B$) is an isomorphism, for every $B \in \mathrm{Ob}(\mathscr{B})$.

However, notice that the functor $\mathsf{s}_{0_\mathscr{B}} : f\mathscr{A}^o/0_\mathscr{B} \to \mathscr{A}^o$ is an isomorphism of categories (notation of (1.1.27)); whence a natural isomorphism

$$G(0_\mathscr{B}) \xrightarrow{\sim} \operatorname*{colim}_{\mathscr{A}^o} F \xrightarrow{\sim} F(0_\mathscr{A}) = 0$$

where the last identity holds, since F is additive. Next, for any $B_1, B_2 \in \mathrm{Ob}(\mathscr{B})$ consider the functor

$$\Phi : (f\mathscr{A}^o/B_1) \times (f\mathscr{A}^o/B_2) \to f\mathscr{A}^o/B_1 \oplus B_2 \qquad ((A_1, \psi_1), (A_2, \psi_2)) \mapsto (A_1 \oplus A_2, \psi_1 \oplus \psi_2).$$

Claim 3.7.40. The functor Φ is cofinal.

Proof of the claim. We apply the criterion of proposition 1.5.2. Indeed, let

$$i := (A, \psi : B_1 \oplus B_2 \to fA)$$

be any object of $f\mathscr{A}^o/B_1 \oplus B_2$ and

$$j := ((A_1, \varphi_1 : B_1 \to fA_1), (A_2, \varphi_2 : B_2 \to fA_2))$$
$$j' := ((A'_1, \varphi'_1 : B_1 \to fA'_1), (A'_2, \varphi'_2 : B_2 \to fA'_2))$$

any two objects of $(f\mathscr{A}^o/B_1) \times (f\mathscr{A}^o/B_2)$, and suppose that $\beta : i \to \Phi j$ and $\beta' : i \to \Phi j'$ are morphisms in $f\mathscr{A}^o/B_1 \oplus B_2$, given by morphisms $\beta : A_1 \oplus A_2 \to A$ and $\beta' : A'_1 \oplus A'_2 \to A$ in $\mathscr{A}$ such that $f\beta \circ (\varphi_1 \oplus \varphi_2) = \psi = f\beta' \circ (\varphi'_1 \oplus \varphi'_2)$. We let

$$j'' := ((A_1 \oplus A'_1, \delta_1 : B_1 \to f(A_1 \oplus A'_1)), (A_2 \oplus A'_2, \delta_2 : B_2 \to f(A_2 \oplus A'_2))$$

where $\delta_1 := (\varphi_1 \oplus \varphi'_1) \circ \Delta_{B_1}$, and likewise for δ_2. Let also

$$A_1 \oplus A_2 \xleftarrow{p} A_1 \oplus A'_1 \oplus A_2 \oplus A'_2 \xrightarrow{p'} A'_1 \oplus A'_2$$

be the natural projections, which define morphisms

$$\Phi p : \Phi j \to \Phi j'' \qquad \Phi p' : \Phi j' \to \Phi j'' \qquad \text{in } f\mathscr{A}^o/B_1 \oplus B_2$$

A simple inspection shows that $\Phi(p) \circ \beta = \Phi(p') \circ \beta'$, and therefore $i/\Phi(f\mathscr{A}^o/B_1 \oplus B_2)$ is connected, whence the claim. ♢

In light of claim 3.7.40, we are reduced to checking that the natural morphism

$$\operatorname*{colim}_{(f\mathscr{A}^o/B_1)\times(f\mathscr{A}^o/B_2)} F \circ \mathsf{s}_{B_1 \oplus B_2} \circ \Phi \to GB_1 \oplus GB_2$$

is an isomorphism, for any $B_1, B_2 \in \mathrm{Ob}(\mathscr{B})$. The latter assertion follows easily by inspecting the definitions, since F is additive. Lastly, a similar argument shows that f_*F is additive, whenever the same holds for F : the reader can spell out the proof as an exercise.

(ii): One may argue as in remark 1.3.6(ii) : in view of (3.7.38), we see that, for every object A of $\mathscr{A}$, both $h^\dagger_{fA}$ and $f_! h^\dagger_A$ represent the same functor : details left to the reader. □

Lemma 3.7.41. *For any abelian category $\mathscr{A}$, the following holds :*

(i) *$\mathscr{A}$ is finitely complete and finitely cocomplete.*

(ii) *The image of any morphism $f : A \to B$ of $\mathscr{A}$ exists in $\mathscr{A}$, and we have*

$$\mathrm{Coker}\, \pi_f = \mathrm{Im}\, f \qquad \textit{in } \mathrm{Sub}(B)$$

(notation of (1.1.2)*, example* 1.2.26 *and remark* 3.7.29(v)*).*

Proof. (i): By proposition 1.2.22(i,ii), it suffices to check that all equalizers and coequalizers are representable in $\mathscr{A}$. However, let $g, g' : X \to Y$ be any pair of morphisms in $\mathscr{A}$ with same soruces and targets; it easily seen that $\mathrm{Ker}\,(g-g')$ (resp. $\mathrm{Coker}\,(g-g')$) represents the equalizer (resp. the coequalizer) of g and g', whence the assertion.

(ii): Suppose that f factors through a subobject $g : C \to B$ of B; there follows a natural morphism

$$\mathrm{Coker}\, f \to \mathrm{Coker}\, g$$

which in turns induces a morphism $\mathrm{Ker}\,\pi_f \to \mathrm{Ker}\,\pi_g$ of subobjects of B. But since $\mathscr{A}$ is abelian, $\mathrm{Ker}\,\pi_g$ is also the cokernel of $\iota_g : \mathrm{Ker}\, g \to C$ (notation of remark 3.7.29(v)). However, $\mathrm{Ker}\, g = 0$ by remark 3.7.29(vi), hence $\mathrm{Coker}\,\iota_g = C$, whence the contention. □

Definition 3.7.42. Let $\mathscr{A}$ be any abelian category with zero object $0 \in \mathrm{Ob}(\mathscr{A})$, and

$$0 \xrightarrow{0} A \xrightarrow{f} B \xrightarrow{g} C \xrightarrow{0} 0$$

a sequence of morphisms in $\mathscr{A}$.

(i) We say that the sequence (f, g) is *exact* if $\mathrm{Ker}\, g = \mathrm{Im}\, f$.
(ii) We say that the sequence $(0, f, g)$ is *left exact* if both $(0, f)$ and (f, g) are exact.
(iii) We say that the sequence $(f, g, 0)$ is *right exact* if both (f, g) and $(g, 0)$ are exact.
(iv) We say that the sequence $(0, f, g, 0)$ is *short exact* if $(0, f, g)$ is left exact and $(f, g, 0)$ is right exact.

In other words, the sequence $(0, f, g)$ is left exact if and only if f is a monomorphism, and A represents $\mathrm{Ker}\, g$. Likewise, $(f, g, 0)$ is right exact if and only if g is an epimorphism and the image of f represents $\mathrm{Ker}\, g$. The terminology is explained by the following :

Lemma 3.7.43. *Let $F : \mathscr{A} \to \mathscr{B}$ be any additive functor between abelian categories. Then :*

(i) *F is left exact if and only if it transforms left exact sequences of $\mathscr{A}$ into left exact sequences of $\mathscr{B}$.*
(ii) *F is right exact if and only if it transforms right exact sequences of $\mathscr{A}$ into right exact sequences of $\mathscr{B}$.*
(iii) *F is exact if and only if it transforms short exact sequences of $\mathscr{A}$ into short exact sequences of $\mathscr{B}$.*

Proof. (i): Any left exact functor transforms kernels into kernels and monomorphisms into monomorphisms (proposition 1.3.18(i)), so the condition is necessary. Conversely, suppose that F fulfills this condition; since F is additive, it commutes with finite products, so it suffices to check that it also commutes with equalizers (proposition 1.3.22(i)). Arguing as in the proof of lemma 3.7.41(i), we reduce to checking that F commutes with kernels. But this follows by considering the left exact sequence

$$0 \to \mathrm{Ker}\, f \to A \xrightarrow{f} B \qquad \text{for any morphism } f \text{ of } \mathscr{A}$$

and its image under F. Assertion (ii) admits the dual proof, and (iii) follows by considering the similar short exact sequences

$$0 \to \mathrm{Ker}\, f \to A \to \mathrm{Im}\, f \to 0 \qquad 0 \to \mathrm{Im}\, f \to B \to \mathrm{Coker}\, f \to 0$$

for every f as in the foregoing, and arguing as in the proof of (i). □

Definition 3.7.44. An *abelian tensor category* is a tensor category $(\mathscr{C}, \otimes, \Phi, \Psi)$ such that $\mathscr{C}$ is an abelian category, and the functor $\otimes$ induces bilinear pairings

$$\mathrm{Hom}_{\mathscr{C}}(A, B) \times \mathrm{Hom}_{\mathscr{C}}(A', B') \to \mathrm{Hom}_{\mathscr{C}}(A \otimes A', B \otimes B') \quad : \quad (f, g) \mapsto f \otimes g$$

for every $A, A', B, B' \in \mathrm{Ob}(\mathscr{C})$.

Remark 3.7.45. Let $(\mathscr{A}, \otimes, \Phi, \Psi)$ be a tensor category, such that $\mathscr{A}$ is abelian. If $\mathscr{A}$ admits an internal Hom functor $\mathscr{H}om$, the functor $-\otimes A$ is right exact, and the functor $\mathscr{H}om(A, -)$ is left exact for every $A \in \mathrm{Ob}(\mathscr{A})$, so both are additive, by virtue of remark 3.7.34(iii). Especially, $\mathscr{A}$ is an abelian tensor category, in this case.

Lemma 3.7.46. *Let $\mathscr{A}$ be any additive category with small* Hom*-sets, and $\Sigma \subset \mathrm{Ob}(\mathscr{A})$ a small subset. We have :*

(i) *If $\mathscr{A}$ is abelian, there exists a small full abelian subcategory $\mathscr{B}$ of $\mathscr{A}$ such that $\Sigma \subset \mathrm{Ob}(\mathscr{B})$.*
(ii) *If $\mathscr{A}$ is small, there exist a complete and cocomplete abelian tensor category $(\mathscr{C}, \otimes)$ with internal* Hom *functor, and a fully faithful additive functor $\mathscr{A} \to \mathscr{C}$.*

Proof. (i): Let $\mathscr{B}_0$ be the full subcategory of $\mathscr{A}$ such that $\mathrm{Ob}(\mathscr{B}_0) = \Sigma$; clearly $\mathscr{B}_0$ is small. Next, for any subcategory $\mathscr{D}$ of $\mathscr{A}$, denote by $\mathscr{D}'$ a subcategory of $\mathscr{A}$ obtained as follows. For every morphism φ of $\mathscr{D}$, we pick objects in $\mathscr{A}$ representing the kernel and cokernel of φ, and for any two objects of $\mathscr{D}$, we pick an object in $\mathscr{A}$ representing their product; let $\Sigma' \subset \mathrm{Ob}(\mathscr{A})$ be the resulting subset. Then $\mathscr{D}'$ is the full subcategory of $\mathscr{A}$ such that $\mathrm{Ob}(\mathscr{D}') = \mathrm{Ob}(\mathscr{D}) \cup \Sigma'$. It is easily seen that $\mathscr{D}'$ is small, whenever the same holds for $\mathscr{D}$. Then we set inductively $\mathscr{B}_{i+1} := \mathscr{B}'_i$ for every $i \in \mathbb{N}$. The full subcategory $\mathscr{B}$ of $\mathscr{A}$ with $\mathrm{Ob}(\mathscr{B}) = \bigcup_{i\in\mathbb{N}} \mathrm{Ob}(\mathscr{B}_i)$ is still small, and it is abelian, by construction.

(ii): We let $\mathscr{C} := \mathsf{Fun}(\mathscr{A}, \mathbb{Z}\text{-}\mathbf{Mod})$. Then $\mathscr{C}$ is an abelian category, by virtue of remark 3.7.37(ii), and since $\mathbb{Z}\text{-}\mathbf{Mod}$ is complete and cocomplete, the same holds for $\mathscr{C}$; moreover, the standard tensor product of abelian groups defines a tensor category structure with internal Hom functor on $\mathbb{Z}\text{-}\mathbf{Mod}$, and the latter is inherited by $\mathscr{C}$ (remarks 3.7.5(ii) and 3.7.12(vi)). It is clear that these two structures amount to an abelian tensor category, and the group-valued Yoneda embedding is the sought fully faithful functor. □

3.7.47. Let $\mathscr{A}$ be an additive category with small Hom-sets, and

$$h^\dagger : \mathscr{A}^o \to \mathscr{A}^\dagger := \mathsf{Fun}(\mathscr{A}, \mathbb{Z}\text{-}\mathbf{Mod})$$

the fully faithful group-valued Yoneda embedding. For every abelian group G, denote by $G_\mathscr{A} : \mathscr{A} \to \mathbb{Z}\text{-}\mathbf{Mod}$ the constant functor with value G : so, $G_\mathscr{A}(A) := G$ for every $A \in \mathrm{Ob}(\mathscr{A})$, and $G_\mathscr{A}(\varphi) := \mathbf{1}_G$ for every morphism φ in $\mathscr{A}$. Since $\mathscr{A}^\dagger$ is an abelian tensor category with an internal Hom functor $\mathscr{H}om$ (see the proof of lemma 3.7.46(ii)), we may define

$$G \otimes_\mathbb{Z} A := \mathscr{H}om(G_\mathscr{A}, h^\dagger_{A^o}) \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A}).$$

If G is free of finite rank, $G \otimes_\mathbb{Z} A$ is a finite direct sum of copies of A, and therefore lies in the essential image of $h^\dagger$; the same holds for a finitely generated G, provided $\mathscr{A}$ is an abelian category : indeed, we may write G as a cokernel of a map $L_1 \to L_2$ of free abelian groups of finite rank, and since the functor $\mathscr{H}om(-, h^\dagger_A)$ is right exact, we see that $G \otimes_\mathbb{Z} A$ is the kernel of a morphism of $\mathscr{A}^o$ (*i.e.* the cokernel of a morphism of $\mathscr{A}$), so it is represented by an object of $\mathscr{A}$. Moreover, if $\varphi : G \to H$ is any morphism of abelian groups, we have an obvious induced morphism $\varphi_\mathscr{A} : G_\mathscr{A} \to H_\mathscr{A}$, whence a morphism $\varphi \otimes_\mathbb{Z} A := \mathscr{H}om(\varphi_\mathscr{A}, h^\dagger_A)$.

Thus, if $\mathscr{A}$ is abelian, after replacing $G \otimes_\mathbb{Z} A$ by an isomorphic object, we obtain a well defined functor

$$\mathbb{Z}\text{-}\mathbf{Mod}_{\mathrm{fg}} \times \mathscr{A} \to \mathscr{A} \qquad (G, A) \mapsto G \otimes_\mathbb{Z} A \tag{3.7.48}$$

where $\mathbb{Z}\text{-}\mathbf{Mod}_{\mathrm{fg}}$ is the full subcategory of $\mathbb{Z}\text{-}\mathbf{Mod}$ whose objects are the finitely generated abelian groups. This functor is not unique, but any two such functors are naturally isomorphic. If $\mathscr{A}$ is only additive, we can still define such a tensor product functor on the category $\mathbb{Z}\text{-}\mathbf{Mod}_{\mathrm{fft}} \times \mathscr{A} \to \mathscr{A}$, where $\mathbb{Z}\text{-}\mathbf{Mod}_{\mathrm{fft}}$ is the full subcategory of $\mathbb{Z}\text{-}\mathbf{Mod}_{\mathrm{fg}}$ whose objects are the free abelian groups of finite rank.

Remark 3.7.49. Keep the notation of (3.7.47); we have :

(i) From the construction, it is clear that (3.7.48) is a *biadditive* functor, *i.e.*, for every abelian group G, and every $A \in \mathrm{Ob}(\mathscr{A})$, the restrictions $G \otimes -$ and $- \otimes A$ of (3.7.48) are additive.

(ii) Suppose that $\mathscr{A}$ is cocomplete; since the tensor product is right exact, it follows easily that (3.7.48) extends to the whole of $\mathbb{Z}$-$\mathbf{Mod}$: details left to the reader.

4. SITES AND TOPOI

In this chapter, we assemble some generalities concerning sites and topoi. The main reference for this material is [8].

4.1. **Topologies and sites.** As in the previous chapter, we fix a universe U such that $\mathbb{N} \in \mathsf{U}$, and small means U-small throughout. Especially, a presheaf on any category takes its values in U, unless explicitly stated otherwise.

Definition 4.1.1. Let $\mathscr{C}$ be a category.

(i) A *topology* on $\mathscr{C}$ is the datum, for every $X \in \mathrm{Ob}(\mathscr{C})$, of a set $J(X)$ of sieves of $\mathscr{C}/X$, fulfilling the following conditions :
   (a) (Stability under base change) For every morphism $f : Y \to X$ of $\mathscr{C}$, and every $\mathscr{S} \in J(X)$, the sieve $\mathscr{S} \times_X f$ lies in $J(Y)$.
   (b) (Local character) Let X be any object of $\mathscr{C}$, and $\mathscr{S}$, $\mathscr{S}'$ two sieves of $\mathscr{C}/X$, with $\mathscr{S} \in J(X)$. Suppose that, for every object $f : Y \to X$ of $\mathscr{S}$, the sieve $\mathscr{S}' \times_X f$ lies in $J(Y)$. Then $\mathscr{S}' \in J(X)$.
   (c) For every $X \in \mathrm{Ob}(\mathscr{C})$, we have $\mathscr{C}/X \in J(X)$.

(ii) In the situation of (i), the elements of $J(X)$ shall be called the *sieves covering* X. Moreover, say that $\mathscr{S}$ is the sieve of $\mathscr{C}/X$ generated by a family $(f_i : X_i \to X \mid i \in I)$ of morphisms. If $\mathscr{S}$ is a sieve covering X, we say that the family $(f_i \mid i \in I)$ *covers* X, or that it is a *covering family of* X.

(iii) The datum $(\mathscr{C}, J)$ of a category $\mathscr{C}$ and a topology $J := (J(X) \mid X \in \mathrm{Ob}(\mathscr{C}))$ on $\mathscr{C}$ is called a *site*, and then $\mathscr{C}$ is also called the *category underlying* the site $(\mathscr{C}, J)$. We say that $(\mathscr{C}, J)$ is a *small site*, if $\mathscr{C}$ is a small category.

(iv) The set of all topologies on $\mathscr{C}$ is partially ordered by inclusion: given two topologies J_1 and J_2 on $\mathscr{C}$, we say that J_1 is *finer* than J_2, if $J_2(X) \subset J_1(X)$ for every $X \in \mathrm{Ob}(\mathscr{C})$.

Example 4.1.2. Let T be any topological space, and $\mathscr{T}$ the set of open subsets of T, which is partially ordered by inclusion, and can thus be regarded naturally as a category, as in example 1.1.6(iii). Then the category $\mathscr{T}$ carries a natural topology J_T in the sense of definition 4.1.1 : namely, for every $U \in \mathscr{T}$ we declare that the elements of $J_T(U)$ are the sieves $\mathscr{S} \subset \mathscr{T}/U$ such that $\bigcup_{(f:U'\to U)\in\mathscr{S}} U' = U$. In other words, a family $(U'_i \to U \mid i \in I)$ of morphisms of $\mathscr{T}$ covers U for the topology J_T if and only if $\bigcup_{i\in I} U_i = U$.

Remark 4.1.3. Let $(\mathscr{C}, J)$ be any site.

(i) Any finite intersection of sieves covering an object X, again covers X. Indeed, say that $\mathscr{S}_1$ and $\mathscr{S}_2$ are two sieves covering X; set $\mathscr{S} := \mathscr{S}_1 \cap \mathscr{S}_2$ and let $f : Y \to X$ be any object of $\mathscr{S}_1$. Then $\mathscr{S} \times_X f = \mathscr{S}_2 \times_X f \in J(Y)$, so the assertion follows from the local character of J.

(ii) Also, any sieve of $\mathscr{C}/X$ containing a covering sieve is again a covering sieve. Indeed, if $\mathscr{S} \subset \mathscr{S}'$, then $\mathscr{S}' \times_X f = \mathscr{C}/Y$ for every object $f : Y \to X$ of $\mathscr{S}$.

(iii) Let $f_\bullet := (f_i : Y_i \to X \mid i \in I)$ be a family of objects of $\mathscr{C}/X$ that generates a sieve $\mathscr{S}$ covering X, and for every $i \in I$, let $(g_{ij} : Z_{ij} \to Y_i \mid i \in J_i)$ be a family of objects of $\mathscr{C}/Y_i$ that generates a sieve $\mathscr{S}_i$ covering Y_i. Then the family $(f_i \circ g_{ij} : Z_{ij} \to X \mid i \in I,\ j \in J_i)$ is a refinement of $f_\bullet$ (see definition 3.5.1(ii)) and generates a sieve $\mathscr{S}'$ covering X. Indeed, say that $f : Y \to X$ lies in $\mathscr{S}$, and pick $i \in I$ such that f factors through f_i and a morphism $g : Y \to Y_i$; then it is easily seen that $\mathscr{S}_i \times_{Y_i} g \subset \mathscr{S}' \times_X f$.

4.1.4. Suppose that $\mathscr{C}$ has small Hom-sets. Then, in view of remark 3.5.2(ii), a topology can also be defined by assigning, to any object X of $\mathscr{C}$, a family $J'(X)$ of subobjects of h_X, called the *subobjects covering* X, such that :

(a) For every $X \in \mathrm{Ob}(\mathscr{C})$, every $R \in J'(X)$, and every morphism $Y \to X$ in $\mathscr{C}$, the fibre product $R \times_X Y$ lies in $J'(Y)$.
(b) Say that $X \in \mathrm{Ob}(\mathscr{C})$, and let R, R' be two subobjects of h_X, such that $R \in J'(X)$. Suppose that, for every $Y \in \mathrm{Ob}(\mathscr{C})$, and every morphism $f : h_Y \to R$, we have $R' \times_X Y \in J'(Y)$. Then $R' \in J'(X)$.
(c) $h_X \in J'(X)$ for every $X \in \mathrm{Ob}(\mathscr{C})$.

This viewpoint is adopted in the following :

Definition 4.1.5. Let V be a universe, $C := (\mathscr{C}, J)$ a site, and $F \in \mathrm{Ob}(\mathscr{C}^\wedge_{\mathsf{V}})$.

(i) We say that F is a *separated* V*-presheaf* (resp. a V*-sheaf*) on C, if for every $X \in \mathrm{Ob}(\mathscr{C})$, every subobject R covering X, and every universe V' containing V and such that the category $\mathscr{C}$ has V'-small Hom-sets, the induced morphism :

$$F(X) = \mathrm{Hom}_{\mathscr{C}^\wedge_{\mathsf{V}'}}(h_X, F) \to \mathrm{Hom}_{\mathscr{C}^\wedge_{\mathsf{V}'}}(R, F)$$

is injective (resp. is bijective). For $\mathsf{V} = \mathsf{U}$, we shall just say separated presheaf instead of separated U-presheaf, and likewise for sheaves.

(ii) We let $C^\sim_{\mathsf{V}}$ (resp. $C^{\mathrm{sep}}_{\mathsf{V}}$) be the full subcategory of $\mathscr{C}^\wedge_{\mathsf{V}}$ whose objects are the V-sheaves (resp. the separated V-presheaves) on C. For $\mathsf{V} = \mathsf{U}$, this category will be usually denoted simply $C^\sim$ (resp. C^{sep}).

4.1.6. In the situation of definition 4.1.5(i), say that $R = h_{\mathscr{S}}$ for some sieve $\mathscr{S}$ covering X. In light of (3.5.3), (1.4.5) and proposition 1.2.6(ii), we get a natural identification :

$$\mathrm{Hom}_{\mathscr{C}^\wedge_{\mathsf{V}'}}(R, F) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{C}^\wedge_{\mathsf{V}'}}(\operatorname*{colim}_{\mathscr{S}} h_{\mathscr{C}} \circ \mathsf{s}_{\mathscr{S}}, F) \xrightarrow{\sim} \lim_{\mathscr{S}^o} F \circ \mathsf{s}^o_{\mathscr{S}}.$$

Let also $(S_i \to X \mid i \in I)$ be a generating family for $\mathscr{S}$. Combining lemma 3.5.6, example 3.1.16(i) and (3.1.15), we get a natural isomorphism :

$$\mathrm{Hom}_{\mathscr{C}^\wedge_{\mathsf{V}'}}(R, F) \xrightarrow{\sim} \mathrm{Equal}\Big(\prod_{i\in I} \mathsf{Cart}_{\mathscr{C}}(\mathscr{C}/S_i, \mathscr{F}ib(F)) \rightrightarrows \prod_{(i,j)\in I\times I} \mathsf{Cart}_{\mathscr{C}}(\mathscr{C}/S_{ij}, \mathscr{F}ib(F))\Big)$$

which – again by (3.1.15) – we may rewrite more simply as :

$$\mathrm{Hom}_{\mathscr{C}^\wedge_{\mathsf{V}'}}(R, F) \xrightarrow{\sim} \mathrm{Equal}\Big(\prod_{i\in I} F(S_i) \rightrightarrows \prod_{(i,j)\in I\times I} \mathrm{Hom}_{\mathscr{C}^\wedge_{\mathsf{V}'}}(h_{S_i} \times_{h_X} h_{S_j}, F)\Big).$$

The above equalizer can be described explicitly as follows. It consists of all the systems

$$(a_i \mid i \in I) \qquad \text{with } a_i \in F(S_i) \text{ for every } i \in I$$

such that, for every $i, j \in I$ and every object $Y \to X$ of $\mathscr{C}/X$, we have :

$$(4.1.7) \qquad F(g_i)(a_i) = F(g_j)(a_j) \qquad \text{for every pair } (S_i \xleftarrow{g_i} Y \xrightarrow{g_j} S_j) \text{ of morphisms in } \mathscr{C}/X.$$

If all $S_{ij} := S_i \times_X S_j$ are representable in $\mathscr{C}$, the latter expression takes the more familiar form:

$$\mathrm{Hom}_{\mathscr{C}^\wedge_{\mathsf{V}'}}(R, F) \xrightarrow{\sim} \mathrm{Equal}\Big(\prod_{i\in I} F(S_i) \rightrightarrows \prod_{(i,j)\in I\times I} F(S_{ij})\Big).$$

Remark 4.1.8. Let $C := (\mathscr{C}, J)$ be a site such that $\mathscr{C}$ is a category with small Hom-sets.

(i) The arguments in (4.1.6) yield also the following. A presheaf F on $\mathscr{C}$ is separated (resp. is a sheaf) on C, if and only if every covering sieve of C is a sieve of 1-descent (resp. of 2-descent) for the fibration $\mathsf{s}_F : \mathscr{F}ib(F) \to \mathscr{C}$ of (3.1.15).

(ii) Let $F : \mathscr{A} \to \mathscr{B}$ be a fibration between two categories, and $i \leq 2$ an integer. For every $X \in \mathrm{Ob}(\mathscr{B})$, let $J^i_F(X)$ denote the set of all sieves $\mathscr{S} \subset \mathscr{B}/X$ of universal F-i-descent. Then we claim that J^i_F is a topology on $\mathscr{B}$. Indeed, it is clear that J^i_F fulfills conditions (a) and (c) of definition 4.1.1(i), and condition (b) follows from proposition 3.5.38.

(iii) Let F be a presheaf on $\mathscr{C}$. We deduce from (i) and (ii) that the topology $J^F := J^2_{\mathsf{s}_F}$ is the finest on $\mathscr{C}$ for which F is a sheaf. A subobject $R \subset h_X$ (for any $X \in \mathrm{Ob}(\mathscr{C})$) lies in $J^F(X)$ if and only if the natural map $F(X') \to \mathrm{Hom}_{\mathscr{C}^\wedge}(R \times_X X', F)$ is bijective for every morphism $X' \to X$ in $\mathscr{C}$.

(iv) More generally, if $(F_i \mid i \in I)$ is any family of presheaves on $\mathscr{C}$, there exists a finest topology for which each F_i is a sheaf : namely, the intersection of the topologies J^{F_i} as in (iii).

(v) As an important special case, we deduce the existence of a finest topology J on $\mathscr{C}$ such that all representable presheaves are sheaves on $(\mathscr{C}, J)$. This topology $\mathrm{Can}_{\mathscr{C}}$ is called the *canonical topology* on $\mathscr{C}$. We thus associate to every category $\mathscr{C}$ a *canonical site*

$$\mathrm{Can}(\mathscr{C}) := (\mathscr{C}, \mathrm{Can}_{\mathscr{C}}).$$

(vi) Another interesting case of (iv) is obtained by taking the family of all presheaves on $\mathscr{C}$. The corresponding topology J on $\mathscr{C}$ can be easily described explicitly : namely, one takes $J(X) := \{\mathscr{C}/X\}$ for every $X \in \mathrm{Ob}(\mathscr{C})$.

Example 4.1.9. Let $\mathscr{C}$ be a category, $X \in \mathrm{Ob}(\mathscr{C})$ any object, and $\mathscr{S} \subset \mathscr{C}/X$ a sieve.

(i) We say that $\mathscr{S}$ is an *epimorphic sieve* (resp. a *strict epimorphic sieve*) if for every $Y \in \mathrm{Ob}(\mathscr{C})$ the natural map

$$h_Y(X) \to \mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}}, h_Y)$$

is injective (resp. bijective). We say that $\mathscr{S}$ is a *universal epimorphic sieve* (resp. a *universal strict epimorphic sieve*) if $\mathscr{S} \times_X h$ is epimorphic (resp. strict epimorphic) for every morphism $h : Y \to X$ of $\mathscr{C}$. From remark 4.1.8(iii,v) we see that $\mathscr{S}$ is universal strict epimorphic if and only if it covers X in the canonical topology of $\mathscr{C}$.

(ii) We say that a family of morphisms $f_\bullet := (f_i : X_i \to X \mid i \in I)$ of $\mathscr{C}$ is *epimorphic* (resp. *strict epimorphic*) if it generates an epimorphic (resp. strictly epimorphic) sieve. This is the same as saying for every $Y \in \mathrm{Ob}(\mathscr{C})$, the natural map

$$\mathrm{Hom}_{\mathscr{C}}(X, Y) \to \prod_{i \in I} \mathrm{Hom}_{\mathscr{C}}(X_i, Y) \qquad g \mapsto (g \circ f_i \mid i \in I) \tag{4.1.10}$$

is injective (resp. and its image consists of all the systems of morphisms $(g_i : X_i \to Y \mid i \in I)$ such that, for every $Z \in \mathrm{Ob}(\mathscr{C})$, every $i, j \in I$, and every pair of morphisms $X_j \xleftarrow{h_j} Z \xrightarrow{h_i} X_i$ with $f_i \circ h_i = f_j \circ h_j$, we have $g_i \circ h_i = g_j \circ h_j$).

(iii) We say that a family $f_\bullet$ as in (ii) is *effective epimorphic*, if it is strict epimorphic, and moreover the fibre products $X_i \times_X X_j$ are representable in $\mathscr{C}$ for every $i, j \in I$. This is the same as saying that for every $Y \in \mathrm{Ob}(\mathscr{C})$ the map (4.1.10) identifies $\mathrm{Hom}_{\mathscr{C}}(X, Y)$ with the equalizer of the two natural maps

$$\prod_{i \in I} \mathrm{Hom}_{\mathscr{C}}(X_i, Y) \rightrightarrows \prod_{(i,j) \in I \times I} \mathrm{Hom}_{\mathscr{C}}(X_i \times_X X_j, Y).$$

(iv) A family $f_\bullet$ as in (ii) is called *universal epimorphic* (resp. *universal effective epimorphic*) if (a) the fibre products $Y_i := X_i \times_X Y$ are representable in $\mathscr{C}$, for every $i \in I$ and every morphism $Y \to X$ in $\mathscr{C}$, and (b) all the resulting families $(Y_i \to Y \mid i \in I)$ are still epimorphic (resp. effective epimorphic). Then clearly such a family generates a universal epimorphic sieve (resp. a universal strict epimorphic sieve).

(v) We say that a morphism $f : X' \to X$ of $\mathscr{C}$ is an *effective epimorphism* (resp. a *universal epimorphism*, resp. a *universal effective epimorphism*) if the family $\{f\}$ has the corresponding property. Hence, f is an effective epimorphism if the fibre product $X' \times_X X'$ is representable in $\mathscr{C}$, and the induced diagram

$$X' \times_X X' \overset{p_1}{\underset{p_2}{\rightrightarrows}} X' \xrightarrow{f} X$$

identifies X with the coequalizer of the two projections p_1 and p_2. (Notice that this condition implies that f is an epimorphism). Likewise, f is a universal epimorphism (resp. a universal effective epimorphism) if for every morphism $Y \to X$, the fibre product $X' \times_X Y$ is representable in $\mathscr{C}$ and $f \times_X Y : X' \times_X Y \to Y$ is an epimorphism (resp. an effective epimorphism).

(vi) Suppose that all fibre products are representable in $\mathscr{C}$; in this case, proposition 1.2.18(ii) implies that a morphism $X' \to X$ of $\mathscr{C}$ is a universal epimorphism if and only if it is an epimorphism and the coproduct $X \amalg_{X'} X$ is a universal colimit, in the sense of example 1.4.17(ii).

(vii) Combining (vi) with example 1.4.17(iv), we conclude that all epimorphisms of $\mathbf{Set}$ are universal. Also, it is easily seen that all epimorphisms of $\mathbf{Set}$ are effective, and hence universal effective. More generally, If $\mathscr{C}$ is a small category, example 1.2.24(i) and corollary 1.4.3(ii) imply that all epimorphisms in $\mathscr{C}^\wedge$ are universal effective.

4.1.11. Let $C := (\mathscr{C}, J)$ be a small site; directly from definition 4.1.5 (and from (1.4.6)), we see that the category $C^\sim$ is complete, and the fully faithful inclusion $C^\sim \to \mathscr{C}^\wedge$ commutes with all limits. Moreover, given a presheaf F on $\mathscr{C}$, it is possible to construct a solution set for F relative to this functor, and therefore one may apply theorem 1.5.13 to produce a left adjoint. However, a more direct and explicit construction of the left adjoint can be given; the latter also provides some additional information which is hard to extract from the former method. Namely, for every $X \in \mathrm{Ob}(\mathscr{C})$, endow $J(X)$ with the partial ordering induced by inclusion of sieves. Notice that $J(X)$ is small and cofiltered, for every such X, hence the opposite ordered set $J(X)^o$ is filtered. For a given presheaf F on $\mathscr{C}$, set

$$F^+(X) := \operatorname*{colim}_{\mathscr{S} \in J(X)^o} \mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}}, F)$$

where the transition map $\mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}}, F) \to \mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}'}, F)$ is induced by the monomorphism $h_{\mathscr{S}'} \to h_{\mathscr{S}}$ of subobjects of h_X, for every inclusion $\mathscr{S}' \subset \mathscr{S}$ of sieves covering X. Let $(\tau_{\mathscr{S}} : \mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}}, F) \to F^+(X) \mid \mathscr{S} \in J(X))$ be the universal cocone. For a morphism $f : Y \to X$ in $\mathscr{C}$ and a sieve $\mathscr{S} \in J(X)$, the natural projection $h_{\mathscr{S}} \times_X Y \to h_{\mathscr{S}}$ induces a map

$$\mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}}, F) \to \mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}} \times_X Y, F) \xrightarrow{\tau_{\mathscr{S} \times_X f}} F^+(Y)$$

whence a map $F^+f : F^+(X) \to F^+(Y)$, after taking colimits. Likewise, every morphism $F \to F'$ of presheaves on $\mathscr{C}$ induces a map $\mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}}, F) \to \mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}}, F')$, for every $X \in \mathrm{Ob}(\mathscr{C})$ and every $\mathscr{S} \in J(X)$, whence a map $F^+(X) \to F'^+(X)$, after taking colimits. Thus, we have a functor :

$$\mathscr{C}^\wedge \to \mathscr{C}^\wedge \qquad F \mapsto F^+. \tag{4.1.12}$$

with a natural transformation $F(X) \to F^+(X)$, since $\mathscr{C}/X \in J(X)$ for every $X \in \mathrm{Ob}(\mathscr{C})$.

Theorem 4.1.13. *In the situation of* (4.1.11)*, the following holds :*

(i) *The inclusion functor* $i : C^\sim \to \mathscr{C}^\wedge$ *admits the left adjoint*

$$\mathscr{C}^\wedge \to C^\sim \qquad F \mapsto F^a := (F^+)^+. \tag{4.1.14}$$

For every presheaf F*, we call* F^a *the* sheaf associated with F.

(ii) *Moreover, the functor* (4.1.14) *is exact.*

Proof. We begin with the following :

Claim 4.1.15. Let F be a separated presheaf on $\mathscr{C}$, and $\mathscr{S}_1 \subset \mathscr{S}_2$ two sieves covering some $X \in \mathrm{Ob}(\mathscr{C})$. Then the natural map $\mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}_2}, F) \to \mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}_1}, F)$ is injective.

Proof of the claim. We may find a generating family $(f_i : S_i \to X \mid i \in I_2)$ for $\mathscr{S}_2$, and a subset $I_1 \subset I_2$, such that $(f_i \mid i \in I_1)$ generates $\mathscr{S}_1$. Let $s, s' : h_{\mathscr{S}_2} \to F$, whose images agree in $\mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}_1}, F)$. By (4.1.6), s and s' correspond to families $(s_i \mid i \in I_2)$, $(s'_i \mid i \in I_2)$ with $s_i, s'_i \in F(S_i)$ for every $i \in I_2$, fulfilling the system of identities (4.1.7), and the foregoing condition means that $s_i = s'_i$ for every $i \in I_1$. We need to show that $s_i = s'_i$ for every $i \in I_2$. Hence, let $i \in I_2$ be any element; by assumption, the natural map

$$F(S_i) \to \mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}_1} \times_X S_i, F)$$

is injective. However, the objects of $\mathscr{S}_1 \times_X f_i$ are all the morphisms $g_i : Y \to S_i$ in $\mathscr{C}$ such that $f_i \circ g_i = f_j \circ g_j$ for some $j \in I_1$ and some $g_j : Y \to S_j$ in $\mathscr{C}$. If we apply the identities (4.1.7) to these maps g_i, g_j, we deduce that :

$$F(g_i)(s_i) = F(g_j)(s_j) = F(g_j)(s'_j) = F(g_i)(s'_i).$$

In other words, s_i and s'_i have the same image in $\mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}_1} \times_X S_i, F)$, hence they agree, as claimed. ◊

Claim 4.1.16. (i) The functor (4.1.12) is left exact.

(ii) For every $F \in \mathrm{Ob}(\mathscr{C}^\wedge)$, the presheaf F^+ is separated.

(iii) If F is a separated presheaf on $\mathscr{C}$, then F^+ is a sheaf on C.

Proof of the claim. (i) is clear, since $J(X)^o$ is filtered for every $X \in \mathrm{Ob}(\mathscr{C})$.

(ii): Let $s, s' \in F^+(X)$, and suppose that the images of s and s' agree in $\mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}}, F^+)$, for some $\mathscr{S} \in J(X)$. We may find a sieve $\mathscr{T} \in J(X)$ such that s and s' come from elements $\overline{s}, \overline{s}' \in \mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{T}}, F)$. Let $(g_i : S_i \to X \mid i \in I)$ be a family of generators for $\mathscr{S}$; in view of (4.1.6), the images of s and s' agree in $F^+(S_i)$ for every $i \in I$. The latter means that, for every $i \in I$, there exists $\mathscr{S}_i \in J(S_i)$, refining $\mathscr{T} \times_X g_i$, such that the images of $\overline{s}$ and $\overline{s}'$ agree in $\mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}_i}, F)$. For every $i \in I$, let $(g_{i\lambda} : T_{i\lambda} \to S_i \mid \lambda \in \Lambda_i)$ be a family of generators for $\mathscr{S}_i$, and consider the sieve $\mathscr{T}'$ of $\mathscr{C}/X$ generated by $(g_i \circ g_{i\lambda} : T_{i\lambda} \to X \mid i \in I, \lambda \in \Lambda_i)$. Then $\mathscr{T}'$ covers X (remark 4.1.3(iii)) and refines $\mathscr{T}$, and the images of $\overline{s}$ and $\overline{s}'$ agree in $\mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{T}'}, F)$ (as one sees easily, again by virtue of (4.1.6)). This shows that $s = s'$, whence the contention.

(iii): In view of (ii), it suffices to show that the natural map $F^+(X) \to \mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}}, F^+)$ is surjective for every $\mathscr{S} \in J(X)$. Hence, say that $s \in \mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}}, F^+)$, and let $(S_i \mid i \in I)$ be a generating family for $\mathscr{S}$. By (4.1.6), s corresponds to a system $(s_i \in F^+(S_i) \mid i \in I)$ such that the following holds. For every $i, j \in I$, and every pair of morphisms $u_i : Y \to S_i$ and $u_j : Y \to S_j$ in $\mathscr{C}/X$, we have

$$F^+(u_i)(s_i) = F^+(u_j)(s_j). \tag{4.1.17}$$

For every $i \in I$, let $\mathscr{S}_i \in J(S_i)$ such that s_i is the image of some $\overline{s}_i \in \mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}_i}, F)$. For every u_i, u_j as above, set $\mathscr{S}_{ij} := (\mathscr{S}_i \times_{S_i} u_i) \cap (\mathscr{S}_j \times_{S_j} u_j)$; since F is separated, (4.1.17) and claim 4.1.15 imply that the images of $\overline{s}_i$ and $\overline{s}_j$ agree in $\mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}_{ij}}, F)$, for every $i, j \in I$.

However, for every $i \in I$, let $(g_{i\lambda} : T_{i\lambda} \to S_i \mid \lambda \in \Lambda_i)$ be a generating family for $\mathscr{S}_i$; then $\overline{s}_i$ corresponds to a compatible system of sections $\overline{s}_{i\lambda} \in F(T_{i\lambda})$, and $\mathscr{S}_{ij}$ is the sieve of all morphisms $f : Z \to Y$ such that

$$u_i \circ f = g_{i\lambda} \circ f'_i \qquad \text{and} \qquad u_j \circ f = g_{j\mu} \circ f'_j$$

for some $\lambda \in \Lambda_i$, $\mu \in \Lambda_j$ and some $f'_i : Z \to T_{i\lambda}$, $f'_j : Z \to T_{j\mu}$, so by construction we have

$$F(f'_i)(\overline{s}_{i\lambda}) = F(f'_j)(\overline{s}_{j\mu}) \qquad \text{for every } i, j \in I \text{ and } \lambda \in \Lambda_i,\ \mu \in \Lambda_\mu. \tag{4.1.18}$$

Lastly, let $\mathscr{T}$ be the sieve of $\mathscr{C}/X$ generated by $(g_i \circ g_{i\lambda} : T_{i\lambda} \to X \mid i \in I, \lambda \in \Lambda_i)$; then $\mathscr{T}$ covers X (remark 4.1.3(iii)), and (4.1.18) shows that the system $(F(g_{i\lambda})(\overline{s}_{i\lambda}) \mid i \in I, \lambda \in \Lambda_i)$ defines an element of $\mathrm{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{T}}, F)$, whose image in $F^+(X)$ agrees with s. ◊

From claim 4.1.16 we see that the rule : $F \mapsto F^a := (F^+)^+$ defines a left exact functor $\mathscr{C}^\wedge \to C^\sim$, with natural transformations $\eta_F : F \Rightarrow i(F^a)$ for every $F \in \mathrm{Ob}(\mathscr{C}^\wedge)$ and $\varepsilon_G : (iG)^a \Rightarrow G$ for every $G \in \mathrm{Ob}(C^\sim)$ fulfilling the triangular identities of (1.1.13). The theorem follows. □

Remark 4.1.19. Let $C := (\mathscr{C}, J)$ be a small site.

(i) It has already been remarked that $C^\sim$ is complete, and from theorem 4.1.13 we also deduce that $C^\sim$ is cocomplete, and the functor (4.1.14) (resp. the inclusion functor $i : C^\sim \to \mathscr{C}^\wedge$) commutes with all colimits (resp. with all limits); more precisely, if $F : I \to C^\sim$ is any functor from a small category I, we have a natural isomorphism in $C^\sim$ (resp. in $\mathscr{C}^\wedge$) :

$$\operatorname*{colim}_I F \xrightarrow{\sim} (\operatorname*{colim}_I i \circ F)^a \qquad (\text{resp. } \ i(\lim_I F) \xrightarrow{\sim} \lim_I i \circ F)$$

(proposition 1.3.25(iii,iv)); especially, limits in $C^\sim$ are computed argumentwise. Also, all colimits and all epimorphisms are universal in $C^\sim$ (see examples 1.4.17(ii,iv) and 4.1.9(v,vii)), and filtered colimits in $C^\sim$ commute with finite limits, since the same holds in $\mathscr{C}^\wedge$.

(ii) Furthermore, $C^\sim$ is well-powered and co-well-powered, since the same holds for $\mathscr{C}^\wedge$. Especially, every morphism $f : F \to G$ in $C^\sim$ admits a well defined image (see example 1.2.26(i)) that can be constructed explicitly as the subobject $(\mathrm{Im}\, i(f))^a$ (details left to the reader).

(iii) By composing with the Yoneda embedding, we obtain a functor

$$h^a_C : \mathscr{C} \to C^\sim \quad : \quad X \mapsto (h_X)^a \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C})$$

and since the functor $(-)^a : \mathscr{C}^\wedge \to C^\sim$ commutes with small colimits, lemma 1.4.8 yields a natural isomorphism :

$$\operatorname*{colim}_{\mathscr{F}ib(F)} h^a_C \circ \mathsf{s}_F \xrightarrow{\sim} F \qquad \text{for every sheaf } F \text{ on } C.$$

(iv) From the proof of claim 4.1.16 it is clear that the functor

$$\mathscr{C}^\wedge \to C^{\mathrm{sep}} \qquad F \mapsto F^{\mathrm{sep}} := \mathrm{Im}(F \to F^+)$$

is left adjoint to the inclusion $C^{\mathrm{sep}} \to \mathscr{C}^\wedge$. Moreover, we have a natural identification :

$$F^a \xrightarrow{\sim} (F^{\mathrm{sep}})^+ \qquad \text{for every } F \in \mathrm{Ob}(\mathscr{C}^\wedge).$$

(v) Let V be a universe such that $\mathsf{U} \subset \mathsf{V}$; from the definitions, it is clear that the fully faithful inclusion $\mathscr{C}^\wedge_\mathsf{U} \subset \mathscr{C}^\wedge_\mathsf{V}$ restricts to a fully faithful inclusion

$$C^\sim_\mathsf{U} \subset C^\sim_\mathsf{V}.$$

Moreover, by inspecting the proof of theorem 4.1.13, we deduce an essentially commutative diagram of categories :

$$\begin{array}{ccc} \mathscr{C}^\wedge_\mathsf{U} & \longrightarrow & C^\sim_\mathsf{U} \\ \downarrow & & \downarrow \\ \mathscr{C}^\wedge_\mathsf{V} & \longrightarrow & C^\sim_\mathsf{V} \end{array}$$

whose vertical arrows are the inclusions, and whose horizontal arrows are the functors $F \mapsto F^a$.

In practice, one often encounters sites that are not small, but which share many of the properties of small sites. These more general situations are encompassed by the following :

Definition 4.1.20. Let $C := (\mathscr{C}, J)$ be a site.

(i) A *topologically generating family* for C is a subset $G \subset \mathrm{Ob}(\mathscr{C})$, such that, for every $X \in \mathrm{Ob}(\mathscr{C})$, the family

$$G/X := \bigcup_{Y \in G} \{Y\} \times \mathrm{Hom}_{\mathscr{C}}(Y, X) \subset \mathrm{Ob}(\mathscr{C}/X)$$

generates a sieve covering X.

(ii) We say that C is a U-*site*, if $\mathscr{C}$ has small Hom-sets, and C admits an essentially small topologically generating family.

4.1.21. Let $C := (\mathscr{C}, J)$ be a U-site, and G an essentially small topologically generating family for C. For every $X \in \mathrm{Ob}(\mathscr{C})$, denote by $J_G(X) \subset J(X)$ the set of all sieves covering X which are generated by a subset of G/X (notation of definition 4.1.20(i)).

Lemma 4.1.22. *With the notation of* (4.1.21)*, for every $X \in \mathrm{Ob}(\mathscr{C})$ the following holds :*

(i) *$J_G(X)$ is an essentially small set.*

(ii) *$J_G(X)$ is a coinitial subset of $J(X)$ (for the partial order given by inclusion of sieves).*

Proof. (i) is left to the reader.

(ii): Let $\mathscr{S} \in J(X)$, and say that $\mathscr{S}$ is generated by a family $(f_i : S_i \to X \mid i \in I)$ of objects of $\mathscr{C}/X$ (indexed by some not necessarily small set I). Let $\mathscr{S}'$ be the sieve generated by

$$\bigcup_{i \in I} \{f_i \circ g \mid g \in G/S_i\}.$$

It is easily seen that $\mathscr{S}' \subset \mathscr{S}$ and $\mathscr{S}' \in J_G(X)$. □

Remark 4.1.23. (i) In the situation of (4.1.21), let V be a universe with $\mathsf{U} \subset \mathsf{V}$, and such that C is a V-small site, so that we have a well defined functor $(-)^+ : \mathscr{C}^\wedge_\mathsf{V} \to \mathscr{C}^\wedge_\mathsf{V}$, as in (4.1.11). Lemma 4.1.22 implies that the natural map :

$$\mathop{\mathrm{colim}}_{\mathscr{S} \in J_G(X)^o} \mathrm{Hom}_{\mathscr{C}^\wedge}(h_\mathscr{S}, F) \to F^+(X)$$

is bijective. Therefore, if F is a U-presheaf, $F^+(X)$ is essentially U-small, and then the same holds for $F^a(X)$. In other words, the restriction to $\mathscr{C}^\wedge_\mathsf{U}$ of the functor $\mathscr{C}^\wedge_\mathsf{V} \to C^\sim_\mathsf{V} : F \mapsto F^a$ is isomorphic to a functor that factors through $C^\sim$.

(ii) We deduce that theorem 4.1.13 holds, more generally, when C is an arbitrary U-site. Likewise, a simple inspection shows that remark 4.1.19(i,iv,v) holds when C is only assumed to be a U-site.

Proposition 4.1.24. *Let $C := (\mathscr{C}, J)$ be a U-site. The following holds :*

(i) *A morphism in $C^\sim$ is an isomorphism if and only if it is both a monomorphism and an epimorphism.*

(ii) *All epimorphisms in $C^\sim$ are universal effective.*

Proof. (i): Let $\varphi : F \to G$ be a monomorphism in $C^\sim$; then the morphism of presheaves $i(\varphi) : iF \to iG$ is also a monomorphism, and it is easily seen that the cocartesian diagram

$$\mathscr{D} \quad : \quad \begin{array}{ccc} iF & \xrightarrow{i(\varphi)} & iG \\ {\scriptstyle i(\varphi)}\downarrow & & \downarrow{\scriptstyle \alpha} \\ iG & \longrightarrow & iG \amalg_{iF} iG \end{array}$$

is also cartesian, hence the same holds for the induced diagram of sheaves $\mathscr{D}^a$. If moreover, φ is an epimorphism, then α^a is an isomorphism, hence the same holds for $\varphi = (i(\varphi))^a$.

(ii): Let $f : F \to G$ be an epimorphism in $C^\sim$; in view of remarks 4.1.19(i) and 4.1.23(ii), it suffices to show that f is effective. However, set $G' := \mathrm{Im}(i(f))$, and let $p_i : F \times_G F \to F$ (for $i = 1, 2$) be the two projections. Suppose $\varphi : F \to X$ is a morphism in $C^\sim$ such that $\varphi \circ p_1 = \varphi \circ p_2$; since $i(F \times_G F) = iF \times_{iG} iF = iF \times_{G'} iF$, the morphism $i(\varphi)$ factors through a (unique) morphism $\psi : G' \to X$. On the other hand, it is easily seen that $(G')^a = G$, hence φ factors through the morphism $\psi^a : G \to X$. □

Remark 4.1.25. Proposition 4.1.24(i) implies that every morphism $\varphi : X \to Y$ in $C^{\sim}$ factors uniquely (up to unique isomorphism) as the composition of an epimorphism followed by a monomorphism. Indeed; such a factorization is provided by the natural morphisms $X \to \mathrm{Im}(\varphi)$ and $\mathrm{Im}(\varphi) \to Y$ (see example 1.2.26(i)). If $X \xrightarrow{\varphi'} Z \to Y$ is another such factorization, then by definition φ' factors through a unique monomorphism $\psi : \mathrm{Im}(\varphi) \to Z$. However, ψ is an epimorphism, since the same holds for φ'. Hence ψ is an isomorphism.

Proposition 4.1.26. *Let $(\mathscr{C}, J)$ be a* U*-site, $X \in \mathrm{Ob}(\mathscr{C})$, and R any subobject of h_X. The following conditions are equivalent :*

(a) *The inclusion map $i : R \to h_X$ induces an isomorphism on associated sheaves*

$$i^a : R^a \xrightarrow{\sim} h^a_X.$$

(b) *R covers X.*

Proof. (b)⇒(a) : By definition, the natural map $R^a(X) \to \mathrm{Hom}_{\mathscr{C}^\wedge}(R, R^a)$ is bijective, hence there exists a morphism $f : h_X \to R^a$ in $\mathscr{C}^\wedge$ whose composition with i is the unit of adjunction $R \to R^a$. Therefore, $f^a : h^a_X \to R^a$ is a left inverse for i^a. On the other hand, we have a commutative diagram :

$$\begin{array}{ccc} \mathrm{Hom}_{\mathscr{C}^\wedge}(h^a_X, h^a_X) & \longrightarrow & \mathrm{Hom}_{\mathscr{C}^\wedge}(R^a, h^a_X) \\ \downarrow & & \downarrow \\ h^a_X(X) & \longrightarrow & \mathrm{Hom}_{\mathscr{C}^\wedge}(R, h^a_X) \end{array}$$

whose bottom and vertical arrows are bijective, so that the same holds also for the top arrow. Set $g := i^a \circ f^a$, and notice that $g \circ i^a = i^a$, therefore g must be the identity of h^a_X, whence the contention.

(a)⇒(b): Let $\eta_X : h_X \to h^a_X$ be the unit of adjunction, and set $j := (i^a)^{-1} \circ \eta_X : h_X \to R^a$. By remarks 4.1.19(iv) and 4.1.23(ii), we may find a covering subobject $i_1 : R_1 \to h_X$, and a morphism $j_1 : R_1 \to R^{\mathrm{sep}}$ whose image in $\mathrm{Hom}_{\mathscr{C}^\wedge}(R_1, R^a)$ equals $j \circ i_1$. Denote by $\eta'_X : h_X \to h^{\mathrm{sep}}_X$ the unit of adjunction; by construction, the two morphisms

$$i^{\mathrm{sep}} \circ j_1, \eta'_X \circ i_1 : R_1 \to h^{\mathrm{sep}}_X$$

have the same image in $\mathrm{Hom}_{\mathscr{C}^\wedge}(R_1, h^a_X)$. This means that there exists a subobject $i_2 : R_2 \to R_1$ covering X, such that $i^{\mathrm{sep}} \circ j_1 \circ i_2 = \eta'_X \circ i_1 \circ i_2$.

Next, let $Y_\bullet := (Y_\lambda \to X \mid \lambda \in \Lambda)$ be a generating family for the sieve of $\mathscr{C}/X$ corresponding to R_2. There follows, for every $\lambda \in \Lambda$, a commutative diagram :

$$\begin{array}{ccc} h_{Y_\lambda} & \xrightarrow{j_\lambda} & R^{\mathrm{sep}} \\ {\scriptstyle i_\lambda}\downarrow & & \downarrow{\scriptstyle i^{\mathrm{sep}}} \\ h_X & \xrightarrow{\eta'_X} & h^{\mathrm{sep}}_X. \end{array} \tag{4.1.27}$$

Then, for every $\lambda \in \Lambda$ there exists a covering subobject $s_\lambda : R_\lambda \to h_{Y_\lambda}$ such that j_λ lifts to some $t_\lambda : R_\lambda \to R$, and we pick a generating family $(Z_{\lambda\mu} \to Y_\lambda \mid \mu \in \Lambda_\lambda)$ for the sieve of $\mathscr{C}/Y_\lambda$ corresponding to R_λ; after replacing $Y_\bullet$ by the resulting family $(Z_{\lambda\mu} \to X \mid \lambda \in \Lambda,\ \mu \in \Lambda_\lambda)$ (which still covers X, by virtue of remark 4.1.3(iii)), we may assume that (4.1.27) lifts to a commutative diagram

$$\begin{array}{ccc} h_{Y_\lambda} & \xrightarrow{t_\lambda} & R \\ {\scriptstyle i_\lambda}\downarrow & & \downarrow \\ h_X & \xrightarrow{\eta'_X} & h^{\mathrm{sep}}_X. \end{array}$$

for every $\lambda \in \Lambda$. Then there exists a covering subobject $s'_\lambda : R'_\lambda \to h_{Y_\lambda}$ such that $i \circ t_\lambda \circ s'_\lambda = i_\lambda \circ s'_\lambda$ in $\mathrm{Hom}_{\mathscr{C}^\wedge}(R'_\lambda, h_X)$. Lastly, set

$$R' := \bigcup_{\lambda \in \Lambda} \mathrm{Im}(i_\lambda \circ s'_\lambda : R'_\lambda \to h_X)$$

(notice that $R' \in \mathrm{Ob}(\mathscr{C}^\wedge_{\mathsf{U}})$ even in case Λ is not a small set). It is easily seen that R' is a covering subobject of X, and the inclusion map $R' \to h_X$ factors through R, so R covers X as well. ☐

Definition 4.1.28. Let $(\mathscr{C}, J)$ be a site such that $\mathscr{C}$ has small Hom-sets, and let $\varphi : F \to G$ be a morphism in $\mathscr{C}^\wedge$.

(i) We say that φ is a *covering morphism* if, for every $X \in \mathrm{Ob}(\mathscr{C})$ and every morphism $h_X \to G$ in $\mathscr{C}^\wedge$, the image of the induced morphism $F \times_G h_X \to h_X$ is a covering subobject of h_X.

(ii) We say that φ a *bicovering morphism* if both φ and the diagonal morphism $F \to F \times_G F$ induced by φ, are covering morphisms.

Remark 4.1.29. (i) In the situation of definition 4.1.28, let $S := \{X_i \to X \mid i \in I\}$ be a family of morphisms in $\mathscr{C}$, and pick a universe V containing U, such that I is V-small. Using remark 3.5.2(iii), it is easily seen that S covers X if and only if the induced morphism in $\mathscr{C}^\wedge_{\mathsf{V}}$

$$\coprod_{i \in I} h_{X_i} \to h_X$$

is a covering morphism.

(ii) With the notation of definition 4.1.28, recall that, by Yoneda's lemma, the set of morphisms $h_X \to G$ in $\mathscr{C}^\wedge$ is naturally identified with GX. Fix $s \in GX$, and let $\psi_s : h_X \to G$ be the corresponding morphism; under this identification, for every $Y \in \mathrm{Ob}(\mathscr{C})$ the image of the induced map $(F \times_{(\varphi,\psi_s)} h_X)(Y) \to h_X(Y)$ is then the set of all morphisms $f : Y \to X$ such that $(Gf)(s)$ lies in the image of the map $\varphi(f) : FY \to GY$. Thus φ is a covering morphism if and only if for every $X \in \mathrm{Ob}(\mathscr{C})$ and every $s \in GX$, the sieve of $\mathscr{C}/X$ generated by all morphisms $f : Y \to X$ in $\mathscr{C}$ such that $(Gf)(s) \in \mathrm{Im}(\varphi_Y : FY \to GY)$ covers X. In other words, φ is a covering morphism if and only if for every $X \in \mathrm{Ob}(\mathscr{C})$ and every $s \in GX$ there exists a covering family $(f_i : Y_i \to X \mid i \in I)$ such that $(Gf_i)(s) \in \mathrm{Im}(\varphi_{Y_i})$ for every $i \in I$.

(iii) Likewise, the diagonal morphism $F \to F \times_G F$ induced by φ is a covering morphism if and only if for every $X \in \mathrm{Ob}(\mathscr{C})$ and every two sections $s, s' \in FX$ such that $\varphi_X(s) = \varphi_X(s')$, the set of all morphisms $f : Y \to X$ in $\mathscr{C}$ such that $(Ff)(s) = (Ff)(s')$ generates a sieve covering X. This is the same as saying that for every such X and every such pair (s, s') there exists a covering family $(f_i : Y_i \to X \mid i \in I)$ such that $(Ff_i)(s) = (Ff_i)(s')$ for every $i \in I$.

Corollary 4.1.30. *Let $C := (\mathscr{C}, J)$ be a U-site, and $\varphi : F \to G$ a morphism in $\mathscr{C}^\wedge$. We have :*

(i) *φ is a covering morphism if and only if $\varphi^a : F^a \to G^a$ is an epimorphism in $C^\sim$.*

(ii) *The diagonal morphism $F \to F \times_G F$ induced by φ is a covering morphism if and only if φ^a is a monomorphism in $C^\sim$.*

(iii) *φ is a bicovering morphism if and only if $\varphi^a : F^a \to G^a$ is an isomorphism in $C^\sim$.*

Proof. Let V be a universe with $\mathsf{U} \subset \mathsf{V}$, and such that $\mathscr{C}$ is V-small. Clearly φ is a covering (resp. bicovering) morphism in $\mathscr{C}^\wedge_{\mathsf{U}}$ if and only if the same holds for the image of φ under the fully faithful inclusion $\mathscr{C}^\wedge_{\mathsf{U}} \subset \mathscr{C}^\wedge_{\mathsf{V}}$. So we may replace U by V, and assume that C is a small site.

(i): Suppose that φ^a is an epimorphism; let X be any object of $\mathscr{C}$, and $h_X \to G$ a morphism. Since the epimorphisms of $C^\sim$ are universal (remark 4.1.19(i)), the induced morphism

$$(\varphi \times_G X)^a : (F \times_G h_X)^a \to h_X^a$$

is an epimorphism. Let $R \subset h_X$ be the image of $\varphi \times_G h_X$; then the induced morphism $R^a \to h^a_X$ is both a monomorphism and an epimorphism, so it is an isomorphism, by proposition 4.1.24(i). Hence R is a covering subobject, according to proposition 4.1.26.

Conversely, suppose that φ is a covering morphism. By remark 4.1.19(iii), G is the colimit of a family $(h^a_{X_i} \mid i \in I)$ for certain $X_i \in \mathrm{Ob}(\mathscr{C})$. By definition, the image R_i of the induced morphism $\varphi \times_G X_i : F \times_G h_{X_i} \to h_{X_i}$ covers X_i, for every $i \in I$. Now, the induced morphism $F \times_G h_{X_i} \to R_i$ is an epimorphism, and the morphism $R^a_i \to h^a_{X_i}$ is an isomorphism (proposition 4.1.26), hence $(\varphi \times_G X_i)^a$ is an epimorphism, and then the same holds for

$$\operatorname*{colim}_{i\in I}(\varphi \times_G X_i)^a : \operatorname*{colim}_{i\in I} F^a \times_{G^a} h^a_{X_i} \to \operatorname*{colim}_{i\in I} h^a_{X_i} = G^a$$

which is isomorphic to φ^a, since the colimits of $C^\sim$ are universal (remark 4.1.19(i)); so φ^a is an epimorphism.

(ii): If $\delta : F \to F \times_G F$ is a covering morphism, the foregoing shows that the induced morphism $\delta^a : F^a \to F^a \times_{G^a} F^a$ is both an epimorphism and a monomorphism, hence it is an isomorphism (proposition 4.1.24(i)), so φ^a is a monomorphism (proposition 1.2.18(i)). Conversely, if φ^a is a monomorphism, δ^a is an isomorphism, hence δ is a covering morphism, by (i).

(iii) follows from (i), (ii) and proposition 4.1.24(i). ☐

Remark 4.1.31. (i) Let $C := (\mathscr{C}, J)$ be a site such that $\mathscr{C}$ has small Hom-sets, and V a universe containing U, such that $\mathscr{C}^\wedge$ is V-small. For every presheaf F on $\mathscr{C}$, let $J^\wedge(F)$ be the set of all sieves $\mathscr{S} \subset \mathscr{C}^\wedge/F$ such that the natural morphism

$$\coprod_{(f:G\to F)\in\mathrm{Ob}(\mathscr{S})} G \to F$$

is a covering morphism in $\mathscr{C}^\wedge_{\mathsf{V}}$. Notice that $\mathscr{S} \in J^\wedge(F)$ if and only if there exists a generating family $(f_i : F_i \to F \mid i \in I)$ for $\mathscr{S}$, indexed by a V-small set I, such that the natural morphism $\amalg_{i\in I} F_i \to F$ is a covering morphism. Since the functor $(-)^a : \mathscr{C}^\wedge_{\mathsf{V}} \to C^\sim_{\mathsf{V}}$ commutes with arbitrary V-small colimits, corollary 4.1.30(i) says that the latter condition holds if and only if the induced morphism $\amalg_{i\in I} F^a_i \to F^a$ is an epimorphism in $C^\sim_{\mathsf{V}}$.

(ii) We claim that the system $(J^\wedge(F) \mid F \in \mathrm{Ob}(\mathscr{C}^\wedge))$ is a topology on $\mathscr{C}^\wedge$. Indeed, it is clear from the definition that if $\mathscr{S} \in J^\wedge(F)$, then $\mathscr{S} \times_F f$ lies in $J^\wedge(F')$ for every morphism $f : F' \to F$ in $\mathscr{C}^\wedge$. Next, let $\mathscr{S}, \mathscr{S}' \subset \mathscr{C}^\wedge/F$ be two sieves, with $\mathscr{S} \in J^\wedge(F)$ and such that $\mathscr{S}' \times_F f \in J^\wedge(F')$ for every $(f : F' \to F) \in \mathrm{Ob}(\mathscr{S})$. By the foregoing, this means that the induced morphism $\amalg_{(g:G\to F)\in\mathrm{Ob}(\mathscr{S}')} G^a \times_{F^a} F'^a \to F'^a$ is an epimorphism in $C^\sim_{\mathsf{V}}$ for every such f. Since (in every category) an arbitrary coproduct of epimorphisms is an epimorphism, it follows that both of the following morphisms are epimorphisms :

$$\coprod_{(f:F'\to F)\in\mathrm{Ob}(\mathscr{S})} \; \coprod_{(g:G\to F)\in\mathrm{Ob}(\mathscr{S}')} G^a \times_{F^a} F'^a \to \coprod_{(f:F'\to F)\in\mathrm{Ob}(\mathscr{S})} F'^a \to F^a$$

and then so is their composition. But $f \circ (g \times_F F') : G \times_F F' \to F$ lies in $\mathscr{S}'$ for every $f \in \mathrm{Ob}(\mathscr{S})$ and every $g \in \mathrm{Ob}(\mathscr{S}')$, so $\mathscr{S}' \in J^\wedge(F)$, as required. We denote the resulting site

$$C^\wedge := (\mathscr{C}^\wedge, J^\wedge).$$

In light of remark 4.1.29(ii) it is easily seen that $C^\wedge$ is independent of the choice of V.

4.2. **Continuous and cocontinuous functors.** We now begin the study of those functors that are compatible with given topologies on their domain and codomain of definition; as explained hereafter, such compatibility can manifest itself in two distinct fashions :

Definition 4.2.1. Let $C = (\mathscr{C}, J)$ and $C' = (\mathscr{C}', J')$ be two sites, and $g : \mathscr{C} \to \mathscr{C}'$ a functor.

(i) We say that g is *continuous* for the topologies J and J', if the following holds. For every universe V and every V-sheaf F on C', the V-presheaf $g^\wedge_{\mathsf{V}} F$ is a V-sheaf on C (notation of (1.2.2)). In this case, $g^\wedge_{\mathsf{V}}$ clearly induces by restriction a functor

$$\widetilde{g}_{\mathsf{V}*} : C'^{\sim}_{\mathsf{V}} \to C^{\sim}_{\mathsf{V}}.$$

(ii) We say that g is *cocontinuous* for the topologies J and J' if the following holds. For every $X \in \mathrm{Ob}(\mathscr{C})$, and every covering sieve $\mathscr{S}' \in J'(gX)$, the sieve $g^{-1}_{|X}\mathscr{S}'$ covers X in C (notation of definition 3.5.1(iii) and (1.1.26)).

Example 4.2.2. Let T, T' be two topological spaces, and $f : T \to T'$ a continuous map; denote by $\mathscr{T}$ (resp. $\mathscr{T}'$) the category of open subsets of T (resp. of $\mathscr{T}'$), endowed with its natural topology as in example 4.1.2. Then f induces a functor $f^{-1} : \mathscr{T}' \to \mathscr{T} : U \mapsto f^{-1}U$, and it is easily seen that f^{-1} is a continuous functor, according to definition 4.2.1(i).

Lemma 4.2.3. *Let $C = (\mathscr{C}, J)$ and $C' = (\mathscr{C}', J')$ be two sites, $g : \mathscr{C} \to \mathscr{C}'$ a functor, and V a universe such that $\mathscr{C}$ is V-small and $\mathscr{C}'$ has small* Hom*-sets. The following conditions are equivalent :*

(a) *For every V-sheaf F on C', the presheaf $g^\wedge_{\mathsf{V}} F$ is a V-sheaf on C.*
(b) *For every morphism $\varphi : F \to G$ of V-presheaves on $\mathscr{C}$ that is bicovering for the topology J, the morphism $g_{\mathsf{V}!}(\varphi) : g_{\mathsf{V}!}F \to g_{\mathsf{V}!}G$ is bicovering for the topology J'.*
(c) *For every $X \in \mathrm{Ob}(\mathscr{C})$ and every subobject $R \subset h_X$ covering X for the topology J, the induced morphism of presheaves $g_{\mathsf{V}!}R \to g_{\mathsf{V}!}h_X$ is bicovering for the topology J'.*
(d) *g is continuous for the topologies J and J'.*

Proof. (a)⇒(b): By virtue of remark 1.3.6(iv) we may replace V by a larger universe, and assume that $\mathscr{C}$ and $\mathscr{C}'$ are V-small. Then, by corollary 4.1.30(iii), the morphism $\varphi^a : F^a \to G^a$ is an isomorphism, and we need to check that $g_{\mathsf{V}!}(\varphi)^a$ is an isomorphism. To this aim, let H be any V-sheaf on C'; we get a commutative diagram :

$$\begin{array}{ccccccc}
\mathrm{Hom}_{\mathscr{C}'^\wedge}(g_{\mathsf{V}!}(G)^a, H) & \longrightarrow & \mathrm{Hom}_{\mathscr{C}'^\wedge}(g_{\mathsf{V}!}(G), H) & \longrightarrow & \mathrm{Hom}_{\mathscr{C}^\wedge}(G, g^\wedge_{\mathsf{V}} H) & \longleftarrow & \mathrm{Hom}_{\mathscr{C}^\wedge}(G^a, g^\wedge_{\mathsf{V}} H) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\mathrm{Hom}_{\mathscr{C}'^\wedge}(g_{\mathsf{V}!}(F)^a, H) & \longrightarrow & \mathrm{Hom}_{\mathscr{C}'^\wedge}(g_{\mathsf{V}!}(F), H) & \longrightarrow & \mathrm{Hom}_{\mathscr{C}^\wedge}(F, g^\wedge_{\mathsf{V}} H) & \longleftarrow & \mathrm{Hom}_{\mathscr{C}^\wedge}(F^a, g^\wedge_{\mathsf{V}} H)
\end{array}$$

whose horizontal arrows are bijections, due to (a). Since φ^a is bijective, the right-most vertical arrow is bijective, hence the same holds for the left-most vertical arrow, whence the contention.

(b)⇒(c) and (d)⇒(a) are trivial.

(c)⇒(d): Let V' be a universe, and F a V'-sheaf on C'; we need to check that $g^\wedge_{\mathsf{V}'} F$ is a sheaf on C. To this aim, we may replace V' by a larger universe, and assume that $\mathsf{V} \subset \mathsf{V}'$, and that $\mathscr{C}$ and $\mathscr{C}'$ are V'-small; then by remark 1.3.6(iv) and corollary 4.1.30(iii) we see that for every $X \in \mathrm{Ob}(\mathscr{C})$ and every covering subobject $R \subset h_X$ the induced morphism $g_{\mathsf{V}'!}(R)^a \to g_{\mathsf{V}'!}(h_X)^a$ is an isomorphism. Now, we have a commutative diagram :

$$\begin{array}{ccccc}
\mathrm{Hom}_{\mathscr{C}^\wedge}(h_X, g^\wedge_{\mathsf{V}'} F) & \longrightarrow & \mathrm{Hom}_{\mathscr{C}'^\wedge}(g_{\mathsf{V}'!}h_X, F) & \longleftarrow & \mathrm{Hom}_{\mathscr{C}'^\wedge}(g_{\mathsf{V}'!}(h_X)^a, F) \\
\downarrow & & \downarrow & & \downarrow \\
\mathrm{Hom}_{\mathscr{C}^\wedge}(R, g^\wedge_{\mathsf{V}'} F) & \longrightarrow & \mathrm{Hom}_{\mathscr{C}'^\wedge}(g_{\mathsf{V}'!}R, F) & \longleftarrow & \mathrm{Hom}_{\mathscr{C}'^\wedge}(g_{\mathsf{V}'!}(R)^a, F)
\end{array}$$

whose horizontal arrows are bijections; moreover, the right-most vertical arrow is bijective as well, hence the same holds for the left-most vertical arrow, which is the contention. □

Lemma 4.2.4. *In the situation of definition* 4.2.1*, consider the following conditions :*

(a) *g is continuous.*

(b) *For every covering family* $(X_i \to X \mid i \in I)$ *in* C*, the family* $(gX_i \to gX \mid i \in I)$ *covers* gX *in* C'*.*
(c) *For every small covering family* $(X_i \to X \mid i \in I)$ *in* C*, the family* $(gX_i \to gX \mid i \in I)$ *covers* gX *in* C'*.*
(d) *For every universe* V*, and every* V*-presheaf* F *on* $\mathscr{C}'$ *that is separated for the topology* J'*, the presheaf* $g^{\wedge}_{\mathsf{V}}F$ *is separated for the topology* J*, so that* $g^{\wedge}_{\mathsf{V}}$ *restricts to a functor*

$$g^{\mathrm{sep}}_{\mathsf{V}*} : C'^{\mathrm{sep}}_{\mathsf{V}} \to C^{\mathrm{sep}}_{\mathsf{V}}.$$

Then (a)⇒(b)⇔(d)⇒(c)*. Moreover, if all fibre products are representable in* $\mathscr{C}$*, and* g *commutes with fibre products, then* (b)⇒(a)*. Furthermore, if* C *is a* U*-site, then* (c)⇒(b)*.*

Proof. Obviously (b)⇒(c).

(a)⇒(b): After replacing U by a larger universe, we may assume that I is a small set and both $\mathscr{C}$ and $\mathscr{C}'$ are small. Let F be any sheaf on C'; by assumption, $g^{\wedge}F$ is a sheaf on C, hence the natural map :

$$F(gX) = g^{\wedge}F(X) \to \prod_{i\in I} g^{\wedge}F(X_i) = \prod_{i\in I} F(gX_i)$$

is injective (by (4.1.6)). This means that the induced morphism

$$\coprod_{i\in I} h^a_{gX_i} \to h^a_{gX} \qquad (4.2.5)$$

is an epimorphism in $C'^{\sim}$. Then the assertion follows from corollary 4.1.30 and remark 4.1.29(i).

(d)⇒(b) is similar : we may assume that I, $\mathscr{C}$ and $\mathscr{C}'$ are small. If F is any separated presheaf on C', then by assumption $g^{\wedge}F$ is separated on C, and arguing as in the foregoing, we deduce that the induced morphism $\amalg_{i\in I} h^{\mathrm{sep}}_{gX_i} \to h^{\mathrm{sep}}_{gX}$ is an epimorphism in C'^{sep}, and then (4.2.5) is an epimorphism in $C'^{\sim}$, so we conclude, again by corollary 4.1.30 and remark 4.1.29(i).

(b)⇒(d): let F be a separated V-presheaf on C', and $(X_i \to X \mid i \in I)$ any covering family in C; in view of (4.1.6), it suffices to show that the induced map

$$F(gX) = g^{\wedge}_{\mathsf{V}}F(X) \to \prod_{i\in I} g^{\wedge}_{\mathsf{V}}F(X_i) = \prod_{i\in I} F(gX_i)$$

is injective. But this is clear, since $(gX_i \to gX \mid i \in I)$ is a covering family in C'.

Next, suppose that (b) holds, the fibre products in $\mathscr{C}$ are representable, and g commutes with all fibre products. For every $i, j \in I$, set $X_{ij} := X_i \times_X X_j$. To show that (a) holds, it suffices – in view of (4.1.6) – to prove :

Claim 4.2.6. The natural map

$$g^{\wedge}F(X) \to \mathrm{Hom}_{\mathscr{C}^{\wedge}}\Big(\mathrm{Coequal}\Big(\coprod_{i,j\in I} h_{X_{ij}} \rightrightarrows \coprod_{i\in I} h_{X_i}\Big), g^{\wedge}F\Big)$$

is bijective.

Proof of the claim. Since $g_!$ is right exact, and due to (1.3.7), this is the same as the natural map

$$F(gX) \to \mathrm{Hom}_{\mathscr{C}'^{\wedge}}\Big(\mathrm{Coequal}\Big(\coprod_{i,j\in I} h_{gX_{ij}} \rightrightarrows \coprod_{i\in I} h_{gX_i}\Big), F\Big).$$

However, by assumption $gX_{ij} = gX_i \times_{gX} gX_j$, and then the claim follows by applying (4.1.6) to the covering family $(gX_i \to gX \mid i \in I)$. ◊

Lastly, suppose that C is a U-site; in order to show that (c)⇒(b), we remark more precisely :

Claim 4.2.7. Let C be a U-site, $\mathscr{F} := (\varphi_i : X_i \to X \mid i \in I)$ any covering family. Then there exists a small set $J \subset I$ such that the subfamily $(\varphi_i \mid i \in J)$ covers X.

Proof of the claim. Let $\mathscr{S} \subset \mathscr{C}/X$ be the sieve generated by $\mathscr{S}$. By lemma 4.1.22, we may find a small covering family $\mathscr{F}' := (\psi_i : X'_i \to X \mid i \in I')$ (*i.e.* such that I' is small), that generates a sieve $\mathscr{S}' \subset \mathscr{S}$. Then, for every $i \in I'$ we may find $\gamma(i) \in I$ such that ψ_i factors through $\varphi_{\gamma(i)}$. The subset $J := \gamma I'$ will do. ◊

Let $\mathscr{F}$ and J be as in claim 4.2.7; then the sieve $g\mathscr{S}$ generated by $(g(\varphi_i) \mid i \in I)$ contains the sieve $g\mathscr{S}'$ generated by $(g(\varphi_i) \mid i \in J)$. Especially, if $g\mathscr{S}'$ is a covering sieve, the same holds for $g\mathscr{S}$, whence the contention. □

4.2.8. In the situation of definition 4.2.1, let V be a universe with $\mathsf{U} \subset \mathsf{V}$, such that C is a V-site, and $\mathscr{C}'$ has V-small Hom-sets. Then we may define a functor

$$\breve{g}^*_{\mathsf{V}} : C'^{\sim}_{\mathsf{V}} \to C^{\sim}_{\mathsf{V}} \qquad F \mapsto (g^{\wedge}_{\mathsf{V}} \circ i_{C'} F)^a$$

(where $i_{C'} : C'^{\sim}_{\mathsf{V}} \to \mathscr{C}'^{\wedge}_{\mathsf{V}}$ is the forgetful functor). On the other hand, if C is a V-small site and C' is a V-site, we can define the functors

$$g^a_{\mathsf{V}!} : \mathscr{C}^{\wedge}_{\mathsf{V}} \to C'^{\sim}_{\mathsf{V}} \qquad F \mapsto (g_{\mathsf{V}!}F)^a \qquad \text{and} \qquad \widetilde{g}^*_{\mathsf{V}} := g^a_{\mathsf{V}!} \circ i_C : C^{\sim}_{\mathsf{V}} \to C'^{\sim}_{\mathsf{V}}.$$

As usual, if $\mathsf{V} = \mathsf{U}$ we often omit the subscript U. Later we shall generalize these constructions to the case where both C and C' are V-sites : see corollary 4.3.19. For now we remark :

Lemma 4.2.9. *In the situation of definition* 4.2.1*, let* V *be a universe with* $\mathsf{U} \subset \mathsf{V}$*, such that* $\mathscr{C}$ *is* V*-small, and* $\mathscr{C}'$ *has* V*-small* Hom*-sets. Then the following conditions are equivalent :*

(a) *g is a cocontinuous functor.*
(b) *For every covering morphism $\varphi : F \to G$ in $\mathscr{C}'^{\wedge}$, the morphism $g^{\wedge}(\varphi) : g^{\wedge}F \to g^{\wedge}G$ is covering.*
(c) *For every bicovering morphism $\varphi : F \to G$ in $\mathscr{C}'^{\wedge}$, the morphism $g^{\wedge}(\varphi) : g^{\wedge}F \to g^{\wedge}G$ is bicovering.*
(d) *For every $X \in \mathrm{Ob}(\mathscr{C}')$ and every covering subobject R of h_X, the induced morphism $g^{\wedge}R \to g^{\wedge}h_X$ is bicovering.*
(e) *For every $F \in \mathrm{Ob}(C^{\sim}_{\mathsf{V}})$, the V-presheaf $g_{\mathsf{V}*}F$ is a V-sheaf on C' (see remark* 1.3.6(i)*).*

When these conditions hold, the restriction of $g_{\mathsf{V}*}$ is a right adjoint to $\breve{g}^*_{\mathsf{V}}$ denoted

$$\breve{g}_{\mathsf{V}*} : C^{\sim}_{\mathsf{V}} \to C'^{\sim}_{\mathsf{V}}$$

Proof. After replacing V by U, we may assume that $\mathscr{C}$ is small, and $\mathscr{C}'$ has small Hom-sets. Recall that the unit of the natural adjunction for the pair $(g_!, g^{\wedge})$ assigns to every $X \in \mathrm{Ob}(\mathscr{B})$ the morphism $\eta_X : h_X \to g^{\wedge}(g_! h_X) \xrightarrow{\sim} g^{\wedge}(h_{gX})$ such that $\eta_X(s) := Fs$ for every $X' \in \mathrm{Ob}(\mathscr{C})$ and every $(s : X' \to X) \in h_X(X')$: see remark 1.3.6(v). We notice :

Claim 4.2.10. Let $X \in \mathrm{Ob}(\mathscr{C})$, and $\mathscr{T}' \subset \mathscr{C}'/gX$ a covering sieve; set $\mathscr{T} := g^{-1}_{|X}\mathscr{T}'$. Then :

$$h_{\mathscr{T}} = g^{\wedge}(h_{\mathscr{T}'}) \times_{g^{\wedge}(h_{gX})} h_X.$$

Proof of the claim. For every $X' \in \mathrm{Ob}(\mathscr{C})$, the set $(g^{\wedge}(h_{\mathscr{T}'}) \times_{g^{\wedge}(h_{gX})} h_X)(X')$ consists of the pairs (t, s) where $t : gX' \to gX$ is an object of $\mathscr{T}'$ and $s : X' \to X$ is a morphism in $\mathscr{C}$, such that $g(s) = t$. In other words, this is the set of all $s \in h_X(X')$ such that $g(s) \in \mathrm{Ob}(\mathscr{T}')$. This is precisely the definition of $h_{\mathscr{T}}(X')$. ◊

(a)⇒(b): Let $X \in \mathrm{Ob}(\mathscr{C})$ and $\psi : h_X \to g^{\wedge}G$ any morphism in $\mathscr{C}^{\wedge}$. By adjunction, ψ corresponds to a morphism $\psi' : h_{gX} \to G$ in $\mathscr{C}'^{\wedge}$, such that $\psi = g^{\wedge}(\psi') \circ \eta_X$. By assumption, ψ' induces a covering morphism $F \times_G h_{gX} \to h_{gX}$, whose image is therefore of the form $h_{\mathscr{S}'}$ for some covering sieve $\mathscr{S}' \in J'(gX)$. Since $g^{\wedge}$ is exact, the epimorphism $\pi : F \times_G h_{gX} \to h_{\mathscr{S}'}$

induces an epimorphism $g^\wedge(\pi) : g^\wedge(F \times_G h_{gX} \to h_{gX}) \to g^\wedge(h_{\mathscr{S}'})$, and notice the following commutative diagram whose three square subdiagrams are cartesian :

$$\begin{array}{ccccc}
g^\wedge(F) \times_{g^\wedge(G)} h_X & \longrightarrow & g^\wedge(h_{\mathscr{S}'}) \times_{g^\wedge(h_{gX})} h_X & \longrightarrow & h_X \\
\downarrow & & \downarrow & & \downarrow {\scriptstyle \eta_X} \\
g^\wedge(F \times_G h_{gX}) & \xrightarrow{g^\wedge(\pi)} & g^\wedge(h_{\mathscr{S}'}) & \longrightarrow & g^\wedge(h_{gX}) \\
\downarrow & & & & \downarrow {\scriptstyle g^\wedge(\psi')} \\
g^\wedge(F) & & \longrightarrow & & g^\wedge(G)
\end{array}$$

In view of claim 4.2.10, we deduce that the image of the morphism $g^\wedge(F) \times_{g^\wedge(G)} h_X \to h_X$ induced by $g^\wedge(\varphi)$ is $h_{\mathscr{S}}$, where $\mathscr{S} := g^{-1}_{|X}\mathscr{S}'$; but $\mathscr{S}$ is a covering sieve of X, since g is cocontinuous. This shows that (b) holds.

(b)⇒(c): If φ is a bicovering morphism, (b) implies that both $g^\wedge(\varphi)$ and the morphism $\delta : g^\wedge(F) \to g^\wedge(F \times_G F)$ induced by φ are covering morphisms. However, $g^\wedge$ is exact, so δ is naturally identified with the diagonal morphism $g^\wedge(F) \to g^\wedge(F) \times_{g^\wedge(G)} g^\wedge(F)$ induced by $g^\wedge(\varphi)$; thus, $g^\wedge(\varphi)$ is bicovering.

(c)⇒(d) is obvious.

(d)⇒(e): Let F be any sheaf on C; we have to show that the natural map

$$g_*F(Y) \to \mathrm{Hom}_{\mathscr{C}'^\wedge}(R, g_*F)$$

is bijective, for every $Y \in \mathrm{Ob}(\mathscr{C}')$, and every covering subobject of h_Y. By adjunction (and by corollary 4.1.30), this is the same as saying that the monomorphism $g^\wedge(R) \to g^\wedge(h_Y)$ is a covering morphism, which holds by assumption (d).

(e)⇒(a): The assumption implies that, for every sheaf F on C, every $X \in \mathrm{Ob}(\mathscr{C})$, and every covering sieve $\mathscr{S}' \subset \mathscr{C}'/gX$, the natural map

$$g_*F(gX) \to \mathrm{Hom}_{\mathscr{C}'^\wedge}(h_{\mathscr{S}'}, g_*F)$$

is bijective. By adjunction, the same then holds for the natural map

$$\mathrm{Hom}_{\mathscr{C}^\wedge}(g^\wedge(h_{gX}), F) \to \mathrm{Hom}_{\mathscr{C}^\wedge}(g^\wedge(h_{\mathscr{S}'}), F)$$

so the induced morphism $g^\wedge(h_{\mathscr{S}'}) \to g^\wedge(h_{gX})$ is bicovering (proposition 4.1.26). Also, this morphism is a monomorphism (since $g^\wedge$ commutes with all limits); therefore, after base change along the unit of adjunction $\eta_X : h_X \to g^\wedge(h_{gX})$, we deduce a covering monomorphism

$$g^\wedge(h_{\mathscr{S}'}) \times_{g^\wedge(h_{gX})} h_X \to h_X.$$

Then the contention follows from claim 4.2.10.

Lastly, the assertion concerning the left adjoint $\breve{g}^*_{\mathsf{U}}$ is immediate from the definitions. □

Lemma 4.2.11. *Let $C' := (\mathscr{C}', J')$ be a U-site, $C := (\mathscr{C}, J)$ a small site, and $g : \mathscr{C} \to \mathscr{C}'$ a continuous functor. Then the following holds :*

(i) *The functor $\widetilde{g}^*_{\mathsf{U}} : C^\sim_{\mathsf{U}} \to C'^\sim_{\mathsf{U}}$ of* (4.2.8) *is left adjoint to $\widetilde{g}_{\mathsf{U}*}$.*

(ii) *The natural diagrams of functors :*

$$\begin{array}{ccc}
\mathscr{C} & \xrightarrow{g} & \mathscr{C}' \\
{\scriptstyle h^a_{\mathscr{C}}} \downarrow & & \downarrow {\scriptstyle h^a_{\mathscr{C}'}} \\
C^\sim_{\mathsf{U}} & \xrightarrow{\widetilde{g}^*_{\mathsf{U}}} & C'^\sim_{\mathsf{U}}
\end{array}
\qquad
\begin{array}{ccc}
\mathscr{C}^\wedge_{\mathsf{U}} & \xrightarrow{(-)^a} & C^\sim_{\mathsf{U}} \\
& {\scriptstyle g^a_{\mathsf{U}!}} \searrow \quad \swarrow {\scriptstyle \widetilde{g}^*_{\mathsf{U}}} & \\
& C'^\sim_{\mathsf{U}} &
\end{array}$$

are essentially commutative. (Notation of theorem 4.1.13.*)*

Proof. The first assertion is straightforward, and the commutativity of the square diagram in (ii) is reduced to the corresponding assertion for (1.3.7), which has already been remarked. To show the commutativity for the triangular diagram in (ii), it suffices to check that for every presheaf F on $\mathscr{C}$ and every sheaf G of C' the natural map $\eta_F : F \to i_C(F^a)$ induces a bijection

$$\mathrm{Hom}_{C'^\sim}(\widetilde{g}^*_{\mathsf{U}}(F^a), G) \stackrel{\sim}{\to} \mathrm{Hom}_{C'^\sim}(g^a_{\mathsf{U}!}(F), G).$$

However, by adjunction, the latter is naturally identified with the map

$$\mathrm{Hom}_{\mathscr{C}^\wedge}(F^a, g^\wedge_{\mathsf{U}} G) \to \mathrm{Hom}_{\mathscr{C}^\wedge}(F, g^\wedge_{\mathsf{U}} G) \tag{4.2.12}$$

induced by η_F; but $g^\wedge_{\mathsf{U}} G$ is a sheaf, since g is continuous, so (4.2.12) is indeed bijective. □

4.2.13. Let $(\mathscr{C}, J)$ be a small site, $(\mathscr{C}', J')$ a U-site, $u : \mathscr{C} \to \mathscr{C}'$ a continuous (resp. cocontinuous) functor. Let also V be a universe such that $\mathsf{U} \subset \mathsf{V}$. Then it follows easily from remark (1.3.6)(iv) and lemma 4.2.11(i) (resp. from lemma 4.2.9), and from remark 4.1.23(ii) that we have essentially commutative diagrams of categories :

$$\begin{array}{ccc} C^\sim_{\mathsf{U}} & \underset{\widetilde{u}_{\mathsf{U}*}}{\overset{\widetilde{u}^*_{\mathsf{U}}}{\rightleftarrows}} & C'^\sim_{\mathsf{U}} \\ \downarrow & & \downarrow \\ C^\sim_{\mathsf{V}} & \underset{\widetilde{u}_{\mathsf{V}*}}{\overset{\widetilde{u}^*_{\mathsf{V}}}{\rightleftarrows}} & C'^\sim_{\mathsf{V}} \end{array} \qquad \text{(resp.} \qquad \begin{array}{ccc} C^\sim_{\mathsf{U}} & \underset{\breve{u}^*_{\mathsf{U}}}{\overset{\breve{u}_{\mathsf{U}*}}{\rightleftarrows}} & C'^\sim_{\mathsf{U}} \\ \downarrow & & \downarrow \\ C^\sim_{\mathsf{V}} & \underset{\breve{u}^*_{\mathsf{V}}}{\overset{\breve{u}_{\mathsf{V}*}}{\rightleftarrows}} & C'^\sim_{\mathsf{V}} \end{array} \text{)}$$

whose vertical arrows are the inclusion functors. More generally, the diagram for $\breve{u}_{\mathsf{U}*}$ is well defined and essentially commutative, whenever C is a U-site, and $\mathscr{C}'$ has small Hom-sets.

Lemma 4.2.14. (i) *Let $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two sites, and $v : \mathscr{C} \to \mathscr{C}'$, $u : \mathscr{C}' \to \mathscr{C}$ two functors, such that v is left adjoint to u. The following conditions are equivalent:*

(a) *u is continuous.*
(b) *v is cocontinuous.*

(ii) *Moreover, when these conditions hold, then for every universe V such that $\mathscr{C}$ and $\mathscr{C}'$ are V-small, we have natural isomorphisms of functors :*

$$\widetilde{u}_{\mathsf{V}*} \stackrel{\sim}{\to} \breve{v}_{\mathsf{V}*} \qquad \widetilde{u}^*_{\mathsf{V}} \stackrel{\sim}{\to} \breve{v}^*_{\mathsf{V}}.$$

Proof. In view of lemma 4.2.3, we may replace U by a larger universe, after which we may assume that C and C' are small sites. In this case, the lemma follows from lemma 4.2.9 and proposition 1.3.25(i). □

Lemma 4.2.15. *Let $(\mathscr{C}, J)$ be a small site, $(\mathscr{C}', J')$ a U-site, $u : \mathscr{C} \to \mathscr{C}'$ a continuous and cocontinuous functor. Then we have :*

(i) *$\widetilde{u}_* = \breve{u}^*$ and this functor admits the left adjoint $\widetilde{u}^*$ and the right adjoint $\breve{u}_*$.*
(ii) *We have a natural isomorphism of functors*

$$(-)^a \circ u^\wedge \stackrel{\sim}{\to} \widetilde{u}_* \circ (-)^a \ : \ \mathscr{C}'^\wedge \to C^\sim.$$

(iii) *$\widetilde{u}^*$ is fully faithful if and only if the same holds for $\breve{u}_*$.*
(iv) *If u is fully faithful, then the same holds for $\widetilde{u}^*$. The converse holds, provided the topologies J and J' are coarser than the canonical topologies.*

Proof. (i) is clear by inspecting the definitions.

(ii): For every presheaf G on $\mathscr{C}'$, let $i_G : G \to G^a$ be the natural morphism; due to lemma 4.2.9 the induced morphism $u^\wedge(i_G) : u^\wedge G \to u^\wedge(G^a)$ is bicovering, and notice that $u^\wedge(G^a)$ is a sheaf, since u is continuous. Thus, $u^\wedge(i_G)$ factors through the natural morphism $i_{u^\wedge G} : u^\wedge G \to (u^\wedge G)^a$ and a unique morphism in $C^\sim$

$$\omega_G : (u^\wedge G)^a \to u^\wedge(G^a).$$

Since $i_{u^\wedge G}$ is bicovering, the same holds for ω_G, *i.e.* the latter is an isomorphism of on $C^\sim$. It is then easily seen that the rule $G \mapsto \omega_G$ yields the sought isomorphism.

Assertion (iii) follows from (i) and proposition 1.1.20(iv). Next, suppose that u is fully faithful; then the same holds for $\breve{u}_*$ (corollary 1.5.19(ii)), so the claim follows from (iii). Lastly, suppose that $\widetilde{u}^*$ is fully faithful, and both J and J' are coarser than the canonical topologies on $\mathscr{C}$ and $\mathscr{C}'$. In such case, the Yoneda embedding for $\mathscr{C}$ (resp. $\mathscr{C}'$) realizes $\mathscr{C}$ (resp. $\mathscr{C}'$) as a full subcategory of $C^\sim$ (resp. of $C'^\sim$). Then, from (1.3.7) and the explicit expression of $\widetilde{u}^*$ provided by lemma 4.2.11(i), we deduce that u is fully faithful. □

Definition 4.2.16. Let $C := (\mathscr{C}, J)$ be a site, $\mathscr{B}$ any category, and $g : \mathscr{B} \to \mathscr{C}$ a functor. Pick a universe V such that $\mathscr{B}$ is V-small and C is a V-site. According to remark 4.1.8(iv), there is a finest topology J_g on $\mathscr{B}$ such that, for every V-sheaf F on C, the V-presheaf $g^\wedge F$ is a V-sheaf on $(\mathscr{B}, J_g)$. By lemma 4.2.3, the topology J_g is independent of the chosen universe V. We call J_g the *topology induced via g by J on $\mathscr{B}$*. Clearly g is continuous for the sites $(\mathscr{B}, J_g)$ and C.

Lemma 4.2.17. *In the situation of definition* 4.2.16*, let X be any object of $\mathscr{B}$, and $R \subset h_X$ any subobject in $\mathscr{B}^\wedge$. We have :*

(i) *$R \in J_g(X)$ if and only if for every morphism $Y \to X$ in $\mathscr{B}$, the induced morphism $g_{\mathsf{V}!}(R \times_X Y) \to h_{g(Y)}$ is a bicovering morphism in $\mathscr{C}^\wedge_\mathsf{V}$ (for the topology J on $\mathscr{C}$).*

(ii) *Suppose moreover, that either one of the following condition holds:*
 (a) *The functor $g^a_{\mathsf{V}!} : \mathscr{B}^\wedge_\mathsf{V} \to C^\sim_\mathsf{V}$ commutes with all fibre products.*
 (b) *All fibre products are representable in $\mathscr{B}$, and g commutes with fibre products.*

Then a family $(f_i : B_i \to B \mid i \in I)$ of morphisms of $\mathscr{B}$ generates a covering sieve of J_g if and only if $(g(f_i) : gB_i \to gB \mid i \in I)$ generates a covering sieve of J.

Proof. (i): According to remark 4.1.8(iii), we have $R \in J_g(X)$ if and only if for every morphism $Y \to X$ in $\mathscr{C}$ the natural morphism $\varphi_Y : R \times_X Y \to h_Y$ induces a bijection

$$(g^\wedge_\mathsf{V} G)(Y) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{B}^\wedge}(R \times_X Y, g^\wedge_\mathsf{V} G) \qquad \text{for every } G \in \mathrm{Ob}(C^\sim_\mathsf{V}).$$

By adjunction, this is equivalent to saying that φ_Y induces a bijection

$$G(gY) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{C}^\wedge}(g_{\mathsf{V}!}(R \times_X Y), G) \qquad \text{for every } G \in \mathrm{Ob}(C^\sim_\mathsf{V}).$$

The latter is in turn naturally identified with the map

$$\mathrm{Hom}_{C^\sim_\mathsf{V}}(g_{\mathsf{V}!}(\varphi_Y)^a, G) : \mathrm{Hom}_{C^\sim_\mathsf{V}}(h^a_{gY}, G) \to \mathrm{Hom}_{C^\sim_\mathsf{V}}(g_{\mathsf{V}!}(R \times_X Y)^a, G).$$

By Yoneda's lemma, it follows that $R \in J_g(R)$ if and only if $g_{\mathsf{V}!}(\varphi_Y)^a$ is an isomorphism, and this is equivalent to the stated condition, by corollary 4.1.30.

(ii): Suppose first that condition (a) holds. Notice that since $\mathscr{B}$ is V-small, we may assume that the indexing set I is V-small as well. Let $R \subset h_B$ (resp. $R' \subset h_{gB}$) be the subobject generated by the family $(f_i \mid i \in I)$ (resp. $(g(f_i) \mid i \in I)$); if R is a covering subobject of h_B for J_g, then R' is a covering subobject of h_{gB} for J, by lemma 4.2.4. Conversely, suppose that R' is a covering subobject of h_{gB} for J; according to (i) and corollary 4.1.30, we need to check that the inclusion $j : R \to h_B$ induces an isomorphism $g^a_{\mathsf{V}!}(R \times_B B') \to h^a_{gB'}$ for every morphism $B' \to B$ in $\mathscr{B}$. Since $g^a_{\mathsf{V}!}$ commutes with fibre products, we are then easily reduced to checking that j induces an isomorphism $g^a_{\mathsf{V}!}(j) : g^a_{\mathsf{V}!}R \to h^a_B$. However, $g^a_{\mathsf{V}!}(j)$ is a monomorphism, since $g^a_{\mathsf{V}!}$ commutes with fibre products (proposition 1.3.18(i)). To show that $g^a_{\mathsf{V}!}(j)$ is an epimorphism, let $S := \coprod_{i \in I} h_{B_i}$ (which is an object of $\mathscr{B}^\wedge_\mathsf{V}$, since I is V-small) and denote by $j' : S \to h_B$ the morphism induced by the morphisms f_i. The image of $g^a_{\mathsf{V}!}(j)$ contains the image of $g^a_{\mathsf{V}!}(j')$; on the other hand, $g^a_{\mathsf{V}!}$ commutes with coproducts, since it is a left adjoint, and we have natural identifications : $g^a_{\mathsf{V}!}(h_{B_i}) = h^a_{gB_i}$ for every $i \in I$. Thus, the image of $g^a_{\mathsf{V}!}(j')$ equals that of the morphism $\varphi : \coprod_{i \in I} h^a_{gB_i} \to h^a_B$ induced by the morphisms $g(f_i)$. But since R' is a covering subobject, φ is an epimorphism, so the same holds for $g^a_{\mathsf{V}!}(j)$.

Next, suppose that condition (b) holds, and let $f_\bullet := (f_i : B_i \to B \mid i \in I)$ be a family of morphisms of $\mathscr{B}$ such that $(g(f_i) \mid i \in I)$ covers gB in the topology J. Set $B_{ij} := B_i \times_B B_j$ for every $i, j \in I$; the subobject $R \subset h_B$ generated by $f_\bullet$ is the coequalizer in $\mathscr{B}^\wedge$ of the natural projections

$$\textstyle\coprod_{i,j\in I} h_{B_{ij}} \rightrightarrows \coprod_{i\in I} h_{B_i}$$

and according to (i) we need to check that for every morphism $B' \to B$ the induced morphism $g_{\mathsf{V}!}(R \times_B B') \to h_{gB'}$ is a bicovering morphism. However, set as well $B'_i := B_i \times_B B'$ and $B'_{ij} := B_{ij} \times_B B'$ for every $i, j \in I$; then $R \times_B B'$ is the coequalizer of the induced projections

$$\textstyle\coprod_{i,j\in I} h_{B'_{ij}} \rightrightarrows \coprod_{i\in I} h_{B'_i}.$$

On the other hand, $g_{\mathsf{V}!}$ commutes with coequalizers and coproducts, since it is a left adjoint; in view of remark 1.3.6(ii) we deduce that $g_{\mathsf{V}!}(R \times_B B')$ is the coequalizer of the projections

$$\textstyle\coprod_{i,j\in I} h_{gB'_{ij}} \rightrightarrows \coprod_{i\in I} h_{gB'_i}.$$

But by assumption we have as well $gB'_i = gB_i \times_{gB} gB'$, whence $h_{gB_i} = h_{gB'_i} \times_{h_{gB}} h_{B'}$, and likewise for $h_{gB'_{ij}}$, for every $i, j \in I$ (corollary 1.4.3(vi)). We conclude that $g_{\mathsf{V}!}(R \times_B B')$ is the subobject of $h_{B'}$ generated by the family $(g(f_i) \times_{gB} gB' \to gB' \mid i \in I)$, and it is therefore a covering subobject, as required. □

Remark 4.2.18. (i) In the situation of lemma 4.2.17, let V' be another universe with $\mathsf{V} \subset \mathsf{V}'$, and F a V'-presheaf on $\mathscr{B}$. According to lemma 1.4.8, F is naturally isomorphic to the colimit of the functor $h_{\mathscr{B}} \circ \mathsf{s}_F : \mathscr{F}ib(F) \to \mathscr{B}^\wedge_{\mathsf{V}} \subset \mathscr{B}^\wedge_{\mathsf{V}'}$, where $\mathsf{s}_F : \mathscr{F}ib(F) \to \mathscr{B}$ is the source functor. For every finite subset $S \subset \mathrm{Ob}(\mathscr{F}ib(F))$, let $F_S \subset F$ be the subobject generated by the union of the images of all the morphisms $h_{(X,s)} : h_B \to F$ with $(B, s) \in S$ (notation of (1.4.7)), and notice that F_S is isomorphic to an object of $\mathscr{B}^\wedge_{\mathsf{V}}$. After replacing each F_S by an isomorphic object of $\mathscr{B}^\wedge_{\mathsf{V}}$, we obtain therefore F as the filtered colimit of a system $(F_S \mid S \in \Sigma_F)$ of objects of $\mathscr{B}^\wedge_{\mathsf{V}}$, indexed by the set Σ_F of all finite subsets of $\mathrm{Ob}(\mathscr{F}ib(F))$.

(ii) Now, let $F_1 \xrightarrow{\varphi_1} F_0 \xleftarrow{\varphi_2} F_2$ be two morphisms in $\mathscr{B}^\wedge_{\mathsf{V}}$. Consider the set $\Sigma(\varphi_1, \varphi_2)$ of all triples (S_0, S_1, S_2) where S_i is a finite subset of $\mathrm{Ob}(\mathscr{F}ib(F_i))$ for $i = 0, 1, 2$, and $(B, \varphi_j \circ s) \in S_0$ for $j = 1, 2$ and every $(B, s) \in S_j$. We endow $\Sigma(\varphi_1, \varphi_2)$ with the partial order such that $(S_0, S_1, S_2) \geq (S'_0, S'_1, S'_2)$ if and only if $S'_i \subset S_i$ for $i = 0, 1, 2$. We have a natural functor

$$\tau : \Sigma(\varphi_1, \varphi_2) \to \mathscr{B}^\wedge_{\mathsf{V}} \qquad (S_0, S_1, S_2) \mapsto F_{S_1} \times_{F_{S_0}} F_{S_2}$$

and by a simple inspection we see that the colimit of τ is naturally isomorphic to $F_1 \times_{F_0} F_2$.

(iii) We deduce that $G := g^a_{\mathsf{V}'!}(F_1 \times_{F_0} F_2)$ is naturally isomorphic to the colimit of $g^a_{\mathsf{V}'!} \circ \tau$, since $g^a_{\mathsf{V}'!}$ is a left adjoint; but $g^a_{\mathsf{V}'!} \circ \tau$ is in turn naturally isomorphic to the functor $g^a_{\mathsf{V}!} \circ \tau$, by lemma 4.2.11(ii). Suppose now that $g^a_{\mathsf{V}!}$ commutes with all fibre products of $\mathscr{B}^\wedge_{\mathsf{V}}$. Then G is also naturally isomorphic to the filtered colimit of the system

$$(g^a_{\mathsf{V}!} F_{1,S_1} \times_{g^a_{\mathsf{V}!} F_{0,S_0}} g^a_{\mathsf{V}!} F_{2,S_2} \mid (S_0, S_1, S_2) \in \Sigma(\varphi_1, \varphi_2)).$$

But since filtered colimits in $\mathscr{B}^\wedge_{\mathsf{V}'}$ commute with fibre products, the latter is naturally isomorphic to the fibre product $G_1 \times_{G_0} G_2$, where G_i is the filtered colimit of the system $(g^a_{\mathsf{V}'!} F_{S_i} \mid S_i \in \Sigma_{F_i})$ (notice that the projections $\Sigma(\varphi_1, \varphi_2) \to \Sigma_{F_i} : (S_0, S_1, S_2) \to S_i$ are obviously coinitial functors). But again, since $g^a_{\mathsf{V}'!}$ commutes with filtered colimits, G_i is naturally isomorphic to $g^a_{\mathsf{V}'!}(F_i)$. We conclude that $g^a_{\mathsf{V}'!}$ commutes with fibre products as well. In particular, condition (ii.a) of lemma 4.2.17 is independent of the choice of universe V.

4.3. **Morphisms of sites.** We observed in example 4.2.2 that every continuous map of topological spaces $f : T \to T'$ induces a continuous functor $u := f^{-1} : \mathscr{T}' \to \mathscr{T}$ between the corresponding categories of open subsets. It is well known that the induced functor on categories of sheaves $\widetilde{u}^* : \mathscr{T}^\sim \to \mathscr{T}'^\sim$ is moreover *exact*, whereas for a general continuous functor g between arbitrary sites, only the right exactness of $\widetilde{g}^*$ is always assured. The exactness of $\widetilde{g}^*$ therefore singles out an interesting class of continuous functors, which will play an important role in our discussion of topoi, and – even more crucially – for the study of the functorial properties of the categories of stacks, in section 5.4. In this section we carry out a preliminary investigation of this class of functors, and prove a useful characterization. Let us begin with :

Definition 4.3.1. (i) Let $C = (\mathscr{C}, J)$ and $C' = (\mathscr{C}', J')$ be two sites, and V a universe such that C and C' are V-small. A *morphism of sites* $C' \to C$ is the datum of a continuous functor $g : \mathscr{C} \to \mathscr{C}'$, such that the left adjoint $\widetilde{g}^*_{\mathsf{V}}$ of $\widetilde{g}_{\mathsf{V}*}$ is exact (notation of definition 4.2.1(i)).

(ii) Let U' be a universe with $\mathsf{U} \in \mathsf{U}'$; the U'-small U-sites are the objects of a 2-category

$$(\mathsf{U}, \mathsf{U}')\text{-}\mathbf{Site}$$

whose 1-cells are the morphisms of sites, and whose 2-cells $\beta : g \Rightarrow g'$ are the natural transformations $g' \Rightarrow g$ between the underlying functors of such morphisms, with the obvious composition laws for 1-cells and 2-cells.

(iii) We shall also be interested in the 2-category of U-*lex-sites*

$$(\mathsf{U}, \mathsf{U}')\text{-lex.}\mathbf{Site}$$

defined as the 2-subcategory of $(\mathsf{U}, \mathsf{U}')$-$\mathbf{Site}$ whose objects are the finitely complete U'-small U-sites and whose 1-cells are the morphisms of sites g as in (i) such that the underlying functor $g : \mathscr{C} \to \mathscr{C}'$ is left exact. For any two such morphisms g, g', the 2-cells $g \Rightarrow g'$ are the same as in $(\mathsf{U}, \mathsf{U}')$-$\mathbf{Site}$.

Remark 4.3.2. (i) With the notation of definition 4.3.1(ii), two different choices of the auxiliary universe U' *do not* necessarily yield 2-equivalent 2-categories; nevertheless, such choices are usually ininfluent in the proofs of our results, so we mostly omit mentioning them explicitly, and write U-$\mathbf{Site}$ and U-lex.$\mathbf{Site}$ for these 2-categories. When the choice of U is clear from the context, we shall likewise drop the mention of U, and write just $\mathbf{Site}$ and lex.$\mathbf{Site}$.

(ii) On the other hand, the following proposition 4.3.9 will show that the definition of morphism of sites $g : (\mathscr{C}', J') \to (\mathscr{C}, J)$ depends only on the underlying functor $g : \mathscr{C} \to \mathscr{C}'$, and not on the choice of a universe V such that C and C' are V-small.

(iii) Let $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two sites, $u : C' \to C$ a morphism of sites, and S a set. The *constant presheaf on* $\mathscr{C}$ *with value* S is the constant functor $c_S : \mathscr{C}^o \to \mathbf{Set}$ associated with S (see (1.2.9)), and the *constant sheaf on* C *with value* S is the associated sheaf c_S^a. Clearly we have $c_S = \amalg_{s \in S} c_{\{s\}}$, and each presheaf $c_{\{s\}}$ is a final object of the category $\mathscr{C}^\wedge$. It follows that $c_S^a = \amalg_{s \in S} c_{\{s\}}^a$, and $c_{\{s\}}^a$ is a final object of $C^\sim$ (example 1.2.16(iv)). Since $\widetilde{u}^*$ commutes with all colimits and is left exact by assumption, we deduce that $\widetilde{u}^*(c_S^a)$ is naturally isomorphic to the constant sheaf with value S on C'. This assertion may fail for general continuous functors.

For our characterization of morphisms of sites, we shall need the following :

Definition 4.3.3. Let $(\mathscr{B}, J)$ be a site, $F : \mathscr{C} \to \mathscr{B}$ a fibration, and fix a cleavage $\boldsymbol{\lambda}$ for F, so that for every $X \in \mathrm{Ob}(\mathscr{C})$ and every morphism $f : B \to FX$ we have the cartesian morphism $\boldsymbol{\lambda}(X, f) : f^*X \to X$. We say that F is *locally cofiltered* (relative to the topology J) if the following holds for every $B \in \mathrm{Ob}(\mathscr{B})$ and every $X, X' \in \mathrm{Ob}(\mathscr{C}_B)$:

(a) There exists a covering family $(B_i \to B \mid i \in I)$ in the topology J with $\mathrm{Ob}(\mathscr{C}_{B_i}) \neq \varnothing$ for every $i \in I$.

(b) There exist a covering family $(f_i : B_i \to B \mid i \in I)$ in the topology J, and for every $i \in I$ an object $Y_i \in \mathrm{Ob}(\mathscr{C}_{B_i})$ with two morphisms $f_i^* X \leftarrow Y_i \to f_i^* X'$ in $\mathscr{C}_{B_i}$.
(c) For every pair of morphisms $g, g' : X' \to X$ in $\mathscr{C}_B$ there exist a covering family $(f_i : B_i \to B \mid i \in I)$ in the topology J, and for every $i \in I$ a morphism $h_i : Y_i \to f_i^* X'$ in $\mathscr{C}_{B_i}$ such that $f_i^*(g) \circ h_i = f_i^*(g') \circ h_i$.

4.3.4. In the situation of definition 4.3.3, suppose that $(\mathscr{B}, J)$ and $\mathscr{C}$ are small; we consider the functor

$$\int_a^{\boldsymbol{\lambda}} : \mathscr{C}^\wedge \to (\mathscr{B}, J)^\sim \qquad G \mapsto \Big(\int^{\boldsymbol{\lambda}} G\Big)^a$$

where $\int^{\boldsymbol{\lambda}} : \mathscr{C}^\wedge \to \mathscr{B}^\wedge$ is defined as in example 3.1.14(iv). Recall that the sections of $\int^{\boldsymbol{\lambda}} G(B)$ are the equivalence classes $[X, t]$ of pairs (X, t) consisting of an object X of $F^{-1}B$ and a section $t \in GX$, for the equivalence relations on the set of such pairs explicited in example 1.2.23(i).

Lemma 4.3.5. *With the notation of* (4.3.4)*, let L be any presheaf on $\mathscr{C}$, and $M := \int^{\boldsymbol{\lambda}} L$. Let also $B \in \mathrm{Ob}(\mathscr{B})$ and $(X, t), (X', t')$ two pairs consisting of objects $X, X' \in F^{-1}B$ and sections $t \in LX$, $t' \in LX'$. If $[X, t] = [X', t']$ in $M(B)$, there exist a covering family $(f_j : B_j \to B \mid j \in I)$ for the topology J, and for each $j \in I$ morphisms $g_j : X_i \to X$, $g'_j : X_i \to X'$ in $\mathscr{C}$ such that $Fg_j = Fg'_j = f_j$ and $(Lg_j)(t) = (Lg'_j)(t')$.*

Proof. As in the proof of proposition 1.5.21(ii) we shall say that a diagram of $F^{-1}B$ is a pair of finite sets (A, A') with $A \subset \mathrm{Ob}(F^{-1}B)$, $A' \subset \mathrm{Morph}(F^{-1}B)$, such that the source and target of every element of A' lie in A. We notice :

Claim 4.3.6. Let (A, A') be any diagram of $F^{-1}B$. There exist a covering family $(f_j : B_j \to B \mid j \in I)$ and for every $j \in I$ an object Y_j of $F^{-1}B_j$ with a system of morphisms $(g_{jX} : Y_j \to X \mid X \in A)$ such that the following holds. For every $j \in I$, every $X, X', X'' \in A$ and every $h : X \to X''$, $h' : X' \to X''$ in A' we have $h \circ g_{jX} = h' \circ g_{jX'}$.

Proof of the claim. Let $X_1, \dots, X_n$ be the elements of A. Since F is locally cofiltered, by a simple induction on n we find a covering family $f'_\bullet := (f'_{j'} : B_{j'} \to B \mid j' \in I')$ and morphisms $g'_{j'i} : Y'_{j'} \to X_i$ such that $Fg'_{j'i} = f'_{j'}$ for every $j' \in I'$ and $i = 1, \dots, n$. Next, let $T \subset A' \times A'$ be the subset of all pairs (h, h') such that h and h' have the same target; we show that for every $T' \subset T$, and every $j' \in I'$ there exist a covering family $f''_{\bullet\bullet} := (f''_{j'\lambda} : B_{j'\lambda} \to B_{j'} \mid \lambda \in \Lambda_{j'})$ and morphisms $g''_{j'\lambda} : Y_{j'\lambda} \to Y'_{j'}$ with $Fg''_{j'\lambda} = f''_{j'\lambda}$ and

$$h \circ g'_{j'i} \circ g''_{j'\lambda} = h' \circ g'_{j'i'} \circ g''_{j'\lambda}$$

for every $\lambda \in \Lambda_{j'}$, every $i, i', k = 1, \dots, n$ and every $(h : X_i \to X_k, h' : X_{i'} \to X_k)$ in T'. The claim will follow for $T' = T$, by letting $f_\bullet$ be the covering family $(f'_j \circ f''_{j'\lambda} : B_{j'\lambda} \to B \mid j' \in I, \ \lambda \in \Lambda_{j'})$, and letting $g_{\bullet\bullet}$ be the system of morphisms $g'_{j'i} \circ g''_{j'\lambda}$.

Now, if $T' = \varnothing$, there is nothing to show. Thus, let $(h_0, h_1) \in T'$; by induction on the cardinality of T', we may assume that the assertion is known for the subset $T'' := T' \setminus \{(h_0, h_1)\}$. After replacing $f'_\bullet$ by the covering family $(f'_j \circ f''_{j'\lambda} \mid j' \in I, \ \lambda \in \Lambda_{j'})$ and the system $g'_{\bullet\bullet}$ with the system of morphisms $g'_{j'i} \circ g''_{j'\lambda}$, we may then assume that $h \circ g'_{j'i} = h' \circ g'_{j'i'}$ for every $i, i' = 1, \dots, n$, every $j \in I'$ and every $(h, h') \in T''$ such that the sources of h and h' are i and i' respectively. We may assume that the common target of h_0 and h_1 is X_1, and say that their sources are X_{i_0} and X_{i_1} respectively. Since F is locally cofiltered, there exist a covering family $f''_{\bullet\bullet}$ and a system of morphisms $g''_{\bullet\bullet}$ as in the foregoing, such that $h_0 \circ g'_{j'i_0} \circ g''_{j'\lambda} = h_1 \circ g'_{j'i_1} \circ g''_{j'\lambda}$ for every $j' \in I$ and every $\lambda \in \Lambda_{j'}$. Clearly with these choices for $f''_{\bullet\bullet}$ and $g''_{\bullet\bullet}$ the sought identities hold whenever $(h, h') \in T'$, as required. ◊

Now, the condition $[X, t] = [X', t']$ means that for some $k \in \mathbb{N}$ there exist objects of $F^{-1}B$

$$X_0, Y_0, X_1, Y_1, \dots, Y_k, X_{k+1}$$

and sections $t_i \in LX_i$ for $i = 0, \dots, k+1$, with $X_0 = X$, $X_{k+1} = X'$, $t_0 = t$ and $t_{k+1} = t'$, as well as morphisms

$$X_i \xleftarrow{q_i} Y_i \xrightarrow{q'_i} X_{i+1} \qquad \text{such that } (Lq_i)(t_i) = (Lq'_i)(t_{i+1}) \text{ for } i = 0, \dots, k.$$

We apply claim 4.3.6 to the diagram formed by all the objects X_i, Y_i and all the morphisms q_i, q'_i, to find a covering family $(f_j : B_j \to B \mid j \in I)$ and morphisms $h_j : Z_j \to Y_i$ with $Fh_j = f_j$, such that $g_{ij} := q_i \circ h_j = q'_i \circ h_j$ for every $j \in I$ and $i = 0, \dots, k$. It follows that $(Lg_{0j})(t_0) = (Lg_{1j})(t_1) = \cdots = (Lg_{k+1,j})(t_{k+1})$ for every $j \in I$. Then the assertion holds with $g_j := g_{0j}$ and $g'_j := g_{k+1,j}$ for every $j \in I$. □

Proposition 4.3.7. *With the notation of* (4.3.4)*, we have :*

(i) *The functor* $\int^{\boldsymbol{\lambda}}$ *commutes with all colimits.*

(ii) *If* F *is a locally cofiltered fibration,* $\int_a^{\boldsymbol{\lambda}}$ *is exact.*

Proof. (i): Since the colimits in $\mathscr{B}^\wedge$ are computed argumentwise (corollary 1.4.3(ii)), we are reduced to checking that for every $B \in \mathrm{Ob}(\mathscr{B})$ the functor

$$\mathscr{C}^\wedge \to \mathbf{Set} \qquad G \mapsto \operatorname*{colim}_{(F^{-1}B)^o} G \circ \iota_B^o$$

commutes with colimits. However, the functor $\iota_B^\wedge : \mathscr{C}^\wedge \to (F^{-1}B)^\wedge$ induced by the inclusion functor $\iota_B : F^{-1}B \to \mathscr{C}$ commutes with colimits (again, by corollary 1.4.3(ii)), so we come down to checking that the functor $\mathrm{Colim}_{(F^{-1}B)^o} : (F^{-1}B)^\wedge \to \mathbf{Set}$ of remark 1.3.3(ii) commutes with colimits, which is clear, as the latter is a left adjoint.

(ii): In light of (i), and since the functor $G \mapsto G^a$ commutes with colimits, it suffices to check that $\int_a^{\boldsymbol{\lambda}}$ is left exact, and by proposition 1.3.22(i) we are reduced to showing that $\int_a^{\boldsymbol{\lambda}}$ commutes with equalizers and finite non-empty products, and that it preserves final objects.

Thus, let E be the presheaf on $\mathscr{C}$ such that $E(X) = \{\varnothing\}$ for every $X \in \mathrm{Ob}(\mathscr{C})$, and set $E' := \int^{\boldsymbol{\lambda}} E$. For every $B \in \mathrm{Ob}(\mathscr{B})$ and every $s \in E'^a(B)$ there is a covering family $B_\bullet := (B_i \to B \mid i \in I)$ in the topology J, and for every $i \in I$ an object X_i of $F^{-1}B_i$ such that s is represented by the system of section $([X_i, \varnothing]) \in E'(B_i)$. Conversely, every such system defines a section of $E'^a(B)$. Now, since F is locally cofiltered there exists such a covering family $B_\bullet$ of B with the property that $\mathrm{Ob}(F^{-1}B_i)$ is not empty for every $i \in I$; by picking arbitrary $X_i \in \mathrm{Ob}(F^{-1}B_i)$ for each i we obtain therefore a section of $E'^a(B)$; this shows that $E'^a(B) \neq \varnothing$ for every $B \in \mathrm{Ob}(\mathscr{B})$. Next, let $s := ([X_i, \varnothing] \mid i \in I)$ and $s' := ([X'_i, \varnothing] \mid i \in I)$ be two sections of $E'^a(B)$, with $FX_i = FX'_i = B_i$ for every $i \in I$. Since F is locally cofiltered, we may find for every $i \in I$ a covering family $(f_{i\lambda} : B_{i\lambda} \to B_i \mid \lambda \in \Lambda_i)$ and morphisms $g_{i\lambda} : Y_{i\lambda} \to X_i$, $g'_{i\lambda} : Y_{i\lambda} \to X'_i$ in $\mathscr{C}$ with $Fg_{i\lambda} = Fg'_{i\lambda} = f_{i\lambda}$ for every $\lambda \in \Lambda_i$. Then both s and s' are represented by the system $([Y_{i\lambda}, \varnothing] \mid i \in I,\ \lambda \in \Lambda_i)$. This proves that $E'^a(B)$ contains a unique section for every $B \in \mathrm{Ob}(\mathscr{B})$, *i.e.* E'^a is the final object of $(\mathscr{B}, J)^\sim$, as required.

To check that $\int_a^{\boldsymbol{\lambda}}$ commutes with finite products, let G_1, G_2 be two presheaves on $\mathscr{C}$, and set

$$G := G_1 \times G_2 \qquad H := \int^{\boldsymbol{\lambda}} G \qquad H_i := \int^{\boldsymbol{\lambda}} G_i \qquad \text{for } i = 1, 2.$$

We need to check that the projections $G \to G_i$ induce an isomorphism $\omega : H^a \xrightarrow{\sim} H_1^a \times H_2^a$. To this aim, let as well $B \in \mathrm{Ob}(\mathscr{B})$ and $s \in (H_1^a \times H_2^a)(B)$. Hence s is represented by the datum of a covering family $(f_j : B_j \to B \mid j \in I)$ and sections $s_{ij} \in H_i(B_j)$ for $i = 1, 2$ and every $j \in I$, fulfilling the following compatibility condition. For every $B' \in \mathrm{Ob}(\mathscr{B})$, every $j, j' \in I$ and every pair of morphisms $g : B' \to B_j$, $g' : B' \to B_{j'}$ such that $f_j \circ g_j = f_{j'} \circ g'$, we have $H_i(g)(s_{ij}) = H_i(g')(s_{ij'})$ for $i = 1, 2$. By example 1.2.23(i), each s_{ij} is the class $[X_{ij}, t_{ij}]$ of a pair consisting of an object X_{ij} of $F^{-1}B_j$ and a section $t_{ij} \in G_iX_{ij}$. Since F is locally cofiltered, we may then find for every $j \in I$ a covering family $(f_{j\lambda} : B_{j\lambda} \to B_j \mid \lambda \in \Lambda_j)$ and for every $j \in I$ and every $\lambda \in \Lambda_j$ an object $Y_{j\lambda}$ of $F^{-1}B_{j\lambda}$ and morphisms $g_{ij\lambda} : Y_{j\lambda} \to X_{ij}$ in $\mathscr{C}$ with $Fg_{ij\lambda} = f_{j\lambda}$ for $i = 1, 2$. With this notation, set $t_{ij\lambda} := (G_i g_{ij\lambda})(t_{ij})$; we have

$$[Y_{j\lambda}, t_{ij\lambda}] = H_i(f_{j\lambda})(s_{ij}) \qquad \text{for } i = 1, 2, \text{ every } j \in I \text{ and every } \lambda \in \Lambda_j.$$

Thus, the class $\tau_{j\lambda} := [Y_{j\lambda}, (t_{1j\lambda}, t_{2j\lambda})]$ is a section of $H(Y_{j\lambda})$ for every $j \in I$ and $\lambda \in \Lambda_j$. Lastly, the family $(f_j \circ f_{j\lambda} : B_{j\lambda} \to B \mid j \in I,\ \lambda \in \Lambda_j)$ covers B, and the system of sections $\tau_{\bullet\bullet}$ defines a section of $H^a(B)$ whose image under ω_B agrees with s. This shows that ω is an epimorphism. In order to check that ω is a monomorphism, consider $t, t' \in H^a(B)$ whose images agree in $(H_1^a \times H_2^a)(B)$; we may find a covering family $f_\bullet := (f_j : B_j \to B \mid j \in I)$ such that t and t' can be represented by compatible systems of sections $t_\bullet := ([X_j, (t_{1j}, t_{2j})] \mid j \in I)$, $t'_\bullet := ([X'_j, (t'_{1j}, t'_{2j})] \mid j \in I)$ with $X_j, X'_j \in F^{-1}B_j$ and $t_{ij}, t'_{ij} \in G_i X_j$ for $i = 1, 2$ and every $j \in I$. By assumption, the resulting systems $([X_j, t_{ij}] \mid j \in I)$ and $([X'_j, t'_{ij}] \mid j \in I)$ represent the same sections of $H_i^a(B)$ for $i = 1, 2$. This means that there exists for every $j \in I$ a covering family $(f_{j\lambda} : B_{j\lambda} \to B_j \mid \lambda \in \Lambda_j)$ such that if we set $t_{ij\lambda} := G_i(\boldsymbol{\lambda}(f_{j\lambda}, X_j))(t_{ij})$ and $t'_{ij\lambda} := G_i(\boldsymbol{\lambda}(f_{j\lambda}, X'_j))(t'_{ij})$, we have

$$[f^*_{j\lambda} X_j, t_{ij\lambda}] = [f^*_{j\lambda} X'_j, t'_{ij\lambda}] \qquad \text{in } H_i(B_{j\lambda}) \text{ for } i = 1, 2, \text{ every } j \in I \text{ and every } \lambda \in \Lambda_j.$$

After replacing $f_\bullet$ by the covering family $(f_j \circ f_{j\lambda} : B_{j\lambda} \to B \mid j \in I,\ \lambda \in \Lambda_j)$ and the systems $t_\bullet$, $t'_\bullet$ by $([f^*_{j\lambda} X_j, (t_{1j\lambda}, t_{2j\lambda})] \mid j \in I,\ \lambda \in \Lambda)$ and $([f^*_{j\lambda} X'_j, (t'_{1j\lambda}, t'_{2j\lambda})] \mid j \in I,\ \lambda \in \Lambda)$, we may therefore assume from start that

$$[X_j, t_{ij}] = [X'_j, t'_{ij}] \qquad \text{in } H_i(B_j) \text{ for } i = 1, 2 \text{ and every } j \in I.$$

By lemma 4.3.5, we may then find for $i = 1, 2$ and every $j \in I$ a covering family $(f_{ij\lambda} : B_{ij\lambda} \to B_j \mid \lambda \in \Lambda_{ij})$ and morphisms $g_{ij\lambda} : Y_{ij\lambda} \to X_j$, $g'_{ij\lambda} : Y_{ij\lambda} \to X'_j$ in $\mathscr{C}$ such that $Fg_{ij\lambda} = Fg'_{ij\lambda} = f_{ij\lambda}$ and $t_{ij\lambda} := (G_i g_{ij\lambda})(t_{ij}) = (G_i g'_{ij\lambda})(t'_{ij})$ for every $\lambda \in \Lambda_{ij}$.

For $i = 1, 2$ and every $j \in I$, let $\mathscr{S}_{ij} \subset \mathscr{B}/B_j$ be the sieve generated by the family $f_{ij\bullet}$, and pick a generating family $(f'_\sigma : B_\sigma \to B_j \mid \sigma \in \Sigma_j)$ for the sieve $\mathscr{S}_{1j} \cap \mathscr{S}_{2j}$, which covers B_j as well in the topology J. Set $\Sigma := \bigcup_{j \in I} \{j\} \times \Sigma_j$. By definition, this means that for $i = 1, 2$ and every $(j, \sigma) \in \Sigma$ there exist $\lambda \in \Lambda_{1j}$, $\lambda' \in \Lambda_{2j}$ and a commutative diagram in $\mathscr{B}$:

$$\begin{array}{ccc} B_\sigma & \xrightarrow{h_\sigma} & B_{1j\lambda} \\ {\scriptstyle h'_\sigma}\downarrow & \searrow^{f'_\sigma} & \downarrow{\scriptstyle f_{1j\lambda}} \\ B_{2j\lambda'} & \xrightarrow[f_{2j\lambda'}]{} & B_j. \end{array}$$

With this notation, we set $Z_{1j\sigma} := h^*_\sigma Y_{1j\lambda}$, $Z_{2j\sigma} := h'^*_\sigma Y_{2j\lambda'}$ and :

$$s_{1j\sigma} := G_1(\boldsymbol{\lambda}(h_\sigma, Y_{1j\lambda}))(t_{1j\lambda}) \quad s_{2j\sigma} := G_2(\boldsymbol{\lambda}(h'_\sigma, Y_{2j\lambda}))(t_{2j\lambda}) \qquad \text{for every } (j, \sigma) \in \Sigma.$$

Then, both compatible systems $([X_j, t_{1j}] \mid j \in I)$ and $([X'_j, t'_{1j}] \mid j \in I)$ agree with the compatible system $([Z_{1\sigma}, s_{1\sigma}] \mid \sigma \in \Sigma)$ in $H_1^a(B)$, and both compatible systems $([X_j, t_{2j}] \mid j \in I)$ and $([X'_j, t'_{2j}] \mid j \in I)$ agree with the compatible system $([Z_{2\sigma}, s_{2\sigma}] \mid \sigma \in \Sigma)$ in $H_2^a(B)$.

Since F is locally cofiltered, we may find for every $\sigma \in \Sigma$ a covering family $(f_{\sigma\lambda} : B_{\sigma\lambda} \to B_\sigma \mid \lambda \in \Lambda_\sigma)$ and morphisms $g_{i\sigma\lambda} : Z_{\sigma\lambda} \to Z_{i\sigma}$, with $Fg_{i\sigma\lambda} = f_{\sigma\lambda}$ for $i = 1, 2$. Set $s_{i\sigma\lambda} := (G_i g_{i\sigma\lambda})(s_{i\sigma})$ for $i = 1, 2$, every $\sigma \in \Sigma$ and every $\lambda \in \Lambda_\sigma$. Hence both t and t' are represented by the compatible system of sections $([Z_{\sigma\lambda}, (s_{1\sigma\lambda}, s_{2\sigma\lambda})] \mid \sigma \in \Sigma,\ \lambda \in \Lambda_\sigma)$, so $t = t'$.

Lastly, let $\varphi_1, \varphi_2 : G_1 \to G_2$ be two morphisms of presheaves on $\mathscr{C}$, and $E \subset G_1$ the equalizer of φ_1 and φ_2; set also $H_i := \int^{\boldsymbol{\lambda}} G_i$, $\psi_i := \int^{\boldsymbol{\lambda}} \varphi_i$ for $i = 1, 2$, and denote by E' the equalizer of $\psi_1^a, \psi_2^a : H_1^a \to H_a^2$. We need to check that the induced morphism $E^a \to E'$ is an isomorphism. Thus, let $B \in \mathrm{Ob}(\mathscr{B})$ and $s \in E'(B)$; by remark 4.1.19(i), the set $E'(B)$

is the equalizer of the induced maps $\psi_1^a(B), \psi_2^a(B) : H_1^a(B) \to H_2^a(B)$, so we may find a covering family $(f_j : B_j \to B \mid j \in I)$ such that s is represented by a compatible system $t_\bullet := ([X_j, t_j] \mid j \in I)$ with $X_j \in \mathrm{Ob}(F^{-1}B_j)$ and $t_j \in G_1(B_j)$ for every $j \in I$, such that the systems $([X_j, (\varphi_{1X_j})(t_j)] \mid j \in I)$ and $([X_j, (\varphi_{2X_j})(t_j)] \mid j \in I)$ represent the same section of $H_2^a(B)$. This means that for every $j \in I$ there exists a covering family $f_\bullet := (f_{j\lambda} : B_{j\lambda} \to B_j \mid \lambda \in \Lambda_j)$ such that if we set $t_{j\lambda} := G_1(\boldsymbol{\lambda}(f_{j\lambda}, X_j))(t_j)$ we get the following identity in $H_2(B_{j\lambda})$:

$$[f_{j\lambda}^* X_j, \varphi_{1X_j}(t_{j\lambda})] = [f_{j\lambda}^* X_j, \varphi_{2X_j}(t_{j\lambda})] \qquad \text{for } i = 1, 2, \text{ every } j \in I \text{ and every } \lambda \in \Lambda_j.$$

After replacing $f_\bullet$ by the covering family $(f_{j\lambda} \circ f_j : B_{j\lambda} \to B \mid j \in I, \ \lambda \in \Lambda_j)$ and $t_\bullet$ by the compatible system $([f_{j\lambda}^* X_j, t_{j\lambda}] \mid j \in I, \ \lambda \in \Lambda_j)$ we may then assume that

$$[X_j, (\varphi_{1X_j})(t_j)] = [X_j, (\varphi_{2X_j})(t_j)] \qquad \text{in } H_2(B_j) \text{ for every } j \in I.$$

By lemma 4.3.5 we may then find for every $j \in I$ a covering family $(f_{j\lambda} : B_{j\lambda} \to B_j \mid \lambda \in \Lambda_j)$ and morphisms $g_{j\lambda}, g'_{j\lambda} : Y_{j\lambda} \to X_j$ in $\mathscr{C}$ such that $Fg_{j\lambda} = Fg'_{j\lambda} = f_{j\lambda}$ and

$$G_2(g_{j\lambda})((\varphi_{1X_j})(t_j)) = G_2(g'_{j\lambda})((\varphi_{2X_j})(t_j)) \qquad \text{for every } \lambda \in \Lambda_j.$$

Set $\Sigma := \bigcup_{j\in I}\{j\} \times \Lambda_j$; since F is locally cofiltered, for every $\sigma \in \Sigma$ we may then find a covering family $(f'_{\sigma\lambda'} : B'_{\sigma\lambda'} \to B_\sigma \mid \lambda' \in \Lambda'_\sigma)$ and a morphism $h_{\sigma\lambda'} : Y_{\sigma\lambda'} \to Y_\sigma$ in $\mathscr{C}$ such that $Fh_{\sigma\lambda'} = f'_{\sigma\lambda'}$ and $g_{\sigma\lambda'} := g_\sigma \circ h_{\sigma\lambda'} = g'_\sigma \circ h_{\sigma\lambda'}$ for every $\lambda' \in \Lambda'_\sigma$. Set $t_{j\lambda\lambda'} := G_1(g_{j\lambda\lambda'})(t_j)$ for every $(j, \lambda) \in \Sigma$ and every $\lambda' \in \Lambda'_{(j,\lambda)}$. The compatible system $([Y_{\sigma\lambda'}, t_{\sigma\lambda'}] \mid \sigma \in \Sigma, \ \lambda' \in \Lambda'_\sigma)$ represents again the section s, and by construction we have $\varphi_{1Y_{\sigma\lambda'}}(t_{\sigma\lambda'}) = \varphi_{2Y_{\sigma\lambda'}}(t_{\sigma\lambda'})$ for every $\sigma \in \Sigma$ and every $\lambda' \in \Lambda'_\sigma$. This proves that s lies in the image of the map $E^a(B) \to E'(B)$, so the natural morphism $E^a \to E'$ is an epimorphism. To see that it is also a monomorphism, consider two sections s, s' of $E^a(B)$ whose images agree in $E'(B)$; we may find a covering family $(f_j : B_j \to B \mid i \in I)$ and compatible systems $([X_j, t_j] \mid j \in I)$, $([X'_j, t'_j] \mid j \in I)$ with $FX_j = FX'_j = B_j$ and $t_j \in G_1X_j$, $t'_j \in G_1X'_j$ for every $j \in I$. Arguing as in the foregoing, we may then assume that $[X_j, t_j] = [X'_j, t'_j]$ in $H_1(B_j)$ for every $j \in I$. Then by lemma 4.3.5 there exist for every $j \in I$ a covering family $(f_{j\lambda} : b_{j\lambda} \to B_j \mid j \in \Lambda_j)$ and morphims $g_{j\lambda} : Y_{j\lambda} \to X_j$, $g'_{j\lambda} : Y_{j\lambda} \to X'_j$ in $\mathscr{C}$ such that $Fg_{j\lambda} = Fg'_{j\lambda} = f_{j\lambda}$ and $t_{j\lambda} := (G_1 g_{j\lambda})(t_j) = (G_1 g'_{j\lambda})(t'_j)$ for every $\lambda \in \Lambda_j$. Clearly $\varphi_{1Y_{j\lambda}}(t_{j\lambda}) = \varphi_{2Y_{j\lambda}}(t_{j\lambda})$ for every $j \in I$ and every $\lambda \in \Lambda_j$; thus, both s and s' are represented by the compatible system $([Y_{j\lambda}, t_{j\lambda}] \mid j \in I, \ \lambda \in \Lambda_j)$, and the proof is concluded. ☐

4.3.8. Let $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two sites, $g : \mathscr{C} \to \mathscr{C}'$ a given functor, and V a universe such that C and C' are V-small. We shall apply proposition 4.3.7 to the split fibration $\mathsf{s} : \mathscr{C}'/g\mathscr{C} \to \mathscr{C}'$ associated with g, with its canonical cleavage $\boldsymbol{\lambda}$ (see example 3.2.3). Let also $\mathsf{t} : \mathscr{C}'/g\mathscr{C} \to \mathscr{C}$ be the target functor (see (1.1.28)); with this notation, notice that

$$g_{\mathsf{V}!} = \int^{\boldsymbol{\lambda}} \circ \ \mathsf{t}^\wedge.$$

In light of proposition 4.3.7, it follows already that if s is locally cofiltered, then the functors $g^a_{\mathsf{V}!}$ and $\widetilde{g}^*_{\mathsf{V}} : C^\sim_{\mathsf{V}} \to C'^\sim_{\mathsf{V}}$ are exact. In fact, we have :

Proposition 4.3.9. *With the notation of* (4.3.8)*, the following conditions are equivalent :*

(a) *g is a morphism of sites $C' \to C$.*
(b) *The fibration s is locally cofiltered, and for every covering family $(f_i : X_i \to X \mid i \in I)$ for the topology J, the family $(g(f_i) : gX_i \to gX \mid i \in I)$ covers gX relative to J'.*

Proof. (a)⇒(b) : Since g is continuous, we know already that it transforms covering families for J into covering families for J' (lemma 4.2.4). Notice as well that $g^a_{\mathsf{V}!} = \widetilde{g}^*_{\mathsf{V}} \circ (-)^a$ (lemma 4.2.11(ii)); since $\widetilde{g}^*_{\mathsf{V}}$ is exact, the same holds then for $g^a_{\mathsf{V}!}$.

Let us check next that condition (a) of definition 4.3.3 holds for s. To this aim, consider the final object E of $C^\sim$ such that $E(X) = \{\varnothing\}$ for every $X \in \mathrm{Ob}(\mathscr{C})$. By assumption, $\widetilde{g}^*_{\mathsf{V}}(E)$ is the final object of $C'^\sim_{\mathsf{V}}$, *i.e.* $(\widetilde{g}^*_{\mathsf{V}}E)(X')$ is a set with one element for every $X' \in \mathrm{Ob}(\mathscr{C}')$. However, every section of $(\widetilde{g}^*_{\mathsf{V}}E)(X')$ is represented by the datum of a covering family $(X'_j \to X' \mid j \in I)$ in the topology J', and a system of sections $([X'_j \to gX_j, \varnothing] \mid j \in I)$; especially, $\mathrm{Ob}(\mathsf{s}^{-1}X'_j) \neq \varnothing$ for every $j \in I$, as required.

Next, let $l_i : X' \to gX_i$ for $i = 1, 2$ be two objects of $\mathsf{s}^{-1}X'$; in order to check condition (b) of definition 4.3.3 we need to exhibit a covering family $(f_j : X'_j \to X' \mid j \in I)$ and for every $j \in I$ an object $h_j : X'_j \to gY_j$ of $\mathsf{s}^{-1}X'_j$ and morphisms $k_{ij} : Y_j \to X_i$ in $\mathscr{C}$ that make commute the diagram

(4.3.10)
$$\begin{array}{ccccc} X' & \xleftarrow{f_j} & X'_j & \xrightarrow{h_j} & gY_j \\ & {\scriptstyle l_i}\searrow & & \swarrow{\scriptstyle g(k_{ij})} & \\ & & gX_i & & \end{array} \qquad \text{for } i = 1, 2.$$

To this aim, set $H_i := g_{\mathsf{V}!}(h_{X_i}) = h_{gX_i}$ for $i = 1, 2$, and $H := g_{\mathsf{V}!}(h_{X_1} \times h_{X_2})$. The pair (l_1, l_2) yields a section $l_\bullet$ of $(H_1 \times H_2)(X')$; on the other hand, since $g^a_{\mathsf{V}!}$ is exact, the natural morphism $\omega : H \to H_1 \times H_2$ induces an isomorphism on associated sheaves in $C'^\sim$. Especially, there exists a covering family $(f_j \mid j \in I)$ as sought, such that for every $j \in I$ the section $(H_1 \times H_2)(f_j)(l_\bullet) = (l_1 \circ f_j, l_2 \circ f_j)$ agrees with the image under ω of a section $[h_j : X'_j \to gY_j, (k_{1j}, k_{2j})]$ of $H(X'_j)$. Unwinding the definition, we obtain precisely a diagram (4.3.10).

Lastly, let $l_i : X' \to gX_i$ for $i = 1, 2$ be two objects of $\mathsf{s}^{-1}X'$, and $t_1, t_2 : X_1 \to X_2$ two morphisms in $\mathscr{C}$ such that $g(t_1) \circ l_1 = l_2 = g(t_2) \circ l_1$; in order to verify condition (c) of definition 4.3.3 we need to exhibit a covering family $(f_j : X'_j \to X' \mid j \in I)$ and for every $j \in I$ an object $h_j : X'_j \to gY_j$ of $\mathsf{s}^{-1}X'_j$ with a morphism $k_j : Y_j \to X_1$ such that

(4.3.11)
$$l_1 \circ f_j = g(k_j) \circ h_j \qquad \text{and} \qquad t_1 \circ k_j = t_2 \circ k_j.$$

To this aim, let $t_{i*} : h_{X_1} \to h_{X_2}$ be the morphism of presheaves on $\mathscr{C}$ induced by t_i, for $i = 1, 2$; we set $H_i := g_{\mathsf{V}!}(h_{X_i}) = h_{gX_i}$ for $i = 1, 2$, and denote by E the equalizer of t_{1*} and t_{2*}, and by E' the equalizer of $g_{\mathsf{V}!}(t_{1*}), g_{\mathsf{V}!}(t_{2*}) : H_1 \to H_2$. Since $g^a_{\mathsf{V}!}$ is exact, the natural morphism $\omega : g_{\mathsf{V}!}E \to E'$ induces an isomorphism on associated sheaves in $C^\sim$. On the other hand, l_1 defines a section of $E'(X')$; it follows that there exists a covering family $(f_j : X'_j \to X' \mid j \in I)$ such that for every $j \in I$ the section $(E'f_j)(l_1)$ agrees with the image under ω of a section $[h_j : X'_j \to gY_j, k_j]$ of $(g_{\mathsf{V}!}E')(X'_j)$. Unwinding the definitions, we obtain the identities (4.3.11).

(b)⇒(a): We have already noticed that if s is locally cofiltered, the functor $\widetilde{g}^*_{\mathsf{V}}$ is exact. In order to check that g is continuous, let us consider any sheaf F on $\mathscr{C}'$, any $X \in \mathrm{Ob}(\mathscr{C})$, and any covering subobject $R \subset h_X$ for the topology J. We need to show that the natural map

$$F(gX) \simeq \mathrm{Hom}_{\mathscr{C}^\wedge_{\mathsf{V}}}(h_X, g^*_{\mathsf{V}}F) \to \mathrm{Hom}_{\mathscr{C}^\wedge_{\mathsf{V}}}(R, g^*_{\mathsf{V}}F)$$

is bijective. By adjunction, the latter is naturally identified with the induced map

$$\mathrm{Hom}_{\mathscr{C}'^\wedge_{\mathsf{V}}}(g_{\mathsf{V}!}(h_X), F) \to \mathrm{Hom}_{\mathscr{C}'^\wedge_{\mathsf{V}}}(g_{\mathsf{V}!}(R), F)$$

so we come down to checking that the morphism $\varphi : (g_{\mathsf{V}!}R)^a \to (g_{\mathsf{V}!}h_X)^a = h^a_{gX}$ induced by the inclusion $R \to h_X$ is an isomorphism. However, we know already that the functor $g^a_{\mathsf{V}!}$ is exact, so φ is a monomorphism. Next, let $(f_j : X_j \to X \mid j \in I)$ be a V-small family of generators for the covering sieve of X corresponding to R; there follows a covering morphism

$$S := \coprod_{j \in I} h_{X_j} \to R \to h_X \qquad \text{in } \mathscr{C}^\wedge$$

whose image under $g_{\mathsf{V}!}$ is still a covering morphism : indeed, $g_{\mathsf{V}!}$ commutes with coproducts since it is a left adjoint, so $g_{\mathsf{V}!}(S)$ is the coproduct of the family $(h_{gX_j} \mid j \in I)$, and by assumption g transforms covering families for the topology J into covering families for the topology J'. Thus, the morphism $g_{\mathsf{V}!}R \to g_{\mathsf{V}!}h_X$ induces an epimorphism as well on associated sheaves, whence the contention. □

Example 4.3.12. In the situation of (4.3.8), suppose that C is a lex-site and g is left exact. Then g is a morphism of sites if and only if for every covering family $(f_i : X_i \to X \mid i \in I)$ for the topology J, the family $(g(f_i) : gX_i \to gX \mid i \in I)$ covers gX relative to J'. Indeed, under this assumption, the category $X/g\mathscr{C}$ is cofiltered for every $X \in \mathrm{Ob}(\mathscr{C}')$ (example 1.3.16(i)), so the source fibration $\mathsf{s} : \mathscr{C}'/g\mathscr{C} \to \mathscr{C}'$ is trivially locally cofiltered, and the assertion follows from proposition 4.3.9.

Theorem 4.3.13. *Let $(\mathscr{C}, J)$ be a U-site, $\mathscr{C}'$ a category, $g : \mathscr{C}' \to \mathscr{C}$ a functor, and endow $\mathscr{C}'$ with the topology J' induced by g. Suppose that the following conditions hold :*

- (a) *For every $X \in \mathrm{Ob}(\mathscr{C})$ there exists a family $(gY_i \to X \mid i \in I)$ of objects of $g\mathscr{C}'/X$ that covers X in the topology J.*
- (b) *For every $Y, Y' \in \mathrm{Ob}(\mathscr{C}')$ and every morphism $\varphi : gY \to gY'$ in $\mathscr{C}$ there exist :*
  - (b.i) *a family $(\psi_i : Z_i \to Y \mid i \in I)$ of objects of $\mathscr{C}'/Y$ such that the family $(g(\psi_i) : gZ_i \to gY \mid i \in I)$ covers gY in the topology J*
  - (b.ii) *for each $i \in I$ a morphism $\nu_i : Z_i \to Y'$ such that $\varphi \circ g(\psi_i) = g(\nu_i)$.*
- (c) *For every pair of morphisms $\varphi, \varphi' : Y \to Y'$ in $\mathscr{C}'$ such that $g(\varphi) = g(\varphi')$ there exists a family $(\psi_i : Z_i \to Y \mid i \in I)$ of objects of $\mathscr{C}'/Y$ such that the family $(g(\psi_i) : gZ_i \to gY \mid i \in I)$ covers gY in the topology J, and $\varphi \circ \psi_i = \varphi' \circ \psi_i$ for every $i \in I$.*

Then we have :

- (i) *g is cocontinuous for the topologies J, J' and is a morphism of sites $(\mathscr{C}, J) \to (\mathscr{C}', J')$.*
- (ii) *g induces an equivalence $\widetilde{g}_* : (\mathscr{C}, J)^\sim \xrightarrow{\sim} (\mathscr{C}', J')^\sim$.*
- (iii) *A family $(\psi_i : Y_i \to Y \mid i \in I)$ of morphisms of $\mathscr{C}'$ generates a covering sieve of J' if and only if $(g(\psi_i) : gY_i \to gY \mid i \in I)$ generates a covering sieve of J.*

Proof. Suppose first that both $\mathscr{C}$ and $\mathscr{C}'$ are small. Let $\mathsf{s} : \mathscr{C}/g\mathscr{C}' \to \mathscr{C}$ be the fibration associated with g, as in (4.3.8); we remark :

Claim 4.3.14. The fibration s is locally cofiltered.

Proof of the claim. To check condition (a) of definition 4.3.3, let $X \in \mathrm{Ob}(\mathscr{C})$; we need to find a covering family $(X_j \to X \mid j \in I)$ for the topology J, such that $\mathrm{Ob}(\mathsf{s}^{-1}X_j) \neq \varnothing$ for every $j \in I$. However, by condition (a) of the theorem we have a covering family $(gY_j \to X \mid j \in I)$ for X; we may then choose $X_j := gY_j$, since then $\mathbf{1}_{gY_j} \in \mathrm{Ob}(\mathsf{s}^{-1}X_j)$ for every $j \in I$.

Next, we check condition (b) of definition 4.3.3 : consider any $X \in \mathrm{Ob}(\mathscr{C})$ and morphisms $\varphi_i : X \to gY_i$ in $\mathscr{C}'$ for $i = 1, 2$; we need to find a covering family $(f_j : X_j \to X \mid j \in I)$ such that for every $j \in I$ there exist a morphism $\psi_j : X_j \to gZ_j$ in $\mathscr{C}$ and morphisms $\nu_{ij} : Z_j \to Y_i$ with $g(\nu_{ij}) \circ \psi_j = \varphi_i \circ f_j$ for $i = 1, 2$. To this aim, we use first condition (a) of the theorem to find a covering family $f'_\bullet := (f'_j : gY'_j \to X \mid j \in I')$; then, by condition (b) of the theorem we find for every $j \in I'$ a family $(f'_{j\lambda} : Y'_{j\lambda} \to Y'_j \mid \lambda \in \Lambda_j)$ such that $(g(f'_{j\lambda}) \mid \lambda \in \Lambda_j)$ covers gY'_j, and such that for every $\lambda \in \Lambda_j$ there exists a morphism $h_{j\lambda} : Y'_{j\lambda} \to Y_1$ with $g(h_{j\lambda}) = \varphi_1 \circ f'_j \circ g(f'_{j\lambda})$. We may then replace $f'_\bullet$ by the family $(f'_j \circ g(f'_{j\lambda}) : gY'_{j\lambda} \to X \mid j \in I', \lambda \in \Lambda_j)$, and assume from start that for every $j \in I'$ there exists a morphism $h_j : Y'_j \to Y_1$ such that $g(h_j) = \varphi_1 \circ f'_j$. Next, we apply again condition (b) of the theorem to find for every $j \in I'$ a family $(f''_{j\lambda'} : Y''_{j\lambda'} \to Y'_j \mid \lambda' \in \Lambda'_j)$ such that $(g(f''_{j\lambda'}) \mid \lambda' \in \Lambda'_j)$ covers gY'_j, and such that for every $\lambda' \in \Lambda'_j$ there exists a morphism $h'_{j\lambda'} : Y''_{j\lambda'} \to Y_2$ with $g(h'_{j\lambda'}) = \varphi_2 \circ f'_j \circ g(f''_{j\lambda'})$. We may then further replace $f'_\bullet$ by the family $(f'_j \circ g(f''_{j\lambda'}) : gY''_{j\lambda'} \to X \mid j \in I', \lambda' \in \Lambda'_j)$, and the system $(h_j \mid j \in I')$ by the system $(h_j \circ f''_{j\lambda'} : Y''_{j\lambda'} \to Y_1 \mid j \in I',\ \lambda' \in \Lambda'_j)$, and assume from start that there exists as well for every $j \in I'$ a morphism $h'_j : Y'_j \to Y_2$ such that $g(h'_j) = \varphi_2 \circ f'_j$. Then we set $X_j := gY'_j$, $Z_j := Y'_j$, $\psi_j := \mathbf{1}_{X_j}$, $\nu_{1j} := h_j$ and $\nu_{2j} := h'_j$ for every $j \in I'$; clearly the resulting family $f_\bullet$ and systems of morphisms $\psi_\bullet$, $\nu_{\bullet\bullet}$ will do.

Lastly, we check condition (c) of definition 4.3.3 : let $X \in \mathrm{Ob}(\mathscr{C})$ and consider morphisms $\varphi : X \to gY_1$ in $\mathscr{C}$ and $\psi, \psi' : Y_1 \to Y_2$ in $\mathscr{C}'$ such that $g(\psi) \circ \varphi = g(\psi') \circ \varphi$; we need to find a covering family $(f_j : X_j \to X \mid j \in I)$ and for every $j \in I$ morphisms $h_j : X_j \to gZ_j$ in $\mathscr{C}$ and $\nu_j : Z_j \to Y_1$ in $\mathscr{C}'$ such that $\varphi \circ f_j = g(\nu_j) \circ h_j$ and $\psi \circ \nu_j = \psi' \circ \nu_j$. To this aim, we use conditions (a) and (b) of the theorem to get first a covering family $f'_\bullet := (f'_j : gY_j \to X \mid j \in I)$, and then for every $j \in I$ a family $(f''_{j\lambda} : Y_{j\lambda} \to Y_j \mid \lambda \in \Lambda_j)$ such that $(g(f''_{j\lambda}) \mid \lambda \in \Lambda_j)$ covers gY_j, and such that for every $\lambda \in \Lambda_j$ there exists a morphism $\nu'_{j\lambda} : Y_{j\lambda} \to Y_1$ with $g(\nu'_{j\lambda}) = \varphi \circ f'_j \circ g(f''_{j\lambda})$. After replacing $f'_\bullet$ by the family $(f'_j \circ g(f''_{j\lambda}) \mid j \in I,\ \lambda \in \Lambda_j)$, we may assume that for every $j \in I$ there exists a morphism $\nu'_j : Y_j \to Y_1$ such that $g(\nu'_j) = \varphi \circ f'_j$. Especially, notice that $g(\psi \circ \nu'_j) = g(\psi' \circ \nu'_j)$ for every $j \in I$. By condition (c) of the theorem, there exists therefore for every $j \in I$ a family $(\nu'_{j\lambda'} : Y'_{j\lambda'} \to Y_j \mid \lambda' \in \Lambda'_j)$ such that $(g(\nu'_{j\lambda'}) \mid \lambda' \in \Lambda'_j)$ covers gY_j and $\psi \circ \nu'_j \circ \nu'_{j\lambda'} = \psi' \circ \nu'_j \circ \nu_{j\lambda}$ for every $\lambda' \in \Lambda_j$. Set $I := \bigcup_{j \in I} \{j\} \times \Lambda_j$; for every $(j, \lambda') \in I$ we let $X_{j\lambda'} := gY_{j\lambda'}$, $f_{j\lambda'} := f'_j \circ g(\nu'_{j\lambda'})$, $h_{j\lambda'} := \mathbf{1}_{X_{j\lambda'}}$ and $\nu_{j\lambda'} := \nu'_j \circ \nu'_{j\lambda'}$. Clearly the resulting covering family $f_{\bullet\bullet}$ and systems of morphisms $h_{\bullet\bullet}$, $\nu_{\bullet\bullet}$ will do. ◊

(iii) follows from claim 4.3.14, lemmata 4.2.17(ii) and 4.2.4, and proposition 4.3.9.

(i): The continuity of g holds by definition of J'; then g is a morphism of sites, by claim 4.3.14 and proposition 4.3.9. To check the cocontinuity, let $Y \in \mathrm{Ob}(\mathscr{C}')$ and $f_\bullet := (f_j : X_j \to gY \mid j \in I)$ a family of morphisms in $\mathscr{C}$ generating a covering sieve $\mathscr{S}$ of gY; we need to show that $g^{-1}_{|Y}\mathscr{S}$ is a covering sieve of Y for the topology J'. However, by (a) we may find for every $j \in I$ a family $(f_{j\lambda} : gY_{j\lambda} \to X_j \mid \lambda \in \Lambda_j)$ covering X_j in the topology J; let $\mathscr{S}' \subset \mathscr{S}$ be the sieve generated by the system $(f'_{j\lambda} := f_j \circ f_{j\lambda} : gY_{j\lambda} \to gY \mid j \in I,\ \lambda \in \Lambda_j)$. Clearly $\mathscr{S}'$ covers gY in the topology J, and by remark 4.1.3(ii) it suffices to check that $g^{-1}_{|Y}\mathscr{S}'$ is a covering sieve for Y, so we may replace $f_\bullet$ by the family $f'_{\bullet\bullet}$, and assume from start that for every $j \in I$ we have $X_j = gY_j$ for some $Y_j \in \mathrm{Ob}(\mathscr{C}')$. By condition (b), we may then find for every $j \in I$ a family $(h_{j\lambda} : Y_{j\lambda} \to Y_j \mid \lambda \in \Lambda_j)$ of morphisms in $\mathscr{C}'$ such that the family $(g(h_{j\lambda}) \mid \lambda \in \Lambda_j)$ covers gY_j in the topology J, and for every $j \in I$ and $\lambda \in \Lambda_j$ a morphism $k_{j\lambda} : Y_{j\lambda} \to Y$ in $\mathscr{C}'$ such that $f''_{j\lambda} := f_j \circ g(h_{j\lambda}) = g(k_{j\lambda})$. Let $\mathscr{S}'' \subset \mathscr{S}$ be the sieve generated by the system $(f''_{j\lambda} : gY_{j\lambda} \to gY \mid j \in I,\ \lambda \in \Lambda_j)$. Then $\mathscr{S}''$ covers gY in the topology J, and it suffices to check that $\mathscr{T} := g^{-1}_{|Y}\mathscr{S}''$ covers Y in the topology J'. However, $\mathscr{T}$ contains the family $(k_{j\lambda} \mid j \in I,\ \lambda \in \Lambda_j)$, which covers Y, by virtue of (iii). The assertion follows.

Claim 4.3.15. (i) Let $\varphi : G \to G'$ be a morphism of presheaves on $\mathscr{C}$ such that $g^\wedge(\varphi) : g^\wedge G \to g^\wedge G'$ is an isomorphism in $\mathscr{C}'^\wedge$. Then φ is a bicovering morphism.

(ii) Let (η', ε') be a unit and counit for the adjoint pair $(\widetilde{g}^*, \widetilde{g}_*)$. In order to prove assertion (ii) of the theorem, it suffices to check that $\eta' : \mathbf{1}_{(\mathscr{C}', J')^\sim} \Rightarrow \widetilde{g}_*\widetilde{g}^*$ is an isomorphism of functors.

Proof of the claim. (i): Indeed, let $X \in \mathrm{Ob}(\mathscr{C})$ and $s \in G'X$; by condition (a) there exists a covering family $(f_i : gY_i \to X \mid i \in I)$, and by assumption $(G'f_i)(s) \in \mathrm{Im}(\varphi_{gY_i})$ for every $i \in I$, so φ is a covering morphism, by remark 4.1.29(ii). Likewise, let $s, s' \in GX$ such that $t := \varphi_X(s) = \varphi_X(s')$; it follows that $\varphi_{gY_i}((Gf_i)(s)) = \varphi_{gY_i}((Gf_i)(s')) = (G'f_i)(t)$, whence $(Gf_i)(s) = (Gf_i)(s')$ for every $i \in I$. In light of remark 4.1.29(iii), the assertion follows.

(ii): Indeed, if η' is an isomorphism, the triangular identities of (1.1.13) show that $g^\wedge(\varepsilon'_G)$ will also be an isomorphism for every sheaf G on $(\mathscr{C}, J)$, hence ε'_G will be an isomorphism, by (i), and to conclude it will suffice to invoke proposition 1.1.20(i,iii). ◊

(ii): From (i) and lemma 4.2.15(ii) we get an isomorphism of functors $\mathscr{C}^\wedge \to (\mathscr{C}', J')^\sim$

$$\omega : (-)^a \circ g^\wedge \stackrel{\sim}{\to} \widetilde{g}_* \circ (-)^a.$$

Let now $\eta : \mathbf{1}_{\mathscr{C}'^\wedge} \Rightarrow g^\wedge \circ g_!$ and $\varepsilon : g_! \circ g^\wedge \Rightarrow \mathbf{1}_{\mathscr{C}^\wedge}$ be the unit and counit of the natural adjunction for the pair of functors $(g_!, g^\wedge)$, as in remark 1.3.6(iii). We consider the natural transformations of functors on $(\mathscr{C}', J')^\sim$ and respectively on $(\mathscr{C}, J)^\sim$

$$\eta'_F : F \xrightarrow{(\eta_F)^a} (g^\wedge g_! F)^a \xrightarrow{\omega_{g_! F}} (g^\wedge \circ g^a_!)(F) \qquad \varepsilon'_G : (g^a_! \circ g^\wedge)(G) \xrightarrow{(\varepsilon_F)^a} G.$$

A little diagram chase shows that the pair (η', ε') fulfills the triangular identities of (1.1.13), so these are the unit and counit of an adjunction for the pair $(\widetilde{g}^*, \widetilde{g}_*)$. By claim 4.3.15(ii), we are thus reduced to showing that η_F is a bicovering morphisms, for every presheaf F on $\mathscr{C}'$.

We check first that η_F is a covering morphism : thus, let $X \in \mathrm{Ob}(\mathscr{C}'^\wedge)$, and $s \in (g^\wedge g_! F)(X)$; then s is a class $[\varphi : gX \to gY, \sigma]$, where φ is a morphism in $\mathscr{C}$, and $\sigma \in FY$. By condition (b) there exists a family $(f_j : X_j \to X \mid j \in I)$ of morphisms of $\mathscr{C}'$ such that $(\varphi(f_j) \mid j \in I)$ is a covering family for the topology J, and such that for every $j \in I$ there exists a morphism $h_j : X_i \to Y$ with $g(h_j) = \varphi \circ g(f_j)$. Set $\sigma_j := (Fh_j)(\sigma) \in FX_i$ for every $j \in I$; then $\eta_{F,X_j}(\sigma_j)$ is the class $[\mathbf{1}_{gX_j}, \sigma_j]$ in $(g^\wedge g_! F)(X_j)$ for every $j \in I$. On the other hand, $(g^\wedge g_! F)(f_j)(s) = [\varphi \circ g(f_j) : gX_j \to gY, \sigma]$ for every $j \in I$. According to remark 4.1.29(ii), it suffices then to show that $[\mathbf{1}_{gX_j}, \sigma_j] = [\varphi \circ g(f_j), \sigma]$ in $(g^\wedge g_! F)(X_j)$, for every $j \in I$. But h_j yields a morphism $gX_j/h_j : (X_j, \mathbf{1}_{gX_j}) \to (Y, \varphi \circ g(f_j))$ in $gX_j/g\mathscr{C}'$ whence the assertion.

Next, let $t, t' \in FX$ be two sections such that $\eta_{F,X}(t) = \eta_{F,X}(t')$, *i.e.* $[\mathbf{1}_{gX}, t] = [\mathbf{1}_{gX}, t']$ in $(g_! F)(gX)$. According to lemma 4.3.5, there exist a covering family $(f_j : gX_j \to gX \mid j \in I)$ for the topology J, and morphisms $\varphi_j : gX_j \to gY_j$ in $\mathscr{C}$ and $h_j h'_j : Y_j \to X$ in $\mathscr{C}'$ such that

$$g(h_j) \circ \varphi_j = g(h'_j) \circ \varphi_j = f_j \qquad \text{and} \qquad (Fh_j)(t) = (Fh'_j)(t') \qquad \text{for each } j \in I.$$

Then, by condition (b), we may find for every $j \in I$ a family $(f'_{j\lambda} : X_{j\lambda} \to X_j \mid \lambda \in \Lambda_j)$ such that $(g(f'_{j\lambda}) \mid \lambda \in \Lambda_j)$ is a covering family for the topology J, and such that for every $\lambda \in \Lambda_j$ there exists a morphism $\nu_{j\lambda} : X_{j\lambda} \to Y_j$ with $g(\nu_{j\lambda}) = \varphi_j \circ g(f'_{j\lambda})$. After replacing $(f_j \mid j \in \Lambda)$ by the covering family $(f_j \circ g(f'_{j\lambda}) : X_{j\lambda} \to X \mid j \in I,\ \lambda \in \Lambda)$, and $(\varphi_j \mid j \in J)$ by the system of morphisms $(\varphi_j \circ g(f'_{j\lambda}) \mid j \in I,\ \lambda \in \Lambda_j)$, we may then assume that for every $j \in I$ there exists a morphism $\nu_j : X_j \to Y_j$ such that $\varphi_j = g(\nu_j)$, in which case we have $g(h_j \circ \nu_j) = g(h'_j \circ \nu_j) = f_j$ for every $j \in I$. Then, by condition (c) there exists for every $j \in I$ a family $(f''_{j\lambda'} : X'_{j\lambda'} \to X_j \mid \lambda' \in \Lambda'_j)$ of morphisms in $\mathscr{C}'$ such that $(g(f''_{j\lambda'}) \mid \lambda' \in \Lambda'_j)$ is a covering family for the topology J, and such that $h_j \circ \nu_j \circ f''_{j\lambda'} = h'_j \circ \nu_j \circ f''_j$. After replacing $(f_j \mid j \in \Lambda)$ by the covering family $(f_j \circ g(f''_{j\lambda'}) : X_{j\lambda'} \to X \mid j \in I,\ \lambda' \in \Lambda'_j)$ and $(\nu_j \mid j \in I)$ by the system $(\nu_j \circ f''_{j\lambda'} \mid j \in I,\ \lambda' \in \Lambda'_j)$, we may then assume that $\mu_j := h_j \circ \nu_j = h'_j \circ \nu_j$ for every $j \in I$. It follows that $(F\mu_j)(t) = (F\mu_j)(t')$ for every $j \in I$; lastly, the family $(\mu_j : X_j \to X \mid j \in I)$ covers X in the topology J', by virtue of (iii). In view of remark 4.1.29(iii), we conclude that η_F is a bicovering morphism, as stated.

This completes the proof of the theorem in case $\mathscr{C}$ and $\mathscr{C}'$ are small. Lastly, consider the case where $(\mathscr{C}, J)$ is a U-site and $\mathscr{C}'$ is a general category, and pick a universe V such that $\mathscr{C}$ and $\mathscr{C}'$ are V-small. The theorem then applies to the functor $\widetilde{g}_{\mathsf{V}*}$, so the latter is an equivalence, and we also get assertions (i) and (iii), which are independent of the universe U. It remains therefore only to check that $\widetilde{g}_{\mathsf{U}*}$ is an equivalence, and taking into account the commutative diagram

$$\begin{array}{ccc} (\mathscr{C}, J)^\sim_{\mathsf{U}} & \xrightarrow{\widetilde{g}_{\mathsf{U}*}} & (\mathscr{C}', J')^\sim_{\mathsf{U}} \\ \downarrow & & \downarrow \\ (\mathscr{C}, J)^\sim_{\mathsf{V}} & \xrightarrow{\widetilde{g}_{\mathsf{V}*}} & (\mathscr{C}', J')^\sim_{\mathsf{V}} \end{array}$$

(whose vertical arrows are the fully faithful inclusion functors), we already see that $\widetilde{g}_{\mathsf{U}*}$ is fully faithful. We notice :

Claim 4.3.16. For every covering family $(f_i : X_i \to X \mid i \in I)$ in the topology J there exists an essentially small subset $I' \subset I$ such that $(f_i : X_i \to X \mid i \in I')$ is still a covering family.

Proof of the claim. Pick an essentially small topologically generating family $G \subset \mathrm{Ob}(\mathscr{C})$ for the site $(\mathscr{C}, J)$; then for every $i \in I$ there exists a covering family $(f_{i\lambda} : X_{i\lambda} \to X_i \mid \lambda \in \Lambda_i)$ with $X_{i\lambda} \in G$ for every $\lambda \in \Lambda_i$. Set $\Lambda := \bigcup_{i \in I} \{i\} \times \Lambda_i$; the family $(f'_{i\lambda} := f_i \circ f_{i\lambda} : X_{i\lambda} \to X \mid (i, \lambda) \in \Lambda)$ covers X in the topology J. Since $\mathrm{Hom}_{\mathscr{C}}(X_{i\lambda}, X)$ is a small set for every $(i, \lambda) \in \Lambda$, we may then find an essentially small subset $\Lambda' \subset \Lambda$ such that $(f'_{i\lambda} \mid (i, \lambda) \in \Lambda')$ is still covering; then we can take for $I' \subset I$ the image of Λ' under the projection $\Lambda \to I$. ◊

Now, let F be any U-sheaf on $(\mathscr{C}', J')$; we know already that there exists a V-sheaf G on $(\mathscr{C}, J)$ such that $\widetilde{g}_{*\mathsf{V}} G$ is isomorphic to F, and we need to check that GX is essentially small for every $X \in \mathrm{Ob}(\mathscr{C})$. But by condition (a) we may find a covering family $(gY_i \to X \mid i \in I)$, and by claim 4.3.16 we may assume that I is small. Then the induced map $GX \to \prod_{i \in I} G(gY_i)$ is injective, and $G(gY_i) \overset{\sim}{\to} FY_i$ is essentially small for every $i \in I$, whence the contention. □

Remark 4.3.17. (i) Notice that if g is full (resp. faithful), then condition (b) (resp. (c)) of theorem 4.3.13 is trivially satisfied.

(ii) It follows easily that theorem 4.3.13 generalizes [17, §2.1, Prop.], which in turn generalizes the implication (i)⇒(ii) in [8, Exp.III, Th.4.1]. One can also show that conditions (a), (b) and (c) of the theorem are implied by conditions $(\mathscr{L}0)$, $(\mathscr{L}1)$ and $(\mathscr{L}2)$ of [9, Exp.V, Déf.8.1.1], hence theorem 4.3.13 generalizes as well [9, Exp.V, Prop.8.1.12].

(iii) A necessary and sufficient condition for a morphism of sites to induce an equivalence of topoi is given in [46, Th.4.7].

(iv) In the situation of theorem 4.3.13, one can show that $(\mathscr{C}', J')$ does not necessarily have an essentially small topological generating family, and does not necessarily have essentially small Hom-sets, but every essentially small subcategory $\mathscr{B} \subset \mathscr{C}'$ is contained in an essentially small subcategory $\mathscr{B}' \subset \mathscr{C}'$ such that the restriction $\mathscr{B}' \to \mathscr{C}$ of g still satisfies conditions (a)–(c) of theorem 4.3.13.

We may now generalize lemma 4.2.11 to any continuous functor between U-sites. Indeed, we notice the following further application of theorem 4.3.13, which appears in [8, Exp.III, Th.4.1].

Proposition 4.3.18. *Let $C := (\mathscr{C}, J)$ be a U-site, G a topologically generating family for C. Denote by $\mathscr{G}$ the full subcategory of $\mathscr{C}$ with $\mathrm{Ob}(\mathscr{G}) = G$, and endow $\mathscr{G}$ with the topology $J_{\mathscr{G}}$ induced by J via the inclusion functor $u : \mathscr{G} \to \mathscr{C}$. Then :*

(i) *u is cocontinuous for the topologies $J, J_{\mathscr{G}}$ and is a morphism of sites $C \to (\mathscr{G}, J_{\mathscr{J}})$.*
(ii) *The induced functor $\widetilde{u}_* : C^\sim \to (\mathscr{G}, J_{\mathscr{G}})^\sim$ is an equivalence.*
(iii) *A family $(\psi_i : Y_i \to Y \mid i \in I)$ of morphisms of $\mathscr{G}$ generates a covering sieve of $J_{\mathscr{G}}$ if and only if it generates a covering sieve of J.*
(iv) *$(\mathscr{G}, J_{\mathscr{G}})$ is a U-site.*

Proof. (i),(ii),(iii): We apply the criterion of theorem 4.3.13, and taking into account remark 4.3.17(i) we are reduced to checking condition (a) of the theorem. The latter holds by definition of topologically generating family.

(iv): Pick an essentially small topologically generating family $H \subset \mathrm{Ob}(\mathscr{C})$ for the site C. With claim 4.3.16, we get an essentially small subset $G' \subset G$ such that every $X \in H$ has a covering family $(X_i \to X \mid i \in I)$ in the topology J, with $X_i \in G'$ for every $i \in I$. By (iii) and remark 4.1.3(iii), G' is then a topologically generating family for both C and $(\mathscr{G}, J_{\mathscr{G}})$. □

Corollary 4.3.19. *Let $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two U-sites, $g : \mathscr{C} \to \mathscr{C}'$ a functor, and V, V' a pair of universes with $\mathsf{U} \subset \mathsf{V} \subset \mathsf{V}'$. We have :*

(i) *If g is continuous, the following holds :*

(a) *The functor $\widetilde{g}_{\mathsf{V}*} : C'^{\sim}_{\mathsf{V}} \to C^{\sim}_{\mathsf{V}}$ admits a left adjoint $\widetilde{g}^*_{\mathsf{V}} : C^{\sim}_{\mathsf{V}} \to C'^{\sim}_{\mathsf{V}}$.*

(b) *There are essentially commutative diagrams of categories :*

$$\begin{array}{ccc} C^{\sim}_{\mathsf{V}} & \xrightarrow{\widetilde{g}^*_{\mathsf{V}}} & C'^{\sim}_{\mathsf{V}} \\ {\scriptstyle i}\downarrow & & \downarrow{\scriptstyle i'} \\ C^{\sim}_{\mathsf{V}'} & \xrightarrow{\widetilde{g}^*_{\mathsf{V}'}} & C'^{\sim}_{\mathsf{V}'} \end{array} \qquad \begin{array}{ccc} \mathscr{C} & \xrightarrow{g} & \mathscr{C}' \\ {\scriptstyle h^a_{\mathscr{C}}}\downarrow & & \downarrow{\scriptstyle h^a_{\mathscr{C}'}} \\ C^{\sim}_{\mathsf{U}} & \xrightarrow{\widetilde{g}^*_{\mathsf{U}}} & C'^{\sim}_{\mathsf{U}} \end{array}$$

where i and i' are the inclusion functors.

(c) *Suppose moreover that $\mathscr{C}$ is finitely complete and g is left exact. Then $\widetilde{g}^*_{\mathsf{V}}$ is exact.*

(ii) *If g is cocontinuous, the following holds :*

(a) *The functor $\breve{g}^*_{\mathsf{V}} : C'^{\sim}_{\mathsf{V}} \to C^{\sim}_{\mathsf{V}}$ admits a right adjoint $\breve{g}_{\mathsf{V}*} : C^{\sim}_{\mathsf{V}} \to C'^{\sim}_{\mathsf{V}}$.*

(b) *There is an essentially commutative diagram of categories :*

$$\begin{array}{ccc} C^{\sim}_{\mathsf{V}} & \xrightarrow{\breve{g}_{\mathsf{V}*}} & C'^{\sim}_{\mathsf{V}} \\ \downarrow & & \downarrow \\ C^{\sim}_{\mathsf{V}'} & \xrightarrow{\breve{g}_{\mathsf{V}'*}} & C'^{\sim}_{\mathsf{V}'} \end{array}$$

whose vertical arrows are the inclusion functors.

(iii) *If g is continuous and cocontinuous, we have natural isomorphisms of functors :*

$$\widetilde{g}_{\mathsf{V}*} \xrightarrow{\sim} \breve{g}^*_{\mathsf{V}} \;:\; C'^{\sim}_{\mathsf{V}} \to C^{\sim}_{\mathsf{V}} \qquad\qquad (-)^a \circ g^{\wedge}_{\mathsf{V}} \xrightarrow{\sim} \widetilde{g}_{\mathsf{V}*} \circ (-)^a \;:\; \mathscr{C}'^{\wedge}_{\mathsf{V}} \to C^{\sim}_{\mathsf{V}}.$$

Proof. (i.a): We choose an essentially small topologically generating family G for C, and define the site $(\mathscr{G}, J_{\mathscr{G}})$ and the continuous functor $u : (\mathscr{G}, J_{\mathscr{G}}) \to C$ as in proposition 4.3.18. By applying lemma 4.2.11(i) to the continuous functor $v := g \circ u$, we deduce that $\widetilde{v}_{\mathsf{V}*} = \widetilde{u}_{\mathsf{V}*} \circ \widetilde{g}_{\mathsf{V}*}$ admits a left adjoint. Then the assertion follows from proposition 4.3.18(ii).

(i.b): More precisely, $\widetilde{g}^*_{\mathsf{V}} = \widetilde{v}^*_{\mathsf{V}} \circ \widetilde{u}_{\mathsf{V}*}$. Thus, the essential commutativity of the left diagram follows from (4.2.13). Likewise, the essential commutativity of the right diagram follows from that of the left diagram (with $\mathsf{V} := \mathsf{U}$ and V' large enough so that $\mathscr{C}$ is V'-small) together with lemma 4.2.11(ii).

(i.c) holds by example 4.3.12.

(ii.a): Let u and h be as in the foregoing; from proposition 4.3.18(i) we deduce that h is cocontinuous, hence $\breve{h}^*_{\mathsf{V}} = \breve{u}^*_{\mathsf{V}} \circ \breve{g}^*_{\mathsf{V}}$ admits a right adjoint; however $\breve{u}^*_{\mathsf{V}} = \widetilde{u}_{\mathsf{V}*}$ (lemma 4.2.15(i)), and the latter is an equivalence (proposition 4.3.18(ii)), whence the contention.

(ii.b): More precisely, $\breve{g}_{\mathsf{V}*} = \breve{h}_{\mathsf{V}*} \circ \widetilde{u}^*_{\mathsf{V}}$, hence the assertion follows from (4.2.13).

(iii): In view of (i.b) and (ii.b), in order to prove the assertion, we may assume that $\mathscr{C}$ and $\mathscr{C}'$ are V-small, and this case is already covered by lemma 4.2.15(i,ii). □

The last result of this section will show the representability of the 2-limit of any (small) cofiltered system of lex-sites. The proof shall use the following :

Lemma 4.3.20. *Let I be a small filtered category, U' a universe, and*

$$\mathscr{C}_\bullet : I \to \mathsf{U}'\text{-}\mathbf{Cat} \qquad i \mapsto \mathscr{C}_i \qquad (\varphi : i \to j) \mapsto (\mathscr{C}_\varphi : \mathscr{C}_i \to \mathscr{C}_j)$$

any pseudo-functor such that $\mathscr{C}_i$ is finitely complete for every $i \in \mathrm{Ob}(I)$ and $\mathscr{C}_\varphi$ is a left exact functor for every morphism φ of I. Let also $(\mathscr{C}, \pi_\bullet)$ be a 2-colimit of $\mathscr{C}_\bullet$. Then $\mathscr{C}$ is finitely complete and $\pi_i : \mathscr{C}_i \to \mathscr{C}$ is a left exact functor for every $i \in \mathrm{Ob}(I)$.

Proof. Notice that the assertions depend only on the equivalence class of the category $\mathscr{C}$; hence, we may suppose that $(\mathscr{C}, \pi_\bullet)$ is the strong 2-colimit of $\mathscr{C}_\bullet$ described explicitly by example 3.3.13(i), *i.e.* $\mathscr{C} = \mathscr{F}ib(\mathscr{C}_\bullet)[\Sigma^{-1}]$, where Σ is the set of cartesian morphisms of $\mathscr{F}ib(\mathscr{C}_\bullet)$; then

π_i is induced by the inclusion functor of the fibre category $F^{-1}(i) = \mathscr{C}_i$ into $\mathscr{F}ib(\mathscr{C}_\bullet)$, where $F : \mathscr{F}ib(\mathscr{C}_\bullet) \to I^o$ is the natural projection. By proposition 1.2.22(i)), in order to check that $\mathscr{C}$ is finitely complete it suffices to show the following two claims :

Claim 4.3.21. All finite products are representable in $\mathscr{C}_\bullet$.

Proof of the claim. By a simple induction we are easily reduced to showing that the product of two objects $(i_1^o, X_1), (i_2^o, X_2)$ is representable (here we have $i_1^o, i_2^o \in \mathrm{Ob}(I^o)$ and $X_t \in \mathrm{Ob}(\mathscr{C}_{i_t})$ for $t = 1, 2$: see (3.1.18)). Since I^o is cofiltered, we may find $i \in \mathrm{Ob}(I)$ and morphisms $\varphi_t^o : i^o \to i_t^o$ for $t = 1, 2$; then (i_t^o, X_t) is isomorphic to $(i, \mathscr{C}_{\varphi_t} X_t)$ in $\mathscr{C}$ for $t = 1, 2$, so we may assume that $i = i_1 = i_2$. Since $\mathscr{C}_i$ is finitely complete, the product $X_1 \times X_2$ is representable in $\mathscr{C}_i$, say by an object P, and let $(p_t : P \to X_t \mid t = 1, 2)$ be a universal cone. Let us check that

$$(q_t := (\mathbf{1}_{i^o}, p_t) : (i^o, P) \to (i^o, X_t) \mid t = 1, 2)$$

is a universal cone in $\mathscr{C}$. Indeed, let (j^o, Y) be any object of $\mathscr{C}$ and $(r_t : (j^o, Y) \to (i^o, X_t) \mid t = 1, 2)$ a pair of morphisms of $\mathscr{C}$; we need to show that there exists a unique morphism

$$(4.3.22) \qquad r : (j^o, Y) \to (i^o, P) \qquad \text{in } \mathscr{C} \text{ such that} \qquad q_t \circ r = r_t \qquad \text{for } t = 1, 2.$$

By example 3.3.13(ii) we can write $r_t = g_t \circ s_t^{-1}$, where $s_t : (j_t^o, Y_t) \to (j^o, Y)$ and $g_t : (j_t^o, Y_t) \to (i^o, X_t)$ are morphisms of $\mathscr{F}ib(\mathscr{C}_\bullet)$, and s_t is cartesian, for $t = 1, 2$. By (CF3) of definition 1.6.14(i) we may then find an object (j'^o, Y') of $\mathscr{C}$ and morphisms $s'_t : (j'^o, Y') \to (j_t^o, Y_t)$ of $\mathscr{F}ib(\mathscr{C}_\bullet)$ such that $s'' := s_1 \circ s'_1 = s_2 \circ s'_2$ and such that s'_1 is cartesian; therefore s'' is an isomorphism in $\mathscr{C}$, so it suffices to check that there exists a unique morphism $r' : (j'^o, Y') \to (i^o, P)$ in $\mathscr{C}$ with $q_t \circ r' = r_t \circ s''$ for $t = 1, 2$. Thus, we may assume that r_t is the class of a morphism $(\rho_t^o, f_t) : (j^o, Y) \to (i^o, X_t)$ for $t = 1, 2$ (notation of (3.1.18), so here $\rho_t : i \to j$ is a morphism of I and $f_t : Y \to \mathscr{C}_{\rho_t} X_t$ is a morphism of $\mathscr{C}_j$ for $t = 1, 2$). Since I is filtered, we may then find a morphism $\rho' : j \to j'$ in I such that $\rho' \circ \rho_1 = \rho' \circ \rho_2$, and since $(\rho'^o, \mathbf{1}_{\mathscr{C}_\rho} Y) : (j'^o, \mathscr{C}_\rho Y) \to (j^o, Y)$ is an isomorphism in $\mathscr{C}$, we may further replace (ρ_t^o, f_t) by its composition with $(\rho'^o, \mathbf{1}_{\mathscr{C}_\rho} Y)$ for $t = 1, 2$, and assume as well that $\rho := \rho_1 = \rho_2$. In this situation set $P' = \mathscr{C}_\rho P$ and $X'_t := \mathscr{C}_\rho X_t$, $p'_t := \mathscr{C}_\rho(p_t)$ for $t = 1, 2$; we notice that r_t factors through a morphism $r'_t := (\mathbf{1}_{j^o}, f'_t) : (j^o, Y) \to (j^o, X'_t)$ and the cartesian morphism $(\rho, \mathbf{1}_{X'_t}) : (j^o, X'_t) \to (i^o, X_t)$, and moreover

$$(\rho, \mathbf{1}_{X'_t}) \circ (\mathbf{1}_{j^o}, p'_t) = (\mathbf{1}_{i^o}, p_t) \circ (\rho, \mathbf{1}_{P'}) \qquad \text{in } \mathscr{F}ib(\mathscr{C}_\bullet) \text{ for } t = 1, 2.$$

Since $\mathscr{C}_\rho$ is left exact, the cone $(p'_t : P' \to X'_t \mid t = 1, 2)$ is universal in $\mathscr{C}_j$, so there exists a unique morphism $g' : Y \to P'$ in $\mathscr{C}_j$ such that $p'_t \circ g' = f'_t$ for $t = 1, 2$. It follows that $r := (\rho, g') : (j^o, Y) \to (i^o, P)$ fulfills the condition of (4.3.22). It remains to check the uniqueness of r. Thus, let $r' : (j^o, Y) \to (i^o, P)$ be another morphism of $\mathscr{C}$ that verifies the identities of (4.3.22). We have $r' = g' \circ s'^{-1}$ for some morphisms g' and s' of $\mathscr{F}ib(\mathscr{C}_\bullet)$ with s' cartesian, and we are reduced to checking that $g' = r \circ s'$. We may then assume that r' is the class of a morphism (ρ'^o, g'') of $\mathscr{F}ib(\mathscr{C}_\bullet)$. Moreover, the identities (4.3.22) for r' mean that there exist cartesian morphisms $v_t : (k_t^o, Y'_t) \to (j^o, Y)$ such that $q_t \circ r' \circ v_t = r_t \circ v_t$ in $\mathscr{F}ib(\mathscr{C}_\bullet)$ for $t = 1, 2$. By (CF3) we may find an object (k^o, Y'') of $\mathscr{F}ib(\mathscr{C}_\bullet)$ and morphisms $v'_t : (k^o, Y'') \to (k_t^o, Y'_t)$ in $\mathscr{F}ib(\mathscr{C}_\bullet)$ with v'_1 cartesian, and such that $v'' := v_1 \circ v'_1 = v_2 \circ v'_2$. Since v'' is an isomorphism in $\mathscr{C}$, it suffices to check that $r \circ v'' = r' \circ v''$, and we may therefore assume that the identities (4.3.22) hold already in the category $\mathscr{F}ib(\mathscr{C}_\bullet)$, for both r and r'.

We may next find a morphism $\nu : j' \to j$ in I such that $\nu \circ \rho = \nu \circ \rho'$, and it suffices to check that $(\nu^o, \mathbf{1}_{\mathscr{C}_\nu Y}) \circ r = (\nu^o, \mathbf{1}_{\mathscr{C}_\nu Y}) \circ r'$. We may therefore assume that $\rho = \rho'$. Then both r and r' factor uniquely through morphisms $(\mathbf{1}_{j^o}, u), (\mathbf{1}_{j^o}, u') : (j^o, Y) \to (j^o, P')$ and the cartesian morphism $(\rho^o, \mathbf{1}_{P'}) : (j^o, P') \to (i^o, P)$, and we have

$$(\mathbf{1}_{j^o}, p'_t) \circ (\mathbf{1}_{j^o}, u) = r'_t = (\mathbf{1}_{j^o}, p'_t) \circ (\mathbf{1}_{j^o}, u') \qquad \text{in } \mathscr{F}ib(\mathscr{C}_\bullet) \text{ for } t = 1, 2.$$

Since P' represents $X'_1 \times X'_2$ in $\mathscr{C}_j$, we conclude that $u = u'$, whence $r = r'$ as required. $\lozenge$

Claim 4.3.23. All equalizers are representable in $\mathscr{C}$.

Proof of the claim. Let $(i_1^o, X_1), (i_2^o, X_2)$ be objects of $\mathscr{C}$ and $f_1, f_2 : (i_1^o, X_1) \to (i_2^o, X_2)$ morphisms of $\mathscr{C}$. We need to represent the equalizer of f_1 and f_2, and arguing as in the foregoing we may assume that $i := i_1 = i_2$, and also that f_t is the class of a morphism (φ_t, g_t) of $\mathscr{F}ib(\mathscr{C}_\bullet)$ for $t = 1, 2$. Then we may further reduce to the case where $\varphi := \varphi_1 = \varphi_2$. After replacing (i_2^o, X_2) by $(i_1^o, \mathscr{C}_\varphi X_2)$, we may then assume that $f_t = (\mathbf{1}_{i^o}, g_t) : (i^o, X_1) \to (i^o, X_2)$ for $t = 1, 2$. By assumption, the equalizer of g_1 and g_2 in $\mathscr{C}_i$ is representable by some $E \in \mathrm{Ob}(\mathscr{C}_i)$, and the universal cone for this equalizer amounts to a morphism $u : E \to X_1$ in $\mathscr{C}_i$ such that $g_1 \circ u = g_2 \circ u$. We claim that (i^o, E) represents the equalizer of f_1 and f_2, and that the morphism $(\mathbf{1}_{i^o}, u) : (i^o, E) \to (i^o, X_1)$ yields a universal cone for this equalizer. Indeed, let (j^o, Y) be an object of $\mathscr{C}$ and $h : (j^o, Y) \to (i^o, X_1)$ a morphism in $\mathscr{C}$ such that $f_1 \circ h = f_2 \circ h$; we need to show that h factors uniquely through u and a morphism $h' : (j^o, Y) \to (i^o, E)$. We reduce easily to the case where h is the class of a morphism $(\psi^o, k) : (j^o, Y) \to (i^o, X_1)$ of $\mathscr{F}ib(\mathscr{C}_\bullet)$ such that $(\mathbf{1}_{i^o}, g_1) \circ (\psi^o, k) = (\mathbf{1}_{i^o}, g_2) \circ (\psi^o, k)$ in $\mathscr{F}ib(\mathscr{C}_\bullet)$. In this situation, set $E' := \mathscr{C}_\psi E$, $u' := \mathscr{C}_\psi u$, $X'_t := \mathscr{C}_\psi X_t$ and $g'_t := \mathscr{C}_\psi g_t$ for $t = 1, 2$. Then (ψ^o, k) factors uniquely through the morphism $(\mathbf{1}_{j^o}, k) : (j^o, Y) \to (j^o, X'_1)$ and the cartesian morphism $(\psi^o, \mathbf{1}_{X'_1}) : (j^o, X'_1) \to (i^o, X_1)$, and we have $(\mathbf{1}_{j^o}, g'_1) \circ (\mathbf{1}_{j^o}, k) = (\mathbf{1}_{j^o}, g'_2) \circ (\mathbf{1}_{j^o}, k)$. Since $\mathscr{C}_\psi$ is left exact, E' represents the equalizer of g'_1 and g'_2 in $\mathscr{C}_j$, so there exists a unique morphism $k' : Y \to E'$ in $\mathscr{C}_j$ such that $u' \circ k' = k$. Then $h := (\psi, u')$ is the sought morphism. The verification of the uniqueness of h is analogous to that of the corresponding assertion in the proof of claim 4.3.21 : the details shall be left to the reader. $\lozenge$

Lastly, the constructions in the proof of claims 4.3.21 and 4.3.23 show that the functors π_i commute with finite products and equalizers, so they are left exact, by proposition 1.3.22(i). $\square$

4.3.24. Let now I be a small cofiltered category and $C_\bullet : I \to (\mathsf{U}, \mathsf{U}')\text{-lex}.\mathbf{Site}$ any pseudo-functor. For every $i \in \mathrm{Ob}(I)$, say that $C_i = (\mathscr{C}_i, J_i)$, and denote by $\mathscr{C}_\bullet : I^o \to \mathsf{U}'\text{-}\mathbf{Cat}$ the composition of $C_\bullet^o$ with the forgetful functor ${}^o(\mathsf{U}, \mathsf{U}')\text{-lex}.\mathbf{Site}^o \to \mathsf{U}'\text{-}\mathbf{Cat}$. We let $(\mathscr{C}, \pi_\bullet)$ be a strong 2-colimit of the pseudo-functor $\mathscr{C}_\bullet$ (theorem 3.3.9), and we endow $\mathscr{C}$ with the coarsest topology J such that all the functors $\pi_i : \mathscr{C}_i \to \mathscr{C}$ are continuous for the topologies J_i and J. In light of example 4.3.12 and lemma 4.3.20, we see that $C := (\mathscr{C}, J)$ is a lex-site, and we obtain a well defined pseudo-cone $\pi_\bullet^o : \mathsf{F}_C \Rightarrow C_\bullet$.

Proposition 4.3.25. *In the situation of* (4.3.24)*, let $F \in \mathrm{Ob}(\mathscr{C}^\wedge_{\mathsf{U}})$ be any presheaf. We have :*

(i) *The pair $(C, \pi_\bullet^o)$ is a strong 2-limit of $C_\bullet$.*
(ii) *F is a sheaf on C if and only if $\pi_i^\wedge(F)$ is a sheaf on C_i for every $i \in \mathrm{Ob}(I)$.*

Proof. (i): Let $D := (\mathscr{D}, J_{\mathscr{D}})$ be any finitely complete U-site, and $\varphi_\bullet : \mathsf{F}_D \Rightarrow C_\bullet$ any pseudo-cone. Hence for each $i \in \mathrm{Ob}(I)$ the functor $\varphi_i : \mathscr{C}_i \to \mathscr{D}$ is left exact and continuous for the topologies J_i and $J_{\mathscr{D}}$. There results a pseudo-cocone $\varphi_\bullet^a : \mathscr{C}_\bullet \Rightarrow \mathsf{F}_{\mathscr{D}}$, whence a unique functor $\varphi : \mathscr{C} \to \mathscr{D}$ such that $\mathsf{F}_\varphi \odot \pi_\bullet^o = \varphi^a$. The assertion then follows immediately from :

Claim 4.3.26. (i) The functor φ is left exact.

(ii) The functor φ is a morphism of sites $C \to D$.
(iii) C is a U-site.

Proof of the claim. (i): It suffices to check that φ commutes with all finite products and all equalizers of $\mathscr{C}$ (proposition 1.3.22(i)). Thus, let X_1, X_2 be two objects of $\mathscr{C}$, and P another object that represents $X_1 \times X_2$; pick also a universal cone for this product, given by a pair of morphisms $p_\bullet := (p_t : P \to X_t \mid t = 1, 2)$. By inspecting the proof of claim 4.3.21, we see that there exist $i \in \mathrm{Ob}(I)$ and objects $P', X'_1, X'_2 \in \mathrm{Ob}(\mathscr{C}_i)$ such that P' represents $X'_1 \times X'_2$ and the cone $p_\bullet$ is isomorphic to $\mathscr{C}_i * p'_\bullet$, where $p'_\bullet := (p'_t : P' \to X'_t \mid t = 1,2)$ is a universal cone in $\mathscr{C}_i$. Then $\varphi * p_\bullet$ is isomorphic to $\varphi_i * p'_\bullet$, and the latter is universal, since φ_i is left exact. This shows that φ commutes with binary products, and hence with all finite products. Similarly, by inspecting the proof of claim 4.3.23 we see that the universal cone of every equalizer in $\mathscr{C}$ is isomorphic to $\mathscr{C}_i * \tau$, for some $i \in \mathrm{Ob}(I)$ and with τ the universal cone of some equalizer in $\mathscr{C}_i$; then again we deduce easily that φ commutes with equalizers.

(ii): In view of (i) and example 4.3.12, it suffices to show that φ is continuous for the topologies J and $J_{\mathscr{D}}$. To this aim, let J' be the topology on $\mathscr{C}$ induced by $J_{\mathscr{D}}$ via φ; it suffices to check that $J \subset J'$. However, from lemma 4.2.4 we see that J is the coarsest topology on $\mathscr{C}$ such that for every $i \in \mathrm{Ob}(I)$, every $X \in \mathrm{Ob}(\mathscr{C}_i)$ and every covering family $(g_\lambda : X_\lambda \to X \mid \lambda \in \Lambda)$ for the topology J_i, the sieve generated by the family $(\pi_i(g_\lambda) \mid \lambda \in \Lambda)$ lies in $J(\pi_i(X))$. Thus, consider any such covering family $(g_\lambda \mid \lambda \in \Lambda)$; according to lemma 4.2.17(ii.b) we are further reduced to checking that the family $(\varphi \circ \pi_i(g_\lambda) \mid \lambda \in \Lambda)$ covers $\varphi \circ \pi_i(X) = \varphi_i(X)$ for the topology $\mathscr{D}$. Since $\varphi \circ \pi_i$ is continuous and $\mathscr{C}_i$ is finitely complete, the latter follows again from lemma 4.2.4.

(iii): For every $i \in \mathrm{Ob}(I)$ pick an essentially small topologically generating family $G_i \subset \mathrm{Ob}(\mathscr{C}_i)$ for the site C_i. It suffices to show that $G := \bigcup_{i \in \mathrm{Ob}(I)} \pi_i(G_i)$ is a topologically generating family for the site C. Thus, let $X \in \mathrm{Ob}(\mathscr{C})$ be any object; by inspecting the construction of $\mathscr{C}$ we find $i \in \mathrm{Ob}(I)$ and $X_i \in \mathrm{Ob}(\mathscr{C}_i)$ such that $X = \pi_i(X_i)$, and by assumption the family $\mathscr{F} := \bigcup_{Y \in G_i} \mathrm{Hom}_{\mathscr{C}_i}(Y, X_i)$ covers X_i for the topology J_i. Hence $(\pi_i(g) \mid g \in \mathscr{F}) \subset \bigcup_{Z \in G} \mathrm{Hom}_{\mathscr{C}}(Z, X)$ covers X for the topology J, whence the contention. ◇

(ii): The condition is obviously necessary. For the converse, we consider the finest topology J'' on $\mathscr{C}$ such that F is a sheaf on the site $(\mathscr{C}, J'')$ (see remark 4.1.8(iii)); it then suffices to show that $J \subset J''$. In view of remark 4.1.8(iii), we come down to checking the following. For every $i \in \mathrm{Ob}(I)$, every $X \in \mathrm{Ob}(\mathscr{C}_i)$, every covering family $(g_\lambda : X_\lambda \to X \mid \lambda \in \Lambda)$ for the topology J_i and every morphism $f : Y \to \pi_i X$ in $\mathscr{C}$, the family

$$(Y \times_{\pi_i X} \pi_i(g_\lambda) : Y \times_{\pi_i X} \pi_i X_\lambda \to Y \mid \lambda \in \Lambda)$$

generates a sieve of 2-descent for the fibration $\mathscr{F}ib(F) \to \mathscr{C}$ of (3.1.15). But recall that $\mathscr{C} = \mathscr{F}ib(\mathscr{C}_\bullet)[\Sigma^{-1}]$, where Σ denotes the set of cartesian morphisms of $\mathscr{F}ib(\mathscr{C}_\bullet)$. With this notation, we have $\pi_i X = (i^o, X)$ and $Y = (j^o, Y') = \pi_j Y'$ for some $j \in \mathrm{Ob}(I)$ and $Y' \in \mathrm{Ob}(\mathscr{C}_j)$. We are then easily reduced to the case where f is the class of a morphism $(\varphi^o, t) : (j^o, Y') \to (i^o, X)$ of $\mathscr{F}ib(\mathscr{C}_\bullet)$, for some morphism $\varphi : i \to j$ in I and $t : Y' \to \mathscr{C}_\varphi X$ in $\mathscr{C}_j$. Notice now the commutative diagrams :

$$\begin{array}{ccc} \pi_j(\mathscr{C}_\varphi X_\lambda) & \xrightarrow{\pi_j(\mathscr{C}_\varphi g_\lambda)} & \pi_j(\mathscr{C}_\varphi X) \\ {\scriptstyle (\varphi, \mathbf{1}_{\mathscr{C}_\varphi X_\lambda})}\downarrow & & \downarrow{\scriptstyle (\varphi, \mathbf{1}_{\mathscr{C}_\varphi X})} \\ \pi_i(X_\lambda) & \xrightarrow{\pi_i(g_\lambda)} & \pi_i(X) \end{array} \qquad \text{for every } \lambda \in \Lambda$$

whose vertical arrows are cartesian morphisms of $\mathscr{F}ib(\mathscr{C}_\bullet)$, so they are isomorphisms in $\mathscr{C}$. Moreover, the continuity of $\mathscr{C}_\varphi$ implies that the family $(\mathscr{C}_\varphi(g_\lambda) \mid \lambda \in \Lambda)$ covers $\mathscr{C}_\varphi X$ for the topology J_j. Furthermore, we have $(\varphi^o, t) = (\mathbf{1}_{j^o}, t) \circ (\varphi, \mathbf{1}_{\mathscr{C}_\varphi X})$. Thus, we may replace $(g_\lambda \mid \lambda \in \Lambda)$ by $(\mathscr{C}_\varphi(g_\lambda) \mid \lambda \in \Lambda)$ and assume that $i = j$ and $\varphi = \mathbf{1}_i$. In this situation, since π_i is left exact, we have natural identifications for every $\lambda, \mu \in \Lambda$:

$$Y_\lambda := Y \times_{\pi_i X} \pi_i X_\lambda \xrightarrow{\sim} \pi_i(Y' \times_X X_\lambda) \qquad Y_\lambda \times_Y Y_\mu \xrightarrow{\sim} \pi_i(Y' \times_X X_\lambda \times_X X_\mu).$$

So finally we are reduced to checking that the natural map from $F(\pi_i Y')$ to the equalizers of the restriction maps

$$\prod_{\lambda\in\Lambda} F\circ\pi_i(Y'\times_X X_\lambda) \rightrightarrows \prod_{\lambda,\mu\in\Lambda} F\circ\pi_i(Y'\times_X X_\lambda\times_X X_\mu)$$

is a bijection. But this is clear, since by assumption $F\circ\pi_i$ is a sheaf on C_i. □

Remark 4.3.27. In the situation of (4.3.24), we also claim that $C^\sim$ represents the 2-limit of the induced pseudo-functor

$$C^\sim_\bullet : I \to \mathsf{U}'\text{-}\mathbf{Cat} \qquad i\mapsto C^\sim_{i,\mathsf{U}} \qquad (\varphi : i\to j)\mapsto (C^\sim_\varphi : C^\sim_{i,\mathsf{U}} \to C^\sim_{j,\mathsf{U}}).$$

Indeed, on the one hand, the natural functor (see definition 2.5.1(ii))

$$\mathsf{PsFun}(\mathscr{C}, \mathbf{Set}^o) \to \mathsf{PsNat}(\mathscr{C}_\bullet, \mathsf{F}_{\mathbf{Set}^o}) \qquad (G : \mathscr{C}\to\mathbf{Set}^o)\mapsto \mathsf{F}_G\odot\pi_\bullet$$

is an equivalence; but we have $\mathsf{PsFun}(\mathscr{C}, \mathbf{Set}^o) = \mathscr{C}^\wedge$, and a pseudo-cocone $G_\bullet : \mathscr{C}_\bullet \Rightarrow \mathsf{F}_{\mathbf{Set}^o}$ is the datum of a system of presheaves G_i on $\mathscr{C}_i$ for every $i\in \mathrm{Ob}(I)$, with isomorphisms

$$\tau^G_\varphi : G_i \xrightarrow{\sim} \mathscr{C}^\wedge_\varphi G_j \qquad \text{in } \mathscr{C}^\wedge_i \text{ for every morphism } \varphi : i\to j \text{ in } I$$

fulfilling the usual coherence axioms. Under these identifications, a presheaf G on $\mathscr{C}$ corresponds to the datum $(G_\bullet, \tau^G_\bullet)$ with $G_i := \pi^\wedge_i G$ for every $i\in\mathrm{Ob}(I)$, and with

$$\tau^G_\varphi := (\tau^\pi_\varphi)^\wedge_G : \pi^\wedge_i G \xrightarrow{\sim} \mathscr{C}^\wedge_\varphi\circ\pi^\wedge_j G$$

where $(\tau^\pi_\varphi)^\wedge : \pi^\wedge_i \xrightarrow{\sim} \mathscr{C}^\wedge_\varphi\circ\pi^\wedge_j$ is the isomorphism of functors induced by the coherence constraint $\tau^\pi_\varphi : \pi_j \xrightarrow{\sim} \mathscr{C}_\varphi\circ\pi_i$ of the universal pseudo-cone $\pi_\bullet : \mathsf{F}_\mathscr{C} \Rightarrow \mathscr{C}_\bullet$, for every morphism $\varphi : i\to j$ in I. On the other hand, by proposition 4.3.25(ii), the presheaf G is a sheaf on C if and only if G_i is a presheaf on C_i for every $i\in\mathrm{Ob}(I)$. Summing up, we obtain a natural equivalence between $C^\sim$ and the category of pairs $(G_\bullet, \tau^G_\bullet)$ as above, such that G_i is a sheaf on C_i for every $i\in\mathrm{Ob}(I)$. But the latter is just a description of the category

$$\mathsf{Cart}_{I^o}(I^o, \mathscr{F}ib(C^\sim_\bullet))$$

which represents the 2-limit of $C^\sim_\bullet$, by the proof of theorem 3.3.9.

4.4. **Topoi.** Let U, U' be a pair of universes with $\mathsf{U}\in\mathsf{U}'$. A (U,U')-*topos* is a U'-small category with U-small Hom-sets which is equivalent to the category of sheaves on a U-small site. We shall often omit the explicit mention of U', and call "U-topos" such a category, or even just "topos" unless this may give rise to ambiguities.

Remark 4.4.1. Let T be any U-topos.

(i) Remark 4.1.19(i,ii) can be summarized by saying that T is a complete and cocomplete, well-powered and co-well-powered category. Moreover, every epimorphism in T is universal effective, every colimit is universal, and all filtered colimits in T commute with finite limits.

(ii) It follows from (i) that a small family $(F_i\to F \mid i\in I)$ of morphisms of T is a covering family for the canonical topology if and only if the induced morphism $\amalg_{i\in I}F_i \to F$ is an epimorphism in T.

(iii) Say that $T = C^\sim$, for a small site $C := (\mathscr{C}, J)$; then the set $\{h^a_X \mid X\in\mathrm{Ob}(\mathscr{C})\}$ is a small topologically generating family for the canonical site $\mathrm{Can}(T)$ (see remark 4.1.8(v)). Indeed, by virtue of remark 4.1.19(iii) we may find for every $F\in\mathrm{Ob}(T)$ a family $(X_i \mid i\in I)$ of objects of $\mathscr{C}$ with an epimorphism $\amalg_{i\in I}h^a_{X_i}\to F$ in the category $\mathscr{C}^\sim$, so the resulting family $(h^a_{X_i}\to F \mid i\in I)$ covers F for the canonical topology, by (ii). Especially, $\mathrm{Can}(T)$ is a U-site.

(iv) On the other hand, by proposition 4.3.18(ii), if C is a U-site, then $C^\sim$ is isomorphic to a U-topos.

Theorem 4.4.2. *Let $C := (\mathscr{C}, J)$ be a site such that $\mathscr{C}$ has small* Hom*-sets. We have :*

(i) *The Yoneda embedding $\mathscr{C} \to \mathscr{C}^\wedge$ is a morphism of sites $h_\mathscr{C} : C^\wedge \to C$ (notation of remark* 4.1.31(ii)*) and is cocontinuous for the topologies J and $J^\wedge$. Moreover the topology J is induced by $J^\wedge$ via the functor $h_\mathscr{C}$.*

(ii) *Suppose that C is a U-site. Then also the forgetful functor $i : C^\sim \to \mathscr{C}^\wedge$, its left adjoint $(-)^a : \mathscr{C}^\wedge \to C^\sim$ and the Yoneda embedding $h^a_C : \mathscr{C} \to C^\sim$ are morphisms of sites $C^\wedge \to \mathrm{Can}(C^\sim)$, $\mathrm{Can}(C^\sim) \to C^\wedge$ and $\mathrm{Can}(C^\sim) \to C$ respectively.*

(iii) *Moreover, in the situation of* (ii) *the functors $(-)^a$ and h^a_C are cocontinuous for the topologies J, $J^\wedge$ and $\mathrm{Can}_{C^\sim}$, and the topologies J and $J^\wedge$ are induced by the canonical topology of $C^\sim$, via the functors $h^a_C : \mathscr{C} \to C^\sim$ and $(-)^a$ respectively. Furthermore, for every universe V containing U, the functors i, $h_\mathscr{C}$, h^a_C, $(-)^a$ induce equivalences :*

$$\begin{array}{ccc} \mathrm{Can}(C^\sim)^\sim_\mathsf{V} & \overset{((-)^a)^\sim_*}{\underset{\widetilde{\imath}_*}{\rightleftarrows}} & (C^\wedge)^\sim_\mathsf{V} \\ & {\scriptstyle \widetilde{h}^a_{C*}} \searrow \quad \swarrow {\scriptstyle \widetilde{h}_{\mathscr{C}*}} & \\ & C^\sim_\mathsf{V}. & \end{array}$$

(iv) *For every topos T, the Yoneda embedding induces an equivalence*

$$h_T : T \to \mathrm{Can}(T)^\sim \qquad F \mapsto h_F.$$

Proof. (i): Pick a universe V containing U, and such that $C^\wedge$ is a V-site; denote by J' the topology on $\mathscr{C}$ induced by $J^\wedge$ on $\mathscr{C}$ via $h_\mathscr{C}$. Notice that condition (a) of theorem 4.3.13 holds for the functor $h_\mathscr{C}$, by virtue of remark 4.4.1(iii), and conditions (b) and (c) hold as well, since $h_\mathscr{C}$ is fully faithful (remark 4.3.17(i)). By theorem 4.3.13(iii) it follows that a family of morphisms $(Y_i \to Y \mid i \in I)$ in $\mathscr{C}$ covers Y in the topology J' if and only if the family $(h_{Y_i} \to h_Y \mid i \in I)$ covers h_Y in the topology $J^\wedge$. Combining with remark 4.1.29(i) we deduce that $J' = J$. Moreover, by theorem 4.3.13(ii), the functor $(h_\mathscr{C})^\sim_{\mathsf{V}*} : (C^\wedge)^\sim_\mathsf{V} \to C^\sim_\mathsf{V}$ is an equivalence, so the same holds for its left adjoint $(h^*_\mathscr{C})^\sim_\mathsf{V}$, and especially, $h_\mathscr{C}$ is a morphism of sites, as stated.

(ii): Let us remark :

Claim 4.4.3. The functor $(-)^a : \mathscr{C}^\wedge \to C^\sim$ satisfies conditions (a),(b),(c) of theorem 4.3.13 for the topology $\mathrm{Can}_{C^\sim}$.

Proof of the claim. Indeed, to check condition (a) it suffices to remark that $(iF)^a$ is isomorphic to F, for every $F \in \mathrm{Ob}(C^\sim)$. Next, let $F, G \in \mathrm{Ob}(\mathscr{C}^\wedge)$ and $\varphi : F^a \to G^a$ a morphism in $C^\sim$; we may find a family $(f_j : h_{X_j} \to F \mid j \in I)$ of morphisms in $\mathscr{C}^\wedge$ such that the induced morphism $\mu : \amalg_{j\in I} h_{X_j} \to F$ is an epimorphism (lemma 1.4.8). The composition

$$\varphi_j : h_{X_j} \xrightarrow{f_j} F \to F^a \xrightarrow{\varphi} G^a \qquad \text{for every } j \in J$$

corresponds to a section $\sigma_j \in G^a(X_j)$. Then we may find for every $j \in I$ a covering family $(f_{jk} : X_{jk} \to X_j \mid k \in I_j)$ for the topology J, and a section $\sigma_{jk} : G(X_{jk})$ for every $k \in I_j$, whose image in $G^a(X_{jk})$ agrees with $G^a(f_{jk})(\sigma_j)$. The section σ_{jk} corresponds to a morphism $\psi_{jk} : h_{X_{jk}} \to G$ in $\mathscr{C}^\wedge$, whose composition with the natural morphism $G \to G^a$ agrees with $\varphi_j \circ h_{f_{jk}}$. Moreover, for every $j \in J$ the resulting morphism $\nu_j : \amalg_{k\in I_j} h_{X_{jk}} \to h_{X_j}$ of $\mathscr{C}^\wedge$ induces an epimorphism ν^a in $C^\sim$ (remark 4.1.29(i) and corollary 4.1.30(i)); likewise μ^a is an epimorphism in $C^\sim$, by virtue of proposition 1.3.25(v). Thus, the family $(f^a_j \circ h^a_{f_{jk}} : h^a_{X_{jk}} \to F^a \mid j \in I,\ k \in I_j)$ covers F^a for the topology $\mathrm{Can}_{C^\sim}$ (remark 4.4.1(ii)), and by construction we have $\varphi \circ (f_j \circ h_{f_{jk}})^a = \psi^a_{jk}$ for every $j \in I$ and every $k \in I_j$. This shows that condition (b) holds. Lastly, let $\varphi, \varphi' : F \to G$ be two morphisms of $\mathscr{C}^\wedge$ such that $\varphi^a = \varphi'^a$, and choose again a family $(f_j : h_{X_j} \to F \mid j \in I)$ as in the foregoing; each f_j corresponds to a section $\sigma_j \in FX_j$, and by assumption the images of $\varphi_{X_j}(\sigma_j)$ and $\varphi'_{X_j}(\sigma_j)$ agree in $G^a(X_j)$. Then we may find for every $j \in I$ a covering family $(f_{jk} : X_{jk} \to X_j \mid k \in I_j)$ such that

$$\varphi_{X_{jk}} \circ (Ff_{jk})(\sigma_j) = (Gf_{jk}) \circ \varphi_{X_j}(\sigma_j) = (Gf_{jk}) \circ \varphi'_{X_j}(\sigma_j) = \varphi'_{X_{jk}} \circ (Ff_{jk})(\sigma_j)$$

for every $k \in I_j$. Again, the family $(f_j^a \circ h^a_{f_{jk}} : h^a_{X_{jk}} \to F^a \mid j \in I,\ k \in I_j)$ covers F^a for the topology $\mathrm{Can}_{C^\sim}$, and $\varphi \circ f_j \circ h_{f_{jk}} = \varphi' \circ f_j \circ h_{f_{jk}}$ for every $j \in I$ and every $k \in I_j$. This shows that also condition (c) holds. ♢

Let J' be the topology on $\mathscr{C}^\wedge$ induced by $\mathrm{Can}_{C^\sim}$ via the functor $(-)^a$; since $C^\sim$ is isomorphic to a U-site (remark 4.4.1(iv)), theorem 4.3.13 and claim 4.4.3 imply that $(-)^a : (\mathscr{C}^\wedge, J') \to \mathrm{Can}(C^\sim)$ is continuous and cocontinuous, and a family $(F_j \to F \mid j \in I)$ of morphisms in $\mathscr{C}^\wedge$ generates a covering sieve for the topology J' if and only if the family $(F_j^a \to F^a \mid j \in I)$ generates a covering sieve for the topology $\mathrm{Can}_{C^\sim}$. But the latter condition holds if and only if the family $(F_j \to F \mid j \in I)$ generates a covering sieve for the topology $J^\wedge$, by virtue of remark 4.1.31(i). In other words, $J' = J^\wedge$, and thus theorem 4.3.13 also says that $(-)^a$ induces an equivalence $((-)^a)^\sim_{\mathsf{V}*} : \mathrm{Can}(C^\sim)^\sim_{\mathsf{V}} \xrightarrow{\sim} (\mathscr{C}^\wedge, J')^\sim_{\mathsf{V}}$ for every universe V containing U. Then also the left adjoint of $((-)^a)^\sim_{\mathsf{V}*}$ is an equivalence, and especially $(-)^a : \mathrm{Can}(C^\sim) \to C^\wedge$ is a morphism of sites. Lastly, since $(-)^a \circ i = \mathbf{1}_{C^\sim}$, we see that $\tilde{\imath}_{\mathsf{V}*} : (C^\wedge)^\sim_{\mathsf{V}} \to \mathrm{Can}(C^\sim)^\sim_{\mathsf{V}}$ is an equivalence as well, and so is its left adjoint (which is $((-)^a)^\sim_{\mathsf{V}*}$); especially, $i : C^\wedge \to \mathrm{Can}(C^\sim)$ is a morphism of sites.

Claim 4.4.4. The Yoneda embedding $h^a_C : \mathscr{C} \to C^\sim$ fulfills conditions (a),(b),(c) of theorem 4.3.13, for the canonical topology on $C^\sim$.

Proof of the claim. Indeed, condition (a) has already been noticed in remark 4.4.1(iii). Next, let $X, Y \in \mathrm{Ob}(\mathscr{C})$ and $\varphi : h^a_X \to h^a_Y$ any morphism of $C^\sim$; then φ corresponds to a section $s \in h^a_Y(X)$, which in turn is represented by the datum of a covering family $(f_i : X_i \to X \mid i \in I)$ for the topology J and a compatible system of morphisms $(s_i : X_i \to Y \mid i \in I)$ in $\mathscr{C}$. With this notation, $h^a_{f_i}(s)$ is the image of s in $h^a_Y(X_i)$, so we get $h^a_{s_i} = \varphi \circ h^a_{f_i}$ for every $i \in I$. Lastly, the family $(h^a_{f_i} : h^a_{X_i} \to h^a_X \mid i \in I)$ covers $h^a_{X_i}$ in the canonical topology, by remarks 4.4.1(ii) and 4.1.29(i) and corollary 4.1.30(i).

To check condition (c), consider morphisms $\varphi, \psi : X \to Y$ in $\mathscr{C}$ such that $h^a_\varphi = h^a_\psi$. The latter means that the images $\overline{\varphi}$ and $\overline{\psi}$ of φ and ψ agree in $h^a_Y(X)$, so there exists a covering family $(f_i : X_i \to X \mid i \in I)$ such that $h^a_Y(f_i)(\overline{\varphi}) = h^a_Y(f_i)(\overline{\psi})$ for every $i \in I$. This in turn translates as the identity $\varphi \circ f_i = \psi \circ f_i$ for every $i \in I$. To conclude, we observe as in the foregoing that the family $(h^a_{f_i} : h^a_{X_i} \to h^a_X \mid i \in I)$ covers h^a_X in the topology $\mathrm{Can}_{C^\sim}$. ♢

Let J' be the topology on $\mathscr{C}$ induced by $\mathrm{Can}_{C^\sim}$ via $h^a_{\mathscr{C}}$; since we have already noticed that $C^\sim$ is isomorphic to a U-site, claim 4.4.4 and theorem 4.3.13 imply that $h^a_{\mathscr{C}}$ induces an equivalence $H_{\mathsf{V}} := (h^a_C)^\sim_{\mathsf{V}*} : \mathrm{Can}(C^\sim)^\sim_{\mathsf{V}} \xrightarrow{\sim} (\mathscr{C}, J')^\sim_{\mathsf{V}}$ for every universe V containing U. Moreover, arguing as in the foregoing we deduce that $J' = J$. Thus, we get an equivalence $H : \mathrm{Can}(C^\sim)^\sim \xrightarrow{\sim} C^\sim$, which as usual implies that $h^a_C : C^\sim \to C$ is a morphism of sites, concluding the proof of (ii) and (iii). Lastly, by a simple inspection we see that $H \circ h_{C^\sim}$ is naturally isomorphic to $\mathbf{1}_{C^\sim}$, whence (iv). □

Definition 4.4.5. (i) Let S and T be two topoi. A *morphism of topoi* $f : T \to S$ is a datum

$$(f^*, f_*, \eta) \qquad \text{where} \qquad f_* : T \to S \qquad f^* : S \to T$$

are two functors such that f^* is left exact and left adjoint to f_*, and $\eta : \mathbf{1}_S \Rightarrow f_*f^*$ is a unit of an adjunction ϑ for the pair (f^*, f_*) (these are sometimes called *geometric morphisms* : see [30, Def.2.12.1]). We shall say that η and ϑ are respectively *the unit and the adjunction of* f.

(ii) Let $f := (f^*, f_*, \eta_f) : T'' \to T'$ and $g := (g^*, g_*, \eta_g) : T' \to T$ be two morphisms of topoi. The composition $g \circ f$ is the morphism

$$(f^* \circ g^*, g_* \circ f_*, (g_* * \eta_f * g^*) \odot \eta_g) : T'' \to T$$

(see remark 1.1.17(i)). To check the associativity of this composition law, it suffices to notice that $(g_* * \eta_f * g^*) \odot \eta_g$ is the unit of the composition of the adjunctions determined by η_f and η_g, as defined in remark 1.1.17(i). For every topos T, let $i_T : \mathbf{1}_T \stackrel{\sim}{\to} \mathbf{1}_T$ be the identity automorphism of $\mathbf{1}_T$; the datum

$$(\mathbf{1}_T, \mathbf{1}_T, , i_T)$$

yields a morphism of topoi $T \to T$ which is neutral for left and right compositions relative to the foregoing composition law.

(iii) Let $f, g : T \to S$ be two morphisms of topoi. A *natural transformation* $\tau : f \Rightarrow g$ is just a natural transformation of functors $\tau_* : f_* \Rightarrow g_*$. Notice that, in view of remark 1.1.17(ii), the datum of τ_* is the same as the datum of a natural transformation $\tau^* : g^* \Rightarrow f^*$.

(iv) Let U' be a universe with $\mathsf{U} \in \mathsf{U}'$; the $(\mathsf{U}, \mathsf{U}')$-topoi are the objects of the 2-category

$$(\mathsf{U}, \mathsf{U}')\text{-}\mathbf{Topos}$$

whose 1-cells are the morphisms of topoi, and whose 2-cells are the natural transformations between such morphisms. Obviously this category depends on the choice of U', but two different choices are related by a 2-equivalence of 2-categories, so we shall usually omit mentioning an explicit choice of U', and write U-$\mathbf{Topos}$ for this 2-category. Moreover, when the choice of U is clear from the context, we shall likewise drop the mention of U and write just $\mathbf{Topos}$.

Example 4.4.6. Let $T_\bullet := (T_i \mid i \in I)$ be any U-small family of $(\mathsf{U}, \mathsf{U}')$-topoi.

(i) The product category $T := \prod_{i \in I} T_i$ is a topos (see example 1.2.25(i)). Indeed, pick for each $i \in I$ a small site $C_i := (\mathscr{C}_i, J_i)$ with an equivalence $C_i^\sim \stackrel{\sim}{\to} T_i$; according to example 1.2.25(i), the coproduct of the family of categories $(\mathscr{C}_i \mid i \in I)$, is represented by a category $\mathscr{C}$ whose set of objects is the disjoint union $\amalg_{i \in I} \mathrm{Ob}(\mathscr{C}_i)$. We endow $\mathscr{C}$ with the topology J such that $J(i, X) := J_i(X)$ for every $(i, X) \in \mathrm{Ob}(\mathscr{C})$. Then it is easily seen that there is a natural isomorphism of categories

$$(\mathscr{C}, J)^\sim \stackrel{\sim}{\to} \prod_{i \in I} C_i^\sim .$$

However, the product of the categories $C_i^\sim$ also represents the 2-product, in the 2-category U'-$\mathbf{Cat}$, of the same family of categories, and the standard universal cone is also a universal pseudo-cone (see example 3.3.12); there follows an equivalence of categories

$$(\mathscr{C}, J)^\sim \stackrel{\sim}{\to} T$$

whence the contention.

(ii) Moreover, T represents the 2-coproduct of the family $T_\bullet$ in the 2-category $\mathbf{Topos}$. Indeed, for every $i \in I$ let $\pi_i : T \to T_i$ be the projection functor. We define a right adjoint $e_i : T_i \to T$ for π_i by the rule : $X \mapsto (X_j \mid j \in I)$ for every $X \in \mathrm{Ob}(T_i)$, where $X_i := X$ and $X_j := 1_{T_j}$ is a fixed choice of a final object in T_j, for every $j \in I \setminus \{i\}$. It is easily seen that π_i is left exact, and there is a natural choice of adjunction for the pair (π_i, e_i), whence a well defined morphism of topoi

$$\varphi_i : T_i \to T \qquad \text{such that } \varphi_i^* = \pi_i \text{ and } \varphi_{i*} := e_i.$$

Next, let S be another topos, and $(\psi_i : T_i \to S \mid i \in I)$ a given family of morphisms of topoi. By the universal property of the product, there exists a unique functor $\lambda^* : S \to T$ such that

$$\varphi_i^* \circ \lambda^* = \psi_i^* \qquad \text{for every } i \in I \tag{4.4.7}$$

and it is easily seen that λ^* is left exact. We construct a right adjoint $\lambda_* : T \to S$ for λ^* by the following rule. Given any object $X_\bullet := (X_i \mid i \in I)$ of T, let $\lambda_*(X_\bullet)$ be any object of S representing the product $\prod_{i \in I} \psi_{i*} X_i$, and fix as well a universal cone $(p_i^X : \lambda_*(X_\bullet) \to$

$\psi_{i*}X_i \mid i \in I)$. Then, for every morphism $f_\bullet : X_\bullet \to Y_\bullet$ in T there is a unique morphism $\lambda_*(f_\bullet) : \lambda_*(X_\bullet) \to \lambda_*(Y_\bullet)$ that makes commute the diagram

$$\begin{array}{ccc} \lambda_*(X_\bullet) & \xrightarrow{\lambda_*(f_\bullet)} & \lambda_*(Y_\bullet) \\ {\scriptstyle p_i^X}\downarrow & & \downarrow{\scriptstyle p_i^Y} \\ \psi_{i*}X_i & \xrightarrow{\psi_{i*}f_i} & \psi_{i*}Y_i \end{array} \qquad \text{for every } i \in I.$$

Thus, the rules $X_\bullet \mapsto \lambda_*(X_\bullet)$ and $f_\bullet \mapsto \lambda_*(f_\bullet)$ yield a well defined functor as sought, unique up to unique isomorphism. Then it is easily seen that λ^* is left adjoint to λ_*, and there is even a natural choice of adjunction for the pair (λ^*, λ_*) (details left to the reader), so the latter yields a well defined morphism of topoi $\lambda : T \to S$. Lastly, (4.4.7) implies that $\lambda_* \circ \varphi_*$ is right adjoint to ψ_i^*, whence an isomorphism of functors

$$\lambda_* \circ \varphi_* \xrightarrow{\sim} \psi_{i*} \qquad \text{for every } i \in I$$

which shows that the system $(\varphi_i \mid i \in I)$ is a universal pseudo-cocone, whence the contention.

Proposition 4.4.8. *Let T, T' be two topoi, $f : T \to T'$ a left exact functor, φ a morphism of T.*

- (i) *If f commutes with all small colimits in T, the following holds :*
  - (a) *f is continuous for the canonical topologies on T and T'.*
  - (b) *There exists a morphism of topoi $F : T' \to T$, unique up to unique isomorphism, such that $F^* = f$.*
- (ii) *f is conservative if and only if it reflects epimorphisms.*
- (iii) *If f is exact, the natural morphism $f(\mathrm{Im}\,\varphi) \to \mathrm{Im}(f\varphi)$ is an isomorphism.*

Proof. (i.a): Let $S := \{g_i : X_i \to X \mid i \in I\}$ be a small covering family of morphisms in Can_T; by lemma 4.2.4, it suffices to show that $fS := \{f(g_i) \mid i \in I\}$ is a covering family in $\mathrm{Can}_{T'}$. However, our assumption implies that the induced morphism $\amalg_{i \in I} X_i \to X$ is an epimorphism, hence the same holds for the induced morphism $\amalg_{i \in I} fX_i \to fX$ in T' (by proposition 1.3.18(ii)). But all epimorphisms are universal effective in T' (remark 4.4.1(i)), hence $(f(g_i) \mid i \in I)$ is a universal effective family, as required.

(i.b): By corollary 4.3.19(i.a,i.c), the functor f gives rise to a morphism of topoi

$$(\widetilde{f}^*, \widetilde{f}_*, \eta) : \mathrm{Can}(T')^\sim \to \mathrm{Can}(T)^\sim$$

(where η is any choice of unit of adjunction), and it suffices to show that $\widetilde{f}^*$ is isomorphic to f, under the natural identifications $T \xrightarrow{\sim} \mathrm{Can}(T)^\sim$, $T' \xrightarrow{\sim} \mathrm{Can}(T')^\sim$ given by the Yoneda embeddings. The latter follows from corollary 4.3.19(i.b).

(iii) follows easily from remark 4.1.25.

(ii) follows from propositions 4.1.24(i) and 1.3.21. □

Remark 4.4.9. (i) Let us consider the 2-category $(\mathsf{U}, \mathsf{U}')$-$\mathbf{Topos}^*$ whose objects are the same as those of the 2-category $(\mathsf{U}, \mathsf{U}')$-$\mathbf{Topos}$, and such that for every two U-topoi T and S, the 1-cells $f : T \to S$ are the left exact functors $f : S \to T$ that commute with all small colimits. For any pair of such functors $f, f' : S \to T$, the 2-cells $\beta : f \Rightarrow f'$ of $(\mathsf{U}, \mathsf{U}')$-$\mathbf{Topos}^*$ are the natural transformations $\beta : f' \Rightarrow f$. As usual, we shall often write U-$\mathbf{Topos}^*$ or just $\mathbf{Topos}^*$ for this 2-category. We have a natural strict pseudo-functor

$$(-)^* : \mathbf{Topos} \to \mathbf{Topos}^*$$

that is the identity on objects, and assigns to every morphism $f := (f^*, f_*, \eta_f) : T \to S$ of topoi the functor $f^* : S \to T$, and to every natural transformation $\beta : (f^*, f_*, \eta_f) \Rightarrow (g^*, g_*, \eta_g)$ the adjoint transformation $(\beta, \eta_f, \eta_g)^\dagger : g^* \Rightarrow f^*$. Then proposition 4.4.8(i.b) can be restated by saying that $(-)^*$ is a strict 2-equivalence of 2-categories.

(ii) Notice also the strict pseudo-functors

$$\mathsf{U}'\text{-}\mathbf{Cat}^o \xleftarrow{(-)^*} \mathbf{Topos} \xrightarrow{(-)_*} \mathsf{U}'\text{-}\mathbf{Cat}$$

defined as follows. The pseudo-functor $(-)_*$ is the identity map on objects : $T \mapsto T$, and is given on morphisms by the rule : $(F_*, F^*, \eta_F) \mapsto F_*$ (notation of definition 4.4.5(i)). On natural transformations it is also the identity : $(\tau : (F^*, F_*, \eta_F) \Rightarrow (G^*, G_*, \eta_G)) \mapsto (\tau : F_* \Rightarrow G_*)$.

The pseudo-functor $(-)^*$ is given on objects by the rule : $T \mapsto T^o$, and on morphisms by the rule : $(F^*, F_*, \eta_F) \mapsto (F^*)^o$. On natural transformations it is defined by the rule :

$$(\tau : (F^*, F_*, \eta_F) \Rightarrow (G^*, G_*, \eta_G)) \mapsto ((\tau, \vartheta_F, \vartheta_G)^{\dagger o} : F^{*o} \Rightarrow G^{*o})$$

where ϑ^F and ϑ^G are the adjunctions for the pairs (F^*, F_*) and respectively (G^*, G_*) whose units are η_F and respectively η_G, and $(\tau, \vartheta_F, \vartheta_G)^\dagger$ is the adjoint to τ, as in remark 1.1.17(ii). The pseudo-functoriality of $(-)^*$ follows straightforwardly from remark 1.1.17(iv,v) : the details shall be left to the reader.

Example 4.4.10. Let T be a topos.

(i) Say that $T = (\mathscr{C}, J)^\sim$ for a small site $(\mathscr{C}, J)$. According to remark 4.1.8(vi), the category $\mathscr{C}^\wedge$ is also a topos, and since the functor $F \mapsto F^a$ of theorem 4.1.13 is left exact, it determines a morphism of topoi $T \to \mathscr{C}^\wedge$. (On the other hand, the category $T^\wedge$ is too large to be a U-topos.)

(ii) Let $f := (f^*, f_*, \eta) : T \to S$ be any morphism of topoi; we have an essentially commutative diagram whose horizontal arrows are the Yoneda embeddings :

$$\begin{array}{ccc} T & \xrightarrow{h_T} & \mathrm{Can}(T)^\sim \\ {\scriptstyle f_*}\downarrow & & \downarrow{\scriptstyle (f^*)^\sim_*} \\ S & \xrightarrow{h_S} & \mathrm{Can}(S)^\sim. \end{array}$$

Indeed, an isomorphism $(f^*)^\sim_* \circ h_T \xrightarrow{\sim} h_S \circ f_*$ is given explicitly as follows. Let ϑ be the adjunction for the pair (f^*, f_*) resulting from the unit η. So, ϑ consists of a system of bijections:

$$h_X \circ f^*(Y) = \mathrm{Hom}_T(f^*Y, X) \xrightarrow{\vartheta_{Y,X}} \mathrm{Hom}_S(Y, f_*X) = h_{f_*X}(Y)$$

natural in $X \in \mathrm{Ob}(T)$ and $Y \in \mathrm{Ob}(S)$. The naturality with respect to morphisms $Y' \to Y$ in S then implies that the rule $Y \mapsto \vartheta_{Y,X}$ is an isomorphism of sheaves $\vartheta_{\bullet,X} : h_X \circ f^* \xrightarrow{\sim} h_{f_*X}$ for every $X \in \mathrm{Ob}(T)$. Lastly, the naturality with respect to morphisms $X \to X'$ in T says that the rule $X \mapsto \vartheta_{\bullet,X}$ yields an isomorphism of functors as sought : the details are left to the reader.

4.4.11. *Global section functors.* In view of theorem 4.4.2(iv), the objects of any topos T may be thought of as sheaves on $\mathrm{Can}(T)$, and one uses often the suggestive notation

$$X(S) := \mathrm{Hom}_T(S, X) \qquad \text{for every } X, S \in \mathrm{Ob}(T).$$

The elements of $X(S)$ are also called the *S-sections* of X. If 1_T is any final object of T, one defines the *global sections functor* $\Gamma : T \to \mathbf{Set}$ by the rule :

$$U \mapsto \Gamma(T, U) := U(1_T).$$

Moreover Γ admits a left adjoint :

$$(-)_T : \mathbf{Set} \to T \ : \ S \mapsto S_T := S \times 1_T$$

(the coproduct of S copies of 1_T) and one calls S_T the *constant sheaf with value S*.

Proposition 4.4.12. *With the notation of* (4.4.11)*, we have :*

(i) *The functor $(-)_T$ is exact, hence the pair $((-)_T, \Gamma)$ yields a morphism of topoi*

$$\Gamma_T : T \to \mathbf{Set}.$$

(ii) *For every pair of morphisms of topoi* $u, v : T \to \mathbf{Set}$ *there exists a unique natural transformation* $\beta : u_* \Rightarrow v_*$*, and* β *is an isomorphism of functors.*

(iii) *For every morphism* $f : T \to S$ *of topoi, there exists a unique isomorphism :*

$$\Gamma_S \circ f \stackrel{\sim}{\to} \Gamma_T.$$

Proof. (See [8, Exp.IV, §4.3]). For the proof of (i), we may assume that $T = C^\sim$ for a small site $C := (\mathscr{C}, J)$. Then, for every (small) set S, let $c_S : \mathscr{C}^o \to \mathbf{Set}$ be the constant presheaf on $\mathscr{C}$ with value S; since the colimits in $\mathscr{C}^o$ are computed argumentwise (corollary 1.4.3(ii)), we have $c_S = \coprod_{s \in S} c_{\{s\}}$, whence $S_T = c_S^a$, since the functor $(-)^a$ commutes with small colimits. Since $(-)^a$ is an exact functor (theorem 4.1.13(ii)), it suffices to check that the same holds for the functor $\mathbf{Set} \to \mathscr{C}^o : S \mapsto c_S$. But more precisely, the latter commutes with all small limits and all small colimits, again because the latter are computed argumentwise.

(ii): Since u^* is exact, $u^*(\{\varnothing\})$ is a final object of T, and we get natural bijections :

$$u_* X \stackrel{\sim}{\to} \mathrm{Hom}_{\mathbf{Set}}(\{\varnothing\}, u_* X) \stackrel{\sim}{\to} \mathrm{Hom}_T(u^*(\{\varnothing\}), X) \qquad \text{for every } X \in \mathrm{Ob}(T)$$

i.e. the presheaf $u_* : T \to \mathbf{Set}$ on the category T^o is represented by the initial object $u^*(\{\varnothing\})^o$. The same applies to v_*, and then Yoneda's lemma yields natural bijections

$$\mathrm{Hom}_{(T^o)^\wedge}(u_*, v_*) \stackrel{\sim}{\to} \mathrm{Hom}_T(v^*(\{\varnothing\}), u^*(\{\varnothing\})) \stackrel{\sim}{\to} \{\varnothing\}$$

whence the contention.

(iii) is an immediate consequence of (ii). □

Remark 4.4.13. (i) If T is a U-topos, $C := (\mathscr{C}, J)$ is a U-lex-site, and $g : \mathrm{Can}(T) \to C$ is a morphism of sites, then the underlying functor $g : \mathscr{C} \to T$ is left exact. Indeed, by corollary 4.3.19(i.b) we have an essentially commutative diagram of functors whose vertical arrows are the Yoneda embeddings :

(4.4.14)
$$\begin{array}{ccc} \mathscr{C} & \xrightarrow{g} & T \\ {\scriptstyle h^a_{\mathscr{C}}}\downarrow & & \downarrow{\scriptstyle h_T} \\ C^\sim & \xrightarrow{\widetilde{g}^*} & \mathrm{Can}(T)^\sim. \end{array}$$

Then, h_T is an equivalence (theorem 4.4.2(iv)) and $\widetilde{g}^*$ is left exact, since g is a morphism of sites; it suffices therefore to show that $h^a_{\mathscr{C}}$ is left exact. But the functor $(-)^a : \mathscr{C}^\wedge \to C^\sim$ is left exact by theorem 4.1.13(ii), so the assertion follows from corollary 1.4.3(vi).

(ii) Every morphism of U-sites $u : C' \to C$ induces a morphism of topoi

$$\widetilde{u} := (\widetilde{u}^*, \widetilde{u}_*, \widetilde{\eta}^u) : C'^\sim \to C^\sim$$

after choosing a unit $\widetilde{\eta}^u$ for the adjoint pair $(\widetilde{u}^*, \widetilde{u}_*)$ (corollary 4.3.19(i)).

(iii) Conversely, a morphism $(f^*, f_*, \eta) : T \to S$ of topoi determines a morphism of sites

$$f^* : \mathrm{Can}(T) \to \mathrm{Can}(S).$$

Indeed, $g := f^* : S \to T$ is continuous for the canonical topologies, by virtue of proposition 4.4.8(i), and by corollary 4.3.19(i.b) we have an essentially commutative diagram of functors as in (4.4.14), with $\mathscr{C} := S$ and $C = \mathrm{Can}(S)$. In this case, both vertical arrows of (4.4.14) are equivalences (theorem 4.4.2(iv)). Since g is left exact, it then follows that the same holds for $\widetilde{g}^*$, whence the assertion.

(iv) Likewise, for every pair of U-sites $C := (\mathscr{C}, J), C' := (\mathscr{C}', J')$, for every cocontinuous functor $v : \mathscr{C} \to \mathscr{C}'$, it is clear that $\breve{v}^*$ is an exact functor, so v induces a morphism of topoi

$$\breve{v} := (\breve{v}^*, \breve{v}_*, \breve{\eta}^v) : C^\sim \to C'^\sim$$

(corollary 4.3.19(ii)), after choosing a unit $\breve{\eta}^v$ for the adjoint pair $(\breve{v}^*, \breve{v}_*)$.

(v) In the situation of (iv), suppose that v admits a right adjoint u. Then u is continuous for the topologies of the sites C and C', and $\widetilde{u}^*$ is isomorphic to $\breve{v}^*$ (lemma 4.2.14). Especially, $\widetilde{u}^*$ is exact, so u is a morphism of sites, and we have an isomorphism of morphisms of topoi :

$$\widetilde{u} \stackrel{\sim}{\to} \breve{v}.$$

4.4.15. We define as follows a pair of pseudo-functors

$$\mathbf{Site} \underset{\mathrm{Can}}{\overset{\mathsf{T}}{\rightleftarrows}} \mathbf{Topos}.$$

Let C be a U-site; by remark 4.4.1(iv) we may find an isomorphism of topoi

$$\omega_C : C^\sim \stackrel{\sim}{\to} \mathsf{T}(C)$$

with a U-topos $\mathsf{T}(C)$, and it is easily seen that we may take this topos to be also U'-small. Then the rule : $C \mapsto \mathsf{T}(C)$ defines the pseudo-functor T on objects. Next, let $g : C \to C'$ be any morphism of U-sites; by remark 4.4.13(ii), any choice of a unit η^g for the adjoint pair $(\widetilde{g}^*, \widetilde{g}_*)$ yields a morphism of topoi $\widetilde{g} : C^\sim \to C'^\sim$. There follows easily a unique morphism of U-topoi

$$\mathsf{T}(g) := (\mathsf{T}(g)^*, \mathsf{T}(g)_*, \eta^{\mathsf{T}(g)}) : \mathsf{T}(C) \to \mathsf{T}(C')$$

that is identified with $(\widetilde{g}^*, \widetilde{g}_*, \eta^g)$ via the isomorphisms ω_C and $\omega_{C'}$ (details left to the reader). Lastly, let $\beta : g \Rightarrow g'$ be a natural transformation between morphisms of sites $g, g' : C \to C'$; there follows a natural transformation $\beta^\wedge : g'^\wedge \Rightarrow g^\wedge$ (notation of (1.2.2)) that induces by restriction a natural transformation

$$\beta^\sim_* : \widetilde{g}'_* \Rightarrow \widetilde{g}_*$$

which is in turn identified via ω_C and $\omega_{C'}$ with a unique natural transformation

$$\mathsf{T}(\beta) : \mathsf{T}(g')_* \Rightarrow \mathsf{T}(g)_*.$$

If $g'' : C \to C'$ is a third morphism of sites and $\beta' : g' \Rightarrow g''$ is another natural transformation, it is clear that

$$\mathsf{T}(\beta' \odot \beta) = \mathsf{T}(\beta) \odot \mathsf{T}(\beta').$$

Likewise, if $h, h' : C' \to C''$ is another pair of morphisms of sites and $\alpha : h \Rightarrow h'$ is another natural transformation, we deduce easily from (1.2.2) the identity :

$$\mathsf{T}(\alpha * \beta) = \mathsf{T}(\beta) * \mathsf{T}(\alpha).$$

For a composable pair $C \xrightarrow{g} C' \xrightarrow{g'} C''$ of morphisms of U-sites, it is easily seen that $\mathsf{T}(g')_* \circ \mathsf{T}(g)_* = \mathsf{T}(g' \circ g)_*$, and the coherence constraint $\gamma^{\mathsf{T}}_{g,g'}$ of T is given by $\mathbf{1}_{\mathsf{T}(g' \circ g)_*}$. Likewise, $\mathsf{T}(\mathbf{1}_C)_* = \mathbf{1}_{\mathsf{T}(C)}$ for every U-site C, and the coherence constraint δ^{T}_C is given by the identity automorphism of $\mathbf{1}_{\mathsf{T}(C)}$. Then the required coherence axioms are trivially satified; however, notice that T is *not* a strict pseudo-functor, since we do not have necessarily $\mathsf{T}(g)^* \circ \mathsf{T}(g')^* = \mathsf{T}(g' \circ g)^*$. This completes the construction of T.

The pseudo-functor Can assigns to every U-topos T the U-site $\mathrm{Can}(T)$ and to every morphism of U-topoi $f : T \to S$ the morphism of sites $f^* : \mathrm{Can}(T) \to \mathrm{Can}(S)$ (see remark 4.4.13(iii)). Lastly, let $(f^*, f_*, \eta^f), (g^*, g_*, \eta^g) : T \to S$ be two morphisms of topoi and $\beta : f_* \Rightarrow g_*$ a natural transformation; then we let $\mathrm{Can}(\beta) := (\beta, \eta^f, \eta^g)^\dagger : g^* \Rightarrow f^*$, the adjoint transformation of β, as defined in remark 1.1.17(ii). Taking into account remark 1.1.17(iv,v,vi), we easily see that these rules define a strict pseudo-functor Can as sought.

Remark 4.4.16. Notice that the pseudo-functor Can factors through the inclusion strict pseudo-functor $\mathsf{lex}.\mathbf{Site} \to \mathbf{Site}$. We then get as well a pair of pseudo-functors :

$$\mathsf{lex}.\mathbf{Site} \underset{\mathsf{lex}.\mathrm{Can}}{\overset{\mathsf{lex}.\mathsf{T}}{\rightleftarrows}} \mathbf{Topos}.$$

where $\mathsf{lex.T}$ is the restriction of T.

Theorem 4.4.17. (i) *The pseudo-functor* T *is right* 2*-adjoint to the pseudo-functor* Can.
(ii) *The pseudo-functor* $\mathsf{lex.T}$ *is right* 2*-adjoint to the pseudo-functor* $\mathsf{lex.}\mathrm{Can}$.
(iii) *The pseudo-functors* Can *and* $\mathsf{lex.}\mathrm{Can}$ *are fully faithful.*

Proof. (i): We construct as follows a pseudo-natural equivalence $\mathsf{h}_\bullet : \mathbf{1}_{\mathbf{Topos}} \Rightarrow \mathsf{T}\circ\mathrm{Can}$. For every U-topos T, we choose a quasi-inverse $\mathsf{h}^*_T : \mathsf{T}\circ\mathrm{Can}(T) \to T$ for the composition $\mathsf{h}_{T*} : T \to \mathsf{T}\circ\mathrm{Can}(T)$ of the Yoneda embedding $h_T : T \to \mathrm{Can}(T)^\sim$ with the isomorphism $\omega_{\mathrm{Can}(T)}$ of (4.4.15). We also fix an isomorphism of functors $\eta^{\mathsf{h}_T} : \mathbf{1}_{\mathsf{T}\circ\mathrm{Can}(T)} \xrightarrow{\sim} \mathsf{h}_{T*}\circ\mathsf{h}^*_T$, and we consider the morphism of U-topoi :

$$\mathsf{h}_T := (\mathsf{h}^*_T, \mathsf{h}_{T*}, \eta^{\mathsf{h}_T}) : T \to \mathsf{T}\circ\mathrm{Can}(T).$$

In order to show that the rule $T \mapsto \mathsf{h}_T$ defines the sought pseudo-natural equivalence, we need to explicit its coherence constraint; the latter amounts to an isomorphism of functors

$$\tau^{\mathsf{h}}_f : \mathsf{T}(f^*)_*\circ\mathsf{h}_{T*} \xrightarrow{\sim} \mathsf{h}_{S*}\circ f_*$$

for every morphism of U-topoi $(f^*, f_*, \eta^f) : T \to S$. However, example 4.4.10(ii) yields an isomorphism of functors $\tau^h_f : (f^*)^\sim_* \circ h_T \xrightarrow{\sim} h_S\circ f_*$, so we can take :

$$\tau^{\mathsf{h}}_f := \omega_{(S,\mathrm{Can}_S)} * \tau^h_f.$$

To check the coherence axioms for τ^{h}, notice first that T and Can are unital pseudo-functors, so that the first coherence axiom amounts to the identity : $\tau^{\mathsf{h}}_{\mathbf{1}_T} = \mathbf{1}_{\mathsf{h}_{T*}}$ for every U-topos T. The latter follows from the identity : $\tau^h_{\mathbf{1}_T} = \mathbf{1}_{h_T}$, which is clear from the construction of τ^h.

Next, for two morphisms of U-topoi $f := (f^*, f_*, \eta^f) : T \to T'$, $g := (g^*, g_*, \eta^g) : T' \to T''$, we come down to checking that

$$(\eta^h_g * f_*) \odot ((g^*)^\sim_* * \eta^h_f) = \eta^h_{g\circ f}. \tag{4.4.18}$$

Now, recall that η^h_f is induced by the unique adjunction ϑ^f for the pair (f^*, f_*) whose unit is η^f, and likewise for η^h_g and $\eta^h_{g\circ f}$; on the other hand, $\eta^h_{g\circ f}$ is precisely the unit of the adjunction $\vartheta^g\circ\vartheta^f$ (notation of remark 1.1.17(i)). From this, the identity (4.4.18) follows straightforwardly.

Likewise, let $f, f' : T \to S$ be two morphisms of topoi, and $\beta : f \Rightarrow f'$ a natural transformation; in order to check the naturality of τ^{h} we come down to showing that :

$$\tau^h_{f'} \odot (\beta^\dagger)^\sim_* = (h_S * \beta) \odot \tau^h_f.$$

The latter follows by inspecting the characterization of $\beta^\dagger$ furnished by remark 1.1.17(iii), and this completes the construction of $\mathsf{h}_\bullet$. From the pseudo-natural equivalence $\mathsf{h}_\bullet$ we construct the sought 2-adjunction as the composition of the pseudo-natural transformation

$$H_{\mathsf{T}} * (\mathrm{Can}^o \times \mathbf{1}_{\mathbf{Site}}) : \mathrm{Hom}_{\mathbf{Site}}(\mathrm{Can}, -) \Rightarrow \mathrm{Hom}_{\mathbf{Topos}}(\mathsf{T}\circ\mathrm{Can}, \mathsf{T})$$

with the pseudo-natural transformation

$$H_{\mathbf{Topos}} * (\mathsf{h}^o_\bullet \times \mathbf{1}_{\mathbf{Topos}}) : \mathrm{Hom}_{\mathbf{Topos}}(\mathsf{T}\circ\mathrm{Can}, \mathsf{T}) \Rightarrow \mathrm{Hom}_{\mathbf{Topos}}(\mathbf{1}_{\mathbf{Topos}}, \mathsf{T}).$$

This composition assigns to every U-topos T and every U-site C a functor

$$\Phi_{T,C} : \mathrm{Hom}_{\mathbf{Site}}(\mathrm{Can}(T), C) \to \mathrm{Hom}_{\mathbf{Topos}}(T, \mathsf{T}(C))$$

as required, and it remains to check that this functor is an equivalence for every such T and C.

Explicitly, $\Phi_{T,C}$ assigns to every morphism of sites $g : \mathrm{Can}(T) \to C$ the morphism of topoi $\mathsf{T}(g)\circ\mathsf{h}_T : T \to \mathsf{T}(C)$, and to every 2-cell $\beta : g \Rightarrow g'$ of $\mathbf{Site}$ the natural transformation $\mathsf{T}(\beta) * \mathsf{h}_T : \mathsf{T}(g)\circ\mathsf{h}_T \Rightarrow \mathsf{T}(g')\circ\mathsf{h}_T$. Let us show the essential surjectivity : thus, say that $C = (\mathscr{C}, J)$, and let $f := (f^*, f_*, \eta^f) : T \to \mathsf{T}(C)$ be a morphism of topoi; from theorem 4.4.2(ii) we see that $g := f^*\circ\omega_C\circ h^a_{\mathscr{C}} : \mathscr{C} \to T$ is a morphism of sites $g : \mathrm{Can}(T) \to C$, and we have an isomorphism of functors $h_T \circ g \xrightarrow{\sim} \widetilde{g}^* \circ h^a_{\mathscr{C}}$ (corollary 4.3.19(i.b)). We deduce an isomorphism :

$$\mathsf{h}_{T*} \circ f^* \circ \omega_C \circ h^a_{\mathscr{C}} \xrightarrow{\sim} \omega_{\mathrm{Can}(T)} \circ \widetilde{g}^* \circ h^a_{\mathscr{C}}. \tag{4.4.19}$$

Claim 4.4.20. Let D be any category, $k, k' : C^\sim \to D$ two functors, $\lambda : k \circ h^a_{\mathscr{C}} \xrightarrow{\sim} k' \circ h^a_{\mathscr{C}}$ an isomorphism of functors, and suppose that k commutes with all small colimits. Then there exists an isomorphism of functors $\lambda' : k \xrightarrow{\sim} k'$.

Proof of the claim. Let $G \subset \mathrm{Ob}(\mathscr{C})$ be an essentially small topologically generating subset, $\mathscr{G} \subset \mathscr{C}$ the full subcategory with $\mathrm{Ob}(\mathscr{G}) = G$; endow $\mathscr{G}$ with the topology $J_{\mathscr{G}}$ induced by J via the inclusion functor $u : \mathscr{G} \to \mathscr{C}$, and set $G := (\mathscr{G}, J_{\mathscr{G}})$. Then $\widetilde{u}_* : C^\sim \to G^\sim$ is an equivalence (proposition 4.3.18), hence the same holds for its left adjoint $\widetilde{u}^* : G^\sim \to C^\sim$. According to corollary 4.3.19(i.b), we have an isomorphism of functors $\mu : \widetilde{u}^* \circ h^a_{\mathscr{G}} \xrightarrow{\sim} h^a_{\mathscr{C}} \circ i$. There follows a unique isomorphism $\lambda' : k \circ \widetilde{i}^* \circ h^a_{\mathscr{G}} \xrightarrow{\sim} k' \circ \widetilde{i}^* \circ h^a_{\mathscr{G}}$ such that

$$(k' * \mu) \odot \lambda' = (\lambda * i) \odot (k * \omega).$$

Now, if $k \circ \widetilde{i}^*$ and $k' \circ \widetilde{i}^*$ are isomorphic, the same follows for k and k', since $\widetilde{i}^*$ is an equivalence (details left to the reader). Thus, we may replace C by G and λ by λ', and assume from start that C is a small site. Next, let $F \in \mathrm{Ob}(C^\sim)$; we have a universal cocone τ^F given by the rule :

$$(X, s) \mapsto (\tau^F_{(X,s)} : h^a_X \to F) \qquad \text{for every } (X, s) \in \mathrm{Ob}(\mathscr{F}ib(F))$$

where $\tau^F_{(X,s)}$ is characterized as the morphism of sheaves whose composition with the natural morphism of presheaves $h_X \to h^a_X$ is the unique morphism of presheaves $t^F_{(X,s)} : h_X \to F$ such that $(t^F_{(X,s)})_X(\mathbf{1}_X) = s$ (remark 4.1.19(iii)). By assumption, the cocone $k * \tau^F$ is still universal, hence there exists a unique isomorphism $\lambda'_F : kF \xrightarrow{\sim} k'F$ that makes commute the diagram :

$$\begin{array}{ccc} k(h^a_X) & \xrightarrow{k(\tau^F_{(X,s)})} & kF \\ {\scriptstyle \lambda_X}\downarrow & & \downarrow{\scriptstyle \lambda'_F} \\ k'(h^a_X) & \xrightarrow{k'(\tau^F_{(X,s)})} & k'F \end{array} \qquad \text{for every } (X, s) \in \mathrm{Ob}(\mathscr{F}ib(F))$$

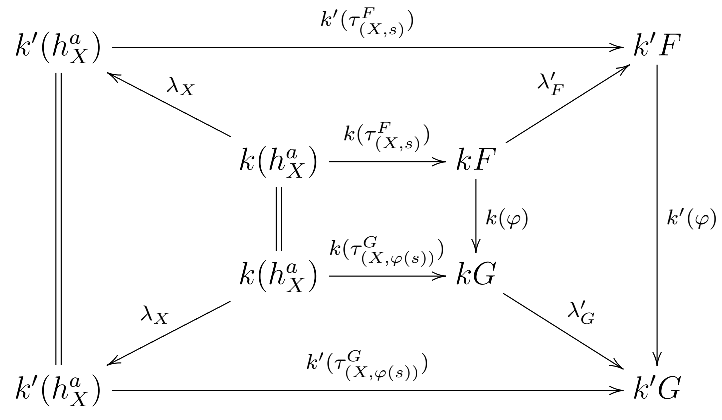
and we are reduced to checking that the rule : $F \mapsto \lambda'_F$ is a natural transformation $k \Rightarrow k'$. Thus, let $\varphi : F \to G$ be any morphism of sheaves on C; recall that φ induces a functor

$$\mathscr{F}ib(\varphi) : \mathscr{F}ib(F) \to \mathscr{F}ib(G) \qquad (X, s) \mapsto (X, \varphi_X(s))$$

and the foregoing characterizations of τ^F and τ^G easily imply that :

$$\varphi \circ \tau^F_{(X,s)} = \tau^G_{(X,\varphi_X(s))} \qquad \text{for every } (X, s) \in \mathrm{Ob}(\mathscr{F}ib(F)). \tag{4.4.21}$$

Consider now for every $(X, s) \in \mathrm{Ob}(\mathscr{F}ib(F))$ the diagram :



We have to prove the commutativity of the right trapezoidal subdiagram, and by (4.4.21), the inner and outer square subdiagrams both commute; moreover, also the upper and lower trapezoidal subdiagrams commute, by construction. Now, since by assumption the cocone $k * \tau^F$ is still universal, it suffices to check that $k'(\varphi) \circ \lambda'_F \circ k(\tau^F_{(X,s)}) = \lambda'_G \circ k(\varphi) \circ k(\tau^F_{(X,s)})$. The latter follows from a straightforward diagram chase, left to the reader. ◊

Since $\widetilde{g}^*$ commutes with small colimits, claim 4.4.20 and (4.4.19) yield an isomorphism :

$$\mathsf{h}_{T*} \circ f^* \circ \omega_C \stackrel{\sim}{\to} \omega_{\mathrm{Can}(T)} \circ \widetilde{g}^*.$$

From this, we further deduce an isomorphism of functors :

$$f^* \stackrel{\sim}{\to} \mathsf{h}_T^* \circ \mathsf{T}(g)^*$$

whence, finally, an isomorphism of their respective right adjoint functors : $\mathsf{T}(g)_* \circ \mathsf{h}_{T*} \stackrel{\sim}{\to} f_*$.

Next, we check that $\Phi_{T,C}$ is faithful : let $g, g' : \mathrm{Can}(T) \to C$ be two morphisms of sites, and $\beta, \beta' : g \Rightarrow g'$ two 2-cells of $\mathbf{Site}$ such that $\mathsf{T}(\beta)_* * \mathsf{h}_T = \mathsf{T}(\beta')_* * \mathsf{h}_T$; we need to show that $\beta = \beta'$. However, the condition means that $\widetilde{\beta}_* \circ h_T = \widetilde{\beta}'_* \circ h_T$; *i.e.* for every $X \in \mathrm{Ob}(T)$, every $A \in \mathrm{Ob}(\mathscr{C})$ and every morphism $\varphi : gA \to X$ in T, we have $\varphi \circ \beta_A = \varphi \circ \beta'_A$. Letting $X := gA$ and $\varphi := \mathbf{1}_{gA}$, we get $\beta_A = \beta'_A$, for every $A \in \mathrm{Ob}(\mathscr{C})$, as required.

Lastly, in order to check that $\Phi_{T,C}$ is full, let $\alpha : \mathsf{T}(g) \circ \mathsf{h}_T \Rightarrow \mathsf{T}(g') \circ \mathsf{h}_T$ be any natural transformation, with g and g' as in the foregoing. This is the same as a natural transformation $\alpha' : \widetilde{g}_* \circ h_T \Rightarrow \widetilde{g}'_* \circ h_T$. The latter assigns to every $X \in \mathrm{Ob}(T)$ a morphism of sheaves $\alpha'_X : h_X \circ g^o \to h_X \circ g'^o$; in particular, for every $A \in \mathrm{Ob}(\mathscr{C})$, we deduce a map

$$(\alpha'_{gA})_A : \mathrm{Hom}_T(gA, gA) \to \mathrm{Hom}_T(g'A, gA) \qquad \text{and we set :} \qquad \beta_A := (\alpha'_{gA})_A(\mathbf{1}_{gA}).$$

Let us check that the rule : $A \mapsto \beta_A$ yields a natural transformation $\beta : g' \to g$. Indeed, let $\varphi : A \to B$ be any morphism of $\mathscr{C}$; we need to show that $g(\varphi) \circ \beta_A = \beta_B \circ g'(\varphi)$. However, the naturality of the rule $X \mapsto \alpha'_X$ for every $X \in \mathrm{Ob}(T)$ implies the identity :

$$g(\varphi) \circ (\alpha'_{gA})_A(\mathbf{1}_{gA}) = (\alpha'_{gB})_A(g(\varphi))$$

and the naturality of the rule : $Y \mapsto (\alpha'_{gB})_Y$ for every $Y \in \mathrm{Ob}(\mathscr{C})$ yields the identity :

$$(\alpha'_{gB})_A(g(\varphi)) = (\alpha'_{gB})_B(\mathbf{1}_{gB}) \circ g'(\varphi)$$

whence the contention. It remains to check that $\mathsf{T}(\beta)_* * \mathsf{h}_T = \alpha$, or equivalently, that $\widetilde{\beta}_* * h_T = \alpha'$. The latter comes down to the identity : $(\alpha'_X)_A(\varphi) = \varphi \circ \beta_A$ for every $X \in \mathrm{Ob}(T)$, every $A \in \mathrm{Ob}(\mathscr{C})$ and every morphism $\varphi : gA \to X$ in T. This identity in turn follows easily from the naturality of the rule : $X \mapsto \alpha'_X$ (details left to the reader).

(ii): Notice that – by virtue of example 4.3.12 – the same rules defining $\mathsf{h}_\bullet$ also yield a pseudo-natural transformation $\mathbf{1_{Topos}} \Rightarrow \mathsf{lex.T} \circ \mathsf{lex.Can}$. We use this pseudo-natural transformation as in the foregoing to construct the sought 2-adjunction for the pair $(\mathsf{lex.Can}, \mathsf{lex.T})$; the details shall be left to the reader.

(iii): Since $\mathsf{h}_\bullet$ is a pseudo-natural equivalence, the assertion for Can follows from corollary 2.4.29. The same arguments applies to $\mathsf{lex.Can}$. □

Remark 4.4.22. As an application of theorem 4.4.17 we deduce the representability of the 2-limit of any cofiltered system of topoi. Indeed, let I be a small cofiltered category, and $T_\bullet : I \to (\mathsf{U}, \mathsf{U}')\text{-}\mathbf{Topos}$ any pseudo-functor. By proposition 4.3.25, the pseudo-functor $\mathsf{lex.Can} \circ T_\bullet : I \to \mathsf{lex.}\mathbf{Site}$ admits a 2-limit $(C, \pi_\bullet)$. By theorem 4.4.17(ii) and proposition 2.5.9(i), the pair $(\mathsf{lex.T}(C), \mathsf{lex.T} * \pi_\bullet)$ is a 2-limit of the pseudo-functor $\mathsf{lex.T} \circ \mathsf{lex.Can} \circ T_\bullet : I \to (\mathsf{U}, \mathsf{U}')\text{-}\mathbf{Topos}$. But by theorem 4.4.17(iii) and corollary 2.4.29, we have a pseudo-natural equivalence $\omega : \mathsf{lex.T} \circ \mathsf{lex.Can} \stackrel{\sim}{\to} \mathbf{1_{Topos}}$, so $(\mathsf{lex.T}(C), (\omega * T_\bullet) \odot (\mathsf{lex.T} * \pi_\bullet))$ is a 2-limit for $T_\bullet$ (lemma

2.5.3). Combining with remark 4.3.27, we see that the 2-limit of $T_\bullet$ is also a 2-limit of the induced pseudo-functor

$$I \to \mathsf{U}'\text{-}\mathbf{Cat} \qquad i \mapsto T_i \qquad (\varphi : i \to j) \mapsto (T_{\varphi *} : T_i \to T_j).$$

4.5. **Fibred sites.** The formalism developed in this section and the next one shall allow us to deal with families of sites or of topoi, indexed by arbitrary categories. Especially, we will explain how to combine the members of such a family into a single *total site* or *total topos*.

Definition 4.5.1. (i) Let $\mathscr{C}$ be a category and V a universe. A *fibred site with* V*-small fibres over* $\mathscr{C}$ is a datum $(\mathscr{A}, p, J_\bullet)$ consisting of a fibration with V-small fibre categories

$$p : \mathscr{A} \to \mathscr{C}$$

and of a topology J_X on the fibre category $\mathscr{A}_X$, for every $X \in \mathrm{Ob}(\mathscr{C})$, such that the following holds. For every cleavage $\boldsymbol{\lambda}$ of p and every morphism $\varphi : X \to Y$ in $\mathscr{C}$, the functor $\mathsf{c}_\varphi : \mathscr{A}_Y \to \mathscr{A}_X$ is a morphism of sites $(\mathscr{A}_X, J_X) \to (\mathscr{A}_Y, J_Y)$, where $\mathsf{c} : \mathscr{C}^o \to \mathsf{V}\text{-}\mathbf{Cat}$ is the pseudo-functor associated with $\boldsymbol{\lambda}$.

(ii) A datum $(\mathscr{A}, p, J_\bullet)$ as in (i) is a *fibred lex-site with* V*-small fibres* if $(\mathscr{A}_X, J_X)$ is a lex-site for every $X \in \mathrm{Ob}(\mathscr{C})$ and the functors c_φ are left exact for every morphism φ of $\mathscr{C}$ and every cleavage $\boldsymbol{\lambda}$ with associated pseudo-functor c. As usual, we shall mostly omit mentioning the universe V, unless the omission would be source of ambiguities.

(iii) Let $(\mathscr{A}, p, J_\bullet)$ be a fibred site over the category $\mathscr{C}$. We endow $\mathscr{A}$ with the coarsest topology $J_{\mathscr{A}}$ such that the inclusion functor $\mathscr{A}_X \to \mathscr{A}$ is continuous for the topologies J_X and $J_{\mathscr{A}}$, for every $X \in \mathrm{Ob}(\mathscr{C})$. The *total site* of $(\mathscr{A}, p, J_\bullet)$ is the resulting site

$$(\mathscr{A}, J_{\mathscr{A}}).$$

(iv) Let $(\mathscr{A}, p, J_\bullet)$ and $(\mathscr{A}', p', J'_\bullet)$ be two fibred sites over $\mathscr{C}$. A *morphism of fibred sites*

$$\varphi : (\mathscr{A}, p, J_\bullet) \to (\mathscr{A}', p', J'_\bullet)$$

is a $\mathscr{C}$-cartesian functor $\varphi : \mathscr{A}' \to \mathscr{A}$ whose restriction $\varphi_X : \mathscr{A}'_X \to \mathscr{A}_X$ is a morphism of sites $(\mathscr{A}_X, J_X) \to (\mathscr{A}'_X, J'_X)$, for every $X \in \mathrm{Ob}(\mathscr{C})$. If $(\mathscr{A}, p, J_\bullet)$ and $(\mathscr{A}', p', J'_\bullet)$ are fibred lex-sites, we say that φ is a *morphism of fibred lex-sites*, if it is $\mathscr{C}$-cartesian, and the restriction $\varphi_X : (\mathscr{A}_X, J_X) \to (\mathscr{A}'_X, J'_X)$ is a morphism of lex-sites, for every $X \in \mathrm{Ob}(\mathscr{C})$.

Remark 4.5.2. (i) With the notation of definition 4.5.1, it is clear that if there exists a cleavage of p with associated pseudo-functor c, such that c_φ is a morphism of sites $(\mathscr{A}_X, J_X) \to (\mathscr{A}_Y, J_Y)$ for every morphism $\varphi : X \to Y$, then the same holds for every cleavage of p (and in this case, p is a fibred site). Likewise, if c_φ is also left exact for every such φ, then the same holds for every cleavage of p (and then p is a fibred lex-site).

(ii) Let $(\mathscr{A}, p, J_\bullet)$ and $(\mathscr{A}, J_{\mathscr{A}})$ be as in definition 4.5.1(iii). By lemma 4.2.4, we have $\mathscr{S} \in J_{\mathscr{A}}(A)$ for every $A \in \mathrm{Ob}(\mathscr{A})$ and every sieve $\mathscr{S} \subset \mathscr{A}/A$ such that

$$\mathscr{S} \cap (\mathscr{A}_{pA}/A) \in J_{pA}(A). \tag{4.5.3}$$

(iii) In the situation of (ii), suppose moreover that $\mathscr{C}$ is small and $(\mathscr{A}_X, J_X)$ is a U-site for every $X \in \mathrm{Ob}(\mathscr{C})$; under these assumptions, the fibre category $\mathscr{A}_X$ has small Hom-sets for every such X, but the same does not necessarily hold for the category $\mathscr{A}$. However, for every $A, A' \in \mathrm{Ob}(\mathscr{A})$ the set $\mathrm{Hom}_{\mathscr{A}}(A, A')$ is essentially small : indeed, let $\boldsymbol{\lambda}$ be a cleavage for $\mathscr{A}$ and c its associated pseudo-functor; since every morphism $f : A' \to A$ in $\mathscr{A}$ factors as a morphism $A' \to \mathsf{c}_{p(f)}A$ of $\mathscr{A}_{pA'}$ and the cartesian morphism $\boldsymbol{\lambda}(A, p(f)) : \mathsf{c}_{p(f)}A \to A$, the assertion follows easily. Thus, after replacing $\mathscr{A}$ by an isomorphic category, we may assume that $\mathscr{A}$ has small Hom-sets, and in this case we claim that $(\mathscr{A}, J_{\mathscr{A}})$ is a U-site. Indeed, choose for every $X \in \mathrm{Ob}(\mathscr{C})$ an essentially small topologically generating family $G_X \subset \mathrm{Ob}(p^{-1}X)$

for $(\mathscr{A}_X, J_X)$; then it is clear from (ii) that $\bigcup_{X\in\mathrm{Ob}(\mathscr{C})} G_X$ is an essentially small topologically generating family for $(\mathscr{A}, J_{\mathscr{A}})$.

(iv) Clearly the fibred sites (resp. the fibred lex-sites) over $\mathscr{C}$ with V-small fibres are the objects of a 2-category :

$$\mathsf{V}\text{-fib}.\mathbf{Site}(\mathscr{C}) \qquad \text{(resp. } \mathsf{V}\text{-fib.lex}.\mathbf{Site})$$

whose 1-cells are the morphisms of fibred sites (resp. of fibred lex-sites), and whose 2-cells $g \Rightarrow g'$ are the natural $\mathscr{C}$-transformations $g' \Rightarrow g$ between the underlying functor of such morphisms, with the obvious composition laws for 1-cells and 2-cells. We have an obvious forgetful strict pseudo-functor :

$$\mathsf{V}\text{-fib}.\mathbf{Site}(\mathscr{C}) \to {}^o(\mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C}))^o \qquad (\mathscr{A}, p, J_\bullet) \mapsto (\mathscr{A}, p).$$

(v) Let $\mathscr{C}$ be a category with V-small Hom-sets and whose set of objects is essentially V-small. Taking into account theorem 3.1.24, it is easily seen that the pseudo-functor $\mathscr{F}ib_{\mathscr{C}}$ induces strict and strong 2-equivalences of 2-categories :

$$\underline{\mathscr{F}ib_{\mathscr{C}}} : \mathsf{PsFun}(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Site}) \to \mathsf{V}\text{-fib}.\mathbf{Site}(\mathscr{C})$$
$$\mathsf{lex}.\underline{\mathscr{F}ib_{\mathscr{C}}} : \mathsf{PsFun}(\mathscr{C}, \mathsf{V}\text{-lex}.\mathbf{Site}) \to \mathsf{V}\text{-fib.lex}.\mathbf{Site}(\mathscr{C}).$$

Namely, we have an obvious forgetful strict pseudo-functor

$$\Phi : \mathsf{V}\text{-}\mathbf{Site} \to {}^o(\mathsf{V}\text{-}\mathbf{Cat})^o \qquad (\mathscr{A}, J) \mapsto \mathscr{A}$$

whence a pseudo-functor $\mathsf{PsFun}(\mathscr{C}, \Phi) : \mathsf{PsFun}(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Site}) \to \mathsf{PsFun}(\mathscr{C}, {}^o(\mathsf{V}\text{-}\mathbf{Cat})^o)$ (see remark 2.2.17(i)). Then, since ${}^o\mathscr{C}^o = \mathscr{C}^o$, we have a strict isomorphism of 2-categories :

$$\mathsf{PsFun}(\mathscr{C}, {}^o(\mathsf{V}\text{-}\mathbf{Cat})^o) \xrightarrow{\sim} {}^o\mathsf{PsFun}(\mathscr{C}^o, \mathsf{V}\text{-}\mathbf{Cat})^o$$

(see (2.2.13)) and a strict and strong 2-equivalence

$${}^o\mathscr{F}ib^o_{\mathscr{C}} : {}^o\mathsf{PsFun}(\mathscr{C}^o, \mathsf{V}\text{-}\mathbf{Cat})^o \xrightarrow{\sim} {}^o(\mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C}))^o.$$

The composition $\mathsf{PsFun}(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Site}) \to {}^o(\mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C}))^o$ of these pseudo-functors assigns to every pseudo-functor

$$\underline{\mathscr{A}} : \mathscr{C} \to \mathsf{V}\text{-}\mathbf{Site} \qquad X \mapsto (\mathscr{A}_X, J_X)$$

the fibration $\mathscr{A}' := \mathscr{F}ib({}^o(\Phi \circ \underline{\mathscr{A}})^o)$ whose fibre category $\mathscr{A}'_X$ over every $X \in \mathrm{Ob}(\mathscr{C})$ is naturally identified with $\mathscr{A}_X$. Then $\underline{\mathscr{F}ib}(\underline{\mathscr{A}})$ is the fibred site $(\mathscr{A}', J'_\bullet)$ where J'_X is the topology on $\mathscr{A}'_X$ corresponding to J_X under this identification $\mathscr{A}'_X \xrightarrow{\sim} \mathscr{A}_X$, for every $X \in \mathrm{Ob}(\mathscr{C})$.

(vi) By remark 2.4.31, the pseudo-functor $\underline{\mathscr{F}ib_{\mathscr{C}}}$ admits a strict and strong pseudo-inverse

$$\underline{\mathsf{c}}^\bullet : \mathsf{V}\text{-fib}.\mathbf{Site} \to \mathsf{PsFun}(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Site}) \qquad \underline{\mathscr{A}} := (\mathscr{A}, p, J_\bullet) \mapsto \underline{\mathsf{c}}^{\underline{\mathscr{A}}}$$

which, to every fibred site $(\mathscr{A}, p, J_\bullet)$ over $\mathscr{C}$, assigns the pseudo-functor $\mathsf{c}^{\mathscr{A}} : \mathscr{C}^o \to \mathsf{V}\text{-}\mathbf{Cat}$ associated with a cleavage of $\mathscr{A}$, and for every $X \in \mathrm{Ob}(\mathscr{C})$, endows the category $\mathsf{c}^{\mathscr{A}}_X = \mathscr{A}_X$ with the topology J_X. Obviously $\underline{\mathsf{c}}^\bullet$ restricts to a strict and strong pseudo-inverse for $\mathsf{lex}.\underline{\mathscr{F}ib_{\mathscr{C}}}$.

4.5.4. Let $\mathscr{C}$ be a category, $(\mathscr{A}, p, J_\bullet)$ a fibred lex-site over $\mathscr{C}$, and $(\mathscr{A}, J_{\mathscr{A}})$ its total site. For every $X \in \mathrm{Ob}(\mathscr{C})$ denote by $i_X : \mathscr{A}_X \to \mathscr{A}$ the inclusion functor. We have :

Proposition 4.5.5. *In the situation of* (4.5.4)*, the following holds :*

(i) *The functor i_X commutes with fibre products and equalizers for every $X \in \mathrm{Ob}(\mathscr{C})$.*

(ii) *For every $A \in \mathrm{Ob}(\mathscr{A})$ and every sieve $\mathscr{S} \subset \mathscr{A}/A$, we have $\mathscr{S} \in J_{\mathscr{A}}(A)$ if and only if $\mathscr{S}$ satisfies condition* (4.5.3)*.*

(iii) *The functor i_X is both continuous and cocontinuous for the topologies J_X and $J_{\mathscr{A}}$, for every $X \in \mathrm{Ob}(\mathscr{C})$.*

(iv) *A presheaf F on $\mathscr{A}$ is a sheaf for the topology $J_{\mathscr{A}}$ if and only if $i^\wedge_X F$ is a sheaf on $(\mathscr{A}_X, J_X)$ for every $X \in \mathrm{Ob}(\mathscr{C})$.*

(v) *Suppose moreover that $\mathscr{C}$ is small, and $(\mathscr{A}_X, J_X)$ is a* U*-site for every $X \in \mathrm{Ob}(\mathscr{C})$. Then we have an essentially commutative diagram of categories :*

$$\begin{array}{ccc} \mathscr{A}^\wedge & \xrightarrow{i_X^\wedge} & \mathscr{A}_X^\wedge \\ {\scriptstyle (-)^a}\downarrow & & \downarrow{\scriptstyle (-)^a} \\ (\mathscr{A}, J_{\mathscr{A}})^\sim & \xrightarrow{i_{X*}^\sim} & (\mathscr{A}_X, J_X)^\sim \end{array} \qquad \textit{for every } X \in \mathrm{Ob}(\mathscr{C}).$$

Proof. Choose a cleavage $\boldsymbol{\lambda}$ for p and let $\mathsf{c} : \mathscr{C}^o \to \mathsf{V}\text{-}\mathbf{Cat}$ be the associated pseudo-functor (for some universe V such that $\mathscr{A}_X$ is a V-small category for every $X \in \mathrm{Ob}(\mathscr{C})$).

(i): Let $A' \xrightarrow{f'} A \xleftarrow{f''} A''$ be two morphisms in $\mathscr{A}_X$; pick $P \in \mathrm{Ob}(\mathscr{A}_X)$ representing $A' \times_A A''$ in $\mathscr{A}_X$, and let $A' \xleftarrow{q'} P \xrightarrow{q''} A''$ be a universal cone. Let then $B \in \mathrm{Ob}(\mathscr{A})$ be any object and $A' \xleftarrow{g'} B \xrightarrow{g''} A''$ two morphisms in $\mathscr{A}$ such that $f' \circ g' = f'' \circ g''$. It follows easily that $\varphi := p(g') = p(g'')$, so g' (resp. g'') factors through a morphism $h' : B \to \mathsf{c}_\varphi A'$ (resp. $h'' : B \to \mathsf{c}_\varphi A''$) in $\mathscr{A}_{pB}$ and the cartesian morphism $\boldsymbol{\lambda}(A', \varphi) : \mathsf{c}_\varphi A' \to A'$ (resp. $\boldsymbol{\lambda}(A'', \varphi) : \mathsf{c}_\varphi A'' \to A''$), and since c_φ is left exact, we get a unique morphism $h : B \to \mathsf{c}_\varphi P$ in $\mathscr{A}_{pB}$ such that $\mathsf{c}_\varphi(q') \circ h = h'$ and $\mathsf{c}_\varphi(q'') \circ h = h''$. Then $k := \boldsymbol{\lambda}(\varphi, P) \circ h : B \to P$ is the unique morphism in $\mathscr{A}$ such that $q' \circ k = g'$ and $q'' \circ k = g''$. This shows that P represents the fibre product of A' and A'' over A in $\mathscr{A}$. Similarly one shows the assertion for equalizers : the details shall be left to the reader.

(ii): In view of (i) and lemma 4.2.4, it suffices to check that the family $\mathscr{J}$ of sieves verifying condition (4.5.3) yields a topology on $\mathscr{A}$. Now, condition (c) of definition 4.1.1(i) obviously holds for $\mathscr{J}$. Next, let $\mathscr{S} \subset \mathscr{A}/A$ be a sieve fulfilling condition (4.5.3), and $f : A' \to A$ a morphism of $\mathscr{A}$; we set $\varphi := p(f)$ and factor f through a morphism $f' : A' \to A'' := \mathsf{c}_\varphi A$ in $p^{-1}A'$ and the cartesian morphism $f'' := \boldsymbol{\lambda}(A, \varphi) : A'' \to A$. Then let $\mathscr{S}' := \mathscr{S} \times_A f''$, and notice that if $(g_\lambda : B_\lambda \to A \mid \lambda \in \Lambda)$ generates $\mathscr{S}_{|A} := \mathscr{S} \cap (\mathscr{A}_{pA}/A)$, then the family $(\mathsf{c}_\varphi(g_\lambda) : \mathsf{c}_\varphi B_\lambda \to A'' \mid \lambda \in \Lambda)$ lies in $\mathscr{S}'$, and the latter family covers A'' for the topology $J_{pA''}$, since c_φ is continuous for the topologies J_{pA} and $J_{pA''}$, and since $\mathscr{S}_{|A}$ covers A for the topology J_{pA}. Then $\mathscr{S} \times_A f = \mathscr{S}' \times_{A''} f'$ contains the family $(A' \times_{A''} \mathsf{c}_\varphi B_\lambda \to A' \mid \lambda \in \Lambda)$, which covers A' for the topology $J_{pA'}$. This shows that condition (a) of definition 4.1.1(i) holds for $\mathscr{J}$. Lastly, let $\mathscr{S} \subset \mathscr{A}/A$ be an element of $\mathscr{J}$, and consider another sieve $\mathscr{T} \subset \mathscr{A}/A$ such that for every $(f : A' \to A) \in \mathrm{Ob}(\mathscr{S})$ the sieve $\mathscr{T} \times_A f$ lies in $\mathscr{J}$. Let $\mathscr{S}_{|A} \subset \mathscr{A}_{pA}/A$ be as in the foregoing, and define likewise $\mathscr{T}_{|A}$; then $\mathscr{S}_{|A} \in J_{pA}(A)$ and it is easily seen that

$$\mathscr{T}_{|A} \times_A f = (\mathscr{T} \times_A f) \cap (\mathscr{A}_{pA'}/A') \qquad \text{for every } (f : A' \to A) \in \mathrm{Ob}(\mathscr{S}_{|A}).$$

Hence $\mathscr{T}_{|A} \in J_{pA}(A)$, so $\mathscr{T} \in \mathscr{J}$; this shows that $\mathscr{J}$ fulfills condition (b) of definition 4.1.1(i).

(iii) follows immediately from (ii).

(v): Pick a universe V containing U, and such that $\mathscr{A}$ is V-small; in view of remarks 4.1.23(i) and 4.5.2(iii) we are easily reduced to checking the essential commutativity of the diagram :

$$\begin{array}{ccc} \mathscr{A}_{\mathsf{V}}^\wedge & \xrightarrow{i_{X,\mathsf{V}}^\wedge} & \mathscr{A}_{X,\mathsf{V}}^\wedge \\ {\scriptstyle (-)^+}\downarrow & & \downarrow{\scriptstyle (-)^+} \\ \mathscr{A}_{\mathsf{V}}^\wedge & \xrightarrow{i_X^\wedge} & \mathscr{A}_{X,\mathsf{V}}^\wedge \end{array} \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C})$$

where the functors $(-)^+$ are defined as in (4.1.11). We may then replace U by V and assume that $\mathscr{A}$ is a small category. For every $X \in \mathrm{Ob}(\mathscr{C})$ and every $A \in \mathrm{Ob}(\mathscr{A}_X)$ we endow $J_X(A)$ and $J_{\mathscr{A}}(A)$ with the ordering induced by inclusion of sieves, and consider the map

$$J_X(A) \to J_{\mathscr{A}}(A) \qquad \mathscr{S} \mapsto \mathscr{S}^*$$

that assigns to every $\mathscr{S} \in J_X(A)$ the sieve $\mathscr{S}^* \in J_{\mathscr{A}}(A)$ generated by $\mathrm{Ob}(\mathscr{S}) \subset \mathrm{Ob}(\mathscr{A}/A)$. This map is obviously injective, and according to (ii), its image is a cofinal subset in the opposite ordered set $J_{\mathscr{A}}(A)^o$. Moreover, for every morphism $f : A' \to A$ in $\mathscr{A}_X$, clearly we have

$$(\mathscr{S} \times_A f)^* = \mathscr{S}^* \times_A f \qquad \text{for every } \mathscr{S} \in J_X(A).$$

Furthermore, for every such $\mathscr{S}$ and every presheaf F on $\mathscr{A}_X$, we have a natural identification of $F(\mathscr{S}) := \mathrm{Hom}_{\mathscr{A}_X^\wedge}(h_{\mathscr{S}}, F)$ with the equalizer of the two natural maps (see (4.1.6))

$$\mathrm{Equal}\Big(\prod_{(B\to A)\in\mathrm{Ob}(\mathscr{S})} F(B) \rightrightarrows \prod_{(B\to A\leftarrow B')\in\mathrm{Ob}(\mathscr{S})\times\mathrm{Ob}(\mathscr{S})} F(B\times_A B')\Big) \tag{4.5.6}$$

and for every inclusion $\mathscr{S}' \subset \mathscr{S}$ of sieves covering A, the map $F(\mathscr{S}) \to F(\mathscr{S}')$ corresponds, under this identification, to the restriction of the projection

$$\prod_{(B\to A)\in\mathrm{Ob}(\mathscr{S})} F(B) \to \prod_{(B\to A)\in\mathrm{Ob}(\mathscr{S}')} F(B). \tag{4.5.7}$$

Recall that

$$F^+(A) := \operatorname*{colim}_{\mathscr{S}\in J_X(A)^o} F(\mathscr{S})$$

and for every morphism $f : A' \to A$ in $\mathscr{A}_X$, the map $F^+(f) : F^+(A) \to F^+(A')$ is the colimit of the maps $F(\mathscr{S}) \to F(\mathscr{S} \times_A f) \to F^+(A')$ induced by the projection $\mathscr{S} \times_A f \to \mathscr{S}$, for every $\mathscr{S} \in J_X(A)^o$. Now, if $F = i_X^\wedge G$ for a presheaf G on $\mathscr{A}$, it follows from (4.1.6) that the equalizer (4.5.6) is also naturally identified with $G(\mathscr{S}^*)$, and likewise, for every inclusion of sieves $\mathscr{S}' \subset \mathscr{S}$ in $J_X(A)$, the map $G(\mathscr{S}^*) \to G(\mathscr{S}'^*)$ corresponds to the restriction of (4.5.7), under this same identification. After taking colimits, we thus get an isomorphism

$$(i_X^\wedge G)^+(A) \xrightarrow{\sim} G^+(A)$$

natural in both the presheaf G and the object $A \in \mathrm{Ob}(\mathscr{A}_X)$. The assertion follows.

(iv): The condition is obviously necessary. For the converse, let F be a presheaf on $\mathscr{A}$ such that $i_X^\wedge(F)$ is a sheaf on $(\mathscr{A}_X, J_X)$ for every $X \in \mathrm{Ob}(\mathscr{C})$; denote by F^a the sheaf on $(\mathscr{A}, J_{\mathscr{A}})$ associated with F, and by $j : F \to F^a$ the natural map of presheaves. For every $X \in \mathrm{Ob}(\mathscr{C})$ we get a commutative diagram of presheaves on $\mathscr{A}_X$:

$$\begin{array}{ccc} i_X^\wedge(F) & \xrightarrow{i_X^\wedge(j)} & i_X^\wedge(F^a) \\ \downarrow & & \downarrow \\ (i_X^\wedge F)^a & \xrightarrow{(i_X^\wedge(j))^a} & (i_X^\wedge F^a)^a \end{array}$$

whose vertical arrows are isomorphisms, by assumption. On the other hand, in view of (v), the morphism $(i_X^\wedge(j))^a$ is naturally identified with $i_X^\wedge(j^a) : i_X^\wedge(F^a) \to i_X^\wedge((F^a)^a)$; now, j^a is an isomorphism, hence the same holds for $i_X^\wedge(j^a)$, and then also for $i_X^\wedge(j)$, for every $X \in \mathrm{Ob}(\mathscr{C})$. But this means that j is already an isomorphism, *i.e.* F is a sheaf on $(\mathscr{A}, J_{\mathscr{A}})$. □

Example 4.5.8. In the situation of (4.5.4), suppose that $\mathscr{C}$ admits a final object X_0. Then the functor i_{X_0} is a morphism of sites $(\mathscr{A}, J_{\mathscr{A}}) \to (\mathscr{A}_{X_0}, J_X)$. Indeed, let A_0 be any final object of $\mathscr{A}_{X_0}$; it is easily seen that A_0 is also a final object of $\mathscr{A}$, and taking into account propositions 1.3.22(i) and 4.5.5(i) we deduce that i_{X_0} is left exact. Then the assertion follows from proposition 4.5.5(iii) and example 4.3.12.

Proposition 4.5.9. *Let $u : (\mathscr{A}', p', J'_\bullet) \to (\mathscr{A}, p, J_\bullet)$ be a morphism of fibred lex-sites over a category $\mathscr{C}$, and denote by $(\mathscr{A}, J_{\mathscr{A}})$, $(\mathscr{A}', J_{\mathscr{A}'})$ the corresponding total sites. Then u is a morphism of sites $(\mathscr{A}', J_{\mathscr{A}'}) \to (\mathscr{A}, J_{\mathscr{A}})$.*

Proof. Proposition 4.5.5(i,ii) easily implies that u is continuous for the topologies $J_{\mathscr{A}}$ and $J_{\mathscr{A}'}$, so it remains only to check that the fibration $\mathsf{s} : \mathscr{A}'/u\mathscr{A} \to \mathscr{A}'$ is locally cofiltered for the topology $J_{\mathscr{A}'}$ (proposition 4.3.9). Thus, let $X \in \mathrm{Ob}(\mathscr{C})$ and $A' \in \mathrm{Ob}(\mathscr{A}'_X)$; the fibration $\mathsf{s}_{(X)} : \mathscr{A}'_X/u_X\mathscr{A}_X \to \mathscr{A}'_X$ is locally cofiltered, by proposition 4.3.9, hence there exists a covering family $g_\bullet := (g_\lambda : A'_\lambda \to A' \mid \lambda \in \Lambda)$ relative to the topology J'_X such that $\mathrm{Ob}(\mathsf{s}^{-1}_{(X)}A'_\lambda) \neq \varnothing$ for every $\lambda \in \Lambda$; but the family $g_\bullet$ covers A' also relative to the topology $J_{\mathscr{A}'}$ (proposition 4.5.5(ii)), so s fulfills condition (a) of definition 4.3.3. To check condition (b), consider morphisms $f_i : A' \to uA_i$ in $\mathscr{A}'$ for $i = 1, 2$, and let $\varphi_i : X \to Y_i$ be the image of f_i in $\mathscr{C}$ for $i = 1, 2$. Pick any cleavage for $\mathscr{A}$, and let c be its associated pseudo-functor; then $f_i = u(f''_i) \circ f'_i$ where $f'_i : A' \to u(\mathsf{c}_{\varphi_i}A_i)$ is a morphism in $\mathscr{A}'_X$ and $f''_i : \mathsf{c}_{\varphi_i}A_i \to A_i$ is a cartesian morphism of $\mathscr{A}$, for $i = 1, 2$. Since $\mathsf{s}_{(X)}$ is locally cofiltered, we may then find a covering family $g_\bullet$ as in the foregoing, and for every $\lambda \in \Lambda$ a morphism $f_\lambda : A'_\lambda \to uA_\lambda$ in $\mathscr{A}'_X$ and morphisms $h_{i,\lambda} : A_\lambda \to \mathsf{c}_{\varphi_1}A_1$ in $\mathscr{A}_X$ for $i = 1, 2$, such that $u(h_{i,\lambda}) \circ f_\lambda = f'_i \circ g_\lambda$. Then we get morphisms in $\mathscr{A}/u\mathscr{A}'$

$$(A'_\lambda/f''_i \circ h_{i,\lambda}) : (A'_\lambda, f_\lambda) \to (A'_\lambda, f_i \circ g_\lambda) \qquad \text{for } i = 1, 2 \text{ and every } \lambda \in \Lambda$$

whence the contention. Lastly, let $(f_i : A' \to uA_i \mid i = 1, 2)$ be a pair of morphisms in $\mathscr{A}'$, and $h_1, h_2 : A_1 \to A_2$ two morphisms of $\mathscr{A}$ with $u(h_i) \circ f_1 = f_2$ for $i = 1, 2$. Let $\varphi_i : X \to Y_i$ be the image of f_i in $\mathscr{C}$ for $i = 1, 2$; there exist morphisms $h'_1, h'_2 : \mathsf{c}_{\varphi_1}A_1 \to \mathsf{c}_{\varphi_2}A_2$ in $\mathscr{A}_X$ and cartesian morphisms $f'_i : \mathsf{c}_{\varphi_i}A_i \to A_i$ in $\mathscr{A}$ such that $h_i \circ f'_1 = f'_2 \circ h'_i$ for $i = 1, 2$. Since $\mathsf{s}_{(X)}$ is locally cofiltered, we may then find $g_\bullet$ as in the foregoing, and for every $\lambda \in \Lambda$ a morphism $f_\lambda : A'_\lambda \to uA_\lambda$ in $\mathscr{A}'_X$ and a morphism $h_\lambda : A_\lambda \to \mathsf{c}_{\varphi_1}A_1$ in A_X such that $h'_1 \circ h_\lambda = h'_2 \circ h_\lambda$. It follows that $h_1 \circ f'_1 \circ h_\lambda = h_2 \circ f'_1 \circ h_\lambda$, which shows that condition (c) holds as well for s. □

Remark 4.5.10. Let V be any universe. Proposition 4.5.9 says that the rule that assigns to every fibred lex-site over $\mathscr{C}$ with V-small fibres its total site defines a strict pseudo-functor

$$\mathsf{totSite} : \mathsf{V}\text{-}\mathsf{fib.lex.}\mathbf{Site}(\mathscr{C}) \to \mathsf{V}\text{-}\mathbf{Site}$$

that assigns to every morphism of lex-sites the underlying functor, and is the identity on 2-cells.

4.5.11. Let $(\mathscr{A}, p, J_\bullet)$ be a fibred site over a category $\mathscr{C}$, and $u : \mathscr{C}' \to \mathscr{C}$ any functor. Set $\mathscr{A}' := \mathsf{Fib}(u)^*\mathscr{A}$, and recall that for every $X \in \mathrm{Ob}(\mathscr{C}')$ the natural projection $\pi : \mathscr{A}' \to \mathscr{A}$ restricts to an isomorphism of categories $\pi_X : \mathscr{A}'_X \xrightarrow{\sim} \mathscr{A}_{uX}$. Then we get a fibred site denoted

$$\mathscr{C}' \times_{(\mathscr{C},u)} (\mathscr{A}, p, J_\bullet) \qquad \text{or more simply} \qquad \mathscr{C}' \times_{\mathscr{C}} (\mathscr{A}, p, J_\bullet)$$

whose underlying fibration is $p' : \mathscr{A}' \to \mathscr{C}'$ and where the topology J_X on $\mathscr{A}'_X$ is induced by J_X via the isomorphism π_X, for every $X \in \mathrm{Ob}(\mathscr{C}')$. Obviously, if $(\mathscr{A}, p, J_\bullet)$ is a fibred lex-site, the same holds for $\mathscr{C}' \times_{\mathscr{C}} (\mathscr{A}, p, J_\bullet)$, and in this case, proposition 4.5.5(ii,iv) easily implies that π is a continuous and cocontinuous functor for the respective total sites $(\mathscr{A}, J_{\mathscr{A}}), (\mathscr{A}', J_{\mathscr{A}'})$.

4.5.12. In the situation of (4.5.11), let $v : \mathscr{C}' \to \mathscr{C}$ be another functor, and $\beta : u \Rightarrow v$ any natural transformation. After choosing a cleavage $\boldsymbol{\lambda}$ for the fibration $\mathscr{A}$, we attach to β a $\mathscr{C}'$-cartesian functor $\mathsf{Fib}(\beta)^*_{\mathscr{A}} : \mathsf{Fib}(v)^*\mathscr{A} \to \mathsf{Fib}(u)^*\mathscr{A}$, as in (3.1.29). Explicitly, let c be the pseudo-functor associated with $\boldsymbol{\lambda}$; then for every $X \in \mathrm{Ob}(\mathscr{C}')$ the restriction $\mathscr{A}_{vX} \to \mathscr{A}_{uX}$ of $\mathsf{Fib}(\beta)^*_{\mathscr{A}}$ is given by the functor c_{β_X}. Hence, $\mathsf{Fib}(\beta)^*_{\mathscr{A}}$ is a morphism of fibred sites denoted :

$$\beta \times_{\mathscr{C}} (\mathscr{A}, p, J_\bullet) : \mathscr{C}' \times_{(\mathscr{C},u)} (\mathscr{A}, p, J_\bullet) \to \mathscr{C}' \times_{(\mathscr{C},v)} (\mathscr{A}, p, J_\bullet).$$

It is easily seen that $\beta \times_{\mathscr{C}} (\mathscr{A}, p, J_\bullet)$ is independent, up to isomorphisms of morphisms of fibred sites, of the choice of cleavage $\boldsymbol{\lambda}$: the details shall be left to the reader.

4.5.13. Let $\mathscr{C}, \mathscr{D}$ be two small categories, $t : \mathscr{D} \to \mathscr{C}$ a functor, and $u : (\mathscr{A}_0, p_0, J_{0,\bullet}) \to (\mathscr{A}_1, p_1, J_{1,\bullet})$ a morphism of fibred lex sites over $\mathscr{C}$. Set

$$(\mathscr{B}_i, q_i, J'_{i,\bullet}) := \mathscr{D} \times_{\mathscr{C}} (\mathscr{A}_i, p_i, J_{i,\bullet}) \qquad \text{for } i = 0, 1$$

(notation of (4.5.11)). Clearly u induces a morphism of fibred lex sites

$$v := \mathscr{D} \times_{\mathscr{C}} u : (\mathscr{B}_0, q_0, J'_{0,\bullet}) \to (\mathscr{B}_1, q_1, J'_{1,\bullet}).$$

Then u and v are also morphisms of the respective total sites $u : (\mathscr{A}_0, J_0) \to (\mathscr{A}_1, J_1)$ and $v : (\mathscr{B}_0, J'_0) \to (\mathscr{B}_1, J'_1)$ (proposition 4.5.9). For $i = 0, 1$, let $\pi_i : \mathscr{B}_i \to \mathscr{A}_i$ be the projection. We deduce a commutative diagram of categories :

$$\mathscr{E} \quad : \quad \begin{array}{ccc} \mathscr{A}_0^{\sim} & \xrightarrow{\widetilde{u}_*} & \mathscr{A}_1^{\sim} \\ {\scriptstyle \widetilde{\pi}_{0*}} \downarrow & & \downarrow {\scriptstyle \widetilde{\pi}_{1*}} \\ \mathscr{B}_0^{\sim} & \xrightarrow{\widetilde{v}_*} & \mathscr{B}_1^{\sim} \end{array}$$

and notice that each functor of the diagram $\mathscr{E}$ admits a left adjoint; after choosing an adjunction for each of the resulting adjoint pairs of functors, we can view $\mathscr{E}$ as a square of links, oriented by the identity $\mathbf{1}_{\widetilde{\pi}_{1*} \circ \widetilde{u}_*}$ (see (2.3.8)).

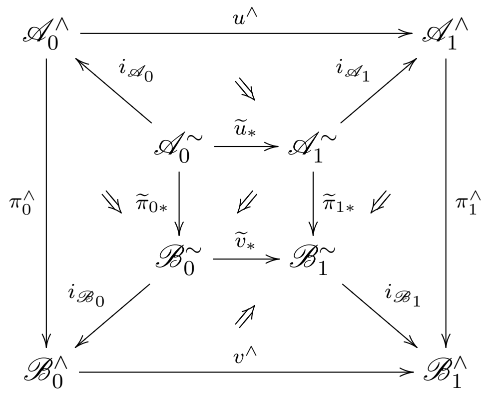
Proposition 4.5.14. *In the situation of* (4.5.13)*, suppose that* $(\mathscr{A}_{i,X}, J_{i,X})$ *is a* U*-site for every* $X \in \mathrm{Ob}(\mathscr{C})$ *and* $i = 0, 1$*. Then the base change transformation*

$$\Upsilon(\mathscr{E}) : \widetilde{v}^* \circ \widetilde{\pi}_{1*} \to \widetilde{\pi}_{0*} \circ \widetilde{u}^*$$

is an isomorphism of functors.

Proof. We consider first the oriented diagram of categories :

$\mathscr{E}'$:



whose diagonal arrows are the inclusion functors, and all whose orientations are identities. Moreover, each functor in $\mathscr{E}'$ still admits a left adjoint, so as usual $\mathscr{E}'$ can be regarded as an oriented diagram of links. By adding a further identity orientation for the "front face" we obtain a cubical diagram as in (2.3.21), which obviously commutes on 2-cells, except that the orientations do not agree with those of the corresponding diagram in (2.3.21), nor with those of its variant considered in remark 2.3.22(iii). However, the induced diagram ${}^\dagger\mathscr{E}'$ of adjoint squares as in (2.3.8) still commutes on 2-cells, due to proposition 2.3.4, and moreover its orientations agree with those of the variant from remark 2.3.22(iii). More precisely, the left and right faces of ${}^\dagger\mathscr{E}'$ are oriented by ${}^o(\mathbf{1}_{i_{\mathscr{B}_1} \circ \widetilde{v}_*})^\dagger$ and respectively ${}^o(\mathbf{1}_{i_{\mathscr{A}_1} \circ \widetilde{u}_*})^\dagger$, and the top and bottom faces are oriented by ${}^o(\mathbf{1}_{i_{\mathscr{B}_1} \circ \widetilde{\pi}_{1*}})^\dagger$ and respectively ${}^o(\mathbf{1}_{i_{\mathscr{B}_0} \circ \widetilde{\pi}_{0*}})^\dagger$.

Claim 4.5.15. The base change transformations

$$\Upsilon(\mathbf{1}_{i_{\mathscr{B}_1} \circ \widetilde{\pi}_{1*}}) : (-)^a_{\mathscr{B}_1} \circ \pi_1^\wedge \to \widetilde{\pi}_{1*} \circ (-)^a_{\mathscr{A}_1} \qquad \text{and} \qquad \Upsilon(\mathbf{1}_{i_{\mathscr{B}_0} \circ \widetilde{\pi}_{0*}}) : (-)^a_{\mathscr{B}_0} \circ \pi_0^\wedge \to \widetilde{\pi}_{0*} \circ (-)^a_{\mathscr{A}_0}$$

are isomorphisms of functors.

Proof of the claim. We check the assertion for $\Upsilon(\mathbf{1}_{i_{\mathscr{B}_0}\circ\widetilde{\pi}_{0*}})$; the same argument shall apply also to $\Upsilon(\mathbf{1}_{i_{\mathscr{B}_1}\circ\widetilde{\pi}_{1*}})$. Since $i_{\mathscr{B}_0}$ is a fully faithful functor, the counit $\varepsilon^{\mathscr{B}_0}$ of the chosen adjunction for the pair $((-)^a_{\mathscr{B}_0}, i_{\mathscr{B}_0})$ is an isomorphism (proposition 1.1.20(iii)), so we are reduced to checking that $((-)^a_{\mathscr{B}_0}\circ\pi_0^\wedge)*\eta^{\mathscr{A}_0}$ is an isomorphism, where $\eta^{\mathscr{A}_0}$ and $\varepsilon^{\mathscr{A}_0}$ are the unit and counit of an adjunction for the pair $((-)^a_{\mathscr{A}_0}, i_{\mathscr{A}_0})$. But recall that there exists an isomorphism of functors : $(-)^a_{\mathscr{B}_0}\circ\pi_0^\wedge \xrightarrow{\sim} \widetilde{\pi}_{0*}\circ(-)^a_{\mathscr{A}_0}$ (corollary 4.3.19(iii)), so it suffices to show that $(-)^a_{\mathscr{A}_0}*\eta^{\mathscr{A}_0}$ is an isomorphism. However, $\varepsilon^{\mathscr{A}_0}$ is an isomorphism, since $i_{\mathscr{A}_0}$ is fully faithful, hence the contention follows from the triangular identities of (1.1.13). ◊

In light of claim 4.5.15, proposition 2.3.10, and remark 2.3.22(i,iii), we are then reduced to showing that the base change transformation

$$\Upsilon(\mathbf{1}_{\pi_1^\wedge\circ u^\wedge}) : v_!\circ\pi_1^\wedge \to \pi_0^\wedge\circ u_!$$

is an isomorphism of functors. To this aim, recall that for every $A_0\in\mathrm{Ob}(\mathscr{A}_0)$ and every presheaf F on $\mathscr{A}_1$, the set $u_!F(A_0)$ represents the colimit of the functor

$$F\circ\mathsf{t}^o_{A_0} : (A_0/u\mathscr{A}_1)^o \to \mathbf{Set}$$

where t_{A_0} denotes the usual target functor as in (1.1.27). Thus, $u_!F(A_0)$ is the set of equivalence classes $[s,\varphi]_u$ of pairs (s,φ), where $\varphi : A_0\to uA_1$ is a morphism of $\mathscr{A}_0$, and $s\in FA_1$. For every morphism $\psi : A_0\to A'_0$ in $\mathscr{A}_0$, the map $u_!F(\psi)$ is given by the rule : $[s,\varphi]_u\mapsto[s,\varphi\circ\psi]_u$ for every such $[s,\varphi]_u$. Moreover, for every morphism $f : F\to F'$ of presheaves on $\mathscr{A}_0$, the morphism $u_!f : u_!F\to u_!F'$ is given by the rule : $[s,\varphi]_u\mapsto[f_{A_1}(s),\varphi]_u$ for every such $[s,\varphi]_u$. We have a standard adjunction for the pair $(u_!, u^\wedge)$ whose unit and counit (η^u,ε^u) are given by the following rules, for every presheaf F on $\mathscr{A}_1$ and F' on $\mathscr{A}_0$:

$$\eta^u_{F,A_1}(s) := [s,\mathbf{1}_{uA_1}]_u \in u^\wedge u_!F(A_1) \qquad \text{for every } A_1\in\mathrm{Ob}(\mathscr{A}_1) \text{ and every } s\in FA_1$$
$$\varepsilon^u_{F',A_0}[s, A_0\xrightarrow{\varphi} uA'_1]_u := F'\varphi(s)\in F'A_0 \qquad \text{for every } s\in F(uA'_1).$$

A similar description applies to the functor $v_!$ and the unit and counit of its standard adjunction. Thus, for every such F, the morphism $(v_!\pi_1^\wedge*\eta^u)_F : v_!\pi_1^\wedge F\to v_!\pi_1^\wedge u^\wedge u_!F$ is given by the rule:

$$[s, B_0\xrightarrow{\varphi} vB_1]_v \mapsto [[s,\mathbf{1}_{u\pi_1B_1}]_u,\varphi]_v \qquad \text{for every } s\in F\pi_1B_1$$

and the morphism $(\varepsilon^v*\pi_0^\wedge u_!)_F : v_!v^\wedge\pi_0^\wedge u_!F\to\pi_0^\wedge u_!F$ is given by the rule :

$$[[t,\pi_0vA'_1\xrightarrow{\psi}uA''_1]_u, A_0\xrightarrow{\varphi}vA'_1]_v \mapsto \pi_0^\wedge u_!F(\varphi)[t,\pi_0vA'_1\xrightarrow{\psi}uA''_1]_u = [t,\psi\circ\pi_0(\varphi)]_u$$

for every $t\in FA''_1$. Summing up, $\Upsilon(\mathbf{1}_{\pi_1^\wedge\circ u^\wedge})$ is then given by the rule :

$$[s, B_0\xrightarrow{\varphi}vB_1]_v \mapsto [s,\pi_0(\varphi)]_u \qquad \text{for every } s\in F\pi_1B_1.$$

Consider then the functor

$$\rho^{B_0} : (B_0/v\mathscr{B}_1)^o \to (\pi_0B_0/u\mathscr{A}_1)^o \qquad (B_0\xrightarrow{\varphi}vB_1)\mapsto(\pi_0B_0\xrightarrow{\pi_0(\varphi)}\pi_0vB_1 = u\pi_1B_1)$$

and notice that $\mathsf{t}^o_{\pi_0B_0}\circ\rho^{B_0} = \pi_1^o\circ\mathsf{t}^o_{B_0}$, so that ρ^{B_0} induces a morphism of presheaves on the category $\mathbf{Set}^o$, as in (the dual of) remark 1.2.11(i) :

$$\operatorname*{colim}_{(\pi_0B_0/u\mathscr{A}_1)^o} F\circ\mathsf{t}^o_{\pi_0B_0} \to \operatorname*{colim}_{(\mathscr{B}_0/v\mathscr{B}_1)^o} F\circ\pi_1^o\circ\mathsf{t}^o_{B_0}$$

which corresponds to a map $\omega : v_!\pi_1^\wedge F(B_0)\to\pi_0^\wedge u_!F(B_0)$, and by a direct inspection it is easily seen that $\omega = \Upsilon(\mathbf{1}_{\pi_1^\wedge\circ u^\wedge})_{F,B_0}$. In view of proposition 1.5.2, we are then reduced to showing :

Claim 4.5.16. For every $X\in\mathrm{Ob}(\mathscr{B}_0)$ we have :
(i) The categories $X/v\mathscr{B}_1$ and $\pi_0X/u\mathscr{A}_1$ are cofiltered.
(ii) The functor ρ^X is cofinal.

Proof of the claim. (i): We show that $X/v\mathscr{B}_1$ is cofiltered; the same argument shall apply to $\pi_0 X/u\mathscr{A}_1$ as well. Indeed, let us check that $X/v\mathscr{B}_1$ is not the empty category : to this aim, let $v_{q_0X} : \mathscr{B}_{1,q_0X} \to \mathscr{B}_{0,q_0X}$ be the restriction of v to the fibre categories over q_0X, so it suffices to check that $X/v_{q_0X}\mathscr{B}_{1,q_0X}$ is not empty; but $\mathscr{B}_{1,q_0X}$ is finitely complete, hence it admits a final object Y_0, and vY_0 is a final object of $\mathscr{B}_{0,q_0X}$, since v is left exact. The unique morphism $X \to vY_0$ is then an object of $X/v_{q_0X}\mathscr{B}_{1,q_0X}$.

Next, consider two objects $(Y_1, \varphi_1), (Y_2, \varphi_2)$ of $X/v\mathscr{B}_1$; for $i = 1, 2$ we may find cartesian morphisms $\beta_i : Y'_i \to Y_i$ in $\mathscr{B}_1$ such that $q_1(\beta_i) = q_0(\varphi_i)$, and then there exists a unique morphism $\varphi'_i : X \to vY'_i$ in the fibre category $\mathscr{B}_{0,q_0X}$ such that $v(\beta_i) \circ \varphi'_i = \varphi_i$. The pair (Y'_i, φ'_i) is an object of $X/v\mathscr{B}_1$, and β_i is a morphism $(Y'_i, \varphi'_i) \to (Y_i, \varphi_i)$ for $i = 1, 2$. Since $\mathscr{B}_{1,q_0X}$ is finitely complete, the product $Z := Y'_1 \times Y'_2$ is representable, and since v_{q_0X} is left exact, vZ represents $vY'_1 \times vY'_2$, whence a morphism $\psi' : X \to vZ$ in $\mathscr{B}_{0,q_0X}$ whose composition with the projection $v(p_i) : vZ \to vY'_i$ agrees with φ'_i, for $i = 1, 2$. Thus, $(Z, \psi') \in \mathrm{Ob}(X/v\mathscr{B}_1)$ and we have morphisms $(Z, \psi') \xrightarrow{X/p_i} (Y'_i, \varphi'_i) \xrightarrow{X/\beta_i} (Y_i, \varphi_i)$ for $i = 1, 2$.

Lastly, let $X/\alpha_1, X/\alpha_2 : (Y_1, \varphi_1) \to (Y_2, \varphi_2)$ be two morphisms of $X/v\mathscr{B}_1$. We find cartesian morphisms $\beta_i : Y'_i \to Y_i$ in $\mathscr{B}_1$ such that $q_1(\beta_i) = q_0(\varphi_i)$ for $i = 1, 2$, and notice that $q_1(\alpha_1 \circ \beta_1) = q_0(\varphi_2) = q_1(\alpha_2 \circ \beta_1)$. Then there exist unique morphisms $\alpha'_i : Y'_1 \to Y'_2$ in $\mathscr{B}_{1,q_0X}$ such that $\beta_2 \circ \alpha'_i = \alpha_i \circ \beta_1$ for $i = 1, 2$. Since $\mathscr{B}_{1,q_0X}$ is finitely complete, the equalizer of the pair (α'_1, α'_2) is representable in $\mathscr{B}_{1,q_0X}$ by a morphism $\lambda' : E \to Y'_1$ in $\mathscr{B}_{1,q_0X}$. Set $\lambda := \beta_1 \circ \lambda'$; it follows that $\alpha_1 \circ \lambda = \alpha_2 \circ \lambda$. Moreover, for $i = 1, 2$ we may find a morphism $\varphi'_i : X \to vY'_i$ in $\mathscr{B}_{0,q_0X}$ such that $v(\beta_i) \circ \varphi'_i = \varphi_i$. We compute :

$$v(\beta_2 \circ \alpha'_1) \circ \varphi'_1 = v(\alpha_1 \circ \beta_1) \circ \varphi'_1 = v(\alpha_1) \circ \varphi_1 = \varphi_2 = v(\alpha_2) \circ \varphi_1 = v(\alpha_2 \circ \beta_1) \circ \varphi'_1 = v(\beta_2 \circ \alpha'_2) \circ \varphi'_1$$

whence $v(\alpha'_1) \circ \varphi'_1 = v(\alpha'_2) \circ \varphi'_1$, since $v(\beta_2)$ is cartesian. However, $v(\lambda)$ is the equalizer of the pair $(v(\alpha'_1), v(\alpha'_2))$, since v_{q_0X} is left exact; so finally φ'_1 factors through a unique morphism $\varphi''_1 : X \to vE$ and $v(\lambda') : vE \to vY'_1$. Thus, we get a morphism $X/\lambda : (E, \varphi''_1) \to (Y_1, \varphi_1)$ in $X/v\mathscr{B}_1$ such that $(X/\alpha_1) \circ (X/\lambda) = (X/\alpha_2) \circ (X/\lambda)$, whence the contention.

(ii): In view of (i), it suffices to show that conditions (a) and (b) of lemma 1.5.7(i) hold for ρ^X. To this aim, let $u_{q_0X} : \mathscr{A}_{1,q_0X} \to \mathscr{A}_{0,q_0X}$ be the restriction of u to the fibre categories, and (Y, φ) any object of $(\pi_0 X/u\mathscr{A}_1)^o$. Arguing as in the proof of (i), we find $(Y', \varphi') \in \mathrm{Ob}((\pi_0 X/u_{q_0X}\mathscr{A}_{1,q_0X})^o)$ and a morphism $(Y, \varphi) \to (Y', \varphi')$ in $(\pi_0 X/u\mathscr{A}_1)^o$. But notice that ρ^X restricts to an isomorphism of categories $(X/v_{q_0X}\mathscr{B}_{1,q_0X})^o \xrightarrow{\sim} (\pi_0 X/u_{q_0X}\mathscr{A}_{1,q_0X})^o$. Condition (a) is an immediate consequence. Lastly, let $(Y, \varphi) \in \mathrm{Ob}(X/v\mathscr{B}_1)$, $(Z, \varphi') \in \mathrm{Ob}(\pi_0 X/u\mathscr{A}_1)$, and a pair of morphisms in $\pi_0 X/u\mathscr{A}_1$:

$$\pi_0 X/\beta_i : \rho^X(Y, \varphi) = (\pi_1 Y, \pi_0(\varphi)) \to (Z, \varphi') \qquad i = 1, 2.$$

Hence, $\beta_1, \beta_2 : \pi_1 Y \to Z$ are morphisms of $\mathscr{B}_1$ with $u(\beta_1) \circ \pi_0(\varphi) = u(\beta_2) \circ \pi_0(\varphi)$. Arguing as in the proof of (i) we find a cartesian morphism $\beta : Y' \to Y$ in $\mathscr{B}_1$ and a morphism $\psi : X \to vY'$ in $\mathscr{B}_{0,q_0X}$ with $v(\beta) \circ \psi = \varphi$. Notice that $p_1(\beta_1 \circ \pi_1(\beta)) = p_0(\varphi') = p_1(\beta_2 \circ \pi_1(\beta))$. Then we may find $Z'' \in \mathrm{Ob}(\mathscr{A}_{1,q_0X})$ and a cartesian morphism $\gamma : Z'' \to Z$ in $\mathscr{A}_1$ such that $p_1(\gamma) = p_0(\varphi')$, and for $i = 1, 2$, a morphism $\beta''_i : \pi_1 Y' \to Z'$ in $\mathscr{A}_{1,q_0X}$ such that $\beta_1 \circ \pi_1(\beta) = \gamma \circ \beta''_i$. Since π_1 restricts to an isomorphism $\mathscr{B}_{1,q_0X} \xrightarrow{\sim} \mathscr{A}_{1,q_0X}$, there exist $Z' \in \mathrm{Ob}(\mathscr{B}_{1,q_0X})$ with $\pi_1 Z' = Z''$, and unique morphisms $\beta'_i : Y' \to Z'$ in $\mathscr{B}_{1,q_0X}$ such that $\pi_1(\beta'_i) = \beta''_i$ for $i = 1, 2$. We compute :

$$\begin{aligned} u(\gamma) \circ u\pi_1(\beta'_1) \circ \pi_0(\psi) = u(\beta_1 \circ \pi_1(\beta)) \circ \pi_0(\psi) &= u(\beta_1) \circ \pi_0(\varphi) \\ &= u(\beta_2) \circ \pi_0(\varphi) \\ &= u(\beta_2 \circ \pi_1(\beta)) \circ \pi_0(\psi) \\ &= u(\gamma) \circ u\pi_1(\beta'_2) \circ \pi_0(\psi). \end{aligned}$$

Since $u(\gamma)$ is cartesian and π_0 restricts to an isomorphism $\mathscr{B}_{0,q_0X} \xrightarrow{\sim} \mathscr{A}_{0,q_0X}$, we conclude that $v(\beta'_1) \circ \psi = v(\beta'_2) \circ \psi$. Let $\lambda : E \to Y'$ be the equalizer of the pair (β'_1, β'_2) in $\mathscr{B}_{1,q_0X}$; since v_{q_0X} is left exact, $v(\lambda) : vE \to vY'$ represents the equalizer of $(v(\beta'_1), v(\beta'_2))$ in $\mathscr{A}_{1,q_0X}$, so finally ψ factor through $v(\lambda)$ and a unique morphism $\mu : X \to vE$ in $\mathscr{A}_{1,q_0X}$. We have $(E, \mu) \in \mathrm{Ob}(X/v\mathscr{B}_1)$, and a morphism $X/(\beta \circ \lambda) : (E, \mu) \to (Y, \varphi)$ in $X/v\mathscr{B}_1$ such that $\rho^X(X/(\beta \circ \lambda))$ equalizes π_0X/β_1 and π_0X/β_2 in $(\pi_0X/u\mathscr{A}_1)^o$. This concludes the proof of condition (b). □

4.6. **Fibred topoi.** For every small category I, we consider next the 2-category

$$\mathsf{PsFun}(I, \mathbf{Topos})$$

whose objects $T : I \to \mathbf{Topos}$ shall be called the *fibred topoi over* I. The 1-cells, that is the pseudo-natural transformations $\omega : T \Rightarrow S$ shall be called *morphisms of fibred topoi over* I, and denoted by a simple arrow $T \to S$. The 2-cells, *i.e.* the modifications $\omega \rightsquigarrow \omega'$ in $\mathsf{PsFun}(I, \mathbf{Topos})$ shall be called also *transformations* of morphisms of fibred topoi over I.

Remark 4.6.1. (i) Recall that the definition of the 2-category $\mathbf{Topos}$ involves the choice of two universes U, U' with $\mathsf{U} \in \mathsf{U}'$, so that every object of $\mathbf{Topos}$ is both a U-topos and a small U'-category (see definition 4.4.5(iv)). Then, consider any pseudo-functor

$$F : I \to \mathsf{U}'\text{-}\mathbf{Cat}$$

such that (a): F_i is an U-topos for every $i \in \mathrm{Ob}(I)$, and (b): for every morphism $\varphi : i \to j$ of I there exists a morphism of topoi $f_\varphi : F_i \to F_j$ with $F_\varphi = f_{\varphi*}$. Then we get a fibred topos T over I such that $T_i := F_i$ for every $i \in \mathrm{Ob}(I)$ and $T_\varphi := f_\varphi$ for every morphism φ of I. This fibred topos depends on the choice of the morphisms of topoi f_φ, but any two such choices yield isomorphic fibred topoi over I.

(ii) In particular, any *functor* $F : I \to \mathsf{U}'\text{-}\mathbf{Cat}$ fulfilling (a) and (b) can be regarded as a fibred topos over I; in this case, the coherence constraint (δ^T, γ^T) of the resulting T shall be given by identity automorphisms of functors :

$$\delta^T_i = \mathbf{1}_{T_i} \qquad \gamma^T_{\varphi,\psi} = \mathbf{1}_{T_\varphi \circ T_\psi} \qquad \text{in } \mathsf{U}'\text{-}\mathbf{Cat}$$

which are however *not necessarily* identity 2-cells of the 2-category $\mathbf{Topos}$, since one does not necessarily have $f^*_\psi \circ f^*_\varphi = f^*_{\psi\circ\varphi}$, nor $f^*_{\mathbf{1}_i} = \mathbf{1}_{T_i}$. Hence, even when it is given by an actual functor, T will only in general be a (non-strict) pseudo-functor, when regarded as a fibred topos.

(iii) From the pseudo-functors of remark 4.4.9(ii) we deduce two strict pseudo-functors :

$$\mathsf{PsFun}(I^o, \mathsf{U}'\text{-}\mathbf{Cat})^o \xleftarrow{[-]^*} \mathsf{PsFun}(I, \mathbf{Topos}) \xrightarrow{[-]_*} \mathsf{PsFun}(I, \mathsf{U}'\text{-}\mathbf{Cat}).$$

- Namely, $[-]_*$ assigns to every fibred topos $T : I \to \mathbf{Topos}$ over I the composition

$$T_* := (-)_* \circ T : I \to \mathsf{U}'\text{-}\mathbf{Cat} \qquad i \mapsto T_i \qquad (i \xrightarrow{\varphi} j) \mapsto (T_{\varphi*} : T_i \to T_j)$$

and to every morphism of fibred topoi $\omega : T \to S$ the pseudo-natural transformation $\omega_* := (-)_* * \omega : T_* \Rightarrow S_*$. To every transformation $\Xi : \omega \rightsquigarrow \omega'$ it assigns the modification

$$\Xi_* := (-)_* \circ \Xi : \omega_* \rightsquigarrow \omega'_*.$$

- Likewise, $[-]^*$ assigns to every fibred topos T over I the pseudo-functor

$$T^* := ((-)^* \circ T)^o : I^o \to \mathsf{U}'\text{-}\mathbf{Cat} \qquad i^o \mapsto T^o_i \qquad (j^o \xrightarrow{\varphi^o} i^o) \mapsto (T^{*o}_\varphi : T^o_j \to T^o_i)$$

and to every morphism of fibred topoi $\omega : T \to S$ the pseudo-natural transformation $\omega^* := ((-)^* * \omega)^o : S^* \Rightarrow T^*$. To every transformation $\Xi : \omega \rightsquigarrow \omega'$ it assigns the modification

$$\Xi^* := ((-)^* \circ \Xi)^o : \omega^* \rightsquigarrow \omega'^*.$$

4.6.2. There are several useful ways of attaching a fibration to any fibred topos T over I : namely, with the notation of (3.1.18) and remark 4.6.1(iii), we can consider the fibrations

$$\pi : \mathscr{F}ib(T_*) \to I^o \qquad \text{and} \qquad \pi' : \mathscr{F}ib(T^*) \to I.$$

More precisely, we have strict pseudo-functors :

$$\mathsf{U}'\text{-}\mathsf{Fib}(I)^o \xleftarrow{\mathscr{F}ib_I^o \circ [-]^*} \mathsf{PsFun}(I, \mathbf{Topos}) \xrightarrow{\mathscr{F}ib_{I^o} \circ [-]_*} \mathsf{U}'\text{-}\mathsf{Fib}(I^o).$$

• We have also a natural pseudo-functor from fibred topoi over I to fibred sites over I : namely, the composition

$$\underline{\mathrm{Can}} : \mathsf{PsFun}(I, \mathbf{Topos}) \xrightarrow{\mathsf{PsFun}(I, \mathrm{Can})} \mathsf{PsFun}(I, \mathsf{U}'\text{-}\mathbf{Site}) \xrightarrow{\underline{\mathscr{F}ib}_I} \mathsf{U}'\text{-fib.}\mathbf{Site}(I)$$

where $\mathrm{Can} : \mathbf{Topos} \to \mathbf{Site}$ is the pseudo-functor of (4.4.15), and $\underline{\mathscr{F}ib}_I$ is the 2-equivalence of remark 4.5.2(v). Explicitly, $\underline{\mathrm{Can}}(T)$ is given as follows. Since I is a usual category, we have ${}^oI^o = I^o$, so T^* induces a pseudo-functor

$$I^o \xrightarrow{{}^oT^*} {}^o(\mathsf{U}'\text{-}\mathbf{Cat}) \xrightarrow{(-)^o} \mathsf{U}'\text{-}\mathbf{Cat} \qquad i^o \mapsto T_i \qquad (j^o \xrightarrow{\varphi} i^o) \mapsto (T^*_\varphi : T_j \to T_i)$$

where $(-)^o$ denotes the strict isomorphism of example 2.1.24. The fibration

$$p : \underline{\mathrm{Can}}(T) := \mathscr{F}ib((-)^o \circ {}^oT^*) \to I$$

carries a natural structure of fibred lex-site : namely, the category $p^{-1}(i)$ is naturally identified with T_i for every $i \in \mathrm{Ob}(I)$, and inherits the latter's canonical topology; also, p admits a natural cleavage whose associated pseudo-functor c is identified with $(-)^o \circ {}^oT^*$, so for every morphism $\varphi : i \to j$ of I the functor $\mathsf{c}_\varphi : p^{-1}(j) \to p^{-1}(i)$ is in turn identified with the left exact functor $T^*_\varphi : T_j \to T_i$, which is continuous for the canonical topologies (remark 4.4.13(iii)).

• Conversely, to every fibred site we may attach a fibred topos, via the pseudo-functors

$$\underline{\mathsf{T}} : \mathsf{U}'\text{-fib.}\mathbf{Site}(I) \xrightarrow{\underline{\mathsf{c}}^\bullet} \mathsf{PsFun}(I, \mathsf{U}'\text{-}\mathbf{Site}) \xrightarrow{\mathsf{PsFun}(I, \mathsf{T})} \mathsf{PsFun}(I, \mathbf{Topos})$$

$$\underline{\mathsf{lex.T}} : \mathsf{U}'\text{-fib.lex.}\mathbf{Site}(I) \xrightarrow{\mathsf{lex.}\underline{\mathsf{c}}^\bullet} \mathsf{PsFun}(I, \mathsf{U}'\text{-lex.}\mathbf{Site}) \xrightarrow{\mathsf{PsFun}(I, \mathsf{lex.T})} \mathsf{PsFun}(I, \mathbf{Topos})$$

where $\mathsf{T} : \mathbf{Site} \to \mathbf{Topos}$ and $\mathsf{lex.T} : \mathsf{lex.}\mathbf{Site} \to \mathbf{Topos}$ are as in (4.4.15), and $\underline{\mathsf{c}}^\bullet$ (resp. $\mathsf{lex.}\underline{\mathsf{c}}^\bullet$) is a strict and strong pseudo-inverse for $\underline{\mathscr{F}ib}_I$ (resp. for $\mathsf{lex.}\underline{\mathscr{F}ib}_I$: see remark 4.5.2(vi)).

Lemma 4.6.3. *With the notation of* (4.6.2)*, there exists a natural isomorphism of I-categories*

$$\mathscr{F}ib(T^*) \xrightarrow{\sim} \mathscr{F}ib(T_*)^o.$$

Proof. For every morphism $\varphi : i \to j$ of I, let $(\eta_\varphi, \varepsilon_\varphi)$ be the unit and counit for the adjunction for the pair $(T^*_\varphi, T_{\varphi*})$ that defines the morphism of topoi $T_\varphi : T_i \to T_j$. This adjunction assigns to every morphism $f : T^*_\varphi Y \to X$ (for any $X \in \mathrm{Ob}(T_i)$ and $Y \in \mathrm{Ob}(T_j)$) an adjoint morphism

$$f^\dagger := T_{\varphi*}(f) \circ \eta_{\varphi,Y} : Y \to T_{\varphi*}X.$$

Notice that $\mathscr{F}ib(T^*)$ and $\mathscr{F}ib(T_*)$ have the same set of objects, and the morphisms of $\mathscr{F}ib(T^*)$ (resp. $\mathscr{F}ib(T_*)$) are the pairs (φ, f) where $\varphi : i \to j$ is a morphism of I and $f : T^*_\varphi Y \to X$ (resp. $f : Y \to T_{\varphi*}X$) is a morphism of T_i (resp. of T_j). We claim that the rules

$$(i, X) \mapsto (i, X) \qquad (\varphi, f) \mapsto (\varphi, f^\dagger)$$

yield the sought isomorphism of categories. Indeed, denote also by (δ, γ) the coherence constraint of the pseudo-functor T^*; hence

$$\gamma_{(\varphi,\psi)} : T^*_{\psi\varphi} \xrightarrow{\sim} T^*_\varphi T^*_\psi \qquad \text{and} \qquad \delta_i : T^*_{\mathbf{1}_i} \xrightarrow{\sim} \mathbf{1}_{T_i}$$

are isomorphisms of functors, for every $i \in \mathrm{Ob}(I)$ and every pair of morphisms $\varphi : i \to j$ and $\psi : j \to k$ in I, and according to remark 1.1.17(ii), there follow adjoint isomorphisms

$$\gamma^\dagger_{(\varphi,\psi)} : T_{\psi*}T_{\varphi*} \xrightarrow{\sim} T_{\psi\circ\varphi*} \qquad \text{and} \qquad \delta^\dagger_i : \mathbf{1}_{T_i} \xrightarrow{\sim} T_{\mathbf{1}_i*}.$$

With this notation, we need to check the identity

$$(f \circ T^*_\varphi g \circ \gamma_{(\varphi,\psi),Z})^\dagger = \gamma^\dagger_{(\varphi,\psi),X} \circ T_{\psi*}(f^\dagger) \circ g^\dagger$$

for every pair of morphisms $(\varphi, f : T^*_\varphi Y \to X)$ and $(\psi, g : T^*_\psi Z \to Y)$ of $\mathscr{F}ib(T^*)$. However, on the one hand we have

$$(f \circ T^*_\varphi(g) \circ \gamma_{(\varphi,\psi),Z})^\dagger = T_{\psi\varphi*}(f \circ T^*_\varphi g \circ \gamma_{(\varphi,\psi),Z}) \circ \eta_{\psi\varphi,Z}$$

and on the other hand :

$$\begin{aligned}\gamma^\dagger_{(\varphi,\psi),X} \circ T_{\psi*}(f^\dagger) \circ g^\dagger &= \gamma^\dagger_{(\varphi,\psi),X} \circ T_{\psi*}T_{\varphi*}(f) \circ T_{\psi*}(\eta_{\varphi,Y}) \circ T_{\psi*}(g) \circ \eta_{\psi,Z} \\ &= T_{\psi\varphi*}(f) \circ \gamma^\dagger_{(\varphi,\psi),T^*_\varphi Y} \circ T_{\psi*}T_{\varphi*}T^*_\varphi(g) \circ T_{\psi*}(\eta_{\varphi,T^*_\psi Z}) \circ \eta_{\psi,Z} \\ &= T_{\psi\varphi*}(f) \circ \gamma^\dagger_{(\varphi,\psi),T^*_\varphi Y} \circ T_{\psi*}T_{\varphi*}T^*_\varphi(g) \circ \eta_{(\varphi,\psi),Z}\end{aligned}$$

where $(\eta_{(\varphi,\psi)}, \varepsilon_{(\varphi,\psi)})$ denotes the unit and counit of the adjunction that defines the composition $T_\psi \circ T_\varphi : T_i \to T_k$, by virtue of remark 1.1.17(i). Thus, we are reduced to checking that :

$$T_{\psi\varphi*}(T^*_\varphi g \circ \gamma_{(\varphi,\psi),Z}) \circ \eta_{\psi\varphi,Z} = \gamma^\dagger_{(\varphi,\psi),T^*_\varphi Y} \circ T_{\psi*}T_{\varphi*}T^*_\varphi(g) \circ \eta_{(\varphi,\psi),Z}.$$

But we have $\gamma^\dagger_{(\varphi,\psi),T^*_\varphi Y} \circ T_{\psi*}T_{\varphi*}T^*_\varphi(g) = T_{\psi\varphi*}T^*_\varphi(g) \circ \gamma^\dagger_{(\varphi,\psi),T^*_\varphi T^*_\psi Z}$, so we are further reduced to showing the identity :

$$T_{\psi\varphi*}(\gamma_{(\varphi,\psi),Z}) \circ \eta_{\psi\varphi,Z} = \gamma^\dagger_{(\varphi,\psi),T^*_\varphi T^*_\psi Z} \circ \eta_{(\varphi,\psi),Z}.$$

But using the explicit expressions of remark 1.1.17(ii) we see that :

$$\gamma^\dagger_{(\varphi,\psi)} * T^*_\varphi T^*_\psi = (T_{\psi\varphi*} * \varepsilon_{(\varphi,\psi)} * T^*_\varphi T^*_\psi) \odot (T_{\psi\varphi*} * \gamma_{(\varphi,\psi)} * T_{\psi*}T_{\varphi*}T^*_\varphi T^*_\psi) \odot (\eta_{\psi\varphi} * T_{\psi*}T_{\varphi*}T^*_\varphi T^*_\psi)$$

and on the other hand

$$(\eta_{\psi\varphi} * T_{\psi*}T_{\varphi*}T^*_\varphi T^*_\psi) \odot \eta_{(\varphi,\psi)} = (T_{\psi\varphi*}T^*_{\psi\varphi} * \eta_{(\varphi,\psi)}) \odot \eta_{\psi\varphi}$$

so it suffices to check that :

$$\gamma_{(\varphi,\psi)} = (\varepsilon_{(\varphi,\psi)} * T^*_\varphi T^*_\psi) \odot (\gamma_{(\varphi,\psi)} * T_{\psi*}T_{\varphi*}T^*_\varphi T^*_\psi) \odot (T^*_{\psi\varphi} * \eta_{(\varphi,\psi)}).$$

The latter follows from the identity :

$$(\gamma_{(\varphi,\psi)} * T_{\psi*}T_{\varphi*}T^*_\varphi T^*_\psi) \odot (T^*_{\psi\varphi} * \eta_{(\varphi,\psi)}) = (T^*_\varphi T^*_\psi * \eta_{(\varphi,\psi)}) \odot \gamma_{(\varphi,\psi)}$$

together with the triangular identities for $(\eta_{(\varphi,\psi)}, \varepsilon_{(\varphi,\psi)})$. □

Definition 4.6.4. (i) For any two categories $\mathscr{A}, \mathscr{B}$ and any functor $F : \mathscr{A} \to \mathscr{B}$ we denote

$$\Sigma(\mathscr{A}/\mathscr{B})$$

the *category of sections of* F, which is the subcategory of $\mathsf{Fun}(\mathscr{B}, \mathscr{A})$ whose objects are the functors $G : \mathscr{B} \to \mathscr{A}$ such that $F \circ G = \mathbf{1}_\mathscr{B}$ and whose morphisms are the natural transformations $\beta : G \Rightarrow G'$ with $F * \beta = i_\mathscr{B}$ (where $i_\mathscr{B}$ is the identity automorphism of $\mathbf{1}_\mathscr{B}$).

(ii) Let T be a fibred topos over I, and π, π' its associated fibrations as in (4.6.2); we let :

$$\mathsf{Top}(T)_* := \Sigma(\mathscr{F}ib(T_*)/I^o) \qquad \text{and} \qquad \mathsf{Top}(T) := \Sigma(\mathscr{F}ib(T^*)/I)^o.$$

By virtue of lemma 4.6.3 and remark 1.1.19(i) we have a natural isomorphism of categories :

$$\mathsf{Top}(T) \xrightarrow{\sim} \mathsf{Top}(T)_*. \qquad (4.6.5)$$

4.6.6. Let $\omega : T \to S$ be any morphism of fibred topoi over I. From the pseudo-natural transformations $\omega^* : S^* \Rightarrow T^*$ and $\omega_* : T_* \Rightarrow S_*$ we get the functors

$$\mathscr{F}ib(\omega^*) : \mathscr{F}ib(S^*) \to \mathscr{F}ib(T^*)$$
$$\mathscr{F}ib(\omega_*) : \mathscr{F}ib(T_*) \to \mathscr{F}ib(S_*)$$

(notation of (3.1.19)); whence functors

$$\mathsf{Top}(\omega)^* : \mathsf{Top}(S) \to \mathsf{Top}(T) \qquad E \mapsto \mathscr{F}ib(\omega^*) \circ E$$
$$\mathsf{Top}(\omega)_* : \mathsf{Top}(T)_* \to \mathsf{Top}(S)_* \qquad E \mapsto \mathscr{F}ib(\omega_*) \circ E.$$

By virtue of (4.6.5) we may then identify $\mathsf{Top}(\omega)_*$ with a functor which we shall also denote

$$\mathsf{Top}(\omega)_* : \mathsf{Top}(T) \to \mathsf{Top}(S).$$

Moreover, ω also induces a morphism of fibred sites

$$\underline{\mathrm{Can}}(\omega) := \mathscr{F}ib((-)^o * {}^o\omega^*) : \underline{\mathrm{Can}}(T) \to \underline{\mathrm{Can}}(S).$$

Let $\omega : T \to S$ and $\nu : S \to U$ be two morphisms of fibred topoi over I. A simple inspection of the definition shows that

$$\begin{aligned} \mathsf{Top}(\omega)^* \circ \mathsf{Top}(\nu)^* &= \mathsf{Top}(\nu \circ \omega)^* \\ \mathsf{Top}(\nu)_* \circ \mathsf{Top}(\omega)_* &= \mathsf{Top}(\nu \circ \omega)_* \\ \underline{\mathrm{Can}}(\nu) \circ \underline{\mathrm{Can}}(\omega) &= \underline{\mathrm{Can}}(\nu \circ \omega). \end{aligned} \tag{4.6.7}$$

4.6.8. Let $\omega, \omega' : T \to S$ be two morphisms of fibred topoi over I, and $\Xi : \omega \rightsquigarrow \omega'$ a transformation. Then Ξ induces natural transformations

$$\mathscr{F}ib(\Xi_*) : \mathscr{F}ib(\omega_*) \Rightarrow \mathscr{F}ib(\omega'_*) \qquad \mathscr{F}ib(\Xi^*) : \mathscr{F}ib(\omega^*) \Rightarrow \mathscr{F}ib(\omega'^*)$$

whence natural transformations :

$$\mathsf{Top}(\Xi)^* : \mathsf{Top}(\omega')^* \Rightarrow \mathsf{Top}(\omega)^* \qquad E \mapsto \mathscr{F}ib(\Xi^*) * E$$
$$\mathsf{Top}(\Xi)_* : \mathsf{Top}(\omega)_* \Rightarrow \mathsf{Top}(\omega')_* \qquad E \mapsto \mathscr{F}ib(\Xi_*) * E.$$

Moreover, Ξ induces a natural transformation of morphisms of fibred sites :

$$\underline{\mathrm{Can}}(\Xi) := \mathscr{F}ib((-)^o \circ {}^o\Xi^*) : \underline{\mathrm{Can}}(\omega') \to \underline{\mathrm{Can}}(\omega).$$

Remark 4.6.9. (i) Let T be a fibred topos over I with coherence constraint (δ^T, γ^T), and $T^u : I \to \mathbf{Topos}$ the unital pseudo-functor associated with T (proposition 2.4.3); by (4.6.7) and remark 2.2.14(i), the pseudo-natural isomorphism $\alpha^T : T \stackrel{\sim}{\to} T^u$ induces an isomorphism of categories $\mathsf{Top}(\alpha^T)^* : \mathsf{Top}(T^u) \stackrel{\sim}{\to} \mathsf{Top}(T)$. Then the following description of $\mathsf{Top}(T^u)$ – obtained by direct inspection – also applies to $\mathsf{Top}(T)$, up to natural isomorphism of categories:

- the objects of $\mathsf{Top}(T^u)$ are the systems $E_\bullet := ((E_i, E_\varphi) \mid i \in \mathrm{Ob}(I), \varphi \in \mathrm{Morph}(I))$ with $E_i \in \mathrm{Ob}(T_i)$ for every $i \in \mathrm{Ob}(I)$ and where

  $$E_\varphi : T^*_\varphi E_j \to E_i \qquad \text{for every } \varphi : i \to j \text{ in } I$$

  is a morphism of T_i, such that the following diagram commutes :

  $$\begin{array}{ccc} T^*_\psi T^*_\varphi E_k & \xrightarrow{T^*_\psi E_\varphi} & T^*_\psi E_j \\ {\scriptstyle (\gamma^{T^u}_{(\varphi,\psi)})^\dagger_{E_k}} \uparrow & & \downarrow {\scriptstyle E_\varphi} \\ T^*_{\psi\circ\varphi} E_k & \xrightarrow{E_{\psi\circ\varphi}} & E_i \end{array}$$

  for every pair of morphisms $i \xrightarrow{\varphi} j \xrightarrow{\psi} k$ of I, and $E_{\mathbf{1}_i} = \mathbf{1}_{E_i}$ for every $i \in \mathrm{Ob}(I)$.

- the morphisms $f_\bullet : E_\bullet \to F_\bullet$ are the systems $(f_i \mid i \in \mathrm{Ob}(I))$ where $f_i : E_i \to F_i$ is a morphism of T_i for every $i \in \mathrm{Ob}(I)$, such that the following diagram commutes :

$$\begin{array}{ccc} T^*_\varphi E_j & \xrightarrow{T^*_\varphi f_j} & T^*_\varphi F_j \\ {\scriptstyle E_\varphi}\downarrow & & \downarrow{\scriptstyle F_\varphi} \\ E_i & \xrightarrow{f_i} & F_i \end{array} \qquad \text{for every morphism } \varphi : i \to j \text{ of } I.$$

- the composition of morphisms $f_\bullet : E_\bullet \to F_\bullet$ and $g_\bullet : F_\bullet \to G_\bullet$ is defined by the obvious rule : $(g_\bullet \circ f_\bullet)_i := g_i \circ f_i$ for every $i \in \mathrm{Ob}(I)$.

(ii) Likewise, notice that for every unital fibred topos T over I, the objects of $\mathsf{Top}(T)_*$ are the systems $F_\bullet := (F_i, F_\varphi \mid i \in \mathrm{Ob}(I),\ \varphi \in \mathrm{Morph}(I))$ with $F_i \in \mathrm{Ob}(T_i)$ for every $i \in \mathrm{Ob}(I)$ and $F_\varphi : F_j \to T_{\varphi*}F_i$ a morphism of T_j, for every morphism $\varphi : i \to j$ of I. This datum is required to satisfy the identity

$$\gamma^T_{(\varphi,\psi),F_i} \circ (T_{\varphi*}F_\varphi) \circ F_\psi = F_{\psi\circ\varphi}$$

for every pair $i \xrightarrow{\varphi} j \xrightarrow{\psi} k$ of morphisms of I, and $F_{\mathbf{1}_i} = \mathbf{1}_{F_i}$ for every $i \in \mathrm{Ob}(I)$, where, as usual, γ^T denotes the coherence constraint of T. The morphisms $f_\bullet : F_\bullet \to F'_\bullet$ are the systems $(f_i : F_i \to F'_i \mid i \in \mathrm{Ob}(I))$ where f_i is a morphism of T_i for every $i \in \mathrm{Ob}(I)$ and

$$F'_\varphi \circ f_j = (T_{\varphi*}f_i) \circ F_\varphi \qquad \text{for every morphism } \varphi : i \to j \text{ of } I.$$

(iii) To every morphism $\omega : T \to S$ of fibred topoi over I there corresponds a morphism of unital fibred topoi $\omega^u : T^u \to S^u$ (see remark 2.4.2(i)); thus, in order to describe $\mathsf{Top}(\omega)^*$, we may assume without loss of generality that T and S are unital. In this case, we get the following explicit description. By definition, the coherence constraint of ω assigns to every morphism $\varphi : i \to j$ of I a natural transformation

$$\begin{array}{ccc} S_j & \xrightarrow{\omega^*_j} & T_j \\ {\scriptstyle S^*_\varphi}\downarrow & \swArrow_{\tau^{\omega\dagger}_\varphi} & \downarrow{\scriptstyle T^*_\varphi} \\ S_i & \xrightarrow[\omega^*_i]{} & T_i. \end{array}$$

Then $\mathsf{Top}(\omega)^*$ is given by the rule : $E_\bullet \mapsto ((\omega^*_i(E_i), E^\omega_\varphi) \mid i \in \mathrm{Ob}(I), \varphi \in \mathrm{Morph}(I))$, with

$$E^\omega_\varphi : T^*_\varphi \circ \omega^*_j(E_j) \xrightarrow{\tau^{\omega\dagger}_{\varphi,E_j}} \omega^*_i \circ S^*_\varphi(E_j) \xrightarrow{\omega^*_i(E_\varphi)} \omega^*_i(E_i)$$

and by assigning to every morphism $g_\bullet : E_\bullet \to E'_\bullet$ of $\mathsf{Top}(S)$ the morphism

$$(\omega^*_i(g_i) : \omega^*_i(E_i) \to \omega^*_i(E'_i) \mid i \in \mathrm{Ob}(I)).$$

Proposition 4.6.10. *The functor* $\mathsf{Top}(\omega)^*$ *is left adjoint to* $\mathsf{Top}(\omega)_*$.

Proof. Arguing as in remark 4.6.9(i), we reduce easily to the case where T and S are unital. In light of the identification (4.6.5), it suffices to exhibit an adjunction for the pair of functors

$$\mathsf{Top}(S)_* \underset{\Omega_*}{\overset{\Omega^*}{\rightleftarrows}} \mathsf{Top}(T)$$

resulting from the pair $(\mathsf{Top}(\omega)^*, \mathsf{Top}(\omega)_*)$ via these identifications. Explicitly, Ω^* assigns to every object $F_\bullet$ of $\mathsf{Top}(S)_*$ (see remark 4.6.9(ii)) the following object of $\mathsf{Top}(T)$:

$$(\omega^*_i(F_i), F^\Omega_\varphi := \omega^*_i(F^\dagger_\varphi) \circ (\tau^\omega_\varphi)^\dagger_{F_j} \mid i \in \mathrm{Ob}(I),\ \varphi \in \mathrm{Morph}(I))$$

where $F^\dagger_\varphi : T^*_\varphi F_j \to F_i$ is the morphism of T_i corresponding to F_φ under the adjunction of T_φ, *i.e.* $F^\dagger_\varphi = \varepsilon^{T_\varphi}_{E_i} \circ (T^*_\varphi F_\varphi)$, where ε^{T_φ} is the counit of the adjunction of T_φ. For every morphism $f_\bullet : F_\bullet \to F'_\bullet$ of $\mathsf{Top}(S)_*$ we have $\Omega^*(f_\bullet) = (\omega^*_i f_i \mid i \in \mathrm{Ob}(I))$.

Likewise, Ω_* assigns to every object $E_\bullet$ of $\mathsf{Top}(T)$ the following object of $\mathsf{Top}(S)_*$:

$$(\omega_{i*}(E_i), E^\Omega_\varphi := (\tau^\omega_\varphi)^{-1}_{E_i} \circ \omega_{j*}(E^\dagger_\varphi) \mid i \in \mathrm{Ob}(I),\ \varphi \in \mathrm{Morph}(I))$$

where $E^\dagger_\varphi : E_j \to T_{\varphi*}E_i$ is the morphism of T_j corresponding to E_φ under the adjunction of T_φ, *i.e.* $E^\dagger_\varphi = (T_{\varphi*}E_\varphi) \circ \eta^{T_\varphi}_{E_j}$, where η^{T_φ} is the unit of T_φ. For every morphism $g_\bullet : E_\bullet \to E'_\bullet$ of $\mathsf{Top}(T)$ we have $\Omega_*(g_\bullet) = (\omega_{i*}g_i \mid i \in \mathrm{Ob}(I))$.

Now, let $\beta : \Omega^*(F_\bullet) \to E_\bullet$ be a morphism of $\mathsf{Top}(T)$; thus, β is a system of morphisms $(\beta_i : \omega^*_i(F_i) \to E_i \mid i \in \mathrm{Ob}(I))$ such that the following diagram commutes :

(4.6.11)
$$\begin{array}{ccc} T^*_\varphi \omega^*_j F_j & \xrightarrow{T^*_\varphi \beta_j} & T^*_\varphi E_j \\ {\scriptstyle F^\Omega_\varphi}\downarrow & & \downarrow{\scriptstyle E_\varphi} \\ \omega^*_i F_i & \xrightarrow{\beta_i} & E_i \end{array} \qquad \text{for every morphism } i \xrightarrow{\varphi} j \text{ of } I.$$

Our candidate adjunction assigns to β the system of morphisms

$$\beta^\dagger := (\beta^\dagger_i := \omega_{i*}(\beta_i) \circ \eta^{\omega_i}_{F_i} : F_i \to \omega_{i*}E_i \mid i \in \mathrm{Ob}(I))$$

where η^{ω_i} is the unit of $\omega_i : T_i \to S_i$, so $\beta^\dagger_i$ is the morphism corresponding to β_i under the adjunction of ω_i. Thus, we need to show the commutativity of the diagram :

$$\begin{array}{ccc} F_j & \xrightarrow{\beta^\dagger_j} & \omega_{j*}E_j \\ {\scriptstyle F_\varphi}\downarrow & & \downarrow{\scriptstyle E^\Omega_\varphi} \\ S_{\varphi*}F_i & \xrightarrow{S_{\varphi*}(\beta^\dagger_i)} & S_{\varphi*}\omega_{i*}E_i \end{array} \qquad \text{for every morphism } i \xrightarrow{\varphi} j \text{ of } I.$$

Set $R := \omega_j \circ T_\varphi$, and let η^R and ε^R be the unit and counit of R; we consider the diagram :

$$\begin{array}{ccccccc} F_j & \xrightarrow{\eta^R_{F_j}} & R_*R^*F_j & \xrightarrow{R_*(F^\Omega_\varphi)} & R_*\omega^*_i F_i & \xrightarrow{(\tau^\omega_\varphi)^{-1}_{\omega^*_i F_i}} & S_{\varphi*}\omega_{i*}\omega^*_i F_i \\ {\scriptstyle \beta^\dagger_j}\downarrow & & \downarrow{\scriptstyle R_*T^*_\varphi(\beta_j)} & & \downarrow{\scriptstyle R_*(\beta_i)} & & \downarrow{\scriptstyle S_{\varphi*}\omega_{i*}(\beta_i)} \\ \omega_{j*}E_j & \xrightarrow[\omega_{j*}(\eta^{T_\varphi}_{E_j})]{} & R_*T^*_\varphi E_j & \xrightarrow[R_*(E_\varphi)]{} & R_*E_i & \xrightarrow[(\tau^\omega_\varphi)^{-1}_{E_i}]{} & S_{\varphi*}\omega_{i*}E_i. \end{array}$$

Recalling that $\eta^R_{F_j} = \omega_{j*}(\eta^{T_\varphi}_{\omega^*_j F_j}) \circ \eta^{\omega_j}_{F_j}$, we see that the left square commutes, by naturality of η^{T_φ}. The commutativity of the central square follows trivially from that of (4.6.11), and that of the right square follows from the naturality of τ^ω_φ. Notice now that the composition of the three bottom horizontal arrows equals E^Ω_φ. We are therefore reduced to checking the identity :

$$(\tau^\omega_\varphi)^{-1}_{\omega^*_i F_i} \circ R_*(F^\Omega_\varphi) \circ \eta^R_{F_j} = S_{\varphi*}(\eta^{\omega_i}_{F_i}) \circ F_\varphi.$$

We compute :

$$\begin{aligned}
R_*(F^\Omega_\varphi)\circ\eta^R_{F_j} &= R_*(\omega_i^*(F^\dagger_\varphi)\circ\tau^{\omega\dagger}_{\varphi,F_j})\circ\eta^R_{F_j} \\
&= R_*\omega_i^*(F^\dagger_\varphi)\circ R_*(\varepsilon^R_{\omega_i^*S^*_\varphi F_j})\circ R_*R^*(\tau^\omega_{\varphi,\omega_i^*S^*_\varphi F_j}\circ\eta^{S_\varphi\circ\omega_i}_{F_j})\circ\eta^R_{F_j} \\
&= R_*\omega_i^*(F^\dagger_\varphi)\circ R_*(\varepsilon^R_{\omega_i^*S^*_\varphi F_j})\circ\eta^R_{R_*\omega_i^*S^*_\varphi F_j}\circ\tau^\omega_{\varphi,\omega_i^*S^*_\varphi F_j}\circ\eta^{S_\varphi\circ\omega_i}_{F_j} \\
&= R_*\omega_i^*(F^\dagger_\varphi)\circ\tau^\omega_{\varphi,\omega_i^*S^*_\varphi F_j}\circ\eta^{S_\varphi\circ\omega_i}_{F_j} \\
&= \tau^\omega_{\varphi,\omega_i^*F_i}\circ S_{\varphi*}\omega_{i*}\omega_i^*(F^\dagger_\varphi)\circ\eta^{S_\varphi\circ\omega_i}_{F_j} \\
&= \tau^\omega_{\varphi,\omega_i^*F_i}\circ S_{\varphi*}\omega_{i*}\omega_i^*(\varepsilon^{S_\varphi}_{E_i})\circ S_{\varphi*}\omega_{i*}\omega_i^*S^*_\varphi(F_\varphi)\circ\eta^{S_\varphi\circ\omega_i}_{F_j} \\
&= \tau^\omega_{\varphi,\omega_i^*F_i}\circ S_{\varphi*}\omega_{i*}\omega_i^*(\varepsilon^{S_\varphi}_{E_i})\circ\eta^{S_\varphi\circ\omega_i}_{S_{\varphi*}F_i}\circ F_\varphi.
\end{aligned}$$

So we are further reduced to showing that :

$$S_{\varphi*}\omega_{i*}\omega_i^*(\varepsilon^{S_\varphi}_{E_i})\circ\eta^{S_\varphi\circ\omega_i}_{S_{\varphi*}F_i} = S_{\varphi*}(\eta^{\omega_i}_{F_i}).$$

But we have

$$\begin{aligned}
S_{\varphi*}\omega_{i*}\omega_i^*(\varepsilon^{S_\varphi}_{E_i})\circ\eta^{S_\varphi\circ\omega_i}_{T_{\varphi*}F_i} &= S_{\varphi*}\omega_{i*}\omega_i^*(\varepsilon^{S_\varphi}_{E_i})\circ S_{\varphi*}(\eta^{\omega_i}_{S^*_\varphi S_{\varphi*}F_i})\circ\eta^{S_\varphi}_{S_{\varphi*}F_i} \\
&= S_{\varphi*}(\omega_{i*}\omega_i^*(\varepsilon^{S_\varphi}_{E_i})\circ\eta^{\omega_i}_{S^*_\varphi S_{\varphi*}F_i})\circ\eta^{S_\varphi}_{S_{\varphi*}F_i} \\
&= S_{\varphi*}(\eta^{\omega_i}_{F_i})\circ S_{\varphi*}(\varepsilon^{S_\varphi}_{F_i})\circ\eta^{S_\varphi}_{S_{\varphi*}F_i}
\end{aligned}$$

so it suffices to invoke the triangular identities for the pair $(\eta^{S_\varphi},\varepsilon^{S_\varphi})$ to conclude.

Likewise one shows that for every morphism $\lambda : F_\bullet \to \Omega_*E_\bullet$ in $\mathsf{Top}(S)_*$, the system

$$(\lambda_i^\dagger := \varepsilon^{\omega_i}_{E_i}\circ\omega_i^*(\lambda_i) : \omega_i^*F_i \to E_i \mid i\in\mathrm{Ob}(I))$$

is a morphism $\Omega^*F_\bullet \to E_\bullet$ in $\mathsf{Top}(T)$: the verification shall be left to the reader. In view of remark 1.1.17(ii), it is then clear that these two rules yield mutually inverse bijections between $\mathrm{Hom}_{\mathsf{Top}(T)}(\Omega^*(F_\bullet),E_\bullet)$ and $\mathrm{Hom}_{\mathsf{Top}(S)_*}(F_\bullet,\Omega_*(E_\bullet))$. Lastly, the naturality of the rule $(\beta : \Omega^*(F_\bullet)\to E_\bullet)\mapsto\beta^\dagger$ with respect to both $F_\bullet$ and $E_\bullet$ follows directly from the same property for the adjunction of each morphism ω_i (details left to the reader). □

Remark 4.6.12. In the situation of proposition 4.6.10, denote by $\lambda_S : \mathsf{Top}(S) \xrightarrow{\sim} \mathsf{Top}(S)_*$ the natural isomorphism of (4.6.5). Then we have $\mathsf{Top}(\omega)_*\circ\mathsf{Top}(\omega)^* = \lambda_S^{-1}\circ\Omega_*\circ\Omega^*\circ\lambda_S$, and $\mathsf{Top}(\omega)^*\circ\mathsf{Top}(\omega)_* = \Omega^*\circ\Omega_*$. It follows that from the proof of proposition 4.6.10 we can extract an adjunction for the pair $(\mathsf{Top}(\omega)^*,\mathsf{Top}(\omega)_*)$, whose unit $\eta^{\mathsf{Top}(\omega)}$ and counit $\varepsilon^{\mathsf{Top}(\omega)}$ are given explicitly by the rules :

$$F_\bullet\mapsto(\eta^{\omega_i}_{F_i}\mid i\in\mathrm{Ob}(I)) \qquad E_\bullet\mapsto(\varepsilon^{\omega_i}_{E_i}\mid i\in\mathrm{Ob}(I))$$

where $(\eta^{\omega_i},\varepsilon^{\omega_i})$ are the unit and counit for the adjoint pair (ω_i^*,ω_{i*}), for every $i\in\mathrm{Ob}(I)$.

4.6.13. Let $\pi : \mathscr{A}\to I$ and $\rho : J\to I$ be any two functors; we have an obvious functor

$$\Sigma(\mathscr{A}/\rho)^* : \Sigma(\mathscr{A}/I)\to\Sigma(J\times_I\mathscr{A}/J) \qquad (G : I\to\mathscr{A})\mapsto J\times_I G$$

that assigns to every morphism $\alpha : G\Rightarrow G'$ in $\Sigma(\mathscr{A}/I)$ the natural transformation $J\times_I\alpha : J\times_I G\Rightarrow J\times_I G'$. Especially, if I and J are small categories, and T is any fibred topos over I, recalling the natural identification $\mathscr{F}ib((T\circ\rho)^*)\xrightarrow{\sim}J\times_I\mathscr{F}ib(T^*)$ of remark 3.1.5(ii), we deduce a functor

$$\mathsf{Top}(T/\rho)^* := \Sigma(\mathscr{F}ib(T^*)/\rho)^{*o} : \mathsf{Top}(T)\to\mathsf{Top}(T\circ\rho).$$

Explicitly, $\mathsf{Top}(T/\rho)^*$ assigns to every $E_\bullet$ as in remark 4.6.9(i) the datum $(E_{\rho(j)},E_{\rho(\varphi)}\mid j\in\mathrm{Ob}(J),\ \varphi\in\mathrm{Morph}(J))$, and to every morphism $f_\bullet : E_\bullet\to F_\bullet$ of $\mathsf{Top}(T)$, the morphism of

$\mathsf{Top}(T \circ \rho)$ given by the system $(f_{\rho(j)} : E_{\rho(j)} \to F_{\rho(j)} \mid j \in \mathrm{Ob}(J))$. We wish next to exhibit left and right adjoints for $\mathsf{Top}(T/\rho)^*$. To this aim, we observe more generally :

Proposition 4.6.14. *Let $\rho : J \to I$ be a functor between small categories, U' a universe containing U, and $\mathsf{c} : I^o \to \mathsf{U}'$-$\mathbf{Cat}$ any pseudo-functor such that*

(a) *The category c_i is complete for every $i \in \mathrm{Ob}(I)$.*

(b) *The functor $\mathsf{c}_f : \mathsf{c}_i \to \mathsf{c}_{i'}$ commutes with small limits, for every morphism $i' \xrightarrow{f} i$ in I.*

Then $\Sigma(\mathscr{F}ib(\mathsf{c})/\rho)^* : \Sigma(\mathscr{F}ib(\mathsf{c})/I) \to \Sigma(\mathscr{F}ib(\mathsf{c} \circ \rho^o)/J)$ admits a right adjoint.

Proof. By proposition 2.4.3 we may assume that c is unital. Now, set $\mathscr{A} := \mathscr{F}ib(\mathsf{c})$, denote by $\pi : \mathscr{A} \to I$ the projection, and let $F_\bullet : J \to J \times_I \mathscr{A}$ be any object of $\Sigma(J \times_I \mathscr{A}/J)$; hence $F_\bullet$ assigns to every $j \in \mathrm{Ob}(J)$ an object $F_j \in \mathsf{c}_{\rho(j)}$, and to every morphism $\psi : j \to j'$ in J a morphism $F_\psi : F_j \to \mathsf{c}_{\rho(\psi)} F_{j'}$ of $\mathsf{c}_{\rho(j)}$. We set

$$\Lambda_i(j, \varphi) := \mathsf{c}_\varphi F_j \qquad \text{for every } i \in \mathrm{Ob}(I) \text{ and } (j, \varphi : i \to \rho(j)) \in \mathrm{Ob}(i/\rho J).$$

For every morphism $(j, \varphi) \xrightarrow{i/\psi} (j', \varphi')$ of $i/\rho J$ we define $\Lambda_i(i/\psi) : \Lambda_i(j, \varphi) \to \Lambda_i(j', \varphi')$ as the composition

$$\mathsf{c}_\varphi F_j \xrightarrow{\mathsf{c}_\varphi F_\psi} \mathsf{c}_\varphi \mathsf{c}_{\rho(\psi)} F_{j'} \xrightarrow{(\gamma^{\mathsf{c}}_{\varphi, \rho(\psi)})_{F_{j'}}} \mathsf{c}_{\varphi'} F_{j'}$$

where γ^{c} is the coherence constraint of c. Also, for every morphism $f : i' \to i$ in I, let us set

$$\Lambda_f(j, \varphi) := (\gamma^{\mathsf{c}}_{f, \varphi})^{-1}_{F_j} : \Lambda_{i'}(j, \varphi \circ f) \to \mathsf{c}_f(\Lambda_i(j, \varphi)) \qquad \text{for every } (j, \varphi) \in \mathrm{Ob}(i/\rho J).$$

Claim 4.6.15. (i) The rules : $(j, \varphi) \mapsto \Lambda_i(j, \varphi)$ and $i/\psi \mapsto \Lambda(i/\psi)$ for every object (j, φ) and morphism i/ψ of $i/\rho J$ define a functor

$$\Lambda_i^{F_\bullet} : i/\rho J \to \pi^{-1}(i) \qquad \text{for every } i \in \mathrm{Ob}(I).$$

(ii) Let the functor $f/\rho J : i/\rho J \to i'/\rho J$ be as in (1.1.27). The rule : $(j, \varphi) \mapsto \Lambda_f(j, \varphi)$ defines a natural transformation

$$\Lambda_f^{F_\bullet} : \Lambda_{i'}^{F_\bullet} \circ (f/\rho J) \Rightarrow \mathsf{c}_f \circ \Lambda_i^{F_\bullet}.$$

Proof of the claim. (i): Since c is unital, a simple inspection shows that $\Lambda_i(\mathbf{1}_{(j,\varphi)}) = \mathbf{1}_{\Lambda(j,\varphi)}$ for every $(j, \varphi) \in \mathrm{Ob}(\rho J/i)$. Next consider a pair of morphisms $(j, \varphi) \xrightarrow{i/\psi} (j', \varphi') \xrightarrow{i/\psi'} (j'', \varphi'')$ of $i/\rho J$. We have

$$\begin{aligned}
\Lambda_i(i/\psi') \circ \Lambda_i(i/\psi) &= (\gamma^{\mathsf{c}}_{\varphi', \rho(\psi')})_{F_{j''}} \circ \mathsf{c}_{\varphi'} F_{\psi'} \circ (\gamma^{\mathsf{c}}_{\varphi, \rho(\psi)})_{F_{j'}} \circ \mathsf{c}_\varphi F_\psi \\
&= (\gamma^{\mathsf{c}}_{\varphi', \rho(\psi')})_{F_{j''}} \circ (\gamma^{\mathsf{c}}_{\varphi, \rho(\psi)} * \mathsf{c}_{\rho(\psi')})_{F_{j'}} \circ \mathsf{c}_\varphi \mathsf{c}_{\rho(\psi)}(F_{\psi'}) \circ \mathsf{c}_\varphi F_\psi \\
&= (\gamma^{\mathsf{c}}_{\varphi', \rho(\psi')})_{F_{j''}} \circ (\gamma^{\mathsf{c}}_{\varphi, \rho(\psi)} * \mathsf{c}_{\rho(\psi')})_{F_{j'}} \circ \mathsf{c}_\varphi((\gamma^{\mathsf{c}\,-1}_{\rho(\psi), \rho(\psi')})_{F_{j''}} \circ F_{\psi' \circ \psi}) \\
&= (\gamma^{\mathsf{c}}_{\varphi, \rho(\psi' \circ \psi)})_{F_{j''}} \circ \mathsf{c}_\varphi F_{\psi' \circ \psi} \\
&= \Lambda_i(i/\psi' \circ \psi)
\end{aligned}$$

whence the contention.

(ii): It suffices to remark the commutativity of the diagram :

$$\begin{array}{ccccc}
\mathsf{c}_{\varphi \circ f} F_j & \xrightarrow{\mathsf{c}_{\varphi \circ f} F_\psi} & \mathsf{c}_{\varphi \circ f} \mathsf{c}_{\rho(\psi)} F_{j'} & \xrightarrow{(\gamma^{\mathsf{c}}_{\varphi \circ f, \rho(\psi)})_{F_{j'}}} & \mathsf{c}_{\rho(\psi) \circ \varphi \circ f} F_{j'} \\
\big\downarrow {\scriptstyle (\gamma^{\mathsf{c}}_{f,\varphi})^{-1}_{F_j}} & & \big\downarrow {\scriptstyle (\gamma^{\mathsf{c}}_{f,\varphi})^{-1}_{\mathsf{c}_{\rho(\psi)} F_{j'}}} & & \big\downarrow {\scriptstyle (\gamma^{\mathsf{c}}_{f,\varphi'})^{-1}_{F_{j'}}} \\
\mathsf{c}_f \mathsf{c}_\varphi F_j & \xrightarrow[\mathsf{c}_f \mathsf{c}_\varphi F_\psi]{} & \mathsf{c}_f \mathsf{c}_\varphi \mathsf{c}_{\rho(\psi)} F_{j'} & \xrightarrow[\mathsf{c}_f(\gamma^{\mathsf{c}}_{\varphi, \rho(\psi)})_{F_{j'}}]{} & \mathsf{c}_f \mathsf{c}_{\rho(\psi) \circ \varphi} F_{j'}
\end{array}$$

for every morphism $(i/\psi) : (j, \varphi) \to (j', \varphi')$ of $i/\rho J$. $\Diamond$

In view of claim 4.6.15(i), for every $i \in \mathrm{Ob}(I)$ we choose $\lambda(F_\bullet, i) \in \mathrm{Ob}(\mathsf{c}_i)$ representing the limit of $\Lambda_i^{F_\bullet}$, and a universal cone $\tau^{F_\bullet,i} : c_{\lambda(F_\bullet,i)} \Rightarrow \Lambda_i^{F_\bullet}$. In view of claim 4.6.15(ii) there follows a cone

$$\Upsilon_f^{F_\bullet} := \Lambda_f^{F_\bullet} \odot (\tau^{F_\bullet,i'} * (f/\rho J)) : c_{\lambda(F_\bullet,i')} \Rightarrow \mathsf{c}_f \circ \Lambda_i^{F_\bullet}.$$

On the other hand, notice that the cone $\mathsf{c}_f * \tau^{F_\bullet,i} : c_{\mathsf{c}_f\lambda(F_\bullet,i)} \Rightarrow \mathsf{c}_f \circ \Lambda_i^{F_\bullet}$ is still universal, since c_f commutes with small limits; hence there exists a unique morphism in $\mathsf{c}_{i'}$

$$\lambda(F_\bullet, f) : \lambda(F_\bullet, i') \to \mathsf{c}_f\lambda(F_\bullet, i) \qquad \text{such that} \qquad (\mathsf{c}_f * \tau^{F_\bullet,i}) \odot c_{\lambda(F_\bullet,f)} = \Upsilon_f^{F_\bullet}.$$

Claim 4.6.16. The rules : $i \mapsto \lambda(F_\bullet, i)$ and $f \mapsto \lambda(F_\bullet, f)$ for every $i \in \mathrm{Ob}(I)$ and every morphism f of I define a functor

$$\lambda(F_\bullet) : I \to \mathscr{A}.$$

Proof of the claim. Since c is unital, a simple inspection shows that $\Lambda_{\mathbf{1}_i}^{F_\bullet} = \mathbf{1}_{\Lambda_i^{F_\bullet}}$ for every $i \in \mathrm{Ob}(I)$, whence $\lambda(F_\bullet, \mathbf{1}_i) = \mathbf{1}_{\lambda(F_\bullet,i)}$. Next, let $i'' \xrightarrow{f'} i' \xrightarrow{f} i$ be two morphisms of I; we need to check that $\lambda(F_\bullet, f) \circ \lambda(F_\bullet, f') = \lambda(F_\bullet, f \circ f')$, and by the universality of $\mathsf{c}_{f\circ f'} * \tau^{F_\bullet,i}$ it suffices to show that $X := (\mathsf{c}_{f\circ f'} * \tau^{F_\bullet,i}) \odot c_{\lambda(F_\bullet,f)\circ\lambda(F_\bullet,f')} = (\mathsf{c}_{f\circ f'} * \tau^{F_\bullet,i}) \odot c_{\lambda(F_\bullet,f\circ f')}$. We compute :

$$\begin{aligned}
X &= (\mathsf{c}_{f\circ f'} * \tau^{F_\bullet,i}) \odot c_{(\gamma^T_{f',f})_{\lambda(F_\bullet,i)}} \odot c_{\mathsf{c}_{f'}\lambda(F_\bullet,f)} \odot c_{\lambda(F_\bullet,f')} \\
&= (\gamma^{\mathsf{c}}_{f,f'} * \Lambda_i^{F_\bullet}) \odot (\mathsf{c}_{f'}\mathsf{c}_f * \tau^{F_\bullet,i}) \odot c_{\mathsf{c}_{f'}\lambda(F_\bullet,f)} \odot c_{\lambda(F_\bullet,f')} \\
&= (\gamma^{\mathsf{c}}_{f,f'} * \Lambda_i^{F_\bullet}) \odot \mathsf{c}_{f'} * (\Lambda_f^{F_\bullet} \odot (\tau^{F_\bullet,i'} * (f/\rho J))) \odot c_{\lambda(F_\bullet,f')} \\
&= (\gamma^{\mathsf{c}}_{f,f'} * \Lambda_i^{F_\bullet}) \odot (\mathsf{c}_{f'} * \Lambda_f^{F_\bullet}) \odot ((\Lambda_{f'}^{F_\bullet} \odot (\tau^{F_\bullet,i''} * (f'/\rho J))) * (f/\rho J)) \\
&= (\gamma^{\mathsf{c}}_{f,f'} * \Lambda_i^{F_\bullet}) \odot (\mathsf{c}_{f'} * \Lambda_f^{F_\bullet}) \odot (\Lambda_{f'}^{F_\bullet} * (f/\rho J)) \odot (\tau^{F_\bullet,i''} * (f \circ f'/\rho J)).
\end{aligned}$$

So we are reduced to checking that

$$(\gamma^{\mathsf{c}}_{f,f'} * \Lambda_i^{F_\bullet}) \odot (\mathsf{c}_{f'} * \Lambda_f^{F_\bullet}) \odot (\Lambda_{f'}^{F_\bullet} * (f/\rho J)) = \Lambda_{f\circ f'}^{F_\bullet}.$$

But the latter follows directly from the coherence axioms for γ^{c}. ◊

It is clear that the functor $\lambda(F_\bullet)$ of claim 4.6.16 is a section of the projection $\mathscr{A} \to I$. Next, let $\beta_\bullet : F_\bullet \to F'_\bullet$ be any morphism of $\Sigma(J \times_I \mathscr{A}/J)$; we deduce easily a natural transformation

$$\Lambda_i^{\beta_\bullet} : \Lambda_i^{F_\bullet} \Rightarrow \Lambda_i^{F'_\bullet} \qquad (j, \varphi) \mapsto (\mathsf{c}_\varphi\beta_j : \mathsf{c}_\varphi F_j \to \mathsf{c}_\varphi F'_j) \qquad \text{for every } i \in \mathrm{Ob}(I)$$

such that

$$(\mathsf{c}_f\Lambda_i^{\beta_\bullet}) \odot \Lambda_f^{F_\bullet} = \Lambda_f^{F'_\bullet} \odot (\Lambda_{i'}^{\beta_\bullet} * (f/\rho J)) \qquad \text{for every morphism } f : i' \to i \text{ of } I \tag{4.6.17}$$

whence a unique morphism in c_i

$$\lambda(\beta_\bullet, i) : \lambda(F_\bullet, i) \to \lambda(F'_\bullet, i) \qquad \text{such that} \qquad \tau^{F'_\bullet,i} \odot c_{\lambda(\beta_\bullet,i)} = \Lambda_i^{\beta_\bullet} \odot \tau^{F_\bullet,i}.$$

Claim 4.6.18. The rule $i \mapsto \lambda(\beta_\bullet, i)$ defines a natural transformation

$$\lambda(\beta_\bullet) : \lambda(F_\bullet) \Rightarrow \lambda(F'_\bullet).$$

Proof of the claim. Let $f : i' \to i$ be any morphism of I; as usual, we reduce to checking the identity : $X := (\mathsf{c}_f * \tau^{F'_\bullet,i}) \odot c_{\lambda(F'_\bullet,f)} \odot c_{\lambda(\beta_\bullet,i')} = Y := (\mathsf{c}_f * \tau^{F'_\bullet,i}) \odot (\mathsf{c}_f * c_{\lambda(\beta_\bullet,i)}) \odot c_{\lambda(F_\bullet,f)}$. We compute :

$$\begin{aligned}
X &= \Upsilon_f^{F'_\bullet} \odot c_{\lambda(\beta_\bullet,i')} = \Lambda_f^{F'_\bullet} \odot (\Lambda_{i'}^{\beta_\bullet} \odot \tau^{F_\bullet,i'}) * (f/\rho J) \\
Y &= \mathsf{c}_f(\Lambda_i^{\beta_\bullet} \odot \tau^{F_\bullet,i}) \odot c_{\lambda(F_\bullet,f)} = \mathsf{c}_f\Lambda_i^{\beta_\bullet} \odot \Upsilon_f^{F_\bullet}
\end{aligned}$$

so the assertion follows from (4.6.17). ◊

Let $\beta_\bullet : F_\bullet \to F'_\bullet$ and $\beta'_\bullet : F'_\bullet \to F''_\bullet$ be two morphisms of $\Sigma(J \times_I \mathscr{A}/J)$; by a simple inspection we see that $\Lambda_i^{\beta'_\bullet \circ \beta_\bullet} = \Lambda_i^{\beta'_\bullet} \odot \Lambda_i^{\beta_\bullet}$ for every $i \in \mathrm{Ob}(I)$, whence $\lambda(\beta'_\bullet \circ \beta_\bullet) = \lambda(\beta'_\bullet) \odot \lambda(\beta_\bullet)$. It is also easily seen that $\lambda(\mathbf{1}_{F_\bullet}) = \mathbf{1}_{\lambda(F_\bullet)}$ for every object $F_\bullet$ of $\Sigma(J \times_I \mathscr{A}/J)$, so we have finally obtained a functor

$$\Sigma(\mathscr{A}/\rho)_* : \Sigma(J \times_I \mathscr{A}/J) \to \Sigma(\mathscr{A}/I) \qquad F_\bullet \mapsto \lambda(F_\bullet) \qquad (\beta_\bullet : F_\bullet \to F'_\bullet) \mapsto \lambda(\beta_\bullet).$$

To see that $\Sigma(\mathscr{A}/\rho)_*$ is the sought right adjoint, consider any objects $E_\bullet$ of $\Sigma(\mathscr{A}/I)$ and $F_\bullet$ of $\Sigma(J \times_I \mathscr{A}/J)$, and a morphism $\beta_\bullet : E_\bullet \to \lambda(F_\bullet)$ in $\Sigma(\mathscr{A}/I)$. It is easily seen that the rule :

$$j \mapsto \beta_j^\dagger : E_{\rho(j)} \xrightarrow{\beta_{\rho(j)}} \lambda(F_\bullet, \rho(j)) \xrightarrow{\tau^{F_\bullet,\rho(j)}_{(j,\mathbf{1}_{\rho(j)})}} F_j \qquad \text{for every } j \in \mathrm{Ob}(J)$$

defines a morphism $\beta_\bullet^\dagger : J \times_I E_\bullet \to F_\bullet$ in $\Sigma(J \times_I \mathscr{A}/J)$ (details left to the reader). Conversely, let $\alpha_\bullet : J \times_I E_\bullet \to F_\bullet$ be a morphism in $\Sigma(J \times_I \mathscr{A}/J)$; for every $i \in \mathrm{Ob}(I)$ and $(j, \varphi) \in \mathrm{Ob}(i/\rho J)$ we let $\tau^{\alpha_\bullet,i}_{(j,\varphi)} := \mathsf{c}_\varphi \alpha_j \circ E_\varphi : E_i \to \mathsf{c}_\varphi F_j$. It is easily seen that the rule : $(j, \varphi) \mapsto \tau^{\alpha_\bullet,i}_{(j,\varphi)}$ defines a cone $\tau^{\alpha_\bullet,i} : c_{E_i} \Rightarrow \Lambda_i^{F_\bullet}$ (details left to the reader); there follows a unique morphism

$$\alpha_i^\dagger : E_i \to \lambda(F_\bullet, i) \qquad \text{in } \mathsf{c}_i \text{ such that} \qquad \tau^{F_\bullet,i} \odot c_{\alpha_i^\dagger} = \tau^{\alpha_\bullet,i}.$$

Claim 4.6.19. The rule $i \mapsto \alpha_i^\dagger$ defines a morphism $\alpha_\bullet^\dagger : E_\bullet \to \lambda(F_\bullet)$ in $\Sigma(\mathscr{A}/I)$.

Proof of the claim. As usual we reduce to checking that

$$X := (\mathsf{c}_f * \tau^{F_\bullet,i}) \odot c_{\mathsf{c}_f \alpha_i^\dagger} \odot c_{E_f} = Y := (\mathsf{c}_f * \tau^{F_\bullet,i}) \odot c_{\lambda(F_\bullet,f)} \odot c_{\alpha_{i'}^\dagger}$$

for every morphism $f : i' \to i$ in I. However, we have :

$$X = (\mathsf{c}_f * \tau^{\alpha,i}) \odot c_{E_f} \qquad Y = \Upsilon_f^{F_\bullet} \odot c_{\alpha_{i'}^\dagger} = \Lambda_f^{F_\bullet} \odot (\tau^{\alpha,i'} * (f/\rho J)).$$

So we come down to checking that

$$(\mathsf{c}_f \mathsf{c}_\varphi \alpha_j) \circ (\mathsf{c}_f E_\varphi) \circ E_f = (\gamma^{\mathsf{c}}_{f,\varphi})^{-1}_{F_j} \circ \mathsf{c}_{\varphi \circ f} \alpha_j \circ E_{\varphi \circ f} \qquad \text{for every } (j, \varphi) \in \mathrm{Ob}(i/\rho J).$$

To this aim, it suffices to notice that we have : $(\gamma^{\mathsf{c}}_{f,\varphi})_{F_j} \circ (\mathsf{c}_f \mathsf{c}_\varphi \alpha_j) = \mathsf{c}_{\varphi \circ f} \alpha_j \circ (\gamma^{\mathsf{c}}_{f,\varphi})_{E_{\rho(j)}}$ and $(\gamma^{\mathsf{c}}_{f,\varphi})_{E_{\rho(j)}} \circ (\mathsf{c}_f E_\varphi) \circ E_f = E_{\varphi \circ f}$. ◊

Claim 4.6.20. For every morphism $\alpha_\bullet : J \times_I E_\bullet \to F_\bullet$ in $\Sigma(J \times_I \mathscr{A}/J)$ and $\beta_\bullet : E_\bullet \to \lambda(F_\bullet)$ in $\Sigma(\mathscr{A}/I)$ we have $(\alpha_\bullet^\dagger)^\dagger = \alpha_\bullet$ and $(\beta_\bullet^\dagger)^\dagger = \beta_\bullet$.

Proof of the claim. The assertion concerning $\alpha_\bullet$ follows by direct inspection. Next, let us consider for every $i \in \mathrm{Ob}(I)$ and every $(j, \varphi) \in \mathrm{Ob}(i/\rho J)$ the diagram of morphisms in c_i

$$\mathscr{D}_{(j,\varphi)} \quad : \quad \begin{array}{ccccc} E_i & \xrightarrow{E_\varphi} & \mathsf{c}_\varphi E_{\rho(j)} & \xrightarrow{\mathsf{c}_\varphi \beta_{\rho(j)}} & \mathsf{c}_\varphi \lambda(F_\bullet, \rho(j)) \\ & \searrow^{\beta_i} & & \nearrow_{\lambda(F_\bullet,\varphi)} & \downarrow{\scriptstyle \mathsf{c}_\varphi \tau^{F_\bullet,\rho(j)}_{(j,\mathbf{1}_{\rho(j)})}} \\ & & \lambda(F_\bullet, i) & \xrightarrow[\tau^{F_\bullet,i}_{(j,\varphi)}]{} & \mathsf{c}_\varphi F_j. \end{array}$$

The assertion is equivalent to the commutativity of $\mathscr{D}_{(j,\varphi)}$ for every such i and (j, φ). However, notice that $(\Lambda_\varphi^{F_\bullet})_{(j,\mathbf{1}_{\rho(j)})} = \mathbf{1}_{\mathsf{c}_\varphi F_j}$, since c is unital; this implies that the lower triangular subdiagram commutes. The commutativity of the upper triangular subdiagram is clear. ◊

Lastly, it is easily seen that the rule : $\beta_\bullet \mapsto \beta_\bullet^\dagger$ is natural in both $E_\bullet$ and $F_\bullet$ (details left to the reader); in view of claim 4.6.20, this rule then establishes the sought adjunction between $\Sigma(\mathscr{A}/\rho)^*$ and $\Sigma(\mathscr{A}/\rho)_*$. □

Corollary 4.6.21. *In the situation of* (4.6.13)*, the functor* $\mathsf{Top}(T/\rho)^*$ *admits both a left and a right adjoint, denoted respectively :*

$$\mathsf{Top}(T/\rho)_! : \mathsf{Top}(T \circ \rho) \to \mathsf{Top}(T) \qquad \textit{and} \qquad \mathsf{Top}(T/\rho)_* : \mathsf{Top}(T \circ \rho) \to \mathsf{Top}(T).$$

Proof. It is easily seen that the isomorphism of categories (4.6.5) (and the corresponding one for $T \circ \rho$) identifies the functor $\mathsf{Top}(T/\rho)^*$ with $\Sigma(\mathscr{F}ib(T_*)/\rho^o)^*$, hence the existence of the right adjoint $\mathsf{Top}(T/\rho)_*$ follows from proposition 4.6.14. On the other hand, by applying the same proposition to $\Sigma(\mathscr{F}ib(T^*)/\rho)^* : \Sigma(\mathscr{F}ib(T^*)/I) \to \Sigma(\mathscr{F}ib(T \circ \rho)^*/J)$ we see that the latter admits as well a right adjoint, hence its opposite functor $\mathsf{Top}(T/\rho)^*$ admits a left adjoint. □

Remark 4.6.22. (i) Let $\rho : J \to I$ be any functor between small categories and T any fibred topos over I. Corollary 4.6.21 implies that the functor $\mathsf{Top}(T/\rho)^*$ commutes with all small limits and all small colimits (proposition 1.3.25(iii,iv)).

(ii) Let $\mathbb{1}$ be a final object of the category $\mathbf{Cat}$ (*i.e.* a category with one object and one morphism); for every $t \in \mathrm{Ob}(I)$ we have a unique functor $\rho^t : \mathbb{1} \to I$ that sends the unique object of $\mathbb{1}$ to t. Clearly $\mathsf{Top}(T \circ \rho^t) = T_t$ and the induced functor

$$\mathsf{Top}(T/\rho^t)^* : \mathsf{Top}(T) \to T_t$$

assigns to every datum $E_\bullet$ as in remark 4.6.9(i) the object E_t and to every morphism $f_\bullet : E_\bullet \to F_\bullet$ of $\mathsf{Top}(T)$ the morphism $f_t : E_t \to F_t$ of T_t. The assertion that $\mathsf{Top}(T/\rho^t)^*$ commutes with limits and colimits for every $t \in \mathrm{Ob}(I)$ then means that *the small limits and colimits in the category* $\mathsf{Top}(T)$ *are computed fibrewise*.

(iii) Moreover, the observation of (ii) determines the limits and colimits in $\mathsf{Top}(T)$ up to unique isomorphism. Indeed, let $F : \Lambda \to \mathsf{Top}(T)$ be any functor from a small category Λ, and let $(L_\bullet, \tau)$ be a pair consisting of an object $L_\bullet$ of $\mathsf{Top}(T)$ representing the colimit of F, and a universal cocone $\tau : F \Rightarrow c_{L_\bullet}$. By (ii) we know that $L_t \in \mathrm{Ob}(T_t)$ represents the colimit of $F^t := \mathsf{Top}(T/\rho^t)^* \circ F : \Lambda \to T_t$ and $\tau^t := \mathsf{Top}(T/\rho^t)^* * \tau : F^t \Rightarrow c_{L_t}$ is a universal cocone for every $t \in \mathrm{Ob}(I)$. Now, let $\varphi : s \to t$ be any morphism in I; we get a natural transformation

$$F^\varphi : T^*_\varphi \circ F^t \Rightarrow F^s \qquad \lambda \mapsto ((F\lambda)_\varphi : T^*_\varphi(F\lambda)_t \to (F\lambda)_s).$$

Since T^*_φ admits a right adjoint, the cocone $T^*_\varphi * \tau^t : T^*_\varphi \circ F^t \Rightarrow c_{T^*_\varphi L_t}$ is still universal (proposition 1.3.25(iv)), hence there exists a unique morphism

$$L'_\varphi : T^*_\varphi L_t \to L_s \qquad \text{in } T_s \text{ such that} \qquad \tau^s \odot F^\varphi = c_{L'_\varphi} \odot (T^*_\varphi * \tau^t).$$

But then we must have $L'_\varphi = L_\varphi$ necessarily, so $L_\bullet$ is completely determined by a choice of universal cocones $(\tau^t \mid t \in \mathrm{Ob}(I))$. Likewise we see that the limit of F is completely determined by the choice of a system of pairs $(M_t, \mu^t : F^t \Rightarrow c_{M_t} \mid t \in \mathrm{Ob}(I)$ with $M_t \in \mathrm{Ob}(T_t)$ representing the limit of F^t, and μ_t a universal cone, for every $t \in \mathrm{Ob}(I)$.

(iv) By direct inspection, we see that the functor

$$\mathsf{Top}(T/\rho^t)_! : T_t \to \mathsf{Top}(T)$$

assigns to every $E \in \mathrm{Ob}(T_t)$ the datum $(E_i, E_\varphi \mid i \in \mathrm{Ob}(I), \varphi \in \mathrm{Morph}(I))$ such that :

$$E_i := \coprod_{f : i \to t} T^*_f E \qquad \text{for every } i \in \mathrm{Ob}(I)$$

where the f ranges over all the morphisms $i \to t$ in I. For every morphism $\varphi : i \to j$ of I, the morphism $E_\varphi : T^*_\varphi E_j \to E_i$ is the unique one fitting in the commutative diagram :

$$\begin{array}{ccc} T^*_\varphi T^*_f E & \xrightarrow{\gamma^{T^*}_{\varphi,f}} & T^*_{f\circ\varphi} E \\ \downarrow & & \downarrow \\ E_j & \xrightarrow{E_\varphi} & E_i \end{array} \qquad \text{for every morphism } f : j \to t \text{ in } I$$

where γ^{T^*} is the coherence constraint of T^*, and where the vertical arrows are induced by the chosen universal cocones for the representatives E_i and E_j of the foregoing coproducts. For every morphism h in T_t, the morphism $\mathsf{Top}(T/\rho^t)_!(h)$ is the natural transformation that assigns to every $i \in \mathrm{Ob}(I)$ the coproduct of morphisms $\coprod_{f:i\to t} T^*_f(h)$: details left to the reader.

4.6.23. Let T be a fibred topos over I; we consider the associated fibred lex-site $\pi : \underline{\mathrm{Can}}(T) \to I$ as in (4.6.2), and its total site $(\underline{\mathrm{Can}}(T), J)$. Also, for every $t \in \mathrm{Ob}(I)$, we denote by $i_t : T_t \to \underline{\mathrm{Can}}(T)$ the inclusion functor.

Theorem 4.6.24. (i) *With the notation of* (4.6.23)*, we have a natural equivalence of categories:*

$$a_T : \mathsf{Top}(T) \xrightarrow{\sim} (\underline{\mathrm{Can}}(T), J)^\sim_{\mathsf{U}}$$

and a morphism of sites :

$$b_T : \mathrm{Can}(\mathsf{Top}(T)) \to (\underline{\mathrm{Can}}(T), J)$$

fitting into an essentially commutative diagram (notation of remark 4.6.22(ii)*) :*

$$\begin{array}{ccccc} \mathrm{Can}(\mathsf{Top}(T))^\sim_{\mathsf{U}} & \xleftarrow{h_{\mathsf{Top}(T)}} & \mathsf{Top}(T) & \xrightarrow{\mathsf{Top}(T/\rho^t)^*} & T_t \\ & \searrow^{b^\sim_{T*}} & \downarrow{a_T} & & \downarrow{h_{T_t}} \\ & & (\underline{\mathrm{Can}}(T), J)^\sim_{\mathsf{U}} & \xrightarrow{(i_t)^\sim_{\mathsf{U}*}} & \mathrm{Can}(T_t)^\sim_{\mathsf{U}} \end{array} \qquad \textit{for every } t \in \mathrm{Ob}(I).$$

(ii) *The category* $\mathsf{Top}(T)$ *is an* U*-topos, which we call the* total topos *of the fibred topos* T.

Proof. Let us remark more generally :

Claim 4.6.25. For every pseudo-functor $\mathsf{c} : I \to \mathsf{lex.Site}$ there exists a natural isomorphism of categories (notation of (4.4.15) and remarks 4.5.10 and 4.5.2(v)) :

$$\alpha_{\mathsf{c}} : \mathsf{Top}(\mathsf{T} \circ \mathsf{c}) \xrightarrow{\sim} \mathsf{T}(\mathsf{totSite} \circ \underline{\mathscr{F}ib}_I(\mathsf{c})).$$

Proof of the claim. By proposition 2.4.3, we may assume that c is unital, and we let γ^{c} be the coherence constraint of c. By proposition 4.5.5(iv), a presheaf F on the total site of $\underline{\mathscr{F}ib}_I(\mathsf{c})$ is a sheaf if and only if its restriction F_i to each fibre site c_i is a sheaf. Hence, such a sheaf F is the datum $F_\bullet := (F_i, F_\varphi : F_j \to (\mathsf{c}_\varphi)^\sim_* F_i \mid i \in \mathrm{Ob}(I),\ (\varphi : i \to j) \in \mathrm{Morph}(I))$ of a system of sheaves and morphisms of sheaves that make commute the diagrams

$$\begin{array}{ccc} F_k & \xrightarrow{F_{\psi\circ\varphi}} & (\mathsf{c}_{\psi\circ\varphi})^\sim_* F_i \\ \downarrow{F_\psi} & & \uparrow{(\gamma^{\mathsf{c}}_{\varphi,\psi})^\sim_{*,F_i}} \\ (\mathsf{c}_\psi)^\sim_* F_j & \xrightarrow{(\mathsf{c}_\psi)^\sim_* F_\varphi} & (\mathsf{c}_\psi)^\sim_* \circ (\mathsf{c}_\varphi)^\sim_* F_i \end{array}$$

for every pair of morphisms $i \xrightarrow{\varphi} j \xrightarrow{\psi} k$ of I. Namely, $F_{\varphi,X} := F(\varphi, \mathbf{1}_{\mathsf{c}_\varphi X}) : F_j X \to F_i(\mathsf{c}_\varphi X)$ for every such φ, and every $X \in \mathrm{Ob}(T_j)$. Recall now that, for every site $(\mathscr{C}, J)$, the topos $\mathsf{T}(\mathscr{C}, J)$ is isomorphic to $(\mathscr{C}, J)^\sim$; especially, $\mathsf{T}(\mathsf{c}_i)$ is isomorphic to the category of sheaves on the site c_i, for every $i \in \mathrm{Ob}(I)$. Under this identification, we then see that a datum $F_\bullet$ as in the foregoing corresponds precisely to an object of the category $\mathsf{Top}(\mathsf{T} \circ \mathsf{c})_*$, and likewise it is easily seen that the morphisms of $\mathsf{Top}(\mathsf{T} \circ \mathsf{c})_*$ correspond naturally to the morphisms of sheaves on the total site of $\underline{\mathscr{F}ib}_I(\mathsf{c})$. Then the sought isomorphism is the composition of this natural identification with the isomorphism $\mathsf{Top}(\mathsf{T} \circ \mathsf{c})_* \xrightarrow{\sim} \mathsf{Top}(\mathsf{T} \circ \mathsf{c})_*$ of lemma 4.6.3. ◊

Recall now that the unit $\eta : \mathbf{1_{Topos}} \to \mathsf{T} \circ \mathrm{Can}$ of the 2-adjoint pair $(\mathrm{Can}, \mathsf{T})$ is a pseudo-natural equivalence (theorem 4.4.17(iii)); there follows a pseudo-natural equivalence $\eta_T : T \xrightarrow{\sim} \mathsf{T} \circ \mathrm{Can} \circ T$. Then the sought equivalence a_T is the composition of $\mathsf{Top}(\eta_T) : \mathsf{Top}(T) \to \mathsf{Top}(\mathsf{T} \circ \mathrm{Can} \circ T)$ with the isomorphism $\alpha_{\mathrm{Can}\circ T}$ of claim 4.6.25. The essential commutativity of the square subdiagram of the diagram of (i) follows by direct inspection.

Now, $(\underline{\mathrm{Can}}(T), J)$ is isomorphic to an U-site (remark 4.5.2(iii)), hence $(\underline{\mathrm{Can}}(T), J)^\sim_{\mathsf{U}}$ is isomorphic to an U-topos (remark 4.4.1(iv)), whence (ii). Especially, for every pseudo-functor $\mathsf{c} : I \to \mathsf{lex}.\mathbf{Site}$ the category $\mathsf{Top}(\mathsf{T} \circ \mathsf{c})$ is an U-topos, and then the 2-adjunction of theorem 4.4.17 assigns to the isomorphism α_{c} of claim 4.6.25 a morphism of sites :

$$\beta_{\mathsf{c}} : \mathrm{Can}(\mathsf{Top}(\mathsf{T} \circ \mathsf{c})) \to \mathsf{totSite} \circ \underline{\mathscr{F}ib}_I(\mathsf{c})$$

so that we may let $b_T := \beta_{\mathrm{Can}\circ T} \circ \mathrm{Can}(\mathsf{Top}(\eta_T))$. The essential commutativity of the triangular subdiagram of (i) follows from the explicit construction of the unit of this 2-adjunction, provided by the proof of theorem 4.4.17. □

Remark 4.6.26. (i) By unwinding the constructions in the proof of theorem 4.6.24, we see that the equivalence a_T assigns to every object $E := ((E_i, E_\varphi) \mid i \in \mathrm{Ob}(I), \varphi \in \mathrm{Morph}(I))$ of $\mathsf{Top}(T)$ the datum $(h_{E_i}, g_{E_\varphi} \mid i \in \mathrm{Ob}(I), \varphi \in \mathrm{Morph}(I))$, consisting of the sheaf h_{E_i} on T_i represented by E_i for every $i \in \mathrm{Ob}(I)$, and the morphism

$$g_{E_\varphi} : h_{E_j} \xrightarrow{h_{E^\dagger_\varphi}} h_{T_{\varphi *}E_i} \xrightarrow{\sim} (T^*_\varphi)^\sim_* h_{E_i} \qquad \text{for every } (i \xrightarrow{\varphi} j) \in \mathrm{Morph}(I).$$

Here $E^\dagger_\varphi$ is the adjoint to the morphism E_φ, relative to the adjunction for the pair $(T^*_\varphi, T_{\varphi *})$ that defines the morphism of topoi $T_\varphi : T_i \to T_j$. The natural identification $h_{T_{\varphi *}E_i} \xrightarrow{\sim} (T^*_\varphi)^\sim_* h_{E_i}$ is deduced as well from the same adjunction, so the morphism of sheaves g_{E_φ} turns out be given by the rule : $(f : X \to E_j) \mapsto (E_\varphi \circ T^*_\varphi f)$ for every $X \in \mathrm{Ob}(S_j)$ and every $f \in h_{E_j}(X)$.

(ii) On the other hand, the morphism of sites b_T of theorem 4.6.24 is a composition

$$\underline{\mathrm{Can}}(T) \xrightarrow{h^a_{\underline{\mathrm{Can}}(T)}} (\underline{\mathrm{Can}}(T), J)^\sim \xrightarrow{a_T^{-1}} \mathsf{Top}(T)$$

where we have denoted by a_T^{-1} any choice of a quasi-inverse of a_T. To describe b_T more explicitly, consider any $(i, X) \in \mathrm{Ob}(\underline{\mathrm{Can}}(T))$; hence $i \in \mathrm{Ob}(I)$ and $X \in \mathrm{Ob}(T_i)$; the proof of theorem 4.6.24 assigns to (i, X) the system $(F(i, X)_j, F(i, X)_\varphi \mid j \in \mathrm{Ob}(I), \varphi \in \mathrm{Morph}(I))$ where $F(i, X)_j$ is the restriction to $\mathrm{Can}(T_j)$ of the sheaf $h^a_{(i,X)}$ on $(\underline{\mathrm{Can}}(T), J)$. Now, let $G(i, X)_j$ be the restriction of $h_{(i,X)}$ to T_j; for every $Y \in \mathrm{Ob}(T_j)$ we have

$$G(i, X)_j(Y) = \{(\varphi, f) \mid \varphi \in \mathrm{Hom}_I(j, i), f \in \mathrm{Hom}_{T_j}(Y, T^*_\varphi X)\}.$$

For every morphism $h : Y' \to Y$ in T_j, the map $G(i, X)_j(h)$ is given by the rule : $(\varphi, f) \mapsto (\varphi, f \circ h)$. Then set

$$[i, X, j] := \coprod_{\varphi : j \to i} T^*_\varphi X \in \mathrm{Ob}(T_j)$$

and fix a universal cocone $(e_{X,\varphi} : T^*_\varphi X \to [i, X, j] \mid j \xrightarrow{\varphi} i)$. Notice the morphism of presheaves

$$G(i, X)_j \to h_{[i,X,j]} \qquad (\varphi, f : Y \to T^*_\varphi X) \mapsto (e_{X,\varphi} \circ f : Y \to [i, X, j]). \tag{4.6.27}$$

Let us check that (4.6.27) is bicovering. Indeed, (4.6.27) is clearly a monomorphism, hence it suffices to show that it is a covering morphism. Thus, let $f : Y \to [i, X, j]$ be any morphism on T_j and for every $\varphi \in \mathrm{Hom}_I(j, i)$ set $Y_\varphi := Y \times_{[i,X,j]} T^*_\varphi$. The induced cocone

$(e_\varphi : Y_\varphi \to Y \mid j \xrightarrow{\varphi} i)$ is still universal (remark 4.4.1(i)) hence it defines a covering family for Y in the canonical topology of T_j (remark 4.4.1(ii)). But clearly $f \circ e_\varphi$ lies in the image of the map $G(i,X)_j(Y_\varphi) \to h_{[i,X,j]}(Y_\varphi)$ for every $\varphi : j \to i$, whence the contention. Hence, (4.6.27) induces an isomorphism $G(i,X)^a_j \xrightarrow{\sim} h_{[i,X,j]}$, from the sheaf $G(i,X)^a_j$ on $\mathrm{Can}(T_j)$ associated with the presheaf $G(i,X)_j$; the latter is naturally isomorphic to $F(i,X)_j$, by proposition 4.5.5(v). Summing up, we have exhibited a natural isomorphism of sheaves on $\mathrm{Can}(T_j)$:

$$F(i,X)_j \xrightarrow{\sim} h_{[i,X,j]} \qquad \text{for every } j \in \mathrm{Ob}(I).$$

(iii) Next, according to the proof of theorem 4.6.24, for every morphism $\psi : j \to k$ in I, the morphism of sheaves $F(i,X)_\psi : F(i,X)_k \to (T^*_\psi)^\sim_* F(i,X)_j$ assigns to every $Y \in \mathrm{Ob}(T_k)$ the map $h^a_{(i,X)}(\psi, \mathbf{1}_{T^*_\psi Y}) : h^a_{(i,X)}(k,Y) \to h^a_{(i,X)}(j, T^*_\psi Y)$. Then, for every such φ and Y let

$$G(i,X)_{\psi,Y} := h_{(i,X)}(\psi, \mathbf{1}_{T^*_\psi Y}) : G(i,X)_k(Y) \to (T^*_\psi)^\wedge G(i,X)_j(Y).$$

Explicitly, if γ^{T^*} denotes the coherence constraint of the pseudo-functor T^*, we get :

$$G(i,X)_{\psi,Y}(\varphi, f) = (\varphi \circ \psi, \gamma^{T^*}_{(\psi,\varphi),X} \circ T^*_\varphi f) \qquad \text{for every } (\varphi, f) \in G(i,X)_k(Y).$$

The rule : $Y \mapsto G(i,X)_{\psi,Y}$ defines a morphism $G(i,X)_\psi : G(i,X)_k(Y) \to (T^*_\psi)^\wedge G(i,X)_j$ of presheaves, and $G(i,X)^a_\psi = F(i,X)_\psi$ for every morphism ψ of I. Now, denote by $[i,X,\psi] : T^*_\psi[i,X,k] \to [i,X,j]$ the unique morphism in T_j fitting into the commutative diagrams :

$$\begin{array}{ccc} T^*_\psi T^*_\varphi X & \xrightarrow{\gamma^{T^*}_{(\psi,\varphi),X}} & T^*_{\varphi\circ\psi} X \\ {\scriptstyle T^*_\psi(e_{X,\varphi})}\downarrow & & \downarrow{\scriptstyle e_{X,\varphi\circ\psi}} \\ T^*_\psi[i,X,k] & \xrightarrow{[i,X,\psi]} & [i,X,j] \end{array} \qquad \text{for every } \varphi : k \to i.$$

The foregoing discussion easily implies that we have a commutative diagram of sheaves :

$$\begin{array}{ccc} F(i,X)_k & \xrightarrow{\sim} & h_{[i,X,k]} \\ {\scriptstyle F(i,X)_\psi}\downarrow & & \downarrow{\scriptstyle h^\dagger_{[i,X,\psi]}} \\ (T^*_\psi)^\sim_* F(i,X)_j & \xrightarrow{\sim} & (T^*_\psi)^\sim_* h_{[i,X,j]} \end{array}$$

whose horizontal arrows are the isomorphisms constructed in (ii), and the adjoint $h^\dagger_{[i,X,\psi]}$ of $h_{[i,X,\psi]}$ is described explicitly as in (i). Summing up, we find that (up to natural isomorphism) the functor b_T is given by the rule :

$$(i,X) \mapsto ([i,X,j], [i,X,\psi] \mid j \in \mathrm{Ob}(I), \psi \in \mathrm{Morph}(I)) \qquad \text{for every } (i,X) \in \mathrm{Ob}(\underline{\mathrm{Can}}(T)).$$

Corollary 4.6.28. *Let I, J be two small categories, and T, S two fibred topoi over I. We have :*

(i) *For every morphism $\omega : T \to S$ of fibred topoi over I, let $\eta^{\mathsf{Top}(\omega)}$ be the unit of the adjunction for the pair of functors $(\mathsf{Top}(\omega)^*, \mathsf{Top}(\omega)_*)$ provided by remark 4.6.12. Then $(\mathsf{Top}(\omega)^*, \mathsf{Top}(\omega)_*, \eta^{\mathsf{Top}(\omega)})$ is a morphism of topoi :*

$$\mathsf{Top}(\omega) : \mathsf{Top}(T) \to \mathsf{Top}(S).$$

(ii) *For every functor $\rho : J \to I$, let $\eta^{\mathsf{Top}(T/\rho)}$ be the unit of any adjunction for the pair $(\mathsf{Top}(T/\rho)^*, \mathsf{Top}(T/\rho)_*)$. Then $(\mathsf{Top}(T/\rho)^*, \mathsf{Top}(T/\rho)_*, \eta^{\mathsf{Top}(T/\rho)})$ is a morphism of topoi :*

$$\mathsf{Top}(T/\rho) : \mathsf{Top}(T \circ \rho) \to \mathsf{Top}(T).$$

(iii) *For every pair $\omega : T \to S$, $\nu : S \to U$ of morphisms of fibred topoi over I, we have :*

$$\mathsf{Top}(\nu \circ \omega) = \mathsf{Top}(\nu) \circ \mathsf{Top}(\omega).$$

Proof. Assertion (ii) is clear from remark 4.6.22(i).

(i): In view of proposition 4.6.10 and theorem 4.6.24, there remains only to check that $\mathsf{Top}(\omega)^*$ is left exact. Arguing as in remark 4.6.9(i,iii) we may assume that T and S are unital; then a functor $E_\bullet : J \to \mathsf{Top}(S)$ assigns to every $j \in \mathrm{Ob}(J)$ a datum $E_{\bullet,j} := (E_{ij}, E_{\varphi,j} \mid i \in \mathrm{Ob}(I),\ \varphi \in \mathrm{Morph}(I))$ as in remark 4.6.9(i), and to every morphism $f : j \to j'$ a system of morphisms $(E_{i,f} : E_{ij} \to E_{ij'} \mid i \in \mathrm{Ob}(I))$ such that

$$E_{\varphi,j'} \circ S^*_\varphi E_{i',f} = E_{i,f} \circ E_{\varphi,j} \qquad \text{for every morphism } \varphi : i \to i' \text{ of } I.$$

The limit of $E_\bullet$ in the category $\mathsf{Top}(S)$ is the same as the colimit of $E^o_\bullet$ in the category $\Sigma(\mathscr{F}ib(S^*)/I)$, and we construct the latter following remark 4.6.22(iii). Thus, for every $i \in \mathrm{Ob}(I)$ we consider the functor $(E^o_\bullet)^i : J \to \mathscr{F}ib(S^*)$ given by the rules : $j \mapsto E_{ij}$ for every $j \in \mathrm{Ob}(J)$ and $f \mapsto E^o_{i,f}$ for every morphism f of J. Then $(E^o_\bullet)^i$ factors through the inclusion functor $S^o_i \to \mathscr{F}ib(S^*)$, and the colimit of the resulting functor $(\overline{E}{}^o_\bullet)^i : J \to S^o_i$ in S^o_i is the limit of the opposite functor $\overline{E}{}^i_\bullet : J^o \to S_i$, so we pick $L(i) \in \mathrm{Ob}(S_i)$ representing the latter limit and a universal cone $\tau^i : c_{L(i)} \Rightarrow \overline{E}{}^i_\bullet$. Next, every morphism $\varphi : i \to i'$ in I induces a natural transformation

$$\overline{E}{}^\varphi_\bullet : S^*_\varphi \circ \overline{E}{}^{i'}_\bullet \Rightarrow \overline{E}{}^i_\bullet \qquad j \mapsto E_{\varphi,j} : S^*_\varphi E_{i'j} \to E_{ij}.$$

Then there exists a unique morphism $L(\varphi) : S^*_\varphi L(i') \to L(i)$ of S_i fitting into the commutative diagram :

$$\mathscr{D} \quad : \quad \begin{array}{ccc} S^*_\varphi \circ c_{L(i')} & \xRightarrow{\ c_{L(\varphi)}\ } & c_{L(i)} \\ {\scriptstyle S^*_\varphi * \tau^{i'}} \Downarrow & & \Downarrow {\scriptstyle \tau^i} \\ S^*_\varphi \circ \overline{E}{}^{i'}_\bullet & \xRightarrow{\ \overline{E}{}^\varphi_\bullet\ } & \overline{E}{}^i_\bullet \end{array}$$

and remark 4.6.22(iii) shows that $L_\bullet := (L(i), L(\varphi) \mid i \in \mathrm{Ob}(I)\ \varphi \in \mathrm{Morph}(I))$ is an object of $\mathsf{Top}(S)$ representing the limit of $E_\bullet$, and the system of cones $(\tau^i \mid i \in \mathrm{Ob}(I))$ adds up to a universal cone $\tau : c_{L_\bullet} \Rightarrow E_\bullet$. Now, set

$$F_\bullet := \mathsf{Top}(\omega)^* \circ E_\bullet : J \to \mathsf{Top}(T).$$

We define likewise the functors $\overline{F}{}^i_\bullet : J \to T_i$ for every $i \in \mathrm{Ob}(I)$ and the natural transformations $\overline{F}{}^\varphi_\bullet : T^*_\varphi \circ \overline{F}{}^{i'}_\bullet \Rightarrow \overline{F}{}^i_\bullet$ for every morphism $\varphi : i \to i'$ of I; then by a simple inspection we deduce from $\mathscr{D}$ the commutative diagram

$$\mathscr{D}^\omega \quad : \quad \begin{array}{ccc} T^*_\varphi \circ c_{\omega^*_{i'} L(i')} & \xRightarrow{\ c_{L(\varphi)^\omega}\ } & c_{\omega^*_i L(i)} \\ {\scriptstyle T^*_\varphi * \omega^*_{i'} * \tau^{i'}} \Downarrow & & \Downarrow {\scriptstyle \omega^*_i * \tau^i} \\ T^*_\varphi \circ \overline{F}{}^{i'}_\bullet & \xRightarrow{\ \overline{F}{}^\varphi_\bullet\ } & \overline{F}{}^i_\bullet \end{array}$$

with $(\omega^*_i L(i), L(\varphi)^\omega \mid i \in \mathrm{Ob}(I),\ \varphi \in \mathrm{Morph}(I)) := \mathsf{Top}(\omega)^* L_\bullet$ as in remark 4.6.9(ii). Lastly, if J is a finite category, then by assumption $\omega^*_i * \tau^i$ is still a universal cone for every $i \in \mathrm{Ob}(I)$, and therefore the commutativity of $\mathscr{D}^\omega$ determines again $L(\varphi)^\omega$ uniquely. In this case, remark 4.6.22(iii) shows that $\mathsf{Top}(\omega)^* L_\bullet$ represents the limit of $F_\bullet$ and $\mathsf{Top}(\omega)^* * \tau$ is a universal cone.

(iii) follows easily from the explicit description of $\eta^{\mathsf{Top}(\omega)}, \eta^{\mathsf{Top}(\nu)}$ and $\eta^{\mathsf{Top}(\nu\circ\omega)}$ given by remark 4.6.12. □

Remark 4.6.29. Let I be any small category.

(i) From corollary 4.6.28(i,iii) it follows easily that the rules : $T \mapsto \mathsf{Top}(T)$, $\omega \mapsto \mathsf{Top}(\omega)$ and $\Xi \mapsto \mathsf{Top}(\Xi)_*$ for every fibred topos T over I, every morphism ω of such fibred topoi, and every transformation Ξ of such morphisms, define a strict pseudo-functor

$$\mathsf{Top} : \mathsf{PsFun}(I, \mathbf{Topos}) \to \mathbf{Topos}.$$

(ii) It is also easily seen that the isomorphisms of claim 4.6.25 yield a pseudo-natural isomorphism of pseudo-functors :

$$\alpha_\bullet : \mathsf{Top} \circ \mathsf{PsFun}(I, \mathsf{lex.T}) \stackrel{\sim}{\to} \mathsf{T} \circ \mathsf{totSite} \circ \mathsf{lex.}\underline{\mathscr{F}ib}_I.$$

Moreover, let $\underline{\mathsf{c}}^\bullet$: $\mathsf{fib.lex.}\mathbf{Site}(I) \to \mathsf{PsFun}(I, \mathsf{lex.}\mathbf{Site})$ be a strict and strong pseudo-inverse for the 2-equivalence $\mathsf{lex.}\underline{\mathscr{F}ib}_I$ (see remark 4.5.2(v)); then from $\alpha_\bullet * \underline{\mathsf{c}}^\bullet$ we deduce a pseudo-natural isomorphism of pseudo-functors (notation of (4.6.2)) :

$$\mathsf{a}_\bullet : \mathsf{Top} \circ \underline{\mathsf{lex.T}} \stackrel{\sim}{\to} \mathsf{T} \circ \mathsf{totSite}.$$

By 2-adjunction, from $\alpha_\bullet$ and $\mathsf{a}_\bullet$ we then deduce as well pseudo-natural transformations

$$\beta_\bullet : \mathrm{Can} \circ \mathsf{Top} \circ \mathsf{PsFun}(I, \mathsf{lex.T}) \to \mathsf{totSite} \circ \mathsf{lex.}\underline{\mathscr{F}ib}_I \qquad \mathsf{c} \mapsto \beta_{\mathsf{c}}$$
$$\mathsf{b}_\bullet : \mathrm{Can} \circ \mathsf{Top} \circ \underline{\mathsf{lex.T}} \to \mathsf{totSite}$$

where β_{c} is defined as in the proof of theorem 4.6.24 : the details are left to the reader.

(iii) Lastly, the rule $T \mapsto a_T$ of theorem 4.6.24(i) defines the pseudo-natural equivalence :

$$a_\bullet := \mathsf{PsFun}(I, \eta) \odot (\mathsf{a}_\bullet * \underline{\mathrm{Can}}) : \mathsf{Top} \stackrel{\sim}{\to} \mathsf{T} \circ \mathsf{totSite} \circ \underline{\mathrm{Can}}$$

where $\eta : \mathbf{1_{Topos}} \to \mathsf{T} \circ \mathrm{Can}$ is the unit of the 2-adjoint pair $(\mathrm{Can}, \mathsf{T})$. Again by 2-adjunction, the rule : $T \mapsto b_T$ yields likewise a pseudo-natural transformation

$$b_\bullet : \mathrm{Can} \circ \mathsf{Top} \to \mathsf{totSite} \circ \underline{\mathrm{Can}}.$$

4.7. **Localization and points of a topos.** Let $\mathscr{C}$ be a category, and $f : Y \to X$ any morphism of $\mathscr{C}$. We consider the source functor $\mathsf{s}_X : \mathscr{C}/X \to \mathscr{C}$ as in (1.1.24), and the induced functor

$$(\mathsf{s}_X)_{|f} : (\mathscr{C}/X)/f \to \mathscr{C}/(\mathsf{s}_X f) = \mathscr{C}/Y$$

as in (1.1.26), which is obviously an isomorphism of categories, hence it induces a bijection :

$$\{\text{sieves of } \mathscr{C}/Y\} \stackrel{\sim}{\to} \{\text{sieves of } (\mathscr{C}/X)/f\} \qquad \mathscr{S} \mapsto (\mathsf{s}_X)^{-1}_{|f}\mathscr{S}$$

(notation of definition 3.5.1(iii)). Fix a universe V with $\mathsf{U} \subset \mathsf{V}$ and such that $\mathscr{C}$ is V-small, so that the functor $(\mathsf{s}_X)_{\mathsf{V}!} : (\mathscr{C}/X)^\wedge_{\mathsf{V}} \to \mathscr{C}^\wedge_{\mathsf{V}}$ is well defined. We notice that for every subobject R of the presheaf h_f on $\mathscr{C}/X$, the presheaf $(\mathsf{s}_X)_{\mathsf{V}!}R$ is a subobject of h_Y : more precisely, in light of (1.4.11) we see that for a sieve $\mathscr{S}$ of $(\mathscr{C}/X)/f$ and a sieve $\mathscr{T}$ of $\mathscr{C}/Y$, we have :

$$h_{\mathscr{T}} = (\mathsf{s}_X)_{\mathsf{V}!}h_{\mathscr{S}} \quad \Leftrightarrow \quad \mathscr{S} = (\mathsf{s}_X)^{-1}_{|f}\mathscr{T}. \tag{4.7.1}$$

Let now J be a topology on $\mathscr{C}$; endow $\mathscr{C}/X$ with the topology J_X induced by J via s_X, and set

$$C := (\mathscr{C}, J) \qquad C/X := (\mathscr{C}/X, J_X).$$

Since $(\mathsf{s}_X)_{\mathsf{V}!}$ commutes with fibre products (proposition 1.4.13(vi.c)), lemma 4.2.17(ii.a) says that a subobject $R \subset h_f$ covers f for the topology J_X if and only if the induced morphism $(\mathsf{s}_X)_{\mathsf{V}!}R \to (\mathsf{s}_X)_{\mathsf{V}!}(h_f) = h_Y$ covers Y for the topology J. In other words, a family of morphisms $(h_\lambda/X : (f_\lambda : Y_\lambda \to Y) \to f \mid \lambda \in \Lambda)$ covers f for the topology J_X if and only if the family $(h_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ covers Y for the topology J. In view of (4.7.1), it follows easily that s_X is both continuous and cocontinuous for the topologies J and J_X.

4.7.2. Suppose now that C is a U-site; then the same holds for C/X as well : indeed, if $G \subset \mathrm{Ob}(\mathscr{C})$ is an essentially small topologically generating family for C, then $G/X \subset \mathrm{Ob}(\mathscr{C}/X)$ is an essentially small topologically generating family for C/X (notation of definition 4.1.20(i)). By virtue of corollary 4.3.19, the functor $\widetilde{\mathsf{s}}_{X*} \simeq \check{\mathsf{s}}^*_X : C^\sim \to (C/X)^\sim$ admits therefore both a left adjoint $\widetilde{\mathsf{s}}^*_X$ and a right adjoint $\check{\mathsf{s}}_{X*}$. We introduce a special notation and terminology for these functors :

- The functor $\widetilde{\mathsf{s}}_{X*}$ shall be also denoted j^*_X, and called the functor of *restriction to* X.
- The functor $\check{\mathsf{s}}_{X*}$ shall be denoted j_{X*}, and called the *direct image* functor.

- The functor $\widetilde{\mathsf{s}}_X^*$ shall be denoted $j_{X!}$, and called the functor of *extension by empty*.

Thus, j_X^* is right adjoint to $j_{X!}$, and left adjoint to j_{X*}. However, a left adjoint for j_X^* can be exhibited alternatively by a more explicit construction, which will allow us to extract some useful additional properties of the category $(C/X)^\sim$. Indeed, even though $\mathscr{C}/X$ is not necessarily U-small, we can invoke proposition 1.4.13(vi.a) and remark 4.1.23(ii), in order to define a functor by the same rule as in (4.2.8), namely

$$j_{X!} : (C/X)^\sim_{\mathsf{U}} \to C^\sim_{\mathsf{U}} \qquad F \mapsto (\mathsf{s}_{X!} \circ i_{C/X}F)^a$$

where $i_{C/X} : (C/X)^\sim \to (\mathscr{C}/X)^\wedge$ is the forgetful functor. Moreover, remark 4.1.19(v) (and again remark 4.1.23(ii)) implies that this functor is (isomorphic to) the restriction of $(\widetilde{\mathsf{s}}_X)^*_{\mathsf{V}}$, and since the inclusion functor $C^\sim_{\mathsf{U}} \to C^\sim_{\mathsf{V}}$ is fully faithful, we deduce that it is also a left adjoint to j_X^*. Furthermore, recall that $\mathsf{s}_{X!}$ factors through the source functor $\mathsf{s}_{h_X} : \mathscr{C}^\wedge/h_X \to \mathscr{C}^\wedge$ and an equivalence $e_X : (\mathscr{C}/X)^\wedge \xrightarrow{\sim} \mathscr{C}^\wedge/h_X$ (proposition 1.4.13(vi.b)); consequently, $j_{X!}$ factors through the source functor $\mathsf{s}_{h_X^a} : C^\sim/h_X^a \to C^\sim$ and the composition

$$\widetilde{e}_X : (C/X)^\sim \xrightarrow{i_{C/X}} (\mathscr{C}/X)^\wedge \xrightarrow{e_X} \mathscr{C}^\wedge/h_X \xrightarrow{(-)^a_{|h_X}} C^\sim/h_X^a$$

where $(-)^a_{|h_X}$ is induced by $(-)^a : \mathscr{C}^\wedge \to C^\sim$ and the object $h_X \in \mathrm{Ob}(\mathscr{C}^\wedge)$, as in (1.1.26).

Remark 4.7.3. (i) Let $g : Y \to Z$ be any morphism in $\mathscr{C}$; then we have the sites C/Y and C/Z as in (4.7), as well as the functor $g_* : \mathscr{C}/Y \to \mathscr{C}/Z$ of (1.1.25). The isomorphism of categories $(\mathsf{s}_Z)_{|g} : (\mathscr{C}/Z)/g \xrightarrow{\sim} \mathscr{C}/Y$ identifies g_* with the source functor $\mathsf{s}_g : (\mathscr{C}/Z)/g \to \mathscr{C}/Z$. Hence, the discussion of (4.7.2) applies to g_* as well, and since $\mathsf{s}_Z \circ g_* = \mathsf{s}_Y$, we see that J_Y is the topology induced by J_Z via g_* on $\mathscr{C}/Y$; so, g_* is continuous and cocontinuous for the topologies J_Y and J_Z. Moreover, if C is a U-site, then $(\widetilde{g}_*)_* : (C/Z)^\sim \to (C/Y)^\sim$ admits a left adjoint $(\widetilde{g}_*)^*$ and a right adjoint $(\breve{g}_*)_*$. In agreement with the foregoing, we let

$$j_g^* := (\widetilde{g}_*)_* \qquad j_{g*} := (\breve{g}_*)_* \qquad j_{g!} := (\widetilde{g}_*)^*.$$

Clearly $j_g^* \circ j_Z^* = j_Y^*$, and we have isomorphisms of functors : $j_{Z*} \circ j_{g*} \xrightarrow{\sim} j_{Y*}$ and $j_{Z!} \circ j_{g!} \xrightarrow{\sim} j_{Y!}$.

(ii) By propositions 4.4.8(i) and 1.3.25(iii,iv), we also see that the pairs (j_X^*, j_{X*}) and (j_g^*, j_{g*}) determine morphisms of topoi, unique up to unique isomorphism :

$$j_X : (C/X)^\sim \to C^\sim \qquad j_g : (C/Y)^\sim \to (C/Z)^\sim.$$

(iii) Suppose that all finite products of $\mathscr{C}$ are representable. Then for every $X \in \mathrm{Ob}(\mathscr{C})$, the source functor s_X admits a right adjoint

$$p_X : \mathscr{C} \to \mathscr{C}/X \qquad Y \mapsto (p_{X,Y} : X \times Y \to X)$$

where $X \times Y$ is any choice of a representative for the product of X and Y, and $p_{X,Y}$ is the corresponding natural projection : see proposition 1.4.13(iii). Since s_X is cocontinuous for the topologies J and J_X, the functor p_X is a morphism of sites $C/X \to C$ (remark 4.4.13(v)), and we have an isomorphism of morphisms of topoi :

$$j_X \xrightarrow{\sim} \widetilde{p}_X.$$

Proposition 4.7.4. *With the notation of* (4.7.2)*, the following holds :*

(i) *The functor $\widetilde{e}_X$ is an equivalence.*

(ii) *We have essentially commutative diagrams :*

$$\begin{array}{ccc} (C/X)^\sim & \xrightarrow{i_{C/X}} & (\mathscr{C}/X)^\wedge \\ {\scriptstyle \widetilde{e}_X}\downarrow & & \downarrow{\scriptstyle e_X} \\ C^\sim/h_X^a & \xrightarrow{(i_C)_{|h_X}} & \mathscr{C}^\wedge/h_X \end{array} \qquad \begin{array}{ccc} (\mathscr{C}/X)^\wedge & \xrightarrow{(-)^a} & (C/X)^\sim \\ {\scriptstyle e_X}\downarrow & & \downarrow{\scriptstyle \widetilde{e}_X} \\ \mathscr{C}^\wedge/h_X & \xrightarrow{(-)^a_{|h_X}} & C^\sim/h_X^a \end{array}$$

where $(i_C)_{|h_X}$ *and* $(-)^a_{|h_X}$ *are the functors attached to the adjoint pair* $((-)^a, i_C)$ *and the object* $h_X \in \mathrm{Ob}(\mathscr{C}^\wedge)$*, as in example* 1.2.28(i).

Proof. Let $\eta_F : h_X \to h_X^a$ be the natural morphism in $\mathscr{C}^\wedge$. We remark :

Claim 4.7.5. For every presheaf F on $\mathscr{C}/X$ there exists a cartesian diagram in $\mathscr{C}^\wedge$:

$$\begin{array}{ccc} \mathsf{s}_{X!}(F^a) & \longrightarrow & (\mathsf{s}_{X!}F)^a \\ {\scriptstyle e_X(F^a)}\downarrow & & \downarrow{\scriptstyle e_X(F)^a} \\ h_X & \xrightarrow{\eta_X} & h_X^a. \end{array}$$

Proof of the claim. As already pointed out in the proof of proposition 1.4.13(vi.b), the presheaf $\mathbb{1}_{\mathscr{C}/X} := h_{\mathbf{1}_X}$ is a final object of $(\mathscr{C}/X)^\wedge$, and the equivalence e_X assigns to every presheaf F on $\mathscr{C}/X$ the h_X-presheaf $e_X(F) : \mathsf{s}_{X!}F \to \mathsf{s}_{X!}(\mathbb{1}_{\mathscr{C}/X}) \xrightarrow{\sim} h_X$ deduced from the unique morphism $F \to \mathbb{1}_{\mathscr{C}/X}$. Moreover, e_X admits the quasi-inverse

$$e'_X : \mathscr{C}^\wedge/h_X \to (\mathscr{C}/X)^\wedge \qquad (\varphi : G \to h_X) \mapsto \mathsf{s}_X^\wedge(G) \times_{\mathsf{s}_X^\wedge(h_X)} \mathbb{1}_{\mathscr{C}/X}$$

where the fibre product is defined via the unit of adjunction $\eta_{\mathbb{1}} : \mathbb{1}_{\mathscr{C}/X} \to \mathsf{s}_X^\wedge(\mathsf{s}_{X!}\mathbb{1}_{\mathscr{C}/X}) \xrightarrow{\sim} \mathsf{s}_X^\wedge(h_X)$ and the morphism $\mathsf{s}_X^\wedge(\varphi)$. Thus, we have a natural isomorphism

$$F \xrightarrow{\sim} \mathsf{s}_X^\wedge(\mathsf{s}_{X!}F) \times_{\mathsf{s}_X^\wedge(h_X)} \mathbb{1}_{\mathscr{C}/X} \qquad \text{in } (\mathscr{C}/X)^\wedge.$$

On the other hand, the functor $\mathsf{s}_X^\wedge$ commutes with the functor $G \mapsto G^a$ (corollary 4.3.19(iii)), so there follows an isomorphism

$$F^a \xrightarrow{\sim} \mathsf{s}_X^\wedge(\mathsf{s}_{X!}F)^a \times_{\mathsf{s}_X^\wedge(h_X^a)} \mathbb{1}_{\mathscr{C}/X} \qquad \text{in } (C/X)^\sim.$$

But it is easily seen that the morphism $\eta_{\mathbb{1}}^a : \mathbb{1}_{\mathscr{C}/X} \to \mathsf{s}_X^\wedge(h_X^a)$ is the composition of $\eta_{\mathbb{1}}$ and the natural morphism $\mathsf{s}_X^\wedge(h_X) \to \mathsf{s}_X^\wedge(h_X^a)$, so we get a commutative diagram with cartesian squares:

$$\begin{array}{ccccc} F^a & \xrightarrow{\alpha} & \mathsf{s}_X^\wedge((\mathsf{s}_{X!}F)^a \times_{h_X^a} h_X) & \longrightarrow & \mathsf{s}_X^\wedge(\mathsf{s}_{X!}F)^a \\ \downarrow & & \downarrow & & \downarrow \\ \mathbb{1}_{\mathscr{C}/X} & \longrightarrow & \mathsf{s}_X^\wedge(h_X) & \longrightarrow & \mathsf{s}_X^\wedge(h_X^a). \end{array}$$

Especially, α induces an isomorphism $F^a \xrightarrow{\sim} e'_X((\mathsf{s}_{X!}F)^a \times_{h_X^a} h_X)$, whence an isomorphism

$$e_X(F^a) \xrightarrow{\sim} ((\mathsf{s}_{X!}F)^a \times_{h_X^a} h_X \to h_X)$$

and the claim follows. ◊

(i): Let $\varphi : G \to h_X^a$ be any object of $C^\sim/h_X^a$; set $G' := G \times_{h_X^a} h_X$, and let $\varphi' : G' \to h_X$ be the induced projection. Let also $F := e'_X(\varphi')$, which is a presheaf on $\mathscr{C}/X$. We claim that F is a sheaf for the topology J_X. Indeed, by claim 4.7.5 we have an isomorphism in $\mathscr{C}^\wedge/h_X$:

$$\mathsf{s}_{X!}(F^a) \xrightarrow{\sim} (\mathsf{s}_{X!}F)^a \times_{h_X^a} h_X \xrightarrow{\sim} G'^a \times_{h_X^a} h_X \xrightarrow{\sim} G'$$

and since e'_X is quasi-inverse to e_X, we have an isomorphism of h_X-presheaves $\mathsf{s}_{X!}(F) \xrightarrow{\sim} G'$. Thus, $F \xrightarrow{\sim} F^a$ in $(\mathscr{C}/X)^\wedge$, as required. Next we claim that the resulting functor

$$\widetilde{e}'_X : C^\sim/h_X^a \to (C/X)^\sim \qquad (\varphi : G \xrightarrow{\varphi} h_X^a) \mapsto e'_X(G \times_{h_X^a} h_X \xrightarrow{\varphi \times_{h_X^a} h_X} h_X)$$

is a quasi-inverse for $\widetilde{e}_X$. Indeed, for every φ as in the foregoing we have an isomorphism

$$\widetilde{e}_X \circ \widetilde{e}'_X(\varphi) \xrightarrow{\sim} (\varphi \times_{h_X^a} h_X)^a \xrightarrow{\sim} \varphi \qquad \text{in } C^\sim/h_X^a$$

which is natural with respect to φ. Lastly, for every sheaf F on C/X we have $\widetilde{e}'_X \circ \widetilde{e}_X(F) = e'_X((e_X(F)^a \times_{h_X^a} h_X)$, which is isomorphic to $e'_X(e_X(F)) \simeq F$, by claim 4.7.5.

(ii): For every sheaf F on C/X, claim 4.7.5 yields an isomorphism :

$$e_X(i_{C/X}F) \stackrel{\sim}{\to} (\widetilde{e}_X(F) \times_{h^a_X} h_X \to h_X).$$

The essential commutativity of the left square diagram in (ii) is an immediate consequence; since e_X and $\widetilde{e}_X$ are both equivalences, and since $(-)^a_{|h_X}$ is left adjoint to $(i_C)_{|h_X}$, we deduce the essential commutativity also for the right square diagram. □

Remark 4.7.6. (i) Under the equivalence $\widetilde{e}_X$ of proposition 4.7.4, the functor j^*_X is identified with the functor :

$$C^\sim \to C^\sim/h^a_X \qquad F \mapsto (F \times h^a_X \to h^a_X)$$

and $j_{X!}$ is identified with the source functor $\mathsf{s}_{h^a_X} : C^\sim/h^a_X \to C^\sim$ of (1.1.24).

(ii) Likewise, the functor j^*_g of remark 4.7.3(i) is identified with the functor

$$C^\sim/h^a_Z \to C^\sim/h^a_Y \qquad (F \to h^a_Z) \mapsto (F \times_{h^a_Z} h^a_Y \mapsto h^a_Y)$$

and $j_{g!}$ is identified with the functor $(h^a_g)_* : C^\sim/h^a_Y \to C^\sim/h^a_Z$ induced by $h^a_g : h^a_Y \to h^a_Z$.

Proposition 4.7.7. *Let $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}'; J')$ be two sites, $u : \mathscr{C} \to \mathscr{C}'$ a continuous functor, X any object of $\mathscr{C}$. Then we have :*

(i) *The functor $u_{|X} : \mathscr{C}/X \to \mathscr{C}'/uX$ is continuous for the sites C/X and C'/uX.*

(ii) *We have essentially commutative diagrams :*

$$\begin{array}{ccc} (C'/uX)^\sim & \xrightarrow{\widetilde{u_{|X*}}} & (C/X)^\sim \\ {\scriptstyle \widetilde{e}_{uX}}\downarrow & & \downarrow{\scriptstyle \widetilde{e}_X} \\ C'^\sim/h^a_{uX} & \xrightarrow{(\widetilde{u}_*)_{|h^a_X}} & C^\sim/h^a_X \end{array} \qquad \begin{array}{ccc} (C/X)^\sim & \xrightarrow{\widetilde{u_{|X}}^*} & (C'/uX)^\sim \\ {\scriptstyle \widetilde{e}_X}\downarrow & & \downarrow{\scriptstyle \widetilde{e}_{uX}} \\ C^\sim/h^a_X & \xrightarrow{(\widetilde{u}^*)_{|h^a_X}} & C'^\sim/h^a_{uX}. \end{array}$$

(iii) *If u is a morphism of sites $C' \to C$, then $u_{|X}$ is a morphism of sites $C'/uX \to C/X$.*

Proof. (i): Combining propositions 4.7.4(ii) and 1.4.19(i) with example 1.2.28(iii) we get an essentially commutative diagram, whose vertical arrows are equivalences :

$$\begin{array}{ccc} (C'/uX)^\sim & \xrightarrow{(u_{|X})^\wedge \circ i_{C'/X}} & (\mathscr{C}/X)^\wedge \\ {\scriptstyle \widetilde{e}_{uX}}\downarrow & & \downarrow{\scriptstyle e_X} \\ C'^\sim/h^a_{uX} & \xrightarrow{(u^\wedge \circ i_{C'})_{|h_X}} & \mathscr{C}^\wedge/h_X. \end{array}$$

Now, let F be a sheaf on C'/uX, and denote by $\varphi : G \to h^a_{uX}$ the h^a_{uX}-sheaf $\widetilde{e}_{uX}(F)$. By proposition 4.7.4(ii), it suffices to show that $(u^\wedge \circ i_{C'})_{|h_X}(\varphi) \simeq (u^\wedge G \times_{u^\wedge h^a_{uX}} h_X \to h_X)$ lies in the essential image of $(i_C)_{|h_X}$. But the morphism $h_X \to u^\wedge h^a_{uX}$ is the composition of the natural morphisms $h_X \to h^a_X$ and $h^a_X \to u^\wedge h^a_{uX}$, hence $u^\wedge G \times_{u^\wedge h^a_{uX}} h_X \stackrel{\sim}{\to} G' \times_{h^a_X} h_X$, with $G' := u^\wedge G \times_{u^\wedge h^a_{uX}} h^a_X$, and the latter is a sheaf on C, since u is continuous, whence the contention.

(ii): Recall that we have a natural isomorphism $\widetilde{u}^*(h^a_X) \stackrel{\sim}{\to} h^a_{uX}$ in $C'^\sim$ (lemma 4.2.11(ii)). By example 1.2.28(i), we deduce an adjoint pair of functors :

$$(\widetilde{u}^*)_{|h^a_X} : C^\sim/h^a_X \to C'^\sim/h^a_{uX} \qquad (\widetilde{u}_*)_{|h^a_X} : C'^\sim/h^a_{uX} \to C^\sim/h^a_X.$$

Now, the proof of (i) yields a natural isomorphism of functors :

$$\begin{aligned} \widetilde{e}_X \circ (u_{|X})^\sim_* &\stackrel{\sim}{\to} (-)^a_{|h_X} \circ e_X \circ i_{C/X} \circ (u_{|X})^\sim_* \\ &\stackrel{\sim}{\to} (-)^a_{|h_X} \circ e_X \circ (u_{|X})^\wedge \circ i_{C'/uX} \\ &\stackrel{\sim}{\to} (-)^a_{|h_X} \circ (u^\wedge \circ i_{C'})_{|h_X} \circ \widetilde{e}_{uX} \end{aligned}$$

and a direct inspection of the constructions shows that $(-)^a_{|h_X} \circ (u^\wedge \circ i_{C'})_{|h_X}$ is isomorphic to the functor $(\widetilde{u}_*)_{|h^a_X}$, so that the left square diagram of (ii) is essentially commutative. Since $\widetilde{e}_X$ and $\widetilde{e}_{uX}$ are equivalences, we deduce that the same holds also for the right square diagram.

(iii): By assumption, the functor $\widetilde{u}^*$ is left exact, so the same holds for $(\widetilde{u}^*)_{|h^a_X}$ (proposition 1.4.19(ii)), and by (ii) the same follows for $\widetilde{u_{|X}}^*$, whence the contention. □

Example 4.7.8. (i) Let T be a topos, and $U \in \mathrm{Ob}(T)$ any object. By proposition 4.7.4(i) and remark 4.7.3(iii), we have a natural equivalence

$$(\mathrm{Can}(T)/U)^\sim \xrightarrow{\sim} \mathrm{Can}(T)^\sim/h_U$$

identifying the functor $j^*_U : \mathrm{Can}(T)^\sim \to (\mathrm{Can}(T)/U)^\sim$ with $p_{h_U} : \mathrm{Can}(T)^\sim \to \mathrm{Can}(T)^\sim/h_U$. The source functor $\mathsf{s}_{h_U} : \mathrm{Can}(T)^\sim/h_U \to \mathrm{Can}(T)^\sim$ is a *left* adjoint for p_{h_U}, but the latter admits also a *right* adjoint, which is naturally identified with $j_{U*} : (\mathrm{Can}(T)/U)^\sim \to \mathrm{Can}(T)^\sim$. On the other hand, the Yoneda equivalence $T \xrightarrow{\sim} \mathrm{Can}(T)^\sim$ induces an equivalence $T/U \xrightarrow{\sim} \mathrm{Can}(T)^\sim/h_U$, which shows that T/U is a topos, and identifies p_{h_U} in turn with the functor

$$p_U : T \to T/U \qquad X \mapsto X_{|U} := (X \times U \to U).$$

Hence, the latter is a morphisms of U-sites $\mathrm{Can}(T) \to \mathrm{Can}(T/U)$, and we denote again by

$$j_U := (j^*_U, j_{U*}, \eta^U) : T/U \to T$$

the corresponding morphism of topoi. Moreover, the source functor s_U is a left adjoint for j^*_U, and shall be denoted also by $j_{U!} : T/U \to T$. Likewise, any morphism $f : U' \to U$ in T determines, up to unique isomorphism, a morphism of topoi

$$j_f := (j^*_f, j_{f*}, \eta^f) : T/U' \to T/U$$

with an isomorphism $j_U \circ j_f \xrightarrow{\sim} j_{U'}$ of morphisms of topoi.

(ii) Recall that the target functor $\mathsf{t} : \mathsf{Morph}(T) \to T$ is a fibration (example 3.1.3(iii)); pick a cleavage for t, and let $\mathsf{c} : T^o \to \mathsf{V}\text{-}\mathbf{Cat}$ be its associated pseudo-functor (for a universe V such that T is V-small). We may choose the cleavage so that for every morphism $f : U' \to U$, the functor $\mathsf{c}_f : T/U \to T/U'$ agrees with j^*_f (the details are left to the reader). Notice then that $\mathsf{c}^o : T \to \mathsf{V}\text{-}\mathbf{Cat}^o$ factors through the forgetful strict pseudo-functor

$$\mathsf{Link}(\mathsf{V}\text{-}\mathbf{Cat}^o) \to \mathsf{V}\text{-}\mathbf{Cat}^o \qquad \mathscr{A} \mapsto \mathscr{A} \qquad (F, G, \eta, \varepsilon) \mapsto F$$

and a pseudo-functor

$$T \to \mathsf{Link}(\mathsf{V}\text{-}\mathbf{Cat}^o) \qquad U \mapsto T/U \qquad (U' \xrightarrow{f} U) \mapsto (j^*_f, j_{f*}, \eta^f, \varepsilon^f)$$

where ε^f is the counit for the adjunction of the pair (j^*_f, j_{f*}), whose unit is η^f. We compose the latter with the strict isomorphism of 2-categories $\mathsf{Link}(\mathsf{V}\text{-}\mathbf{Cat}^o) \xrightarrow{\sim} {}^o\mathsf{Link}(\mathsf{V}\text{-}\mathbf{Cat})$ provided by proposition 2.3.4, and notice that the resulting pseudo-functor maps T to the strong sub-2-category ${}^o\mathbf{Topos}$ of ${}^o\mathsf{Link}(\mathsf{V}\text{-}\mathbf{Cat})$. Thus, we obtain a well defined fibred topos over T :

$$T/- : T = {}^oT \to \mathbf{Topos} \qquad U \mapsto T/U \qquad (U' \xrightarrow{f} U) \mapsto j_f.$$

(iii) In case U is a subobject of the final object 1_T of T, the morphism j_U of (i) is called an *open subtopos* of T. In this case we denote by $\mathsf{C}U$ the full subcategory of T such that

$$\mathrm{Ob}(\mathsf{C}U) = \{X \in \mathrm{Ob}(T) \mid j^*_U X = 1_{T/U}\}.$$

Then $\mathsf{C}U$ is a topos, called the *complement of* U *in* T, and the inclusion functor $i_* : \mathsf{C}U \to T$ admits a left adjoint $i^* : T \to \mathsf{C}U$, namely, the functor which assigns to every $X \in \mathrm{Ob}(T)$ the push-out $X_{|\complement U}$ in the cocartesian diagram :

$$\begin{array}{ccc} X \times U & \xrightarrow{p_X} & X \\ {\scriptstyle p_U}\downarrow & & \downarrow \\ U & \longrightarrow & X_{|\complement U} \end{array}$$

where p_X and p_U are the natural projections. Moreover, i^* is an exact functor, hence the adjoint pair (i^*, i_*) defines a morphism of topoi $\complement U \to T$, unique up to unique isomorphism. (See [8, Exp.IV, Prop.9.3.4].)

Remark 4.7.9. (i) Let $f : T' \to T$ be a morphism of topoi, $U \in \mathrm{Ob}(T)$, and let us fix final objects 1_T of T and $1_{T'}$ of T'. For every $Y \in \mathrm{Ob}(T')$, let also $u_Y : Y \to 1_{T'}$ be the unique morphism in T'. Suppose that $s : T' \to T/U$ is a morphism of topoi with an isomorphism $\omega : f \xrightarrow{\sim} j_U \circ s$. Hence, we have a functorial isomorphism (notation of remark 1.1.17(ii))

$$\omega^\dagger_X : s^*(j^*_U X) \xrightarrow{\sim} f^*X \qquad \text{for every } X \in \mathrm{Ob}(T).$$

So, $s^*\mathbf{1}_U \xrightarrow{\sim} f^*1_T$ is a final object of T', hence $u_{s^*\mathbf{1}_U} : s^*\mathbf{1}_U \to 1_{T'}$ is an isomorphism. Let $\Delta_U : \mathbf{1}_U \to (U \times U \xrightarrow{j^*_U(U)} U)$ be the diagonal morphism; then

$$\sigma(s, \omega) := \omega^\dagger_U \circ s^*(\Delta_U) \circ u^{-1}_{s^*\mathbf{1}_U} : 1_{T'} \to f^*U$$

is an element of $\Gamma(T', f^*U)$ (notation (4.4.11)). Moreover, for every object $\varphi : X \to U$ of T/U, we have a cartesian diagram in T/U :

$$\mathscr{D} \quad : \quad \begin{array}{ccccc} X & & \xrightarrow{\Gamma_\varphi} & & X \times U \\ & \searrow^{\varphi} & & \swarrow^{j^*_U X} & \\ {\scriptstyle \varphi/U}\downarrow & & U & & \downarrow{\scriptstyle j^*_U \varphi} \\ & \nearrow_{\mathbf{1}_U} & & \nwarrow_{j^*_U U} & \\ U & & \xrightarrow[\Delta_U]{} & & U \times U \end{array}$$

where Γ_φ is the graph of φ, and $s^*\mathscr{D}$ is isomorphic to the cartesian diagram (in T') :

$$\mathscr{E} \quad : \quad \begin{array}{ccc} s^*\varphi & \xrightarrow{\omega^\dagger_X \circ s^*\Gamma_\varphi} & f^*X \\ {\scriptstyle u_{s^*\mathbf{1}_U} \circ s^*(\varphi/U)}\downarrow & & \downarrow{\scriptstyle f^*\varphi} \\ 1_{T'} & \xrightarrow{\sigma(s,\omega)} & f^*U. \end{array}$$

This shows that s^* – and therefore also s – is determined, up to isomorphism, by $\sigma(s, \omega)$.

(ii) Conversely, if $\sigma \in \Gamma(T', f^*U)$ is any global section, we may define a functor $s^* : T/U \to T'$ by means of the cartesian diagram $\mathscr{E}$: this amounts to choosing a representative in T' for the fibre product $1_{T'} \times_{(\sigma, f^*\varphi)} f^*X$, for every object $\varphi : X \to U$ of T/U. We claim that there exists an isomorphism of functors

$$s^* \circ j^*_U \xrightarrow{\sim} f^*.$$

Indeed, recall that $j^*_U X = (q_X : X \times U \to U)$, where $X \times U$ is a representative of the product of X and U in T, and q_X is the natural projection; let also $p_X : X \times U \to X$ be the other projection. Likewise, pick a representative $f^*X \times f^*U$ for the fibre product of f^*X and f^*U in T', and let $p_{f^*X} : f^*X \times f^*U \to f^*X$ and $q_{f^*X} : f^*X \times f^*U \to f^*U$ be the projections.

Since f^* is left exact, there exists a unique isomorphism $\lambda_X : f^*X \times f^*U \xrightarrow{\sim} f^*(X \times U)$ in T' such that $f^*(p_X) \circ \lambda_X = p_{f^*X}$ and $f^*(q_X) \circ \lambda_X = q_{f^*X}$. We deduce a commutative diagram :

$$\begin{array}{ccccc} f^*X & \xrightarrow{\mathbf{1}_{f^*X} \times (\sigma \circ u_{f^*X})} & f^*X \times f^*U & \xrightarrow{\lambda} & f^*(X \times U) \\ {\scriptstyle u_{f^*X}} \downarrow & & \downarrow {\scriptstyle q_{f^*X}} & \swarrow {\scriptstyle f^*j_U^*X} & \\ 1_{T'} & \xrightarrow{\sigma} & f^*U & & \end{array}$$

whose square subdiagram is cartesian (the details are left to the reader). The assertion follows straightforwardly. Let us also define a functor $t : T' \to T'/f^*U$, by the rule :

$$tY := \sigma \circ u_Y \qquad \text{for every } Y \in \mathrm{Ob}(T').$$

By inspecting the diagram $\mathscr{E}$, we deduce natural bijections :

$$\mathrm{Hom}_{T'}(Y, s^*\varphi) \xrightarrow{\sim} \mathrm{Hom}_{T'/f^*U}(tY, f^*\varphi) \qquad \text{for every } Y \in \mathrm{Ob}(T') \text{ and } \varphi \in \mathrm{Ob}(T/U).$$

Since f^* is exact, it follows easily that s^* is left exact (indeed, s^* commutes with all the limits with which f^* commutes). Moreover, since all colimits are universal in T (see (4.1.19)(i)), it is easily seen that s^* commutes with all colimits. Then, by proposition 4.4.8(i.b), the functor s^* determines a morphism of topoi $s : T' \to T/U$, unique up to unique isomorphism, with an isomorphism $f \xrightarrow{\sim} j_U \circ s$.

(iii) Next, let $s, s' : T' \to T/U$ be two morphisms of topoi, $\omega : f \xrightarrow{\sim} j_U \circ s$ and $\omega' : f \xrightarrow{\sim} j_U \circ s'$ two isomorphisms, and $\beta : s \Rightarrow s'$ any natural transformation such that

$$(j_U * \beta) \odot \omega = \omega'. \tag{4.7.10}$$

By remark 1.1.17(iv,vi), it follows that $\omega'^\dagger = \omega^\dagger \odot (\beta^\dagger * j_U^*)$. We may then compute :

$$\begin{aligned} \sigma(s', \omega') = \omega'^\dagger_U \circ s'^*(\Delta_U) \circ u^{-1}_{s'^*\mathbf{1}_U} &= \omega^\dagger_U \circ \beta^\dagger_{j_U^*U} \circ s'^*(\Delta_U) \circ u^{-1}_{s'^*\mathbf{1}_U} \\ &= \omega^\dagger_U \circ s^*(\Delta_U) \circ \beta^\dagger_{\mathbf{1}_U} \circ u^{-1}_{s'^*\mathbf{1}_U} \\ &= \sigma(s, \omega). \end{aligned}$$

By considering the cartesian diagram $\mathscr{E}$ of (i), we then deduce that for every object $\varphi : X \to U$ of T/U there exists a unique isomorphism

$$\lambda_\varphi : s'^*\varphi \xrightarrow{\sim} s^*\varphi \qquad \text{such that} \qquad \omega^\dagger_X \circ s^*\Gamma_\varphi \circ \lambda_\varphi = \omega'^\dagger_X \circ s'^*\Gamma_\varphi.$$

Since $\omega^\dagger_X$ is an isomorphism, the latter identity yields :

$$s^*\Gamma_\varphi \circ \lambda_\varphi = s^*\Gamma_\varphi \circ \beta^\dagger_\varphi.$$

However, Γ_φ is a monomorphism, hence the same holds for $s^*\Gamma_\varphi$ (proposition 1.3.18(i)), whence $\lambda_\varphi = \beta^\dagger_\varphi$. Hence, β is *the unique isomorphism of functors* $s \xrightarrow{\sim} s'$ verifying (4.7.10).

(iv) Lastly, consider a morphism $\psi : U \to V$ of T, and $\sigma \in \Gamma(T', f^*U)$. Let $s^U : T/U \to T'$ be the morphism of topoi deduced from σ as in (ii), with its associated isomorphism of functors $\omega^U : s^{U*} \circ j_U^* \xrightarrow{\sim} f^*$. Likewise, let $s^V : T/V \to T'$ be the morphism of topoi and $\omega^V : s^{V*} \circ j_V^* \xrightarrow{\sim} f^*$ the isomorphism deduced, again as in (ii), from $f^*(\psi) \circ \sigma \in \Gamma(T', f^*V)$. A direct inspection of the constructions yields a natural isomorphism of functors

$$\beta : s^{V*} \xrightarrow{\sim} s^{U*} \circ j_\psi^* \qquad \text{such that} \qquad \omega^V = \omega^U \odot (s^{U*} * \gamma^{\dagger -1}_{\psi,V}) \odot (\beta * j_V^*)$$

where $\gamma_{\psi,V} : j_V \circ j_\psi \xrightarrow{\sim} j_U$ is the coherence constraint of the fibred topos $T/-$ of example 4.7.8(ii). In view of (iii), it follows easily that for every pair (s, ω) as in (i) we have :

$$\sigma(j_\psi \circ s, (\gamma^{-1}_{\psi,V} * s) \odot \omega) = f^*(\psi) \circ \sigma(s, \omega)$$

Definition 4.7.11. Let T be a topos.

(i) A *point* of T (or a T*-point*) is a morphism of topoi $\mathbf{Set} \to T$. If $\xi = (\xi^*, \xi_*)$ is a point, and F is any object of T, the set $\xi^* F$ is usually denoted by F_ξ.

(ii) If ξ is a T-point, and $f : T \to S$ is any morphism of topoi, we denote by $f(\xi)$ the S-point $f \circ \xi$. If $\beta : \xi \to \xi'$ is any morphism of T-points, we let likewise $f(\beta) := f_* * \beta$.

(iii) A *neighborhood* of ξ is a pair (U, a), where $U \in \mathrm{Ob}(T)$, and $a \in U_\xi$. A morphism of neighborhoods $(U, a) \to (U', a')$ is a morphism $f : U \to U'$ in T such that $f_\xi(a) = a'$. The category of all neighborhoods of ξ shall be denoted $\mathbf{Nbd}(\xi)$.

(iv) A family $(f_\lambda : T_\lambda \to T \mid \lambda \in \Lambda)$ of morphisms of topoi is *conservative*, if the functor

$$T \to \prod_{\lambda \in \Lambda} T_\lambda \qquad F \mapsto (f_\lambda^* F \mid \lambda \in \Lambda)$$

is conservative (definition 1.1.4(ii)) (the product $\prod_{\lambda \in \Lambda} T_\lambda$ is formed in a sufficiently large universe containing U). We say that T *has enough points*, if T has a conservative set of points.

(v) Consider a graph Γ (see definition 1.6.1(i)) and a system $(C_S \mid S \in \mathrm{Ob}(\mathbf{Topos}))$, where C_S is a given set of morphisms of graphs $\Gamma \to S$, for every topos S, such that $f^*\varphi \in C_{S'}$, for every $\varphi \in C_S$ and every morphism $f : S' \to S$ of topoi. Let $T_\bullet := (T_\lambda \xrightarrow{f_\lambda} T \mid \lambda \in \Lambda)$ be a conservative family of morphisms of topoi, and $\mathbf{P}(S, \varphi)$ a property defined on elements $\varphi \in C_S$, for every topos S; we say that $\mathbf{P}$ *can be checked on* $T_\bullet$, if for every $\varphi \in C_T$ we have :

- $\mathbf{P}(T, \varphi)$ holds if and only if $\mathbf{P}(T_\lambda, f_\lambda^* \circ \varphi)$ holds for every $\lambda \in \Lambda$.

Moreover, we say that $\mathbf{P}$ *can be checked on stalks*, if for every topos S and every conservative set Ω of S-points, the property $\mathbf{P}$ can be checked on Ω.

Example 4.7.12. Let T be a topos, and $(U_\lambda \to 1_T \mid \lambda \in \Lambda)$ any family of morphisms of T covering the final object 1_T (for the canonical topology of T); then the induced family of morphisms of topoi $(j_{U_\lambda} : T/U_\lambda \to T \mid \lambda \in \Lambda)$ is conservative. For the proof, we easily reduce to the case where Λ is a small set, by lemma 4.1.22; then it suffices to recall that, by remark 4.4.1(i), every $X \in \mathrm{Ob}(T)$ is the coequalizer of the induced pair of morphisms of T

$$\coprod_{\lambda,\mu \in \Lambda} U_\lambda \times U_\mu \times X \rightrightarrows \coprod_{\lambda \in \Lambda} U_\lambda \times X$$

(the details are left to the reader).

Remark 4.7.13. (i) With the notation of definition 4.7.11, notice that

$$\mathbf{Nbd}(\xi)^o = \mathscr{F}ib(\xi^*)$$

where the fibration $\pi : \mathscr{F}ib(\xi^*) \to T^o$ is defined as in (3.1.15).

(ii) Moreover, the category $\mathbf{Nbd}(\xi)$ is finitely complete. Indeed, let Λ be any finite category, and $F : \Lambda \to \mathbf{Nbd}(\xi)$ any functor; say that $F\lambda = (U_\lambda, a_\lambda)$ for every $\lambda \in \mathrm{Ob}(\Lambda)$. Then it is easily seen that the limit of F is represented by (U, a), where $U \in \mathrm{Ob}(T)$ represents the limit of the functor $\pi^o \circ F : \Lambda \to T$, and $a \in U_\xi = \lim_\Lambda \xi^* \circ \pi^o \circ F$ is the unique element whose image under the induced projection $U_\xi \to U_{\lambda,\xi}$ agrees with a_λ, for every $\lambda \in \mathrm{Ob}(\Lambda)$.

(iii) Let ξ be a point of the topos T; from (ii) it follows that the category $\mathbf{Nbd}(\xi)$ is cofiltered.

(iv) In view of (i) and (1.4.7), for every $F \in \mathrm{Ob}(T)$ there is a natural cocone :

$$\mathbf{Nbd}(\xi)^o \underset{c_{F_\xi}}{\overset{\mathrm{Hom}_T(\pi, F)}{\underset{\Downarrow \tau_{\xi,F}}{\rightrightarrows}}} \mathbf{Set}$$

assigning to every neighborhood (U, a) of ξ, the map $\tau_{\xi,F}(U, a) : \mathrm{Hom}_T(U, F) \to F_\xi$ such that $s \mapsto s_\xi(a)$ for every $s : U \to F$. Then lemma 1.4.8 says that $\tau_{\xi,F}$ induces a natural bijection

$$\text{(4.7.14)} \qquad \operatorname*{colim}_{\mathbf{Nbd}(\xi)^o} \mathrm{Hom}_T(\pi, F) \xrightarrow{\sim} F_\xi \qquad \text{for every } F \in \mathrm{Ob}(T).$$

(v) It follows from remark 4.7.9(iii), that a neighborhood (U, a) of ξ is the same as the datum of an isomorphism class of a point ξ_U of the topos T/U which lifts ξ, *i.e.* such that $\xi \simeq j_U(\xi_U)$. Moreover, say that $\xi_{U'}$ is another lifting of ξ, corresponding to a neighborhood (U', a') of ξ; then, by inspecting the constructions of remark 4.7.9(i,ii) we see that, under this identification, a morphism $(U, a) \to (U', a')$ of neighborhoods of ξ corresponds to the datum of :

$$\text{a morphism } \varphi : U \to U' \text{ in } T \text{ and an isomorphism } j_\varphi(\xi_U) \xrightarrow{\sim} \xi_{U'} \text{ of } T\text{-points}$$

where j_φ is the morphism of topoi $T/U \to T/U'$ induced by φ.

Proposition 4.7.15. *Let T be a topos with enough points; we have :*

(i) *For every object U of T, the topos T/U has enough points.*

(ii) *More precisely, let Ω be a conservative set of T-points, and denote by $j_U^{-1}\Omega$ the set of all T/U-points ξ_U such that there exists $\xi \in \Omega$ with an isomorphism $\xi \xrightarrow{\sim} j_U(\xi_U)$; then $j_U^{-1}\Omega$ is a conservative set of T/U-points.*

Proof. Let $\varphi : X \to Y$ be a morphism in T/U such that φ_ξ is an epimorphism for every $\xi \in j_U^{-1}\Omega$; by proposition 1.3.21(ii), it suffices to show that φ is an epimorphism, and the latter will follow, if we show that the same holds for $j_{U!}\varphi$. Thus suppose by way of contradiction, that $j_{U!}\varphi$ is not an epimorphism; then there exist $\xi \in \Omega$ and $y \in (j_{U!}Y)_\xi$, such that y does not lie in the image of $(j_{U!}\varphi)_\xi$. Let $a := (j_{U!}\pi_Y)_\xi(y) \in U_\xi$, where $\pi_Y : Y \to 1_{T/U} = \mathbf{1}_U$ is the unique morphism in T/U. By remark 4.7.13(v), we may find a lifting $(\xi_U : \mathbf{Set} \to T/U, \omega_U)$ of ξ such that

$$\sigma(\xi_U, \omega_U) = a \tag{4.7.16}$$

where $\sigma(\xi_U, \omega_U)$ is defined as in remark 4.7.9(i). After replacing ξ by $j_U(\xi_U)$, we may assume that $\omega_U = \mathbf{1}_\xi$, in which case (4.7.16) means that $a = \xi_U^*\Delta_U$, where $\Delta_U : 1_{T/U} \to j_U^* j_{U!} 1_{T/U}$ is the unit of adjunction (*i.e* the diagonal $U \to U \times U$). We have a commutative diagram of sets :

$$\begin{array}{ccc} \xi_U^* X & \xrightarrow{\xi_U^*\varphi} & \xi_U^* Y \\ {\scriptstyle \xi_U^*\Delta_X}\downarrow & & \downarrow{\scriptstyle \xi_U^*\Delta_Y} \\ (j_{U!}X)_\xi & \xrightarrow{(j_{U!}\varphi)_\xi} & (j_{U!}Y)_\xi = \xi_U^*(j_U^* j_{U!} Y) \end{array}$$

where $\Delta_X : X \to j_U^* j_{U!} X$ is the unit of adjunction, and likewise for Δ_Y. More plainly, $\Delta_Y : Y \times 1_{T/U} \to Y \times (j^* j_{U!} 1_{T/U})$ is the product $\mathbf{1}_Y \times \Delta_U$, and under this identification, $\xi_U^*\Delta_Y$ is the mapping $\xi_U^* Y \to \xi_U^* Y \times (j^* j_{U!} 1_{T/U})$ given by the rule : $z \mapsto (z, a)$ for every $z \in \xi_U^* Y$. Especially, we see that y lies in the image of $\xi_U^*\Delta_Y$. But by assumption, the map $\xi_U^*\varphi$ is surjective, hence y lies in the image of $(j_{U!}\xi)_\xi$, a contradiction. □

4.7.17. Remark 4.7.13(v) prompts the following construction. Let us consider the fibred topos

$$T/- : T \to \mathbf{Topos} \qquad U \mapsto T/U \qquad (U' \xrightarrow{\varphi} U) \mapsto (T/U' \xrightarrow{j_\varphi} T/U)$$

of example 4.7.8(ii). Denote also by 1_T a fixed final object of T, and for every $U \in \mathrm{Ob}(T)$ let $\varphi_U : U \to 1_T$ be the unique morphism in T; the source functor yields a natural isomorphism $T/1_T \xrightarrow{\sim} T$ that identifies $j_{\varphi_U} : T/U \to T/1_T$ with $j_U : T/U \to T$. Moreover, the rule : $U \mapsto \varphi_U$ clearly defines a natural transformation

$$\varphi_\bullet : \mathbf{1}_T \Rightarrow c_{1_T}$$

where $c_{1_T} : T \to T$ is the constant functor with value 1_T. For a sufficiently large universe V, example 2.2.7(i) yields a strict pseudo-functor $H_{\mathbf{Topos}} : \mathbf{Topos}^o \times \mathbf{Topos} \to \mathsf{V}\text{-}\mathbf{Cat}$ which restricts to a strict pseudo-functor

$$\mathrm{Pt} : \mathbf{Topos} \to \mathsf{V}\text{-}\mathbf{Cat} \qquad S \mapsto \mathrm{Pt}(S) := \mathrm{Hom}_{\mathbf{Topos}}(\mathbf{Set}, S)$$

assigning to every topos S the category of S-points. We consider the composition

$$\mathrm{Pt}_T := \mathrm{Pt} \circ (T/-) : T \to \mathsf{V}\text{-}\mathbf{Cat} \qquad U \mapsto \mathrm{Pt}(T/U)$$

as well as the pseudo-natural transformation

$$\mathrm{Pt}_T * \varphi_\bullet : \mathrm{Pt}_T \Rightarrow \mathsf{F}_{\mathrm{Pt}(T)}$$

from Pt_T to the constant pseudo-functor $\mathsf{F}_{\mathrm{Pt}(T)}$ with value $\mathrm{Pt}(T)$. There follows a cartesian functor of fibrations over T^o :

$$\mathscr{F}ib(\mathrm{Pt}_T * \varphi_\bullet) : \mathscr{F}ib(\mathrm{Pt}_T) \to T^o \times \mathrm{Pt}(T).$$

Let also $\sigma_\xi : T^o \to T^o \times \mathrm{Pt}(T)$ be the cartesian section such that $\sigma_\xi(U) := (U, \xi)$ for every $U \in \mathrm{Ob}(T)$. Lastly, we consider the 2-cartesian diagram in the category $\mathsf{Fib}(T^o)$:

$$\begin{array}{ccc} \mathscr{L}(\xi) := \mathscr{F}ib(\mathrm{Pt}_T) \overset{2}{\underset{T^o \times \mathrm{Pt}(T)}{\times}} T^o & \longrightarrow & \mathscr{F}ib(\mathrm{Pt}_T) \\ \big\downarrow & & \big\downarrow {\scriptstyle \mathscr{F}ib(\mathrm{Pt}_T * \varphi_\bullet)} \\ T^o & \xrightarrow{\ \sigma_\xi\ } & T^o \times \mathrm{Pt}(T) \end{array}$$

and we set

$$\mathbf{Lift}(\xi) := \mathscr{L}(\xi)^o.$$

Taking into account theorem 3.3.25(ii), we see that for every $U \in \mathrm{Ob}(T)$, the fibre $\mathscr{L}(\xi)_U$ of the fibration $\mathscr{L}(\xi) \to T^o$ is the category whose objects are the pairs (ξ_U, ω_U), where ξ_U is a T/U-point, and $\omega_U : \xi \overset{\sim}{\to} j_U(\xi_U)$ is an isomorphism of T-points. The morphisms $(\xi_U, \omega_U) \to (\xi'_U, \omega'_U)$ are the morphisms of T/U-points

$$\beta : \xi_U \to \xi'_U \qquad \text{such that} \qquad \omega_{U'} = j_U(\beta) \odot \omega_U$$

(with the obvious composition law). Hence, the objects of $\mathbf{Lift}(\xi)$ are the triples (U, ξ_U, ω_U) with $U \in \mathrm{Ob}(T)$ and $(\xi_U, \omega_U) \in \mathrm{Ob}(\mathscr{L}(\xi)_U)$. The morphisms $(U, \xi_U, \omega_U) \to (V, \xi_V, \omega_V)$ are the pairs (φ, β), where $\varphi : U \to V$ is a morphism in T, and $\beta : \xi_V \to j_\varphi(\xi_U)$ is a morphism of T/V-points, such that

$$(\gamma_{\varphi,V} * \xi_U) \odot j_V(\beta) \odot \omega_V = \omega_U$$

where $\gamma_{\varphi,V} : j_V \circ j_\varphi \overset{\sim}{\to} j_U$ is the coherence constraint of $T/-$. Then, remark 4.7.9 shows that $\mathscr{L}(\xi)$ is a fibration in groupoids, and we have an equivalence of categories :

(4.7.18) $$N_\xi : \mathbf{Lift}(\xi) \overset{\sim}{\to} \mathbf{Nbd}(\xi) \qquad (U, \xi_U, \omega_U) \mapsto (U, \sigma(\xi_U, \omega_U))$$

where $\sigma(\xi_U, \omega_U) \in U_\xi$ is defined as in remark 4.7.9(i).

4.7.19. Notice next that, since $\mathscr{L}(\xi)$ is a fibration in groupoids, the natural projection $\mathscr{L}(\xi) \to \mathscr{F}ib(\mathrm{Pt}_T)$ factors through the inclusion pseudo-functor $\mathscr{F}ib(\mathrm{Pt}_T^\times) = \mathscr{F}ib(\mathrm{Pt}_T)^\times \to \mathscr{F}ib(\mathrm{Pt}_T)$ (notation of remark 3.4.8(iii)). To every small set X, we wish now to attach a functor

$$\Xi^X : \mathscr{F}ib(\mathrm{Pt}^\times) \to \mathbf{Set} \qquad (\zeta : \mathbf{Set} \to S) \mapsto \zeta^* \zeta_* X.$$

To this aim, according to remark 3.1.23(i), it will suffice to exhibit a lax-natural transformation

$$\alpha^X : {}^o\mathrm{Pt}^\times \Rightarrow {}^o\mathsf{F}_{\mathbf{Set}}$$

where $\mathsf{F}_{\mathbf{Set}}$ is the constant pseudo-functor $\mathbf{Topos} \to \mathsf{V}\text{-}\mathbf{Cat}$ with value $\mathbf{Set}$. We need therefore to give for every $S \in \mathrm{Ob}(\mathbf{Topos})$ a functor $\alpha^X_S : \mathrm{Pt}(S)^\times \to \mathbf{Set}$, together with a coherence constraint for the resulting system $(\alpha^X_S \mid S \in \mathrm{Ob}(\mathbf{Topos}))$. Now, let us set

$$\alpha^X_S(\xi) := \zeta^* \zeta_* X \qquad \text{for every } \zeta \in \mathrm{Ob}(\mathrm{Pt}(S)).$$

Next, let $\beta : \zeta \stackrel{\sim}{\to} \zeta'$ be any morphism in $\mathrm{Pt}(S)^\times$; *i.e.* $\beta : \zeta_* \stackrel{\sim}{\to} \zeta'_*$ is an isomorphism of functors. Then we define $\alpha^X_S(\beta) : \zeta^*\zeta_*X \to \zeta'^*\zeta'_*X$ as the composition

$$\zeta^*\zeta_*X \xrightarrow{(\zeta^**\beta)_X} \zeta^*\zeta'_*X \xrightarrow{(\beta^\dagger*\zeta'_*)^{-1}_X} \zeta'^*\zeta'_*X$$

where $\beta^\dagger : \zeta'^* \stackrel{\sim}{\to} \zeta^*$ is the transpose of the natural transformation β (see remark 1.1.17(ii)). From remark 1.1.17(vi) we see already that $\alpha^X_S(\mathbf{1}_\zeta) = \mathbf{1}_{\zeta^*\zeta_*X}$. Next, let $\beta' : \zeta' \to \zeta''$ be another morphism of $\mathrm{Pt}(S)^\times$; we compute :

$$\begin{aligned}\alpha^X_S(\beta')\circ\alpha^X_S(\beta) &= ((\beta'^\dagger * \zeta''_*)^{-1}\odot(\zeta'^* * \beta')\odot(\beta^\dagger * \zeta'_*)^{-1}\odot(\zeta^* * \beta))_X \\ &= ((\beta'^\dagger * \zeta''_*)^{-1}\odot(\beta^\dagger * \zeta''_*)^{-1}\odot(\zeta^* * \beta')\odot(\zeta^* * \beta))_X \\ &= (((\beta'\odot\beta)^\dagger * \zeta''_*)^{-1}\odot(\zeta^* * (\beta'\odot\beta)))_X \\ &= \alpha^X_S(\beta'\odot\beta)\end{aligned}$$

where the second equality follows from (1.1.11), and the third follows from remark 1.1.17(vi). Next, let $f : S \to S'$ be any morphism of topoi, and $\varepsilon^f : f^*\circ f_* \Rightarrow \mathbf{1}_S$ the counit of the adjoint pair (f^*, f_*); our candidate coherence constraint for $\alpha^X_\bullet$ assigns to every S-point ζ the map

$$\tau^X_{f,\zeta} : f(\zeta)^*f(\zeta)_*X = \zeta^*\circ f^*\circ f_*\circ\zeta_*X \xrightarrow{(\zeta^**\varepsilon^f*\zeta_*)_X} \zeta^*\zeta_*X$$

(see example 2.2.6(ii)). We need to check that the rule $\zeta \mapsto \tau^X_{f,\zeta}$ yields a natural transformation

$$\tau^X_f : \alpha^X_{S'}\circ\mathrm{Pt}(f)^\times \Rightarrow \alpha^X_S.$$

Thus, let $\beta : \zeta_* \stackrel{\sim}{\to} \zeta'_*$ be any morphism of $\mathrm{Pt}(S)^\times$; the assertion comes down to showing the commutativity of the diagram :

$$\begin{array}{ccccc} \zeta^*f^*f_*\zeta_*X & \xrightarrow{(\zeta^*f^*f_**\beta)_X} & \zeta^*f^*f_*\zeta'_*X & \xrightarrow{((f_**\beta)^\dagger*f_*\zeta'_*)^{-1}_X} & \zeta'^*f^*f_*\zeta'_*X \\ {\scriptstyle (\zeta^**\varepsilon^f*\zeta_*)_X}\downarrow & & {\scriptstyle (\zeta^**\varepsilon^f*\zeta'_*)_X}\downarrow & & \downarrow{\scriptstyle (\zeta'^**\varepsilon^f*\zeta'_*)_X} \\ \zeta^*\zeta_*X & \xrightarrow{(\zeta^**\beta)_X} & \zeta^*\zeta'_*X & \xrightarrow{(\beta^\dagger*\zeta'_*)^{-1}_X} & \zeta'^*\zeta'_*X \end{array}$$

However, the commutativity of the left square subdiagram follows from the naturality of $\zeta^* * \varepsilon^f$. Next, recall that $(f_* * \beta)^\dagger = \beta^\dagger * f^*$ (remark 1.1.17(vi)); then the commutativity of the right square subdiagram follows by applying (1.1.11) to the natural transformations $\beta^\dagger$ and $\varepsilon^f * \zeta'_*$.

Lastly, we have to check the coherence axioms for $\tau^X_\bullet$. Since ${}^o\mathrm{Pt}^\times$ and ${}^o\mathsf{F}_{\mathbf{Set}}$ are both strict pseudo-functors, we come down to showing that

$$\tau^X_{\mathbf{1}_S} = \mathbf{1}_{\alpha^X_S} \qquad\text{and}\qquad \tau^X_g \boxminus \tau^X_f = \tau^X_{g\circ f}$$

for every topos S and every pair of morphisms of topoi $S \xrightarrow{f} S' \xrightarrow{g} S''$ (see remark 2.2.5(i)). These follow easily by direct inspection. This completes the construction of α^X, and thus also of $\Xi^X := \mathscr{F}ib(\alpha^X)$. After composing with the projection $\mathscr{L}(\xi) \to \mathscr{F}ib(\mathrm{Pt}^\times_T) \to \mathscr{F}ib(\mathrm{Pt}^\times)$, we deduce a functor

$$\Xi^{X,\xi} : \mathbf{Lift}(\xi)^o \to \mathbf{Set} \qquad (U, \xi_U, \omega_U) \mapsto \xi^*_U\xi_{U*}X.$$

Lemma 4.7.20. (i) *For every $(S,\zeta) \in \mathrm{Ob}(\mathscr{F}ib(\mathrm{Pt}^\times))$ and every set X, let $\varepsilon^{(S,\zeta)}_X : \zeta^*\zeta_*X \to X$ be the counit of adjunction. Then the rule : $(S,\zeta) \mapsto \varepsilon^{(S,\zeta)}_X$ defines a natural cocone*

$$\Xi^X \Rightarrow c_X.$$

(ii) *The cocone of* (i) *induces a natural bijection :*

$$\operatorname*{colim}_{\mathbf{Lift}(\xi)^o} \Xi^{X,\xi} \stackrel{\sim}{\to} X \qquad \textit{for every (small) set } X.$$

Proof. (i): Let $\nu^X : {}^o\mathrm{Pt}^\times \Rightarrow {}^o\mathsf{F}_{\mathbf{Set}}$ be the strict pseudo-natural transformation such that

$$\nu^X_S : \mathrm{Pt}(S)^\times \to \mathbf{Set}$$

is the constant functor with value X, for every topos S (*i.e.* $\nu^X_S(\zeta) := X$ for every S-point ζ, and $\nu^X_S(\beta) = \mathbf{1}_X$ for every invertible morphism β of S-points). For every such S, let also

$$\varepsilon^{(S,\bullet)}_X : \mathrm{Ob}(\mathrm{Pt}(S)) \to \mathrm{Morph}(\mathbf{Set})$$

be the map that associates with every S-point ζ, the map of sets $\varepsilon^{(S,\zeta)}_X$. We notice :

Claim 4.7.21. The rule : $S \mapsto \varepsilon^{(S,\bullet)}_X$ for every topos S, defines a modification :

$$\varepsilon^{(\bullet,\bullet)}_X : \nu^X \rightsquigarrow \alpha^X.$$

Proof of the claim. First, we need to check that $\varepsilon^{(S,\bullet)}_X$ is a natural transformation $\alpha^X_S \Rightarrow \nu^X_S$, for every topos S. The latter assertion amounts to the commutativity of the diagram :

$$\begin{array}{ccc} \zeta^*\zeta_*X & \xrightarrow{\varepsilon^{(S,\zeta)}_X} & X \\ {\scriptstyle \alpha^X_S(\beta)}\downarrow & & \| \\ \zeta'^*\zeta'_*X & \xrightarrow{\varepsilon^{(S,\zeta')}_X} & X \end{array}$$

for every isomorphism $\beta : \zeta \stackrel{\sim}{\to} \zeta'$ of S-points. Since $(\beta^\dagger * \zeta'_*)^{-1}_X = ((\beta^{-1})^\dagger * \zeta'_*)_X$ (remark 1.1.17(iv)), this is in turn the same as the identity :

$$\varepsilon^{(S,\zeta')}_X \circ ((\beta^{-1})^\dagger * \zeta'_*)_X = \varepsilon^{(S,\zeta)}_X \circ (\zeta^* * \beta^{-1})_X$$

which follows from remark 1.1.17(iii). Next, we need to check the compatibility condition for $\varepsilon^{(S,\bullet)}_X$, which comes down to the identity :

$$\varepsilon^{(S,\zeta)}_X \odot \tau^X_f = \varepsilon^{(S,f(\zeta))}_X$$

for every morphism of topoi $f : S \to S'$ and every S-point ζ, where τ^X_f denotes the coherence constraint of α^X. The latter follows by direct inspection. ◊

By remark 3.1.23(ii), the sought cocone is then $\mathscr{F}ib(\varepsilon^{(\bullet,\bullet)}_X) : \Xi^X \Rightarrow \mathscr{F}ib(\nu^X) = c_X$.

(ii): Let $\pi : \mathscr{F}ib(\mathrm{Pt}^\times) \to \mathbf{Topos}^o$ be the fibration arising from the strict pseudo-functor $\mathrm{Pt}^\times$. We let $\mathscr{C}$ be the fibre product in the cartesian square of categories :

$$\begin{array}{ccccc} \mathsf{Morph}(\mathscr{F}ib(\mathrm{Pt}^\times)) & \xrightarrow{p} & \mathscr{C} & \xrightarrow{\mathsf{s}'} & \mathscr{F}ib(\mathrm{Pt}^\times) \\ & {\scriptstyle \mathsf{Morph}(\pi)}\searrow & {\scriptstyle \pi'}\downarrow & & \downarrow{\scriptstyle \pi} \\ & & \mathsf{Morph}(\mathbf{Topos}^o) & \xrightarrow{\mathsf{s}} & \mathbf{Topos}^o \end{array}$$

where s and $\mathsf{s}' \circ p$ are the source functors. By remark 3.1.27(ii), we have a natural identification

$$\mathscr{C} \stackrel{\sim}{\to} \mathscr{F}ib(\mathrm{Pt}^\times \circ \mathsf{s}^o)$$

and recall that $\mathsf{Morph}(\pi)$ is a fibration as well, by example 3.1.9. To every morphism of topoi $f : S' \to S$, we attach the functor

$$\Sigma^X_f : \pi'^{-1}(f) = \mathrm{Pt}(S)^\times \to \mathbf{Set} \qquad \zeta \mapsto \Gamma(S', f^*\zeta_*X)$$

where $\Gamma(S', -) : S' \to \mathbf{Set}$ is defined as in (4.4.11), after fixing a final object $1_{S'}$ of S'. To every isomorphism $\alpha : \zeta_1 \stackrel{\sim}{\to} \zeta_2$ of S-points, the functor Σ^X_f assigns the map

$$\Sigma^X_f(\alpha) := \Gamma(S', f^*\alpha_X) : \Gamma(S', f^*\zeta_{1*}X) \to \Gamma(S', f^*\zeta_{2*}X).$$

Next, notice that if $(S'_1 \xrightarrow{f_1} S_1)^o$ and $(S'_2 \xrightarrow{f_2} S_2)^o$ are two objects of $\mathsf{Morph}(\mathbf{Topos}^o)$, then a morphism $f_1^o \to f_2^o$ in this category is a commutative diagram of morphisms of topoi :

$$\mathscr{D}_{g,g'} \qquad : \qquad \begin{array}{ccc} S'_2 & \xrightarrow{f_2} & S_2 \\ {\scriptstyle g'}\downarrow & & \downarrow{\scriptstyle g} \\ S'_1 & \xrightarrow{f_1} & S_1. \end{array}$$

The (split) cleavage $\mathrm{Pt}^\times \circ \mathsf{s}^o$ of $\mathscr{C}$ associates with $\mathscr{D}_{g,g'}$ the functor

$$\mathrm{Pt}(g)^\times : \mathrm{Pt}(S_2)^\times \to \mathrm{Pt}(S_1)^\times \qquad \zeta \mapsto g(\zeta)$$

that assigns to every morphism α of $\mathrm{Pt}(S_2)^\times$ the morphism $g(\alpha)$ of $\mathrm{Pt}(S_1)^\times$. To the diagram $\mathscr{D}_{g,g'}$ and every object ζ of $\mathrm{Pt}(S_2)^\times$ we attach as well the map :

$$\tau_\zeta^{g,g'} : \Gamma(S'_1, f_1^* g_* \zeta_* X) \xrightarrow{\Gamma(S'_1, \Upsilon(\mathscr{D}_{g,g'}) * \zeta_*)_X} \Gamma(S'_1, g'_* f_2^* \zeta_* X) \xrightarrow{\omega^{g'}_{f_2^* \zeta_* X}} \Gamma(S'_2, f_2^* \zeta_* X)$$

where $\Upsilon(\mathscr{D}_{g,g'})$ is the base change transformation associated with the diagram $\mathscr{D}_{g,g'}$, viewed as an oriented square diagram of links, whose orientation is the identity (see (2.3.8)). The second map in this composition is induced by the unique isomorphism of morphisms of topoi $\omega^{g'} : \Gamma_{S'_1} \circ g'_* \xrightarrow{\sim} \Gamma_{S'_2}$ (proposition 4.4.12(ii)).

Claim 4.7.22. (i) For every diagram $\mathscr{D}_{g,g'}$, the rule : $\zeta \mapsto \tau_\zeta^{g,g'}$ defines a natural transformation

$$\begin{array}{ccc} \mathrm{Pt}(S_2)^\times & \xrightarrow{\Sigma^X_{f_2}} & \mathbf{Set} \\ {\scriptstyle \mathrm{Pt}(g)^\times}\downarrow & \tau^{g,g'} \Uparrow & \| \\ \mathrm{Pt}(S_1)^\times & \xrightarrow[\Sigma^X_{f_1}]{} & \mathbf{Set}. \end{array}$$

(ii) The rule : $\mathscr{D}_{g,g'} \mapsto \tau^{g,g'}$ provides the coherence constraint for a lax-natural transformation

$$\Sigma^X_\bullet : {}^o(\mathrm{Pt}^\times \circ \mathsf{s}^o) \Rightarrow {}^o\mathsf{F}_{\mathbf{Set}}.$$

Proof of the claim. (i): For every object $(S' \xrightarrow{f} S)^o$ of $\mathsf{Morph}(\mathbf{Topos}^o)$, consider the functor

$$\sigma_f : \mathrm{Pt}(S)^\times \to S \qquad \zeta \mapsto \zeta_* X$$

that assigns to every isomorphism α as in the foregoing, the morphism α_X of S. With this notation, $\tau^{g,g'}$ is the composition of the following oriented squares :

$$\begin{array}{ccccccc} \mathrm{Pt}(S_2)^\times & \xrightarrow{\sigma_{f_2}} & S_2 & \xrightarrow{f_2^*} & S'_2 & \xrightarrow{\Gamma_{S'_2}} & \mathbf{Set} \\ {\scriptstyle \mathrm{Pt}(g)^\times}\downarrow & \mathbf{1}_{g_* \circ \sigma_{f_2}} \Uparrow & {\scriptstyle g_*}\downarrow & \Upsilon(\mathscr{D}_{g,g'}) \Uparrow & \downarrow{\scriptstyle g'_*} & \omega^{g'} \Uparrow & \| \\ \mathrm{Pt}(S_1)^\times & \xrightarrow[\sigma_{f_1}]{} & S_1 & \xrightarrow[f_1^*]{} & S'_2 & \xrightarrow[\Gamma_{S'_1}]{} & \mathbf{Set}. \end{array}$$

(ii): Clearly $\tau^{\mathbf{1}_S, \mathbf{1}_{S'}} = \mathbf{1}_{\Sigma^X_f}$, for every morphism of topoi $f : S' \to S$. According to remark 2.2.5(i), it remains to check the identity

$$\tau^{g,g'} \boxminus \tau^{h,h'} = \tau^{g \circ h, g' \circ h'}$$

for every composable pair of diagrams $\mathscr{D}_{g,g'} : f_1^o \to f_2^o$ and $\mathscr{D}_{h,h'} : f_2^o \to f_3^o$. However, by proposition 2.1.9 we have :

$$\tau^{g,g'} \boxminus \tau^{h,h'} = (\mathbf{1}_{g_* \circ \sigma_{f_2}} \boxminus \mathbf{1}_{h_* \circ \sigma_{f_3}}) \boxplus (\Upsilon(\mathscr{D}_{g,g'}) \boxminus \Upsilon(\mathscr{D}_{h,h'})) \boxplus (\omega^{g'} \boxminus \omega^{h'}).$$

Clearly $\mathbf{1}_{g_*\circ\sigma_{f_2}} \boxminus \mathbf{1}_{h_*\circ\sigma_{f_3}} = \mathbf{1}_{(g\circ h)_*\circ\sigma_{f_3}}$, and we have $\omega^{g'} \boxminus \omega^{h'} = \omega^{g'\circ h'}$, by the uniqueness properties of the isomorphisms $\omega^\bullet$. Lastly, $\Upsilon(\mathscr{D}_{g,g'}) \boxminus \Upsilon(\mathscr{D}_{h,h'}) = \Upsilon(\mathscr{D}_{g,g'} \boxbar \mathscr{D}_{h,h'})$, by proposition 2.3.12(i), whence the claim. $\diamondsuit$

From claim 4.7.22(ii) and remark 3.1.23(i) we deduce a functor $\mathscr{F}ib(\Sigma^X_\bullet) : \mathscr{C} \to \mathbf{Set}$.

Next, notice that, for every object $(S' \xrightarrow{f} S)^o$ of $\mathsf{Morph}(\mathbf{Topos}^o)$, the objects of the fibre category $\mathsf{Morph}(\pi)^{-1}(f)$ are the triples (ζ, ζ', β), where ζ is an S-point, ζ' is an S'-point, and $\beta : \zeta \xrightarrow{\sim} f(\zeta')$ is an isomorphism of S-points. The morphisms $(\zeta_1, \zeta'_1, \beta_1) \to (\zeta_2, \zeta'_2, \beta_2)$ are the pairs (α, α') where $\alpha : \zeta_1 \xrightarrow{\sim} \zeta_2$ and $\alpha' : \zeta'_1 \xrightarrow{\sim} \zeta'_2$ are isomorphisms of S-points and respectively S'-points, such that

$$(f_* * \alpha') \odot \beta_1 = \beta_2 \odot \alpha. \tag{4.7.23}$$

If $(\gamma, \gamma') : (\zeta_2, \zeta'_2, \beta_2) \to (\zeta_3, \zeta'_3, \beta_3)$ is another such morphism, we have

$$(\gamma, \gamma') \circ (\alpha, \alpha') = (\gamma \odot \alpha, \gamma' \odot \alpha') \qquad \text{in } \mathsf{Morph}(\pi)^{-1}(f).$$

The (split) cleavage c of $\mathsf{Morph}(\mathscr{F}ib(\mathrm{Pt}^\times))$ attaches to the diagram $\mathscr{D}_{g,g'}$, the functor

$$\mathsf{c}_{g,g'} : \mathsf{Morph}(\pi)^{-1}(f_2) \to \mathsf{Morph}(\pi)^{-1}(f_1) \qquad (\zeta, \zeta', \beta) \mapsto (g(\zeta), g'(\zeta'), g(\beta))$$

that assigns to every morphism (α, α') of $\mathsf{Morph}(\pi)^{-1}(f_2)$ the morphism $(g(\alpha), g'(\alpha'))$. With this notation, p is the (cartesian) functor associated with the strict pseudo-natural transformation

$$t : \mathsf{c} \Rightarrow \mathrm{Pt}^\times \circ \mathsf{s}^o$$

that assigns to every morphims of topoi $f : S' \to S$ the functor

$$\mathsf{Morph}(\pi)^{-1}(f) \to \mathrm{Pt}(S) \qquad (\zeta, \zeta', \beta) \mapsto \zeta \qquad (\alpha, \alpha') \mapsto \alpha.$$

Now, to every morphism of topoi $f : S' \to S$, and every $(\zeta, \zeta', \beta) \in \mathrm{Ob}(\mathsf{Morph}(\pi)^{-1}(f))$, let us attach the map $b_{f,(\zeta,\zeta',\beta)} : \Gamma(S', f^*\zeta_* X) \to \zeta^*\zeta_* X$ defined as the composition :

$$\Gamma(S', f^*\zeta_*X) \xrightarrow{\Gamma(S', (\eta^{\zeta'} * f^*\zeta_*)_X)} \Gamma(S', \zeta'_*\zeta'^* f^*\zeta_*X) \xrightarrow{\omega^{\zeta'}_{\zeta'^* f^*\zeta_* X}} \zeta'^* f^*\zeta_*X \xrightarrow{(\beta^\dagger * \zeta_*)_X} \zeta^*\zeta_*X$$

where $\eta^{\zeta'} : \mathbf{1}_{S'} \Rightarrow \zeta'_*\zeta'^*$ is the unit of adjunction, and $\omega^{\zeta'} : \Gamma_{S'} \circ \zeta' \xrightarrow{\sim} \mathbf{1}_{\mathbf{Set}}$ is the unique isomorphism of morphisms of topoi provided by proposition 4.4.12(ii).

Claim 4.7.24. (i) For every morphism of topoi $f : S' \to S$, the rule : $(\zeta, \zeta', \beta) \mapsto b_{f,(\zeta,\zeta',\beta)}$ defines a natural transformation

$$b_f : \Sigma^X_f \circ t_f \Rightarrow \alpha^X_S \circ t_f.$$

(ii) The rule : $f \mapsto b_f$ defines a modification

$$b_\bullet : (\alpha^X * \mathsf{s}^o) \odot {}^o t \rightsquigarrow \Sigma^X_\bullet \odot {}^o t.$$

Proof of the claim. (i): Let $(\alpha, \alpha') : (\zeta_1, \zeta'_1, \beta_1) \to (\zeta_2, \zeta'_2, \beta_2)$ be a morphism in $\mathsf{Morph}(\pi)^{-1}(f)$, and set $U := (\zeta'_{2*} * \alpha'^\dagger * f^*\zeta_{2*})^{-1}_X \circ (\zeta'_{2*} * \alpha' * f^*\zeta_{2*})_X$. We notice that :

$$\begin{aligned}(\eta^{\zeta'_2} * f^*\zeta_{2*})_X \circ (f^*(\alpha_X) &= U \circ (\eta^{\zeta'_1} * f^*\zeta_{2*})_X \circ (f^*(\alpha_X) \\ &= U \circ (\zeta'_{1*}\zeta'^*_1 f^* * \alpha)_X \circ (\eta^{\zeta'_1} * f^*\zeta_{1*})_X\end{aligned}$$

where the first equality holds by remark 1.1.17(iii), and the second one follows from (1.1.11). We are then reduced to checking the commutativity of the diagram :

$$\begin{array}{ccccc}
\Gamma(S',\zeta'_{1*}\zeta'^*_1 f^*\zeta_{1*}X) & \xrightarrow{\omega^{\zeta'_1}_{\zeta'^*_1 f^*\zeta_{1*}X}} & \zeta'^*_1 f^*\zeta_{1*}X & \xrightarrow{(\beta^\dagger_1 * \zeta_{1*})_X} & \zeta^*_1\zeta_{1*}X \\
\downarrow{\scriptstyle \Gamma(S',\zeta'_{1*}\zeta'^*_1 f^*\alpha_X)} & & \downarrow{\scriptstyle \zeta'^*_1 f^*\alpha_X} & & \downarrow{\scriptstyle \zeta^*_1\alpha_X} \\
\Gamma(S',\zeta'_{1*}\zeta'^*_1 f^*\zeta_{2*}X) & \xrightarrow{\omega^{\zeta'_1}_{\zeta'^*_1 f^*\zeta_{2*}X}} & \zeta'^*_1 f^*\zeta_{2*}X & \xrightarrow{(\beta^\dagger_1 * \zeta_{2*})_X} & \zeta^*_1\zeta_{2*}X \\
\downarrow{\scriptstyle \Gamma(S',(\alpha' * \zeta'^*_1 f^*\zeta_{2*})_X)} & & \| & & \| \\
\Gamma(S',\zeta'_{2*}\zeta'^*_1 f^*\zeta_{2*}X) & \xrightarrow{\omega^{\zeta'_2}_{\zeta'^*_1 f^*\zeta_{2*}X}} & \zeta'^*_1 f^*\zeta_{2*}X & \xrightarrow{(\beta^\dagger_1 * \zeta_{2*})_X} & \zeta^*_1\zeta_{2*}X \\
\downarrow{\scriptstyle \Gamma(S',(\zeta'_{2*} * \alpha'^\dagger * f^*\zeta_{2*})^{-1}_X)} & & \downarrow{\scriptstyle (\alpha'^\dagger * f^*\zeta_{2*})^{-1}_X} & & \downarrow{\scriptstyle (\alpha^\dagger * \zeta_{2*})^{-1}_X} \\
\Gamma(S',\zeta'_{2*}\zeta'^*_2 f^*\zeta_{2*}X) & \xrightarrow{\omega^{\zeta'_2}_{\zeta'^*_2 f^*\zeta_{2*}X}} & \zeta'^*_2 f^*\zeta_{2*}X & \xrightarrow{(\beta^\dagger_2 * \zeta_{2*})_X} & \zeta^*_2\zeta_{2*}X.
\end{array}$$

However, the commutativity of the top two squares and of the bottom square on the left is clear; the commutativity of the bottom square on the right follows from remark 1.1.17(iv,v) and (4.7.23). Lastly, the commutativity of the left square on the central row follows immediately from the uniqueness properties of the isomorphisms $\omega^{\zeta'_1}$ and $\omega^{\zeta'_2}$ (proposition 4.4.12(ii)), whence the contention.

(ii): Consider a diagram $\mathscr{D}_{g,g'}$ as in the foregoing, and an object (ζ,ζ',β) of $\mathsf{Morph}(\pi)^{-1}(f_2)$. We have to check the compatibility condition :

$$b_{f_2,(\zeta,\zeta',\beta)} \circ \tau^{g,g'}_\zeta = \tau^X_{g,\zeta} \circ b_{f_1,(g(\zeta),g(\zeta'),g(\beta))}.$$

To this aim, notice that $\omega^{g'(\zeta')} = \omega^{\zeta'} \odot (\omega^{g'} * \zeta'_*)$, due to proposition 4.4.12(ii); then it suffices to show the commutativity of the diagram :

$$\begin{array}{ccccc}
\Gamma(S'_1, f^*_1 g_*\zeta_*X) & \xrightarrow{\Gamma(S'_1,\Upsilon(\mathscr{D}_{g,g'})*\zeta_*)_X} & \Gamma(S'_1, g'_*f^*_2\zeta_*X) & \xrightarrow{\omega^{g'}_{f^*_2\zeta_*X}} & \Gamma(S'_2, f^*_2\zeta_*X) \\
\downarrow{\scriptstyle \Gamma(S'_1,(\eta^{g'(\zeta')}*f^*_1g_*\zeta_*)_X)} & & & & \\
\Gamma(S'_1, g'(\zeta')_*g'(\zeta')^*f^*_1g_*\zeta_*X) & & & & \downarrow{\scriptstyle \Gamma(S'_2,(\eta^{\zeta'}*f^*_2\zeta_*)_X)} \\
\downarrow{\scriptstyle \omega^{g'}_{\zeta'_*\zeta'^*g'^*f^*_1g_*\zeta_*X}} & & & & \\
\Gamma(S'_2, \zeta'_*g'(\zeta')^*f^*_1g_*\zeta_*X) & & \xrightarrow{\Gamma(S'_2,(\zeta'^*f^*_2*\varepsilon^g*\zeta_*)_X)} & & \Gamma(S'_2, \zeta'_*\zeta'^*f^*_2\zeta_*X) \\
\downarrow{\scriptstyle \omega^{\zeta'}_{\zeta'^*g'^*f^*_1g_*\zeta_*X}} & & & & \downarrow{\scriptstyle \omega^{\zeta'}_{\zeta'^*f^*_2\zeta_*X}} \\
\zeta'^*g'^*f^*_1g_*\zeta_*X & = & \zeta'^*f^*_2g^*g_*\zeta_*X & \xrightarrow{(\zeta'^*f^*_2*\varepsilon^g*\zeta_*)_X} & \zeta'^*f^*_2\zeta_*X \\
\downarrow{\scriptstyle (g(\beta)^\dagger*g(\zeta)_*)_X} & & & & \downarrow{\scriptstyle (\beta^\dagger*\zeta_*)_X} \\
g(\zeta)^*g(\zeta)_*X & & \xrightarrow{(\zeta^**\varepsilon^g*\zeta_*)_X} & & \zeta^*\zeta_*X.
\end{array}$$

However, the commutativity of the bottom square follows from (1.1.11) and remark 1.1.17(vi), and that of the central square is clear, by the naturality of $\omega^{\zeta'}$. In order to show the commutativity of the top square, set $A := \zeta_*X$, and recall that

$$\Upsilon(\mathscr{D}_{g,g'}) = (g'_*f^*_2 * \varepsilon^g) \odot (\eta^{g'} * f^*_1 g_*) \qquad \text{and} \qquad \eta^{g'(\zeta')} = (g'_* * \eta^{\zeta'} * g'^*) \odot \eta^{g'}$$

(proposition 2.3.10). We are then reduced to checking the commutativity of the diagram :

$$\begin{array}{ccccc}
 & & \Gamma(S'_1, g'_*g'^*f_1^*g_*A) & \xrightarrow{\Gamma(S'_1,(g'_*f_2^* * \varepsilon^g)_A)} & \Gamma(S'_1, g'_*f_2^*A) \\
 & \swarrow^{\Gamma(S'_1,(g'_* * \eta^{\zeta'} * g'^* f_1^*)_A)} & \downarrow{\scriptstyle \omega^{g'}_{g'^*f_1^*g_*A}} & & \downarrow{\scriptstyle \omega^{g'}_{f_2^*A}} \\
\Gamma(S'_1, g'(\zeta')_*g'(\zeta')^*f_1^*g_*A) & & \Gamma(S'_2, g'^*f_1^*g_*A) & \xrightarrow{\Gamma(S'_2,(f_2^* * \varepsilon^g *)_A)} & \Gamma(S'_2, f_2^*A) \\
 & \searrow_{\omega^{g'}_{\zeta'_*g'(\zeta')^*f_1^*g_*A}} & \downarrow{\scriptstyle \Gamma(S'_2,(\eta^{\zeta'} * g'^*f_1^*g_*)_A)} & & \downarrow{\scriptstyle \Gamma(S'_2,(\eta^{\zeta'} * f_2^*)_A)} \\
 & & \Gamma(S'_2, \zeta'_*g'(\zeta')^*f_1^*g_*A) & \xrightarrow{\Gamma(S'_2,(\zeta'_*f_2^* * \varepsilon^g)_A)} & \Gamma(S'_2, \zeta'_*\zeta'^*f_2^*A).
\end{array}$$

However, it is easily seen that the two square subdiagrams and the triangular subdiagram commute (details left to the reader), whence the contention. ◊

From claim 4.7.24(ii) and remark 3.1.23(ii) we get the natural transformation

$$\mathscr{F}ib(b_\bullet) : \mathscr{F}ib(\Sigma^X_\bullet) \circ p \Rightarrow \Xi^X \circ \mathsf{s}' \circ p.$$

Lastly, let $q : \mathscr{L}(\xi) \to \mathscr{F}ib(\mathrm{Pt}^\times)$ be the natural projection, $\mathsf{s}_{\mathscr{L}(\xi)} : \mathsf{Morph}(\mathscr{L}(\xi)) \to \mathscr{L}(\xi)$ the source functor, and set $\mathsf{G} := \mathscr{F}ib(\Sigma^X_\bullet) \circ p \circ \mathsf{Morph}(q)$; we deduce the natural transformation

$$\beta : \mathscr{F}ib(b_\bullet) * \mathsf{Morph}(q) : \mathsf{G} \Rightarrow \Xi^{X,\xi} \circ \mathsf{s}_{\mathscr{L}(\xi)}.$$

By theorem 1.3.4, the latter induces a natural transformation

$$\int^{\mathsf{s}_{\mathscr{L}(\xi)}} \mathsf{G} \Rightarrow \Xi^{X,\xi}. \tag{4.7.25}$$

Notice that, under the natural identification $\mathsf{Morph}(\mathscr{L}(\xi)) \xrightarrow{\sim} \mathsf{Morph}(\mathbf{Lift}(\xi))^o$, the functor $\mathsf{s}_{\mathscr{L}(\xi)}$ correspond to the functor $\mathsf{t}^o_{\mathbf{Lift}(\xi)}$, where $\mathsf{t}_{\mathbf{Lift}(\xi)} : \mathsf{Morph}(\mathbf{Lift}(\xi)) \to \mathbf{Lift}(\xi)$ is the target functor. Moreover, $\mathsf{t}_{\mathbf{Lift}(\xi)}$ is a fibration, by virtue of remark 4.7.13(ii) and example 3.1.3(iii). Furthermore, for every $(U, \xi_U, \omega_U) \in \mathrm{Ob}(\mathbf{Lift}(\xi))$, the fibre category $\mathsf{t}^{-1}(U, \xi_U, \omega_U)$ is

$$\mathbf{Lift}(\xi)/(U, \xi_U, \omega_U) \xrightarrow{\sim} \mathbf{Lift}(\xi_U).$$

Hence, the restriction of β to the fibre category $\mathsf{t}^{-1}(U, \xi_U, \omega_U)$ is a cocone

$$\mathbf{Lift}(\xi_U)^o \underset{c_{\xi_U^*\xi_{U*}X}}{\overset{\mathsf{G}}{\underset{\Downarrow}{\rightrightarrows}}} \mathbf{Set}. \tag{4.7.26}$$

By a direct inspection of the construction, we see that (4.7.26) is the cocone $\tau_{\xi,\xi_{U*}X} * N^o_{\xi_U}$, where $N_{\xi_U} : \mathbf{Lift}(\xi_U) \xrightarrow{\sim} \mathbf{Nbd}(\xi_U)$ is the equivalence (4.7.18), and $\tau_{\xi,\xi_{U*}X}$ is the universal cocone of remark 4.7.13(iv). Hence, (4.7.26) is a universal cocone, for every $(U, \xi_U, \omega_U) \in \mathrm{Ob}(\mathbf{Lift}(\xi))$; taking into account example 3.1.14(iv), we deduce that (4.7.25) is an isomorphism of functors, and we get a natural isomorphism :

$$\operatorname*{colim}_{\mathsf{Morph}(\mathbf{Lift}(\xi))^o} \mathsf{G} \xrightarrow{\sim} \operatorname*{colim}_{\mathbf{Lift}(\xi)^o} \Xi^{X,\xi}.$$

Now, notice that the functor

$$\mathbf{Lift}(\xi)^o \to \mathsf{Morph}(\mathbf{Lift}(\xi))^o \qquad (U, \xi_U, \omega_U) \mapsto \mathbf{1}_{(U,\xi_U,\omega_U)} \tag{4.7.27}$$

is cofinal. A simple inspection reveals that the composition of G with (4.7.27) is the constant functor with value X, whence the contention. □

4.7.28. Suppose now that $T = C^\sim$ for some small site $C := (\mathscr{C}, J)$. For a point ξ of T, we may define another category $\mathbf{Nbd}(\xi, C)$, whose objects are the pairs (U, a) where $U \in \mathrm{Ob}(\mathscr{C})$ and $a \in (h^a_U)_\xi$; the morphisms $(U, a) \to (U', a')$ are the morphisms $f : U \to U'$ in $\mathscr{C}$ such that $(h^a_f)_\xi(a) = a'$. (Notation of remark 4.1.19(iii).) The rule $(U, a) \mapsto (h^a_U, a)$ defines a functor

$$\mathbf{Nbd}(\xi, C) \to \mathbf{Nbd}(\xi). \tag{4.7.29}$$

Proposition 4.7.30. *In the situation of* (4.7.28)*, we have :*

(i) *The category* $\mathbf{Nbd}(\xi, C)$ *is cofiltered.*
(ii) *The functor* (4.7.29) *is cofinal.*

Proof. To begin with, since ξ^* commutes with all colimits, remark 4.1.19(iii) implies easily that, for every object (U, a) of $\mathbf{Nbd}(\xi)$ there exist an object (V, b) of $\mathbf{Nbd}(\xi, C)$ and a morphism $(h^a_V, b) \to (U, a)$ in $\mathbf{Nbd}(\xi)$. Hence, it suffices to show (i).

Thus, let (U_1, a_1) and (U_2, a_2) be two objects of $\mathbf{Nbd}(\xi, C)$; since $\mathbf{Nbd}(\xi)$ is cofiltered, we may find an object (F, b) of $\mathbf{Nbd}(\xi)$ and morphisms $\varphi_i : (F, b) \to (h^a_{U_i}, a_i)$ (for $i = 1, 2$). By the foregoing, we may also assume that $(F, b) = (h^a_V, b)$ for some object (V, b) of $\mathbf{Nbd}(\xi, C)$, in which case $\varphi_i \in h^a_{U_i}(V)$ for $i = 1, 2$. By remark 4.1.19(iv), we may find a sieve $\mathscr{S}$ covering V such that $\varphi_i \in \mathrm{Hom}_{\mathscr{C}^\wedge}(h_\mathscr{S}, h^{\mathrm{sep}}_{U_i})$ for both $i = 1, 2$.

On the other hand, (3.5.3) and proposition 4.1.26 yield a natural isomorphism :

$$\operatorname*{colim}_{\mathscr{S}} h^a \circ \mathsf{s} \xrightarrow{\sim} h^a_V.$$

Therefore, since ξ^* commutes with all colimits, we may find $(f : S \to V) \in \mathrm{Ob}(\mathscr{S})$ and $c \in (h^a_S)_\xi$ such that $h^a_f : (h^a_S, c) \to (h^a_V, b)$ is a morphism of neighborhoods of ξ.

For $i = 1, 2$, denote by $\overline{\varphi}_{S,i} \in h^{\mathrm{sep}}_U(S)$ the image of φ_i (under the map induced by the natural morphism $h_S \to h_\mathscr{S}$ coming from (3.5.3)). Pick any $\varphi_{S,i} \in \mathrm{Hom}_\mathscr{C}(S, V)$ in the preimage of $\overline{\varphi}_{S,i}$; then $\varphi_{S,i}$ defines a morphism $(S, c) \to (U_i, a_i)$ in $\mathbf{Nbd}(\xi, C)$.

Next, suppose that $\varphi_1, \varphi_2 : (U, a) \to (U', a')$ are two morphisms in $\mathbf{Nbd}(\xi, C)$; arguing as in the foregoing, we may find an object (V, b) of $\mathbf{Nbd}(\xi, C)$, and $\psi \in h^{\mathrm{sep}}_U(V) = \mathrm{Hom}_{\mathscr{C}^\wedge}(h^{\mathrm{sep}}_V, h^{\mathrm{sep}}_U)$ whose image in $h^a_U(V)$ yields a morphism $\psi^a : (h^a_V, b) \to (h^a_U, a)$ in $\mathbf{Nbd}(\xi)$, and such that $\varphi^{\mathrm{sep}}_1 \circ \psi = \varphi^{\mathrm{sep}}_2 \circ \psi$ in $h^{\mathrm{sep}}_{U'}(V)$. We may then find a covering subobject $i : R \to h_V$, such that $\varphi_1 \circ (\psi \circ i) = \varphi_2 \circ (\psi \circ i)$ in $\mathrm{Hom}_{\mathscr{C}^\wedge}(R, h'_U)$. Again, by combining (3.5.3) and proposition 4.1.26, we deduce that there exists a morphism $\beta : (V', b') \to (V, b)$ in $\mathbf{Nbd}(\xi, C)$, such that $\varphi_1 \circ (\psi \circ \beta) = \varphi_2 \circ (\psi \circ \beta)$. This completes the proof of (i). □

As a corollary of proposition 4.7.30 and of remark (4.7.13)(iv), we deduce, for every sheaf F on C, a natural isomorphism :

$$\operatorname*{colim}_{\mathbf{Nbd}(\xi,C)^o} F \circ \iota^o_C \xrightarrow{\sim} F_\xi$$

where $\iota_C : \mathbf{Nbd}(\xi, C) \to \mathscr{C}$ is the functor such that $(U, a) \mapsto U$ for every object (U, a).

4.8. **Algebra on a topos.** Let T be any topos, and endow T with the structure of tensor category as explained in example 3.7.10 (so, the tensor functor is given by fixed choices of products for every pairs of objects of T, and any final object 1_T can be taken for unit object of $(T, \otimes)$). We notice that $(T, \otimes)$ admits an internal Hom functor (see remark 3.7.12(ii)). Indeed, let X and X' be any two objects of T. It is easily seen that the presheaf on T :

$$U \mapsto \mathrm{Hom}_{T/U}(X'_{|U}, X_{|U}) = \mathrm{Hom}_T(X' \times U, X)$$

is actually a sheaf on (T, C_T) (notation of example 4.7.8(i)), so it is an object of T, denoted :

$$\mathscr{H}\!om_T(X', X).$$

The functor :

$$T \to T \quad : \quad X \mapsto \mathscr{H}\!om_T(X', X)$$

is right adjoint to the functor $T \to T : Y \mapsto Y \times X'$, so it is an internal Hom functor for X'.

If $f : T \to S$ is a morphism of topoi, and $Y \in \mathrm{Ob}(S)$, we have a natural isomorphism in S :

$$\mathscr{H}om_S(Y, f_*X) \xrightarrow{\sim} f_*\mathscr{H}om_T(f^*Y, X) \tag{4.8.1}$$

which, on every $U \in \mathrm{Ob}(S)$, induces the natural bijection :

$$\mathrm{Hom}_S(Y \times U, f_*X) \xrightarrow{\sim} \mathrm{Hom}_T(f^*Y \times f^*U, X)$$

given by the adjunction (f^*, f_*). By general nonsense, from (4.8.1) we derive a natural morphism in S :

$$f_*\mathscr{H}om_T(X', X) \to \mathscr{H}om_S(f_*X', f_*X)$$

and in T :

$$f^*\mathscr{H}om_S(Y', Y) \xrightarrow{\vartheta_f} \mathscr{H}om_T(f^*Y', f^*Y) \qquad \text{for any } Y, Y' \in \mathrm{Ob}(S).$$

Moreover, if $g : U \to T$ is another morphism of topoi, the diagram :

$$\begin{array}{ccc} g^*f^*\mathscr{H}om_S(Y', Y) & \xrightarrow{g^*\vartheta_f} & g^*\mathscr{H}om_T(f^*Y', f^*Y) \\ & {\scriptstyle\vartheta_{f\circ g}}\searrow \quad \swarrow{\scriptstyle\vartheta_g} & \\ & \mathscr{H}om_U(g^*f^*Y', g^*f^*Y) & \end{array} \tag{4.8.2}$$

commutes, up to a natural isomorphism.

4.8.3. Let A be any object of T, and (X, μ_X) a left A-module for the tensor category structure on T as in (4.8); for every object U of T we obtain a left $A_{|U}$-module (on the topos T/U : see example 4.7.8(i)), by the rule :

$$(X, \mu_X)_{|U} := (X_{|U}, \mu_X \times \mathbf{1}_U).$$

If $(X', \mu_{X'})$ is another left A-module, it is easily seen that the presheaf on T :

$$U \mapsto \mathrm{Hom}_{A_{|U}\text{-}\mathbf{Mod}_l}((X, \mu_X)_{|U}, (X', \mu_{X'})_{|U})$$

is actually a sheaf for the canonical topology, so it is an object of T, denoted :

$$\mathscr{H}om_{A_l}((X, \mu_X), (X', \mu_{X'}))$$

(or just $\mathscr{H}om_{A_l}(X, X')$, if the notation is not ambiguous). The same considerations can be repeated for the sets of morphisms of right B-modules, and of (A, B)-bimodules, so one gets objects $\mathscr{H}om_{B_r}(X, X')$ and $\mathscr{H}om_{(A,B)}(X, X')$. By a simple inspection, we see that these objects are naturally isomorphic to the objects denoted in the same way in (3.7.14), so the notation is not in conflict with *loc.cit.*; it also follows that $\mathscr{H}om_{A_l}(X, X')$ is the equalizer of two morphisms in T :

$$\mathscr{H}om_T(X, X') \rightrightarrows \mathscr{H}om_T(A \times X, X') .$$

In the same vein, let $A, B, C \in \mathrm{Ob}(T)$ be any three objects, S an (A, B)-bimodule, S' a (C, B)-bimodule, and S'' a (C, A)-bimodule. Then the (C, B)-bimodule $\mathscr{H}om_{B_r}(S, S')$ and the (C, B)-bimodule $S'' \otimes_A S$ (see (3.7.17)) are the sheaves on (T, C_T) associated with the presheaves given by the rules : $U \mapsto \mathrm{Hom}_{B_{|U,r}}(S_{|U}, S'_{|U})$, and respectively : $U \mapsto S'(U) \otimes_{M(U)} S(U)$ for every object U of T. Furthermore, the general theory of monoids, their modules and their tensor products, developed in section 3.7 is available in the present situation, so we have a well defined notion of T-monoid (see example 3.7.21(ii) and remark 3.7.24). Via the equivalence of theorem (4.4.2), a T-monoid $\underline{M}$ is also the same as a sheaf of monoids M on the site (T, C_T), and a left (resp. right, resp. bi-) $\underline{M}$-module is the same as the datum of a sheaf S in (T, C_T), such that $S(U)$ is a left (resp. right, resp. bi-) $M(U)$-module, for every object U of T.

4.8.4. Let $f : T_1 \to T_2$ be a morphism of topoi, A_1 an object of T_1, and (X, μ_X) a left A_1-module. Since f_* is left exact, we have a natural isomorphism : $f_*(A_1 \times X) \stackrel{\sim}{\to} f_*A_1 \times f_*X$, so we obtain a left f_*A_1-module :

$$f_*(X, \mu_X) := (f_*X, f_*\mu_X)$$

which we denote just f_*X, unless the notation is ambiguous. Likewise, since f^* is left exact, from any object A_2 of T_2, and any left A_2-module (Y, μ_Y), we obtain a left f^*A_2-module :

$$f^*(Y, \mu_Y) := (f^*Y, f^*\mu_Y).$$

The same considerations apply of course, also to right modules and to bimodules. Furthermore, let A_i, B_i, C_i be three objects of T_i (for $i = 1, 2$); since f_* is left exact, for any (A_1, B_1)-bimodule X and any (C_1, A_1)-bimodule X' we have a natural morphism of (f_*C_1, f_*B_1)-bimodules :

$$f_*X' \otimes_{f_*A_1} f_*X \to f_*(X' \otimes_{A_1} X)$$

and since f^* is exact, for any (A_2, B_2)-bimodule Y and any (C_2, A_2)-bimodule Y' we have a natural isomorphism :

$$f^*Y' \otimes_{f^*A_2} f^*Y \stackrel{\sim}{\to} f^*(Y' \otimes_{A_2} Y)$$

of (f^*C_2, f^*B_2)-bimodules.

4.8.5. The constructions of the previous paragraphs also apply to presheaves on T : this can be seen, *e.g.* as follows. Pick a universe V such that T is V-small; then $T^\wedge_\mathsf{V}$ is a V-topos. Hence, if A is any V-presheaf on T, and $X, X' \in \mathrm{Ob}(T^\wedge_\mathsf{V})$ two left A-modules, we may construct $\mathscr{H}om_{A_l}(X, X')$ as an object in $T^\wedge_\mathsf{V}$. Now, if A, X, X' lie in the full subcategory $T^\wedge_\mathsf{U}$ of $T^\wedge_\mathsf{V}$, it is easily seen that also $\mathscr{H}om_{A_l}(X, X')$ lies in $T^\wedge_\mathsf{U}$. Likewise, if A, B, C are two U-presheaves on T, we may define $X' \otimes_A X$ in $T^\wedge_\mathsf{U}$, for any (A, B)-bimodule X and (C, A)-bimodule X', and this tensor product will still be left adjoint to the $\mathscr{H}om$-functor for presheaves on T.

Moreover, we have a natural morphism of topoi $i_\mathsf{V} : (T, C_T)^\sim_\mathsf{V} \to T^\wedge_\mathsf{V}$, given by the forgetful functor and its left adjoint i^*_V, which is given by the rule : $F \mapsto F^a$: see example 4.4.10(i). The restriction of i^*_V to the full subcategory $T^\wedge_\mathsf{U}$ is isomorphic to a functor that factors through the Yoneda embedding $T \to (T, C_T)^\sim_\mathsf{V}$, therefore the discussion of (4.8.4) specializes to show that, for every U-presheaf A on T, and every A-module $X \in \mathrm{Ob}(T^\wedge_\mathsf{U})$, the object $X^a \in \mathrm{Ob}(T)$ is naturally an A^a-module. Also, for any (A, B)-bimodule X and (C, A)-bimodule X', such that A, B, C, X, X' are U-small, we have a natural isomorphism of (C^a, B^a)-bimodules :

$$X'^a \otimes_{A^a} X^a \stackrel{\sim}{\to} (X' \otimes_A X)^a.$$

The following definition gathers some further notions – specific to monoids over a topos – which shall be used in this work.

Definition 4.8.6. Let T be a topos, $\underline{M}$ a T-monoid, S a left (resp. right, resp. bi-) $\underline{M}$-module.

(i) S is said to be *of finite type*, if there exist a covering family $(U_\lambda \to 1_T \mid \lambda \in \Lambda)$ of the final object of T, and for every $\lambda \in \Lambda$ an integer $n_\lambda \in \mathbb{N}$ and an epimorphism of left (resp. right, resp. bi-) $\underline{M}_{|U_\lambda}$-modules : $\underline{M}^{\oplus n_\lambda}_{|U_\lambda} \to S_{|U_\lambda}$.

(ii) S is *finitely presented*, if there exist a covering family $(U_\lambda \to 1_T \mid \lambda \in \Lambda)$ of the final object of T, and for every $\lambda \in \Lambda$ integers $m_\lambda, n_\lambda \in \mathbb{N}$ and morphisms f_λ, g_λ : $\underline{M}^{\oplus m_\lambda}_{|U_\lambda} \to \underline{M}^{\oplus n_\lambda}_{|U_\lambda}$ whose coequalizer – in the category of left (resp. right, resp. bi-) $\underline{M}_{|U_\lambda}$-modules – is isomorphic to $S_{|U_\lambda}$.

(iii) S is said to be *coherent*, if it is of finite type, and for every object U in T, every submodule of finite type of $S_{|U}$ is finitely presented.

(iv) S is said to be *invertible*, if there exist a covering family $(U_\lambda \to 1_T \mid \lambda \in \Lambda)$, and for every $\lambda \in \Lambda$, an isomorphism $\underline{M}_{|U_\lambda} \stackrel{\sim}{\to} S_{|U_\lambda}$ of left (resp. right, resp. bi-) $\underline{M}_{|U}$-modules. (Thus, every invertible module is finitely presented.)

(v) An ideal $I \subset \underline{M}$ is said to be *invertible*, (resp. *of finite type*, resp. *finitely presented*, resp. *coherent*) if it is such, when regarded as an $\underline{M}$-bimodule.

Example 4.8.7. (i) Take again $T = \mathbf{Set}$. Then an M-module S is of finite type if and only if there exists a finite subset $\Sigma \subset S$, such that $S = M \cdot \Sigma$, with obvious notation. In this case, we say that Σ is a *finite system of generators* of S (and we also say that S is *finitely generated*; likewise, an ideal of finite type is also called finitely generated). We say that S is *cyclic*, if $S = M \cdot s$ for some $s \in S$.

(ii) If S and S' are two M-modules, the coproduct $S \oplus S'$ is the disjoint union of S and S', with scalar multiplication given by the disjoint union of the laws μ_S and $\mu_{S'}$. The product $S \times S'$ is the cartesian product of the underlying sets, with scalar multiplication given by the rule : $x \cdot (s, s') := (x \cdot s, x \cdot s')$ for every $x \in M$, $s, \in S$, $s' \in S'$.

For future use, let us also make the :

Definition 4.8.8. Let T be any topos, $\underline{P}$ a T-monoid, and $(N, +, 0)$ any monoid.

(i) We say that $\underline{P}$ is N-*graded*, if it admits a morphism of monoids $\pi : \underline{P} \to N_T$, where N_T is the constant sheaf of monoids arising from N (the coproduct of copies of the final object 1_T indexed by N). For every $n \in N$ we let $\underline{P}_n := \pi^{-1}(n_T)$, the preimage of the global section corresponding to n. Then

$$\underline{P} = \coprod_{n \in N} \underline{P}_n$$

the coproduct of the objects $\underline{P}_n$, and the multiplication law of $\underline{P}$ restricts to a map $\underline{P}_n \times \underline{P}_m \to \underline{P}_{n+m}$, for every $n, m \in N$. Especially, each $\underline{P}_n$ is a $\underline{P}_0$-module, and $\underline{P}$ is also the direct sum of the $\underline{P}_n$, in the category of $\underline{P}_0$-modules. The morphism π is called the *grading* of $\underline{P}$.

(ii) In the situation of (i), let S be a left (resp. right, resp. bi-) $\underline{P}$-module. We say that S is N-*graded*, if it admits a morphism of $\underline{P}$-modules $\pi_S : S \to N_T$, where N_T is regarded as a $\underline{P}$-bimodule via the grading π of $\underline{P}$. Then S is the coproduct $S = \coprod_{n \in N} S_n$, where $S_n := \pi_S^{-1}(n_T)$, and the scalar multiplication of S restricts to morphisms $\underline{P}_n \times S_m \to S_{n+m}$, for every $n, m \in N$. The morphism π_S is called the *grading* of S.

(iii) A morphism $\underline{P} \to \underline{Q}$ of N-graded T-monoids is a morphism of monoids that respects the gradings, with obvious meaning. Likewise one defines morphisms of N-graded $\underline{P}$-modules.

Example 4.8.9. Take $T = \mathbf{Set}$, and let M be any commutative monoid. Then we claim that the only invertible object in the tensor category M-$\mathbf{Mod}_l$ is M; *i.e.* if S and S' are any two (M, M)-bimodules, then $S \otimes_M S' \simeq M$ if and only if S and S' are both isomorphic to M.

Indeed, let $\varphi : S \otimes_M S' \xrightarrow{\sim} M$ be an isomorphism, and choose $s_0 \in S$, $s'_0 \in S'$ such that $\varphi(s_0 \otimes s'_0) = 1$. Consider the morphisms of left M-modules :

$$M \xrightarrow{\alpha} S \xrightarrow{\beta} M \qquad M \xrightarrow{\alpha'} S' \xrightarrow{\beta'} M$$

such that :

$$\alpha(m) = m \cdot s_0 \quad \beta(s) = \varphi(s \otimes s'_0) \quad \alpha'(m) = m \cdot s'_0 \quad \beta'(s') = \varphi(s_0 \otimes s')$$

for every $m \in M$, $s \in S$, $s' \in S'$; we notice that $\beta \circ \alpha = \mathbf{1}_M = \beta' \circ \alpha'$. There follows natural morphisms :

$$S' \xrightarrow{\gamma} M \otimes_M S' \xrightarrow{\alpha \otimes_M S'} S \otimes_M S' \xrightarrow{\beta \otimes_M S'} M \otimes_M S' \xrightarrow{\gamma^{-1}} S'$$

whose composition is the identity $\mathbf{1}_{S'}$. However, it is easily seen that $\varphi \circ (\alpha \otimes_M S') \circ \gamma = \beta'$ and $\gamma^{-1} \circ (\beta \otimes_M S') \circ \varphi^{-1} = \alpha'$, thus $\alpha' \circ \beta' = \mathbf{1}_{S'}$, hence both α' and β' are isomorphisms, and the same holds for α and β.

Example 4.8.10. Let $\underline{M}$ be a T-monoid, and $\mathscr{L}$ a $\underline{M}$-bimodule. For every $n \in \mathbb{N}$, let $\mathscr{L}^{\otimes n} := \mathscr{L} \otimes_{\underline{M}} \cdots \otimes_{\underline{M}} \mathscr{L}$, the n-fold tensor power of $\mathscr{L}$. The $\mathbb{N}$-graded $\underline{M}$-bimodule

$$\mathrm{Tens}^{\bullet}_{\underline{M}}\mathscr{L} := \coprod_{n \in \mathbb{N}} \mathscr{L}^{\otimes n}$$

is naturally a $\mathbb{N}$-graded T-monoid, with composition law induced by the natural morphisms $\mathscr{L}^{\otimes n} \otimes_{\underline{M}} \mathscr{L}^{\otimes m} \xrightarrow{\sim} \mathscr{L}^{\otimes n+m}$, for every $n, m \in \mathbb{N}$. (Here we set $\mathscr{L}^{\otimes 0} := \underline{M}$.) If $\mathscr{L}$ is invertible, $\mathrm{Tens}^{\bullet}_{\underline{M}}\mathscr{L}$ is a commutative $\mathbb{N}$-graded T-monoid, which we also denote $\mathrm{Sym}^{\bullet}_{\underline{M}}\mathscr{L}$.

Remark 4.8.11. (i) Let $f : T \to S$ be a morphism of topoi, $\underline{M} := (M, \mu_M)$ a T-semigroup, and $\underline{N} := (N, \mu_N)$ a S-semigroup. Then clearly $f_*\underline{M} := (f_*M, f_*\mu_M)$ is a S-semigroup, and $f^*\underline{N} := (f^*N, f^*\mu_N)$ is a T-semigroup.

(ii) Furthermore, if $1_M : 1_T \to M$ (resp. $1_N : 1_S \to N$) is a unit for M (resp. for N), then notice that $f_*1_T = 1_S$ (resp. $f^*1_S = 1_T$), since the final object is the empty product; it follows that f_*1_M (resp. f^*1_S) is a unit for $f_*\underline{M}$ (resp. for $f^*\underline{N}$).

(iii) Obviously, if $\underline{M}$ (resp. $\underline{N}$) is commutative, the same holds for $f_*\underline{M}$ (resp. $f^*\underline{N}$).

(iv) If X is a left $\underline{M}$-module, then f_*X is a left $f_*\underline{M}$-module, and if Y is a left $\underline{N}$-module, then f^*Y is a left $f^*\underline{N}$-module. The same holds for right modules and bimodules.

(v) Moreover, let $\varepsilon_M : f^*f_*\underline{M} \to \underline{M}$ (resp. $\eta_N : \underline{N} \to f_*f^*\underline{N}$) be the counit (resp. unit) of adjunction. Then the counit (resp. unit) :

$$\varepsilon_X : f^*f_*X \to X_{(\varepsilon_M)} \qquad (\text{resp. } \eta_Y : Y \to f_*f^*Y_{(\eta_N)})$$

is a morphism of $f^*f_*\underline{M}$-modules (resp. of $\underline{N}$-modules) (notation of (3.7.26)). (Details left to the reader.)

(vi) Let $\varphi : f^*\underline{N} \to \underline{M}$ be a morphism of T-monoids. Then the functor

$$\underline{N}\text{-}\mathbf{Mod}_l \to \underline{M}\text{-}\mathbf{Mod}_l \quad : \quad Y \mapsto M \otimes_{f^*N} f^*Y$$

is left adjoint to the functor :

$$\underline{M}\text{-}\mathbf{Mod}_l \to \underline{N}\text{-}\mathbf{Mod}_l \quad : \quad X \mapsto f_*X_{(\eta_N)}.$$

(And likewise for right modules and bimodules : details left to the reader.)

(vii) The considerations of (4.8.5) also apply to monoids : we get that, for any presheaf of monoids $\underline{M} := (M, \mu_M, 1_M)$ on T, the datum $\underline{M}^a := (M^a, \mu^a_M, 1^a_M)$ is a T-monoid, and we have a well defined functor :

$$\underline{M}\text{-}\mathbf{Mod}_l \to \underline{M}^a\text{-}\mathbf{Mod}_l \qquad X \mapsto X^a.$$

(And as usual, the same applies to right modules and bimodules.)

4.8.12. Let T be a topos, U any object of T, and $\underline{M}$ a T-monoid. As a special case of remark 4.8.11(i), we have the T/U-monoid $j^*_U\underline{M} = \underline{M}_{|U}$, and if we take $\varphi := \mathbf{1}_{j^*_U\underline{M}}$ in remark 4.8.11(vi), we deduce that the functor

$$j^*_U : \underline{M}\text{-}\mathbf{Mod}_l \to \underline{M}_{|U}\text{-}\mathbf{Mod}_l \qquad Y \mapsto Y_{|U}$$

admits the right adjoint j_{U*}. Now, suppose that $X \to U$ is any left $\underline{M}_{|U}$-module. The scalar multiplication of X is a U-morphism $\mu_X : M \times X \to X$ and $j_{U!}\mu_X$ is the same morphism, seen as a morphism in T (notation of example 4.7.8(i)). In other words, $j_{U!}$ induces a faithful functor on left modules, also denoted :

$$j_{U!} : \underline{M}_{|U}\text{-}\mathbf{Mod}_l \to \underline{M}\text{-}\mathbf{Mod}_l.$$

It is easily seen that this functor is left adjoint to the foregoing functor j^*_U. Especially, this functor is right exact; it is not generally left exact, since it does not preserve the final object (unless $U = 1_T$). However, it does commute with fibre products, and therefore transforms monomorphisms into monomorphisms. All this holds also for right modules and bimodules.

4.8.13. Let T be any category as in example 3.7.21(i), denote by 1_T a final object of T, and by $\underline{M}$ any T-monoid. A *pointed left* $\underline{M}$*-module* is a datum

$$(S, 0_S)$$

consisting of a left $\underline{M}$-module S and a morphism of $\underline{M}$-modules $0_S : 1_T \to S$, where 0 is the final object of M-$\mathbf{Mod}_l$. Often we shall write S instead of $(S, 0_S)$, unless this may give rise to ambiguities. As usual, a morphism $\varphi : S \to T$ of pointed modules is a morphism of M-modules, such that $0_T = \varphi \circ 0_S$. In other words, the resulting category is just $0/M$-$\mathbf{Mod}_l$, and shall be denoted $\underline{M}$-$\mathbf{Mod}_{l\circ}$.

Likewise one may define the category $\underline{M}$-$\mathbf{Mod}_{r\circ}$ of right $\underline{M}$-modules, and $(\underline{M}, \underline{N})$-$\mathbf{Mod}_\circ$ of pointed bimodules, for given T-monoids $\underline{M}$ and $\underline{N}$.

Remark 4.8.14. Let T be a category as in remark 3.7.24.

(i) For reasons that will become readily apparent, for many purposes the categories of pointed modules are more useful than the non-pointed variant of (3.7.22). In any case, we have a faithful functor :

$$\underline{M}\text{-}\mathbf{Mod}_l \to \underline{M}\text{-}\mathbf{Mod}_{l\circ} \qquad S \mapsto S_\circ := (S \oplus 0, 0_S) \tag{4.8.15}$$

where $0_S : 0 \to S \oplus 0$ is the obvious inclusion map. Thus, we may – and often will, without further comment – regard any $\underline{M}$-module as a pointed module, in a natural way. (The same can of course be repeated for right modules and bimodules.)

(ii) In turn, when dealing with pointed M-modules, things often work out nicer if $\underline{M}$ itself is a *pointed* T*-monoid*. The latter is the datum $(\underline{M}, 0_M)$ of a T-monoid $\underline{M}$ and a morphism of $\underline{M}$-modules $0_M : 0 \to M$. A morphism of pointed T-monoids is of course just a morphism $f : \underline{M} \to \underline{M}'$ of T-monoids, such that $f \circ 0_M = 0_{M'}$. As customary, we shall often just write $\underline{M}$ instead of $(\underline{M}, 0_M)$, unless we wish to stress that $\underline{M}$ is pointed.

(iii) Let $(\underline{M}, 0_M)$ be a pointed T-monoid; a *pointed left* $(\underline{M}, 0_M)$*-module* is a pointed left $\underline{M}$-module S, such that $0 \cdot s = 0$ for every $s \in S$. A morphism of pointed left $(\underline{M}, 0_M)$-modules is just a morphism of pointed left $\underline{M}$-modules. As usual, these gadgets form a category $(\underline{M}, 0_M)$-$\mathbf{Mod}_{l\circ}$. Similarly we have the right and bi-module variant of this definition.

(iv) The forgetful functor from the category of pointed T-monoids to the category of T-monoids, admits a left adjoint :

$$\underline{M} \mapsto (\underline{M}_\circ, 0_{M_\circ}).$$

Namely, $M_\circ$ is the $\underline{M}$-module $M \oplus 0$, the zero map $0_{M_\circ} : 0 \to M \oplus 0$ is the obvious inclusion, and the scalar multiplication $M \times M_\circ \to M_\circ$ is extended to a multiplication law $\mu : M_\circ \times M_\circ \to M_\circ$ in the unique way for which $(\underline{M}_\circ, \mu, 0_{M_0})$ is a pointed monoid. The unit of adjunction $\underline{M} \to \underline{M}_\circ$ is the obvious inclusion map.

(v) If $\underline{M}$ is a (non-pointed) monoid, the restriction of scalars

$$(\underline{M}_\circ, 0_{M_\circ})\text{-}\mathbf{Mod}_{l\circ} \to \underline{M}\text{-}\mathbf{Mod}_{l\circ}$$

is an isomorphism of categories. Namely, any pointed left $\underline{M}$-module S is naturally a pointed left $\underline{M}_\circ$-module : the given scalar multiplication $M \times S \to S$ extends to a scalar multiplication $M_\circ \times S \to S$ whose restriction $0 \times S \to S$ factors through the zero section 0_S (and likewise for right modules and bimodules).

(vi) Let T be a topos. The notions introduced thus far for non-pointed T-monoids, also admit pointed variants. Thus, a pointed module $(S, 0_S)$ is said to be *of finite type* if the same holds for S, and S is *finitely presented* if, locally on T, it is the coequalizer of two morphisms between free $\underline{M}$-modules of finite type.

Example 4.8.16. Take $T := \mathbf{Set}$, and let M be any monoid; then a pointed left M-module is just a left M-module S endowed with a distinguished *zero element* $0 \in S$, such that $m \cdot 0 = 0$

for every $m \in M$. A morphism $\varphi : S \to S'$ of pointed left M-modules is just a morphism of left M-modules such that $\varphi(0) = 0$ (and similarly for right modules and bimodules.)

Likewise, a pointed monoid is endowed with a distinguished *zero element*, denoted 0 as usual, such that $0 \cdot x = 0$ for every $x \in M$.

Remark 4.8.17. Let T be a category as in remark 3.7.24, and $\underline{M}$ a T-monoid.

(i) Regardless of whether $\underline{M}$ is pointed or not, the category $\underline{M}\text{-}\mathbf{Mod}_{l\circ}$ is also complete and cocomplete; for instance, if $(S, 0_S)$ and $(S', 0_{S'})$ are two pointed modules, the coproduct $(S'', 0_{S''}) := (S, 0_S) \oplus (S', 0_{S'})$ is defined by the push-out (in the category $\underline{M}\text{-}\mathbf{Mod}_l$) of the cocartesian diagram :

$$\begin{array}{ccc} 0 \oplus 0 & \xrightarrow{0_S \oplus 0_{S'}} & S \oplus S' \\ \downarrow & & \downarrow \\ 0 & \xrightarrow{0_{S''}} & S''. \end{array}$$

Likewise, if $\varphi' : S' \to S$ and $\varphi'' : S'' \to S$ are two morphisms in $\underline{M}\text{-}\mathbf{Mod}_{l\circ}$, the fibre product $S' \times_S S''$ in the category $\underline{M}\text{-}\mathbf{Mod}_l$ is naturally pointed, and represents the fibre product in the category of pointed modules. All this holds also for right modules and bimodules.

(ii) The forgetful functor $\underline{M}\text{-}\mathbf{Mod}_{l\circ} \to T_\circ := 1_T/T$ to the category of pointed objects of T, commutes with all limits, since it is a right adjoint; it also commutes with all colimits. This forgetful functor admits a left adjoint, that assigns to any $\Sigma \in \mathrm{Ob}(T)$ the *free pointed* $\underline{M}$*-module* $\underline{M}^{(\Sigma)\circ}$. If $\underline{M}$ is pointed, the latter is defined as the push-out in the cocartesian diagram

$$\begin{array}{ccc} 1_T \times \Sigma & \longrightarrow & M \times \Sigma \\ \downarrow & & \downarrow \\ 1_T & \longrightarrow & \underline{M}^{(\Sigma)\circ} \end{array}$$

and if $\underline{M}$ is not pointed, one defines it via the equivalence of remark 4.8.14(v) : by a simple inspection we find that in this case $\underline{M}^{(\Sigma)\circ} = (\underline{M}^{(\Sigma)})_\circ$, where $\underline{M}^{(\Sigma)}$ is the free (unpointed) $\underline{M}$-module, as in remark 3.7.24(iii).

Notice as well that the forgetful functors $T_\circ \to T$ and $\underline{M}\text{-}\mathbf{Mod}_{l\circ} \to \underline{M}\text{-}\mathbf{Mod}_l$ both commute with all connected colimits, hence the same also holds for the forgetful functor $\underline{M}\text{-}\mathbf{Mod}_{l\circ} \to T$. (See definition 1.2.19(vii).) The same can be repeated for right modules and bimodules.

(iii) Moreover, if $\varphi : S \to S'$ is any morphism in $\underline{M}\text{-}\mathbf{Mod}_{l\circ}$, we may define $\mathrm{Ker}\,\varphi$ and $\mathrm{Coker}\,\varphi$ (in the category $\underline{M}\text{-}\mathbf{Mod}_{l\circ}$); namely, the kernel is the limit of the diagram $S \xrightarrow{\varphi} S' \leftarrow 0$ and the cokernel is the colimit of the diagram $0 \leftarrow S \xrightarrow{\varphi} S'$. Especially, if S is a submodule of S', we have a well defined quotient S'/S of pointed left $\underline{M}$-modules. Furthermore, we say that a sequence of morphisms of pointed left $\underline{M}$-modules :

$$0 \to S' \xrightarrow{\varphi} S \xrightarrow{\psi} S'' \to 0$$

is *right exact*, if ψ induces an isomorphism $\mathrm{Coker}\,\varphi \xrightarrow{\sim} S''$; we say that it is *left exact*, if φ induces an isomorphism $S' \xrightarrow{\sim} \mathrm{Ker}\,\psi$, and it is *short exact* if it is both left and right exact. (Again, all this can be repeated also for right modules and bimodules.)

Example 4.8.18. Take $T = \mathbf{Set}$, and let M be a pointed or not-pointed monoid. Then the argument from example 3.7.27 can be repeated for the free pointed M-modules : if Σ is any set, we have

$$M^{(\Sigma)\circ} \otimes_M \{1\} \xrightarrow{\sim} \{1\}^{(\Sigma)\circ} = \Sigma_\circ$$

where $\Sigma_\circ$ is the disjoint union of Σ and the final object of $\mathbf{Set}$ (a set with one element). Hence, the cardinality of Σ is an invariant, called the *rank* of the free pointed M-module $M^{(\Sigma)\circ}$, and denoted $\mathrm{rk}^\circ_M M^{(\Sigma)\circ}$.

4.8.19. Let T be a topos, $(\underline{M}, 0_M)$, $(\underline{N}, 0_N)$ and $(\underline{P}, 0_P)$ three pointed T-monoids, S, (resp. S') a pointed $(\underline{M}, \underline{N})$-bimodule (resp. $(\underline{P}, \underline{N})$-bimodule); we denote

$$\mathrm{Hom}_{(\underline{N}, 0_N)_r}(S, S')$$

the set of all morphisms of pointed right $\underline{N}$-modules $S \to S'$. As usual, the presheaf

$$\mathscr{H}om_{(\underline{N}, 0_N)_r}(S, S') \quad : \quad U \mapsto \mathrm{Hom}_{(\underline{N}, 0_N)_{r|U}}(S_{|U}, S'_{|U})$$

(with obvious notation) is a sheaf on (T, C_T), hence it is represented by an object of T. Indeed, this object is also the fibre product in the cartesian diagram :

$$\begin{array}{ccc} \mathscr{H}om_{(\underline{N}, 0_N)_r}(S, S') & \longrightarrow & \mathscr{H}om_{N_r}(S, S') \\ \downarrow & & \downarrow {\scriptstyle 0_S^*} \\ \mathscr{H}om_{N_r}(0, 0) & \xrightarrow{0_{S'*}} & \mathscr{H}om_{N_r}(0, S'). \end{array}$$

Especially, $\mathscr{H}om_{(\underline{N}, 0_N)_r}(S, S')$ is naturally a $(\underline{P}, \underline{M})$-bimodule, and moreover, it is pointed : its zero section represents the unique morphism $S \to S'$ which factors through 0.

Notice also that, for every pointed $(\underline{P}, \underline{M})$-bimodule S'', the tensor product $S'' \otimes_M S$ is naturally pointed, and as in the non-pointed case, the functor

$$(4.8.20) \qquad (\underline{P}, \underline{M})\text{-}\mathbf{Mod}_\circ \to (\underline{P}, \underline{N})\text{-}\mathbf{Mod}_\circ \quad : \quad S'' \mapsto S'' \otimes_M S$$

is left adjoint to the functor

$$(\underline{P}, \underline{N})\text{-}\mathbf{Mod}_\circ \to (\underline{P}, \underline{M})\text{-}\mathbf{Mod}_\circ \quad : \quad S' \mapsto \mathscr{H}om_{(\underline{N}, 0_N)_r}(S, S').$$

By general nonsense, the functor (4.8.20) is right exact; especially, for any right exact sequence $T' \to T \to T'' \to 0$ of pointed $(\underline{P}, \underline{M})$-bimodules, the induced sequence

$$T' \otimes_M S \to T \otimes_M S \to T'' \otimes_M S \to 0$$

is again right exact.

Remark 4.8.21. Suppose $\underline{M}$, $\underline{N}$ and $\underline{P}$ are non-pointed T-monoids, S is a $(\underline{M}, \underline{N})$-bimodule and S'' a $(\underline{P}, \underline{M})$-bimodule.

(i) If S and S'' are pointed, one may define a tensor product $S'' \otimes_M S$ in the category $(\underline{P}, \underline{N})$-$\mathbf{Mod}_\circ$, if one regards S as a pointed $(\underline{M}_\circ, \underline{N}_\circ)$-bimodule, and S'' as a $(\underline{P}_\circ, \underline{M}_\circ)$-bimodule as in remark 4.8.14(v); then one sets simply $S'' \otimes_M S := S'' \otimes_{M_\circ} S$, which is then viewed as a pointed $(\underline{P}, \underline{N})$-bimodule. In this way one obtains a left adjoint to the corresponding internal Hom-functor $\mathscr{H}om_N$ from pointed $(\underline{P}, \underline{N})$-bimodules to pointed $(\underline{P}, \underline{M})$-bimodules (details left to the reader).

(ii) Lastly, if neither S nor S'' is pointed, notice the natural isomorphism :

$$(S'' \otimes_M S)_\circ \xrightarrow{\sim} S''_\circ \otimes_{M_\circ} S_\circ \qquad \text{in the category } (\underline{P}, \underline{N})\text{-}\mathbf{Mod}_\circ.$$

Definition 4.8.22. In the situation of (4.8.19), let $P = N := (1_T)_\circ$, and notice that – with these choices of P and N – a pointed $(\underline{P}, \underline{M})$-bimodule (resp. a pointed $(\underline{M}, \underline{N})$-bimodule) is just a right pointed $\underline{M}$-module (resp. a left pointed $\underline{M}$-module), and a pointed $(\underline{P}, \underline{N})$-module is just a pointed object of T.

(i) We say that S is a *flat* pointed left $\underline{M}$-module (or briefly, that S is $\underline{M}$*-flat*), if the functor (4.8.20) transforms short exact sequences of right pointed $\underline{M}$-modules, into short exact sequences of pointed T-objects. Likewise, we define flat pointed right $\underline{M}$-modules.

(ii) Let $\varphi : \underline{M} \to \underline{M}'$ be a morphism of pointed T-monoids. We say that φ is *flat*, if $\underline{M}'$ is a flat left $\underline{M}$-module, for the module structure induced by φ.

Remark 4.8.23. (i) In the situation of remark 4.8.11(i), suppose that $\underline{M} := (M, 0_M)$ is a pointed T-monoid and $\underline{N} := (N, 0_N)$ a pointed S-monoid. By arguing as in remark 4.8.11(ii), we see that $f^*\underline{N} := (f^*N, f^*0_N)$ is a pointed T-monoid, and $f_*\underline{M} := (f_*M, f_*0_M)$ is a pointed S-monoid.

(ii) Likewise, if $(X, 0_X)$ is a pointed left $\underline{M}$-module, and $(Y, 0_Y)$ a pointed left $\underline{N}$-module, the $f_*(X, 0_X) := (f_*X, f_*0_X)$ is a pointed $f_*\underline{M}$-module, and $f^*(Y, 0_Y) := (f^*Y, f^*0_Y)$ is a pointed $f^*\underline{N}$-module (and likewise for right modules and bimodules).

(iii) Also, just as in remark 4.8.11(vii), the associated sheaf functor $F \mapsto F^a$ transforms a presheaf $\underline{M}$ of pointed monoids on T, into a pointed T-monoid $\underline{M}^a$, and sends pointed left (resp. right, resp. bi-) $\underline{M}$-modules to pointed left (resp. right, resp. bi-) $\underline{M}^a$-modules.

(iv) Moreover, if $\varphi : f^*\underline{N} \to \underline{M}$ is a morphism of pointed T-monoids, then – in view of the discussion of (4.8.19) – the adjunction of remark 4.8.11(vi) extends to pointed modules : we leave the details to the reader.

(v) Furthermore, in the situation of (4.8.12), we may also define a functor

$$j_{U!} : \underline{M}_{|U}\text{-}\mathbf{Mod}_{l\circ} \to \underline{M}\text{-}\mathbf{Mod}_{l\circ}$$

which will be a left adjoint to j_U^*. Indeed, let $(X, 0_X)$ be a left pointed $\underline{M}_{|U}$-module; the functor from (4.8.12) yields a morphism $j_{U!}0_X$ of (non-pointed) $\underline{M}$-modules, and we define $j_{U!}(X, 0_X)$ to be the push-out (in the category $\underline{M}\text{-}\mathbf{Mod}_l$) of the diagram $0 \leftarrow j_{U!}0_X \xrightarrow{j_{U!}0_X} j_{U!}X$. The latter is endowed with a natural morphism $0 \to j_{U!}(X, 0_X)$, so we have a well defined pointed left $\underline{M}$-module. We leave to the reader the verification that the resulting functor, called *extension by zero*, is indeed left adjoint to the restriction functor.

(vi) It is convenient to extend definition 4.8.22 to non-pointed modules and monoids : namely, if S is a non-pointed left $\underline{M}$-module, we shall say that S is *flat*, if the same holds for the pointed left $\underline{M}_\circ$-module $S_\circ$. Likewise, we say that a morphism $\varphi : \underline{M} \to \underline{N}$ of non-pointed T-monoids is *flat*, if the same holds for $\varphi_\circ$.

Lemma 4.8.24. *Let T be a topos, U any object of T, and denote by $i_* : \complement U \to T$ the inclusion functor of the complement of U in T (see example* 4.7.8(iii)*). Let also $\underline{M}$, $\underline{N}$, $\underline{P}$ be three pointed T-monoids. Then the following holds :*

(i) *The functor $j_{U!}$ of extension by zero is faithful, and transforms exact sequences of pointed left $\underline{M}_{|U}$-modules, into exact sequences of pointed left $\underline{M}$-modules (and likewise for right modules and bimodules).*

(ii) *For every pointed $(\underline{M}, \underline{N})$-bimodule S and every pointed $(\underline{P}_{|U}, \underline{M}_{|U})$-bimodule S', the natural morphism of pointed $(\underline{P}, \underline{N})$-modules*

$$j_{U!}(S' \otimes_{M_{|U}} S_{|U}) \to j_{U!}S' \otimes_M S$$

is an isomorphism.

(iii) *If S is flat pointed left $\underline{M}_{|U}$-module, then $j_{U!}S$ is a flat pointed left $\underline{M}$-module (and likewise for right modules).*

(iv) *For every pointed $(\underline{M}, \underline{N})$-bimodule S, and every pointed $(i^*\underline{P}, i^*\underline{M})$-bimodule S', the natural morphism of pointed $(\underline{P}, \underline{N})$-bimodules*

$$i_*S' \otimes_M S \to i_*(S' \otimes_{i^*M} i^*S)$$

is an isomorphism.

(v) *If S is a flat pointed left $i^*\underline{M}$-module, then i_*S is a flat left pointed $\underline{M}$-module (and likewise for right modules).*

(vi) *If S is a flat pointed left $\underline{M}$-module, then $S_{|U}$ is a flat left pointed $\underline{M}_{|U}$-module.*

Proof. (i): Let us show first that $j_{U!}$ is faithful. Indeed, suppose that $\varphi, \psi : S \to S'$ are two morphisms of left pointed $\underline{M}_{|U}$-modules, such that $j_{U!}\varphi = j_{U!}\psi$. We need to show that $\varphi = \psi$.

Let $p : S' \to S''$ be the coequalizer of φ and ψ; then $j_{U!}p$ is the coequalizer of $j_{U!}\varphi$ and $j_{U!}\psi$ (since $j_{U!}$ is right exact); hence we are reduced to showing that a morphism $p : S' \to S''$ is an isomorphism if and only if the same holds for $j_{U!}p$. This follows from remark 3.7.24(ii) and the following more general :

Claim 4.8.25. Let $\varphi : X \to X'$, $A \to X$, $A \to B$ be three morphisms in T. Then φ is a monomorphism (resp. an epimorphism) if and only if the same holds for the induced morphism $\varphi \amalg_A B : X \amalg_A B \to X' \amalg_A B$.

Proof of the claim. We may assume that $T = C^\sim$ for some small site $C := (\mathscr{C}, J)$. Then $\varphi \amalg_A B = (i\varphi \amalg_{iA} iB)^a$, where $i : C^\sim \to \mathscr{C}^\wedge$ is the forgetful functor. Since the functor $F \mapsto F^a$ is exact, we are reduced to the case where $T = \mathscr{C}^\wedge$, and in this case the assertion can be checked argumentwise, *i.e.* we may assume that $T = \mathbf{Set}$, where the claim is obvious. $\Diamond$

Next, we already know that $j_{U!}$ transforms right exact sequences into right exact sequences. To conclude, it suffices then to check that $j_{U!}$ transforms monomorphisms into monomorphisms.To this aim, we apply again remark 3.7.24(ii) and claim 4.8.25.

(ii) is proved by general nonsense, and (iii) is an immediate consequence of (i) and (ii) : we leave the details to the reader.

(iv): By (4.8.4), we have $j_U^*(i_*S' \otimes_M S) \simeq 0 \otimes_{j_U^*M} j_U^*S \simeq 1_{T/U}$, hence $i_*S' \otimes_M S \in \mathrm{Ob}(\mathsf{C}U)$. Notice now that, for every object X of $\mathsf{C}U$, the counit of adjunction $i^*i_*X \to X$ is an isomorphism (proposition 1.1.20(iii)); by the triangular identities of (1.1.13), it follows that the same holds for the unit of adjunction $i_*X \to i_*i^*i_*X$. Especially, the natural morphism :

$$i_*S' \otimes_M S \to i_*i^*(i_*S' \otimes_M S) \xrightarrow{\sim} i_*(i^*i_*S' \otimes_{i^*M} i^*S) \xrightarrow{\sim} i_*(S' \otimes_{i^*M} i^*S).$$

is an isomorphism. The latter is the morphism of assertion (iv).

(v) follows easily from (iv) and its proof.

(vi): In view of (i), it suffices to show that the functor $S' \mapsto j_{U!}(S' \otimes_{M_{|U}} S_{|U})$ transforms exact sequences into exact sequences. The latter follows easily from (ii). $\square$

Proposition 4.8.26. *Let $\mathbf{P}(T, \underline{M}, S)$ be the property : "S is a flat pointed left $\underline{M}$-module" (for a monoid $\underline{M}$ on a topos T). Then $\mathbf{P}$ can be checked on stalks. (See definition* 4.7.11(v).*)*

Proof. Suppose first that S_ξ is a flat left $\underline{M}_\xi$-module for every ξ in a conservative set of T-points; let $\varphi : X \to X'$ be a monomorphism of pointed right $\underline{M}$-modules; by (4.8.4) we have a natural isomorphism

$$(\varphi \otimes_M S)_\xi \xrightarrow{\sim} \varphi_\xi \otimes_{M_\xi} S_\xi$$

in the category of pointed sets, and our assumption implies that these morphisms are monomorphisms. Since an arbitrary product of monomorphisms is a monomorphism, remark 1.2.21(ii) shows that $\varphi \otimes_M S$ is also a monomorphism, whence the contention.

Next, suppose that S is a flat pointed left $\underline{M}$-module. We have to show that the functor

$$S' \mapsto S' \otimes_{M_\xi} S_\xi \qquad (4.8.27)$$

from pointed right $\underline{M}_\xi$-modules to pointed sets, preserves monomorphisms.

However, let (U, ξ_U, ω_U) be any lifting of ξ (see (4.7.17)); in view of (4.8.4), we have

$$P_U(S') := (\xi_U^*\xi_{U*}S') \otimes_{A_\xi} S_\xi \simeq (\xi_U^*\xi_{U*}S') \otimes_{\xi_U^*A_{|U}} \xi_U^*S_{|U} \simeq \xi_U^*(\xi_{U*}S' \otimes_{A_{|U}} S_{|U})$$

and then lemma 4.8.24(vi) implies that the functor $S' \to P_U(S')$ preserves monomorphisms. By lemma 4.7.20, remark 4.7.13(ii) and (4.7.18), the functor (4.8.27) is a filtered colimit of such functors P_U, hence it preserves monomorphisms as well. $\square$

4.8.28. We wish now to introduce a few notions that pertain to the special class of commutative T-monoids. When $T = \mathbf{Set}$, these notions are well known, and we wish to explain quickly that they generalize without problems, to arbitrary topoi.

To begin with, for every category T as in example 3.7.21(i), we denote by $\mathbf{Mnd}_T$ (resp. $\mathbf{Mnd}_{T\circ}$) the category of commutative non-pointed (resp. pointed) T-monoids; in case $T = \mathbf{Set}$, we shall usually drop the subcript, and write just $\mathbf{Mnd}$ (resp. $\mathbf{Mnd}_\circ$). Notice that if $\underline{M}$ is any (pointed or not pointed) commutative T-monoid, every left or right $\underline{M}$-module is a $\underline{M}$-bimodule in a natural way, hence we shall denote indifferently by $\underline{M}$-$\mathbf{Mod}$ (resp. $\underline{M}$-$\mathbf{Mod}_\circ$) the category of non-pointed (resp. pointed) left or right $\underline{M}$-modules.

The following lemma is a special case of a result that holds more generally, for every "algebraic theory" in the sense of [29, Def.3.3.1] (see [29, Prop.3.4.1, Prop.3.4.2]).

Lemma 4.8.29. *Let T be a topos. We have :*

(i) *The category $\mathbf{Mnd}_T$ admits arbitrary limits and colimits.*
(ii) *In the category $\mathbf{Mnd}_T$, filtered colimits commute with all finite limits.*
(iii) *The forgetful functor $\iota : \mathbf{Mnd}_T \to T$ that assigns to a monoid its underlying object of T, commutes with all limits, and with all filtered colimits.*

Proof. (iii): Commutation with limits holds because ι admits a left adjoint : namely, to an object Σ of T one assigns the *free monoid* $\mathbb{N}_T^{(\Sigma)}$ generated by Σ, defined as the sheaf associated with the presheaf of monoids

$$U \mapsto \mathbb{N}^{(\Sigma(U))} \qquad \text{for every } U \in \mathrm{Ob}(T)$$

where $\mathbb{N}$ is the additive monoid of natural numbers (see remark 4.8.11(vii)). One verifies easily that this T-monoid represents the functor

$$\underline{M} \mapsto \mathrm{Hom}_T(\Sigma, \underline{M}) \qquad \mathbf{Mnd}_T \to \mathbf{Set}.$$

Moreover, if I is any small category, and $F : I \to \mathbf{Mnd}_T$ any functor, one checks easily that the limit of $\iota \circ F$ can be endowed with a unique composition law (indeed, the limit of the composition laws of the monoids F_i), such that the resulting monoid represents the limit of F.

A similar argument also shows that $\mathbf{Mnd}_T$ admits arbitrary filtered colimits, and that ι commutes with filtered colimits. It is likewise easy to show that the product of two T-monoids $\underline{M}$ and $\underline{N}$ is also the coproduct of $\underline{M}$ and $\underline{N}$. To complete the proof of (i), it suffices therefore to show that any two maps $f, g : \underline{M} \to \underline{N}$ admit a coequalizer; the latter is obtained as the coequalizer $\underline{N}'$ (in the category T) of the two morphisms :

$$\underline{M} \times \underline{N} \underset{\mu_N \circ (g \times \mathbf{1}_N)}{\overset{\mu_N \circ (f \times \mathbf{1}_N)}{\rightrightarrows}} \underline{N}.$$

We leave to the reader the verification that the composition law of N descends to a (necessarily unique) composition law on $\underline{N}'$.

(ii) follows from (iii) and the fact that the same assertion holds in T (remark 4.4.1(i)). □

Example 4.8.30. (i) For instance, if $T = \mathbf{Set}$, the product $M_1 \times M_2$ of any two commutative monoids is representable in $\mathbf{Mnd}$; its underlying set is the cartesian product of M_1 and M_2, and the composition law is the obvious one.

(ii) As usual, the kernel $\mathrm{Ker}\,\varphi$ (resp. cokernel $\mathrm{Coker}\,\varphi$) of a map of T-monoids $\varphi : \underline{M} \to \underline{N}$ is defined as the fibre product (resp. push-out) of the diagram of T-monoids

$$\underline{M} \xrightarrow{\varphi} \underline{N} \leftarrow \underline{1}_T \qquad (\text{resp. } \underline{1}_T \leftarrow \underline{M} \xrightarrow{\varphi} \underline{N}).$$

Especially, if $\underline{M} \subset \underline{N}$, one defines in this way the quotient $\underline{N}/\underline{M}$.

(iii) Also, if $T = \mathbf{Set}$, and $\varphi_1 : M \to M_1$, $\varphi_2 : M \to M_2$ are two maps in $\mathbf{Mnd}$, the push-out $M_1 \amalg_M M_2$ can be described as follows. As a set, it is the quotient $(M_1 \times M_2)/\!\sim$, where $\sim$ denotes the minimal equivalence relation such that

$$(m_1, m_2 \cdot \varphi_2(m)) \sim (m_1 \cdot \varphi_1(m), m_2) \qquad \text{for every } m \in M, m_1 \in M_1, m_2 \in M_2$$

and the composition law is the unique one such that the projection $M_1 \times M_2 \to M_1 \amalg_M M_2$ is a map of monoids. We deduce the following :

Lemma 4.8.31. *Let G be an abelian group. The following holds :*

(i) *If $\varphi : M \to N$ and $\psi : M \to G$ are two morphisms of monoids (in the topos $T = \mathbf{Set}$), $G \amalg_M N$ is the quotient $(G \times N)/\!\approx$, where $\approx$ is the equivalence relation such that :*

$$(g, n) \approx (g', n') \quad \Leftrightarrow \quad (\psi(a) \cdot g, \varphi(b) \cdot n) = (\psi(b) \cdot g', \varphi(a) \cdot n') \text{ for some } a, b \in M.$$

(ii) *If $\varphi : G \to M$ and $\psi : G \to N$ are two morphisms of monoids, the set underlying $M \amalg_G N$ is the set-theoretic quotient $(M \times N)/G$ for the G-action defined via (φ, ψ^{-1}).*

(iii) *Especially, if M is a monoid and G is a submonoid of M, then the set underlying M/G is the set-theoretic quotient of M by the translation action of G.*

Proof. (i): One checks easily that the relation $\approx$ thus defined is transitive. Let $\sim$ be the equivalence relation defined as in example 4.8.30(iii). Clearly :

$$(g, n \cdot \psi(m)) \approx (g \cdot \varphi(m), n) \qquad \text{for every } g \in G, n \in N \text{ and } m \in M$$

hence $(g, n) \sim (g', n')$ implies $(g, n) \approx (g', n')$. Conversely, suppose that $(\psi(a) \cdot g, \varphi(b) \cdot n) = (\psi(b) \cdot g', \varphi(a) \cdot n')$ for some $g \in G$, $n \in N$ and $a, b \in M$. Then :

$$(g, n) = (g, \varphi(a) \cdot \varphi(a)^{-1} \cdot n) \sim (\psi(a) \cdot g, \varphi(a)^{-1} \cdot n) = (\psi(b) \cdot g', \varphi(a)^{-1} \cdot n)$$

as well as : $(g', n') = (g', \varphi(b) \cdot \varphi(a)^{-1} \cdot n) \sim (\psi(b) \cdot g', \varphi(a)^{-1} \cdot n)$. Hence $(g, n) \sim (g', n')$ and the claim follows.

(ii) follows directly from example 4.8.30(iii), and (iii) is a special case of (ii). □

4.8.32. Let T be a topos. For any T-ring $\underline{R}$, we let $\underline{R}$-$\mathbf{Mod}$ be the category of $\underline{R}$-modules (defined in the usual way); especially, we may consider the T-ring $\mathbb{Z}_T$ (the constant sheaf with value $\mathbb{Z}$: see (4.4.11)). Then $\mathbb{Z}_T$-$\mathbf{Mod}$ is the category of abelian T-groups. The forgetful functor $\mathbb{Z}_T$-$\mathbf{Mod} \to \mathbf{Mnd}_T$ admits a right adjoint :

$$\mathbf{Mnd}_T \to \mathbb{Z}_T\text{-}\mathbf{Mod} \quad : \quad \underline{M} \mapsto \underline{M}^\times.$$

The latter can be defined as the fibre product in the cartesian diagram :

$$\begin{array}{ccc} \underline{M}^\times & \longrightarrow & \underline{M} \times \underline{M} \\ \big\downarrow & & \big\downarrow{\scriptstyle \mu_M} \\ 1_T & \xrightarrow{1_M} & \underline{M}. \end{array}$$

For $i = 1, 2$, let $p_i : \underline{M} \times \underline{M} \to \underline{M}$ be the projections, and $p'_i : \underline{M}^\times \to \underline{M}$ the restriction of p_i; for every $U \in \mathrm{Ob}(T)$, the image of $p'_i(U) : \underline{M}^\times(U) \to \underline{M}(U)$ consists of all sections x which are *invertible*, *i.e.* for which there exists $y \in \underline{M}(U)$ such that $\mu_M(x, y) = 1_M$. It is easily seen that such inverse is unique, hence p'_i is a monomorphism, p'_1 and p'_2 define the same subobject of $\underline{M}$, and this subobject $\underline{M}^\times$ is the largest abelian T-group contained in $\underline{M}$. We say that $\underline{M}$ is *sharp*, if $\underline{M}^\times = 1_T$. The inclusion functor, from the full subcategory of sharp T-monoids, to $\mathbf{Mnd}_T$, admits a left adjoint

$$\underline{M} \mapsto \underline{M}^\sharp := \underline{M}/\underline{M}^\times.$$

We call $\underline{M}^\sharp$ the *sharpening* of $\underline{M}$.

4.8.33. Let $\underline{S}$ be a submonoid of a commutative T-monoid $\underline{M}$, and $F_S : \mathbf{Mnd}_T \to \mathbf{Set}$ the functor that assigns to any commutative T-monoid $\underline{N}$ the set of all morphisms $f : \underline{M} \to \underline{N}$ such that $f(\underline{S}) \subset \underline{N}^\times$. We claim that F_S is representable by a T-monoid $\underline{S}^{-1}\underline{M}$.

In case $T = \mathbf{Set}$, one may realize $\underline{S}^{-1}\underline{M}$ as the quotient $(\underline{S} \times \underline{M})/\sim$ for the equivalence relation such that $(s_1, x_1) \sim (s_2, x_2)$ if and only if there exists $t \in \underline{S}$ such that $ts_1x_2 = ts_2x_1$. The composition law of $\underline{S}^{-1}\underline{M}$ is the obvious one; then the class of a pair (s, x) is denoted naturally by $s^{-1}x$. This construction can be repeated on a general topos : letting $X := \underline{S} \times \underline{M}$, the foregoing equivalence relation can be encoded as the equalizer R of two maps $X \times X \times S \to \underline{M}$, and the quotient under this equivalence relation shall be represented by the coequalizer of two other maps $R \to X$; the reader may spell out the details, if he wishes. Equivalently, $\underline{S}^{-1}\underline{M}$ can be realized as the sheaf on (T, C_T) associated with the presheaf :

$$T \to \mathbf{Mnd} \quad : \quad U \mapsto \underline{S}(U)^{-1}\underline{M}(U)$$

(see remark 4.8.11(vii)). The natural morphism $\underline{M} \to \underline{S}^{-1}\underline{M}$ is called the *localization map*. For $T = \mathbf{Set}$, and $f \in M$ any element, we shall also use the standard notation :

$$M_f := S_f^{-1}M \qquad \text{where } S_f := \{f^n \mid n \in \mathbb{N}\}.$$

Lemma 4.8.34. *Let $f_1 : \underline{M} \to \underline{N}_1$ and $f_2 : \underline{M} \to \underline{N}_2$ be morphisms of T-monoids, $\underline{S} \subset \underline{M}$, $\underline{S}_i \subset \underline{N}_i$ ($i = 1, 2$) three submonoids, such that $f_i(\underline{S}) \subset \underline{S}_i$ for $i = 1, 2$. Then the natural morphism :*

$$(\underline{S}_1 \cdot \underline{S}_2)^{-1}(\underline{N}_1 \amalg_{\underline{M}} \underline{N}_2) \to \underline{S}_1^{-1}\underline{N}_1 \amalg_{\underline{S}^{-1}\underline{M}} \underline{S}_2^{-1}\underline{N}_2$$

is an isomorphism.

Proof. One checks easily that both these T-monoids represent the functor $\mathbf{Mnd}_T \to \mathbf{Set}$ that assigns to any T-monoid $\underline{P}$ the pairs of morphisms (g_1, g_2) where $g_i : \underline{N}_i \to \underline{P}$ satisfies $g_i(\underline{S}_i) \subset \underline{P}^\times$, for $i = 1, 2$, and $g_1 \circ f_1 = g_2 \circ f_2$. The details are left to the reader. □

4.8.35. The forgetful functor $\mathbb{Z}\text{-}\mathbf{Mod}_T \to \mathbf{Mnd}_T$ from abelian T-groups to commutative T-monoids, admits a left adjoint

$$\underline{M} \mapsto \underline{M}^{\mathrm{gp}} := \underline{M}^{-1}\underline{M}.$$

A commutative T-monoid $\underline{M}$ is said to be *integral* if the unit of adjunction $\underline{M} \to \underline{M}^{\mathrm{gp}}$ is a monomorphism. The functor $\underline{M} \mapsto \underline{M}^{\mathrm{gp}}$ commutes with all colimits, since all left adjoints do; it does not commute with arbitrary limits (see example 4.8.36(v)).

We denote by $\mathbf{Int}.\mathbf{Mnd}_T$ the full subcategory of $\mathbf{Mnd}_T$ consisting of all integral monoids; when $T = \mathbf{Set}$, we omit the subscript, and write just $\mathbf{Int}.\mathbf{Mnd}$. The natural inclusion ι : $\mathbf{Int}.\mathbf{Mnd}_T \to \mathbf{Mnd}_T$ admits a left adjoint :

$$\mathbf{Mnd}_T \to \mathbf{Int}.\mathbf{Mnd}_T \quad : \quad \underline{M} \mapsto \underline{M}^{\mathrm{int}}.$$

Namely, $\underline{M}^{\mathrm{int}}$ is the image (in the category T) of the unit of adjunction $\underline{M} \to \underline{M}^{\mathrm{gp}}$. It follows easily that the category $\mathbf{Int}.\mathbf{Mnd}_T$ is cocomplete, since the colimit of a family $(\underline{M}_\lambda \mid \lambda \in \Lambda)$ of integral monoids is represented by

$$(\operatorname*{colim}_{\lambda \in \Lambda} \iota \underline{M}_\lambda)^{\mathrm{int}}.$$

Likewise, $\mathbf{Int}.\mathbf{Mnd}_T$ is complete, and limits commute with the forgetful functor to T; to check this, it suffices to show that

$$L := \lim_{\lambda \in \Lambda} \iota(\underline{M}_\lambda)$$

is integral. However, by lemma 4.8.29(iii) we have $L \subset \prod_{\lambda \in \Lambda} \underline{M}_\lambda \subset \prod_{\lambda \in \Lambda} \underline{M}_\lambda^{\mathrm{gp}}$, whence the claim.

Example 4.8.36. (i) Take $T = \mathbf{Set}$; if M is any monoid, and $a \in M$ is any element, we say that a is *regular*, if the map $M \to M$ given by the rule : $x \mapsto a \cdot x$ is injective. It is easily seen that M is integral if and only if every element of M is regular.

(ii) For an arbitrary topos T, notice that the T-monoid $\underline{G}^a$ associated with a presheaf of groups $\underline{G}$ on T, is a T-group : indeed, the condition $\underline{G}^\times = \underline{G}$ implies $(\underline{G}^a)^\times = \underline{G}^a$, since the functor $F \mapsto F^a$ is exact. More precisely, for every presheaf $\underline{M}$ of monoids on T, we have a natural isomorphism :

$$(\underline{M}^{\mathrm{gp}})^a \xrightarrow{\sim} (\underline{M}^a)^{\mathrm{gp}} \qquad \text{for every } T\text{-monoid } \underline{M}$$

since both functors are left adjoint to the forgetful functor from T-groups to presheaves of monoids on T.

(iii) It follows from (ii) that a T-monoid $\underline{M}$ is integral if and only if $\underline{M}(U)$ is an integral monoid, for every $U \in \mathrm{Ob}(T)$. Indeed, if $\underline{M}$ is integral, then $\underline{M}(U) \subset \underline{M}^{\mathrm{gp}}(U)$ for every such U, so $\underline{M}(U)$ is integral. Conversely, by definition $\underline{M}^{\mathrm{gp}}$ is the sheaf associated with the presheaf $U \mapsto \underline{M}(U)^{\mathrm{gp}}$; now, if $\underline{M}(U)$ is integral, we have $\underline{M}(U) \subset \underline{M}(U)^{\mathrm{gp}}$, and consequently $\underline{M} \subset \underline{M}^{\mathrm{gp}}$, since the functor $F \mapsto F^a$ is exact.

(iv) We also deduce from (ii) that the functor $\underline{M} \mapsto \underline{M}^a$ sends presheaves of integral monoids, to integral T-monoids. Therefore we have a natural isomorphism :

$$(\underline{M}^{\mathrm{int}})^a \xrightarrow{\sim} (\underline{M}^a)^{\mathrm{int}} \tag{4.8.37}$$

as both functors are left adjoint to the forgetful functor from integral T-monoids, to presheaves of monoids on T. In the same vein, it is easily seen that the forgetful functor $\mathbf{Int}.\mathbf{Mnd}_T \to T$ commutes with filtered colimits : indeed, (4.8.37) and lemma 4.8.29(iii) reduce the assertion to showing that the colimit of a filtered system of presheaves of integral monoids is integral, which can be verified directly.

(v) Take $T = \mathbf{Set}$, and let $\varphi : M \to N$ be an injective map of monoids; if N (hence M) is integral, one sees easily that the induced map $\varphi^{\mathrm{gp}} : M^{\mathrm{gp}} \to N^{\mathrm{gp}}$ is also injective. This may fail, when N is not integral : for instance, if M is any integral monoid, and $N := M_\circ$ is the pointed monoid associated with M as in remark 4.8.14(iv), then for the natural inclusion $i : M \to M_\circ$ we have $i^{\mathrm{gp}} = 0$, since $(M_\circ)^{\mathrm{gp}} = \{1\}$.

Lemma 4.8.38. *Let T be a topos with enough points, $\underline{M}$ an integral T-monoid, and $\underline{N} \subset \underline{M}$ a T-submonoid. Then $\underline{M}/\underline{N}$ is an integral T-monoid.*

Proof. In light of example 4.8.36(iv), we are reduced to the case where $T = \mathbf{Set}$. Moreover, since the natural morphism $\underline{M}/\underline{N} \to \underline{N}^{-1}\underline{M}/\underline{N}^{\mathrm{gp}}$ is an isomorphism, we may assume that $\underline{N}$ is an abelian group. Now, notice that $(\underline{M}/\underline{N})^{\mathrm{gp}} = \underline{M}^{\mathrm{gp}}/\underline{N}$ since the functor $P \mapsto P^{\mathrm{gp}}$ commutes with colimits. On the other hand, $\underline{M}/\underline{N}$ is the set-theoretic quotient of $\underline{M}$ by the translation action of $\underline{N}$ (lemma 4.8.31(iii)). This shows that the unit of adjunction $\underline{M}/\underline{N} \to (\underline{M}/\underline{N})^{\mathrm{gp}}$ is injective, as required. ∎

4.8.39. Let M be an integral monoid. Classically, one says that M is *saturated*, if we have :

$$M = \{a \in M^{\mathrm{gp}} \mid a^n \in M \text{ for some integer } n > 0\}.$$

In order to globalize the class of saturated monoid to arbitrary topoi, we make the following :

Definition 4.8.40. Let T be a topos, $\varphi : \underline{M} \to \underline{N}$ a morphism of integral T-monoids.

(i) We say that φ is *exact* if the diagram of commutative T-monoids

$$\mathscr{D}_\varphi \quad : \quad \begin{array}{ccc} \underline{M} & \xrightarrow{\varphi} & \underline{N} \\ \downarrow & & \downarrow \\ \underline{M}^{\mathrm{gp}} & \xrightarrow{\varphi^{\mathrm{gp}}} & \underline{N}^{\mathrm{gp}} \end{array}$$

is cartesian (where the vertical arrows are the natural morphisms).

(ii) For any integer $k > 0$, the *k-Frobenius map* of $\underline{M}$ is the endomorphism $\boldsymbol{k}_M$ of $\underline{M}$ given by the rule : $x \mapsto x^k$ for every $U \in \mathrm{Ob}(T)$ and every $x \in \underline{M}(U)$. We say that $\underline{M}$ is *k-saturated*, if $\boldsymbol{k}_M$ is an exact morphism.

(iii) We say that $\underline{M}$ is *saturated*, if $\underline{M}$ is integral and k-saturated for every integer $k > 0$.

We denote by $\mathbf{Sat}.\mathbf{Mnd}_T$ the full subcategory of $\mathbf{Int}.\mathbf{Mnd}_T$ whose objects are the saturated T-monoids. As usual, when $T = \mathbf{Set}$, we shall drop the subscript, and just write $\mathbf{Sat}.\mathbf{Mnd}$ for this category. The above definition (and several of the related results in section 6.2) is borrowed from [159].

Remark 4.8.41. (i) Clearly, when $T = \mathbf{Set}$, definition 4.8.40(iii) recovers the classical notion of saturated monoid. Again, for usual monoids, it is easily seen that the forgetful functor $\mathbf{Sat}.\mathbf{Mnd} \to \mathbf{Int}.\mathbf{Mnd}$ admits a left adjoint, that assigns to any integral monoid M its *saturation* M^{sat}. The latter is the monoid consisting of all elements $x \in M^{\mathrm{gp}}$ such that $x^k \in M$ for some integer $k > 0$; especially, the torsion subgroup of M^{gp} is always contained in M^{sat}. The easy verification is left to the reader. Clearly, M is saturated if and only if $M = M^{\mathrm{sat}}$. More generally, the unit of adjunction $M \to M^{\mathrm{sat}}$ is just the inclusion map.

(ii) For a general topos T, and a morphism φ as in definition 4.8.40(i), notice that φ is exact if and only if the induced map of monoids $\varphi(U) : \underline{M}(U) \to \underline{N}(U)$ is exact for every $U \in \mathrm{Ob}(T)$. Indeed, if $\mathscr{D}_\varphi$ is cartesian, then the same holds for the induced diagram $\mathscr{D}_\varphi(U)$ of monoids; since the natural map $\underline{M}(U)^{\mathrm{gp}} \to \underline{M}^{\mathrm{gp}}(U)$ is injective (and likewise for $\underline{N}$), it follows easily that the diagram of monoids $\mathscr{D}_{\varphi(U)}$ is cartesian, *i.e.* $\varphi(U)$ is exact. For the converse, notice that $\mathscr{D}_\varphi$ is of the form $(h\mathscr{D}_\varphi)^a$, where $h : T \to T^\wedge$ is the Yoneda embedding, and $F \mapsto F^a$ denotes the associated sheaf functor $T^\wedge \to (T, C_T)^\sim = T$; the assumption means that $h\mathscr{D}$ is a cartesian diagram in $T^\wedge$, hence $\mathscr{D}$ is exact in T, since the associated sheaf functor is exact.

(iii) Example 4.8.36(iii) and (ii) imply that a T-monoid $\underline{M}$ is saturated, if and only if $\underline{M}(U)$ is a saturated monoid, for every $U \in \mathrm{Ob}(T)$. We also remark that, in view of example 4.8.36(ii), the functor $F \mapsto F^a$ takes presheaves of k-saturated (resp. saturated) monoids, to k-saturated (resp. saturated) T-monoids : indeed, if $\eta : \underline{M} \to \underline{M}^{\mathrm{gp}}$ is the unit of adjunction for a presheaf of monoids $\underline{M}$, then $\eta^a : \underline{M}^a \to (\underline{M}^{\mathrm{gp}})^a = (\underline{M}^a)^{\mathrm{gp}}$ is the unit of adjunction for the associated T-monoid, hence it is clear the functor $F \mapsto F^a$ preserves exact morphisms.

(iv) It follows easily that the inclusion functor $\mathbf{Sat}.\mathbf{Mnd}_T \to \mathbf{Int}.\mathbf{Mnd}_T$ admits a left adjoint, namely the functor

$$\mathbf{Int}.\mathbf{Mnd}_T \to \mathbf{Sat}.\mathbf{Mnd}_T \quad : \quad \underline{M} \mapsto \underline{M}^{\mathrm{sat}}$$

that assigns to $\underline{M}$ the sheaf associated with the presheaf $U \to \underline{M}'(U) := \underline{M}(U)^{\mathrm{sat}}$ on T (notice that the functor $\underline{M} \mapsto \underline{M}'$ from presheaves of integral monoids, to presheaves of saturated monoids, is left adjoint to the inclusion functor). Just as in example 4.8.36(iv), we deduce a natural isomorphism

$$(\underline{M}^{\mathrm{sat}})^a \xrightarrow{\sim} (\underline{M}^a)^{\mathrm{sat}} \qquad \text{for every } T\text{-monoid } \underline{M} \tag{4.8.42}$$

since both functors are left adjoint to the forgetful functor from $\mathbf{Sat}.\mathbf{Mnd}_T$, to presheaves of integral monoids on T.

(v) By the usual general nonsense, the saturation functor commutes with all colimits. Moreover, the considerations of (4.8.35) can be repeated for saturated monoids : first, the category $\mathbf{Sat}.\mathbf{Mnd}_T$ is cocomplete, and arguing as in example 4.8.36(iv), one checks that filtered colimits commute with the forgetful functor $\mathbf{Sat}.\mathbf{Mnd}_T \to T$; next, if $F : \Lambda \to \mathbf{Sat}.\mathbf{Mnd}_T$ is a functor from a small category Λ, then for each integer $k > 0$, the induced diagram of integral monoids

$$\lim_\Lambda \mathscr{D}_{\boldsymbol{k}_F} \quad : \quad \begin{array}{ccc} \lim_\Lambda F & \xrightarrow{\lim_\Lambda \boldsymbol{k}_F} & \lim_\Lambda F \\ \downarrow & & \downarrow \\ \lim_\Lambda F^{\mathrm{gp}} & \xrightarrow{\lim_\Lambda \boldsymbol{k}_F^{\mathrm{gp}}} & \lim_\Lambda F^{\mathrm{gp}} \end{array}$$

is cartesian; since the natural morphism

$$(\lim_\Lambda F)^{\mathrm{gp}} \to \lim_\Lambda F^{\mathrm{gp}}$$

is a monomorphism, it follows easily that the limit of F is saturated, hence $\mathbf{Sat}.\mathbf{Mnd}_T$ is complete, and furthermore all limits commute with the forgetful functor to T.

4.8.43. In view of remark 4.8.11(i,ii,iii), a morphism of topoi $f : T \to S$ induces functors :

(4.8.44) $$f_* : \mathbf{Mnd}_T \to \mathbf{Mnd}_S \qquad f^* : \mathbf{Mnd}_S \to \mathbf{Mnd}_T$$

and one verifies easily that (4.8.44) is an adjoint pair of functors.

Lemma 4.8.45. *Let $f : T \to S$ be a morphism of topoi, $\underline{M}$ an S-monoid. We have :*

(i) *If $\underline{M}$ is integral (resp. saturated), $f^*\underline{M}$ is an integral (resp. saturated) T-monoid.*

(ii) *More precisely, there is a natural isomorphism :*

$$f^*(\underline{M}^{\mathrm{int}}) \xrightarrow{\sim} (f^*\underline{M})^{\mathrm{int}} \qquad \textit{(resp. } f^*(\underline{M}^{\mathrm{sat}}) \xrightarrow{\sim} (f^*\underline{M})^{\mathrm{sat}}, \ \textit{if } \underline{M} \textit{ is integral).}$$

(iii) *If φ is an exact morphism of integral S-monoids, then $f^*\varphi$ is an exact morphism of integral T-monoids.*

Proof. To begin with, notice that the adjoint pair (f^*, f_*) of (4.8.44) restricts to a corresponding adjoint pair of functors between the categories of abelian T-groups and abelian S-groups (since the condition $\underline{G} = \underline{G}^\times$ for monoids, is preserved by any left exact functor).

There follows a natural isomorphism :

$$(f^*\underline{M})^{\mathrm{gp}} \xrightarrow{\sim} f^*(\underline{M}^{\mathrm{gp}}) \qquad \text{for every } S\text{-monoid } \underline{M}$$

since both functors are left adjoint to the functor f_* from abelian T-groups to S-monoids. Now, if $\underline{M}$ is an integral S-module, and $\eta : \underline{M} \to \underline{M}^{\mathrm{gp}}$ is the unit of adjunction, it is easily seen that $f^*\eta : f^*\underline{M} \to (f^*\underline{M})^{\mathrm{gp}}$ is also the unit of adjunction. From this and proposition 4.4.8(iii), we deduce the assertion concerning $f^*(\underline{M}^{\mathrm{int}})$.

By the same token, we get assertion (iii) of the lemma. Especially, if $\underline{M}$ is saturated, then the same holds for $f^*\underline{M}$. The assertion concerning $f^*(\underline{M}^{\mathrm{sat}})$ follows by the usual argument. □

Lemma 4.8.46. (i) *The functor f^* of* (4.8.44) *commutes with all finite limits and all colimits.*

(ii) *Let $\mathbf{P}(T, M)$ be the property "M is an integral (resp. saturated) T-monoid". Then $\mathbf{P}$ can be checked on every conservative set of morphisms of topoi (see definition* 4.7.11(v).*)*

Proof. (i): Concerning finite limits, in light of lemma 4.8.29(iii) we are reduced to the assertion that $f^* : S \to T$ is left exact, which holds by definition. Next f^* commutes with colimits, because it is a left adjoint.

(ii): A T-monoid $\underline{M}$ is integral if and only if the unit of adjunction $\eta : \underline{M} \to \underline{M}^{\mathrm{int}}$ is an isomorphism. However, $f^*(\underline{M}^{\mathrm{int}}) \xrightarrow{\sim} (f^*\underline{M})^{\mathrm{int}}$, by lemma 4.8.45(ii), and $f^*\eta : \underline{M} \to (f^*\underline{M})^{\mathrm{int}}$ is the unit of adjunction. The assertion is an immediate consequence. The same argument applies as well to saturated T-monoids. □

Example 4.8.47. (i) For instance, the unique morphism of topoi $\Gamma : T \to \mathbf{Set}$ (see proposition 4.4.12(i,ii)) induces a pair of adjoint functors :

(4.8.48) $$\mathbf{Mnd}_T \to \mathbf{Mnd} \ : \ M \mapsto \Gamma(T, M) \qquad \text{and} \qquad \mathbf{Mnd} \to \mathbf{Mnd}_T \ : \ P \mapsto P_T$$

where P_T is the constant sheaf of monoids on (T, C_T) with value P.

(ii) Specializing lemma 4.8.45(ii) to this adjoint pair, we obtain natural isomorphisms :

$$(M_T)^{\mathrm{int}} \xrightarrow{\sim} (M^{\mathrm{int}})_T \qquad (M_T)^{\mathrm{sat}} \xrightarrow{\sim} (M^{\mathrm{sat}})_T \tag{4.8.49}$$

of functors $\mathbf{Mnd} \to \mathbf{Int}.\mathbf{Mnd}_T$ and $\mathbf{Int}.\mathbf{Mnd} \to \mathbf{Sat}.\mathbf{Mnd}_T$. Especially, if M is an integral (resp. saturated) monoid, then the constant T-monoid M_T is integral (resp. saturated).

(iii) If ξ is any T-point, notice also that the stalk $M_{T,\xi}$ is isomorphic to M, since ξ is a section of $\Gamma : T \to \mathbf{Set}$.

4.8.50. Let T be a topos, $\underline{R}$ a T-ring. We have a forgetful functor $\underline{R}\text{-}\mathsf{Alg} \to \mathbf{Mnd}_T$ that assigns to a (unital, commutative) $\underline{R}$-algebra $(\underline{A}, +, \cdot, 1_A)$ its multiplicative T-monoid $(\underline{A}, \cdot)$. If $T = \mathbf{Set}$, this functor admits a left adjoint $\mathbf{Mnd} \to R\text{-}\mathsf{Alg} : M \mapsto R[M]$. Explicitly, $R[M] = \bigoplus_{x \in M} xR$, and the multiplication law is uniquely determined by the rule :

$$xa \cdot yb := (x \cdot y)ab \qquad \text{for every } x, y \in M \text{ and } a, b \in R.$$

For a general topos T, the above construction globalizes to give a left adjoint

$$\mathbf{Mnd}_T \to \underline{R}\text{-}\mathsf{Alg} \quad : \quad \underline{M} \mapsto \underline{R}[\underline{M}]. \tag{4.8.51}$$

The latter is the sheaf on (T, C_T) associated with the presheaf $U \mapsto \underline{R}(U)[\underline{M}(U)]$, for every $U \in \mathrm{Ob}(T)$. The functor (4.8.51) commutes with arbitrary colimits (since it is a left adjoint); especially, if $\underline{M} \to \underline{M}_1$ and $\underline{M} \to \underline{M}_2$ are two morphisms of monoids, we have a natural identification :

$$\underline{R}[\underline{M}_1 \amalg_{\underline{M}} \underline{M}_2] \xrightarrow{\sim} \underline{R}[\underline{M}_1] \otimes_{\underline{R}[\underline{M}]} \underline{R}[\underline{M}_2]. \tag{4.8.52}$$

By inspecting the universal properties, we also get a natural isomorphism :

$$\underline{S}^{-1}\underline{R}[\underline{M}] \xrightarrow{\sim} \underline{R}[\underline{S}^{-1}\underline{M}] \tag{4.8.53}$$

for every monoid $\underline{M}$ and every submonoid $\underline{S} \subset \underline{M}$.

4.8.54. Likewise, if $\underline{M}$ is any T-monoid, let $\underline{R}[\underline{M}]$-$\mathbf{Mod}$ denote as usual the category of modules over the T-ring $\underline{R}[\underline{M}]$; we have a forgetful functor $\underline{R}[\underline{M}]\text{-}\mathbf{Mod} \to \underline{M}\text{-}\mathbf{Mod}$. When $T = \mathbf{Set}$, this functor admits a left adjoint $M\text{-}\mathbf{Mod} \to R[M]\text{-}\mathbf{Mod} : S \mapsto R[S]$. Explicitly, $R[S]$ is the free R-module with basis given by S, and the $R[M]$-module structure on $R[S]$ is determined by the rule:

$$xa \cdot sb := \mu_S(x, s)ab \qquad \text{for every } x \in M,\ s \in S \text{ and } a, b \in R.$$

For a general topos T, this construction globalizes to give a left adjoint

$$\underline{M}\text{-}\mathbf{Mod} \to \underline{R}[\underline{M}]\text{-}\mathbf{Mod} \quad : \quad (S, \mu_S) \mapsto \underline{R}[S]$$

which is defined as the sheaf associated with the presheaf $U \mapsto \underline{R}(U)[S(U)]$ in $T^\wedge$.

Example 4.8.55. (i) Take $T = \mathbf{Set}$, let $(M, \mu_M, 1_M)$ be any monoid, and Λ any set. Then the coproduct $M^{(\Lambda)}$ of Λ copies of M is representable in the category of monoids, as the subset of M^Λ consisting of all sequences $a_\bullet := (a_\lambda \mid \lambda \in \Lambda)$ such that $\{\lambda \in \Lambda \mid a_\lambda \neq 0\}$ is a finite set; the composition law on $M^{(\Lambda)}$ is the obvious one :

$$a_\bullet \cdot b_\bullet := (\mu_M(a_\lambda, b_\lambda) \mid \lambda \in \Lambda) \qquad \text{for every } a_\bullet, b_\bullet \in M^{(\Lambda)}.$$

(ii) Let also R be any ring, and $(\mathbb{N}, +, 0)$ the monoid of non-negative integers; then the ring

$$R[\mathbb{N}^{(\Lambda)}]$$

is the free polynomial R-algebra $R[T_\lambda \mid \lambda \in \Lambda]$ on the set of variables $(T_\lambda \mid \lambda \in \Lambda)$.

(iii) We shall later encounter also the following variant. Let p be a prime integer, and $(\mathbb{N}[1/p], +, 0)$ the additive monoid of all non-negative rationals of the form a/p^n, for every $a, n \in \mathbb{N}$. Notice that $\mathbb{N}[1/p]$ is the colimit of the direct system of monoids

$$\mathbb{N} \to \mathbb{N} \to \mathbb{N} \cdots$$

with transition maps given by multiplication by p. Then, for every set Λ, the ring

$$R[T_\lambda^{1/p^\infty} \mid \lambda \in \Lambda] := R[\mathbb{N}[1/p]^{(\Lambda)}]$$

is the colimit of the system of R-algebras $R[\mathbb{N}^{(\Lambda)}] \to R[\mathbb{N}^{(\Lambda)}] \to R[\mathbb{N}^{(\Lambda)}] \to \cdots$ with transition maps : $R[T_\lambda \mid \lambda \in \Lambda] \to R[T_\lambda \mid \lambda \in \Lambda]$ such that $T_\lambda \mapsto T_\lambda^p$ for all $\lambda \in \Lambda$. Thus, the system $(T_\lambda^{1/p^n} \mid \lambda \in \Lambda, n \in \mathbb{N})$ is a family of generators for this R-algebras, and the free polynomial R-algebra $R[T_\lambda \mid \lambda \in \Lambda]$ is naturally an R-subalgebra of $R[T_\lambda^{1/p^\infty} \mid \lambda \in \Lambda]$.

4.9. **Torsors on a topos.** In this section we discuss torsors over (not necessarily abelian) group objects of a topos. Then we explain some basic notions concerning the points of the étale and Zariski topoi of a scheme, and we conclude with the proof of Hilbert's theorem 90 (lemma 4.9.27(iv)).

Definition 4.9.1. Let T be a topos, and G a T-group.

(i) A *left G-torsor* is a left G-module (X, μ_X), inducing an isomorphism

$$(\mu_X, p_X) : G \times X \to X \times X$$

(where $p_X : G \times X \to X$ is the natural projection) and such that there exists a covering morphism $U \to 1_T$ in T for which $X(U) \neq \varnothing$. This is the same as saying that the unique morphism $X \to 1_T$ is an epimorphism.

(ii) A *morphism of left G-torsors* is just a morphism of the underlying G-modules. Likewise, we define right G-torsors, G-bitorsors, and morphisms between them. We let:

$$H^1(T, G)$$

be the set of isomorphism classes of right G-torsors.

(iii) A (left or right or bi-) G-torsor (X, μ_X) is said to be *trivial*, if $\Gamma(T, X) \neq \varnothing$.

Remark 4.9.2. (i) In the situation of definition 4.9.1, notice that $H^1(T, G)$ always contains a distinguished element, namely the class of the trivial G-torsor (G, μ_G).

(ii) Conversely, suppose that (X, μ_X) is a trivial left G-torsor, and say that $\sigma \in \Gamma(T, X)$; then we have a cartesian diagram :

$$\begin{array}{ccc} G & \xrightarrow{\mu_\sigma} & X \\ \big\downarrow & & \big\downarrow{\scriptstyle \mathbf{1}_X \times \sigma} \\ G \times X & \xrightarrow{(\mu_X, p_X)} & X \times X \end{array}$$

which shows that (X, μ_X) is isomorphic to (G, μ_G) (and likewise for right G-torsors).

(iii) Notice that every morphism $f : (X, \mu_X) \to (X', \mu_{X'})$ of G-torsors is an isomorphism. Indeed, the assertion can be checked locally on T (*i.e.*, after pull-back by a covering morphism $U \to 1_T$). Then we may assume that X admits a global section $\sigma \in \Gamma(T, X)$, in which case $\sigma' := \sigma \circ f \in \Gamma(T, X')$. Then, arguing as in (ii), we get a commutative diagram :

$$\begin{array}{ccc} & G & \\ {\scriptstyle \mu_\sigma}\swarrow & & \searrow{\scriptstyle \mu_{\sigma'}} \\ X & \xrightarrow{f} & X' \end{array}$$

where both μ_σ and $\mu_{\sigma'}$ are isomorphisms, and then the same holds for f.

(iv) The tensor product of a G-bitorsor and a left G-bitorsor is a left G-torsor. Indeed the assertion can be checked locally on T, so we are reduced to checking that the tensor product of a trivial G-bitorsors and a trivial left G-torsor is the trivial left G-torsor, which is obvious.

(v) Likewise, if $G_1 \to G_2$ is any morphism of T-groups, and X is a left G_1-torsor, it is easily seen that the base change $G_2 \otimes_{G_1} X$ yields a left G_2-torsor (and the same holds for right torsors and bitorsors). Hence the rule $G \mapsto H^1(T,G)$ is a functor from the category of T-groups, to the category of pointed sets. One can check that $H^1(T,G)$ is an essentially small set (see [78, Chap.III, §3.6.6.1]).

(vi) Let $f : T \to S$ be a morphism of topoi; if X is a left G-torsor, the f_*G-module f_*X is not necessarily a f_*G-torsor, since we may not be able to find a covering morphism $U \to 1_S$ such that $f_*X(U) \neq \varnothing$. On the other hand, if H a S-group and Y a left H-torsor, then it is easily seen that f^*Y is a left f^*H-torsor.

4.9.3. Let $f : T' \to T$ be a morphism of topoi, and G a T'-monoid; we define a U-presheaf $R^1 f_*^\wedge G$ on T, by the rule :

$$U \mapsto H^1(T'/f^*U, G_{|f^*U}).$$

(More precisely, since this set is only essentially small, we replace it by an isomorphic small set). If $\varphi : U \to V$ is any morphism in T, and X is any $G_{|f^*V}$-torsor, then $X \times_{f^*V} f^*U$ is a $G_{|f^*U}$-torsor, whose isomorphism class depends only on the isomorphism class of X; this defines the map $R^1 f_*^\wedge G(\varphi)$, and it is clear that $R^1 f_*^\wedge G(\varphi \circ \psi) = R^1 f_*^\wedge G(\psi) \circ R^1 f_*^\wedge G(\varphi)$, for any other morphism $\psi : W \to U$ in T. Lastly, we denote by :

$$R^1 f_* G$$

the sheaf on (T, C_T) associated with the presheaf $R^1 f_*^\wedge G$. Notice that the object $R^1 f_* G$ is *pointed*, *i.e.* it is endowed with a natural global section :

$$\tau_{f,G} : 1_T \to R^1 f_* G$$

namely, the morphism associated with the morphism of presheaves $1_T \to R^1 f_*^\wedge G$ which, for every $U \in \mathrm{Ob}(T)$, singles out the isomorphism class $\tau_{f,G}(U) \in R^1 f_*^\wedge G(U)$ of the trivial $G_{|f^*U}$-torsor.

4.9.4. Let $g : T'' \to T'$ be another morphism of topoi, and G a T''-group. Notice that :

$$f^{*\wedge} R^1 g_*^\wedge G = R^1 (f \circ g)_*^\wedge G$$

hence the natural morphism (in $T'^\wedge$) $R^1 f_*^\wedge G \to R^1 f_* G$ induces a morphism $R^1(f \circ g)_*^\wedge G \to f^{*\wedge} R^1 g_* G$ in $T^\wedge$, which yields, after taking associated sheaves, a morphism in T :

$$R^1 (f \circ g)_* G \to f_* R^1 g_* G. \tag{4.9.5}$$

One sees easily that this is a *morphism of pointed objects* of T, *i.e.* the image of the global section $\tau_{f \circ g, G}$ under this map, is the global section $f_* \tau_{g,G}$.

Next, suppose that $U \in \mathrm{Ob}(T)$ and X is any $g_*G_{|f^*U}$-torsor (on T'/f^*U); we may form the $g^*g_*G_{|g^*f^*U}$-torsor g^*X, and then base change along the natural morphism $g^*g_*G \to G$, to obtain the $G_{|g^*f^*U}$-torsor $G \otimes_{g^*g_*G} g^*X$. This rule yields a map $R^1 f_*^\wedge(g_*G) \to R^1(f \circ g)_*^\wedge G$, and after taking associated sheaves, a natural morphism of pointed objects :

$$R^1 f_*(g_* G) \to R^1 (f \circ g)_* G. \tag{4.9.6}$$

Remark 4.9.7. As a special case, let $h : S' \to S$ be a morphism of topoi, H a S'-group. If we take $T'' := S'$, $T' := S$, $g := h$ and $f : S \to \mathbf{Set}$ the (essentially) unique morphism of topoi, (4.9.6) and (4.9.5) boil down to maps of pointed sets :

$$H^1(S, h_* H) \to H^1(S', H) \to \Gamma(S, R^1 h_* H). \tag{4.9.8}$$

These considerations are summarized in the following :

Theorem 4.9.9. *In the situation of* (4.9.4)*, there exists a natural* exact sequence of pointed objects *of* T *:*

$$1_T \to R^1 f_*(g_*G) \to R^1(f \circ g)_*G \to f_*R^1g_*G.$$

Proof. The assertion means that (4.9.6) identifies $R^1f_*(g_*G)$ with the subobject :

$$R^1(f \circ g)_*G \times_{f_*R^1g_*G} f_*\tau_{g,G}$$

(briefly : the preimage of the trivial global section). We begin with the following :

Claim 4.9.10. In the situation of remark 4.9.7, the sequence of maps (4.9.8) identifies the pointed set $H^1(S, h_*H)$ with the preimage of the trivial global section $\tau_{h,H}$ of R^1h_*H.

Proof of the claim. Notice first that a global section Y of $R^1h_*^\wedge H$ maps to the trivial section $\tau_{h,H}$ of R^1h_*H if and only if there exists a covering morphism $U \to 1_S$ in (S, C_S), such that $Y(h^*U) \neq \varnothing$. Thus, let X be a right h_*H-torsor; the image in $H^1(S', H)$ of its isomorphism class is the class of the H-torsor $Y := h^*X \otimes_{h^*h_*H} H$. The latter defines a global section of R^1h_*H. However, by definition there exists a covering morphism $U \to 1_S$ such that $X(U) \neq \varnothing$, hence also $h^*X(h^*U) \neq \varnothing$, and therefore $Y(h^*U) \neq \varnothing$. This shows that the image of $H^1(S, h_*H)$ lies in the preimage of $\tau_{h,H}$.

Moreover, notice that $h_*Y(U) \neq \varnothing$, hence h_*Y is a h_*H-torsor. Now, let $\varepsilon_H : h^*h_*H \to H$ (resp. $\eta_{h_*H} : h_*H \to h_*h^*h_*H$) be the counit (resp. unit of adjunction); we have a natural morphism $\alpha : h^*X \to Y_{(\varepsilon_H)}$ of h^*h_*H-modules, whence a morphism :

$$h_*\alpha : h_*h^*X \to h_*Y_{(h_*\varepsilon_H)}$$

of $h_*h^*h_*H$-modules. On the other hand, the unit of adjunction $\eta_X : X \to h_*h^*X_{(\eta_{h_*H})}$ is a morphism of h_*H-modules (remark 4.8.11(v)). Since $h_*\varepsilon_H \circ \eta_{h_*H} = \mathbf{1}_{h_*H}$ (see (1.1.13)), the composition $h_*\alpha \circ \eta_X$ is a morphism of h_*H-modules, hence it is an isomorphism, by remark 4.9.2(iii). This implies that the first map of (4.9.8) is injective.

Conversely, suppose that the class of a H-torsor X' gets mapped to $\tau_{h,H}$; we need to show that the class of X' lies in the image of $H^1(S, h_*H)$. However, the assumption means that there exists a covering morphism $U \to 1_S$ such that $X'(h^*U) \neq \varnothing$; by adjunction we deduce that $h_*X'(U) \neq \varnothing$, hence h_*X' is a h_*H-torsor. In order to conclude, it suffices to show that the image in $H^1(S', H)$ of the class of h_*X' is the class of X.

Now, the counit of adjunction $h^*h_*X' \to X'$ is a morphism of h^*h_*H-modules (remark 4.8.11(v)); by adjunction it induces a map $h^*h_*X' \otimes_{h^*h_*H} H \to H$ of H-torsors, which must be an isomorphism, according to remark 4.9.2(iii). ◊

If we apply claim 4.9.10 with $S := T'/f^*U$, $S' := T''/(g^*f^*U)$ and $h := g/(g^*f^*U)$, for U ranging over the objects of T, we deduce an exact sequence of presheaves of pointed sets :

$$1_T \to R^1f_*^\wedge(g_*H) \to R^1(f \circ g)_*^\wedge G \to f^{*\wedge}R^1g_*G$$

from which the theorem follows, after taking associated sheaves. □

4.9.11. Let $f : T' \to T$ be a morphism of topoi, U an object of T, G a T'-group, $p : X \to U$ a right $G_{|U}$-torsor. Then, for every object V of T we have an induced sequence of maps of sets

$$X(f^*V) \xrightarrow{p_*} U(f^*V) \xrightarrow{\partial} R^1f_*^\wedge G(V)$$

where p_* is deduced from p, and for every $\sigma \in U(f^*V)$, we let $\partial(\sigma)$ be the isomorphism class of the right $G_{|f^*V}$-torsor $(X \times_U f^*V \to f^*V)$. Clearly the image of p_* is precisely the preimage of (the isomorphism class of) the trivial $G_{|f^*V}$-torsor. After taking associated sheaves, we deduce a natural sequence of morphisms in T :

$$f_*X \xrightarrow{p} f_*U \xrightarrow{\partial} R^1f_*G \qquad (4.9.12)$$

such that the preimage of the global section $\tau_{f,G}$ is precisely the image in $\Gamma(T', U)$ of the set of global sections of X.

4.9.13. A *ringed topos* is a pair $(T, \mathscr{O}_T)$ consisting of a topos T and a (unital, associative) T-ring $\mathscr{O}_T$, called the *structure ring* of T. A morphism $f : (T, \mathscr{O}_T) \to (S, \mathscr{O}_S)$ of ringed topoi is the datum of a morphism of topoi $f : T \to S$ and a morphism of T-rings :

$$f^\natural : f^*\mathscr{O}_S \to \mathscr{O}_T.$$

We denote, as usual, by $\mathscr{O}_T^\times \subset \mathscr{O}_T$ the subobject representing the invertible sections of $\mathscr{O}_T$. For every object U of T, and every $s \in \mathscr{O}_T(U)$, let $D(s) \subset U$ be the subobject such that :

$$\mathrm{Hom}_T(V, D(s)) := \{\varphi \in U(V) \mid \varphi^* s \in \mathscr{O}_T^\times(V)\}.$$

We say that $(T, \mathscr{O}_T)$ is *locally ringed*, if $D(0) = \varnothing_T$ (the initial object of T), and moreover

$$D(s) \cup D(1-s) = U \qquad \text{for every } U \in \mathrm{Ob}(T), \text{ and every } s \in \mathscr{O}_T(f).$$

A morphism of locally ringed topoi $f : (T, \mathscr{O}_T) \to (S, \mathscr{O}_S)$ is a morphism of ringed topoi such that

$$f^*D(s) = D(f^\natural(U)(f^*s)) \qquad \text{for every } U \in \mathrm{Ob}(S) \text{ and every } s \in \mathscr{O}_S(U).$$

If T has enough points, then $(T, \mathscr{O}_T)$ is locally ringed if and only if the stalks $\mathscr{O}_{T,\xi}$ of the structure ring at all the points ξ of T are local rings. Likewise, a morphism $f : (T, \mathscr{O}_T) \to (S, \mathscr{O}_S)$ of ringed topoi is locally ringed if and only if, for every T-point ξ, the induced map $\mathscr{O}_{S,f(\xi)} \to \mathscr{O}_{T,\xi}$ is a local ring homomorphism.

4.9.14. In the rest of this section we present a few results concerning the special case of topologies on a scheme. Hence, for any scheme X, we shall denote by $X_{\text{ét}}$ (resp. by X_{Zar}) the small étale (resp. the small Zariski) site on X. It is clear that X_{Zar} is a small site, and it is not hard to show that $X_{\text{ét}}$ is a U-site ([9, Exp.VII, §1.7]). The inclusion of underlying categories :

$$u_X : X_{\mathrm{Zar}} \to X_{\text{ét}}$$

is a continuous functor (see definition 4.2.1(i)) commuting with finite limits, whence a morphism of topoi :

$$\widetilde{u}_X := (\widetilde{u}_X^*, \widetilde{u}_{X*}) : X_{\text{ét}}^\sim \to X_{\mathrm{Zar}}^\sim.$$

such that the diagram of functors :

$$\begin{array}{ccc} X_{\mathrm{Zar}} & \xrightarrow{u_X} & X_{\text{ét}} \\ \downarrow & & \downarrow \\ X_{\mathrm{Zar}}^\sim & \xrightarrow{\widetilde{u}_X^*} & X_{\text{ét}}^\sim \end{array}$$

commutes, where the vertical arrows are the Yoneda embeddings (lemma 4.2.11).

The topoi $X_{\mathrm{Zar}}^\sim$ and $X_{\text{ét}}^\sim$ are locally ringed in a natural way, and by faithfully flat descent, we see easily that $\widetilde{u}_{X*}\mathscr{O}_{X_{\text{ét}}} = \mathscr{O}_{X_{\mathrm{Zar}}}$. By inspection, $\widetilde{u}_X$ is a morphism of locally ringed topoi.

4.9.15. For any ring R (of our fixed universe U), denote by Sch/R the category of R-schemes, and by $\mathsf{Sch}/R_{\mathrm{Zar}}$ (resp. $\mathsf{Sch}/R_{\text{ét}}$) the big Zariski (resp. étale) site on Sch/R. For $R = \mathbb{Z}$, we shall usually just write $\mathsf{Sch}_{\mathrm{Zar}}$ and $\mathsf{Sch}_{\text{ét}}$ for these sites. The morphisms u_X of (4.9.13) are actually restrictions of a single morphism of sites :

$$u : \mathsf{Sch}_{\mathrm{Zar}} \to \mathsf{Sch}_{\text{ét}}$$

which, for every universe V such that $\mathsf{U} \in \mathsf{V}$, induces a morphism of V-topoi :

$$\widetilde{u}_{\mathsf{V}} : (\mathsf{Sch}_{\text{ét}})_{\mathsf{V}}^\sim \to (\mathsf{Sch}_{\mathrm{Zar}})_{\mathsf{V}}^\sim.$$

4.9.16. Let X be scheme; a *geometric point* of X is a morphism of schemes $\xi : \mathrm{Spec}\,\kappa \to X$, where κ is an arbitrary separably closed field. Notice that both the Zariski and étale topoi of $\mathrm{Spec}\,\kappa$ are equivalent to the category $\mathbf{Set}$, so ξ induces a topos-theoretic point $\xi^{\sim}_{\text{ét}} : (\mathrm{Spec}\,\kappa)^{\sim}_{\text{ét}} \to X^{\sim}_{\text{ét}}$ of $X^{\sim}_{\text{ét}}$ (and likewise for $X^{\sim}_{\mathrm{Zar}}$). A basic feature of both the Zariski and étale topologies, is that every point of $X^{\sim}_{\mathrm{Zar}}$ and $X^{\sim}_{\text{ét}}$ arise in this way.

More precisely, we say that two geometric points ξ and ξ' of X are *equivalent*, if there exists a third such point ξ'' which factors through both ξ and ξ'. It is easily seen that this is an equivalence relation on the set of geometric points of X, and two topos-theoretic points $\xi^{\sim}_{\text{ét}}$ and $\xi'^{\sim}_{\text{ét}}$ are isomorphic if and only if the same holds for the points $\xi^{\sim}_{\mathrm{Zar}}$ and $\xi'^{\sim}_{\mathrm{Zar}}$, if and only if ξ is equivalent to ξ'.

Definition 4.9.17. Let X be a scheme, x a point of X, and $\overline{x} : \mathrm{Spec}\,\kappa \to X$ a geometric point.

(i) We let $\kappa(x)$ be the residue field of the local ring $\mathscr{O}_{X,x}$, and set

$$|x| := \mathrm{Spec}\,\kappa(x) \qquad \kappa(\overline{x}) := \kappa \qquad |\overline{x}| := \mathrm{Spec}\,\kappa(\overline{x})$$

If $\{x\} \subset X$ is the image of $\overline{x}$, we say that $\overline{x}$ is *localized at* x, and that x is the *support* of $\overline{x}$. We say that $\overline{x}$ is *strict* if $\kappa(\overline{x})$ is a separable closure of $\kappa(x)$.

(ii) We associate with $\overline{x}$ a strict geometric point $\overline{x}^{\mathrm{st}}$, as follows. Let $\kappa(\overline{x}^{\mathrm{st}})$ be the separable closure of $\kappa(x)$ inside $\kappa(\overline{x})$; the inclusion $\kappa(\overline{x}^{\mathrm{st}}) \subset \kappa(\overline{x})$ defines a morphism of schemes :

$$|\overline{x}| \to |\overline{x}^{\mathrm{st}}| := \mathrm{Spec}\,\kappa(\overline{x}^{\mathrm{st}}) \tag{4.9.18}$$

and $\overline{x}$ is the composition of (4.9.18) and a unique strict geometric point localized at x

$$\overline{x}^{\mathrm{st}} : |\overline{x}^{\mathrm{st}}| \to X.$$

(iii) The *localization of* X *at* x is the local scheme

$$X(x) := \mathrm{Spec}\,\mathscr{O}_{X,x}.$$

The *strict henselization of* X *at* $\overline{x}$ is the strictly local scheme

$$X(\overline{x}) := \mathrm{Spec}\,\mathscr{O}_{X,\overline{x}}$$

where $\mathscr{O}_{X,\overline{x}}$ denotes the strict henselization of $\mathscr{O}_{X,x}$ relative to the geometric point $\overline{x}$ ([66, Ch.IV, Déf.18.8.7]) (recall that a local ring is called *strictly local*, if it is henselian with separably closed residue field; a scheme is called *strictly local*, if it is the spectrum of a strictly local ring: see [66, Ch.IV, Déf.18.8.2]). By definition, the geometric point $\overline{x}$ lifts to a unique geometric point of $X(\overline{x})$, which shall be denoted again by $\overline{x}$.

(iv) Moreover, we shall denote by

$$i_x : X(x) \to X \qquad i_{\overline{x}} : X(\overline{x}) \to X(x)$$

the natural morphisms of schemes, and if $\mathscr{F}$ is any sheaf on X_{Zar} (resp. $X_{\text{ét}}$), we let

$$\mathscr{F}(x) := i_x^*\mathscr{F} \qquad \mathscr{F}(\overline{x}) := i_{\overline{x}}^*\mathscr{F}(x)$$

so $\mathscr{F}(x)$ is a sheaf on $X(x)_{\mathrm{Zar}}$ (resp. $X(x)_{\text{ét}}$) and $\mathscr{F}(\overline{x})$ is a sheaf on $X(\overline{x})_{\mathrm{Zar}}$ (resp. $X(\overline{x})_{\text{ét}}$).

(v) If $f : Y \to X$ is any morphism of schemes, we let

$$f^{-1}(x) := Y \times_X |x| \quad f^{-1}(\overline{x}) := Y \times_X |\overline{x}| \qquad Y(x) := Y \times_X X(x) \quad Y(\overline{x}) := Y \times_X X(\overline{x}).$$

Also, if $\overline{y}$ is any geometric point of Y, we define $f(\overline{y})$ as the geometric point $f \circ \overline{y}$ of X, and we call $f(\overline{y})^{\mathrm{st}}$ the *strict image* of $\overline{y}$ in X. Notice that the natural identification $|\overline{y}| = |f(\overline{y})|$ induces a morphism of schemes :

$$|\overline{y}^{\mathrm{st}}| \to |f(\overline{y})^{\mathrm{st}}|.$$

4.9.19. Many discussions concerning the Zariski or étale site of a scheme, only make appeal to general properties of these two topologies, and therefore apply indifferently to either of them, with only minor verbal changes. For this reason, to avoid tiresome repetitions, the following notational device is often useful. Namely, instead of referring each time to X_{Zar} and $X_{\text{ét}}$ in the course of an argument, we shall write just X_τ, with the convention that $\tau \in \{\mathrm{Zar}, \text{ét}\}$ has been chosen arbitrarily at the beginning of the discussion. In the same manner, a τ-point of X will mean a point of the topos $X_\tau^\sim$, and a τ-open subset of X will be any object of the site X_τ. With this convention, a Zar-point is a usual point of X, whereas an ét-point shall be a geometric point. Likewise, if ξ is a given τ-point of X, the localization $X(\xi)$ makes sense for both topologies : if $\tau = \text{ét}$, then $X(\xi)$ is the strict henselization as in definition 4.9.17(ii); if $\tau = \mathrm{Zar}$, then $X(\xi)$ is the usual localization of X at the (Zariski) point ξ. If $\tau = \text{ét}$, the support of ξ is given by definition 4.9.17(i); if $\tau = \mathrm{Zar}$, then the support of ξ is just ξ itself (and correspondingly, in this case ξ is localized at ξ). Furthermore, $\mathscr{O}_{X,\xi}$ is a local ring if $\tau = \mathrm{Zar}$, and it is a strictly local ring, in case $\tau = \text{ét}$.

4.9.20. Let $f : X \to Y$ be a morphism of schemes, $\overline{x}$ a geometric point of X, and set $\overline{y} := f(\overline{x})$. The natural morphism $f_x : X(x) \to Y(y)$ induces a unique local morphism of strictly local schemes

$$f_{\overline{x}} : X(\overline{x}) \to Y(\overline{y})$$

([66, Ch.IV, Prop.18.8.8(ii)]) that fits in a commutative diagram :

$$\begin{array}{ccccccc}
|\overline{x}| & \xrightarrow{\overline{x}} & X(\overline{x}) & \xrightarrow{i_{\overline{x}}} & X(x) & \xrightarrow{i_x} & X \\
\Vert & & \downarrow{\scriptstyle f_{\overline{x}}} & & \downarrow{\scriptstyle f_x} & & \downarrow{\scriptstyle f} \\
|\overline{y}| & \xrightarrow{\overline{y}} & Y(\overline{y}) & \xrightarrow{i_{\overline{y}}} & Y(y) & \xrightarrow{i_y} & Y.
\end{array}$$

Let now $\mathscr{F}$ be any sheaf on $Y_{\text{ét}}$; there follows a natural isomorphism :

$$f_{\overline{x}}^*\mathscr{F}(\overline{y}) \xrightarrow{\sim} (f^*\mathscr{F})(\overline{x}).$$

Notice also the natural bijections :

$$\begin{aligned}
\mathscr{F}_{\overline{y}} &\xrightarrow{\sim} \Gamma(Y(\overline{y}), \mathscr{F}(\overline{y})) \xrightarrow{\sim} \Gamma(|\overline{y}|, \overline{y}^*\mathscr{F}(\overline{y})) \\
f^*\mathscr{F}_{\overline{x}} &\xrightarrow{\sim} \Gamma(X(\overline{x}), f^*\mathscr{F}(\overline{x})) \xrightarrow{\sim} \Gamma(|\overline{x}|, \overline{x}^* f^*\mathscr{F}(\overline{x}))
\end{aligned} \tag{4.9.21}$$

which induce a natural identification :

$$\mathscr{F}_{\overline{y}} \xrightarrow{\sim} f^*\mathscr{F}_{\overline{x}} \quad : \quad \sigma \mapsto f_{\overline{x}}^*(\sigma). \tag{4.9.22}$$

4.9.23. Let X be a scheme, $x, x' \in X$ any two points, such that x is a specialization of x'. Choose a geometric point $\overline{x}$ localized at x. The localization map $\mathscr{O}_{X,x} \to \mathscr{O}_{X,x'}$ induces a natural *specialization morphism* of X-schemes :

$$X(x') \to X(x).$$

Set $W := X(\overline{x}) \times_{X(x)} X(x')$. The natural map $g : W \to X(x')$ is faithfully flat, and is the limit of a cofiltered system of étale morphisms; hence we may find $w \in W$ lying over the closed point of $X(x')$, and the induced map $\kappa(x') \to \kappa(w)$ is algebraic and separable. Choose also a geometric point $\overline{w}$ of W localized at w, and set $\overline{x}' := g(\overline{w})$. Then g induces an isomorphism $g_{\overline{w}} : W(\overline{w}) \xrightarrow{\sim} X(\overline{x}')$, whence a unique morphism

$$X(\overline{x}') \to X(\overline{x}) \tag{4.9.24}$$

which makes commute the diagram :

$$\begin{array}{ccccc} W(\overline{w}) & \xrightarrow{g_{\overline{w}}} & X(\overline{x}') & \xrightarrow{i_{\overline{x}'}} & X(x') \\ {\scriptstyle i_{\overline{w}}}\downarrow & & \downarrow & & \downarrow \\ W(w) & \longrightarrow & X(\overline{x}) & \xrightarrow{i_{\overline{x}}} & X(x) \end{array}$$

where the left bottom arrow is the natural projection, and the right-most vertical arrow is the specialization map. In this situation, we say that $\overline{x}$ is a *specialization* of $\overline{x}'$ (and that $\overline{x}'$ is a *generization* of $\overline{x}$), and we call (4.9.24) a *strict specialization morphism.* Combining with (4.9.21), we obtain the *strict specialization map induced by* (4.9.24)

$$\mathscr{G}_{\overline{x}} \to \mathscr{G}_{\overline{x}'} \qquad (4.9.25)$$

for every sheaf $\mathscr{G}$ on $X_{\text{ét}}$.

Remark 4.9.26. (i) In the situation of (4.9.20), suppose that $\mathscr{G} = f^*\mathscr{F}$ for a sheaf $\mathscr{F}$ on $Y_{\text{ét}}$. Then (4.9.25) is a map $\mathscr{F}_{f(\overline{x})} \to \mathscr{F}_{f(\overline{x}')}$. By inspecting the definition, it is easily seen that the latter agrees with the strict specialization map for $\mathscr{F}$ induced by a unique strict specialization morphism $Y(f(\overline{x}')) \to Y(f(\overline{x}))$.

(ii) Notice that (4.9.24) and (4.9.25) depend not only on the choice of w (which may not be unique, when $X(x)$ is not unibranch) but also on the geometric point $\overline{w}$. Indeed, the group of automorphisms of the $X(x')$-scheme $X(\overline{x}')$ is naturally isomorphic to the Galois group $\mathrm{Gal}(\kappa(x')^{\mathrm{s}}/\kappa(x'))$ ([66, Ch.IV, (18.8.8.1)]).

Lemma 4.9.27. *Let X be a scheme, $\mathscr{F}$ a sheaf on $X_{\text{ét}}$. We have :*

(i) *The counit of the adjunction $\varepsilon_{\mathscr{F}} : \widetilde{u}_X^* \circ \widetilde{u}_{X*}\mathscr{F} \to \mathscr{F}$ is a monomorphism.*
(ii) *Suppose there exist a sheaf $\mathscr{G}$ on X_{Zar}, and an epimorphism $f : \widetilde{u}^*\mathscr{G} \to \mathscr{F}$ (resp. a monomorphism $f : \mathscr{F} \to \widetilde{u}^*\mathscr{G}$). Then $\varepsilon_{\mathscr{F}}$ is an isomorphism.*
(iii) *The functor $\widetilde{u}_X^*$ is fully faithful.*
(iv) (Hilbert 90) $R^1\widetilde{u}_{X*}\mathscr{O}^\times_{X_{\text{ét}}} = 1_{X_{\text{Zar}}}$.

Proof. (i): The assertion can be checked on the stalks. Hence, let ξ be any geometric point of X; we have to show that the natural map $(\widetilde{u}_{X*}\mathscr{F})_\xi \to \mathscr{F}_\xi$ is injective. To this aim, say that $s, s' \in (\widetilde{u}_{X*}\mathscr{F})_\xi$, and suppose that the image of s in $\mathscr{F}_\xi$ agrees with the image of s'; we may find an open neighborhood U of ξ in X_{Zar}, such that s and s' lie in the image of $\mathscr{F}(U)$, and by assumption, there exists an étale morphism $f : V \to U$ such that the images of s and s' coincide in $\mathscr{F}(V)$. However, $f(V) \subset U$ is an open subset ([64, Ch.IV, Th.2.4.6]), and the induced map $V \to f(V)$ is a covering morphism in $X_{\text{ét}}$; it follows that the images of s and s' agree already in $\mathscr{F}(f(V))$, therefore also in $(\widetilde{u}_{X*}\mathscr{F})_\xi$.

(iii): According to proposition 1.1.20(iii), it suffices to show that the unit of the adjunction $\eta_{\mathscr{G}} : \mathscr{G} \to \widetilde{u}_{X*} \circ \widetilde{u}_X^*\mathscr{G}$ is an isomorphism, for every $\mathscr{G} \in \mathrm{Ob}(X^\sim_{\text{Zar}})$. However, we have morphisms :

$$\widetilde{u}_X^*\mathscr{G} \xrightarrow{\widetilde{u}_X^*(\eta_{\mathscr{G}})} \widetilde{u}_X^* \circ \widetilde{u}_{X*} \circ \widetilde{u}_X^*\mathscr{G} \xrightarrow{\varepsilon_{\widetilde{u}_X^*\mathscr{G}}} \widetilde{u}_X^*\mathscr{G}.$$

whose composition is the identity of $\widetilde{u}_X^*\mathscr{G}$ (see (1.1.13)); also, (i) says that $\varepsilon_{\widetilde{u}_X^*\mathscr{G}}$ is a monomorphism, and then it follows formally that it is actually an isomorphism (*e.g.* from the dual of [28, Prop.1.9.3]). Hence the same holds for $\widetilde{u}_X^*(\eta_{\mathscr{G}})$, and by considering the stalks of the latter, we conclude that also $\eta_{\mathscr{G}}$ is an isomorphism, as required.

(ii): Suppose first that $f : \widetilde{u}^*\mathscr{G} \to \mathscr{F}$ is an epimorphism. We have just seen that $\eta_{\mathscr{G}}$ is an isomorphism, therefore we have a morphism $\widetilde{u}^* \circ \widetilde{u}_* f : \widetilde{u}^*\mathscr{G} \to \widetilde{u}^* \circ \widetilde{u}_*\mathscr{F}$ whose composition with $\varepsilon_{\mathscr{F}}$ is f; especially, $\varepsilon_{\mathscr{F}}$ is an epimorphism, so the assertion follows from (i).

In the case of a monomorphism $f : \mathscr{F} \to \widetilde{u}^*\mathscr{G}$, set $\mathscr{H} := \widetilde{u}^*\mathscr{G} \amalg_{\mathscr{F}} \widetilde{u}^*\mathscr{G}$; we may represent f as the equalizer of the two natural maps $j_1, j_2 : \widetilde{u}^*\mathscr{G} \to \mathscr{H}$. However, the natural morphism

$\widetilde{u}^*(\mathscr{G} \amalg \mathscr{G}) \to \mathscr{H}$ is an epimorphism, hence the counit $\varepsilon_{\mathscr{H}}$ is an isomorphism, by the previous case. Then (iii) implies that $j_i = \widetilde{u}^* j'_i$ for morphisms $j'_i : \mathscr{G} \to \widetilde{u}_* \mathscr{H}$ ($i = 1, 2$). Let $\mathscr{F}'$ be the equalizer of j'_1 and j'_2; then $\widetilde{u}^*\mathscr{F}' \simeq \mathscr{F}$, and since we have already seen that the unit of adjunction is an isomorphism, the assertion follows from the triangular identitities of (1.1.13).

(iv): The assertion can be checked on the stalks. To ease notation, set $\mathscr{F} := R^1\widetilde{u}_{X*}\mathscr{O}^\times_{X_{\text{ét}}}$. Let ξ be any geometric point of X, and say that $s \in \mathscr{F}_\xi$; pick a (Zariski) open neighborhood $U \subset X$ of ξ such that s lies in the image of $\mathscr{F}(U)$. We may then find a Zariski open covering $(U_\lambda \to U \mid \lambda \in \Lambda)$ of U, such that the image of s in $\mathscr{F}(U_i)$ is represented by a $\mathscr{O}^\times_{U_\lambda,\text{ét}}$-torsor on $U_{\lambda,\text{ét}}$, for every $\lambda \in \Lambda$. After replacing U by any U_λ containing the support of ξ, we may assume that s is the image of the isomorphism class of some $\mathscr{O}^\times_{U_{\text{ét}}}$-torsor $X_{\text{ét}}$ on $U_{\text{ét}}$. By faithfully flat descent, there exist a $\mathscr{O}^\times_{U_{\text{Zar}}}$-torsor X on U_{Zar}, and an isomorphism of $\mathscr{O}^\times_{U_{\text{ét}}}$-torsors :

$$X_{\text{ét}} \xrightarrow{\sim} \mathscr{O}^\times_{U_{\text{ét}}} \otimes_{\widetilde{u}^*_U \mathscr{O}^\times_{U_{\text{Zar}}}} \widetilde{u}^*_U X.$$

However, after replacing U by a smaller open neighborhood of ξ, we may suppose that $X(U) \neq \varnothing$, therefore $X_{\text{ét}}(U) \neq \varnothing$ as well, *i.e.* s is the image of the trivial section of $\mathscr{F}(U)$. □

5. Stacks

Let $(\mathscr{C}, J)$ be any site, and consider the rule that assigns to every $U \in \text{Ob}(\mathscr{C})$ the category $(U, J_U)^\sim$ of sheaves on $\mathscr{C}/U$, for the topology J_U induced by J via the source functor $\mathscr{C}/U \to \mathscr{C}$. Every morphism $g : U' \to U$ of $\mathscr{C}$ induces a pull-back functor $\widetilde{g}^* : (U, J_U)^\sim \to (U', J_{U'})^\sim$, but if $g' : U'' \to U'$ is another such morphism, the composition $\widetilde{g}'^* \circ \widetilde{g}^*$ is not usually equal, but only *isomorphic* to the pull-back functor induced by $g \circ g'$. Moreover, given a covering family $(U_i \to U \mid i \in I)$, we can describe the category $(U, J_U)^\sim$ only *up to equivalence* in terms of the corresponding categories on the U_i and their intersections; this "gluing up to equivalence" is a 2-categorical manipulation of descent data relative to the given covering, so it involves not only double intersections $U_i \times U_j$, but also triple intersections. Summing up, the rule $U \mapsto (U, J_U)^\sim$ does not quite define a sheaf of categories on C, but rather a kind of 2-categorical analogue of the latter : it is the first example of a structure that is often encountered in algebraic geometry, and whose systematic study is the subject of the *theory of stacks* developed in this chapter.

5.1. **Prestacks and stacks on a site.**

As usual, U will denote a chosen universe, and small will be synonymous with U-small, throughout this section.

Definition 5.1.1. Let $C := (\mathscr{C}, J)$ be a site, $\varphi : \mathscr{A} \to \mathscr{C}$ a fibration, and $i \leq 2$ an integer. We say that φ is an *i-separated prestack* if for every $X \in \text{Ob}(\mathscr{C})$, every $\mathscr{S} \in J(X)$ is a sieve of φ-i-descent (see definition 3.5.10). A 2-separated prestack is called a *stack*. For every universe V, we denote by

$$\mathsf{V}\text{-}i\text{-}\mathsf{PreStack}(C) \qquad (\text{resp. } \mathsf{V}\text{-}\mathsf{Stack}(C)\ )$$

the full 2-subcategory of $\mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C})$ whose objects are the i-separated prestacks (resp. the stacks) on C. Hence $\mathsf{V}\text{-}(-1)\text{-}\mathsf{PreStack}(C) = \mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C})$ and $\mathsf{V}\text{-}2\text{-}\mathsf{PreStack}(C) = \mathsf{V}\text{-}\mathsf{Stack}(C)$. As usual, if $\mathsf{V} = \mathsf{U}$ we often drop the mention of the universe from this notation.

Example 5.1.2. Let $(\mathscr{C}, J)$ be any site, F any presheaf on $\mathscr{C}$, and $\mathsf{s}_F : \mathscr{F}ib(F) \to \mathscr{C}$ the fibration attached to F, as in (3.1.15). Let also $X \in \text{Ob}(\mathscr{C})$ be any object, and $\mathscr{S}$ any sieve of $\mathscr{C}/X$; by (3.1.15) and remark 3.5.2(ii) we have a commutative diagram

$$\begin{array}{ccc} FX = \text{Hom}_{\mathscr{C}^\wedge}(h_X, F) & \longrightarrow & \text{Hom}_{\mathscr{C}^\wedge}(h_{\mathscr{S}}, F) \\ \downarrow & & \downarrow \\ \mathscr{F}ib(F)(X) & \longrightarrow & \mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, \mathscr{F}ib(F)) \end{array}$$

whose vertical arrows are bijections, and whose top (resp. bottom) horizontal arrow is induced by the inclusion $h_{\mathscr{S}} \to h_X$ (resp. $\mathscr{S} \subset \mathscr{C}/X$). We conclude that $\mathscr{F}ib(F)$ is a 0-separated prestack; by the same token, $\mathscr{F}ib(F)$ is a 1-separated prestack (resp. a stack) if and only if F is a separated presheaf (resp. a sheaf). Thus, we get a commutative diagram of functors

$$(5.1.3)\qquad \begin{array}{ccc} (\mathscr{C}, J)^{\sim} & \longrightarrow & \mathsf{Stack}(\mathscr{C}, J) \\ \downarrow & & \downarrow \\ \mathscr{C}^{\wedge} & \xrightarrow{\mathscr{F}ib} & 0\text{-}\mathsf{PreStack}(\mathscr{C}, J) \end{array}$$

(whose vertical arrows are the inclusion functors) which allows us to regard $(\mathscr{C}, J)^{\sim}$ as a full subcategory of $\mathsf{Stack}(\mathscr{C}, J)$.

5.1.4. We can characterize 0-separated and 1-separated prestacks on a small site $C := (\mathscr{C}, J)$ by means of the following construction. Let $\mathscr{A} \to \mathscr{C}$ be any fibration with small fibres. To every $X \in \mathrm{Ob}(\mathscr{C})$ and every pair of cartesian sections $\sigma, \sigma' \in \mathscr{A}(X)$ we attach the presheaf

$$\mathscr{C}art(\sigma, \sigma') : (\mathscr{C}/X)^o \to \mathbf{Set} \qquad (Y \xrightarrow{f} X) \mapsto \mathsf{Cart}_{\mathscr{C}}(\sigma \circ f_*, \sigma' \circ f_*)$$

which assigns to every morphism $(Z \xrightarrow{g} X) \xrightarrow{h/X} (Y \xrightarrow{f} X)$ of $\mathscr{C}/X$ the map

$$\mathscr{C}art(\sigma, \sigma')(f) \to \mathscr{C}art(\sigma, \sigma')(g) \qquad \beta \mapsto \beta * h_*$$

(with $f_* : \mathscr{C}/Y \to \mathscr{C}/X$ and $h_* : \mathscr{C}/Z \to \mathscr{C}/Y$ as in (1.1.25)). Notice that :

$$(5.1.5)\qquad (f_*)^{\wedge}\mathscr{C}art(\sigma, \sigma') = \mathscr{C}art(\sigma \circ f_*, \sigma' \circ f_*) \qquad \text{for every } (Y \xrightarrow{f} X) \in \mathrm{Ob}(\mathscr{C}/X).$$

Moreover, for every $\sigma, \sigma', \sigma'' \in \mathscr{A}(X)$, the system of composition maps

$$\mathsf{Cart}_{\mathscr{C}}(\sigma \circ f_*, \sigma' \circ f_*) \times \mathsf{Cart}_{\mathscr{C}}(\sigma' \circ f_*, \sigma'' \circ f_*) \to \mathsf{Cart}_{\mathscr{C}}(\sigma \circ f_*, \sigma'' \circ f_*) \qquad (\beta, \beta') \mapsto \beta' \odot \beta$$

clearly defines a morphism of presheaves on $\mathscr{C}/X$:

$$(5.1.6)\qquad \mathscr{C}art(\sigma, \sigma') \times \mathscr{C}art(\sigma', \sigma'') \to \mathscr{C}art(\sigma, \sigma'').$$

Furthermore, every pair of isomorphisms of cartesian sections : $\mu : \sigma \xrightarrow{\sim} \tau$, $\mu' : \sigma' \xrightarrow{\sim} \tau'$ induces an isomorphism of presheaves

$$(5.1.7)\quad \mathscr{C}art(\sigma, \sigma') \xrightarrow{\sim} \mathscr{C}art(\tau, \tau') \qquad (\beta : \sigma \circ f_* \Rightarrow \sigma' \circ f_*) \mapsto (\mu' * f_*) \odot \beta \odot (\mu^{-1} * f_*).$$

Lastly, every cartesian functor $F : \mathscr{A} \to \mathscr{A}'$ of $\mathscr{C}$-fibrations yields a morphism of presheaves :

$$(5.1.8)\qquad \mathscr{C}art(\sigma, \sigma') \to \mathscr{C}art(F \circ \sigma, F \circ \sigma') \qquad \beta \mapsto F * \beta.$$

Lemma 5.1.9. *With the notation of* (5.1.4)*, the following conditions are equivalent :*

(a) *The fibration $\mathscr{A} \to \mathscr{C}$ is 0-separated (resp. 1-separated).*
(b) *For every $X \in \mathrm{Ob}(\mathscr{C})$ and every pair of cartesian sections $\sigma, \sigma' \in \mathscr{A}(X)$, the presheaf $\mathscr{C}art(\sigma, \sigma')$ is separated (resp. is a sheaf) on the site C/X (notation of* (4.7)*).*

Proof. Let $X \in \mathrm{Ob}(\mathscr{C})$ be any object, and $\mathscr{S} \subset \mathscr{C}/X$ any covering sieve; choose a generating family $(f_i : Y_i \to X \mid i \in I)$ for $\mathscr{S}$, and for every $i, j \in I$ set $\mathscr{C}/Y_{ij} := \mathscr{C}/Y_i \times_{\mathscr{C}/X} \mathscr{C}/Y_j$. There follows a commutative diagram :

$$\begin{array}{ccccc} \mathscr{A}(X) & \xrightarrow{\mathsf{Cart}_{\mathscr{C}}(j, \mathscr{A})} & \mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, \mathscr{A}) & & \\ & \searrow^{\rho} & \downarrow{\scriptstyle \varepsilon^*} & & \\ & & \prod_{i \in I} \mathscr{A}(Y_i) & \overset{\partial_0^*}{\underset{\partial_1^*}{\rightrightarrows}} & \prod_{i,j \in I} \mathsf{Cart}_{\mathscr{C}}(\mathscr{C}/Y_{ij}, \mathscr{A}) \end{array}$$

where $j : \mathscr{S} \to \mathscr{C}/X$ is the inclusion functor, ρ is the unique functor whose composition with the projection onto the factor $\mathscr{A}(Y_i)$ agrees with $\mathsf{Cart}_{\mathscr{C}}(f_{i*}, \mathscr{A})$, for every $i \in I$, and the functors ε^*, ∂_0^* and ∂_1^* are as in remark 3.5.11. Clearly ε^* is faithful; it follows that ρ is faithful if and only if the same holds for $\mathsf{Cart}_{\mathscr{C}}(j, \mathscr{A})$. On the other hand, the family $((f_i/X) : f_i \to \mathbf{1}_X \mid i \in I)$ of morphisms of $\mathscr{C}/X$ covers $\mathbf{1}_X$, according to (4.7). Taking into account (5.1.5), we conclude easily that $\mathscr{A}$ is 0-separated if and only if all the presheaves $\mathscr{C}art(\sigma, \sigma')$ are separated. Next, by remark 3.5.11 the functor ε^* induces an isomorphism of $\mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, \mathscr{A})$ onto the equalizer E of ∂_0^* and ∂_1^*, and clearly ρ factors through a unique functor $\rho' : \mathscr{A}(X) \to E$. It follows that ρ' is fully faithful if and only if the same holds for $\mathsf{Cart}_{\mathscr{C}}(j, \mathscr{A})$. Again, this means that $\mathscr{A}$ is 1-separated if and only if all the presheaves $\mathscr{C}art(\sigma, \sigma')$ are sheaves. □

Theorem 5.1.10. *Let $C := (\mathscr{C}, J)$ be any small site. The inclusion strict pseudo-functor* $1\text{-}\mathsf{PreStack}(C) \to \mathsf{Fib}(\mathscr{C})$ *admits a strict and strong left 2-adjoint pseudo-functor :*

$$\mathsf{Fib}(\mathscr{C}) \to 1\text{-}\mathsf{PreStack}(C) \qquad \mathscr{A} \mapsto \mathscr{A}^{\mathrm{sep}}.$$

Proof. Let $\mathscr{A} \to \mathscr{C}$ be any fibration with small fibre categories; pick a unital cleavage $\boldsymbol{\lambda}$ for $\mathscr{A}$, and let c be its associated unital pseudo-functor. For every $X \in \mathrm{Ob}(\mathscr{C})$ consider the functor

$$\beta_X^{\boldsymbol{\lambda}} : \mathscr{A}_X \to \mathscr{A}(X) \qquad A \mapsto \beta_{X,A}^{\boldsymbol{\lambda}}$$

defined as in the proof of theorem 3.2.7. For every $A, A' \in \mathrm{Ob}(\mathscr{A}_X)$, consider as well the map

$$\omega_{A,A'} : \mathrm{Hom}_{\mathscr{A}_X}(A, A') \to \mathscr{C}art(\beta_{X,A}^{\boldsymbol{\lambda}}, \beta_{X,A'}^{\boldsymbol{\lambda}})(\mathbf{1}_X) \qquad (f : A \to A') \mapsto \beta_{X,f}^{\boldsymbol{\lambda}}.$$

Let $\mathscr{H}_{A,A'}$ be the sheaf on C/X associated with the presheaf $\mathscr{C}art(\beta_{X,A}^{\boldsymbol{\lambda}}, \beta_{X,A'}^{\boldsymbol{\lambda}})$, and denote

$$\widetilde{\omega}_{A,A'} : \mathrm{Hom}_{\mathscr{A}_X}(A, A') \to H_{A,A'} := \mathscr{H}_{A,A'}(\mathbf{1}_X)$$

the composition of $\omega_{A,A'}$ with the natural map $\mathscr{C}art(\beta_{X,A}^{\boldsymbol{\lambda}}, \beta_{X,A'}^{\boldsymbol{\lambda}})(\mathbf{1}_X) \to H_{A,A'}$. For every $A, A', A'' \in \mathrm{Ob}(\mathscr{A}_X)$, we have morphisms of presheaves as in (5.1.6)

$$\mathscr{C}art(\beta_{X,A}^{\boldsymbol{\lambda}}, \beta_{X,A'}^{\boldsymbol{\lambda}}) \times \mathscr{C}art(\beta_{X,A'}^{\boldsymbol{\lambda}}, \beta_{X,A''}^{\boldsymbol{\lambda}}) \to \mathscr{C}art(\beta_{X,A}^{\boldsymbol{\lambda}}, \beta_{X,A''}^{\boldsymbol{\lambda}})$$

whence a morphism of sheaves $\mathscr{H}_{A,A'} \times \mathscr{H}_{A',A''} \to \mathscr{H}_{A,A''}$, which induces a composition map :

$$H_{A,A'} \times H_{A',A''} \to H_{A,A''}.$$

It is easily seen that this composition law is associative, for every $A, A', A'', A''' \in \mathrm{Ob}(\mathscr{A}_X)$, and $\widetilde{\omega}_{A,A}(\mathbf{1}_A)$ is neutral for left and right composition. Hence, we have a category $\mathscr{A}_X^{\mathrm{sep}}$ whose set of objects is $\mathrm{Ob}(\mathscr{A}_X)$, and such that $\mathrm{Hom}_{\mathscr{A}_X^{\mathrm{sep}}}(A, A') := H_{A,A'}$ for every $A, A' \in \mathrm{Ob}(\mathscr{A}_X)$, with the foregoing composition law. Furthermore, the system of maps $\widetilde{\omega}_{\bullet\bullet}$ yields a functor

$$\widetilde{\omega}^X : \mathscr{A}_X \to \mathscr{A}_X^{\mathrm{sep}}$$

which is the identity map on objects. Next, notice that for every morphism $g : Y \to X$ in $\mathscr{C}$ and every $A \in \mathrm{Ob}(\mathscr{A}_X)$ we have $\beta_{X,A}^{\boldsymbol{\lambda}}(g) = \beta_{Y,\mathsf{c}_g A}^{\boldsymbol{\lambda}}(\mathbf{1}_Y) = \mathsf{c}_g A$; it follows that there exists a unique isomorphism of cartesian sections

$$\beta_{X,A}^{\boldsymbol{\lambda}} \circ g_* \xrightarrow{\sim} \beta_{Y,\mathsf{c}_g A}^{\boldsymbol{\lambda}} \qquad \text{such that} \qquad \mathbf{1}_Y \mapsto \mathbf{1}_{\mathsf{c}_g A}. \tag{5.1.11}$$

By virtue of (5.1.5) and (5.1.7), the isomorphisms (5.1.11) induce an isomorphism of presheaves

$$\mu_{(A,A')}^g : g_*^{\wedge}\mathscr{C}art(\beta_{X,A}^{\boldsymbol{\lambda}}, \beta_{X,A'}^{\boldsymbol{\lambda}}) \xrightarrow{\sim} \mathscr{C}art(\beta_{Y,\mathsf{c}_g A}^{\boldsymbol{\lambda}}, \beta_{Y,\mathsf{c}_g A'}^{\boldsymbol{\lambda}}) \qquad \text{for every } A, A' \in \mathrm{Ob}(\mathscr{A}_X).$$

Since g_* is continuous and cocontinuous for the topologies of C/X and C/Y (remark 4.7.3(i)), combining with lemma 4.2.15(ii) we deduce a natural isomorphism of sheaves on C/Y :

$$\widetilde{\mu}_{(A,A')}^g : j_g^* \mathscr{H}_{A,A'} \xrightarrow{\sim} \mathscr{H}_{\mathsf{c}_g A, \mathsf{c}_g A'}$$

whence a map $\mathsf{d}^g_{A,A'} : H_{A,A'} \xrightarrow{\mathscr{H}_{A,A'}(g/X)} \mathscr{H}_{A,A'}(g) \xrightarrow{\widetilde{\mu}^g_{(A,A'),\mathbf{1}_Y}} H_{\mathsf{c}_g A,\mathsf{c}_g A'}$ and it is then easily seen that the rules : $A \mapsto \mathsf{c}_g A$ for every $A \in \mathrm{Ob}(\mathscr{A}_X)$ and $f \mapsto \mathsf{d}^g_{A,A'}(f)$ for every morphism $f : A \to A'$ of $\mathscr{A}_X^{\mathrm{sep}}$ define a functor

$$\mathsf{d}_g : \mathscr{A}_X^{\mathrm{sep}} \to \mathscr{A}_Y^{\mathrm{sep}}.$$

Furthermore, a direct inspection yields a commutative diagram :

$$\begin{array}{ccc}
\mathrm{Hom}_{\mathscr{A}_X}(A, A') & \xrightarrow{\widetilde{\omega}_{A,A'}} & H_{A,A'} \\
{\scriptstyle \mathsf{c}_{g,(A,A')}}\downarrow & & \downarrow{\scriptstyle \mathsf{d}^g_{A,A'}} \\
\mathrm{Hom}_{\mathscr{A}_Y}(\mathsf{c}_g A, \mathsf{c}_g A') & \xrightarrow{\widetilde{\omega}_{\mathsf{c}_g A,\mathsf{c}_g A'}} & H_{\mathsf{c}_g A,\mathsf{c}_g A'}
\end{array}$$

where $\mathsf{c}_{g,(A,A')}$ is the map given by the functor $\mathsf{c}_g : \mathscr{A}_X \to \mathscr{A}_Y$. In other words :

$$\mathsf{d}_g \circ \widetilde{\omega}^X = \widetilde{\omega}^Y \circ \mathsf{c}_g.$$

Next, let $Y' \xrightarrow{g'} Y \xrightarrow{g} X$ be two morphisms of $\mathscr{C}/X$; for every $A \in \mathrm{Ob}(\mathscr{A}_X)$ there exists a unique isomorphism of cartesian sections

$$(5.1.12) \qquad \beta^{\boldsymbol{\lambda}}_{Y',\mathsf{c}_{g'}\mathsf{c}_g A} \xrightarrow{\sim} \beta^{\boldsymbol{\lambda}}_{Y',\mathsf{c}_{gg'} A} \qquad \text{such that} \qquad \mathbf{1}_{Y'} \mapsto (\gamma^{\mathsf{c}}_{(g,g'),A} : \mathsf{c}_{g'}\mathsf{c}_g A \xrightarrow{\sim} \mathsf{c}_{gg'} A)$$

where $\gamma^{\mathsf{c}}_{(\bullet,\bullet)}$ denotes the coherence constraint of c. Denote by

$$\gamma^{\mathsf{d}}_{(g,g'),A} \in \mathrm{Hom}_{\mathscr{A}^{\mathrm{sep}}_{Y'}}(\mathsf{c}_g\mathsf{c}_{g'} A, \mathsf{c}_{gg'} A)$$

the image of (5.1.12), where the latter is seen as an element of $\mathscr{C}art(\beta^{\boldsymbol{\lambda}}_{Y',\mathsf{c}_{g'}\mathsf{c}_g A}, \beta^{\boldsymbol{\lambda}}_{Y',\mathsf{c}_{gg'} A})(\mathbf{1}_{Y'})$. A direct inspection of the construction yields a commutative diagram :

$$\begin{array}{ccc}
(g \circ g')^\wedge_* \mathscr{C}art(\beta^{\boldsymbol{\lambda}}_{X,A}, \beta^{\boldsymbol{\lambda}}_{X,A'}) & \xrightarrow{g'^\wedge_*(\mu^g_{(A,A')})} & g'^\wedge_* \mathscr{C}art(\beta^{\boldsymbol{\lambda}}_{Y,\mathsf{c}_g A}, \beta^{\boldsymbol{\lambda}}_{Y,\mathsf{c}_g A'}) \\
{\scriptstyle \mu^{g\circ g'}_{(A,A')}}\downarrow & & \downarrow{\scriptstyle \mu^{g'}_{(\mathsf{c}_g A,\mathsf{c}_g A')}} \\
\mathscr{C}art(\beta^{\boldsymbol{\lambda}}_{Y',\mathsf{c}_{gg'} A}, \beta^{\boldsymbol{\lambda}}_{Y',\mathsf{c}_{gg'} A'}) & \xrightarrow{\delta^{g,g'}_{(A,A')}} & \mathscr{C}art(\beta^{\boldsymbol{\lambda}}_{Y',\mathsf{c}_{g'}\mathsf{c}_g A}, \beta^{\boldsymbol{\lambda}}_{Y',\mathsf{c}_{g'}\mathsf{c}_g A'})
\end{array}$$

where $\delta^{g,g'}_{(A,A')}$ is the isomorphism of presheaves (5.1.7) induced by the isomorphisms (5.1.12). Let $(\delta^{g,g'}_{(A,A')})^a$ be the isomorphism of sheaves on C/X associated with $\delta^{g,g'}_{(A,A')}$; there follows a commutative diagram :

$$\begin{array}{ccc}
H_{A,A'} & \xrightarrow{\mathsf{d}^g_{A,A'}} & H_{\mathsf{c}_g A,\mathsf{c}_g A'} \\
{\scriptstyle \mathsf{d}^{gg'}_{A,A'}}\downarrow & & \downarrow{\scriptstyle \mathsf{d}^{g'}_{\mathsf{c}_g A,\mathsf{c}_g A'}} \\
H_{\mathsf{c}_{gg'} A,\mathsf{c}_{gg'} A} & \xrightarrow{\mathsf{d}^{g,g'}_{(A,A')}} & H_{\mathsf{c}_{g'}\mathsf{c}_g A,\mathsf{c}_{g'}\mathsf{c}_g A'}
\end{array}$$

with $\mathsf{d}^{g,g'}_{(A,A')} := (\delta^{g,g'}_{(A,A')})^a_{\mathbf{1}_{Y'}}$. This translates as the commutativity of the diagram :

$$\begin{array}{ccc}
\mathsf{c}_{g'}\mathsf{c}_g A & \xrightarrow{\mathsf{d}_{g'}\circ\mathsf{d}_g(f)} & \mathsf{c}_{g'}\mathsf{c}_g A' \\
{\scriptstyle \gamma^{\mathsf{d}}_{(g,g'),A}}\downarrow & & \downarrow{\scriptstyle \gamma^{\mathsf{d}}_{(g,g'),A'}} \\
\mathsf{c}_{gg'} A & \xrightarrow{\mathsf{d}_{gg'}(f)} & \mathsf{c}_{gg'} A'
\end{array} \qquad \text{for every } f \in \mathrm{Hom}_{\mathscr{A}_X^{\mathrm{sep}}}(A, A')$$

which means that the rule : $A \mapsto \gamma^{\mathsf{d}}_{(g,g'),A}$ yields an isomorphism of functors $\mathsf{d}_{g'} \circ \mathsf{d}_g \xrightarrow{\sim} \mathsf{d}_{gg'}$. Then it is easily seen that the rules : $X \mapsto \mathscr{A}_X^{\mathrm{sep}}$ and $g \mapsto \mathsf{d}_g$ for every $X \in \mathrm{Ob}(\mathscr{C})$ and every morphism g of $\mathscr{C}$ yield a unital pseudo-functor whose coherence constraint is the system of isomorphisms $\gamma^{\mathsf{d}}_{\bullet\bullet}$: the detailed verification shall be left to the reader. Likewise, it follows easily that the rule $X \mapsto \widetilde{\omega}^X$ defines a strict pseudo-natural transformation $\widetilde{\omega}^\bullet : \mathsf{c} \Rightarrow \mathsf{d}$. Set

$$\mathscr{A}^{\mathrm{sep}} := \mathscr{F}ib(\mathsf{d})$$

and let $\boldsymbol{\lambda}^*$ be the distinguished cleavage of $\mathscr{A}^{\mathrm{sep}}$, whose associated pseudo-functor is naturally identified with d (see remark 3.1.27(i)). Then we have a unique cartesian functor

$$\widetilde{\omega}_{\mathscr{A}} : \mathscr{A} \to \mathscr{A}^{\mathrm{sep}}$$

restricting to $\widetilde{\omega}^X : \mathscr{A}_X \to \mathscr{A}^{\mathrm{sep}}_X$ for every $X \in \mathrm{Ob}(\mathscr{C})$. A direct inspection then shows that

$$\beta^{\boldsymbol{\lambda}^*}_{X,A} = \widetilde{\omega}_{\mathscr{A}} \circ \beta^{\boldsymbol{\lambda}}_{X,A} \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C}) \text{ and } A \in \mathrm{Ob}(\mathscr{A}_X)$$

and we have a natural isomorphism of presheaves :

$$\mathscr{H}_{A,A'} \stackrel{\sim}{\to} \mathscr{C}art(\beta^{\boldsymbol{\lambda}^*}_{X,A}, \beta^{\boldsymbol{\lambda}^*}_{X,A'}) \qquad \text{for every } A, A' \in \mathrm{Ob}(\mathscr{A}_X)$$

which identifies the morphism of presheaves induced by $\widetilde{\omega}_{\mathscr{A}}$ as in (5.1.8) :

$$\mathscr{C}art(\beta^{\boldsymbol{\lambda}}_{X,A}, \beta^{\boldsymbol{\lambda}}_{X,A'}) \to \mathscr{C}art(\widetilde{\omega}_{\mathscr{A}} \circ \beta^{\boldsymbol{\lambda}}_{X,A}, \widetilde{\omega}_{\mathscr{A}} \circ \beta^{\boldsymbol{\lambda}}_{X,A'}) = \mathscr{C}art(\beta^{\boldsymbol{\lambda}^*}_{X,A}, \beta^{\boldsymbol{\lambda}^*}_{X,A'})$$

with the natural bicovering morphism of presheaves $\mathscr{C}art(\beta^{\boldsymbol{\lambda}}_{X,A}, \beta^{\boldsymbol{\lambda}}_{X,A'}) \to \mathscr{H}_{A,A'}$. Especially, $\mathscr{C}art(\beta^{\boldsymbol{\lambda}^*}_{X,A}, \beta^{\boldsymbol{\lambda}^*}_{X,A'})$ is a sheaf on C/X for every such X, A, A', so $\mathscr{A}^{\mathrm{sep}}$ is 1-separated over C, by lemma 5.1.9. Consider now any 1-separated fibration $\mathscr{A}'$ over C, and any cartesian functor $F : \mathscr{A} \to \mathscr{A}'$. For every $X \in \mathrm{Ob}(\mathscr{C})$ and $A, A' \in \mathscr{A}_X$, the morphism of presheaves

$$\mathscr{C}art(\beta^{\boldsymbol{\lambda}}_A, \beta^{\boldsymbol{\lambda}}_{A'}) \to \mathscr{C}art(F \circ \beta^{\boldsymbol{\lambda}}_A, F \circ \beta^{\boldsymbol{\lambda}}_{A'}) \tag{5.1.13}$$

as in (5.1.8) factors uniquely through $\mathscr{H}_{A,A'}$, since $\mathscr{C}art(F \circ \beta^{\boldsymbol{\lambda}}_A, F \circ \beta^{\boldsymbol{\lambda}}_{A'})$ is a sheaf on C/X (lemma 5.1.9). There follows a map $F^{\mathrm{sep}}_{A,A'} : H_{A,A'} \to \mathrm{Hom}_{\mathscr{A}'}(FA, FA')$, whose composition with $\widetilde{\omega}_{A,A'}$ equals $F_{A,A'} : \mathrm{Hom}_{\mathscr{A}}(A, A') \to \mathrm{Hom}_{\mathscr{A}'}(FA, FA')$. It is easily seen that the rules : $A \mapsto F^{\mathrm{sep}}A := FA$ and $(A, A') \mapsto F^{\mathrm{sep}}_{A,A'}$ yield a well defined functor $F^{\mathrm{sep}}_{|X} : \mathscr{A}^{\mathrm{sep}}_X \to \mathscr{A}'_X$ such that $F^{\mathrm{sep}}_{|X} \circ \widetilde{\omega}^X$ agrees with the restriction $\mathscr{A}_X \to \mathscr{A}'_X$ of F.

Let $\boldsymbol{\lambda}'$ be a unital cleavage for $\mathscr{A}'$, and c' its associated pseudo-functor; then F corresponds to a pseudo-natural transformation $\alpha : \mathsf{c} \Rightarrow \mathsf{c}'$, and denote by $\tau^\alpha_\bullet$ the coherence constraint of α. For every $X \in \mathrm{Ob}(\mathscr{C})$ and $A \in \mathrm{Ob}(\mathscr{A}_X)$ we have also a unique isomorphism

$$\beta^{\boldsymbol{\lambda}'}_{FA} \stackrel{\sim}{\to} F \circ \beta^{\boldsymbol{\lambda}}_A \qquad \text{such that} \qquad \mathbf{1}_X \mapsto \mathbf{1}_{FA}. \tag{5.1.14}$$

Explicitly, (5.1.14) assigns to every $(g : Y \to X) \in \mathrm{Ob}(\mathscr{C}/X)$ the isomorphism $\tau^\alpha_{g,A} : \mathsf{c}'_g FA \stackrel{\sim}{\to} F\mathsf{c}_g A$ of $\mathscr{A}'_Y$. On the other hand, we have a morphism of presheaves

$$\mathscr{C}art(\beta^{\boldsymbol{\lambda}}_A, \beta^{\boldsymbol{\lambda}}_A) \to \mathscr{C}art(\beta^{\boldsymbol{\lambda}'}_{FA}, \beta^{\boldsymbol{\lambda}'}_{FA}) \tag{5.1.15}$$

described explicitly as follows. For every $(g : Y \to X) \in \mathrm{Ob}(\mathscr{C}/X)$, every morphism of cartesian sections $t_\bullet : \beta^{\boldsymbol{\lambda}}_A \circ g_* \Rightarrow \beta^{\boldsymbol{\lambda}}_{A'} \circ g_*$ is determined by $t_{\mathbf{1}_Y}$: namely, $t_h = \mathsf{c}_h(t_{\mathbf{1}_Y})$ for every $h \in \mathrm{Ob}(\mathscr{C}/Y)$; then (5.1.15) maps every such $t_\bullet$ to the morphism $t'_\bullet : \beta^{\boldsymbol{\lambda}'}_{FA} \circ g_* \Rightarrow \beta^{\boldsymbol{\lambda}'}_{FA'} \circ g_*$ with $t'_h := \mathsf{c}'_h(Ft)$ for every $h \in \mathrm{Ob}(\mathscr{C}/Y)$. With this notation, the condition that τ^α_g is a natural isomorphism $\mathsf{c}'_g \circ F \stackrel{\sim}{\to} F \circ \mathsf{c}_g$ for every $g \in \mathrm{Ob}(\mathscr{C}/X)$ translates as the commutativity of the diagram of presheaves on $\mathscr{C}/X$:

$$\begin{array}{ccc}
\mathscr{C}art(\beta^{\boldsymbol{\lambda}}_A, \beta^{\boldsymbol{\lambda}}_A) & \longrightarrow & \mathscr{C}art(\beta^{\lambda'}_{FA}, \beta^{\boldsymbol{\lambda}'}_{FA'}) \\
\downarrow & & \downarrow \\
\mathscr{C}art(F \circ \beta^{\boldsymbol{\lambda}}_A, F \circ \beta^{\boldsymbol{\lambda}}_A) & \longrightarrow & \mathscr{C}art(F \circ \beta^{\boldsymbol{\lambda}}_A, \beta^{\lambda'}_{FA})
\end{array}$$

whose top horizontal (resp. left vertical) arrow is (5.1.15) (resp. (5.1.13)) and whose other two arrows are the morphisms (5.1.7) induced by the isomorphisms (5.1.14) (and by the identities of $\beta^{\lambda'}_{FA}$ and of $F\circ\beta^{\boldsymbol\lambda}_A$). After taking associated sheaves, we obtain a similar diagram, in which $\mathscr{C}art(\beta^{\boldsymbol\lambda}_A,\beta^{\boldsymbol\lambda}_A)$ is replaced by $\mathscr{H}_{A,A'}$. Unwinding the definitions, we find that the commutativity of the latter diagram yields the commutativity of the following diagram of morphisms of $\mathscr{A}_Y$:

$$\begin{array}{ccc} \mathsf{c}'_g FA & \xrightarrow{\mathsf{c}'_g F^{\mathrm{sep}} f} & \mathsf{c}'_g FA' \\ {\scriptstyle\tau^\alpha_{g,A}}\downarrow & & \downarrow{\scriptstyle\tau^\alpha_{g,A'}} \\ F\mathsf{c}_g A & \xrightarrow{F^{\mathrm{sep}}\mathsf{d}_g f} & F\mathsf{c}_g A' \end{array} \qquad \text{for every } f\in H_{A,A'}.$$

Thus, τ^α_g extends to a natural isomorphism $F^{\mathrm{sep}}_{|Y}\circ\mathsf{c}_g \xrightarrow{\sim} \mathsf{c}'_g\circ F^{\mathrm{sep}}_{|X}$, and then it is clear that the rule $X\mapsto F^{\mathrm{sep}}_{|X}$ yields a pseudo-natural transformation $\alpha' : \mathsf{d}\Rightarrow\mathsf{c}'$ whose coherence constraint is again $\tau^\alpha_\bullet$. Finally, α' corresponds to a unique cartesian functor $F^{\mathrm{sep}} : \mathscr{A}^{\mathrm{sep}}\to\mathscr{A}'$ whose restriction $\mathscr{A}^{\mathrm{sep}}_X\to\mathscr{A}'_X$ agrees with $F^{\mathrm{sep}}_{|X}$ for every $X\in\mathrm{Ob}(\mathscr{C})$. It is then clear that F^{sep} is the unique such cartesian functor whose composition with $\widetilde\omega_{\mathscr{A}}$ equals F. This universal property then easily implies that the rules : $\mathscr{A}\mapsto\mathscr{A}^{\mathrm{sep}}$ and $F\mapsto F^{\mathrm{sep}}$ yield a left adjoint $(-)^{\mathrm{sep}}$ for the inclusion functor $1\text{-}\mathsf{PreStack}(C)\mathsf{Fib}(\mathscr{C})$: the details shall be left to the reader.

Lastly, let $\mu : F\Rightarrow G$ be any natural $\mathscr{C}$-transformation of cartesian functors $F,G:\mathscr{A}\to\mathscr{A}'$ between $\mathscr{C}$-fibrations. Then for every $X\in\mathrm{Ob}(\mathscr{C})$ and every $A\in\mathscr{A}_X$, the morphism $\mu_A : FA\to GA$ determines a unique natural transformation $\mu^*_A : F\circ\beta^{\boldsymbol\lambda}_A\Rightarrow G\circ\beta^{\boldsymbol\lambda}_A$ such that $\mathbf{1}_X\mapsto\mu_A$. There follows for every $A,A'\in\mathrm{Ob}(\mathscr{A})$ a commutative diagram of presheaves :

$$\begin{array}{ccc} \mathscr{C}art(\beta^{\boldsymbol\lambda}_A,\beta^{\boldsymbol\lambda}_{A'}) & \longrightarrow & \mathscr{C}art(F\circ\beta^{\boldsymbol\lambda}_A, F\beta^{\boldsymbol\lambda}_{A'}) \\ \downarrow & & \downarrow \\ \mathscr{C}art(G\circ\beta^{\boldsymbol\lambda}_A, G\circ\beta^{\boldsymbol\lambda}_{A'}) & \longrightarrow & \mathscr{C}art(F\circ\beta^{\boldsymbol\lambda}_A, G\circ\beta^{\boldsymbol\lambda}_{A'}) \end{array}$$

whose top horizontal and left vertical arrows are the morphisms (5.1.13), and whose other two arrows are the morphisms (5.1.7) induced by μ^*_A and $\mu^*_{A'}$. After taking associated sheaves on C/X, we deduce a commutative diagram

$$\begin{array}{ccc} \mathrm{Hom}_{\mathscr{A}^{\mathrm{sep}}}(A,A') & \longrightarrow & \mathrm{Hom}_{\mathscr{B}^{\mathrm{sep}}}(FA,FB) \\ \downarrow & & \downarrow \\ \mathrm{Hom}_{\mathscr{A}^{\mathrm{sep}}}(GA,GA') & \longrightarrow & \mathrm{Hom}_{\mathscr{A}^{\mathrm{sep}}}(FA,GA') \end{array}$$

which shows that μ is also a natural transformation $F^{\mathrm{sep}}\Rightarrow G^{\mathrm{sep}}$. Clearly the rule $\mu\mapsto\mu^{\mathrm{sep}}$ is inverse to the rule $(\nu : F^{\mathrm{sep}}\Rightarrow G^{\mathrm{sep}})\mapsto\nu*\widetilde\omega_{\mathscr{A}}$, so $(-)^{\mathrm{sep}}$ is the sought strong left 2-adjoint of the inclusion pseudo-functor. □

5.1.16. Let $(\mathscr{C},J)$ be a small site. Our next task is to construct the analogue for stacks of the functor $F\mapsto F^+$ on presheaves (see (4.1.11)). To this aim, recall that for every $X\in\mathrm{Ob}(\mathscr{C})$ the set $J(X)$ of sieves covering X is cofiltered, and if $\mathscr{S}'\subset\mathscr{S}$ are two such sieves and $F:\mathscr{E}\to\mathscr{C}$ any fibration, the inclusion functor $i:\mathscr{S}'\to\mathscr{S}$ induces a functor

$$\mathsf{Cart}_{\mathscr{C}}(i,\mathscr{E}) : \mathsf{Cart}_{\mathscr{C}}(\mathscr{S},\mathscr{E})\to\mathsf{Cart}_{\mathscr{C}}(\mathscr{S}',\mathscr{E})$$

whence a well defined filtered system of small categories $C_X := (\mathsf{Cart}_{\mathscr{C}}(\mathscr{S},\mathscr{E})\mid\mathscr{S}\in J(X)^o)$ associated with every object X of $\mathscr{C}$. If $\mathscr{E}$ has small fibres, we may then consider the functor

$$\mathsf{c}^+_F : \mathscr{C}^o\to\mathbf{Cat} \qquad X\mapsto \operatorname*{colim}_{\mathscr{S}\in J(X)^o}\mathsf{Cart}_{\mathscr{C}}(\mathscr{S},\mathscr{E})$$

where the colimit is explicitly given by the construction detailed in example 1.5.10. For any morphism $f : Y \to X$ in $\mathscr{C}$, the corresponding functor $\mathsf{c}^+_F(f) : \mathsf{c}^+_F(X) \to \mathsf{c}^+_F(Y)$ is obtained as follows. For every $\mathscr{S} \in J(X)$, the functor $f_{*|\mathscr{S}} : \mathscr{S} \times_X f \to \mathscr{S}$ induces a functor

$$\mathsf{Cart}_{\mathscr{C}}(f_{*|\mathscr{S}}, \mathscr{E}) : \mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, \mathscr{E}) \to \mathsf{Cart}(\mathscr{S} \times_X f, \mathscr{E}) \to \mathsf{c}^+_F(Y)$$

(see remark 3.5.2(v)) and the system of such functors obviously forms a cocone of vertex $\mathsf{c}^+_F(Y)$ and basis $C_X : J(X)^o \to \mathbf{Cat}$. There follows a unique functor $\mathsf{c}^+_F(f) : \mathsf{c}^+_F(X) \to \mathsf{c}^+_F(Y)$ whose composition with the natural functor $\mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, \mathscr{E}) \to \mathsf{c}^+_F(X)$ agrees with $\mathsf{Cart}_{\mathscr{C}}(f_{*|\mathscr{S}}, \mathscr{E})$ for every $\mathscr{S} \in J(X)$. It is then easily seen that

$$\mathsf{c}^+_F(f \circ g) = \mathsf{c}^+_F(g) \circ \mathsf{c}^+_F(f) \qquad \text{for every pair of morphisms } Z \xrightarrow{g} Y \xrightarrow{f} X \text{ in } \mathscr{C}.$$

With the notation of (3.1.18), we set

$$\mathscr{E}^+ := \mathscr{F}ib(\mathsf{c}^+_F)$$

and let $F^+ : \mathscr{E}^+ \to \mathscr{C}$ be the structure functor of $\mathscr{E}^+$. Recall also that $\mathscr{E}^+$ is endowed with a distinguished split cleavage $\boldsymbol{\lambda}^+_F$ whose associated pseudo-functor is naturally identified with c^+_F (see remark 3.1.27(i)). Thus, the objects of $\mathscr{E}^+$ are represented by the pairs

$$[X, \psi : \mathscr{S} \to \mathscr{E}]$$

with $X \in \mathrm{Ob}(\mathscr{C})$ and ψ is a $\mathscr{C}$-cartesian functor defined on some covering sieve $\mathscr{S} \in J(X)$. A morphism $[f, \sigma] : [X', \psi' : \mathscr{S}' \to \mathscr{E}] \to [X, \psi : \mathscr{S} \to \mathscr{E}]$ is represented by the datum of a morphism $f : X' \to X$ in $\mathscr{C}$, and a natural $\mathscr{C}$-transformation $\sigma : \psi'_{|\mathscr{S}''} \Rightarrow (\psi \circ f_*)_{|\mathscr{S}''}$, where $\mathscr{S}'' \subset \mathscr{S}' \cap (\mathscr{S} \times_X f)$ is a sieve covering X'.

5.1.17. Next, let $F' : \mathscr{E}' \to \mathscr{C}$ be another fibration with small fibres, and $G : \mathscr{E} \to \mathscr{E}'$ any $\mathscr{C}$-cartesian functor; the system of induced functors

$$\mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, G) : \mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, \mathscr{E}) \to \mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, \mathscr{E}') \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C}) \text{ and } \mathscr{S} \in J(X)$$

yields, after taking colimits, a strict pseudo-natural transformation

$$\mathsf{c}^+_G : \mathsf{c}^+_F \Rightarrow \mathsf{c}^+_{F'} \qquad \text{and then a } \mathscr{C}\text{-cartesian functor :} \qquad G^+ := \mathscr{F}ib(\mathsf{c}^+_G) : \mathscr{E}^+ \to \mathscr{E}'^+.$$

Moreover, if $\omega : G \Rightarrow G'$ is any natural $\mathscr{C}$-transformation of $\mathscr{C}$-cartesian functors $G, G' : \mathscr{E} \to \mathscr{E}'$, we get a system of natural transformations

$$\mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, \omega) : \mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, G) \Rightarrow \mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, G') \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C}) \text{ and } \mathscr{S} \in J(X)$$

whence again, after taking colimits, a modification

$$\mathsf{c}^+_\omega : \mathsf{c}^+_G \rightsquigarrow \mathsf{c}^+_{G'} \qquad \text{whence a natural transformation :} \qquad \omega^+ := \mathsf{Fib}(\mathsf{c}^+_\omega) : G^+ \Rightarrow G'^+.$$

It is then clear that the rules : $(F : \mathscr{E} \to \mathscr{C}) \mapsto F^+$, $(G : \mathscr{E} \to \mathscr{E}') \mapsto G^+$ and $(\omega : G \Rightarrow G') \mapsto \omega^+$ yield a well defined strict pseudo-functor

$$(-)^+ : \mathsf{Fib}(\mathscr{C}) \to \mathsf{Fib}(\mathscr{C}).$$

Moreover, since $\mathscr{C}/X \in J(X)$ for every $X \in \mathrm{Ob}(\mathscr{C})$, we have an obvious strict pseudo-natural transformation of strict pseudo-functors :

$$\mathsf{j}_{\mathscr{E}} : \mathsf{Cart}_{\mathscr{C}}(\mathscr{C}/-, \mathscr{E}) \Rightarrow \mathsf{c}^+_{\mathscr{E}}$$

(notation of (3.2.4)), whence a $\mathscr{C}$-cartesian functor

$$j_{\mathscr{E}} := \mathsf{Fib}(\mathsf{j}_F) : \mathsf{C}(\mathscr{E}) \to \mathscr{E}^+$$

and it is clear that the rule $(F : \mathscr{E} \to \mathscr{C}) \mapsto j_{\mathscr{E}}$ yields a strict pseudo-natural transformation of strict pseudo-functors.

Remark 5.1.18. Let $F : \mathscr{E} \to \mathscr{C}$ be any fibration with small fibres, $X \in \mathrm{Ob}(\mathscr{C})$ any object, and $\mathscr{S}$ any sieve of $\mathscr{C}/X$ covering X. By unwinding the definitions, and taking into account lemma 3.1.20(i), we see that a $\mathscr{C}$-cartesian functor $\mathscr{S} \to \mathscr{E}^+$ is the datum of :

- for every object $Y \xrightarrow{f} X$ of $\mathscr{S}$, a sieve $\mathscr{S}^{(f)}$ covering Y and a $\mathscr{C}$-cartesian functor
$$\sigma^{(f)} : \mathscr{S}^{(f)} \to \mathscr{E}$$
- for every morphism $h/X : (Y' \xrightarrow{f'} X) \to (Y \xrightarrow{f} X)$ of $\mathscr{S}$, a sieve $\mathscr{S}^{(h/X)} \subset \mathscr{S}^{(f')} \cap (\mathscr{S}^{(f)} \times_Y h)$ covering Y' and a natural isomorphism of $\mathscr{C}$-functors
$$\sigma^{(h/X)} : \sigma^{(f')}_{|\mathscr{S}^{(h/X)}} \xrightarrow{\sim} (\mathsf{c}^+_F(h)(\sigma^{(f)}))_{|\mathscr{S}^{(h/X)}} = (\sigma^{(f)} \circ h_*)_{|\mathscr{S}^{(h/X)}}$$
where $h_* : \mathscr{S}^{(f)} \times_Y h \to \mathscr{S}^{(f)}$ is the functor $(Z \xrightarrow{g} Y') \mapsto (Z \xrightarrow{h\circ g} Y)$
- for every h/X as in the foregoing and every other morphism $h'/X : (Y'' \xrightarrow{f''} X) \to (Y' \xrightarrow{f} X)$ of $\mathscr{S}_\sigma$, a covering sieve $\mathscr{S}^{(h,h'/X)} \subset \mathscr{S}^{(h'/X)} \cap (\mathscr{S}^{(h/X)} \times_{Y'} h')$ such that

$$(\sigma^{(h/X)} * h'_*)_{|\mathscr{S}^{(h,h'/X)}} \odot \sigma^{(h'/X)}_{|\mathscr{S}^{(h,h'/X)}} = \sigma^{(h\circ h'/X)}_{|\mathscr{S}^{(h,h'/X)}}. \tag{5.1.19}$$

Lemma 5.1.20. *Let $i \leq 2$ be an integer, $F : \mathscr{E} \to \mathscr{C}$ an i-separated prestack, $X \in \mathrm{Ob}(\mathscr{C})$. Then every inclusion $\mathscr{T} \subset \mathscr{S}$ of sieves of $\mathscr{C}/X$ covering X induces an i-faithful functor*
$$j : \mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, \mathscr{E}) \to \mathsf{Cart}_{\mathscr{C}}(\mathscr{T}, \mathscr{E}).$$

Proof. It is an immediate consequence of lemma 3.5.35(i). □

Lemma 5.1.21. *Let $\mathscr{C}$ be a small category, $F : \mathscr{E} \to \mathscr{C}$ a fibration with small fibres. We have :*

(i) *The prestack $F^+ : \mathscr{E}^+ \to \mathscr{C}$ is 0-separated.*
(ii) *If F is a 0-separated prestack, then F^+ is a 1-separated prestack.*
(iii) *If F is a 1-separated prestack, then F^+ is a stack.*
(iv) *If F is a stack, the functor $j_{\mathscr{E}} : \mathsf{C}(\mathscr{E}) \to \mathscr{E}^+$ is an equivalence.*
(v) *There exists an essentially commutative diagram of strict pseudo-functors (notation of definition* 4.1.5(ii)*) :*

$$\begin{array}{ccc} \mathscr{C}^\wedge & \xrightarrow{\mathscr{F}ib} & 0\text{-}\mathsf{PreStack}(\mathscr{C}, J) \\ {\scriptstyle (-)^+}\downarrow & & \downarrow{\scriptstyle (-)^+} \\ (\mathscr{C}, J)^{\mathrm{sep}} & \xrightarrow{\mathscr{F}ib} & 1\text{-}\mathsf{PreStack}(\mathscr{C}, J). \end{array}$$

Proof. Let $X \in \mathrm{Ob}(\mathscr{C})$ be any object, and $\mathscr{T}$ any covering sieve of $\mathscr{C}/X$; let also $[\varphi], [\psi] \in (F^+)^{-1}X$, and $\mathscr{S}$ a sieve covering X such that $[\varphi]$ and $[\psi]$ are represented by $\mathscr{C}$-cartesian functors $\varphi, \psi : \mathscr{S} \to \mathscr{E}$.

(i): Let $[\alpha], [\beta] : [\varphi] \to [\psi]$ be morphisms of $(F^+)^{-1}X$ whose images agree under the functor
$$j : (F^+)^{-1}X \to \mathsf{Cart}_{\mathscr{C}}(\mathscr{T}, \mathscr{E}^+).$$
deduced from the split cleavage c^+_F. We need to check that $\alpha = \beta$. To this aim, may assume that $[\alpha]$ and $[\beta]$ are represented by natural $\mathscr{C}$-transformations $\alpha, \beta : \varphi \Rightarrow \psi$; then, for every $(Y \xrightarrow{f} X) \in \mathrm{Ob}(\mathscr{T})$ there exists a sieve $\mathscr{T}^{(f)} \subset \mathscr{S} \times_X f$ covering Y, such that
$$(\alpha * f_*)_{|\mathscr{T}^{(f)}} = (\beta * f_*)_{|\mathscr{T}^{(f)}}.$$
Now, let $\mathscr{S}' \subset \mathscr{S}$ be the sieve generated by $\bigcup_{f \in \mathrm{Ob}(\mathscr{T})} f_*(\mathrm{Ob}(\mathscr{T}^{(f)}))$; by remark 4.1.3(iii), the sieve $\mathscr{S}'$ covers X, and clearly $\alpha_{|\mathscr{S}'} = \beta_{|\mathscr{S}'}$, whence the contention.

(ii): Let $\alpha : j([\varphi]) \Rightarrow j([\psi])$ be a given natural $\mathscr{C}$-transformation; we need to check that $\alpha = j(\alpha')$ for some sieve $\mathscr{S}' \subset \mathscr{S}$ covering X and some natural $\mathscr{C}$-transformation $\alpha' : \varphi_{|\mathscr{S}'} \Rightarrow \psi_{|\mathscr{S}'}$. However, α is described by a datum as follows :

- For every $(Y \xrightarrow{f} X) \in \mathrm{Ob}(\mathscr{T})$, a sieve $\mathscr{T}^{(f)} \subset \mathscr{S} \times_X f$ covering Y and a natural $\mathscr{C}$-transformation $\alpha^{(f)} : (\varphi \circ f_*)_{|\mathscr{T}^{(f)}} \Rightarrow (\psi \circ f_*)_{|\mathscr{T}^{(f)}}$
- for every morphism $(h/X) : (Y' \xrightarrow{f'} X) \to (Y \xrightarrow{f} X)$ in $\mathscr{T}$, a sieve $\mathscr{T}^{(h/X)}$ covering Y' and contained in $\mathscr{T}^{(f')} \cap (\mathscr{T}^{(f)} \times_Y h)$ such that

$$\alpha^{(f')}_{|\mathscr{T}^{(h/X)}} = (\alpha^{(f)} * h_*)_{|\mathscr{T}^{(h/X)}}.$$

But then, in view of lemma 5.1.20, we may take already $\mathscr{T}^{(h/X)} := \mathscr{T}^{(f')} \cap (\mathscr{T}^{(f)} \times_Y h)$. With this notation, let $\mathscr{S}'$ be the sieve generated by $\bigcup_{f \in \mathrm{Ob}(\mathscr{T})} f_*(\mathrm{Ob}(\mathscr{T}^{(f)}))$; then $\mathscr{S}'$ covers X, by remark 4.1.3(iii). For every $(Y \xrightarrow{g} X) \in \mathrm{Ob}(\mathscr{S}')$, pick any $f \in \mathrm{Ob}(\mathscr{T})$ such that $g = g' \circ f$ for some $g' \in \mathrm{Ob}(\mathscr{T}^{(f)})$, and set

$$\alpha'_g := \alpha^{(f)}_{g'} : \varphi(g) \to \psi(g).$$

Let us check that this definition is independent of the choices of f and g'. Indeed, suppose that $g = g'' \circ f'$ for some other $f' \in \mathrm{Ob}(\mathscr{T})$ and some $g'' \in \mathrm{Ob}(\mathscr{T}^{(f')})$; then we have

$$(\alpha^{(f)} * g'_*)_{|\mathscr{T}'} = (\alpha^{(g)})_{|\mathscr{T}'} = (\alpha^{(f')} * g''_*)_{|\mathscr{T}'} \quad \text{with } \mathscr{T}' := \mathscr{T}^{(g)} \cap (\mathscr{T}^{(f)} \times_Y g') \cap (\mathscr{T}^{(f')} \times_Y g'')$$

and by invoking again lemma 5.1.20, we deduce that

$$(\alpha^{(f)} * g'_*)_{|\mathscr{T}''} = (\alpha^{(f')} * g''_*)_{|\mathscr{T}''} \qquad \text{with } \mathscr{T}'' := (\mathscr{T}^{(f)} \times_Y g') \cap (\mathscr{T}^{(f')} \times_Y g'').$$

Especially, we get : $\alpha^{(f)}_{g'} = (\alpha^{(f)} * g'_*)_{\mathbf{1}_Y} = (\alpha^{(f')} * g''_*)_{\mathbf{1}_Y} = \alpha^{(f')}_{g''}$. It is then clear that α' is a well defined natural $\mathscr{C}$-transformation as sought.

(v) follows now from (ii) and a direct inspection of the construction of the functors $(-)^+$ for presheaves and for prestacks.

(iii): Let $\sigma : \mathscr{T} \to \mathscr{E}^+$ be a $\mathscr{C}$-cartesian functor; hence, this is a datum

$$\Big((\mathscr{S}^{(f)}, \sigma^{(f)} \mid f \in \mathrm{Ob}(\mathscr{T})), (\mathscr{S}^{(h/X)}, \sigma^{(h/X)} \mid f' \xrightarrow{h} f \text{ in } \mathscr{T}), (\mathscr{S}^{(h,h'/X)} \mid f'' \xrightarrow{h'} f' \xrightarrow{h} f \text{ in } \mathscr{T})\Big)$$

as in remark 5.1.18. But then, lemma 5.1.20 says that we may even take :

$$\mathscr{S}^{(h/X)} := \mathscr{S}^{(f')} \cap (\mathscr{S}^{(f)} \times_Y h) \qquad \mathscr{S}^{(h,h'/X)} := \mathscr{S}^{(f'')} \cap (\mathscr{S}^{(f')} \times_{Y'} h') \cap (\mathscr{S}^{(f)} \times_Y (h \circ h'))$$

for every $f \in \mathrm{Ob}(\mathscr{T})$, every morphism $f' \xrightarrow{h} f$ in $\mathscr{T}$, and every pair $f'' \xrightarrow{h'} f' \xrightarrow{h} f$ of morphisms in $\mathscr{T}$. Let $\mathscr{T}' \subset \mathscr{C}/X$ be the sieve generated by $\bigcup_{f \in \mathrm{Ob}(\mathscr{T})} f_*(\mathrm{Ob}(\mathscr{S}^{(f)}))$, which covers X, by remark 4.1.3(iii). We consider the functor

$$G_{\mathscr{T}'} : \mathscr{T}' \to \mathbf{Cat}/(\mathscr{C}/X) \qquad (Y \xrightarrow{g} X) \mapsto (\mathscr{C}/X)/g = \mathscr{C}/Y$$

defined as in (3.5.8), and we construct a pseudo-cocone

$$\psi_\bullet : G_{\mathscr{T}'} \Rightarrow \mathsf{F}_{\mathscr{E}}$$

as follows. For every $(Y \xrightarrow{g} X) \in \mathrm{Ob}(\mathscr{T}')$, choose $g' \in \mathrm{Ob}(\mathscr{T})$ and $g'' \in \mathrm{Ob}(\mathscr{S}^{(g')})$ with

$$g = g' \circ g'' \qquad \text{and set :} \qquad \psi_g := \sigma^{(g')} \circ g''_* : \mathscr{C}/Y \to \mathscr{E}.$$

Next, let $g_1, g_2 \in \mathrm{Ob}(\mathscr{T}')$ and $h/X : (Z_1 \xrightarrow{g_1} X) \to (Z_2 \xrightarrow{g_2} X)$ a morphism of $\mathscr{T}'$; with this notation, we have the $\mathscr{C}$-cartesian functors

$$\sigma^{(g'_1)} \circ g''_{1*}, \sigma^{(g'_2)} \circ (g''_2 \circ h)_* : \mathscr{C}/Z_1 \to \mathscr{E}$$

and two isomorphisms of $\mathscr{C}$-functors

$$(\sigma^{(g'_1)} \circ g''_{1*})_{|\mathscr{S}^{(g_1)}} \xLeftarrow{\sigma^{(g''_1/X)}} \sigma^{(g_1)} \xRightarrow{\sigma^{(g''_2 \circ h/X)}} (\sigma^{(g'_2)} \circ (g''_2 \circ h)_*)_{|\mathscr{S}^{(g_1)}}.$$

Since F is 1-separated, it follows that the composition $\sigma^{(g''_2\circ h/X)}_{|\mathscr{S}(g_1)} \odot (\sigma^{(g''_1/X)})^{-1}_{|\mathscr{S}(g_1)}$ extends uniquely to an isomorphism of $\mathscr{C}$-functors

$$\tau^{\psi}_{h/X} : \psi_{g_1} \xrightarrow{\sim} \psi_{g_2} \circ h_*.$$

We claim that the rule $g \mapsto \psi_g$ yields a pseudo-cocone as sought, with coherence constraint given by the system of isomorphisms $\tau^{\psi}_{\bullet}$. Indeed, let $h'/X : (Z_0 \xrightarrow{g_0} X) \to (Z_1 \xrightarrow{g_1} X)$ be another morphism of $\mathscr{T}'$; then we have as well the isomorphisms of $\mathscr{C}$-functors

$$\begin{array}{ccccc} (\sigma^{(g'_0)} \circ g''_{0*})_{|\mathscr{S}(g_0)} & \xLeftarrow{\sigma^{(g''_0/X)}} & \sigma^{(g_0)} & \xRightarrow{\sigma^{(g''_1\circ h'/X)}} & (\sigma^{(g'_1)} \circ (g''_1 \circ h')_*)_{|\mathscr{S}(g_0)} \\ & & \Big\Downarrow{\scriptstyle \sigma^{(g''_2\circ h'\circ h/X)}} & & \\ & & (\sigma^{(g'_2)} \circ (g''_2 \circ h \circ h')_*)_{|\mathscr{S}(g_0)} & & \end{array}$$

and with this notation, we have :

$$(\tau^{\psi}_{h'/X})_{|\mathscr{S}(g_0)} = \sigma^{(g''_1\circ h'/X)} \odot (\sigma^{(g''_0/X)})^{-1} \qquad (\tau^{\psi}_{h\circ h'/X})_{|\mathscr{S}(g_0)} = (\sigma^{(g''_2\circ h\circ h'/X)}) \odot (\sigma^{(g''_0/X)})^{-1}.$$

Set $\mathscr{S} := \mathscr{S}^{(g''_2\circ h, h'/X)} \cap \mathscr{S}^{(g''_1, h'/X)} \subset \mathscr{S}^{(g_0)}$. We claim that

$$(\tau^{\psi}_{h\circ h'/X})_{|\mathscr{S}} = (\tau^{\psi}_{h/X} * h'_*)_{|\mathscr{S}} \odot (\tau^{\psi}_{h'/X})_{|\mathscr{S}}.$$

Indeed, the latter identity follows by combining the following ones :

$$\sigma^{(g''_2\circ h\circ h'/X)}_{|\mathscr{S}} = (\sigma^{(g''_2\circ h/X)} * h'_*)_{|\mathscr{S}} \odot \sigma^{(h'/X)}_{|\mathscr{S}}$$
$$\sigma^{(g''_1\circ h'/X)}_{|\mathscr{S}} = (\sigma^{(g''_1/X)} * h'_*)_{|\mathscr{S}} \odot \sigma^{(h'/X)}_{|\mathscr{S}}$$

that are provided by remark 5.1.18. Since $\mathscr{S}$ covers Z_0 and F is 1-separated, it follows that

$$\tau^{\psi}_{h\circ h'/X} = (\tau^{\psi}_{h/X} * h'_*) \odot \tau^{\psi}_{h'/X}$$

which shows that τ^{ψ} satisfies the required coherence axioms. By lemma 3.5.9, we deduce that there exist a $\mathscr{C}$-functor $\psi : \mathscr{T}' \to \mathscr{E}$ and an invertible modification $\Xi : \mathsf{F}_\psi \odot \widehat{\varepsilon}_{\mathscr{T}'} \rightsquigarrow \psi_\bullet$, where $\widehat{\varepsilon}_{\mathscr{T}'} : G_{\mathscr{T}'} \Rightarrow \mathsf{F}_{\mathscr{T}'}$ is the universal pseudo-cocone defined as in (3.5.8); explicitly, this amounts to a system of oriented squares with invertible 2-cells :

$$\begin{array}{ccc} \mathscr{C}/Y & \xrightarrow{g_*} & \mathscr{T}' \\ {\scriptstyle g''_*}\big\downarrow & \not\swarrow \Xi_g & \big\downarrow{\scriptstyle \psi} \\ \mathscr{S}^{(g')} & \xrightarrow[\sigma^{(g')}]{} & \mathscr{E} \end{array} \qquad \text{for every } g \in \mathrm{Ob}(\mathscr{T}')$$

from which it follows easily that ψ is $\mathscr{C}$-cartesian (here $g = g' \circ g''$ is the factorisation used to define ψ_g). The compatibility condition for Ξ amounts to the identity :

(5.1.22) $\Xi_{g_2} * h_* = \tau^{\psi}_{h/X} \odot \Xi_{g_1}$ for every morphism $(Z_1 \xrightarrow{g_1} X) \xrightarrow{h/X} (Z_2 \xrightarrow{g_2} X)$ of $\mathscr{T}'$.

Thus, the functor ψ represents an object $[\psi]$ of the fibre category $\mathscr{E}^+(X)$, and to conclude, we need to check that $j([\psi])$ is isomorphic to σ. However, since we know already from (ii) that $\mathscr{E}^+$ is a 1-separated prestack, by lemma 5.1.20 it suffices to find an isomorphism between the images of $j([\psi])$ and σ in $\mathsf{Cart}_{\mathscr{C}}(\mathscr{T}', \mathscr{E}^+)$. This comes down to exhibiting isomorphisms of functors

$$\vartheta_g : \psi \circ g_* \xrightarrow{\sim} \sigma^{(g)} \qquad \text{for every } g \in \mathrm{Ob}(\mathscr{T}')$$

(where $g_* : \mathscr{S}^{(f)} \to \mathscr{T}'$ is the usual functor with $t \mapsto g \circ t$ for every $t \in \mathrm{Ob}(\mathscr{S}^{(f)})$) such that

(5.1.23) $\sigma^{(h/X)} \odot \vartheta_{g_1|\mathscr{S}(h/X)} = (\vartheta_{g_2} * h_*)_{|\mathscr{S}(h/X)}$ for every morphism $g_1 \xrightarrow{h/X} g_2$ of $\mathscr{T}'$.

To this aim, we set :

$$\vartheta_g := (\sigma^{(g''/X)})^{-1} \odot (\Xi_g)_{|\mathscr{S}^{(g)}}.$$

Since $\mathscr{E}$ is 1-separated, the identities (5.1.23) can be checked after restriction to any covering sieve contained in $\mathscr{S}^{(h/X)}$; but on such a suitable sieve we may apply the identities (5.1.19), and combining with (5.1.22) we conclude easily : the details shall be left to the reader.

(iv): It suffices to check that $j_{\mathscr{E}}$ is a fibrewise equivalence when $\mathscr{E}$ is a stack (corollary 3.1.28(i)), and this follows by direct inspection of the definitions. □

Theorem 5.1.24. *For every small site $(\mathscr{C}, J)$, the inclusion strict pseudo-functor*

$$\mathsf{F} : \mathsf{Stack}(\mathscr{C}, J) \to \mathsf{Fib}(\mathscr{C})$$

admits a left 2-adjoint

$$\mathsf{Fib}(\mathscr{C}) \to \mathsf{Stack}(\mathscr{C}, J) \qquad (F : \mathscr{E} \to \mathscr{C}) \mapsto (F^a : \mathscr{E}^a \to \mathscr{C})$$

which assigns to every fibration over $\mathscr{C}$ its associated stack. *Moreover, we have a pseudo-commutative diagram of pseudo-functors (see remark* 2.4.10*) :*

(5.1.25)
$$\begin{array}{ccc} \mathscr{C}^\wedge & \xrightarrow{\mathscr{F}ib} & \mathsf{Fib}(\mathscr{C}) \\ {\scriptstyle (-)^a}\downarrow & & \downarrow{\scriptstyle (-)^a} \\ (\mathscr{C}, J)^\sim & \xrightarrow{\mathscr{F}ib} & \mathsf{Stack}(\mathscr{C}, J) \end{array}$$

whose left vertical arrow is the usual left adjoint to the inclusion functor for presheaves.

Proof. Recall first that the counit of the 2-adjoint pair (F, C) of (3.2.4) is a $\mathscr{C}$-equivalence $\mathsf{ev}^{\mathscr{E}} : \mathsf{C}(\mathscr{E}) \to \mathscr{E}$ for every fibration $F : \mathscr{E} \to \mathscr{C}$ (theorem 3.2.7). Moreover, the unit of the same 2-adjoint pair assigns to every split fibration $(F, \boldsymbol{\lambda})$ a $\mathscr{C}$-equivalence $\eta_{\mathscr{E}} : \mathscr{E} \to \mathsf{C}(\mathscr{E})$, deduced from the strict pseudo-natural equivalence $\beta^{\boldsymbol{\lambda}}$ defined in the proof of theorem 3.2.7 (see remark 3.2.9(i)). There follows a $\mathscr{C}$-equivalence :

$$\omega_{\mathscr{E}} :=: \mathsf{C}(\mathscr{E})^+ \xrightarrow{(\mathsf{ev}^{\mathscr{E}})^+} \mathscr{E}^+ \xrightarrow{\eta_{\mathscr{E}^+}} \mathsf{C}(\mathscr{E}^+).$$

By inspecting the definitions, we see that $\omega_{\mathscr{E}}$ assigns to every object $[X, \varphi : \mathscr{S} \to \mathsf{C}(\mathscr{E})]$ of $\mathsf{C}(\mathscr{E})^+$ the cartesian section $\omega_{\mathscr{E}}([X, \varphi]) \in \mathscr{E}^+(X)$ given by the rule :

$$(f : Y \to X) \mapsto (\mathscr{S} \times_X f \xrightarrow{f_*} \mathscr{S} \xrightarrow{\mathsf{ev}^{\mathscr{E}} \circ \varphi} \mathscr{E})$$

and notice that $\mathsf{ev}^{\mathscr{E}} \circ \varphi \circ f_*(h) = \varphi_{f \circ h}(\mathbf{1}_Z)$ for every $(h : Z \to Y) \in \mathrm{Ob}(\mathscr{S} \times_X f)$. For every morphism $g/X : (f' : Y' \to X) \to (f : Y \to X)$ in $\mathscr{C}/X$, the induced natural transformation $\omega_{\mathscr{E}}([X, \varphi])(g) : \omega_{\mathscr{E}}([X, \varphi])(f') \Rightarrow \omega_{\mathscr{E}}([X, \varphi])(f)$ is the identity $\mathsf{ev}^{\mathscr{E}} \circ \varphi \circ f'_* \xrightarrow{\sim} \mathsf{ev}^{\mathscr{E}} \circ \varphi \circ f_* \circ g_*$.

Claim 5.1.26. (i) For every two $\mathscr{C}$-fibrations $\mathscr{A} \xrightarrow{\varphi} \mathscr{C} \xleftarrow{\varphi'} \mathscr{A}'$, the functor

$$\mathsf{C}_{\mathscr{A}, \mathscr{A}'} : \mathsf{Cart}_{\mathscr{C}}(\mathscr{A}, \mathscr{A}') \to \mathsf{Cart}_{\mathscr{C}}(\mathsf{C}(\mathscr{A}), \mathsf{C}(\mathscr{A}')) \qquad F \mapsto \mathsf{C}(F) \qquad (\alpha : F \Rightarrow F') \mapsto \mathsf{C}(\alpha)$$

is an equivalence.

(ii) For every $\mathscr{C}$-fibration $\mathscr{A} \to \mathscr{C}$ the following diagram of functors commutes:

$$\begin{array}{ccc} \mathsf{Cart}_{\mathscr{C}}(\mathsf{C}(\mathscr{E}), \mathscr{A}) & \xrightarrow{(-)^+} & \mathsf{Cart}_{\mathscr{C}}(\mathsf{C}(\mathscr{E})^+, \mathscr{A}^+) \\ {\scriptstyle \mathsf{C}_{\mathsf{C}(\mathscr{E}), \mathscr{A}}}\downarrow & & \downarrow{\scriptstyle \mathsf{Cart}_{\mathscr{C}}(j_{\mathsf{C}(\mathscr{E})}, \mathscr{A}^+)} \\ \mathsf{Cart}_{\mathscr{C}}(\mathsf{C}(\mathsf{C}(\mathscr{E})), \mathsf{C}(\mathscr{A})) & \xrightarrow{\mathsf{Cart}_{\mathscr{C}}(\mathsf{C}(\mathsf{C}(\mathscr{E})), j_{\mathscr{A}})} & \mathsf{Cart}_{\mathscr{C}}(\mathsf{C}(\mathsf{C}(\mathscr{E})), \mathscr{A}^+). \end{array}$$

Proof of the claim. Assertion (ii) follows by direct inspection. For (i) let us notice the commutative diagram :

$$\begin{array}{ccc} \mathsf{Cart}_{\mathscr{C}}(\mathscr{A},\mathscr{A}') & \xrightarrow{\mathsf{C}_{\mathscr{A},\mathscr{A}'}} & \mathsf{Cart}_{\mathscr{C}}(\mathsf{C}(\mathscr{A}),\mathsf{C}(\mathscr{A}')) \\ & {\scriptstyle \mathsf{Cart}_{\mathscr{C}}(\mathsf{ev}^{\mathscr{A}},\mathscr{A}')} \searrow \quad \swarrow {\scriptstyle \mathsf{Cart}_{\mathscr{C}}(\mathscr{A},\mathsf{ev}^{\mathscr{A}'})} & \\ & \mathsf{Cart}_{\mathscr{C}}(\mathsf{C}(\mathscr{A}),\mathscr{A}') & \end{array}$$

where all arrows except possibly $\mathsf{C}_{\mathscr{A},\mathscr{A}}$ are equivalences; then the same must hold for $\mathsf{C}_{\mathscr{A},\mathscr{A}'}$. ◇

Claim 5.1.27. For every fibration $\mathscr{A} \to \mathscr{C}$ the diagram of functors :

$$\begin{array}{ccc} \mathsf{Cart}_{\mathscr{C}}(\mathscr{E}^+,\mathscr{A}) & \xrightarrow{\mathsf{Cart}_{\mathscr{C}}(j_{\mathscr{E}},\mathscr{A})} & \mathsf{Cart}_{\mathscr{C}}(\mathsf{C}(\mathscr{E}),\mathscr{A}) \\ {\scriptstyle \mathsf{C}_{\mathscr{E}^+,\mathscr{A}}}\downarrow & & \downarrow{\scriptstyle (-)^+} \\ \mathsf{Cart}_{\mathscr{C}}(\mathsf{C}(\mathscr{E}^+),\mathsf{C}(\mathscr{A})) & \xrightarrow{\mathsf{Cart}_{\mathscr{C}}(\omega_{\mathscr{E}},j_{\mathscr{A}})} & \mathsf{Cart}_{\mathscr{C}}(\mathsf{C}(\mathscr{E})^+,\mathscr{A}^+) \end{array}$$

is essentially commutative (notation of claim 5.1.26(i)).

Proof of the claim. Let $G : \mathscr{E}^+ \to \mathscr{A}$ be any $\mathscr{C}$-cartesian functor; the $\mathscr{C}$-cartesian functor $G' := (G \circ j_{\mathscr{E}})^+ : \mathsf{C}(\mathscr{E})^+ \to \mathscr{A}^+$ can be described as follows. Let $[X, \psi : \mathscr{S} \to \mathsf{C}(\mathscr{E})]$ be any object of $\mathsf{C}(\mathscr{E})^+$; then $G'([X,\psi]) = [X, G \circ j_{\mathscr{E}} \circ \psi : \mathscr{S} \to \mathscr{A}]$, and notice that $j_{\mathscr{E}} \circ \psi$ is the $\mathscr{C}$-cartesian functor given by the rule :

$$(f : Y \to X) \mapsto [Y, \psi_f : \mathscr{C}/Y \to \mathscr{E}] \qquad \text{for every } f \in \mathrm{Ob}(\mathscr{S}).$$

On the other hand, the $\mathscr{C}$-cartesian functor $G'' : j_{\mathscr{A}} \circ \mathsf{C}(G) \circ \omega_{\mathscr{E}} : \mathsf{C}(\mathscr{E})^+ \to \mathscr{A}^+$ is described as follows. For any $[X,\psi]$ as in the foregoing, $G''([X,\psi]) = [X, G \circ \psi' : \mathscr{C}/X \to \mathscr{A}]$, where $\psi' : \mathscr{S} \to \mathscr{E}^+$ is the $\mathscr{C}$-cartesian functor given by the rule :

$$(f : Y \to X) \mapsto [Y, \mathsf{ev}^{\mathscr{E}} \circ \psi \circ f_*] \qquad \text{for every } f \in \mathrm{Ob}(\mathscr{C}/X)$$

and notice that $\mathsf{ev}^{\mathscr{E}} \circ \psi \circ f_* : \mathscr{S} \times_X f \to \mathscr{E}$ is in turn given by the rule :

$$(g : Z \to Y) \mapsto \psi_{f \circ g}(\mathbf{1}_Z) \qquad \text{for every } g \in \mathrm{Ob}(\mathscr{S} \times_X f).$$

Let $\psi'' : \mathscr{S} \to \mathscr{A}$ be the restriction of ψ'; then $[X,\psi'] = [X,\psi'']$ in $\mathscr{E}^+$, and $\mathscr{S} \times_X f = \mathscr{C}/Y$ for every $(f : Y \to X) \in \mathrm{Ob}(\mathscr{S})$. For such f, we need to compare the cartesian functors $\psi_f, \mathsf{ev}^{\mathscr{E}} \circ \psi \circ f_* : \mathscr{C}/Y \to \mathscr{E}$. However, $\psi_f(\mathbf{1}_Y) = \mathsf{ev}^{\mathscr{E}} \circ \psi \circ f_*(\mathbf{1}_Y)$, so there exists a unique isomorphism of functors

$$\tau_{\psi,f} : \mathsf{ev}^{\mathscr{E}} \circ \psi \circ f_* \xrightarrow{\sim} \psi_f \qquad \text{such that} \qquad (\tau_{\psi,f})_{\mathbf{1}_Y} = \mathbf{1}_{\psi_f(\mathbf{1}_Y)}.$$

Explicitly, every object $(g : Z \to Y)$ of $\mathscr{C}/Y$ yields a morphism $g/Y : g \to \mathbf{1}_Y$ in $\mathscr{C}/Y$, and therefore $(\tau_{\psi,f})_g$ is determined by the commutativity of the diagram :

$$\begin{array}{ccc} \psi_{f\circ g}(\mathbf{1}_Z) & \xrightarrow{(\tau_{\psi,f})_g} & \psi_f(g) \\ {\scriptstyle (\mathsf{ev}^{\mathscr{E}}\circ\psi * f_*)_{g/Y}}\downarrow & & \downarrow{\scriptstyle \psi_f(g/Y)} \\ \psi_f(\mathbf{1}_Y) & = & \psi_f(\mathbf{1}_Y) \end{array}$$

However, $(\mathsf{ev}^{\mathscr{E}} \circ \psi \circ f_*)_{g/Y} = \psi_f(g/Y) \circ \psi_{g/X,\mathbf{1}_Z}$, so that

$$(\tau_{\psi,f})_g = \psi_{g/X,\mathbf{1}_Z} \qquad \text{for every } (g : Z \to Y) \in \mathrm{Ob}(\mathscr{C}/Y).$$

We claim that we get an isomorphism of $\mathscr{C}$-cartesian functors

$$G([\tau_\psi]) : G''([X,\psi]) \xrightarrow{\sim} G'([X,\psi]) \quad f \mapsto G([\mathbf{1}_Y, \tau_{\psi,f}]) \quad \text{for every } (f : Y \to X) \in \mathrm{Ob}(\mathscr{S}).$$

Indeed, let $g/X : (f' : Y' \to X) \to (f : Y \to X)$ be any morphism in $\mathscr{S}$; the assertion comes down to the commutativity of the diagram :

$$\begin{array}{ccc} G([Y', \mathsf{ev}^{\mathscr{E}} \circ \psi \circ f'_*]) & = & G([Y', \mathsf{ev}^{\mathscr{E}} \circ \psi \circ f_* \circ g_*]) \\ \downarrow{\scriptstyle G([\mathbf{1}_{Y'}, \tau_{\psi,f'}])} & & \downarrow{\scriptstyle G([\mathbf{1}_{Y'}, \tau_{\psi,f*g_*}])} \\ G([Y', \psi_{f'}]) & \xrightarrow{G([\mathbf{1}_{Y'}, \psi_{g/X}])} & G([Y', \psi_f \circ g_*]). \end{array}$$

The latter in turn follows by applying G to the system of identities :

$$\psi_{g/X,h} \circ \psi_{h/X,\mathbf{1}_Z} = \psi_{g\circ h/X,\mathbf{1}_Z} \qquad \text{for every } (h : Z \to Y') \in \mathrm{Ob}(\mathscr{C}/Y')$$

which hold by functoriality of ψ, applied to the morphisms $f' \circ h \xrightarrow{h/X} f' \xrightarrow{g/X} f$ of $\mathscr{S}$.

Next, we check the naturality of the rule $\psi \mapsto G([\tau_\psi])$. Hence, let $[X_i, \psi_i : \mathscr{S}_i \to \mathsf{C}(\mathscr{E})]$ for $i = 1, 2$ be two objects of $\mathsf{C}(\mathscr{E})^+$, and $[t, \sigma] : [X_2, \psi_2] \to [X_1, \psi_1]$ a morphism; *i.e.* $t : X_2 \to X_1$ is a morphism of $\mathscr{C}$ and $\sigma : \psi_{2|\mathscr{S}_3} \Rightarrow (\psi_1 \circ t_*)_{|\mathscr{S}_3}$ is a natural $\mathscr{C}$-transformation defined on a sieve $\mathscr{S}_3 \subset \mathscr{S}_2 \cap (\mathscr{S}_1 \times_{X_1} t)$. We have

$$G'([t, \sigma]) = [t, (G \circ j_{\mathscr{E}}) * \sigma : G \circ j_{\mathscr{E}} \circ \psi_{2|\mathscr{S}_3} \Rightarrow G \circ j_{\mathscr{E}} \circ (\psi_1 \circ t_*)_{|\mathscr{S}_3}].$$

On the other hand, notice that $\omega_{\mathscr{E}}([t, \sigma]) : \omega_{\mathscr{E}}([X_2, \psi_2]) \to \omega_{\mathscr{E}}([X_1, \psi_1])$ is the natural transformation $\sigma' : \psi'_2 \Rightarrow \psi'_1 * t_*$, where ψ'_i is the functor such that $(f : Y \to X_i) \mapsto [Y, \mathsf{ev}^{\mathscr{E}} \circ \psi_i \circ f_*]$ for every $f \in \mathrm{Ob}(\mathscr{C}/X_i)$, and $\sigma'_f := \mathsf{ev}^{\mathscr{E}} * \sigma * f_*$, with $f_* : \mathscr{S}_3 \times_{X_2} f \to \mathscr{S}_3$ for every $f \in \mathrm{Ob}(\mathscr{C}/X_2)$. Explicitly, σ'_f assigns to every $(g : Z \to Y) \in \mathrm{Ob}(\mathscr{S}_3 \times_{X_2} f)$ the morphism

$$\sigma_{f\circ g,\mathbf{1}_Z} : \psi_{2,f\circ g}(\mathbf{1}_Z) \to \psi_{1,t\circ f\circ g}(\mathbf{1}_Z).$$

Thus, we need to check the commutativity of the diagram :

$$\begin{array}{ccc} [X_2, G \circ \psi'_2] & \xrightarrow{G([\tau_{\psi_2}])} & [X_2, G \circ j_{\mathscr{E}} \circ \psi_2] \\ \downarrow{\scriptstyle [t, G*\sigma']} & & \downarrow{\scriptstyle [t, (G\circ j_{\mathscr{E}})*\sigma]} \\ [X_1, G \circ \psi'_1] & \xrightarrow{G([\tau_{\psi_1}])} & [X_1, G \circ j_{\mathscr{E}} \circ \psi_1]. \end{array}$$

which in turn follows from the commutativity of the diagram :

$$\begin{array}{ccc} \psi_{2,f\circ g}(\mathbf{1}_Z) & \xrightarrow{\sigma_{f\circ g,\mathbf{1}_Z}} & \psi_{1,t\circ f\circ g}(\mathbf{1}_Z) \\ \downarrow{\scriptstyle \psi_{2,g/X_2,\mathbf{1}_Z}} & & \downarrow{\scriptstyle \psi_{1,g/X_1,\mathbf{1}_Z}} \\ \psi_{2,f}(g) & \xrightarrow{\sigma_{f,g}} & \psi_{1,t\circ f}(g) \end{array}$$

for every $f \in \mathrm{Ob}(\mathscr{C}/X_2)$ and every $g \in \mathrm{Ob}(\mathscr{S}_3 \times_{X_2} f)$. Since $g/X_1 = t_*(g/X_2)$ in $\mathscr{S}_1$, the assertion holds by naturality of σ. Lastly, the naturality with respect to natural $\mathscr{C}$-transformations $G \Rightarrow G'$ is immediate from the definitions. ◊

Now, let $\mathscr{A} \to \mathscr{C}$ be a stack; then $j_{\mathscr{A}}$ is an equivalence, by lemma 5.1.21(iv), and it follows easily that $\mathsf{Cart}_{\mathscr{C}}(\omega_{\mathscr{E}}, j_{\mathscr{A}})$ is an equivalence as well. The same holds for $\mathsf{C}_{\mathscr{E}^+,\mathscr{A}}$ and $\mathsf{C}_{\mathsf{C}(\mathscr{E}),\mathscr{A}}$, by claim 5.1.26(i). We deduce that the functor $(-)^+$ appearing in the diagrams of claims 5.1.27 and 5.1.26(ii) admits both left and right quasi-inverse functors, so it is an equivalence. By claim 5.1.27, we finally conclude that $\mathsf{Cart}_{\mathscr{C}}(j_{\mathscr{E}}, \mathscr{A})$ is an equivalence as well. Now, set

$$\mathscr{E}^a := \mathscr{E}^{+++}.$$

The composition $\mathsf{Cart}_{\mathscr{C}}(j_{\mathscr{E}}, \mathscr{A}) \circ \mathsf{Cart}_{\mathscr{C}}(j_{\mathscr{E}^+}, \mathscr{A}) \circ \mathsf{Cart}_{\mathscr{C}}(j_{\mathscr{E}^{++}}, \mathscr{A})$ is an equivalence

$$\lambda_{\mathscr{E},\mathscr{A}} : \mathsf{Cart}_{\mathscr{C}}(\mathscr{E}^a, \mathscr{A}) \xrightarrow{\sim} \mathsf{Cart}_{\mathscr{C}}(\mathsf{C}(\mathsf{C}(\mathsf{C}(\mathscr{E}))), \mathscr{A}).$$

The rules $(\mathscr{E},\mathscr{A})\mapsto \mathsf{Cart}_{\mathscr{C}}(\mathscr{E}^a,\mathscr{A})$ and $(\mathscr{E},\mathscr{A})\mapsto \mathsf{Cart}_{\mathscr{C}}(\mathsf{C}(\mathsf{C}(\mathsf{C}(\mathscr{E}))),\mathscr{A})$ yield strict pseudo-functors

$$\mathsf{Cart}_{\mathscr{C}}((-)^a,-),\mathsf{Cart}_{\mathscr{C}}(\mathsf{C}\circ\mathsf{C}\circ\mathsf{C},-):\mathsf{Fib}(\mathscr{C})^o\times\mathsf{Stack}(\mathscr{C},J)\to\mathbf{Cat}$$

and clearly the rule $(\mathscr{E},\mathscr{A})\mapsto\lambda_{\mathscr{E},\mathscr{A}}$ defines a strict pseudo-natural equivalence of functors

$$\lambda:\mathsf{Cart}_{\mathscr{C}}((-)^a,-)\Rightarrow\mathsf{Cart}_{\mathscr{C}}(\mathsf{C}\circ\mathsf{C}\circ\mathsf{C},-).$$

On the other hand, by composing evaluation functors we get as well a strict pseudo-natural equivalence $\mathsf{C}\circ\mathsf{C}\circ\mathsf{C}\Rightarrow\mathbf{1}_{\mathsf{Fib}(\mathscr{C})}$, whence an induced strict pseudo-natural equivalence

$$\lambda':\mathsf{Cart}_{\mathscr{C}}(-,\mathsf{F})\stackrel{\sim}{\to}\mathsf{Cart}_{\mathscr{C}}(\mathsf{C}\circ\mathsf{C}\circ\mathsf{C},-)$$

where $\mathsf{F}:\mathsf{Stack}(\mathscr{C},J)\to\mathsf{Fib}(\mathscr{C})$ is the (forgetful) inclusion strict pseudo-functor. After choosing a quasi-inverse for λ (see theorem 2.4.12) and composing with λ', we obtain the required (non-strict) pseudo-natural equivalence

$$\mathsf{Cart}_{\mathscr{C}}(-,\mathsf{F})\stackrel{\sim}{\to}\mathsf{Cart}_{\mathscr{C}}((-)^a,-).$$

Lastly, the essential commutativity of (5.1.25) follows directly from lemma 5.1.21(v). □

5.2. **Covering morphisms of prestacks.** In this section we wish to characterize the i-faithful functors of prestacks (for $i=0,1,2$), by means of certain conditions that are analogous to those given in definition 4.1.28 for presheaves; to this aim, we make the following :

Definition 5.2.1. Let $(\mathscr{C},J)$ be a site, $F:\mathscr{E}\to\mathscr{C}$ and $F':\mathscr{E}'\to\mathscr{C}$ two fibrations, and $\varphi:\mathscr{E}'\to\mathscr{E}$ a $\mathscr{C}$-cartesian functor.

(i) φ is a 0-*covering* if for every $Y\in\mathrm{Ob}(\mathscr{E})$ there exist a covering family $(f_i:X_i\to FY\mid i\in I)$ and for every $i\in I$ an object $Y'_i\in\mathrm{Ob}(\mathscr{E}'_{X_i})$ and a $\mathscr{C}$-cartesian morphism $h_i:\varphi Y'_i\to Y$ in $\mathscr{E}$ such that $F(h_i)=f_i$.

(ii) φ is a 1-*covering* if for every $X\in\mathrm{Ob}(\mathscr{C})$, every $Y_1,Y_2\in\mathrm{Ob}(\mathscr{E}'_X)$ and every morphism $g:\varphi Y_1\to\varphi Y_2$ in $\mathscr{E}_X$ there exist a covering family $(f_i:X_i\to X\mid i\in I)$, and morphisms $Y_2\stackrel{g_i}{\leftarrow}Z_i\stackrel{h_i}{\to}Y_1$ in $\mathscr{E}'$, where h_i is $\mathscr{C}$-cartesian for every $i\in I$, such that

$$\varphi(g_i)=g\circ\varphi(h_i)\qquad\text{and}\qquad F'(h_i)=f_i.$$

(iii) φ is a 2-*covering* if for every $X\in\mathrm{Ob}(\mathscr{C})$, every $Y_1,Y_2\in\mathrm{Ob}(\mathscr{E}'_X)$, and every pair $g_1,g_2:Y_1\to Y_2$ of morphisms in $\mathscr{E}'_X$ with $\varphi(g_1)=\varphi(g_2)$ there exist a covering family $(f_i:X_i\to X\mid i\in I)$, and for every $i\in I$ a $\mathscr{C}$-cartesian morphism

$$h_i:Z_i\to Y_1\quad\text{in }\mathscr{E}'\text{ such that}\quad g_1\circ h_i=g_2\circ h_i\quad\text{and}\quad F'(h_i)=f_i.$$

Remark 5.2.2. Suppose that $(\mathscr{E}\xrightarrow{F}\mathscr{C},\boldsymbol{\lambda})$ and $(\mathscr{E}'\xrightarrow{F'}\mathscr{C},\boldsymbol{\lambda}')$ are split fibrations over $\mathscr{C}$, and $\varphi:(\mathscr{E}',\boldsymbol{\lambda}')\to(\mathscr{E},\boldsymbol{\lambda})$ is a split cartesian functor. Let c and c' be the strict pseudo-functors associated with $\boldsymbol{\lambda}$ and $\boldsymbol{\lambda}'$. Then we can rephrase the conditions of definition 5.2.1 as follows :

(i) φ is 0-covering if and only if for every $Y\in\mathrm{Ob}(\mathscr{E})$ there exist a covering family $(f_i:X_i\to FY\mid i\in I)$ and for every $i\in I$ an object $Y'_i\in\mathrm{Ob}(\mathscr{E}'_{X_i})$ and an isomorphism $\varphi Y'_i\stackrel{\sim}{\to}\mathsf{c}_{f_i}Y$ in $\mathscr{E}_{X_i}$.

(ii) φ is 1-covering if and only if for every $X\in\mathrm{Ob}(\mathscr{C})$, every $Y_1,Y_2\in\mathrm{Ob}(\mathscr{E}'_X)$ and every morphism $g:\varphi Y_1\to\varphi Y_2$ in $\mathscr{E}_X$ we have a covering family $(f_i:X_i\to X\mid i\in I)$, and for every $i\in I$ a morphism $g_i:\mathsf{c}'_{f_i}Y_1\to\mathsf{c}'_{f_i}Y_2$ in $\mathscr{E}'_{X_i}$ such that $\varphi(g_i)=\mathsf{c}_{f_i}(g)$.

(iii) φ is a 2-*covering* if for every $X\in\mathrm{Ob}(\mathscr{C})$, every $Y_1,Y_2\in\mathrm{Ob}(\mathscr{E}'_X)$, and every pair $g_1,g_2:Y_1\to Y_2$ of morphisms in $\mathscr{E}'_X$ with $\varphi(g_1)=\varphi(g_2)$ there exists a covering family $(f_i:X_i\to X\mid i\in I)$ such that $\mathsf{c}'_{f_i}(g_1)=\mathsf{c}'_{f_i}(g_2)$.

Lemma 5.2.3. *Consider a site $(\mathscr{C}, J)$, and an essentially commutative diagram of the 2-category $\mathsf{Fib}(\mathscr{C})$, whose vertical arrows are equivalences of categories :*

$$\begin{array}{ccc} \mathscr{E}' & \xrightarrow{\varphi} & \mathscr{E} \\ {\scriptstyle\omega'}\downarrow & & \downarrow{\scriptstyle\omega} \\ \mathscr{F}' & \xrightarrow{\psi} & \mathscr{F}. \end{array}$$

Let also $i \in \{0, 1, 2\}$. Then φ is i-covering if and only if the same holds for ψ.

Proof. Denote $\mathscr{E} \xrightarrow{F} \mathscr{C} \xleftarrow{F'} \mathscr{E}'$ and $\mathscr{F} \xrightarrow{G} \mathscr{C} \xleftarrow{G'} \mathscr{F}'$ the respective fibrations. The assumption means that there exists an isomorphism of functors $\beta : \psi \circ \omega' \xrightarrow{\sim} \omega \circ \varphi$ such that $G * \beta = \mathbf{1}_{F'}$.

Suppose that φ is 0-covering, let $Y \in \mathrm{Ob}(\mathscr{F})$ be any object, and set $X := GY$; by assumption there exists $Z \in \mathrm{Ob}(\mathscr{E}_X)$ with an isomorphism $t : \omega Z \xrightarrow{\sim} Y$ in $\mathscr{F}_X$ (corollary 3.1.28(i)). Then there exist a covering family $(f_j : X_j \to X \mid j \in I)$ and for every $j \in I$ a cartesian morphism $h_j : \varphi Z'_j \to Z$ with $Fh_j = f_j$. It follows that

$$h'_j := t \circ \omega(h_j) \circ \beta_{Z'_j} : \psi(\omega' Z'_j) \to Y$$

is cartesian and $Gh'_j = f_j$ for every $j \in I$, so ψ is 0-covering.

Conversely, suppose that ψ is 0-covering; let $Y \in \mathrm{Ob}(\mathscr{E})$ and $X := FY$. By assumption there exist a covering family $(f_j : X_j \to X \mid j \in I)$ and for every $j \in I$ a cartesian morphism $h_j : \psi Z_j \to \omega Y$ with $Gh_j = f_j$. Then we find for every $j \in I$ an isomorphism $t_j : \omega' Z'_j \xrightarrow{\sim} Z_j$ in $\mathscr{F}'_{X_j}$; it follows that $h_j := h \circ \psi(t_j) \circ \beta^{-1}_{Z'_j} : \omega(\varphi Z'_j) \to \omega Y$ is cartesian, and since ω is an equivalence, there exists a unique cartesian morphism $h'_j : \varphi Z'_j \to Y$ in $\mathscr{E}$ with $\omega(h'_j) = h_j$, for every $j \in I$ (details left to the reader); by construction, $Fh'_j = f_j$, so φ is 0-covering.

Next, if φ is 1-covering, let $X \in \mathrm{Ob}(\mathscr{C})$ and $g : \psi Y_1 \to \psi Y_2$ any morphism in $\mathscr{F}_X$. We find isomorphisms $t_i : \omega' Z_i \xrightarrow{\sim} Y_i$ in $\mathscr{F}'_X$ $(i = 1, 2)$, and a morphism $g' : \psi(\omega' Z_1) \to \psi(\omega' Z_2)$ such that $\psi(t_2) \circ g' = g \circ \psi(t_1)$; then $\beta_{Z_2} \circ g' = \omega(g'') \circ \beta_{Z_1}$ for a morphism $g'' : \varphi Z_1 \to \varphi Z_2$ in $\mathscr{E}_X$. By assumption, there exist a covering family $(f_j : X_j \to X \mid j \in I)$ and morphisms $Z_2 \xleftarrow{g_j} W_j \xrightarrow{h_j} Z_1$ in $\mathscr{E}'$ for every $j \in I$, such that h_j is cartesian with $F' h_j = f_j$, and $\varphi(g_j) = g'' \circ \varphi(h_j)$. Set $h'_j := t_1 \circ \omega'(h_j)$ and $g'_j := t_2 \circ \omega'(g_j)$; then h'_j is cartesian with $G'(h'_j) = f_j$, and $\psi(g'_j) = g \circ \psi(h'_j)$ for every $j \in I$. This shows that ψ is 1-covering.

Conversely, suppose that ψ is 1-covering, and let $g : \varphi Y_1 \to \varphi Y_2$ be a morphism in $\mathscr{E}_X$. Then there exist a covering family $(f_j : X_j \to X \mid j \in I)$ and morphisms $\omega' Y_2 \xleftarrow{g_j} Z_j \xrightarrow{h_j} \omega' Y_1$ in $\mathscr{F}'$ such that h_j is cartesian with $G' h_j = f_j$ and $\beta_{Y_2} \circ \psi(g_j) = \omega(g) \circ \beta_{Y_1} \circ \psi(h_j)$ for every $j \in I$. We pick also an isomorphism $t_j : \omega' Z'_j \xrightarrow{\sim} Z_j$ in $\mathscr{F}'_{X_j}$ for every $j \in I$; then there exist a unique cartesian morphism $h'_j : Z'_j \to Y_1$ with $\omega'(h'_j) = h_j \circ t_j$ and a unique morphism $g'_j : Z'_j \to Y_2$ with $\omega'(g'_j) = g_j \circ t_j$. A direct computation shows that $\omega(g \circ \varphi(h'_j)) = \omega(\varphi(g'_j))$, whence $g \circ \varphi(h'_j) = \varphi(g'_j)$ for every $j \in I$. Thus, φ is 1-cartesian.

Lastly, suppose that φ is 2-covering, and let $g_1, g_2 : Y_1 \to Y_2$ be two morphisms in $\mathscr{F}'_X$ such that $\psi(g_1) = \psi(g_2)$. Pick isomorphisms $t_i : \omega' Z_i \xrightarrow{\sim} Y_i$ for $i = 1, 2$; then there exists for $i = 1, 2$ a unique morphism $g'_i : Z_1 \to Z_2$ such that $t_2 \circ \omega'(g'_i) = g_i \circ t_1$. It follows that

$$\begin{aligned} \psi(t_2) \circ \beta^{-1}_{Z_2} \circ \omega(\varphi(g'_1)) &= \psi(t_2) \circ \psi(\omega' g_1) \circ \beta^{-1}_{Z_1} \\ &= \psi(g_1 \circ t_1) \circ \beta^{-1}_{Z_1} \\ &= \psi(g_2 \circ t_1) \circ \beta^{-1}_{Z_1} \\ &= \psi(t_2) \circ \beta^{-1}_{Z_2} \circ \omega(\varphi(g'_2)) \end{aligned}$$

whence $\varphi(g_1') = \varphi(g_2')$. Then we have a covering family $(f_j : X_j \to X \mid j \in I)$ and for every $j \in I$ a cartesian morphism $h_j : W_j \to Z_1$ such that $g_1' \circ h_j = g_2' \circ h_j$ and $Fh_j = f_j$. Hence $h_j' := t_1 \circ \omega'(h_j) : \omega' W_j \to Y_1$ is cartesian with $G'h_j' = f_j$ and $g_1 \circ h_j' = g_2 \circ h_j'$. This proves that ψ is 2-covering. Conversely, suppose that ψ is 2-covering, and let $g_1, g_2 : Y_1 \to Y_2$ be two morphisms in $\mathscr{E}'_X$ such that $\varphi(g_1) = \varphi(g_2)$. Set $g_i' := \omega'(g_i)$ for $i = 1, 2$; then $\psi(g_1') = \psi(g_2')$, so there exist a covering family $(f_j : X_j \to X \mid j \in I)$ and for every $j \in I$ a cartesian morphism $h_j : Z_j \to \omega' Y_1$ such that $g_1' \circ h_j = g_2' \circ h_j$ and $G'h_j = f_j$. For every $j \in I$ pick an isomorphism $t_j : \omega' Z_j' \stackrel{\sim}{\to} Z_j$ in $G'^{-1}X$; there exists a unique cartesian morphism $h_j' : Z_j' \to Y_1$ such that $\omega'(h_j') = h_j \circ t_j$. It is easily seen that $\omega'(g_1 \circ h_j') = \omega'(g_2 \circ h_j')$, whence $g_1 \circ h_j' = g_2 \circ h_j'$, and $F'h_j' = f_j$ for every $j \in I$. Thus, φ is 2-covering. □

Lemma 5.2.4. *Let $(\mathscr{C}, J)$ be a site, $F : \mathscr{E} \to \mathscr{C}$, $F' : \mathscr{E}' \to \mathscr{C}$, $F'' : \mathscr{E}'' \to \mathscr{C}$ three fibrations, $\varphi : \mathscr{E}'' \to \mathscr{E}'$ and $\psi : \mathscr{E}' \to \mathscr{E}$ two cartesian functors, and $i \in \{0, 1, 2\}$. We have:*

(i) *If φ and ψ are i-covering, the same holds for $\psi \circ \varphi$.*
(ii) *If $\psi \circ \varphi$ is i-covering, and φ is j-covering for every $j < i$, then ψ is i-covering.*
(iii) *If $\psi \circ \varphi$ is i-covering and ψ is j-covering for every $j > i$, then φ is i-covering.*

Proof. In view of lemma 5.2.3 and claim 3.2.8 we may replace φ and ψ by $\mathsf{C}(\varphi)$ and $\mathsf{C}(\psi)$, and assume from start that φ and ψ are split cartesian functors. We then denote by c, c' and c'' the strict pseudo-functors associated with the split cleavages of $\mathscr{E}$, $\mathscr{E}'$ and $\mathscr{E}''$ respectively.

(i): Suppose first that $i = 0$, let $Y \in \mathrm{Ob}(\mathscr{E})$ be any object, and set $X := FY$; by assumption there exist a covering family $(f_j : X_j \to X \mid j \in I)$ and for every $j \in I$ an isomorphism $h_j : \psi Y_j' \stackrel{\sim}{\to} \mathsf{c}_{f_j} Y$ in $\mathscr{E}_{X_j}$. Likewise, for every $j \in I$ there exist a covering family $(f_{j\lambda} : X_{j\lambda} \to X_j \mid \lambda \in \Lambda_j)$ and for every $\lambda \in \Lambda_j$ an isomorphism $h_{j\lambda} : \varphi Y''_{j\lambda} \stackrel{\sim}{\to} \mathsf{c}'_{f_{j\lambda}} Y_j'$ in $\mathscr{E}'_{X_{j\lambda}}$. Then the family $(f'_{j\lambda} := f_j \circ f_{j\lambda} \mid j \in I,\ \lambda \in \Lambda_j)$ covers X and $\mathsf{c}_{f_{j\lambda}}(h_j) \circ \psi(h_{j\lambda}) : \psi \circ \varphi(Y''_{j\lambda}) \to \mathsf{c}_{f'_{j\lambda}} Y$ is an isomorphism in $\mathscr{E}_{X_{j\lambda}}$ for every $j \in I$ and $\lambda \in \Lambda_j$, whence the contention, in this case.

Next, suppose that $i = 1$. Let $X \in \mathrm{Ob}(\mathscr{C})$, $Y_1'', Y_2'' \in \mathrm{Ob}(\mathscr{E}''_X)$, and $g : \psi \circ \varphi Y_1'' \to \psi \circ \varphi Y_2''$ any morphism in $\mathscr{E}_X$. By assumption there exist a covering family $(f_j : X_j \to X \mid j \in I)$ and for every $j \in I$ a morphism

$$g_j : \varphi(\mathsf{c}''_{f_j} Y_1'') = \mathsf{c}'_{f_j}(\varphi Y_1'') \to \mathsf{c}'_{f_j}(\varphi Y_2'') = \varphi(\mathsf{c}''_{f_j} Y_2'') \quad \text{in } \mathscr{E}'_{X_j} \text{ such that} \quad \psi(g_j) = \mathsf{c}_{f_j}(g).$$

Since φ is 1-covering, we find for every $j \in I$ a covering family $(f_{j\lambda} : X_{j\lambda} \to X_j \mid \lambda \in \Lambda_j)$ and for every $\lambda \in \Lambda_j$ a morphism

$$g_{j\lambda} : \mathsf{c}''_{f_{j\lambda}}(\mathsf{c}''_{f_j} Y_1'') \to \mathsf{c}''_{f_{j\lambda}}(\mathsf{c}''_{f_j} Y_2'') \qquad \text{in } \mathscr{E}'_{X_j} \text{ such that} \qquad \varphi(g_{j\lambda}) = \mathsf{c}'_{f_{j\lambda}}(g_j).$$

Then the family $(f'_{j\lambda} := f_j \circ f_{j\lambda} \mid j \in I,\ \lambda \in \Lambda_j)$ covers X, and $\psi \circ \varphi(g_{j\lambda}) = \mathsf{c}_{f'_{j\lambda}}(g)$ for every $j \in I$ and every $\lambda \in \Lambda_j$. It follows that $\psi \circ \varphi$ is 1-covering.

Lastly, let $i = 2$; consider morphisms $g_1, g_2 : Y_1'' \to Y_2''$ in $\mathscr{E}''_X$ with $\psi \circ \varphi(g_1) = \psi \circ \varphi(g_2)$. By assumption, there exists a covering family $(f_j : X_j \to X \mid j \in I)$ such that

$$\varphi(\mathsf{c}''_{f_j}(g_1)) = \mathsf{c}'_{f_j}(\varphi(g_1)) = \mathsf{c}'_{f_j}(\varphi(g_2)) = \varphi(\mathsf{c}''_{f_j}(g_2)) \qquad \text{for every } j \in I.$$

We may then find for every $j \in I$ a covering family $(f_{j\lambda} : X_{j\lambda} \to X_j \mid \lambda \in \Lambda_j)$ such that $\mathsf{c}''_{f_{j\lambda}} \circ \mathsf{c}''_{f_j}(g_1) = \mathsf{c}''_{f_{j\lambda}} \circ \mathsf{c}''_{f_j}(g_2)$ for every $\lambda \in \Lambda_j$. We conclude that $\psi \circ \varphi$ is 2-covering.

(ii): Again, we suppose first that $i = 0$, in which case the assumption means that $\psi \circ \varphi$ is 0-covering (and there is no condition on φ), and we need to check that ψ is 0-covering. However, the assertion follows straightforwardly from the definitions (details left to the reader).

Next, suppose that $i = 1$, in which case $\psi \circ \varphi$ is 1-covering and φ is 0-covering. Let $g : \psi Y_1' \to \psi Y_2'$ be a morphism in $\mathscr{E}_X$, for some $X \in \mathrm{Ob}(\mathscr{C})$; by assumption there exist for $t = 1, 2$ a covering family $(f_{tj} : X_{tj} \to X \mid j \in I_t)$ and isomorphisms $h_{tj} : \varphi Y''_{tj} \stackrel{\sim}{\to} \mathsf{c}'_{f_j} Y_t'$ in $F'^{-1} X_j$ for every $j \in I_t$. Notice then that for every morphism $f' : X' \to X_{ti}$ in $\mathscr{C}$ we get an isomorphism $\mathsf{c}'_{f'}(h_{tj}) : \varphi(\mathsf{c}''_{f'}Y''_{tj}) \stackrel{\sim}{\to} \mathsf{c}'_{f_j\circ f'}Y'_t$ in $\mathscr{E}'_{X'}$. We deduce that, after replacing the covering families $f_{1\bullet}$ and $f_{2\bullet}$ by a common refinement, we may assume that $I := I_1 = I_2$ and $f_j := f_{1j} = f_{2j}$ for every $j \in I$. In this situation, for every $j \in I$ there exists a morphism

$$g_j : \psi \circ \varphi(Y''_{1j}) \to \psi \circ \varphi(Y''_{2j}) \qquad \text{in } \mathscr{E}_{X_j} \text{ such that} \qquad \psi(h_{2j}) \circ g_j = \mathsf{c}_{f_j}(g) \circ \psi(h_{1j}).$$

By our assumption on $\psi \circ \varphi$, for every $j \in I$ we then find a covering family $(f_{j\lambda} : X_{j\lambda} \to X_j \mid \lambda \in \Lambda_j)$ and for every $\lambda \in \Lambda_j$ a morphism

$$g_{j\lambda} : Y''_{1j} \to Y''_{1j} \qquad \text{in } \mathscr{E}''_{X_{j\lambda}} \qquad \text{such that} \qquad \psi \circ \varphi(g_{j\lambda}) = \mathsf{c}_{f_{j\lambda}}(g_j).$$

It follows that $\psi(\mathsf{c}'_{f_{j\lambda}}h_{2j}) \circ \psi(\varphi(g_{j\lambda})) = \mathsf{c}_{f_j\circ f_{j\lambda}}(g) \circ \psi(\mathsf{c}'_{f_j}h_{1j})$ for every $j \in I$ and $\lambda \in \Lambda_j$. Since the family $(f_i \circ f_{i\lambda} \mid i \in I,\ \lambda \in \Lambda_i)$ covers X, we conclude that ψ is 1-covering.

Next, suppose that $i = 2$, so $\psi \circ \varphi$ is 2-covering and φ is j-covering for $j = 0, 1$. Let $X \in \mathrm{Ob}(\mathscr{C})$ and $g_1, g_2 : Y'_1 \to Y'_2$ two morphisms of $\mathscr{E}'_X$ such that $\psi(g_1) = \psi(g_2)$. Arguing as in the previous case, we find a covering family $(f_j : X_j \to X \mid j \in I)$ and isomorphisms $h_{tj} : \varphi Y''_{tj} \stackrel{\sim}{\to} \mathsf{c}'_{f_j}Y'_t$ in $\mathscr{E}'_{X_j}$ for $t = 1, 2$ and every $j \in I$. In this situation, for every $j \in I$ and $t = 1, 2$ there exists a unique morphism $g_{tj} : \varphi Y''_{1i} \to \varphi Y''_{2i}$ in $\mathscr{E}'_{X_j}$ such that

$$h_{2j} \circ g_{tj} = \mathsf{c}_{f_j}(g_t) \circ h_{1j}. \tag{5.2.5}$$

Notice that $\psi(h_{2j}) \circ \psi(g_{1j}) = \mathsf{c}'_{f_j}(\psi(g_1)) = \mathsf{c}'_{f_j}(\psi(g_2)) = \psi(h_{2j}) \circ \psi(g_{2j})$, whence

$$\psi(g_{1j}) = \psi(g_{2j}) \qquad \text{for every } j \in I.$$

Then, since φ is 1-covering, for every $j \in I$ and $t = 1, 2$ we find a covering family $f_{tj\bullet} := (f_{tj\lambda} : X_{tj\lambda} \to X_j \mid \lambda \in \Lambda_{tj})$ and morphisms

$$g_{tj\lambda} : \mathsf{c}''_{f_{tj\lambda}}Y''_{1j} \to \mathsf{c}''_{f_{tj\lambda}}Y''_{2j} \qquad \text{in } \mathscr{E}''_{X_{tj\lambda}} \qquad \text{such that} \qquad \varphi(g_{tj\lambda}) = \mathsf{c}'_{f_{tj\lambda}}(g_{tj})$$

and arguing as in the foregoing, we may replace $f_{1j\bullet}$ and $f_{2j\bullet}$ by a common refinement, and assume that $\Lambda_j := \Lambda_{1j} = \Lambda_{2j}$ for every $j \in I$, and $f_{j\lambda} := f_{1j\lambda} = f_{2j\lambda}$, for every $j \in I$ and every $\lambda \in \Lambda_j$. We deduce that

$$\psi \circ \varphi(g_{1j\lambda}) = \mathsf{c}''_{f_{j\lambda}}(\psi(g_{1j})) = \mathsf{c}''_{f_{j\lambda}}(\psi(g_{2j})) = \psi \circ \varphi(g_{2j\lambda}) \qquad \text{for every } j \in I \text{ and } \Lambda \in \Lambda_j.$$

Since $\psi \circ \varphi$ is 2-covering, there exists therefore a covering family $(f_{j\lambda\lambda'} : X_{j\lambda\lambda'} \to X_{j\lambda} \mid \lambda' \in \Lambda_{j\lambda})$ such that $\mathsf{c}''_{f_{j\lambda\lambda'}}(g_{1j\lambda}) = \mathsf{c}''_{f_{j\lambda\lambda'}}(g_{2j\lambda})$ for every $\lambda' \in \Lambda_{j\lambda}$. Therefore $\mathsf{c}'_{f_{j\lambda\lambda'}} \circ \mathsf{c}'_{f_{j\lambda}}(g_{1j}) = \varphi(\mathsf{c}''_{f_{j\lambda\lambda'}}(g_{1j\lambda})) = \varphi(\mathsf{c}''_{f_{j\lambda\lambda'}}(g_{2j\lambda})) = \mathsf{c}'_{f_{j\lambda\lambda'}} \circ \mathsf{c}'_{f_{j\lambda}}(g_{2j})$ for every $j \in I$, $\lambda \in \Lambda_j$ and $\lambda' \in \Lambda_{j\lambda}$. Set $f'_{j\lambda\lambda'} := f_j \circ f_{j\lambda} \circ f_{j\lambda\lambda'}$ for every such j, λ, λ'; combining with (5.2.5), we deduce easily that $\mathsf{c}_{f'_{j\lambda\lambda'}}(g_1) = \mathsf{c}_{f'_{j\lambda\lambda'}}(g_2)$, and we conclude that ψ is 2-covering, as sought.

(iii): The case where $i = 2$ is immediate from the definitions.

Say that $i = 1$, so $\psi \circ \varphi$ is 1-covering and ψ is 2-covering; let $X \in \mathrm{Ob}(\mathscr{C})$ and $g : \varphi Y''_1 \to \varphi Y''_2$ a morphism in $\mathscr{E}'_X$. By assumption, there exist a covering family $(f_j : X_j \to \ \mid j \in I)$ and a morphism $g_j : \mathsf{c}_{f_j}Y''_1 \to \mathsf{c}_{f_j}Y''_2$ in $\mathscr{E}''_{X_j}$ for every $j \in I$ such that

$$\psi \circ \varphi(g_j) = \mathsf{c}_{f_j}(\psi(g)) = \psi(\mathsf{c}'_{f_j}(g)).$$

Then, since ψ is 2-covering, we find for every $j \in I$ a covering family $(f_{j\lambda} : X_{j\lambda} \to X_j \mid \lambda \in \Lambda_j)$ such that $\mathsf{c}'_{f_{j\lambda}}(\varphi(g_j)) = \mathsf{c}'_{f_{j\lambda}} \circ \mathsf{c}'_{f_j}(g)$ for every $\lambda \in \Lambda_j$, *i.e.* $\varphi(\mathsf{c}''_{f_{j\lambda}}(g_j)) = \mathsf{c}'_{f_j\circ f_{j\lambda}}(g)$. This shows that φ is 1-covering.

In order to deal with the case where $i = 0$, let us remark :

Claim 5.2.6. Suppose ψ is j-covering for $j = 1, 2$. Let $X \in \mathrm{Ob}(\mathscr{C})$ and $Z, Z' \in \mathrm{Ob}(\mathscr{E}'_X)$ such that ψZ and $\psi Z'$ are isomorphic in $\mathscr{E}_X$. Then there exists a covering family $(f_j : X_j \to X \mid j \in I)$ such that $\mathsf{c}'_{f_j}Z$ and $\mathsf{c}'_{f_j}Z'$ are isomorphic in $\mathscr{E}'_{X_j}$ for every $j \in I$.

Proof of the claim. Let $l : \psi Z \xrightarrow{\sim} \psi Z'$ be an isomorphism in $\mathscr{E}_X$; since ψ is 1-covering, there exist a covering family $(f'_j : X'_j \to X \mid j \in I)$ and for every $j \in I$ a morphism $l_j : \mathsf{c}'_{f'_j} Z \to \mathsf{c}'_{f'_j} Z'$ such that $\psi(l_j) = \mathsf{c}_{f'_j}(l)$. Likewise, there exist a covering family $(f''_j : X'_j \to X \mid j \in I')$ and for every $j \in I'$ a morphism $l'_j : \mathsf{c}'_{f''_j} Z' \to \mathsf{c}'_{f''_j} Z$ such that $\psi(l'_i) = \mathsf{c}_{f''_j}(l^{-1})$. After replacing $(f'_j \mid j \in I)$ and $(f''_j \mid j \in I')$ by a common refinement, we may then assume that $I = I'$ and $f_j := f'_j = f''_j$ for every $j \in I$ (details left to the reader). It follows that $\varphi(k_j \circ l_j) = \mathsf{c}_{f_j}(\mathbf{1}_Z) = \varphi(\mathbf{1}_{\mathsf{c}'_{f_j} Z})$ and $\varphi(l_j \circ k_j) = \mathsf{c}_{f_j}(\mathbf{1}_{Z'}) = \varphi(\mathbf{1}_{\mathsf{c}'_{f_j} Z'})$ for every $j \in I$. Then, since ψ is 2-covering, for every $j \in I$ there exists a covering family $(f_{j\lambda} : X_{j\lambda} \to X_j \mid \lambda \in \Lambda_j)$ such that $\mathsf{c}'_{f_{j\lambda}}(k_j \circ l_j) = \mathsf{c}'_{f_{j\lambda}}(\mathbf{1}_{\mathsf{c}'_{f_j} Z})$; likewise, for every $j \in I$ there exists a covering family $(f'_{j\lambda} : X'_{j\lambda} \to X_j \mid \lambda \in \Lambda'_j)$ such that $\mathsf{c}'_{f'_{j\lambda}}(l_j \circ k_j) = \mathsf{c}'_{f'_{j\lambda}}(\mathbf{1}_{\mathsf{c}'_{f_j} Z'})$. After replacing these families by a common refinement, we may assume that $\Lambda_j = \Lambda'_j$ for every $j \in I$, and $f_{j\lambda} = f'_{j\lambda}$ for every $j \in I$ and every $\lambda \in \Lambda_j$. Then, set $h_{j\lambda} := f_j \circ f_{j\lambda}$ for every $j \in I$ and every $\lambda \in \Lambda_j$; we deduce easily that $\mathsf{c}'_{f'_{j\lambda}}(l_j)$ is an isomorphism $\mathsf{c}'_{h_{j\lambda}} Z \xrightarrow{\sim} \mathsf{c}'_{h_{j\lambda}} Z'$, whence the claim. ◊

Now, suppose that $\psi \circ \varphi$ is 0-covering and ψ is j-covering for $j = 1, 2$, and let $X \in \mathrm{Ob}(\mathscr{C})$, $Y' \in \mathrm{Ob}(\mathscr{E}'_X)$; by assumption there exist a covering family $(f_j : X_j \to X \mid j \in I)$ and for every $j \in I$ an isomorphism $\psi \circ \varphi Y''_j \xrightarrow{\sim} \mathsf{c}_{f_j} \psi Y' = \psi(\mathsf{c}'_{f_j} Y')$ in $\mathscr{E}_X$. By claim 5.2.6, there exists for every $j \in I$ a covering family $(f_{j\lambda} : X_{j\lambda} \to X_j \mid j \in I)$ such that $\mathsf{c}'_{f_{j\lambda}}(\varphi Y''_j) = \varphi(\mathsf{c}''_{f_{j\lambda}} Y''_j)$ is isomorphic to $\mathsf{c}'_{f_j \circ f_{j\lambda}} Y'$ in $\mathscr{E}'_{X_i}$ for every $\lambda \in \Lambda_j$. This shows that φ is 0-covering, and concludes the proof of the lemma. □

Lemma 5.2.7. *Let $C := (\mathscr{C}, J)$ be a site, $\mathscr{E} \xrightarrow{F} \mathscr{C} \xleftarrow{F'} \mathscr{E}'$ two fibrations, and $\varphi : \mathscr{E} \to \mathscr{E}'$ a $\mathscr{C}$-cartesian functor. The following conditions are equivalent :*

(i) *φ is 1-covering (resp. 2-covering).*

(ii) *For every $X \in \mathrm{Ob}(\mathscr{C})$ and every $\sigma, \sigma' \in \mathscr{E}(X)$, the induced morphism :*

$$\mathscr{C}art(\sigma, \sigma')^a \to \mathscr{C}art(\varphi \circ \sigma, \varphi \circ \sigma')^a \tag{5.2.8}$$

of sheaves on C/X is an epimorphism (resp. a monomorphism).

Proof. Recall that – as described in (5.1.8) – for every X, σ, σ' as in (ii) we have a morphism of presheaves $\varphi^*_{\sigma,\sigma'} : \mathscr{C}art(\sigma, \sigma') \to \mathscr{C}art(\varphi \circ \sigma, \varphi \circ \sigma')$ on $\mathscr{C}/X$, and (5.2.8) is the morphism of associated sheaves $(\varphi^*_{\sigma,\sigma'})^a$ on the site C/X. Then the assertion follows easily by inspecting the definitions, and taking into account corollary 4.1.30(i,ii) and remark 4.1.29(ii,iii). □

Proposition 5.2.9. *Let $(\mathscr{C}, J)$ be a site, $\mathscr{E} \xrightarrow{F} \mathscr{C} \xleftarrow{F'} \mathscr{E}'$ two fibrations, $\varphi : \mathscr{E} \to \mathscr{E}'$ a $\mathscr{C}$-cartesian functor, and $i \in \{0, 1, 2\}$ such that $\mathscr{E}$ is i-separated and $\mathscr{E}'$ is $(i-1)$-separated. Then φ is i-faithful if and only if it is j-covering for every $j \geq 2 - i$.*

Proof. We consider first the case where $i = 0$, so by assumption $\mathscr{E}$ is a 0-separated prestack (and no conditions on $\mathscr{E}'$); the assertion is that φ is faithful if and only if it is 2-covering. However, if φ is faithful, it is obviously 2-covering. Thus, suppose that φ is 2-covering, and let $X \in \mathrm{Ob}(\mathscr{C})$ and $g_1, g_2 : Y \to Z$ two morphisms in $\mathscr{E}_X$ such that $\varphi(g_1) = \varphi(g_2)$; by assumption there exist a covering family $(f_j : X_j \to X \mid j \in I)$ and for every $j \in I$ a cartesian morphism $h_j : Y_j \to Y$ in $\mathscr{E}$ such that $Fh_j = f_j$ and $g_1 \circ h_j = g_2 \circ h_j$. We may then find two cartesian sections $\psi_Y, \psi_Z \in \mathscr{E}(X)$ such that $\psi_Y(\mathbf{1}_X) = Y$ and $\psi_Z(\mathbf{1}_X) = Z$, and for $i = 1, 2$ there exists a unique natural $\mathscr{C}$-transformation $\sigma_i : \psi_Y \Rightarrow \psi_Z$ such that $\sigma_{i,\mathbf{1}_X} = g_i$. It follows that $(\sigma_1)_{|\mathscr{S}} = (\sigma_2)_{|\mathscr{S}}$, so $\sigma_1 = \sigma_2$, since $\mathscr{E}$ is 0-separated; hence $g_1 = g_2$, so φ is faithful.

In case $i = 1$, the prestack $\mathscr{E}$ is 1-separated and $\mathscr{E}'$ is 0-separated, and we need to check that φ is fully faithful if and only if it is j-covering for $j = 1, 2$. Again, if φ is fully faithful, obviously it is j-covering for $j = 1, 2$. Conversely, if the latter condition holds, by the foregoing case we know already that φ is faithful, so it remains only to check that φ is full. Thus, let $X \in \mathrm{Ob}(\mathscr{C})$ and $g : \varphi Y_1 \to \varphi Y_2$ any morphism in $\mathscr{E}'_X$; by assumption, there exist a covering family $(f_j : X_j \to X \mid j \in I)$ and morphisms $Y_2 \xleftarrow{g_j} Z_j \xrightarrow{h_j} Y_1$ with h_j cartesian, such that $Fh_j = f_j$ and $\varphi(g_j) = g \circ \varphi(h_j)$ for every $j \in I$. As in the foregoing, we pick for $i = 1, 2$ a cartesian section $\psi_i \in \mathscr{E}(X)$ such that $\psi_i(\mathbf{1}_X) = Y_i$, and then there exists a unique natural $\mathscr{C}$-transformation $\sigma : \varphi \circ \psi_1 \Rightarrow \varphi \circ \psi_2$ such that $\sigma_{\mathbf{1}_X} = g$. Since $\psi_1(f_j/X) : \psi_1(f_j) \to Y_1$ is cartesian, there exists moreover a unique isomorphism in $F^{-1}X_j$

$$h'_j : \psi_1(f_j) \xrightarrow{\sim} Z_j \qquad \text{such that} \qquad h_j \circ h'_j = \psi_1(f_j/X).$$

Likewise, since $\psi_2(f_j/X) : \psi_2(f_j) \to Y_2$ is cartesian, there exists a unique morphism in $F^{-1}X_j$

$$g'_j : \psi_1(f_j) \to \psi_2(f_j) \qquad \text{such that} \qquad g_j \circ h'_j = \psi_2(f_j/X) \circ g'_j.$$

We get therefore for every $j \in I$ a unique natural $\mathscr{C}$-transformation

$$\sigma_j : \psi_1 \circ f_{j*} \Rightarrow \psi_2 \circ f_{j*} \qquad \text{such that} \qquad \sigma_{j,\mathbf{1}_{X_j}} = g'_j.$$

Claim 5.2.10. $\varphi * \sigma_j = \sigma * f_j$ for every $j \in I$.

Proof of the claim. It suffices to check that $\varphi(\sigma_{j,\mathbf{1}_{X_j}}) = (\sigma * f_j)_{\mathbf{1}_{X_j}}$, *i.e.* $\varphi(g'_j) = \sigma_{f_j}$ for every $j \in I$. However : $\varphi(\psi_2(f_j/X)) \circ \varphi(g') = \varphi(g_j) \circ \varphi(h'_j) = g \circ \varphi(h_j) \circ \varphi(h'_j) = g \circ \varphi(\psi_1(f_j/X)) = \varphi(\psi_2(f_j/X)) \circ \sigma_{f_j}$, whence the assertion, since $\varphi(\psi_2(f_j/X))$ is cartesian. ◊

Recall now that the proof of theorem 3.2.7 yields a natural equivalence $\eta_{\mathsf{C}\mathscr{E})} : \mathsf{C}(\mathscr{E}) \xrightarrow{\sim} \mathsf{C}(\mathsf{C}(\mathscr{E}))$, induced by the strict pseudo-natural equivalence $\beta^{\boldsymbol{\lambda}}$ associated with the natural split cleavage $\boldsymbol{\lambda}$ of $\mathsf{C}(\mathscr{E})$. We set $\psi^*_i := \eta_{\mathsf{C}(\mathscr{E})}(\psi_i)$ for $i = 1, 2$. Explicitly, $\psi^*_i(f) = \psi_i \circ f_*$ for every $f \in \mathrm{Ob}(\mathscr{C}/X)$, and $\psi^*_{i,g/X} = \mathbf{1}_{\psi^*_i(f')}$ for every morphism $g/X : f' \to f$ in $\mathscr{C}/X$. Let $\mathscr{S} \subset \mathscr{C}/X$ be the sieve generated by $(f_j \mid j \in I)$; we construct as follows a natural $\mathscr{C}$-transformation

$$\sigma^\dagger : \psi^*_{|\mathscr{S}} \Rightarrow \psi^*_{|\mathscr{S}}.$$

For every $(f : X' \to X) \in \mathrm{Ob}(\mathscr{S})$, pick $j \in J$ such that there exists a factorisation $f = f_j \circ f'$ for some morphism $f' : X \to X_j$ of $\mathscr{C}$, and set $\sigma^\dagger_f := \sigma_j * f'_*$. Let us check that $\sigma^\dagger_f$ is independent of the choice of factorisation : indeed, if $f = f'' \circ f_k$ for some other $k \in I$ and some morphism $f'' : X' \to X_k$, we have $\varphi * (\sigma_j * f') = \sigma * f_j * f' = \sigma * f_k * f'' = \varphi * (\sigma_k * f'')$ by claim 5.2.10, whence the contention, since φ is faithful. Likewise, the naturality of the rule $f \mapsto \sigma^\dagger_f$ can be checked after composition with φ, where it follows easily (details left to the reader).

Now, since $\mathscr{E}$ is 1-separated, the same holds for $\mathsf{C}(\mathscr{E})$, hence $\sigma^\dagger$ extends to a natural $\mathscr{C}$-transformation $\sigma^* : \psi^*_1 \Rightarrow \psi^*_2$. Then there exists a unique natural $\mathscr{C}$-transformation $\sigma' : \psi_1 \Rightarrow \psi_2$ such that $\eta_{\mathsf{C}(\mathscr{E})}(\sigma') = \sigma^*$. We claim that

$$\varphi * \sigma' = \sigma.$$

Indeed, it suffices to show that $\eta_{\mathsf{C}(\mathscr{E})}(\varphi * \sigma') = \eta_{\mathsf{C}(\mathscr{E})}(\sigma)$, *i.e.* that $\mathsf{C}(\varphi) * \sigma^* = \eta_{\mathsf{C}(\mathscr{E})}(\sigma)$, and since $\mathscr{E}'$ is 0-separated, we are reduced to checking that $(\mathsf{C}(\varphi) * \sigma^*)_{|\mathscr{S}} = \eta_{\mathsf{C}(\mathscr{E})}(\sigma)_{|\mathscr{S}}$, *i.e.* that $\mathsf{C}(\varphi) * \sigma^\dagger = \eta_{\mathsf{C}(\mathscr{E})}(\sigma)_{|\mathscr{S}}$. Then we are further reduced to showing that $\varphi * \sigma^\dagger_{f_j} = \sigma * f_{j*}$ for every $j \in I$. But the latter identities hold by claim 5.2.10. Lastly, set $g' := \sigma'_{\mathbf{1}_X}$; we deduce that $\varphi(g') = g$, and this shows that φ is full, as required.

In case $i = 2$, the prestack $\mathscr{E}'$ is 1-separated and $\mathscr{E}$ is a stack, and we need to check that φ is an equivalence if and only if it is j-covering for $j = 0, 1, 2$. Again, if φ is an equivalence, clearly it is j-covering for all j; conversely, if this condition holds, by the foregoing we know already that φ is fully faithful, so it remains only to check that φ is essentially surjective. To this aim, let $X \in \mathrm{Ob}(\mathscr{C})$ and $Y' \in \mathrm{Ob}(\mathscr{E}'_X)$; by assumption, there exist a covering family $(f_j : X_j \to X \mid j \in I)$ and for every $j \in I$ a cartesian morphism $h_j : \varphi Y_j \to Y'$ with

$F'h_j = f_j$. Pick, for every $j \in I$ a cartesian section $\psi_j \in \mathscr{E}(X_j)$ with $\psi_j(\mathbf{1}_{X_j}) = Y_j$. Now, for every $j,k \in I$ consider the category $\mathscr{C}/X_{jk} := \mathscr{C}/X_j \times_{(f_{j*},f_{k*})} \mathscr{C}/X_k$ (see (3.5.4)). The objects of $\mathscr{C}/X_{jk}$ are the pairs of morphisms $X_j \xleftarrow{f'_j} X' \xrightarrow{f'_k} X_k$ such that $f' := f_j \circ f'_j = f_k \circ f'_k$. We have two natural projections $\mathscr{C}/X_j \xleftarrow{\pi^0_{jk}} \mathscr{C}/X_{jk} \xrightarrow{\pi^1_{jk}} \mathscr{C}/X_k$ that send every such pair (f'_j, f'_k) to f'_j and respectively f'_k. For every such pair (f'_j, f'_k) and $s = j,k$ we get cartesian morphisms $\psi_s(f'_s/X_s) : \psi_s(f'_s) \to Y_s$ such that $F\psi_s(f'_s/X_s) = f'_s$. There follows a unique isomorphism

$$\tau : \varphi \circ \psi_j(f'_j) \xrightarrow{\sim} \varphi \circ \psi_k(f'_k) \qquad \text{such that} \qquad h_k \circ \varphi(\psi_k(f'_k/X_k)) \circ \tau = h_j \circ \varphi(\psi_j(f'_j/X_j))$$

and since φ is fully faithful, we get a unique isomorphism

$$\omega^{ij}_{(f'_j,f'_k)} : \psi_j(f'_j) \xrightarrow{\sim} \psi_k(f'_k) \qquad \text{such that} \qquad \varphi(\omega^{ij}_{(f'_j,f'_k)}) = \tau$$

and we claim that the rule $(f'_j, f'_k) \mapsto \omega^{ij}_{(f'_j,f'_k)}$ yields an isomorphism of functors

$$\omega^{ij} : \psi_j \circ \pi^0_{jk}(f'_j, f'_k) \xrightarrow{\sim} \psi_k \circ \pi^1_{jk}(f'_j, f'_k).$$

Indeed, let $(X_j \xleftarrow{f''_j} X'' \xrightarrow{f''_k} X_k)$ be another object of $\mathscr{C}/X_{jk}$; a morphism $(f''_j, f''_k) \to (f'_j, f'_k)$ is a morphism $t : X'' \to X'$ in $\mathscr{C}$ such that $f'_j \circ t = f''_j$ and $f'_k \circ t = f''_k$, and the assertion amounts to the identity :

$$A := \psi_k(t/X_k) \circ \omega^{jk}_{(f''_j,f''_k)} = B := \omega^{jk}_{(f'_j,f'_k)} \circ \psi_j(t/X_j).$$

However, we have :

$$\begin{aligned} h_k \circ (\varphi \circ \psi_k(f'_k/X_k)) \circ \varphi(A) &= h_k \circ \varphi(\psi_k(f''_k/X_k) \circ \omega^{jk}_{(f''_j,f''_k)}) \\ &= h_j \circ \varphi(\psi_j(f''_j/X_j)) \\ &= h_j \circ \varphi(\psi_j(f'_j/X_j)) \circ \varphi(\psi_j(t/X_j)) \\ &= h_k \circ (\varphi \circ \psi_k(f'_k/X_k)) \circ \varphi(B) \end{aligned}$$

whence the contention, since $h_k \circ (\varphi \circ \psi_k(f'_k/X_k))$ is cartesian and φ is faithful. Next, for every $j,k,l \in I$ set $\mathscr{C}/X_{jkl} := \mathscr{C}/X_{jk} \times_{\mathscr{C}/X} \mathscr{C}/X_l$; the objects of this category are the triples $(f'_j : X' \to X_j, f'_k : X' \to X_k, f'_l : X' \to X_l)$ such that $f_j \circ f'_j = f_k \circ f'_k = f_l \circ f'_l$. We have obvious projection functors

$$\pi^0_{jkl} : \mathscr{C}/X_{jkl} \to \mathscr{C}/X_{kl} \qquad \pi^1_{jkl} : \mathscr{C}/X_{jkl} \to \mathscr{C}/X_{jl} \qquad \pi^2_{jk} : \mathscr{C}/X_{jkl} \to \mathscr{C}/X_{jk}.$$

With this notation, the uniqueness properties of ω^{ij} easily imply the cocycle identity :

$$(\omega^{jk} * \pi^2_{jkl}) \odot (\omega^{kl} * \pi^0_{jkl}) = \omega^{jl} * \pi^1_{jkl} \qquad \text{for every } j,k,l \in I$$

(details left to the reader). Let $\mathscr{S} \subset \mathscr{C}/X$ be the sieve generated by the family $(f_j \mid j \in I)$; in view of proposition 3.5.15, we deduce that there exist a cartesian functor $\psi : \mathscr{S} \to \mathscr{E}$ and a system of isomorphisms $(\eta_j : \psi_j \xrightarrow{\sim} \psi * f_{j*} \mid j \in I)$ fulfilling the compatibility condition

$$(\eta_k * \pi^1_{jk}) \odot \omega^{jk} = \eta_j * \pi^0_{jk} \qquad \text{for every } j,k \in I.$$

Since $\mathscr{E}$ is stack, we may then find a cartesian section $\psi' \in \mathscr{E}(X)$ with an isomorphism $\psi'_{|\mathscr{S}} \xrightarrow{\sim} \psi$. Set $Y := \psi'(\mathbf{1}_X)$; to conclude the proof, it will suffice to exhibit an isomorphism $Y' \xrightarrow{\sim} \varphi Y$ in $\mathscr{E}'$. To this aim, pick as well a cartesian section $\widetilde{\psi} \in \mathscr{E}'(X)$ such that $\widetilde{\psi}(\mathbf{1}_X) = Y'$; we set $\widetilde{\psi}_j := \widetilde{\psi} \circ f_{j*} : \mathscr{C}/X_j \to \mathscr{E}'$ for every $j \in I$. Notice that $\widetilde{\psi}_j \circ \pi^0_{jk} = \widetilde{\psi}_k \circ \pi^1_{jk}$ for every $j,k \in I$.

Since h_j is cartesian, there exists a unique isomorphism $h'_j : \widetilde{\psi}(f_j) \stackrel{\sim}{\to} \varphi Y_j$ in $F'^{-1}X_j$ such that $h_j \circ h'_j = \widetilde{\psi}(f_j/X)$. There follows an isomorphism of cartesian functors

$$\widetilde{\eta}_j : \widetilde{\psi}_j \stackrel{\sim}{\to} \varphi \circ \psi_j \qquad \text{such that} \qquad \widetilde{\eta}_{j,\mathbf{1}_{X_j}} = h'_j \qquad \text{for every } j \in I.$$

Explicitly, for every $(f' : X' \to X_j) \in \mathrm{Ob}(\mathscr{C}/X_j)$, the isomorphism $\widetilde{\eta}_{j,f'} : \widetilde{\psi}_j(f') \stackrel{\sim}{\to} \varphi\circ\psi_j(f')$ is characterized by the identity :

$$\varphi(\psi_j(f'/X_j)) \circ \widetilde{\eta}_{j,f'} = h'_j \circ \widetilde{\psi}_j(f'/X_j) \qquad \text{in } \mathscr{E}'.$$

We claim that the following diagram commutes for every $j, k \in I$:

$$\begin{array}{ccc} \widetilde{\psi}_j \circ \pi^0_{jk} & = & \widetilde{\psi}_k \circ \pi^1_{jk} \\ {\scriptstyle \widetilde{\eta}_j * \pi^0_{jk}} \Downarrow & & \Downarrow {\scriptstyle \widetilde{\eta}_k * \pi^1_{jk}} \\ \varphi \circ \psi_j \circ \pi^0_{jk} & \xRightarrow{\varphi * \omega^{ij}} & \varphi \circ \psi_k \circ \pi^1_{jk}. \end{array}$$

Indeed, let (f'_j, f'_k) be any object of $\mathscr{C}/X_{jk}$; we compute :

$$\begin{aligned} h_k \circ \varphi(\psi_k(f'_k/X_k)) \circ (\widetilde{\eta}_k * \pi^1_{jk})_{(f'_j,f'_k)} &= h_k \circ h'_k \circ \widetilde{\psi}_k(f'_k/X_k) \\ &= \widetilde{\psi}(f_k/X) \circ \widetilde{\psi}(f'_k/X) \\ &= \widetilde{\psi}(f_k \circ f'_k/X) \\ &= \widetilde{\psi}(f_j \circ f'_j/X) \\ &= h_j \circ h'_j \circ \widetilde{\psi}_j(f'_j/X_j) \\ &= h_j \circ \varphi(\psi_j(f'_j/X_j)) \circ \widetilde{\eta}_{j,f'} \\ &= h_k \circ \varphi(\psi_k(f'_k/X_k)) \circ \varphi(\omega^{ij}_{(f'_j,f'_k)}) \circ \widetilde{\eta}_{j,f'} \end{aligned}$$

whence the claim, as usual, since $h_k \circ \varphi(\psi_k(f'_k/X_k))$ is cartesian. In view of proposition 3.5.15, we deduce that there exists a unique isomorphism of cartesian functors

$$\widetilde{\psi}_{|\mathscr{S}} \stackrel{\sim}{\to} \varphi \circ \psi = (\varphi \circ \psi')_{|\mathscr{S}}.$$

But since $\mathscr{E}'$ is 1-separated, the latter comes from a unique isomorphism $\widetilde{\psi} \stackrel{\sim}{\to} \varphi \circ \psi'$, whence the sought isomorphism $Y' \stackrel{\sim}{\to} \varphi Y$. □

Proposition 5.2.11. *Let $(\mathscr{C}, J)$ be a small site, $F : \mathscr{E} \to \mathscr{C}$ a fibration, and $j \in \{0, 1, 2\}$. Then:*

(i) *The unit of adjunction $\eta_{\mathscr{E}} : \mathscr{E} \to \mathscr{E}^a$ is i-covering for $i = 0, 1, 2$.*
(ii) *$\mathscr{E}$ is j-separated if and only if $\eta_{\mathscr{E}}$ is j-faithful.*
(iii) *A cartesian functor $\varphi : \mathscr{E} \to \mathscr{E}'$ of $\mathscr{C}$-fibrations is j-covering if and only if the same holds for the induced functor $\varphi^a : \mathscr{E}^a \to \mathscr{E}'^a$.*

Proof. (i): Quite generally, let $G : \mathscr{A} \to \mathscr{B}$ be a $\mathscr{C}$-cartesian functor of fibrations, and $H : \mathscr{A}' \stackrel{\sim}{\to} \mathscr{A}$ a $\mathscr{C}$-equivalence of categories; then it is easily seen that G is i-covering for some $i \in \{0, 1, 2\}$ if and only if the same holds for $G \circ H$. Taking into account lemma 5.2.4(i), we are therefore reduced to checking :

Claim 5.2.12. The functor $j_{\mathscr{E}} : \mathsf{C}(\mathscr{E}) \to \mathscr{E}^+$ is i-covering for $i = 0, 1, 2$.

Proof of the claim. Let $[X, \psi : \mathscr{S} \to \mathscr{E}]$ be any object of $\mathscr{E}^+$, and pick a generating family $(f_j : X_j \to X \mid j \in I)$ for $\mathscr{S}$; then $(X_j, \psi \circ f_j : \mathscr{C}/X_j \to \mathscr{E})$ is an object of $\mathsf{C}(\mathscr{E})$ and f_j induces a cartesian morphism $j_{\mathscr{E}}(X_j, \psi \circ f_{j*}) \to [X, \psi]$ for every $j \in I$. Thus, $j_{\mathscr{E}}$ is 0-covering.

Next, let $[t,\sigma] : [X',\psi' : \mathscr{C}/X' \to \mathscr{E}] \to [X,\psi : \mathscr{C}/X \to \mathscr{E}]$ be a morphism in $\mathscr{E}^+$. By definition, $t : X' \to X$ is a morphism of $\mathscr{C}$, and $\sigma : \psi'_{|\mathscr{S}} \Rightarrow (\psi \circ t_*)_{|\mathscr{S}}$ is a natural $\mathscr{C}$-transformation defined on a covering sieve $\mathscr{S} \subset \mathscr{C}/X'$. Again, we pick a generating family $(f_j : X'_i \to X' \mid j \in I)$ for $\mathscr{S}$, and denote by $(f_j, h_j) : (X'_j, \psi' \circ f_{j*}) \to (X', \psi')$ the cartesian morphism in $\mathsf{C}(\mathscr{E})$ induced by f_j. Then $\sigma * f_{j*} : \psi' \circ f_{j*} \Rightarrow \psi \circ (t \circ f_j)_*$ defines a morphism $(t \circ f_j, g_j) : (X'_j, \psi' \circ f_{j*}) \to (X, \psi)$ in $\mathsf{C}(\mathscr{E})$ such that $j_{\mathscr{E}}(t \circ f_j, g_j) = [t,\sigma] \circ j_{\mathscr{E}}(f_j, h_j)$ for every $j \in I$. This proves that $j_{\mathscr{E}}$ is 1-covering.

Lastly, let $(t_1,\sigma_1),(t_2,\sigma_2) : (X',\psi' : \mathscr{C}/X' \to \mathscr{E}) \to (X,\psi : \mathscr{C}/X \to \mathscr{E})$ be two morphisms in $\mathsf{C}(\mathscr{E})$ such that $j_{\mathscr{E}}(t_1,\sigma_1) = j_{\mathscr{E}}(t_2,\sigma_2)$. Especially, this means that $t := t_1 = t_2$, and there exists a covering sieve $\mathscr{S} \subset \mathscr{C}/X'$ such that $(\sigma_1)_{|\mathscr{S}} = (\sigma_2)_{|\mathscr{S}}$. We pick a generating family $(f_j : X'_j \to X' \mid j \in I)$ for $\mathscr{S}$, and let $(f_j, h_j) : (X'_j, \psi' \circ f_{j*}) \to (X', \psi')$ be the cartesian morphism induced by f_j; then $(t,\sigma_1) \circ (f_j,h_j) = (t,\sigma_2) \circ (f_j,h_j)$ for every $j \in I$, so $j_{\mathscr{E}}$ is 2-covering. ♢

(ii): From (i) and proposition 5.2.9 we see already that if $\mathscr{E}$ is j-separated, then $\eta_{\mathscr{E}}$ is j-faithful. Suppose then that $\eta_{\mathscr{E}}$ is j-faithful; let $X \in \mathrm{Ob}(\mathscr{C})$ be any object, and $\mathscr{S} \subset \mathscr{C}/X$ any covering sieve; we consider the induced commutative diagram of categories :

$$\begin{array}{ccc} \mathscr{E}(X) & \longrightarrow & \mathsf{Cart}_{\mathscr{C}}(\mathscr{S},\mathscr{E}) \\ {\scriptstyle \mathsf{Cart}_{\mathscr{C}}(\mathscr{C}/X,\eta_{\mathscr{E}})}\downarrow & & \downarrow{\scriptstyle \mathsf{Cart}_{\mathscr{C}}(\mathscr{S},\eta_{\mathscr{E}})} \\ \mathscr{E}^a(X) & \longrightarrow & \mathsf{Cart}_{\mathscr{C}}(\mathscr{S},\mathscr{E}^a) \end{array}$$

whose bottom horizontal arrow is an equivalence, since $\mathscr{E}^a$ is a stack, and whose vertical arrows are j-faithful, by virtue of corollary 3.1.28(ii.a). It follows that the top horizontal arrow is j-faithful as well, which means that $\mathscr{E}$ is j-separated.

(iii): We have an essentially commutative diagram of cartesian functors

$$\begin{array}{ccc} \mathscr{E} & \xrightarrow{\varphi} & \mathscr{E}' \\ \downarrow & & \downarrow \\ \mathscr{E}^a & \xrightarrow{\varphi^a} & \mathscr{E}'^a \end{array}$$

whose vertical arrows are i-covering for $i = 0,1,2$, by (i). Then the assertion follows immediately from lemma 5.2.4(i,ii). □

5.3. **Local calculus of fractions.** Let $C := (\mathscr{C}, J)$ be a site, $\mathscr{A} \to \mathscr{C}$ a fibration; choose a unital cleavage $\boldsymbol{\lambda}$ for $\mathscr{A}$, and let $\mathsf{c} : \mathscr{C}^o \to \mathbf{Cat}$ be the associated unital pseudo-functor. To ease notation, for every morphism $f : X' \to X$ in $\mathscr{C}$ we let $f^* := \mathsf{c}_f : \mathscr{A}_X \to \mathscr{A}_{X'}$, and denote by $\gamma^{\mathsf{c}}_{\bullet,\bullet}$ the coherence constraint of c. Consider a system of sets $\Sigma_\bullet := (\Sigma_X \mid X \in \mathrm{Ob}(\mathscr{C}))$ with :

- $\Sigma_X \subset \mathrm{Morph}(\mathscr{A}_X)$ for every $X \in \mathrm{Ob}(\mathscr{C})$
- $f^*(\Sigma_X) \subset \Sigma_{X'}$ for every morphism $f : X' \to X$ of $\mathscr{C}$.

Proposition 5.3.1. *In the situation of* (5.3)*, there exist a* 1*-separated prestack* $\mathscr{A}\{\Sigma_\bullet^{-1}\}$ *over* C*, and a cartesian functor*

$$L_{\{\Sigma\}} : \mathscr{A} \to \mathscr{A}\{\Sigma_\bullet^{-1}\}$$

with the following properties :

(i) $L_{\{\Sigma\}} f$ *is an isomorphism in* $\mathscr{A}\{\Sigma_\bullet^{-1}\}$*, for every* $f \in \Sigma := \bigcup_{f \in \mathrm{Ob}(\mathscr{C})} \Sigma_X$.

(ii) *For every* 1*-separated prestack* $\mathscr{E}$ *on* C*, and every cartesian functor* $F : \mathscr{A} \to \mathscr{E}$ *such that* Ff *is invertible in* $\mathscr{E}$ *for every* $f \in \Sigma$*, there exists a unique cartesian functor* $F' : \mathscr{A}\{\Sigma_\bullet^{-1}\} \to \mathscr{B}$ *such that* $F = F' \circ L_{\{\Sigma\}}$.

Proof. According to theorem 1.6.9, for every morphism $f : X' \to X$ of $\mathscr{C}$ the functor f^* extends uniquely to a functor $f^*_\Sigma : \mathscr{A}_X[\Sigma_X^{-1}] \to \mathscr{A}_{X'}[\Sigma_{X'}^{-1}]$, and $\gamma^{\mathsf{c}}_{f,g} : f^* \circ g^* \xrightarrow{\sim} (g \circ f)^*$ extends uniquely to an isomorphism of functors $\gamma^{\Sigma}_{f,g} : f^*_\Sigma \circ g^*_\Sigma \xrightarrow{\sim} (g \circ f)^*_\Sigma$ for every composable pair (f, g) of morphisms of $\mathscr{C}$ (corollary 1.6.11). It is then easily seen that the rules : $X \mapsto \mathscr{A}_X[\Sigma_X^{-1}]$ for every $X \in \mathrm{Ob}(\mathscr{C})$ and $f \mapsto f^*_\Sigma$ for every morphism f of $\mathscr{C}$ yield a unital pseudo-functor $\mathsf{c}[\Sigma_\bullet^{-1}] : \mathscr{C}^o \to \mathbf{Cat}$ with coherence constraint $\gamma^{\Sigma}_{\bullet\bullet}$, and we set

$$\mathscr{A}[\Sigma_\bullet^{-1}] := \mathscr{F}ib(\mathsf{c}[\Sigma_\bullet^{-1}]).$$

From theorem 1.6.9 it follows easily that the system of localization functors $\mathscr{A}_X \to \mathscr{A}_X[\Sigma_X^{-1}]$ yields a unique cartesian functor $L' : \mathscr{A} \to \mathscr{A}[\Sigma_\bullet^{-1}]$ such that the following holds. For every fibration $\mathscr{F}$ over $\mathscr{C}$, and every cartesian functor $F : \mathscr{A} \to \mathscr{F}$ such that Ff is invertible in $\mathscr{F}$ for every $f \in \Sigma$, there exists a unique cartesian functor $F' : \mathscr{A}[\Sigma_\bullet^{-1}] \to \mathscr{F}$ such that $F = F' \circ L'$. By theorem 5.1.10 we conclude that the composition of L' with the natural cartesian functor $\mathscr{A}[\Sigma_\bullet^{-1}] \to \mathscr{A}\{\Sigma_\bullet^{-1}\} := \mathscr{A}[\Sigma_\bullet^{-1}]^{\mathrm{sep}}$ fulfills the stated conditions. $\square$

Definition 5.3.2. In the situation of (5.3), we shall say that the system $\Sigma_\bullet$ *admits a right local calculus of fractions* if the following conditions hold for every $X \in \mathrm{Ob}(\mathscr{C})$:

(LCF1) The set Σ_X contains the isomorphisms of $\mathscr{A}_X$.
(LCF2) The set Σ_X fulfills condition (CF2) of definition 1.6.14.
(LCF3) For every morphism $f : A \to B$ in $\mathscr{A}_X$ and every $s : C \to B$ in Σ_X, there exist a covering family $(\varphi_\lambda : X_\lambda \to X \mid \lambda \in \Lambda)$ in the site C, and for every $\lambda \in \Lambda$ a morphism $g_\lambda : D_\lambda \to \varphi^*_\lambda C$ in $\mathscr{A}_{X_\lambda}$ and $t_\lambda : D_\lambda \to \varphi^*_\lambda A$ in Σ_{X_λ} such that $\varphi^*_\lambda(f) \circ t_\lambda = \varphi^*_\lambda(s) \circ g_\lambda$.
(LCF4) If $f, g : A \to B$ are any two morphisms in $\mathscr{A}_X$ such that $s \circ f = s \circ g$ for some $s : B \to C$ in Σ_X, then there exist a covering family $(\varphi_\lambda : X_\lambda \to X \mid \lambda \in \Lambda)$ in the site C and for every $\lambda \in \Lambda$ an element $t_\lambda : D_\lambda \to \varphi^*_\lambda A$ in Σ_{X_λ} such that $\varphi^*(f) \circ t_\lambda = \varphi^*_\lambda(g) \circ t_\lambda$.

5.3.3. In the situation of (5.3), for every $X \in \mathrm{Ob}(\mathscr{C})$ and $A \in \mathrm{Ob}(\mathscr{A}_X)$ let $\Sigma_{X/A}$ be the full subcategory of $\mathscr{A}_X/A$ whose objects are the elements of Σ_X with target equal to A. For every morphism $(Y' \xrightarrow{\varphi'} X) \xrightarrow{\psi/X} (Y \xrightarrow{\varphi} X)$ of $\mathscr{C}/X$ notice that $\psi^* : \mathscr{A}_Y \to \mathscr{A}_{Y'}$ induces a functor

$$(\psi/X)^* : \mathscr{A}_Y/\varphi^*A \to \mathscr{A}_{Y'}/\varphi'^*A \qquad (I \xrightarrow{f} \varphi^*A) \mapsto (\psi^*I \xrightarrow{\gamma^{\mathsf{c}}_{(\psi,\varphi),A} \circ \psi^*(f)} \varphi'^*A)$$

Suppose now that $\Sigma_\bullet$ fulfills condition (LCF1) of definition 5.3.2; then $(\psi/X)^*$ restricts to

$$(\psi/X)^* : \Sigma_{Y/\varphi^*A} \to \Sigma_{Y'/\varphi'^*A}.$$

Moreover, if $(\psi'/X) : (Y'' \xrightarrow{\varphi''} X) \to (Y' \xrightarrow{\varphi'} X)$ is another morphism of $\mathscr{C}/X$, we have an isomorphism in $\Sigma_{Y''/\varphi''^*A}$ for every $(s : I \to \varphi^*A) \in \mathrm{Ob}(\Sigma_{Y/\varphi^*A})$

$$(\gamma^{\mathsf{c}}_{(\psi',\psi),I}/X) : (\psi'/X)^* \circ (\psi/X)^*(s) \xrightarrow{\sim} (\psi \circ \psi'/X)^*(s).$$

Clearly the rule $s \mapsto (\gamma^{\mathsf{c}}_{(\psi',\psi),I}/X)$ yields an isomorphism of functors $\gamma^{\Sigma}_{\psi',\psi} : (\psi'/X)^* \circ (\psi/X)^* \xrightarrow{\sim} (\psi \circ \psi'/X)^*$, and then it easily seen that the rules : $\varphi \mapsto \Sigma_{Y/\varphi^*A}$ for every $(\varphi : Y \to X) \in \mathrm{Ob}(\mathscr{C}/X)$ and $\psi/X \mapsto (\psi/X)^*$ for every morphism ψ/X of $\mathscr{C}/X$ define a unital pseudo-functor $\Sigma_{\bullet/A} : (\mathscr{C}/X)^o \to \mathbf{Cat}$, whose coherence constraint is given by the system of isomorphisms $\gamma^{\Sigma}_{\psi',\psi}$. There follows a fibration

$$S_A := \mathscr{F}ib(\Sigma_{\bullet/A}) \to \mathscr{C}/X$$

and we denote by $\boldsymbol{\lambda}_A$ its natural unital cleavage. Next, for $A, B \in \mathrm{Ob}(\mathscr{A}_X)$ consider the functor

$$\mathscr{H}_{A,B} : S^o_A \to \mathbf{Set} \qquad (Y \xrightarrow{\varphi} X, I \xrightarrow{s} \varphi^*A) \mapsto \{(s, f) \mid f \in \mathrm{Hom}_{\mathscr{A}_Y}(I, \varphi^*B)\}$$

which assigns to every morphism $(\psi/X, h/\varphi^*A) : (\varphi, s) \to (\varphi', s')$ of S_A the map

$$\mathscr{H}_{A,B}(\psi/X, h/\varphi^*A) : \mathscr{H}_{A,B}(\varphi', s') \to \mathscr{H}_{A,B}(\varphi, s) \qquad (s', f) \mapsto (s, ((\psi/X)^*f) \circ h).$$

Lemma 5.3.4. *With the notation of* (5.3.3)*, suppose that the system $\Sigma_\bullet$ admits a right local calculus of fraction. Then the fibration S_A is locally cofiltered over the site C/X.*

Proof. Condition (LCF1) implies immediately condition (a) of definition 4.3.3. Next, let $(\varphi : Y \to X) \in \mathrm{Ob}(\mathscr{C}/X)$, and $(\varphi, s : I \to \varphi^*A)$ and $(\varphi, s' : I' \to \varphi^*A)$ be two objects of Σ_{Y/φ^*A}. By (LCF3) we may find a covering $(\psi_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ for the topology J, and for every $\lambda \in \Lambda$ a morphism $f_\lambda : J \to \psi_\lambda^* I$ in $\mathscr{A}_{Y_\lambda}$ and an element $t_\lambda : J \to \psi_\lambda^* I'$ of Σ_{Y_λ} such that $s''_\lambda := \psi^*_\lambda(s) \circ f_\lambda = \psi^*_\lambda(s') \circ t_\lambda$. By (LCF1) and (LCF2), we have $u_\lambda := \gamma_{(\varphi,\psi_\lambda),A} \circ s''_\lambda \in \Sigma_{Y_\lambda/(\varphi\circ\psi_\lambda)^*A}$ for every $\lambda \in \Lambda$, and it follows that t_λ and f_λ yield morphisms $u_\lambda \to (\psi/X)^*(s')$ and respectively $u_\lambda \to (\psi/X)^*(s)$. Hence S_A fulfills condition (b) of definition 4.3.3.

Lastly, consider two morphisms $(g/\varphi^*A), (g'/\varphi^*) : (s : I \to \varphi^*A) \to (s' : I \to \varphi^*A)$ in Σ_{Y/φ^*A}. In other words, $g, g' : I \to I'$ are morphisms in $\mathscr{A}_Y$ with $s' \circ g = s' \circ g' = s$. By (LCF3) there exist then a covering family $(\psi_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ and for every $\lambda \in \Lambda$ an element $h_\lambda : J \to \psi^*_\lambda I$ of $\Sigma_{\mathscr{A}_{Y_\lambda}}$ with $t_\lambda := \psi^*_\lambda(g) \circ h_\lambda = \psi^*_\lambda(g') \circ h_\lambda$. Notice that $u_\lambda := \psi^*_\lambda(s') \circ t_\lambda = \psi^*_\lambda(s) \circ h_\lambda$ lies in $\Sigma_{Y_\lambda,(\psi_\lambda)^*\varphi^*A}$. Hence h_λ yields a morphism $(h/(\varphi\circ\psi_\lambda)^*A) : \gamma_{(\varphi,\psi_\lambda),A} \circ u_\lambda \to (\psi/X)^*(s)$ in $\Sigma_{Y_\lambda,(\varphi\circ\psi_\lambda)^*A}$ with $(\psi_\lambda/X)^*(g) \circ (h/(\varphi\circ\psi_\lambda)^*A) = (\psi_\lambda/X)^*(g') \circ (h/(\varphi\circ\psi_\lambda)^*A)$. This shows that condition (c) holds as well. ☐

5.3.5. With the notation of (4.3.4), consider the presheaf on $\mathscr{C}/X$ and the sheaf on C/X :

$$M_{A,B} := \int^{\boldsymbol{\lambda}_A} \mathscr{H}_{A,B} \qquad \text{and} \qquad H_{A,B} := \int_a^{\boldsymbol{\lambda}_A} \mathscr{H}_{A,B}.$$

Recall that for every $(\varphi : Y \to X) \in \mathrm{Ob}(\mathscr{C}/X)$, the set $M_{AB}(\varphi)$ consists of the equivalence classes of $[s, f]$ of pairs with $s \in \mathrm{Ob}(\Sigma_{Y/\varphi^*A})$ and $(s, f) \in \mathscr{H}_{AB}(\varphi, s)$. We shall denote by $\{s, f\} \in H_{A,B}(\varphi)$ the image of such a class $[s, f]$. Taking into account lemmata 4.3.5 and 5.3.4 we see that if $\Sigma_\bullet$ admits a right local calculus of fraction, the following holds :

(a) For every $\sigma \in H_{AB}(\varphi)$ we have a covering family $(\varphi_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ in the site C, and for every $\lambda \in \Lambda$ a morphism $g_\lambda : C_\lambda \to \varphi^*_\lambda B$ in $\mathscr{A}_{Y_\lambda}$ and an element $s_\lambda : C_\lambda \to \varphi^*_\lambda A$ of Σ_{Y_λ} such that $H_{AB}(\varphi_\lambda/X)(\sigma)$ is the image of $[s_\lambda, g_\lambda]$ in $H_{AB}(\varphi \circ \varphi_\lambda/X)$.

(b) For every two pairs $(s : I \to \varphi^*A, f), (s' : I' \to \varphi^*A, f') \in \mathscr{H}_{AB}(\varphi, s)$ with $[s, f] = [s', f']$ in $M_{AB}(\varphi, s)$ there exist a covering family $(\varphi_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ in the site C, and for every $\lambda \in \Lambda$ two morphisms in $\mathscr{A}_{Y_\lambda}$

$$\varphi^*_\lambda I' \xleftarrow{t'_\lambda} J_\lambda \xrightarrow{t_\lambda} \varphi^*_\lambda I \qquad \text{with} \qquad (\varphi_\lambda/X)^*(f) \circ t_\lambda = (\varphi_\lambda/X)^*(f') \circ t'_\lambda$$

and such that $(\varphi_\lambda/X)^*(s) \circ t_\lambda = (\varphi_\lambda/X)^*(s') \circ t'_\lambda$ lies in $\Sigma_{Y_\lambda,(\varphi\circ\varphi_\lambda)^*A}$.

Let $\boldsymbol{\lambda}_\Sigma$ and $\boldsymbol{\lambda}_{\{\Sigma\}}$ be the cleavages of $\mathscr{A}[\Sigma_\bullet^{-1}]$ and respectively $\mathscr{A}\{\Sigma_\bullet^{-1}\}$ deduced from the cleavage $\boldsymbol{\lambda}$ of $\mathscr{A}$, as in the proofs of proposition 5.3.1 and theorem 5.1.10. For every $A \in \mathrm{Ob}(\mathscr{A}\{\Sigma_\bullet^{-1}\}_X) = \mathrm{Ob}(\mathscr{A}_X[\Sigma_\bullet^{-1}]) = \mathrm{Ob}(\mathscr{A}_X)$ define the cartesian sections $\beta_A^{\boldsymbol{\lambda}_\Sigma} : \mathscr{C}/X \to \mathscr{A}[\Sigma_\bullet^{-1}]$ and $\beta_{X,A}^{\boldsymbol{\lambda}_{\{\Sigma\}}} : \mathscr{C}/X \to \mathscr{A}\{\Sigma_\bullet^{-1}\}$ as in the proof of claim 3.2.8. Let also $L_\Sigma : \mathscr{A} \to \mathscr{A}[\Sigma_\bullet^{-1}]$ be the localization functor; we have a natural morphism of presheaves on $\mathscr{C}/X$:

$$M_{A,B} \to \mathscr{C}art(\beta_A^{\boldsymbol{\lambda}_\Sigma}, \beta_B^{\boldsymbol{\lambda}_\Sigma}) \qquad \text{for every } A, B \in \mathrm{Ob}(\mathscr{A}_X)$$

which assigns to every $[s, f] \in M_{A,B}(\varphi)$ the unique natural $\mathscr{C}$-transformation $\beta_A^{\boldsymbol{\lambda}_\Sigma} \circ \varphi_* \to \beta_B^{\boldsymbol{\lambda}_\Sigma} \circ \varphi_*$ such that $\mathbf{1}_Y \mapsto L_\Sigma(f) \circ L_\Sigma(s)^{-1}$, for every $\varphi \in \mathrm{Ob}(\mathscr{C}/X)$. We deduce a morphism $H_{A,B} \to \mathscr{C}art(\beta_A^{\boldsymbol{\lambda}_\Sigma}, \beta_B^{\boldsymbol{\lambda}_\Sigma})^a$ of associated sheaves on C/X. But recall that the proof of theorem 5.1.10 yields as well a natural identification

$$\mathscr{C}art(\beta_A^{\boldsymbol{\lambda}_\Sigma}, \beta_B^{\boldsymbol{\lambda}_\Sigma})^a \xrightarrow{\sim} \mathscr{C}art(\beta_A^{\boldsymbol{\lambda}\{\Sigma\}}, \beta_B^{\boldsymbol{\lambda}\{\Sigma\}}).$$

The composition of the latter two morphisms is a morphism of sheaves on C/X :

$$H_{AB} \to \mathscr{C}art(\beta^{\boldsymbol{\lambda}\{\Sigma\}}_{X,A}, \beta^{\boldsymbol{\lambda}\{\Sigma\}}_{X,B}) \qquad \{s,f\} \mapsto L_{\{\Sigma\}}(f) \circ L_{\{\Sigma\}}(s)^{-1}. \tag{5.3.6}$$

Proposition 5.3.7. *Suppose that the system $\Sigma_\bullet$ admits a right local calculus of fraction. Then* (5.3.6) *is an isomorphism of sheaves for every $A, B \in \mathrm{Ob}(\mathscr{A}_X)$.*

Proof. We define for every $X \in \mathrm{Ob}(\mathscr{C})$ a category

$$\mathscr{L}_X$$

whose set of objects is $\mathrm{Ob}(\mathscr{A}_X)$, and such that $\mathrm{Hom}_{\mathscr{L}_X}(A,B) := H_{AB}(\mathbf{1}_X)$ for every $A, B \in \mathrm{Ob}(\mathscr{A}_X)$. For every $A, B, C \in \mathrm{Ob}(\mathscr{A}_X)$, the composition law

$$H_{AB}(\mathbf{1}_X) \times H_{BC}(\mathbf{1}_X) \to H_{AC}(\mathbf{1}_X) \tag{5.3.8}$$

is obtained as follows. Let $(\varphi : Y \to X) \in \mathrm{Ob}(\mathscr{C}/X)$ and $[s : I \to \varphi^* A, f] \in M_{AB}(\varphi)$ and $[s' : I' \to \varphi^* B, f'] \in M_{BC}(\varphi)$ any two sections; by virtue of (LCF3) we may find a covering family $(\varphi_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ and for every $\lambda \in \Lambda$, morphisms in $\mathscr{A}_{Y_\lambda}$:

$$\varphi^*_\lambda I \xleftarrow{s_\lambda} J_\lambda \xrightarrow{f_\lambda} \varphi^*_\lambda I' \qquad \text{such that} \qquad (\varphi_\lambda/X)^*(f) \circ s_\lambda = (\varphi_\lambda/X)^*(s') \circ f_\lambda \quad \text{and} \quad s_\lambda \in \Sigma_{Y_\lambda}.$$

Set $t_\lambda := (\varphi_\lambda/X)^*(s) \circ s_\lambda : J_\lambda \to (\varphi \circ \varphi_\lambda)^* A$ and $g_\lambda := (\varphi_\lambda/X)^*(f') \circ f_\lambda : J_\lambda \to (\varphi \circ \varphi_\lambda)^* B$ for every λ. For $\lambda, \mu \in \Lambda$, consider morphisms $Y_\lambda \xleftarrow{\psi_\lambda} Z \xrightarrow{\psi_\mu} Y_\mu$ such that $\psi := \varphi_\lambda \circ \psi_\lambda = \varphi_\mu \circ \psi_\mu$.

Claim 5.3.9. $H_{AB}(\psi_\lambda/X)\{t_\lambda, g_\lambda\} = H_{AB}(\psi_\mu/X)\{t_\mu, g_\mu\}$.

Proof of the claim. We need to show that $\{(\psi_\lambda/X)^* t_\lambda, (\psi_\lambda/X)^* g_\lambda\} = \{(\psi_\mu/X)^* t_\mu, (\psi_\mu/X)^* g_\mu\}$. However, by (LCF3) we may find a covering family $(\rho_\nu : Z_\nu \to Z \mid \nu \in \Lambda')$ and for every $\nu \in \Lambda'$, morphisms $\rho^*_\nu \psi^*_\mu J_\mu \xleftarrow{s_\nu} J_\nu \xrightarrow{s'_\nu} \rho^*_\nu \psi^*_\lambda J_\lambda$ in $\mathscr{A}_{Z_\nu}$ with $s_\nu \in \Sigma_{Z_\nu}$, and such that

$$(\rho_\nu/Y)^*(\psi_\mu/Y)^*(s_\mu) \circ s_\nu = (\rho_\nu/Y)^*(\psi_\lambda/Y)^*(s_\lambda) \circ s'_\nu.$$

We compute :

$$\begin{aligned}
(\rho_\nu/Y)^*((\psi/X)^*(s') \circ (\psi_\mu/Y)^*(f_\mu)) \circ s_\nu &= (\rho_\nu/Y)^*((\psi_\mu/X)^*((\varphi_\mu/X)^*(s') \circ f_\mu)) \circ s_\nu \\
&= (\rho_\nu/Y)^*((\psi_\mu/X)^*((\varphi_\mu/X)^*(f) \circ s_\lambda)) \circ s_\nu \\
&= (\rho_\nu/Y)^*((\psi/X)^*(f) \circ (\psi_\mu/Y)^*(s_\mu)) \circ s_\nu \\
&= (\rho_\nu/Y)^*((\psi/X)^*(f) \circ (\psi_\lambda/Y)^*(s_\lambda)) \circ s'_\nu \\
&= (\rho_\nu/Y)^*((\psi/X)^*(s') \circ (\psi_\lambda/Y)^*(f_\lambda)) \circ s'_\nu.
\end{aligned}$$

By (LCF4) it follows that for every $\nu \in \Lambda'$ there exist a covering family $(\rho_{\nu\nu'} : Z_{\nu\nu'} \to Z_\nu \mid \nu' \in \Lambda'_\nu)$ and for every $\nu' \in \Lambda'_\nu$ an element $t_{\nu\nu'} : J_{\nu\nu'} \to \rho^*_{\nu\nu'} J_\nu$ of $\Sigma_{Z_{\nu\nu'}}$ such that

$$(\rho_{\nu\nu'}/Y)^*(\rho_\nu/Y)^*((\psi_\mu/Y)^*(f_\mu) \circ s_\nu) \circ t_{\nu\nu'} = (\rho_{\nu\nu'}/Y)^*(\rho_\nu/Y)^*((\psi_\lambda/Y)^*(f_\lambda) \circ s'_\nu) \circ t_{\nu\nu'}.$$

Set $\rho'_{\nu\nu'} := \rho_\nu \circ \rho_{\nu\nu'}$ for every $\nu' \in \Lambda'_\nu$, and

$$T_{\lambda\nu\nu'} := (\psi_\lambda \circ \rho'_{\nu\nu'}/X)^* t_\lambda \qquad G_{\lambda\nu\nu'} := (\psi_\lambda \circ \rho'_{\nu\nu'}/X)^* g_\lambda \qquad \gamma_{\lambda\nu\nu'} := \gamma^{\mathsf{c}}_{(\rho'_{\nu\nu'},\psi_\lambda),J_\lambda}$$

and define likewise $T_{\mu\nu\nu'}$, $G_{\mu\nu\nu'}$ and $\gamma_{\mu\nu\nu'}$. We compute :

$$\begin{aligned}
[T_{\lambda\nu\nu'}, G_{\lambda\nu\nu'}] &= [T_{\lambda\nu\nu'} \circ \gamma_{\lambda\nu\nu'} \circ (\rho_{\nu\nu'}/Z)^*(s'_\nu) \circ t_{\nu\nu'}, G_{\lambda\nu\nu'} \circ \gamma_{\lambda\nu\nu'} \circ (\rho'_{\nu\nu'}/Z)^*(s'_\nu) \circ t_{\nu\nu'}] \\
&= [T_{\mu\nu\nu'} \circ \gamma_{\mu\nu\nu'} \circ (\rho_{\nu\nu'}/Z)^*(s_\nu) \circ t_{\nu\nu'}, G_{\mu\nu\nu'} \circ \gamma_{\mu\nu\nu'} \circ (\rho_{\nu\nu'}/Z)^*(s_\nu) \circ t_{\nu\nu'}] \\
&= [T_{\mu\nu\nu'}, G_{\mu\nu\nu'}]
\end{aligned}$$

whence the contention. ◊

Claim 5.3.9 implies that the system $(\{t_\lambda, g_\lambda\} \mid \lambda \in \Lambda)$ defines a unique section of $H_{AC}(\varphi)$ that we denote $\{s', f'\} \circ \{s, f\}$. Notice that the argument proves as well that the construction of $\{s', f'\} \circ \{s, f\}$ is independent of all auxiliary choices. A direct inspection shows then that we obtain a well defined morphism of presheaves

$$M_{AB} \times M_{BC} \to H_{AC} \qquad ([s, f], [s', f']) \mapsto \{s', f'\} \circ \{s, f\}$$

which therefore induces a unique morphism of sheaves on C/X :

$$H_{AB} \times H_{BC} \to H_{AC} \qquad \text{such that} \qquad (\{s, f\}, \{s', f'\}) \mapsto \{s', f'\} \circ \{s, f\}.$$

Then the sought map (5.3.8) is the map of sets obtained by evaluating the foregoing morphism on the object $\mathbf{1}_X \in \mathrm{Ob}(\mathscr{C}/X)$. Let us check that $\{\mathbf{1}_{\varphi^*B}, \mathbf{1}_{\varphi^*B}\} \circ \sigma = \sigma = \sigma \circ \{\mathbf{1}_{\varphi^*A}, \mathbf{1}_{\varphi^*A}\}$ for every $A, B \in \mathrm{Ob}(\mathscr{A}_X)$ and every $\varphi \in \mathrm{Ob}(\mathscr{C}/X)$: indeed, it suffices to check these identities for $\sigma = \{s, f\}$, for any $(s, f) \in \mathscr{H}_{A,B}(\varphi)$, and the latter follow by simple inspection. Lastly, in order to show the associativity property for our composition law, consider $A, B, C, D \in \mathrm{Ob}(\mathscr{A}_X)$ and $(s : I \to \varphi^*A, f), (s' : I' \to \varphi^*B, f'), (s'' : I'' \to \varphi^*C, f'') \in \mathscr{H}_{AB}(\varphi)$, for some $(\varphi : Y \to X) \in \mathrm{Ob}(\mathscr{C}/X)$. By (LCF3) we may find a covering family $(\varphi_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ and for every $\lambda \in \Lambda$, morphisms in $\mathscr{A}_{Y_\lambda}$:

$$\varphi_\lambda^* I \xleftarrow{t_\lambda} J_\lambda \xrightarrow{g_\lambda} \varphi_\lambda^* I' \xleftarrow{t'_\lambda} J'_\lambda \xrightarrow{g'_\lambda} \varphi_\lambda^* I'' \qquad \text{with} \qquad t_\lambda, t'_\lambda \in \Sigma_{Y_\lambda}$$

such that $(\varphi_\lambda/X)^*(f) \circ t_\lambda = (\varphi_\lambda/X)^* s' \circ g_\lambda$ and $(\varphi_\lambda/X)^*(f') \circ t'_\lambda = (\varphi_\lambda/X)^*(s'') \circ g'_\lambda$. Then we may also find for every $\lambda \in \Lambda$ a covering family $(\varphi_{\lambda\mu} : Y_{\lambda\mu} \to Y_\lambda \mid \mu \in \Lambda_\lambda)$ and for every $\mu \in \Lambda_\lambda$, morphisms in $\mathscr{A}_{Y_{\lambda\mu}}$:

$$\varphi_{\lambda\mu}^* J_\lambda \xleftarrow{t_{\lambda\mu}} J_{\lambda\mu} \xrightarrow{g_{\lambda\mu}} \varphi_{\lambda\mu}^* J'_\lambda \qquad \text{such that} \qquad (\varphi_{\lambda\mu}/Y)^*(g_\lambda) \circ t_{\lambda\mu} = (\varphi_{\lambda\mu}/Y)^*(t_\lambda) \circ g_{\lambda\mu}$$

and with $t_{\lambda\mu} \in \Sigma_{Y_{\lambda\mu}}$. For every such λ and μ set $\psi_{\lambda\mu} := \varphi_\lambda \circ \varphi_{\lambda\mu}$ and

$$(t'_{\lambda\mu}, g'_{\lambda\mu}) := ((\psi_{\lambda\mu}/X)^*(s) \circ (\varphi_{\lambda\mu}/Y)^*(t_\lambda) \circ t_{\lambda\mu}, (\psi_{\lambda\mu}/X)^*(f'') \circ (\varphi_{\lambda\mu}/Y)^*(g_\lambda) \circ g_{\lambda\mu}).$$

It then follows easily that the system $(\{t'_{\lambda\mu}, g'_{\lambda\mu}\} \mid \lambda \in \Lambda, \mu \in \Lambda_\lambda)$ represents both $\{s'', f''\} \circ (\{s', f'\} \circ \{s, f\})$ and $(\{s'', f''\} \circ \{s', f'\}) \circ \{s, f\}$. The sought associativity property is a straightforward consequence. This concludes the construction of $\mathscr{L}_X$.

Next, notice that for every morphism $\varphi : Y \to X$ in $\mathscr{C}$ and every $A, B \in \mathrm{Ob}(\mathscr{A}_X)$ we have a natural isomorphism of presheaves on $\mathscr{C}/Y$:

$$M_{\varphi^*A, \varphi^*B} \xrightarrow{\sim} (\varphi_*)^\wedge M_{A,B}$$

Namely, for every $(\psi : Z \to Y) \in \mathrm{Ob}(\mathscr{C}/Y)$, the isomorphism is given by the map :

$$M_{\varphi^*A, \varphi^*B}(\psi) \xrightarrow{\sim} M_{A,B}(\varphi \circ \psi) \qquad [s, f] \mapsto [\gamma^{\mathsf{c}}_{(\psi,\varphi),A} \circ s, \gamma^{\mathsf{c}}_{(\psi,\varphi),B} \circ f]$$

Since φ_* is continuous and cocontinuous for the sites C/X and C/Y (remark 4.7.3(i)), combining with lemma 4.2.15(ii) there follows a natural isomorphism of sheaves on C/Y :

$$H_{\varphi^*A, \varphi^*B} \xrightarrow{\sim} j_\varphi^* H_{A,B}. \tag{5.3.10}$$

We deduce a map

$$\mathsf{d}_{\varphi,(A,B)} : \mathrm{Hom}_{\mathscr{L}_X}(A, B) \to H_{A,B}(\varphi) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{L}_Y}(\varphi^*A, \varphi^*B)$$

namely the composition of the restriction map $H_{A,B}(\varphi/X) : H_{A,B}(\mathbf{1}_X) \to H_{A,B}(\varphi)$ with the evaluation at $\mathbf{1}_Y \in \mathrm{Ob}(\mathscr{C}/Y)$ of the inverse of the foregoing isomorphism of sheaves. A simple inspection shows that the rules : $A \mapsto \varphi^*A$ and $\sigma \mapsto \mathsf{d}_{\varphi,(A,B)}(\sigma)$ for every $A, B \in \mathscr{A}_X$ and every $\sigma \in \mathrm{Hom}_{\mathscr{L}_X}(A, B)$ yield a well defined functor

$$\mathsf{d}_\varphi : \mathscr{L}_X \to \mathscr{L}_Y.$$

Furthermore, for every pair $Z \xrightarrow{\psi} Y \xrightarrow{\varphi} X$ of morphisms of $\mathscr{C}$, the natural isomorphism $\gamma^{\mathsf{c}}_{\psi,\varphi}$: $\psi^* \circ \varphi^* \xrightarrow{\sim} (\varphi \circ \psi)^*$ induces a natural isomorphism

$$\gamma^{\mathsf{d}}_{\psi,\varphi} : \mathsf{d}_\psi \circ \mathsf{d}_\varphi \xrightarrow{\sim} \mathsf{d}_{\varphi\circ\psi} \qquad A \mapsto \{\mathbf{1}_{\psi^*\varphi^*A}, \gamma^{\mathsf{c}}_{(\psi,\varphi),A}\}.$$

Clearly the rules : $X \mapsto \mathscr{L}_X$ and $\varphi \mapsto \mathsf{d}_\varphi$ for every $X \in \mathrm{Ob}(\mathscr{C})$ and every morphism φ of $\mathscr{C}$ define a unital pseudo-functor $\mathsf{d} : \mathscr{C}^o \to \mathbf{Cat}$, with coherence constraint $\gamma^{\mathsf{d}}_{\bullet,\bullet}$. We set :

$$\mathscr{L} := \mathscr{F}ib(\mathsf{d})$$

and we denote by $\boldsymbol{\lambda}_{\mathscr{L}}$ the natural cleavage of $\mathscr{L}$. Then, for every $X \in \mathrm{Ob}(\mathscr{C})$ and every $A \in \mathrm{Ob}(\mathscr{L}_X)$ let $\beta^{\boldsymbol{\lambda}_{\mathscr{L}}}_{X,A} : \mathscr{C}/X \to \mathscr{L}$ be the cartesian section defined as in the proof of claim 3.2.8; by inspecting the constructions, we see that for every $A, B \in \mathrm{Ob}(\mathscr{L}_X)$, the system of isomorphisms (5.3.10) induces a natural isomorphism of presheaves on $\mathscr{C}/X$:

$$H_{AB} \xrightarrow{\sim} \mathscr{C}art(\beta^{\boldsymbol{\lambda}_{\mathscr{L}}}_{X,A}, \beta^{\boldsymbol{\lambda}_{\mathscr{L}}}_{X,B}).$$

Especially, $\mathscr{C}art(\sigma, \sigma')$ is a sheaf on C/X for every pair of cartesian sections $\sigma, \sigma' \in \mathscr{L}(X)$, and therefore $\mathscr{L}$ is a 1-separated prestack (lemma 5.1.9). We have a natural functor

$$F_X : \mathscr{A}_X \to \mathscr{L}_X \qquad \text{for every } X \in \mathrm{Ob}(\mathscr{C})$$

that is the identity on objects and is given by the rule : $(f : A \to B) \mapsto \{\mathbf{1}_A, f\}$ on morphisms f of $\mathscr{A}_X$. Clearly the rule $X \mapsto F_X$ defines a strict pseudo-natural transformation $F_\bullet : \mathsf{c} \Rightarrow \mathsf{d}$, whence a cartesian functor

$$L := \mathscr{F}ib(F_\bullet) : \mathscr{A} \to \mathscr{L}.$$

By construction, $L(s)$ is an isomorphism in $\mathscr{L}$, for every $s \in \bigcup_{X\in\mathrm{Ob}(\mathscr{C})} \Sigma_X$, hence L factors uniquely through a cartesian functor $L' : \mathscr{A}\{\Sigma_\bullet^{-1}\} \to \mathscr{L}$ and the universal cartesian functor $L_{\{\Sigma\}}$ of proposition 5.3.1. To construct conversely a functor $\mathscr{L} \to \mathscr{A}\{\Sigma_\bullet^{-1}\}$, we begin by evaluating at $\mathbf{1}_X$ the morphism of sheaves (5.3.6), to get a map

$$L''_{X,A,B} : \mathrm{Hom}_{\mathscr{L}_X}(A, B) \to \mathrm{Hom}_{\mathscr{A}\{\Sigma_\bullet^{-1}\}_X}(A, B).$$

Then, a direct inspection of the constructions yields a functor $L''_X : \mathscr{L}_X \to \mathscr{A}\{\Sigma_\bullet^{-1}\}_X$ that is the identity on objects, and is given on morphisms by the rule : $\sigma \mapsto L''_{X,A,B}(\sigma)$ for every $A, B \in \mathrm{Ob}(\mathscr{L}_X)$, and every $\sigma \in \mathrm{Hom}_{\mathscr{L}_X}(A, B)$: the details shall be left to the reader.

Lastly, if $\mathsf{c}_{\{\Sigma\}}$ denotes the pseudo-functor associated with the cleavage $\boldsymbol{\lambda}_{\{\Sigma\}}$, we easily see that the rule : $X \mapsto \mathscr{L}''_X$ for every $X \in \mathrm{Ob}(\mathscr{C})$ defines a strict pseudo-natural $\mathscr{C}$-transformation $L''_\bullet : \mathsf{d} \Rightarrow \mathsf{c}_{\{\Sigma\}}$, whence a cartesian functor

$$L'' := \mathscr{F}ib(L''_\bullet) : \mathscr{L} \to \mathscr{A}\{\Sigma_\bullet^{-1}\}.$$

A direct inspection shows that $L' \circ L'' = \mathbf{1}_{\mathscr{L}}$. In order to show that $L'' \circ L' = \mathbf{1}_{\mathscr{A}\{\Sigma_\bullet^{-1}\}}$, it suffices to check that $L'' \circ L' \circ L_{\{\Sigma\}} = L_{\{\Sigma\}}$, due to the universal property of $L_{\{\Sigma\}}$. Thus, we come down to the proving that $L'' \circ L = L_{\{\Sigma\}}$, which again holds by direct inspection. Summing up, we have proven that L'' is an isomorphism of categories; the proposition follows at once. □

5.4. **Functorial properties of the categories of stacks.** In section 4.2 we have attached to every continuous or cocontinuous functor between sites certain natural functors on the corresponding categories of sheaves. Hereafter we shall likewise associate with such functors certain natural pseudo-functors on the corresponding 2-categories of stacks.

Proposition 5.4.1. *Let $(\mathscr{C}, J)$ and $(\mathscr{C}', J')$ be two sites, $u : \mathscr{C} \to \mathscr{C}'$ a cocontinuous functor, and $i \in \{0, 1, 2\}$. The following holds :*

(i) *For every i-covering cartesian functor $\mathscr{E}_1 \xrightarrow{\varphi} \mathscr{E}_2$ of $\mathscr{C}'$-fibrations $\mathscr{E}_1 \xrightarrow{F_1} \mathscr{C}' \xleftarrow{F_2} \mathscr{E}_2$, the functor* $\mathsf{Fib}(u)^*(\varphi) : \mathscr{C} \times_{\mathscr{C}'} \mathscr{E}_1 \to \mathscr{C} \times_{\mathscr{C}'} \mathscr{E}_2$ *is i-covering (notation of remark* 3.1.5(i)*).*

(ii) *For every i-separated fibration $\mathscr{F} \to \mathscr{C}$, the fibration* $\mathsf{Fib}(u)_*(\mathscr{F})$ *is i-separated.*

Proof. (i): Recall that the objects of $\mathscr{C} \times_{\mathscr{C}'} \mathscr{E}_j$ for $j = 1, 2$ are the pairs (X, Y) with $X \in \mathrm{Ob}(\mathscr{C})$, $Y \in \mathrm{Ob}(\mathscr{E}_j)$, such that $uX = F_j Y$. The morphisms $(X, Y) \to (X', Y')$ are the pairs (f, g) where $f : X \to X'$ is a morphism in $\mathscr{C}$, $g : Y \to Y'$ is a morphism in $\mathscr{E}_j$, and $u(f) = F_j(g)$.

Suppose first that $i = 0$, and let $(X, Y) \in \mathrm{Ob}(\mathscr{C} \times_{\mathscr{C}'} \mathscr{E}_2)$ be any object. By assumption, there exist a covering family $(f'_j : X'_j \to uX \mid j \in I)$ and for every $j \in I$ a cartesian morphism $h_j : \varphi Y_j \to Y$ in $\mathscr{E}_2$ with $F_2 h_j = f'_j$. Let $\mathscr{S} \subset \mathscr{C}'/uX$ be the sieve generated by $(f'_j \mid j \in I)$; since u is cocontinuous, there exists a covering family $(f_k : X_k \to X \mid k \in I')$ such that $u(f_k) \in \mathrm{Ob}(\mathscr{S})$ for every $k \in I'$. Then, for every $k \in I'$ pick $j(k) \in I$ such that $u(f_k) = f'_{j(k)} \circ f''_k$ for some morphism $f''_k : uX_k \to X'_{j(k)}$ in $\mathscr{C}'$, and choose a cartesian morphism $h'_k : Z_k \to Y_{j(k)}$ in $\mathscr{E}_1$ such that $F_1 h'_k = f''_k$. Then $h''_k := h_{j(k)} \circ \varphi(h'_k) : \varphi Z_k \to Y$ is cartesian and $F_2 h''_k = u(f_k)$; therefore $(f_k, h''_k) : (X_k, \varphi Z_k) \to (X, Y)$ is a cartesian morphism in $\mathscr{C} \times_{\mathscr{C}'} \mathscr{E}_2$ for every $j \in I$. This proves that $\mathsf{Fib}(u)^*(\varphi)$ is 0-covering.

Next, suppose that $i = 1$, and let $(\mathbf{1}_X, g) : (X, \varphi Y_1) \to (X, \varphi Y_2)$ be a morphism in $\mathscr{C} \times_{\mathscr{C}'} \mathscr{E}_2$. By assumption there exist a covering family $(f'_j : X'_j \to uX \mid j \in I)$ in $\mathscr{C}'$ and morphisms $Y_2 \xleftarrow{g_j} Z_j \xrightarrow{h_j} Y_1$ in $\mathscr{E}_1$ with h_j cartesian, such that $\varphi(g_j) = g \circ \varphi(h_j)$ and $F_1 h_j = f'_j$ for every $j \in I$. Then, choose a covering family $(f_k : X_k \to X \mid k \in I')$ as in the foregoing, so that for every $k \in I'$ there exist $j(k) \in I$ and a factorization $u(f_k) = f'_{j(k)} \circ f''_k$ for some morphism $f''_k : uX_k \to X'_{j(k)}$ in $\mathscr{C}'$. Choose also for every $k \in I'$ a cartesian morphism $h'_k : Z'_k \to Z_{j(k)}$ with $F_1 h'_k = f''_k$. Then $h''_k := h_{j(k)} \circ h'_k : Z'_k \to Y_1$ is cartesian and $F_1 h''_k = u(f_k)$, so we get a cartesian morphism $(f_k, h''_k) : (X_k, Z'_k) \to (X, Y_1)$ such that $(\mathbf{1}_X, g) \circ (f_k, \varphi(h''_k)) = (f_k, \varphi(g_{j(k)} \circ h'_k))$ for every $k \in I'$. This shows that $\mathsf{Fib}(u)^*(\varphi)$ is 1-covering.

Lastly, say that $i = 2$, and let $(\mathbf{1}_X, g_1), (\mathbf{1}_X, g_2) : (X, Y_1) \to (X, Y_2)$ be two morphisms in $\mathscr{C} \times_{\mathscr{C}'} \mathscr{E}_1$ with $\varphi(g_1) = \varphi(g_2)$. By assumption there exist a covering family $(f'_j : X'_j \to uX \mid j \in I)$ and a cartesian morphism $h_j : Z_j \to Y_1$ in $\mathscr{E}_1$ such that $g_1 \circ h_j = g_2 \circ h_j$ and $F_1 h_j = f'_j$ for every $j \in I$. We pick again a covering family $(f_k : X_k \to X \mid k \in I')$ in $\mathscr{C}$ such that for every $k \in I'$ there exist $j(k) \in I$ and a factorization $u(f_k) = f'_{j(k)} \circ f''_k$, and we choose for every $k \in I'$ a cartesian morphism $h'_k : Z'_k \to Z_{j(k)}$ such that $F_1 h'_k = f''_k$. Then $h''_k := h_{j(k)} \circ h'_k : Z'_k \to Y_1$ is cartesian and $F_1 h''_k = u(f_k)$; therefore $(f_k, h''_k) : (X_k, Z'_k) \to (X, Y_1)$ is cartesian morphism in $\mathscr{C} \times_{\mathscr{C}'} \mathscr{E}_1$ such that $(\mathbf{1}_X, g_1) \circ (f_k, h''_k) = (\mathbf{1}_X, g_2) \circ (f_k, h''_k)$ for every $k \in I'$. This proves that $\mathsf{Fib}(u)^*(\varphi)$ is 2-covering.

(ii): See (3.3.14) for the definition of the pseudo-functor $\mathsf{Fib}(u)_*$. Let $X \in \mathrm{Ob}(\mathscr{C})$ be any object, and $\mathscr{S} \subset \mathscr{C}/X$ a covering sieve; we consider the essentially commutative diagram :

$$\begin{array}{ccccc}
\mathsf{Fib}(u)_*\mathscr{F}(X) & \longrightarrow & \mathsf{Cart}_{\mathscr{C}}(\mathsf{Fib}(u)^*(\mathscr{C}/X), \mathscr{F}) & \longrightarrow & \mathsf{Cart}_{\mathscr{C}}((\mathsf{Fib}(u)^*(\mathscr{C}/X))^a, \mathscr{F}^a) \\
\downarrow & & \downarrow & & \downarrow \\
\mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, \mathsf{Fib}(u)_*\mathscr{F}) & \longrightarrow & \mathsf{Cart}_{\mathscr{C}}(\mathsf{Fib}(u)^*(\mathscr{S}), \mathscr{F}) & \longrightarrow & \mathsf{Cart}_{\mathscr{C}}((\mathsf{Fib}(u)^*(\mathscr{S}))^a, \mathscr{F}^a).
\end{array}$$

We need to show that the left vertical arrow is i-faithful, and we know that the horizontal arrows of the left square subdiagram are equivalences. We are thus reduced to checking that the central vertical arrow is i-faithful. But since $\mathscr{F}$ is i-separated, the unit of adjunction $\mathscr{F} \to \mathscr{F}^a$ is i-faithful (proposition 5.2.11(ii)), so the same holds for the horizontal arrows of the right square subdiagram (corollary 3.1.28(ii.a)), and we are further reduced to checking that the right vertical arrow is an equivalence. To this aim, it suffices to check that the inclusion functor $t : \mathscr{S} \to \mathscr{C}/X$ induces an equivalence $(\mathsf{Fib}(u)^*(\mathscr{S}))^a \xrightarrow{\sim} (\mathsf{Fib}(u)^*(\mathscr{C}/X))^a$ (corollary 3.1.28(ii.b)). Now, recall that $\mathscr{C}/X$ is isomorphic to $\mathscr{F}ib(h_X)$, where h_X is the presheaf on $\mathscr{C}$ represented by X; likewise, $\mathscr{S}$ is isomorphic to $\mathscr{F}ib(h_{\mathscr{S}})$, for a covering subobject $s : h_{\mathscr{S}} \to$

h_X. We deduce natural isomorphisms :

$$(\mathsf{Fib}(u)^*(\mathscr{S}))^a \xrightarrow{\sim} \mathscr{F}ib(u^\wedge h_{\mathscr{S}})^a \xrightarrow{\sim} \mathscr{F}ib((u^\wedge h_{\mathscr{S}})^a)$$

and likewise $(\mathsf{Fib}(u)^*(\mathscr{C}/X))^a \xrightarrow{\sim} \mathscr{F}ib((u^\wedge h_X)^a)$, by theorem 5.1.24 and remark 3.2.9(ii). Clearly, these isomorphisms identify s with $\mathscr{F}ib((u^\wedge s)^a)$; the latter is an isomorphism, according to lemma 4.2.9, whence the contention. □

Definition 5.4.2. Let $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two sites, and $u : \mathscr{C} \to \mathscr{C}'$ a functor. We say that $u : C' \to C$ is a *weak morphism of sites* if for every universe V and every V-stack $\mathscr{E}$ on C', the fibration $\mathsf{V}\text{-}\mathsf{Fib}(u)^*\mathscr{E}$ is a V-stack on C. Then, for every such V, the pseudo-functor $\mathsf{V}\text{-}\mathsf{Fib}(u)^*$ induces by restriction a (strict) pseudo-functor

$$\mathsf{V}\text{-}\mathsf{St}(u)_* : \mathsf{V}\text{-}\mathsf{Stack}(C') \to \mathsf{V}\text{-}\mathsf{Stack}(C).$$

Remark 5.4.3. (i) From example 5.1.2, it follows that every weak morphism of sites $C' \to C$ is a continuous functor for the topologies of C and C'.

(ii) We shall see hereafter that every morphism of sites is a weak morphism of sites.

Proposition 5.4.4. *Let $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two sites, $u : \mathscr{C} \to \mathscr{C}'$ a functor, and V a universe such that $\mathscr{C}$ is V-small and $\mathscr{C}'$ has V-small Hom-sets. The following conditions are equivalent :*

(a) *For every V-stack $\mathscr{E}$ on C', the fibration $\mathsf{V}\text{-}\mathsf{Fib}(u)^*\mathscr{E}$ is a V-stack on C.*
(b) *For every morphism $\varphi : \mathscr{E} \to \mathscr{F}$ in $\mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C})$ that is i-covering for $i = 0, 1, 2$, the morphism $\mathsf{V}\text{-}\mathsf{Fib}(u)_!\varphi : \mathsf{V}\text{-}\mathsf{Fib}(u)_!\mathscr{E} \to \mathsf{V}\text{-}\mathsf{Fib}(u)_!\mathscr{F}$ is i-covering for $i = 0, 1, 2$.*
(c) *For every $X \in \mathrm{Ob}(\mathscr{C})$ and every covering sieve $\mathscr{S} \subset \mathscr{C}/X$, the induced morphism of $\mathscr{C}'$-fibrations $\mathsf{V}\text{-}\mathsf{Fib}(u)_!\mathscr{S} \to \mathsf{V}\text{-}\mathsf{Fib}(u)_!(\mathscr{C}/X)$ is i-covering for $i = 0, 1, 2$.*
(d) *$u : C' \to C$ is a weak morphism of sites.*

Proof. (a)⇒(b): In view of remark 3.3.15(v), we may replace V by a larger universe, and assume that both $\mathscr{C}$ and $\mathscr{C}'$ are V-small. Then, according to propositions 5.2.9 and 5.2.11(iii), the functor $\varphi^a : \mathscr{E}^a \to \mathscr{F}^a$ is an equivalence, and we need to check that $(\mathsf{V}\text{-}\mathsf{Fib}(u)_!\varphi)^a$ is an equivalence. To this aim, for every V-stack $\mathscr{A}$ on C', we consider the diagram :

$$\begin{array}{ccccc}
\mathsf{Cart}_{\mathscr{C}'}(\mathsf{Fib}(u)_!(\mathscr{F})^a, \mathscr{A}) & \longrightarrow & \mathsf{Cart}_{\mathscr{C}'}(\mathsf{Fib}(u)_!(\mathscr{F}), \mathscr{A}) & \longrightarrow & \mathsf{Cart}_{\mathscr{C}}(\mathscr{F}, \mathsf{Fib}(u)^*\mathscr{A}) \\
\downarrow{\scriptstyle \mathsf{Cart}_{\mathscr{C}'}(\mathsf{Fib}(u)_!(\varphi)^a, \mathscr{A})} & & \downarrow{\scriptstyle \mathsf{Cart}_{\mathscr{C}'}(\mathsf{Fib}(u)_!(\varphi), \mathscr{A})} & & \downarrow{\scriptstyle \mathsf{Cart}_{\mathscr{C}}(\varphi, \mathsf{Fib}(u)^*\mathscr{A})} \\
\mathsf{Cart}_{\mathscr{C}'}(\mathsf{Fib}(u)_!(\mathscr{E})^a, \mathscr{A}) & \longrightarrow & \mathsf{Cart}_{\mathscr{C}'}(\mathsf{Fib}(u)_!(\mathscr{E}), \mathscr{A}) & \longrightarrow & \mathsf{Cart}_{\mathscr{C}}(\mathscr{E}, \mathsf{Fib}(u)^*\mathscr{A})
\end{array}$$

whose left square subdiagram is induced by the natural cartesian functors

$$\mathsf{Fib}(u)_!(\mathscr{F}) \to \mathsf{Fib}(u)_!(\mathscr{F})^a \qquad \text{and} \qquad \mathsf{Fib}(u)_!(\mathscr{E}) \to \mathsf{Fib}(u)_!(\mathscr{E})^a$$

and whose right square subdiagram is given by the coherence constraint of the 2-adjunction for the pair $(\mathsf{V}\text{-}\mathsf{Fib}(u)_!, \mathsf{V}\text{-}\mathsf{Fib}(u)^*)$. Thus, both subdiagrams are essentially commutative, and the same then holds for their composition. Moreover, all horizontal arrows are equivalences, so the left-most vertical arrow is an equivalence if and only if the same holds for the right-most one, and in light of lemma 2.1.13(iii) we are reduced to checking that $\mathsf{Cart}_{\mathscr{C}'}(\varphi, \mathsf{Fib}(u)^*\mathscr{A})$ is an equivalence for every such $\mathscr{A}$. But by assumption, $\mathsf{V}\text{-}\mathsf{Fib}(u)^*\mathscr{A}$ is a stack on C, so we have as well the pseudo-commutative diagram

$$\begin{array}{ccc}
\mathsf{Cart}_{\mathscr{C}}(\mathscr{F}^a, \mathsf{Fib}(u)^*\mathscr{A}) & \longrightarrow & \mathsf{Cart}_{\mathscr{C}}(\mathscr{F}, \mathsf{Fib}(u)^*\mathscr{A}) \\
{\scriptstyle \mathsf{Cart}_{\mathscr{C}}(\varphi^a, \mathsf{Fib}(u)^*\mathscr{A})}\downarrow & & \downarrow{\scriptstyle \mathsf{Cart}_{\mathscr{C}}(\varphi, \mathsf{Fib}(u)^*\mathscr{A})} \\
\mathsf{Cart}_{\mathscr{C}}(\mathscr{E}^a, \mathsf{Fib}(u)^*\mathscr{A}) & \longrightarrow & \mathsf{Cart}_{\mathscr{C}}(\mathscr{E}, \mathsf{Fib}(u)^*\mathscr{A})
\end{array}$$

whose horizontal arrows are equivalences. Hence it suffices to show that $\mathsf{Cart}_{\mathscr{C}}(\varphi^a, \mathsf{Fib}(u)^*\mathscr{A})$ is an equivalence for every V-stack $\mathscr{A}$ on C', which follows by invoking again lemma 2.1.13(iii).

(b)⇒(c): This is clear from propositions 5.2.9 and 5.2.11(iii), after inspecting the pseudo-commutative diagram 5.1.25.

(c)⇒(d): Let V′ be any universe; we need to check that $\mathsf{V}'\text{-}\mathsf{Fib}(u)^*\mathscr{E}$ is a V′-stack on C, for every V′-stack $\mathscr{E}$ on C'. To this aim, we can replace V′ by a larger universe, and assume that $\mathsf{V} \subset \mathsf{V}'$, and both $\mathscr{C}$ and $\mathscr{C}'$ are V′-small. Moreover, in light of remark 3.3.15(v) and our assumption (c), we see that for every $X \in \mathrm{Ob}(\mathscr{C})$ and every covering sieve $\mathscr{S} \subset \mathscr{C}/X$, the induced morphism of $\mathscr{C}'$-fibrations $\mathsf{V}'\text{-}\mathsf{Fib}(u)_!\mathscr{S} \to \mathsf{V}'\text{-}\mathsf{Fib}(u)_!(\mathscr{C}/X)$ is i-covering for $i = 0, 1, 2$. Now, the coherence constraint for the 2-adjoint pair $(\mathsf{V}'\text{-}\mathsf{Fib}(u)_!, \mathsf{V}'\text{-}\mathsf{Fib}(u)^*)$ yields an essentially commutative diagram :

$$\begin{array}{ccc}
\mathscr{C}art_{\mathscr{C}}(\mathscr{C}/X, \mathsf{V}'\text{-}\mathsf{Fib}(u)^*\mathscr{E}) & \longrightarrow & \mathscr{C}art_{\mathscr{C}}(\mathscr{S}, \mathsf{V}'\text{-}\mathsf{Fib}(u)^*\mathscr{E}) \\
\downarrow & & \downarrow \\
\mathscr{C}art_{\mathscr{C}'}(\mathsf{V}'\text{-}\mathsf{Fib}(u)_!(\mathscr{C}/X), \mathscr{E}) & \longrightarrow & \mathscr{C}art_{\mathscr{C}'}(\mathsf{V}'\text{-}\mathsf{Fib}(u)_!\mathscr{S}, \mathscr{E})
\end{array}$$

whose vertical arrow are equivalences. Thus, we are reduced to checking that the bottom horizontal arrow is an equivalence. But since $\mathscr{E}$ is a stack, we have as well the following pseudo-commutative commutative diagram, whose vertical arrows are again equivalences :

$$\begin{array}{ccc}
\mathscr{C}art_{\mathscr{C}'}(\mathsf{V}'\text{-}\mathsf{Fib}(u)_!(\mathscr{C}/X)^a, \mathscr{E}) & \longrightarrow & \mathscr{C}art_{\mathscr{C}'}(\mathsf{V}'\text{-}\mathsf{Fib}(u)_!(\mathscr{S})^a, \mathscr{E}) \\
\downarrow & & \downarrow \\
\mathscr{C}art_{\mathscr{C}'}(\mathsf{V}'\text{-}\mathsf{Fib}(u)_!(\mathscr{C}/X), \mathscr{E}) & \longrightarrow & \mathscr{C}art_{\mathscr{C}'}(\mathsf{V}'\text{-}\mathsf{Fib}(u)_!\mathscr{S}, \mathscr{E})
\end{array}$$

Hence, it suffices to check that the top horizontal arrow of this latter diagram is an equivalence. But the functor $\mathsf{V}'\text{-}\mathsf{Fib}(u)_!(\mathscr{S})^a \to \mathsf{V}'\text{-}\mathsf{Fib}(u)_!(\mathscr{C}/X)^a$ is an equivalence, by propositions 5.2.9 and 5.2.11(iii); the contention is an immediate consequence.

(d)⇒(a) is trivial. □

5.4.5. Let $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two sites; we wish to give some useful criteria for a functor $u : \mathscr{C} \to \mathscr{C}'$ to be a weak morphism of sites $C' \to C$. To this aim, we consider the following conditions :

- (C0) For every $X \in \mathrm{Ob}(\mathscr{C})$ and every covering family $(X_i \to X \mid i \in I)$ for the topology J, the family $(uX_i \to uX \mid i \in I)$ covers uX for the topology J'.
- (C1) u is continuous for the topologies J and J'.
- (C2) Condition (C0) holds, and for every $X \in \mathrm{Ob}(\mathscr{C})$, every covering family $(X_i \to X \mid i \in I)$ for the topology J admits a refinement $(X'_i \to X \mid i \in I')$ that still covers X, such that the fibre products $X'_i \times_X X'_j$ and $X'_i \times_X X'_j \times_X X'_k$ are representable in $\mathscr{C}$ for every $i, j, k \in I$ and u commutes with these fibre products.
- (C3) Condition (C0) holds, and there exists a universe V containing U such that $\mathscr{C}$ and $\mathscr{C}'$ are V-small and the functor $u^a_{\mathsf{V}!} : \mathscr{C}^\wedge_{\mathsf{V}} \to C'^{\sim}_{\mathsf{V}}$ commutes with fibre products.
- (C4) $u : C' \to C$ is a morphism of sites.

Remark 5.4.6. (i) Recall that (C1) means that $u^\wedge$ transforms sheaves on C' into sheaves on C. Likewise, according to lemma 4.2.4, condition (C0) holds if and only if $u^\wedge$ transforms separated presheaves on C' into separated presheaves on C.

(ii) We have (C4)⇒(C3)⇒(C1)⇒(C0), by lemma 4.2.4. By inspecting the proof of lemma 4.2.4 we also easily see that (C2)⇒(C1).

(iii) In the situation of (5.4.5), suppose that C is a lex-site and u is left exact. Then example 4.3.12 says that u fulfills condition (C4) if and only if it fullfils condition (C0).

5.4.7. In the situation of (5.4.5), let $\mathscr{A}' \to \mathscr{C}'$ be a fibration, and $X \in \mathrm{Ob}(\mathscr{C})$. Set $\mathscr{A} := \mathsf{Fib}(u)^*\mathscr{A}' \to \mathscr{C}$ and let $\pi : \mathscr{A} \to \mathscr{A}'$ be the natural projection. For every cartesian section $\sigma \in \mathscr{A}'(uX)$ there exists a unique cartesian section

$$u^*_{|X}(\sigma) \in \mathscr{A}(X) \qquad \text{such that} \qquad \pi \circ u^*_{|X}(\sigma) = \sigma \circ u_{|X}.$$

Also, for every pair of cartesian sections $\sigma, \tau \in \mathscr{A}'(uX)$ and every natural $\mathscr{C}$-transformation $\beta : \sigma \Rightarrow \tau$ there exists a unique natural $\mathscr{C}$-transformation

$$u^*_{|X}(\beta) : u^*_{|X}(\sigma) \Rightarrow u^*_{|X}(\tau) \qquad \text{such that} \qquad \pi * u^*_{|X}(\beta) = \beta * u_{|X}.$$

This characterization easily implies that the rules : $\sigma \mapsto u^*_{|X}$ and $\beta \mapsto u^*_{|X}(\beta)$ for every such σ and β, define a functor $u^*_{|X} : \mathscr{A}'(uX) \to \mathscr{A}(X)$ fitting into the commutative diagram :

$$\begin{array}{ccc} \mathscr{A}'(uX) & \xrightarrow{u^*_{|X}} & \mathscr{A}(X) \\ {\scriptstyle \mathsf{ev}^{\mathscr{A}'}_{uX}} \downarrow & & \downarrow {\scriptstyle \mathsf{ev}^{\mathscr{A}}_{X}} \\ \mathscr{A}'_{uX} & \longrightarrow & \mathscr{A}_X \end{array}$$

whose bottom horizontal arrow is the isomorphism of categories induced by π, and whose vertical arrows are the evaluation functors of (3.2.5). Since the latter are equivalences, it follows that the same holds for $u^*_{|X}$. Notice that for every $(f : Y \to X) \in \mathrm{Ob}(\mathscr{C})$ and every cartesian section $\sigma \in \mathscr{A}'(uX)$ we have :

$$u^*_{|Y}(\sigma \circ (uf)_*) = u^*_{|X}(\sigma) \circ f_*$$

(detail left to the reader). Hence, for every pair of cartesian sections $\sigma, \tau \in \mathscr{A}'(uX)$ and every $(f : Y \to X) \in \mathrm{Ob}(\mathscr{C}/X)$ we deduce a bijection

$$\mathsf{Cart}(\sigma, \tau)(uf) \xrightarrow{\sim} \mathsf{Cart}(u^*_{|X}\sigma, u^*_{|X}\tau)(f) \qquad \beta \mapsto u^*_{|Y}\beta.$$

Finally, it is easily seen that this system of bijections amounts to an isomorphism of presheaves

$$u^{\wedge}_{|X}\mathscr{C}art(\sigma, \tau) \xrightarrow{\sim} \mathscr{C}art(u^*_{|X}\sigma, u^*_{|X}\tau).$$

Proposition 5.4.8. *In the situation of* (5.4.5)*, let $F : \mathscr{E} \to \mathscr{C}'$ be any fibration. We have :*

(i) *If $\mathscr{E}$ is* 0*-separated, and* (C0) *holds, then* $\mathsf{Fib}(u)^*(\mathscr{E})$ *is* 0*-separated.*
(ii) *If $\mathscr{E}$ is* 1*-separated, and* (C1) *holds, then* $\mathsf{Fib}(u)^*(\mathscr{E})$ *is* 1*-separated.*
(iii) *If* (C2) *holds, then u is a weak morphism of sites $C' \to C$.*

Proof. To ease notation, set $\mathscr{F} := \mathsf{Fib}(u)^*(\mathscr{E})$, and let $\pi : \mathscr{F} \to \mathscr{E}$ be the natural projection.

(i): Let $X \in \mathrm{Ob}(\mathscr{C})$ be any object, and $\sigma, \tau \in \mathscr{F}(X)$ two cartesian sections; according to lemma 5.1.9 it suffices to show that the presheaf $\mathscr{C}art(\sigma, \tau)$ is separated on the site C/X. However, the discussion of (5.4.7) yields cartesian sections $\sigma', \tau' \in \mathscr{E}(uX)$ with isomorphisms $u^*_{|X}\sigma' \xrightarrow{\sim} \sigma$ and $u^*_{|X}\tau' \xrightarrow{\sim} \tau$, whence isomorphisms of presheaves

$$\mathscr{C}art(\sigma, \tau) \xrightarrow{\sim} \mathscr{C}art(u^*_{|X}\sigma', u^*_{|X}\tau') \xrightarrow{\sim} u^{\wedge}_{|X}\mathscr{C}art(\sigma', \tau').$$

Since $\mathscr{E}$ is 0-separated, lemma 5.1.9 says that $\mathscr{C}art(\sigma', \tau')$ is a separated presheaf on the site C'/uX. On the other hand, the explicit description of the covering sieves of the sites C/X and C'/uX furnished by (4.7) easily implies that the functor $u_{|X}$ also fulfills condition (C0), relative to these sites (details left to the reader). Then the assertion follows from remark 5.4.6(i).

(ii) is similar : arguing as in the foregoing, we are reduced to checking that $u^{\wedge}_{|X}(\mathscr{C}art(\sigma', \tau'))$ is a sheaf on C/X. However, $\mathscr{C}art(\sigma', \tau')$ is a sheaf on C'/uX, by lemma 5.1.9, and $u_{|X}$ is continuous on the sites C/X and C'/uX, by proposition 4.7.7, whence the assertion.

(iii): Suppose that (C2) holds, and that $\mathscr{E}$ is a stack on C'; let $X \in \mathrm{Ob}(\mathscr{C})$ be any object, $\mathscr{S} \subset \mathscr{C}/X$ a sieve covering X, and $\mathscr{S}' \subset \mathscr{S}$ a refinement covering X, generated by a family $f_\bullet := (f_i : X'_i \to X \mid i \in I)$ with the properties of condition (C2). We get restriction functors :

$$\mathscr{F}(X) \xrightarrow{\rho} \mathsf{Cart}_{\mathscr{C}}(\mathscr{S}, \mathscr{F}) \xrightarrow{\rho'} \mathsf{Cart}_{\mathscr{C}}(\mathscr{S}', \mathscr{F})$$

and we need to prove that ρ is an equivalence. We check first that ρ is fully faithful. To this aim, notice that $\mathscr{F}$ is 0-separated by virtue of (i), hence ρ' is faithful (lemma 5.1.20), and we are then easily reduced to showing that $\rho' \circ \rho$ is fully faithful. Now, choose a cleavage c for $\mathscr{E}$, so that $\mathsf{c} \circ u^o$ is a cleavage for $\mathscr{F}$. Then $\mathsf{Cart}_{\mathscr{C}}(\mathscr{S}', \mathscr{F})$ is equivalent to the category of descent data $\mathsf{Desc}(\mathscr{F}, f_\bullet, \mathsf{c} \circ u^o)$ as in (3.5.22). However, π induces an isomorphism of categories $\mathscr{F}_X \xrightarrow{\sim} \mathscr{E}_{uX}$, and since u commutes with the fibre products $X_i \times_X X_j$ and $X_i \times_X X_j \times_X X_k$, a simple inspection shows that the natural functor

$$\mathscr{F}_X \to \mathsf{Desc}(\mathscr{F}, f_\bullet, \mathsf{c} \circ u^o)$$

is naturally identified with the corresponding functor

$$\mathscr{E}_{uX} \to \mathsf{Desc}(\mathscr{E}, u(f_\bullet), \mathsf{c}).$$

The latter is an equivalence, since $\mathscr{E}$ is a stack. Thus $\rho' \circ \rho$ is even an equivalence, and therefore ρ is fully faithful, as stated. Since X and $\mathscr{S}$ are arbitrary, we have thus proved that $\mathscr{F}$ is 1-separated; but then ρ' is fully faithful, again by lemma 5.1.20, and it follows easily that ρ is an equivalence if and only if the same holds for $\rho' \circ \rho$. For the latter, the assertion has just been shown, so finally $\mathscr{F}$ is a stack, as required. □

Lemma 5.4.9. *In the situation of* (5.4.5), *let* $\varphi : \mathscr{E}_1 \to \mathscr{E}_2$ *be a* $\mathscr{C}'$*-cartesian functor between two fibrations over* $\mathscr{C}'$*. Suppose that* (C0) *holds, and moreover that for every* $X \in \mathrm{Ob}(\mathscr{C}')$ *there exists a covering family* $(uY_j \to X \mid j \in I)$ *for the topology* J'*. Let also* $i \in \{0, 1, 2\}$ *such that* $\mathsf{Fib}(u)^*(\varphi)$ *is* i*-covering for the topology* J*. Then* φ *is* i*-covering for the topology* J'*.*

Proof. In view of lemma 5.2.3, we may replace φ by $\mathsf{C}(\varphi)$, and reduce to the case where $\mathscr{E}_1$ and $\mathscr{E}_2$ are split $\mathscr{C}'$-fibrations, and φ is a split cartesian functor. For $t = 1, 2$ let $\mathsf{c}_t : \mathscr{C}' \to \mathbf{Cat}$ be the strict pseudo-functor associated with the split cleavage of $\mathscr{E}_t$. Suppose first that $i = 0$, and let $X \in \mathrm{Ob}(\mathscr{C}')$ and $E \in \mathrm{Ob}(\mathscr{E}_{2,X})$. By assumption, we may find a covering family $(f_j : uY_j \to X \mid j \in I)$ and we set $E_j := \mathsf{c}_{2,f_j} E \in \mathrm{Ob}(\mathscr{E}_{2,uY_j})$ for every $j \in I$. Since $\mathsf{Fib}(u)^*(\varphi)$ is 0-covering, we may find for every $j \in I$ a covering family $(f_{jj'} : Y_{jj'} \to Y_j \mid j' \in \Lambda_j)$ and for every $j' \in \Lambda_j$ an object $E'_{jj'} \in \mathrm{Ob}(\mathscr{E}_{1,uY_{jj'}})$ with an isomorphism $\varphi E'_{jj'} \xrightarrow{\sim} \mathsf{c}_{2,u(f_{jj'})} E_j$. Set $h_{jj'} := f_j \circ u(f_{jj'}) : uY_{jj'} \to X$ for every $j \in I$ and $j' \in \Lambda_j$; since (C0) holds for u, the family $(h_{jj'} \mid j \in I,\ j' \in \Lambda_j)$ covers X, and $\varphi E'_{jj'} \xrightarrow{\sim} \mathsf{c}_{2,h_{jj'}} E$ for every $j \in I$ and $j' \in \Lambda_j$. This shows that φ is 0-covering.

Next, suppose that $i = 1$, and let $X \in \mathrm{Ob}(\mathscr{C}')$ and $g : \varphi E_1 \to \varphi E_2$ a morphism in $\mathscr{E}_{2,X}$. We pick a covering family $(f_j : uY_j \to X \mid j \in I)$, and set $E_{tj} := \mathsf{c}_{1,f_j} E_t$ for $t = 1, 2$ and every $j \in I$; also, let $g_j := \mathsf{c}_{2,f_j}(g) : \varphi E_{1j} \to \varphi E_{2j}$ for every $j \in J$. Since $\mathsf{Fib}(u)^*(\varphi)$ is 1-covering, for every $j \in I$ there exist a covering family $(f_{jj'} : Y_{jj'} \to Y_j \mid j' \in \Lambda_j)$ and for every $j' \in \Lambda_j$ a morphism $g_{jj'} : \mathsf{c}_{1,u(f_{jj'})} E_{1j} \to \mathsf{c}_{1,u(f_{jj'})} E_{2j}$ with $\varphi(g_{jj'}) = \mathsf{c}_{2,u(f_{jj'})}(g_j) = \mathsf{c}_{2,u(f_{jj'}) \circ f_j}(g)$. Arguing as in the foregoing, we easily deduce that φ is 1-covering (details left to the reader).

Lastly, suppose that $i = 2$, and let $X \in \mathrm{Ob}(\mathscr{C}')$ and $g_1, g_2 : E_1 \to E_2$ two morphisms in $\mathscr{E}_{1,X}$ such that $\varphi(g_1) = \varphi(g_2)$. Pick again a covering family $(f_j : uY_j \to X \mid j \in I)$ and set $g_{tj} := \mathsf{c}_{1,f_j}(g_t)$ for $t = 1, 2$ and every $j \in I$. Then $\varphi(g_{1j}) = \varphi(g_{2j})$ for every $j \in I$, and since $\mathsf{Fib}(u)^*(\varphi)$ is 2-covering, there exists for every such j a covering family $(f_{jj'} : Y_{jj'} \to Y_j \mid j' \in \Lambda_j)$ such that $\mathsf{c}_{1,u(f_{jj'})}(g_{1j}) = \mathsf{c}_{1,u(f_{jj'})}(g_{2j})$ for every $j' \in \Lambda_j$. Arguing as in the foregoing, it follows easily that φ is 2-covering. □

5.4.10. Let $C := (\mathscr{C}, J)$ be a small site and define the site $C^{\wedge}_{\mathsf{U}} := (\mathscr{C}^{\wedge}_{\mathsf{U}}, J^{\wedge})$ as in remark 4.1.31(ii). By theorem 4.4.2(i), the Yoneda embedding is a cocontinuous morphism of sites $h_{\mathscr{C}} : C^{\wedge}_{\mathsf{U}} \to C$. Thus, for every universe V containing U and every i-separated V-prestack $\varphi : \mathscr{E} \to \mathscr{C}$ on $\mathscr{C}$, the fibration

$$\mathsf{V}\text{-}\mathsf{Fib}(h_{\mathscr{C}})_*(\mathscr{E}) \to \mathscr{C}^{\wedge}_{\mathsf{U}}$$

is an i-separated prestack for the topology $J^{\wedge}$ (proposition 5.4.1(ii)). Moreover, since $h_{\mathscr{C}}$ is fully faithful, remark 3.3.15(iv) and corollary 2.4.29 imply that the counit of 2-adjunction

$$\mathsf{V}\text{-}\mathsf{Fib}(h_{\mathscr{C}})^* \circ \mathsf{V}\text{-}\mathsf{Fib}(h_{\mathscr{C}})_*(\mathscr{E}) \to \mathscr{E}$$

is an equivalence of categories. Thus, $\mathsf{V}\text{-}\mathsf{Fib}(h_{\mathscr{C}})_*(\mathscr{E})$ is a natural extension of $\mathscr{E}$ to the site $C^{\wedge}$ which contains C as a full subcategory with the topology induced from $J^{\wedge}$.

Remark 5.4.11. (i) In the situation of (5.4.10), we can describe more explicitly the fibration $\mathsf{V}\text{-}\mathsf{Fib}(h_{\mathscr{C}})_*(\mathscr{E})$, as follows. We consider the functor

$$\mathsf{c}^{\triangledown}_{\varphi} : (\mathscr{C}^{\wedge}_{\mathsf{U}})^o \to \mathsf{V}\text{-}\mathbf{Cat} \qquad F \mapsto \mathsf{Cart}_{\mathscr{C}}(\mathscr{F}ib(F), \mathscr{E})$$

which assigns to every morphism of presheaves $\beta : F \to F'$, the functor $\mathsf{Cart}_{\mathscr{C}}(\mathscr{F}ib(\beta), \mathscr{E}) : \mathsf{c}^{\triangledown}_{\varphi}(F') \to \mathsf{c}^{\triangledown}_{\varphi}(F)$. Then, combining remark 3.3.15(ii) and example 3.1.16(iii) we get a natural equivalence of $\mathscr{C}^{\wedge}_{\mathsf{U}}$-categories :

$$\mathsf{V}\text{-}\mathsf{Fib}(h_{\mathscr{C}})_*(\mathscr{E}) \xrightarrow{\sim} \mathscr{F}ib(\mathsf{c}^{\triangledown}_{\varphi}).$$

(ii) Let $i : C^{\sim}_{\mathsf{U}} \to \mathscr{C}^{\wedge}_{\mathsf{U}}$ be the inclusion functor, and $(-)^a : \mathscr{C}^{\wedge}_{\mathsf{U}} \to C^{\sim}_{\mathsf{U}}$ its left adjoint. We have a pseudo-natural equivalence of pseudo-functors :

$$\mathsf{V}\text{-}\mathsf{Fib}((-)^a)_* \xrightarrow{\sim} \mathsf{V}\text{-}\mathsf{Fib}(i)^*.$$

Indeed, let $\mathscr{E}$ be any fibration on $\mathscr{C}^{\wedge}_{\mathsf{U}}$; in view of remark 3.3.15(ii), the fibration $\mathsf{V}\text{-}\mathsf{Fib}((-)^a)_*(\mathscr{E})$ is naturally equivalent to the fibration associated with the strict pseudo-functor

$$F \mapsto \mathsf{Cart}_{\mathscr{C}^{\wedge}_{\mathsf{U}}}((-)^a\mathscr{C}^{\wedge}_{\mathsf{U}}/F, \mathscr{E}) \qquad \text{for every } F \in \mathrm{Ob}(C^{\sim}_{\mathsf{U}}).$$

On the other hand, $\mathsf{C}(\mathsf{Fib}(i)^*(\mathscr{E}))$ is the fibration associated with the strict pseudo-functor

$$F \mapsto \mathsf{Cart}_{\mathscr{C}^{\wedge}_{\mathsf{U}}}(\mathscr{C}^{\wedge}_{\mathsf{U}}/iF, \mathscr{E}) \qquad \text{for every } F \in \mathrm{Ob}(C^{\sim}_{\mathsf{U}}).$$

It suffices then to notice that $(-)^a\mathscr{C}^{\wedge}_{\mathsf{U}}/F = \mathscr{C}^{\wedge}_{\mathsf{U}}/iF$ for every sheaf F on the site C.

Theorem 5.4.12. *Let $C := (\mathscr{C}, J)$ be a small site, $h_{\mathscr{C}} : \mathscr{C} \to \mathscr{C}^{\wedge}_{\mathsf{U}}$ the Yoneda embedding and $i : C^{\sim}_{\mathsf{U}} \to \mathscr{C}^{\wedge}_{\mathsf{U}}$ the inclusion functor. For every universe V containing U we have :*

(i) *The strict pseudo-functor $\mathsf{V}\text{-}\mathsf{Fib}(h_{\mathscr{C}})^*$ restricts to a 2-equivalence ;*

$$\mathsf{V}\text{-}\mathsf{Stack}(C^{\wedge}_{\mathsf{U}}) \xrightarrow{\sim} \mathsf{V}\text{-}\mathsf{Stack}(C).$$

(ii) *Likewise, i and its left adjoint $(-)^a : \mathscr{C}^{\wedge}_{\mathsf{U}} \to C^{\sim}_{\mathsf{U}}$ induce 2-equivalences :*

$$\mathsf{V}\text{-}\mathsf{Stack}(C^{\wedge}_{\mathsf{U}}) \underset{\mathsf{V}\text{-}\mathsf{Fib}((-)^a)^*}{\overset{\mathsf{V}\text{-}\mathsf{Fib}(i)^*}{\rightleftarrows}} \mathsf{V}\text{-}\mathsf{Stack}(\mathrm{Can}(C^{\sim}_{\mathsf{U}})).$$

Proof. (i): Let η and ε be the unit and counit of a 2-adjunction for the pair of pseudo-functors $(\mathsf{V}\text{-}\mathsf{Fib}(h_{\mathscr{C}})^*, \mathsf{V}\text{-}\mathsf{Fib}(h_{\mathscr{C}})_*)$. Since $h_{\mathscr{C}}$ is a cocontinuous morphism of sites $C^{\wedge} \to C$ (theorem 4.4.2(i)), we know already that $\mathsf{V}\text{-}\mathsf{Fib}(h_{\mathscr{C}})_*$ sends V-stacks on C to V-stacks on $C^{\wedge}$ (proposition 5.4.1(ii)); according to corollary 2.4.32(i), it then suffices to show that for every V-stack $\mathscr{E}$ on $C^{\wedge}$ and $\mathscr{E}'$ on C, the fibration $\mathsf{V}\text{-}\mathsf{Fib}(h_{\mathscr{C}})^*(\mathscr{E})$ is a V-stack on C, and $\eta_{\mathscr{E}}$ and $\varepsilon_{\mathscr{E}'}$ are equivalences. The assertion for $\varepsilon_{\mathscr{E}'}$ has already been noticed in (5.4.10). Next, to ease notation, let us drop the prefix V, and set $\mathscr{F} := \mathsf{Fib}(h_{\mathscr{C}})^*(\mathscr{E})$. Let also $i_{\mathscr{F}} : \mathscr{F} \to \mathscr{F}^a$ be the natural morphism of fibrations on $\mathscr{C}$, and denote by

$$\beta_{\mathscr{E}} : \mathscr{E} \to \mathsf{Fib}(h_{\mathscr{C}})_*(\mathscr{F}^a)$$

the composition of $\eta_{\mathscr{E}}$ and $\mathsf{Fib}(h_{\mathscr{C}})_*(i_{\mathscr{F}})$. Then $\varepsilon_{\mathscr{F}^a} \circ (\mathsf{Fib}(h_{\mathscr{C}})^* \beta_{\mathscr{E}})$ is isomorphic to

$$\varepsilon_{\mathscr{F}^a} \circ (\mathsf{Fib}(h_{\mathscr{C}})^* \circ \mathsf{Fib}(h_{\mathscr{C}})_*(i_{\mathscr{F}})) \circ (\mathsf{Fib}(h_{\mathscr{C}})^* \eta_{\mathscr{E}})$$

which is in turn isomorphic to $i_{\mathscr{F}} \circ \varepsilon_{\mathscr{F}} \circ (\mathsf{Fib}(h_{\mathscr{C}})^* \eta_{\mathscr{E}})$, and the latter is isomorphic to $i_{\mathscr{F}}$, by virtue of the triangular modifications associated with the pair (η, ε) (theorem 2.4.24(i)). Since $\varepsilon_{\mathscr{F}^a}$ is an equivalence, and $i_{\mathscr{F}}$ is j-covering for $j = 0, 1, 2$, it follows that $\mathsf{Fib}(h_{\mathscr{C}})^*(\beta_{\mathscr{E}})$ is j-covering for $j = 0, 1, 2$. Since the functor $h_{\mathscr{C}}$ verifies condition (C0) of (5.4.5), lemma 5.4.9 implies that $\beta_{\mathscr{E}}$ is also j-covering for $j = 0, 1, 2$. But $\mathsf{Fib}(h_{\mathscr{C}})_*(\mathscr{E})$ is a stack (proposition 5.4.1(ii)), hence $\beta_{\mathscr{E}}$ is an equivalence (proposition 5.2.9). Therefore, $\mathsf{Fib}(h_{\mathscr{C}})^*(\beta)$ is an equivalence as well, and by the foregoing, the same then holds for $i_{\mathscr{F}}$. The latter means that $\mathsf{Fib}(h_{\mathscr{C}})^*(\mathscr{E})$ is a stack, and it also follows that $\eta_{\mathscr{E}}$ is an equivalence, as sought.

(ii): By theorem 4.4.2(iii), the functor $(-)^a$ is cocontinuous for the topologies $J^\wedge$ and $\mathrm{Can}_{C^\sim}$; taking into account remark 5.4.11(ii) and proposition 5.4.1(ii), it follows that i is a weak morphism of sites $C^\wedge_{\mathsf{U}} \to \mathrm{Can}(C^\sim_{\mathsf{U}})$. Also, $(-)^a$ is a weak morphism of sites $\mathrm{Can}(C^\sim_{\mathsf{U}}) \to C^\wedge_{\mathsf{U}}$, due to proposition 5.4.8(iii). Moreover, since $(-)^a \circ i$ is isomorphic to $\mathbf{1}_{C^\sim}$, we have a pseudo-natural isomorphism of pseudo-functors:

$$\mathsf{V}\text{-}\mathsf{Fib}(i)^* \circ \mathsf{V}\text{-}\mathsf{Fib}((-)^a)^* \xrightarrow{\sim} \mathbf{1}_{\mathsf{V}\text{-}\mathsf{Stack}(\mathrm{Can}(C^\sim))}.$$

Next, let $\mathscr{E}$ be any stack on $C^\wedge$ with V-small fibres; recall that $\mathscr{E}$ is naturally equivalent to the split fibration associated with the strict pseudo-functor $\mathsf{Cart}_{\mathscr{C}^\wedge}(\mathscr{C}^\wedge/-, \mathscr{E})$. Likewise, $\mathsf{V}\text{-}\mathsf{Fib}((-)^a)^* \circ \mathsf{V}\text{-}\mathsf{Fib}(i)^*(\mathscr{E})$ is naturally equivalent to the split fibration associated with the strict pseudo-functor

$$\mathscr{C}^\wedge \to \mathsf{V}\text{-}\mathbf{Cat} \qquad F \mapsto \mathsf{Cart}_{\mathscr{C}^\wedge}(\mathscr{C}^\wedge/F^a, \mathscr{E}).$$

By virtue of corollary 2.4.32(i), we are thus reduced to checking that for every $F \in \mathrm{Ob}(\mathscr{C}^\wedge)$, the natural morphism $j_F : F \to F^a$ induces an equivalence of categories $\mathsf{Cart}_{\mathscr{C}^\wedge}(\mathscr{C}^\wedge/F^a, \mathscr{E}) \xrightarrow{\sim} \mathsf{Cart}_{\mathscr{C}^\wedge}(\mathscr{C}^\wedge/F, \mathscr{E})$. To this aim, we notice :

Claim 5.4.13. For every stack $\mathscr{E}$ on $C^\wedge$ and every bicovering morphism $f : G \to G'$ of $(\mathscr{C}^\wedge)^\wedge_{\mathsf{V}}$ (for the topology $J^\wedge$ of $\mathscr{C}^\wedge$), the functor $\mathsf{Cart}_{\mathscr{C}^\wedge}(\mathscr{F}ib(f), \mathscr{E})$ is an equivalence.

Proof of the claim. Indeed, according to theorem 5.1.24 we have an essentially commutative diagram :

$$\begin{array}{ccc} \mathsf{Cart}_{\mathscr{C}}(\mathscr{F}ib(G'^a), \mathscr{E}) & \xrightarrow{\mathsf{Cart}_{\mathscr{C}}(\mathscr{F}ib(f^a), \mathscr{E})} & \mathsf{Cart}_{\mathscr{C}}(\mathscr{F}ib(G^a), \mathscr{E}) \\ \downarrow & & \downarrow \\ \mathsf{Cart}_{\mathscr{C}}(\mathscr{F}ib(G'), \mathscr{E}) & \xrightarrow{\mathsf{Cart}_{\mathscr{C}}(\mathscr{F}ib(f), \mathscr{E})} & \mathsf{Cart}_{\mathscr{C}}(\mathscr{F}ib(G), \mathscr{E}) \end{array}$$

whose vertical arrows are equivalences. By assumption, $f^a : G^a \to G'^a$ is an isomorphism of sheaves on $(C^\wedge)^\sim_{\mathsf{V}}$, hence the top horizontal arrow is an isomorphism of categories, and therefore the bottom horizontal arrow is an equivalence, as claimed. ◊

In view of claim 5.4.13, and recalling the natural identifications

$$\mathscr{C}^\wedge/F \xrightarrow{\sim} \mathscr{F}ib(h_F) \qquad \mathscr{C}^\wedge/F^a \xrightarrow{\sim} \mathscr{F}ib(h_{F^a})$$

(example 3.1.16(i)), we are then further reduced to showing :

Claim 5.4.14. j_F induces a bicovering morphism $h_{j_F} : h_F \to h_{F^a}$ of $(\mathscr{C}^\wedge)^\wedge_{\mathsf{V}}$.

Proof of the claim. Consider any V-presheaf G on $\mathscr{C}^\wedge$, denote by $G^a \in (C^\wedge)^\sim_{\mathsf{V}}$ the sheaf associated with G, and let $j_G : G \to G^a$ be the natural morphism; since $h_{\mathscr{C}}$ is continuous and cocontinuous for the topologies J and $J^\wedge$ (theorem 4.4.2(i)), lemma 4.2.15(ii) implies that $h^\wedge_{\mathscr{C}}(G^a)$ is a V-sheaf on C, and the morphism of V-presheaves $h^\wedge_{\mathscr{C}}(G) \to h^\wedge_{\mathscr{C}}(G^a)$ on $\mathscr{C}$ is bicovering. Taking $G := h_F$, we get $h^\wedge_{\mathscr{C}}(h_F) = F$, whence an isomorphism $t : h^\wedge_{\mathscr{C}}(h^a_F) \xrightarrow{\sim} F^a$

that identifies $h^\wedge_{\mathscr{C}}(j_G)$ with j_F. Likewise, we have $h^\wedge_{\mathscr{C}}(h_{F^a}) = F^a$, and since $h^\wedge_{\mathscr{C}}$ restricts to an equivalence $(C^\wedge)^\sim_{\mathsf{V}} \stackrel{\sim}{\to} C^\sim_{\mathsf{V}}$ (theorem 4.4.2(iii)), there follows a unique isomorphism $s : h^a_F \stackrel{\sim}{\to} h_{F^a}$ such that $h^\wedge_{\mathscr{C}}(s) = t$. Summing up, we deduce that $h^\wedge_{\mathscr{C}}(s \circ j_G) = j_F = h^\wedge_{\mathscr{C}}(h_{j_F})$; since the functor $h^\wedge_{\mathscr{C}^\wedge} : \mathscr{C}^\wedge \to (\mathscr{C}^\wedge)^\wedge_{\mathsf{V}}$ is fully faithful, we get $s \circ j_G = h_{j_F}$, and since s is an isomorphism, the claim follows. □

Corollary 5.4.15. *In the situation of* (5.4.5)*, suppose that condition* (C3) *holds for some universe* V. *Then u is a weak morphism of sites $C' \to C$.*

Proof. By remark 4.2.18(iii) we may assume that also $\mathscr{C}^\wedge$ and $\mathscr{C}'^\wedge$ are V-small. We consider the essentially commutative diagram :

$$\begin{array}{ccc} \mathscr{C} & \xrightarrow{\quad u \quad} & \mathscr{C}' \\ {\scriptstyle h_{\mathscr{C}}}\downarrow & & \downarrow{\scriptstyle h^a_{C'}} \\ \mathscr{C}^\wedge_{\mathsf{V}} & \xrightarrow{\quad u^a_{\mathsf{V}!} \quad} & C'^\sim_{\mathsf{V}} \end{array}$$

and we endow $\mathscr{C}^\wedge_{\mathsf{V}}$ with the topology $J^\wedge$ as in remark 4.1.31, and $C'^\sim_{\mathsf{V}}$ with its canonical topology. We notice that, with these topologies, the functor $u^a_{\mathsf{V}!}$ satisfies condition (C2) : indeed, condition (C0) holds for $u^a_{\mathsf{V}!}$ by definition of the topology $J^\wedge$; also, all fibre products of $\mathscr{C}^\wedge_{\mathsf{V}}$ are representable, and by assumption $u^a_{\mathsf{V}!}$ commutes with fibre products. Let V' be a universe containing V and such that $\mathsf{C}^\wedge_{\mathsf{V}}$ and $C'^\sim_{\mathsf{V}}$ are V'-small; by the foregoing case, we deduce that V'-$\mathsf{Fib}(u^a_{\mathsf{V}!})^*$ sends stacks on $\mathrm{Can}(C'^\sim_{\mathsf{V}})$ to stacks on $(\mathscr{C}^\wedge_{\mathsf{V}}, J^\wedge)$. On the other hand, theorem 5.4.12 implies that V'-$\mathsf{Fib}(h^a_{C'})^*$ restricts to a 2-equivalence from the 2-category of V'-stacks on $\mathrm{Can}(C'^\sim_{\mathsf{V}})$ to that of V'-stacks on $(\mathscr{C}', J')$, so we may assume that $\mathscr{E} = \mathsf{V}'$-$\mathsf{Fib}(h^a_{C'})^*(\mathscr{E}')$ for some V'-stack on $\mathrm{Can}(C'^\sim_{\mathsf{V}})$, and we set $\mathscr{E}'' := \mathsf{V}'$-$\mathsf{Fib}(u^a_{\mathsf{V}!})^*(\mathscr{E}')$. Then $\mathsf{Fib}(u)^*(\mathscr{E})$ is equivalent to V'-$\mathsf{Fib}(h_{\mathscr{C}})^*(\mathscr{E}'')$, and the latter is a stack, by theorem 5.4.12(i). □

Example 5.4.16. Let V be a universe, $C := (\mathscr{C}, J)$ a V-small site, and $X \in \mathrm{Ob}(\mathscr{C})$. Define the site C/X as in (4.7), and recall that the source functor $\mathsf{s}_X : \mathscr{C}/X \to \mathscr{C}$ is continuous and cocontinuous for the topologies of C and C/X. Moreover, the functor $\mathsf{s}_{\mathsf{V}!}$ commutes with fibre products, by proposition 1.4.13(vi.c), hence condition (C3) holds for s_X, and by corollary 5.4.15 we conclude that s_X is a weak morphism of sites $C \to C/X$.

Proposition 5.4.17. *Let $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two* U*-sites, and $u : C \to C'$ a morphism of sites such that :*

(a) *u induces an equivalence of categories $\widetilde{u}_* : C^\sim \stackrel{\sim}{\to} C'^\sim$.*

(b) *The subset $u(\mathrm{Ob}(\mathscr{C}')) \subset \mathrm{Ob}(\mathscr{C})$ is a topologically generating family for the site C.*

Then, for every universe V *such that C is a* V*-site, the following holds :*

(i) *u induces an equivalence of categories $\widetilde{u}_{\mathsf{V}*} : C^\sim_{\mathsf{V}} \stackrel{\sim}{\to} C'^\sim_{\mathsf{V}}$.*

(ii) *u induces a 2-equivalence of 2-categories* V-$\mathsf{Fib}(u)^* : \mathsf{V}$-$\mathsf{Stack}(C) \stackrel{\sim}{\to} \mathsf{V}$-$\mathsf{Stack}(C')$.

Proof. (i): To ease notation, set $v := \widetilde{u}_*$. Recall that $\mathrm{Can}(C^\sim)$ and $\mathrm{Can}(C'^\sim)$ are isomorphic to U-sites (remark 4.4.1(iv)). By corollary 4.3.19(i.b) and theorem 4.4.2(iii) there follows, for every universe V containing U, an essentially commutative diagram

$$\begin{array}{ccc} \mathrm{Can}(C^\sim)^\sim_{\mathsf{V}} & \xrightarrow{\quad \widetilde{v}_{\mathsf{V}*} \quad} & \mathrm{Can}(C'^\sim)^\sim_{\mathsf{V}} \\ \downarrow & & \downarrow \\ C^\sim_{\mathsf{V}} & \xrightarrow{\quad \widetilde{u}_{\mathsf{V}*} \quad} & C'^\sim_{\mathsf{V}} \end{array}$$

whose vertical arrows are equivalences. Since v is an equivalence, the same holds for $\widetilde{v}_*$, and then also for $\widetilde{u}_*$. Next, let V be any universe such that C is a V-site, and pick another universe

V' containing V and U. We deduce a commutative diagram

$$\begin{array}{ccc} C^\sim_{\mathsf{V}} & \xrightarrow{\widetilde{u}_{\mathsf{V}*}} & C'^\sim_{\mathsf{V}} \\ \downarrow & & \downarrow \\ C^\sim_{\mathsf{V}'} & \xrightarrow{\widetilde{u}_{\mathsf{V}'*}} & C'^\sim_{\mathsf{V}'} \end{array}$$

whose vertical arrows are the fully faithful inclusion functors and whose bottom horizontal arrow is an equivalence, by the foregoing case. It follows already that $\widetilde{u}_{\mathsf{V}*}$ is fully faithful. We may now argue as in the proof of theorem 4.3.13 : let F be any V-sheaf on C'; we know already that there exists a V'-sheaf G on C such that $\widetilde{u}_{*\mathsf{V}'}G$ is isomorphic to F, and we need to check that GX is essentially V-small for every $X \in \mathrm{Ob}(\mathscr{C})$. But by condition (b) we may find a covering family $(uY_i \to X \mid i \in I)$, and by claim 4.3.16 we may assume that I is V-small. Then the induced map $GX \to \prod_{i\in I} G(uY_i)$ is injective, and by assumption $G(uY_i) \simeq FY_i$ is essentially V-small for every $i \in I$, whence the contention.

(ii): Suppose first that V contains U and both $\mathscr{C}^\wedge$ and $\mathscr{C}'^\wedge$ are V-small; notice that u fulfills condition (C3) of (5.4.5) (remark 5.4.6(ii)), and therefore $\mathsf{V}\text{-}\mathsf{Fib}(u)^*$ sends V-stacks on C to V-stacks on C' (corollary 5.4.15). Likewise, $\mathsf{V}\text{-}\mathsf{Fib}(v)^*$ sends V-stacks on $\mathrm{Can}(C^\sim)$ to V-stacks on $\mathrm{Can}(C'^\sim)$. By corollary 4.3.19(i.b) and theorem 5.4.12(ii) we then get a pseudo-commutative diagram

$$\begin{array}{ccc} \mathsf{V}\text{-}\mathsf{Stack}(\mathrm{Can}(C^\sim)) & \xrightarrow{\mathsf{V}\text{-}\mathsf{Fib}(v)^*} & \mathsf{V}\text{-}\mathsf{Stack}(\mathrm{Can}(C'^\sim)) \\ \downarrow & & \downarrow \\ \mathsf{V}\text{-}\mathsf{Stack}(C) & \xrightarrow{\mathsf{V}\text{-}\mathsf{Fib}(u)^*} & \mathsf{V}\text{-}\mathsf{Stack}(C') \end{array}$$

whose vertical arrows are 2-equivalences. Since v is an equivalence, $\mathsf{V}\text{-}\mathsf{Fib}(v)^*$ is also a 2-equivalence, and then the same holds for $\mathsf{V}\text{-}\mathsf{Fib}(u)^*$. Lastly, let V be any universe such that C is a V-small site, and pick a universe V' containing V and U, and such that $\mathscr{C}^\wedge$ and $\mathscr{C}'^\wedge$ are V'-small; we deduce a commutative diagram

$$\begin{array}{ccc} \mathsf{V}\text{-}\mathsf{Stack}(C) & \xrightarrow{\mathsf{V}\text{-}\mathsf{Fib}(u)^*} & \mathsf{V}\text{-}\mathsf{Stack}(C') \\ \downarrow & & \downarrow \\ \mathsf{V}'\text{-}\mathsf{Stack}(C) & \xrightarrow{\mathsf{V}'\text{-}\mathsf{Fib}(u)^*} & \mathsf{V}'\text{-}\mathsf{Stack}(C') \end{array}$$

whose vertical arrows are the fully faithful inclusion strict pseudo-functors, and whose bottom horizontal arrow is a 2-equivalence, by the foregoing case. It follows already that $\mathsf{V}\text{-}\mathsf{Fib}(u)^*$ is fully faithful. We remark :

Claim 5.4.18. Let $T \subset \mathrm{Ob}(\mathscr{C})$ be an essentially V-small topologically generating family of the site C, and $F : \mathscr{E} \to \mathscr{C}$ a V'-stack on C such that $F^{-1}X$ is an essentially V-small category for every $X \in T$. Then $\mathscr{E}$ is equivalent to a V-stack on C.

Proof of the claim. Denote by $\mathscr{T} \subset \mathscr{C}$ the full subcategory with $\mathrm{Ob}(\mathscr{T}) = T$, let $j : \mathscr{T} \to \mathscr{C}$ be the inclusion functor, and endow $\mathscr{T}$ with the topology $J_{\mathscr{T}}$ induced by J via the functor j. Let also $\eta_{\mathscr{E}} : \mathscr{E} \to \mathscr{F} := \mathsf{V}'\text{-}\mathsf{Fib}(j)_* \circ \mathsf{V}'\text{-}\mathsf{Fib}(j)^*(\mathscr{E})$ be the unit of adjunction. By proposition 4.3.18(ii), the functor j is a morphism of V'-sites $C \to (\mathscr{T}, J_{\mathscr{T}})$, hence $\mathscr{E}' := \mathsf{V}'\text{-}\mathsf{Fib}(j)^*(\mathscr{E})$ is a V'-stack on $(\mathscr{T}, J_{\mathscr{T}})$ (remark 5.4.6(ii) and corollary 5.4.15), and by assumption its fibres are V-small, *i.e.* it is a V-stack on $(\mathscr{T}, J_{\mathscr{T}})$. Moreover, since j is cocontinuous for the topologies J and $J_{\mathscr{T}}$ (proposition 4.3.18(i)), we also see that $\mathscr{F}$ is a V'-stack on C (proposition 5.4.1(ii)). Furthermore, since j is fully faithful, the same holds for $\mathsf{V}'\text{-}\mathsf{Fib}(j)_*$ (remark 3.3.15(iv)), so the counit of adjunction $\varepsilon_{\mathscr{E}'} : \mathsf{V}'\text{-}\mathsf{Fib}(j)^*(\mathscr{F}) \to \mathscr{E}'$ is an equivalence. By virtue of the triangular modifications for the pair (η, ε) (theorem 2.4.24(i)), it follows that $\mathsf{V}'\text{-}\mathsf{Fib}(j)^*(\eta_{\mathscr{E}})$ is an equivalence as well, and then it is i-covering for $i = 0, 1, 2$ (proposition 5.2.9). By invoking lemma 5.4.9 we conclude finally that $\eta_{\mathscr{E}}$ is i-covering for $i = 0, 1, 2$, so it is an equivalence, again by proposition 5.2.9. Summing up, we are reduced to checking that if $\mathscr{E}'$ is a V-stack on $(\mathscr{T}, J_{\mathscr{T}})$, then $\mathscr{F}' := \mathsf{V}'\text{-}\mathsf{Fib}(j)_*(\mathscr{E}')$ is a V-stack on C. To this aim, pick any cleavage $\mathsf{c} : \mathscr{T}^o \to \mathsf{V}\text{-}\mathbf{Cat}$ for $\mathscr{E}'$; by construction, the fibre of $\mathscr{F}'$ over any $X \in \mathrm{Ob}(\mathscr{C})$ is the 2-limit of the pseudo-functor $\mathsf{c} \circ \mathsf{t}_{X^o} : X^o/j^o\mathscr{T}^o \to \mathsf{V}\text{-}\mathbf{Cat}$, and it suffices to remark that $X^o/j^o\mathscr{T}^o$ is a V-small category. ◊

Now, by assumption $\mathscr{C}$ admits a V-small topologically generating family T, and by assumption (b), for every $X \in T$ we may find a covering family $(uY_i \to X \mid i \in I_X)$. By claim 4.3.16, for every $X \in T$ there exists then a V-small subset $I'_X \subset I_X$ such that $(uY_i \to X \mid i \in I'_X)$ is still a covering family; set $T' := \{uY_i \mid X \in T,\ i \in I_X\}$. Clearly T' is a V-small topologically generating family for C. Lastly, let $\mathscr{E}'$ be any V-stack on C'; we know already that there exists a V'-stack $\mathscr{E}$ on C such that $\mathsf{V}'\text{-}\mathsf{Fib}(u)^*(\mathscr{E})$ is equivalent to $\mathscr{E}'$. But the latter condition implies that the fibre of $\mathscr{E}$ over each $X \in T'$ is a V-small category; by claim 5.4.18 we deduce that $\mathscr{E}$ is equivalent to a V-stack on C, and this shows that $\mathsf{V}\text{-}\mathsf{Fib}(u)^*$ is a 2-equivalence, as stated. □

Corollary 5.4.19. *For every* U*-site* $C := (\mathscr{C}, J)$ *the inclusion pseudo-functor* $\mathsf{Stack}(C) \to \mathsf{Fib}(\mathscr{C})$ *admits a left* 2*-adjoint*

$$\mathsf{Fib}(\mathscr{C}) \to \mathsf{Stack}(C) \qquad \mathscr{E} \mapsto \mathscr{E}^a.$$

Proof. Let $T \subset \mathrm{Ob}(\mathscr{C})$ be an essentially small topologically generating family, $\mathscr{T} \subset \mathscr{C}$ the full subcategory with $\mathrm{Ob}(\mathscr{T}) = T$, and $j : \mathscr{T} \to \mathscr{C}$ the inclusion functor. Endow $\mathscr{T}$ with the topology $J_{\mathscr{T}}$ induced by J via j. Let also $\mathscr{E} \to \mathscr{C}$ be any fibration with essentially small fibres, and set $\mathscr{E}' := \mathsf{Fib}(j)^*(\mathscr{E})$. Let $\mathscr{E}'^a$ be the stack associated with $\mathscr{E}'$ (theorem 5.1.24), and denote by $i : \mathscr{E}' \to \mathscr{E}'^a$ the natural morphism of fibrations over $\mathscr{T}$. Choose any universe V containing U and such that $\mathscr{C}$ is V-small, and consider the composition

$$\beta_{\mathscr{E}} : \mathscr{E} \xrightarrow{\eta_{\mathscr{E}}} \mathsf{V}\text{-}\mathsf{Fib}(j)_*(\mathscr{E}') \xrightarrow{\mathsf{V}\text{-}\mathsf{Fib}(j)_*(i)} \mathscr{E}^* := \mathsf{V}\text{-}\mathsf{Fib}(j)_*(\mathscr{E}'^a)$$

where $\eta_{\mathscr{E}}$ is the unit of adjunction. By arguing as in the proof of claim 5.4.18, we see that $\mathscr{E}^*$ is a stack with essentially small fibres on C and that $\mathsf{V}\text{-}\mathsf{Fib}(j)^*(\eta_{\mathscr{E}})$ is an equivalence of categories. Moreover, since j is fully faithful, the counit of adjunction $\mathsf{V}\text{-}\mathsf{Fib}(j)^* \circ \mathsf{V}\text{-}\mathsf{Fib}(j)_* \Rightarrow \mathbf{1}_{\mathsf{V}\text{-}\mathsf{Fib}(\mathscr{T})}$ is a pseudo-natural equivalence, so we have an essentially commutative diagram of functors

$$\begin{array}{ccc}
\mathsf{V}\text{-}\mathsf{Fib}(j)^* \circ \mathsf{V}\text{-}\mathsf{Fib}(j)_*(\mathscr{E}') & \xrightarrow{\mathsf{V}\text{-}\mathsf{Fib}(j)^* \circ \mathsf{V}\text{-}\mathsf{Fib}(j)_*(i)} & \mathsf{V}\text{-}\mathsf{Fib}(j)^*(\mathscr{E}^*) \\
\downarrow & & \downarrow \\
\mathscr{E}' & \xrightarrow{\quad i \quad} & \mathscr{E}'^a
\end{array}$$

whose vertical arrows are equivalences of categories. Since i is l-covering for $l = 0, 1, 2$ (proposition 5.2.11(i)), we conclude that the same holds for $\mathsf{V}\text{-}\mathsf{Fib}(j)^*(\beta_{\mathscr{E}})$, and then also for $\beta_{\mathscr{E}}$, by virtue of lemma 5.4.9. Let us denote by $\mathscr{E}^a_{\mathsf{V}}$ the V-stack associated with $\mathscr{E}$ (a priori, its fibres are only essentially V-small), and $i_{\mathsf{V}} : \mathscr{E} \to \mathscr{E}^a_{\mathsf{V}}$ the unit of adjunction; there exists a morphism of fibrations $\omega_{\mathscr{E}} : \mathscr{E}^a_{\mathsf{V}} \to \mathscr{E}^*$, pseudo-natural in $\mathscr{E}$, such that the functor $\omega_{\mathscr{E}} \circ i_{\mathsf{V}}$ is isomorphic to $\beta_{\mathscr{E}}$. Since i_{V} is l-covering for $l = 0, 1, 2$ (proposition 5.2.11(i)), it follows that the same holds for $\omega_{\mathscr{E}}$ (lemma 5.2.4(ii)), and then the latter is an equivalence of categories (proposition 5.2.9). Summing up, the rule : $\mathscr{E} \mapsto \omega_{\mathscr{E}}$ yields a pseudo-natural equivalence of pseudo-functors, so the pseudo-functor given by the rule : $\mathscr{E} \mapsto \mathscr{E}^*$ is the sought left 2-adjoint. □

5.4.20. Let now $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two U-sites, $u : C \to C'$ a weak morphism of sites (definition 5.4.2); then, for every universe V with $\mathsf{U} \subset \mathsf{V}$, the pseudo-functor $\mathsf{V}\text{-}\mathsf{St}(u)_*$ admits a left 2-adjoint

$$\mathsf{V}\text{-}\mathsf{St}(u)^* : \mathsf{V}\text{-}\mathsf{Stack}(C') \to \mathsf{V}\text{-}\mathsf{Stack}(C)$$

defined as follows. We choose an essentially U-small topologically generating subset $G \subset \mathrm{Ob}(\mathscr{C}')$ and let $\mathscr{G} \subset \mathscr{C}'$ be the full subcategory with $\mathrm{Ob}(\mathscr{G}) = G$. We endow $\mathscr{G}$ with the topology $J_\mathscr{G}$ induced by J' via the inclusion functor $j : \mathscr{G} \to \mathscr{C}'$. Recall that j is a morphism of sites $C' \to (\mathscr{G}, J_\mathscr{G})$ and $\widetilde{\jmath}_* : C'^\sim \xrightarrow{\sim} (\mathscr{G}, J_\mathscr{G})^\sim$ is an equivalence (proposition 4.3.18(ii)). Then $\mathsf{V}\text{-}\mathsf{St}(j)_*$ is well defined (remark 5.4.6(ii)) and it is a 2-equivalence (proposition 5.4.17(ii)), and $\mathsf{V}\text{-}\mathsf{St}(u)^*$ is given by the composition :

$$\mathsf{V}\text{-}\mathsf{Stack}(C') \xrightarrow{\mathsf{V}\text{-}\mathsf{St}(j)_*} \mathsf{V}\text{-}\mathsf{Stack}(\mathscr{G}, J_\mathscr{G}) \xrightarrow{\mathsf{V}\text{-}\mathsf{Fib}(u\circ j)_!} \mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C}) \xrightarrow{(-)^a} \mathsf{V}\text{-}\mathsf{Stack}(C)$$

where $(-)^a$ is the pseudo-functor of corollary 5.4.19. It is then easily seen that the resulting pseudo-functor is a left 2-adjoint for $\mathsf{V}\text{-}\mathsf{St}(u)_*$; especially, it is independent, up to pseudo-natural equivalence, of the choice of G (remark 2.4.28(iii)); the details shall be left to the reader. As usual, we shall often omit mentioning V, in case $\mathsf{V} = \mathsf{U}$.

Example 5.4.21. By remark 5.4.6(ii), every morphism of sites $u : C := (\mathscr{C}, J') \to C' := (\mathscr{C}', J)$ fulfills (C3), hence it is a weak morphism of sites (corollary 5.4.15), and so it induces a pseudo-functor $\mathsf{V}\text{-}\mathsf{St}(u)_*$. If C and C' are U-sites, we have also the pseudo-functor $\mathsf{V}\text{-}\mathsf{St}(u)^*$.

Proposition 5.4.22. *Let $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two small sites, $u : C \to C'$ a morphism of sites, $i \in \{0, 1, 2\}$, and $f : \mathscr{E} \to \mathscr{F}$ an i-covering cartesian functor of $\mathscr{C}'$-fibrations. We have :*

(i) *The functor $\mathsf{Fib}(u)_!(f) : \mathsf{Fib}(u)_!(\mathscr{E}) \to \mathsf{Fib}(u)_!(\mathscr{F})$ is i-covering.*
(ii) *If $\mathscr{E}$ and $\mathscr{F}$ are stacks on C', then $\mathsf{St}(u)^*(f) : \mathsf{St}(u)^*(\mathscr{E}) \to \mathsf{St}(u)^*(\mathscr{F})$ is i-covering.*

Proof. We show first the following special case :

Claim 5.4.23. The proposition holds if u is a morphism of lex-sites.

Proof of the claim. By proposition 5.2.11(iii), it suffices to show assertion (i) of the proposition. To this aim, we consider the essentially commutative diagram

$$\begin{array}{ccc} \mathsf{Fib}(u)_!(\mathsf{C}(\mathscr{E})) & \xrightarrow{\mathsf{Fib}(u)_!(\mathsf{C}(f))} & \mathsf{Fib}(u)_!(\mathsf{C}(\mathscr{F})) \\ {\scriptstyle \mathsf{Fib}(u)_!(\mathsf{ev}^\mathscr{E})}\downarrow & & \downarrow{\scriptstyle \mathsf{Fib}(u)_!(\mathsf{ev}^\mathscr{F})} \\ \mathsf{Fib}(u)_!(\mathscr{E}) & \xrightarrow{\mathsf{Fib}(u)_!(f)} & \mathsf{Fib}(u)_!(\mathscr{F}) \end{array}$$

where $\mathsf{ev}^\bullet$ is the pseudo-natural equivalence described in (3.2.5). Then both vertical arrows of the diagram are equivalences (lemma 2.4.11(ii)), so $\mathsf{Fib}(u)_!(f)$ is i-covering if and only if the same holds for $\mathsf{Fib}(u)_!(\mathsf{C}(f))$ (lemma 5.2.3), and by the same token, f is i-covering if and only if the same holds for $\mathsf{C}(f)$. Thus, we may replace f by $\mathsf{C}(f)$, and assume from start that f is a split cartesian functor $(\mathscr{E}, \boldsymbol{\lambda}^\mathscr{E}) \to (\mathscr{F}, \boldsymbol{\lambda}^\mathscr{F})$. In this case, let $\mathsf{c}^\mathscr{E}$ and $\mathsf{c}^\mathscr{F}$ be the strict pseudo-functors associated with the cleavages $\boldsymbol{\lambda}^\mathscr{E}$ and $\boldsymbol{\lambda}^\mathscr{F}$; then $\mathsf{Fib}(u)_!(\mathscr{E})$ is equivalent to the fibration associated with the pseudo-functor

$$\mathsf{d}^\mathscr{E} : \mathscr{C}^o \to \mathbf{Cat} \qquad X \mapsto \underset{(X/u\mathscr{C}')^o}{2\text{-colim}}\, \mathsf{c}^\mathscr{E} \circ \mathsf{t}_X^o$$

where $\mathsf{t}_X : X/u\mathscr{C}' \to \mathscr{C}'$ is the target functor. Hence, $\mathsf{d}_X^\mathscr{E} = \mathscr{F}ib(\mathsf{c}^\mathscr{E} \circ \mathsf{t}_X^o)[\Sigma_{\mathscr{E},X}^{-1}]$, where $\Sigma_{\mathscr{E},X}$ is the set of cartesian morphisms of $\mathscr{F}ib(\mathsf{c}^\mathscr{E} \circ \mathsf{t}_X^o)$ (see the proof of theorem 3.3.9). The universal pseudo-cocone $\pi^{\mathscr{E},X} : \mathsf{c}^{\mathscr{E}} \circ \mathsf{t}^o_X \Rightarrow \mathsf{F}_{\mathsf{d}^{\mathscr{E}}_X}$ is the strict pseudo-natural transformation that assigns to every object $(X', \psi : X \to uX')$ of $(X/u\mathscr{C}')^o$ the functor

$$\pi^{\mathscr{E},X}_{(X',\psi)} : \mathsf{c}^{\mathscr{E}}_{X'} \to \mathsf{d}^{\mathscr{E}}_X \qquad E \mapsto ((X', \psi), E).$$

To every morphism $\varphi : X \to Y$ of $\mathscr{C}$ we then attach the functor

$$\mathsf{d}^{\mathscr{E}}_\varphi : \mathsf{d}^{\mathscr{E}}_Y \to \mathsf{d}^{\mathscr{E}}_X \qquad \text{such that} \qquad \pi^{\mathscr{E},X} * \varphi^{*o} = \mathsf{F}_{\mathsf{d}^{\mathscr{E}}_\varphi} \odot \pi^{\mathscr{E},Y}$$

where $\varphi^* : Y/u\mathscr{C}' \to X/u\mathscr{C}'$ is the functor induced by φ (see example 2.2.8(ii)); unwinding the definitions, we find that $\mathsf{d}^{\mathscr{E}}_\varphi$ is given by the rule :

$$((X', \psi : Y \to uX'), E) \mapsto ((X', \psi \circ \varphi), E) \qquad \text{for every } ((X', \psi), E) \in \mathrm{Ob}(\mathsf{d}^{\mathscr{E}}_Y).$$

Likewise we describe $\mathsf{Fib}(u)_!(\mathscr{F})$ up to equivalence; next, the split cartesian functor f corresponds to a strict pseudo-natural transformation $\mathsf{c}^f : \mathsf{c}^{\mathscr{E}} \Rightarrow \mathsf{c}^{\mathscr{F}}$, and under the foregoing identifications, the cartesian functor $\mathsf{Fib}(u)_!(f)$ corresponds to the strict pseudo-natural transformation $\mathsf{d}^f : \mathsf{d}^{\mathscr{E}} \Rightarrow \mathsf{d}^{\mathscr{F}}$ assigning to every $X \in \mathrm{Ob}(\mathscr{C})$ the functor :

$$\mathsf{d}^f_X : \mathsf{d}^{\mathscr{E}}_X \to \mathsf{d}^{\mathscr{F}}_X \qquad ((X', \psi), E) \mapsto ((X', \psi), \mathsf{c}^f_{X'} E).$$

The objects of $\mathscr{F}ib(\mathsf{d}^{\mathscr{E}})$ are then the data (X, X', ψ, E) with $X \in \mathrm{Ob}(\mathscr{C})$ and $((X', \psi), E) \in \mathrm{Ob}(\mathsf{d}^{\mathscr{E}}_X)$, and likewise for the objects of $\mathscr{F}ib(\mathsf{d}^{\mathscr{F}})$. After this preparation, suppose that f is 0-covering, and let us check that the same holds for $\mathsf{Fib}(u)_!(f)$, where the latter is naturally identified with $\mathscr{F}ib(\mathsf{d}^f)$. Thus, consider any object $(X, X', \psi : X \to uX', F)$ of $\mathscr{F}ib(\mathsf{d}^{\mathscr{F}})$; according to remark 5.2.2, we need to find a covering family $(\varphi_\lambda : Y_\lambda \to X \mid \lambda \in \Lambda)$ and for every $\lambda \in \Lambda$ an object $\underline{E}_\lambda := ((Y'_\lambda, \psi_\lambda), E) \in \mathsf{d}^{\mathscr{E}}_{Y_\lambda}$ with an isomorphism

$$((Y'_\lambda, \psi_\lambda), \mathsf{c}^f_{Y'_\lambda} E_\lambda) = \mathsf{d}^f_{Y_\lambda}((Y'_\lambda, \psi_\lambda), E_\lambda) \xrightarrow{\sim} \mathsf{d}^{\mathscr{F}}_{\varphi_\lambda}((X', \psi), F) = ((X', \psi \circ \varphi_\lambda), F) \qquad \text{in } \mathsf{d}^{\mathscr{F}}_{Y_\lambda}.$$

But since f is 0-covering, there exist a covering $(\tau_\lambda : Y'_\lambda \to X' \mid \lambda \in \Lambda)$ for the topology J' and an object $E_\lambda \in \mathrm{Ob}(\mathsf{c}^{\mathscr{E}}_{Y'_\lambda})$ with an isomorphism $\omega_\lambda : \mathsf{c}^f_{Y'_\lambda} E_\lambda \xrightarrow{\sim} \mathsf{c}^{\mathscr{F}}_{\tau_\lambda} F$ in $\mathsf{c}^{\mathscr{F}}_{Y'_\lambda}$ for every $\lambda \in \Lambda$. Thus, let us set $Y_\lambda := X \times_{uX'} uY'_\lambda$, and denote by $\varphi_\lambda : Y_\lambda \to X$ the induced projection, for every $\lambda \in \Lambda$. Since u is continuous, the family $(u(\tau_\lambda) \mid \lambda \in \Lambda)$ covers uX' for the topology J, and therefore $(\varphi_\lambda \mid \lambda \in \Lambda)$ covers X. Lastly, the sought isomorphism shall be the composition of the isomorphism $((Y'_\lambda, \psi_\lambda), \mathsf{c}^f_{Y'_\lambda} E_\lambda) \xrightarrow{\sim} ((Y'_\lambda, \psi_\lambda), \mathsf{c}^{\mathscr{F}}_{\tau_\lambda} F)$ of $\mathscr{F}ib(\mathsf{c}^{\mathscr{F}} \circ \mathsf{t}^o_{Y_\lambda})$ induced by ω_λ, and the cartesian morphism $((Y'_\lambda, \psi_\lambda), \mathsf{c}^{\mathscr{F}}_{\tau_\lambda} F) \to ((X', \psi \circ \varphi_\lambda), F)$ of $\mathscr{F}ib(\mathsf{c}^{\mathscr{F}} \circ \mathsf{t}^o_{Y_\lambda})$.

Next, suppose that f is 1-covering, and let $((X'_i, \psi_i : X \to uX'_i), E_i)$ for $i = 1, 2$ be two objects of $\mathsf{d}^{\mathscr{E}}_X$ with a morphism $g : ((X'_1, \psi_1), \mathsf{c}^f_{X'_1} E_1) \to ((X'_2, \psi_2), \mathsf{c}^f_{X'_2} E_2)$ in $\mathsf{d}^{\mathscr{F}}_X$. Notice that $(Z/u\mathscr{C}')^o$ is a filtered category for every $Z \in \mathrm{Ob}(\mathscr{C})$ (example 1.3.16(i)), hence $\Sigma_{\mathscr{F},Z}$ admits a right calculus of fraction (example 3.3.13(ii)); moreover, every cartesian morphism $(\sigma, s) : ((Z'', \psi'), F') \to ((Z', \psi), F)$ in $\Sigma_{\mathscr{F},Z}$ admits the factorization :

$$(\sigma, s) = \boldsymbol{\lambda}^{\mathscr{F}}(F, \sigma) \circ (\mathbf{1}_{Z''}, s) \qquad \text{in } \mathscr{F}ib(\mathsf{c}^{\mathscr{F}} \circ \mathsf{t}^o_Z) \tag{5.4.24}$$

where $(\mathbf{1}_{X''}, s)$ is an isomorphism of $\mathsf{c}^{\mathscr{F}}_{X''}$ (lemma 3.1.20(i)), so g can be represented by a pair

$$((X'_1, \psi_1), \mathsf{c}^f_{X'_1} E_1) \xleftarrow{\boldsymbol{\lambda}^{\mathscr{F}}(\mathsf{c}^f_{X'_1} E_1, \rho)} ((X''_1, \psi'_1), \mathsf{c}^{\mathscr{F}}_\rho \circ \mathsf{c}^f_{X'_1} E_1) \xrightarrow{g'} ((X'_2, \psi_2), \mathsf{c}^f_{X'_2} E_2)$$

where $\rho : X''_1 \to X'_1$ is a morphism of $\mathscr{C}'$ and $\psi'_1 : X \to uX''_1$ is a morphism of $\mathscr{C}$ such that $u(\rho) \circ \psi'_1 = \psi_1$. Also, g' is a morphism in $\mathscr{F}ib(\mathsf{c}^{\mathscr{F}} \circ \mathsf{t}^o_X)$. Then in turn, g' is a pair $(X/\mu, t)$, where X/μ is a morphism $(X''_1, \psi'_1) \to (X'_2, \psi_2)$ in $X/u\mathscr{C}'$, *i.e.* a morphism $\mu : X''_1 \to X'_2$ in $\mathscr{C}'$ with $u(\mu) \circ \psi_1 = \psi_2$, and g' is a morphism in $\mathsf{c}^{\mathscr{F}}_{X''_1}$

$$g' : \mathsf{c}^f_{X''_1} \circ \mathsf{c}^{\mathscr{E}}_\rho E_1 = \mathsf{c}^{\mathscr{F}}_\rho \circ \mathsf{c}^f_{X'_1} E_1 \to \mathsf{c}^{\mathscr{F}}_\mu \circ \mathsf{c}^f_{X'_2} E_2 = \mathsf{c}^f_{X''_1} \circ \mathsf{c}^{\mathscr{E}}_\mu E_2.$$

According to remark 5.2.2, we need to exhibit a covering family $(\varphi_\lambda : Y_\lambda \to X \mid \lambda \in \Lambda)$, and for every $\lambda \in \Lambda$ a morphism $g_\lambda : ((X'_1, \psi_1 \circ \varphi_\lambda), E_1) \to ((X'_2, \psi_2 \circ \varphi_\lambda), E_2)$ in $\mathsf{d}^{\mathscr{E}}_{Y_\lambda}$ such that $\mathsf{d}^f_{X'_1}(g_\lambda) = \mathsf{d}^{\mathscr{F}}_{\varphi_\lambda}(g)$. Now, since f is 1-covering, there exist a covering family $(\tau_\lambda : Y''_\lambda \to X''_1 \mid \lambda \in \Lambda)$ and for every $\lambda \in \Lambda$ a morphism

$$g'_\lambda : \mathsf{c}^{\mathscr{E}}_{\tau_\lambda} \circ \mathsf{c}^{\mathscr{E}}_\rho E_1 \to \mathsf{c}^{\mathscr{E}}_{\tau_\lambda} \circ \mathsf{c}^{\mathscr{E}}_\mu E_2 \qquad \text{in } \mathsf{c}^{\mathscr{E}}_{Y''_\lambda} \text{ such that} \qquad \mathsf{c}^f_{Y''_\lambda}(g'_\lambda) = \mathsf{c}^{\mathscr{F}}_{\tau_\lambda}(g').$$

We set $Y_\lambda := X \times_{uX''_1} uY''_\lambda$, and we let $\varphi_\lambda : Y_\lambda \to X$ and $\psi''_\lambda : Y_\lambda \to uY''_\lambda$ be the induced projections for every $\lambda \in \Lambda$; arguing as in the foregoing it is easily seen that the family $(g_\lambda \mid \lambda \in \Lambda)$ covers X, and we define g_λ as the morphism of $\mathsf{d}^{\mathscr{E}}_{Y_\lambda}$ represented by the pair of morphisms :

$$((X'_\lambda, \psi_1 \circ \varphi_\lambda), E_1) \xleftarrow{\boldsymbol{\lambda}^{\mathscr{E}}(E_1, \rho\circ\tau_\lambda)} ((Y''_\lambda, \psi''_\lambda), \mathsf{c}^{\mathscr{E}}_{\rho\circ\tau_\lambda} E_1) \xrightarrow{(Y_\lambda/\mu\circ\tau_\lambda, g'_\lambda)} ((X'_2, \psi_2 \circ \varphi_\lambda), E_2).$$

In view of remark 3.2.2(ii) we see that $\mathsf{d}^f_{Y_\lambda}(g'_\lambda)$ is represented by the pair

$$((X'_\lambda, \psi_1\varphi_\lambda), \mathsf{c}^f_{X'_1} E_1) \xleftarrow{\boldsymbol{\lambda}^{\mathscr{F}}(\mathsf{c}^f_{X'_1} E_1, \rho\tau_\lambda)} ((Y''_\lambda, \psi''_\lambda), \mathsf{c}^f_{Y''_\lambda}\mathsf{c}^{\mathscr{E}}_{\rho\tau_\lambda} E_1) \xrightarrow{(Y_\lambda/\mu\tau_\lambda, \mathsf{c}^{\mathscr{F}}_{\tau_\lambda}(g'))} ((X'_2, \psi_2\varphi_\lambda), \mathsf{c}^f_{X'_2} E_2)$$

and by remark 3.2.2(i) we have :

$$\boldsymbol{\lambda}^{\mathscr{F}}(\mathsf{c}^f_{X'_1} E_1, \rho\tau_\lambda) = \boldsymbol{\lambda}^{\mathscr{F}}(\mathsf{c}^f_{X'_1} E_1, \rho) \circ \boldsymbol{\lambda}^{\mathscr{F}}(\mathsf{c}^{\mathscr{F}}_\rho \mathsf{c}^f_{X'_1} E_1, \tau_\lambda).$$

On the other hand, $(Y_\lambda/\mu \circ \tau_\lambda, \mathsf{c}^{\mathscr{F}}_{\tau_\lambda}(g'))$ is the composition :

$$((Y''_\lambda,\psi''_\lambda), \mathsf{c}^f_{Y''_\lambda}\mathsf{c}^{\mathscr{E}}_{\rho\tau_\lambda} E_1) \xrightarrow{\boldsymbol{\lambda}^{\mathscr{F}}(\mathsf{c}^{\mathscr{F}}_\rho \mathsf{c}^f_{X'_1} E_1, \tau_\lambda)} ((X''_\lambda, \psi'_1\varphi_\lambda), \mathsf{c}^{\mathscr{F}}_\rho \mathsf{c}^f_{X'_1} E_1) \xrightarrow{\mathsf{d}^{\mathscr{F}}_{\varphi_\lambda}(X/\mu, g')} ((X'_2, \psi_2\varphi_\lambda), \mathsf{c}^f_{X'_2} E_1)$$

so $\mathsf{d}^f_{Y_\lambda}(g'_\lambda)$ is also represented by the pair

$$((X'_\lambda, \psi_1\varphi_\lambda), \mathsf{c}^f_{X'_1} E_1) \xleftarrow{\boldsymbol{\lambda}^{\mathscr{F}}(\mathsf{c}^f_{X'_1} E_1, \rho)} ((X''_\lambda, \psi'_1\varphi_\lambda), \mathsf{c}^{\mathscr{F}}_\rho \mathsf{c}^f_{X'_1} E_1) \xrightarrow{\mathsf{d}^{\mathscr{F}}_{\varphi_\lambda}(X/\mu, g')} ((X'_2, \psi_2\varphi_\lambda), \mathsf{c}^f_{X'_2} E_1)$$

which represents $\mathsf{d}^{\mathscr{F}}_{\varphi_\lambda}(g)$ as well, as required.

Lastly, suppose that f is 2-covering, and consider objects $((X'_j, \psi_j), E_j)$ of $\mathsf{d}^{\mathscr{E}}_X$ for $j = 1, 2$, and two morphisms $g_1, g_2 : ((X'_1, \psi_1), E_1) \to ((X'_2, \psi_2), E_2)$ in $\mathsf{d}^{\mathscr{E}}_X$ such that

$$\mathsf{d}^f_X(g_1) = \mathsf{d}^f_X(g_2). \tag{5.4.25}$$

We need to exhibit a covering family $(\varphi_\lambda : Y_\lambda \to X \mid \lambda \in \Lambda)$ such that $\mathsf{d}^{\mathscr{E}}_{\varphi_\lambda}(g_1) = \mathsf{d}^{\mathscr{E}}_{\varphi_\lambda}(g_2)$ for every $\lambda \in \Lambda$. We reduce easily to the case where g_1 and g_2 are two classes of morphisms of $\mathscr{F}ib(\mathsf{c}^{\mathscr{E}} \circ \mathsf{t}^o_X)$. In this case, (5.4.25) means that there exists a cartesian morphism $h : ((X''_1, \psi'_1), F) \to ((X'_1, \psi_1), \mathsf{c}^f_{X'_1} E_1)$ in $\mathscr{F}ib(\mathsf{c}^{\mathscr{F}} \circ \mathsf{t}^o_X)$ such that $\mathscr{F}ib(\mathsf{c}^f \circ \mathsf{t}^o_X)(g_1) \circ h = \mathscr{F}ib(\mathsf{c}^f \circ \mathsf{t}^o_X)(g_2) \circ h$. However, we have a factorization $h = \boldsymbol{\lambda}^{\mathscr{F}}(\mathsf{c}^f_{X'_1} E_1, \mu) \circ (\mathbf{1}_{X''_1}, h')$ as in (5.4.24), where $(\mathbf{1}_{X''_1}, h')$ is an isomorphism of $\mathsf{c}^{\mathscr{F}}_{X''_1}$, so we may assume that $h = \boldsymbol{\lambda}^{\mathscr{F}}(\mathsf{c}^f_{X'_1} E_1, \mu) = \mathscr{F}ib(\mathsf{c}^f \circ \mathsf{t}^o_X)(\boldsymbol{\lambda}^{\mathscr{E}}(E_1, \mu))$. Then we may as well replace g_i by $g_i \circ \boldsymbol{\lambda}^{\mathscr{E}}(E_1, \mu)$ for $i = 1, 2$, and assume from start that

$$\mathscr{F}ib(\mathsf{c}^f \circ \mathsf{t}^o_X)(g_1) = \mathscr{F}ib(\mathsf{c}^f \circ \mathsf{t}^o_X)(g_2).$$

Especially, there exist a morphism $\rho : X'_1 \to X'_2$ in $\mathscr{C}'$ such that $u(\rho) \circ \psi_1 = \psi_2$, and morphisms $g'_i : E_1 \to \mathsf{c}^{\mathscr{E}}_\rho E_2$ such that $g_i = (\rho, g'_i)$ for $i = 1, 2$, and $\mathsf{c}^f_{X'_1}(g'_1) = \mathsf{c}^f_{X'_1}(g'_2)$. Then, since f is 2-covering, we find a covering family $(\tau_\lambda : Y'_\lambda \to X'_1 \mid \lambda \in \Lambda)$ such that

$$\mathsf{c}^{\mathscr{E}}_{\tau_\lambda}(g'_1) = \mathsf{c}^{\mathscr{E}}_{\tau_\lambda}(g'_2) \qquad \text{for every } \lambda \in \Lambda. \tag{5.4.26}$$

We set again $Y_\lambda := X \times_{uX'_1} uY'_\lambda$, and we let $\varphi_\lambda : Y_\lambda \to X$ and $\psi_\lambda : Y_\lambda \to Y'_\lambda$ be the induced projections, for every $\lambda \in \Lambda$. We claim that the resulting covering $(\varphi_\lambda \mid \lambda \in \Lambda)$ of X will do.

Indeed, $\mathsf{d}^{\mathscr{E}}_{\varphi_\lambda}(g_i) : ((X'_1, \psi_1 \circ \varphi_\lambda), E_1) \to ((X'_2, \psi_2 \circ \varphi_\lambda), E_2)$ is represented by the morphism $(Y_\lambda/\rho, g'_i)$ of $\mathscr{F}ib(\mathsf{c}^{\mathscr{E}} \circ \mathsf{t}^o_{Y_\lambda})$ for $i = 1, 2$, and (5.4.26) implies easily that

$$(Y_\lambda/\rho, g'_1) \circ \boldsymbol{\lambda}^{\mathscr{E}}(E_1, \tau_\lambda) = (Y_\lambda/\rho, g'_2) \circ \boldsymbol{\lambda}^{\mathscr{E}}(E_1, \tau_\lambda)$$

where $\boldsymbol{\lambda}^{\mathscr{E}}(E_1, \tau_\lambda) : ((Y'_\lambda, \psi_\lambda), \mathsf{c}^{\mathscr{E}}_{\tau_\lambda} E_1) \to ((X'_1, \psi_1 \circ \varphi_\lambda), E_1)$ is a cartesian morphism of the fibration $\mathscr{F}ib(\mathsf{c}^{\mathscr{E}} \circ \mathsf{t}^o_{Y_\lambda})$, whence the contention. ◊

We consider now the essentially commutative diagram

$$\begin{array}{ccc} \mathsf{Fib}(u)_!(\mathscr{E}) & \xrightarrow{\mathsf{Fib}(u)_!(f)} & \mathsf{Fib}(u)_!(\mathscr{F}) \\ {\scriptstyle \mathsf{Fib}(u)_!(\eta_{\mathscr{E}})}\downarrow & & \downarrow{\scriptstyle \mathsf{Fib}(u)_!(\eta_{\mathscr{F}})} \\ \mathsf{Fib}(u)_!(\mathscr{E}^a) & \xrightarrow{\mathsf{Fib}(u)_!(f^a)} & \mathsf{Fib}(u)_!(\mathscr{F}^a) \end{array}$$

where $\eta_{\mathscr{E}} : \mathscr{E} \to \mathscr{E}^a$ and $\eta_{\mathscr{F}} : \mathscr{F} \to \mathscr{F}^a$ are the natural morphisms, and notice that $\mathsf{Fib}(u)_!(\eta_{\mathscr{E}})^a$ and $\mathsf{Fib}(u)_!(\eta_{\mathscr{F}})^a$ are equivalences, by virtue of proposition 5.4.4. Then $\mathsf{Fib}(u)_!(f)^a$ is i-covering if and only if the same holds for $\mathsf{Fib}(u)_!(f^a)^a$ (lemma 5.2.3), and finally $\mathsf{Fib}(u)_!(f)$ is i-covering if and only if the same holds for $\mathsf{Fib}(u)_!(f^a)$ (proposition 5.2.11(iii)). Summing up, we see that, in order to prove the proposition, we may assume that $\mathscr{E}$ and $\mathscr{F}$ are stacks on C', and moreover, in this case it suffices to show assertion (ii).

Now, by lemma 4.2.11(ii) we have the essentially commutative diagram :

$$\begin{array}{ccc} \mathscr{C}' & \xrightarrow{u} & \mathscr{C} \\ {\scriptstyle h^a_{C'}}\downarrow & & \downarrow{\scriptstyle h^a_C} \\ C'^{\sim}_{\mathsf{U}} & \xrightarrow{\widetilde{u}^*} & C^{\sim}_{\mathsf{U}} \end{array}$$

whose vertical arrows are the Yoneda embeddings. Especially, for every universe V containing U and such that $\mathscr{C}^\wedge_{\mathsf{U}}$ is V-small, $\mathsf{V}\text{-}\mathsf{St}(h^a_{C'})_*$ is a 2-equivalence from the 2-category of stacks on $\mathrm{Can}(C'^{\sim}_{\mathsf{U}})$ to that of stacks on C (theorem 5.4.12), and therefore there exists a cartesian functor $f' : \mathscr{E}' \to \mathscr{F}'$ of V-stacks on $\mathrm{Can}(C'^{\sim}_{\mathsf{U}})$ with an essentially commutative diagram :

$$\mathscr{D} \quad : \quad \begin{array}{ccc} \mathscr{E} & \xrightarrow{\qquad f \qquad} & \mathscr{F} \\ \downarrow & & \downarrow \\ \mathsf{V}\text{-}\mathsf{St}(h^a_{C'})_*(\mathscr{E}') & \xrightarrow{\mathsf{V}\text{-}\mathsf{St}(h^a_{C'})_*(f')} & \mathsf{V}\text{-}\mathsf{St}(h^a_{C'})_*(\mathscr{F}') \end{array}$$

whose vertical arrows are equivalences. We notice :

Claim 5.4.27. Let $C := (\mathscr{C}, J)$ be a small site, $h^a_C : \mathscr{C} \to C^{\sim}$ the Yoneda embedding, $\varphi : \mathscr{A} \to \mathscr{B}$ a morphism of $\mathsf{V}\text{-}\mathsf{Fib}(C^{\sim})$, and $j \in \{0, 1, 2\}$. Then φ is j-covering for the canonical topology of $C^{\sim}$ if and only if $\mathsf{V}\text{-}\mathsf{Fib}(h^a_C)^*(\varphi)$ is j-covering for the topology J.

Proof of the claim. Suppose that φ is j-covering; since h^a_C is cocontinuous for the topologies J (theorem 4.4.2(iii)) and $\mathrm{Can}_{C^{\sim}}$, proposition 5.4.1(i) says that $\mathsf{V}\text{-}\mathsf{Fib}(h^a_C)^*(\varphi)$ is j-covering. The converse follows from lemma 5.4.9. ◊

Since f is i-covering, the same holds for $\mathsf{V}\text{-}\mathsf{St}(h^a_{C'})_*(f')$, by lemma 5.2.3, and then also for f', by claim 5.4.27. Moreover, considering the essentially commutative diagram $\mathsf{V}\text{-}\mathsf{St}(u)^*(\mathscr{D})$ and applying again lemma 5.2.3, we are reduced to checking that $\mathsf{V}\text{-}\mathsf{St}(u)^* \circ \mathsf{V}\text{-}\mathsf{St}(h^a_{C'})_*(f')$ is i-covering. To ease notation, set $S := \mathsf{V}\text{-}\mathsf{St}(h^a_C)_* \circ \mathsf{V}\text{-}\mathsf{St}(h^a_C)^* \circ \mathsf{V}\text{-}\mathsf{St}(u)^* \circ \mathsf{V}\text{-}\mathsf{St}(h^a_{C'})_*$; recalling that $\mathsf{V}\text{-}\mathsf{St}(h^a_C)^*$ is a pseudo-inverse for the 2-equivalence $\mathsf{V}\text{-}\mathsf{St}(h^a_C)_*$, we get an essentially commutative diagram

$$\begin{array}{ccc}\mathsf{V\text{-}St}(u)^* \circ \mathsf{V\text{-}St}(h^a_{C'})_*(\mathscr{E}') & \xrightarrow{\mathsf{V\text{-}St}(u)^*\circ\mathsf{V\text{-}St}(h^a_{C'})_*(f')} & \mathsf{V\text{-}St}(u)^* \circ \mathsf{V\text{-}St}(h^a_{C'})_*(\mathscr{F}') \\ \downarrow & & \downarrow \\ S(\mathscr{E}) & \xrightarrow{S(f')} & S(\mathscr{F})\end{array}$$

whose vertical arrows are equivalences; invoking once again lemma 5.2.3, we are then reduced to checking that $S(f)$ is i-covering. However, we have pseudo-natural equivalences :

$$S \stackrel{\sim}{\to} \mathsf{V\text{-}St}(h^a_C)_* \circ \mathsf{V\text{-}St}(\widetilde{u}^*)^* \circ \mathsf{V\text{-}St}(h^a_{C'})^* \circ \mathsf{V\text{-}St}(h^a_{C'})_* \stackrel{\sim}{\to} \mathsf{V\text{-}St}(h^a_C)_* \circ \mathsf{V\text{-}St}(\widetilde{u}^*)^*$$

which, after applying once more lemma 5.2.3, further reduces to checking that the functor $\mathsf{V\text{-}St}(h^a_C)_* \circ \mathsf{V\text{-}St}(\widetilde{u}^*)^*(f')$ is i-covering. The latter follows from claims 5.4.23 and 5.4.27. □

5.4.28. Let $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two small sites, and $u : \mathscr{C} \to \mathscr{C}'$ a cocontinuous functor; by proposition 5.4.1(ii), the pseudo-functor $\mathsf{Fib}(u)_*$ restricts to a pseudo-functor

$$\mathsf{St}(\breve{u})_* : \mathsf{Stack}(C) \to \mathsf{Stack}(C')$$

and it is easily seen that the latter admits a left 2-adjoint

$$\mathsf{St}(\breve{u})^* : \mathsf{Stack}(C') \xrightarrow{i} \mathsf{Fib}(\mathscr{C}') \xrightarrow{\mathsf{Fib}(u)^*} \mathsf{Fib}(\mathscr{C}) \xrightarrow{(-)^a_C} \mathsf{Stack}(C)$$

with i the inclusion pseudo-functor. On the other hand, by remark 4.4.13(iii,iv), the functor u induces a morphism of sites $\breve{u}^* : \mathrm{Can}(C^\sim) \to \mathrm{Can}(C'^\sim)$, whence a 2-adjoint pair of pseudo-functors $(\mathsf{St}(\breve{u}^*)^*, \mathsf{St}(\breve{u}^*)_*)$. Define also $h^a_C : \mathscr{C} \to C^\sim$, $h^a_{C'} : \mathscr{C}' \to C'^\sim$ as in remark 4.1.19(iii).

Proposition 5.4.29. (i) *In the situation of* (5.4.28)*, we have pseudo-commutative diagrams :*

$$\begin{array}{ccc}\mathsf{Stack}(\mathrm{Can}\, C'^\sim) & \xrightarrow{\mathsf{St}(\breve{u}^*)^*} & \mathsf{Stack}(\mathrm{Can}\, C^\sim) \\ {\scriptstyle \mathsf{St}(h^a_{C'})_*}\downarrow & & \downarrow{\scriptstyle \mathsf{St}(h^a_C)_*} \\ \mathsf{Stack}(C') & \xrightarrow{\mathsf{St}(\breve{u})^*} & \mathsf{Stack}(C)\end{array} \qquad \begin{array}{ccc}\mathsf{Stack}(\mathrm{Can}\, C^\sim) & \xrightarrow{\mathsf{St}(\breve{u}^*)_*} & \mathsf{Stack}(\mathrm{Can}\, C'^\sim) \\ {\scriptstyle \mathsf{St}(h^a_C)_*}\downarrow & & \downarrow{\scriptstyle \mathsf{St}(h^a_{C'})_*} \\ \mathsf{Stack}(C) & \xrightarrow{\mathsf{St}(\breve{u})_*} & \mathsf{Stack}(C').\end{array}$$

(ii) *If u is also a weak morphism of sites $C' \to C$, we have a pseudo-natural equivalence*

$$\mathsf{St}(\breve{u})^* \stackrel{\sim}{\to} \mathsf{St}(u)_*.$$

(iii) *If u admits a right adjoint $v : \mathscr{C}' \to \mathscr{C}$ that is a weak morphism of sites $C \to C'$, we have pseudo-natural equivalences :*

$$\mathsf{St}(v)_* \stackrel{\sim}{\to} \mathsf{St}(\breve{u})_* \qquad \mathsf{St}(v)^* \stackrel{\sim}{\to} \mathsf{St}(\breve{u})^*.$$

Proof. (i): Since $\mathsf{St}(h^a_C)_*$ and $\mathsf{St}(h^a_{C'})_*$ are 2-equivalences (theorem 5.4.12(i,ii)), it suffices to show the pseudo-commutativity of the left square diagram. To this aim, consider the sites $C^\wedge$ and $C'^\wedge$ on the categories $\mathscr{C}^\wedge$ and $\mathscr{C}'^\wedge$ defined in remark 4.1.31(ii), and notice that since $u^\wedge : \mathscr{C}^\wedge \to \mathscr{C}'^\wedge$ commutes with all limits and all colimits, it induces a morphism of topoi $C'^\wedge \to C^\wedge$ (proposition 4.4.8(i)), whence a morphism of sites $u^\wedge : C'^\wedge) \to C^\wedge)$ (remark 4.4.13(iii)); combining with lemma 4.2.9 and theorem 4.4.2(ii) we deduce an essentially commutative diagram of sites:

$$\begin{array}{ccc}\mathrm{Can}(C'^\sim) & \xrightarrow{\breve{u}^*} & \mathrm{Can}(C^\sim) \\ {\scriptstyle (-)^a_{C'}}\downarrow & & \downarrow{\scriptstyle (-)^a_C} \\ C'^\wedge & \xrightarrow{u^\wedge} & C^\wedge.\end{array}$$

Notice as well that $\mathsf{St}((-)^a_C)_* : \mathsf{Stack}(\mathrm{Can}(C^\sim)) \to \mathsf{Stack}(C^\wedge)$ is a 2-equivalence (proposition 5.4.17(ii) and theorem 4.4.2(iii)), and likewise for $\mathsf{St}((-)^a_{C'})_*$. There follows a pseudo-commutative diagram (details left to the reader) :

$$\begin{array}{ccc} \mathsf{Stack}(\mathrm{Can}(C'^\sim)) & \xrightarrow{\mathsf{St}(\breve{u}^*)^*} & \mathsf{Stack}(\mathrm{Can}(C^\sim)) \\ {\scriptstyle \mathsf{St}((-)^a_{C'})_*}\downarrow & & \downarrow{\scriptstyle \mathsf{St}((-)^a_C)_*} \\ \mathsf{Stack}(C'^\wedge) & \xrightarrow{\mathsf{St}(u^\wedge)^*} & \mathsf{Stack}(C^\wedge). \end{array}$$

Thus, we are reduced to checking that the following diagram pseudo-commutes :

$$\begin{array}{ccccc} \mathsf{Fib}(\mathscr{C}'^\wedge) & \xrightarrow{\mathsf{Fib}(u^\wedge)_!} & \mathsf{Fib}(\mathscr{C}^\wedge) & \xrightarrow{(-)^a_{C^\wedge}} & \mathsf{Stack}(C^\wedge) \\ {\scriptstyle \mathsf{Fib}(h_{\mathscr{C}'})^*}\downarrow & & {\scriptstyle \mathsf{Fib}(h_{\mathscr{C}})^*}\downarrow & & \downarrow{\scriptstyle \mathsf{St}(h_{\mathscr{C}})_*} \\ \mathsf{Fib}(\mathscr{C}') & \xrightarrow{\mathsf{Fib}(u)^*} & \mathsf{Fib}(\mathscr{C}) & \xrightarrow{(-)^a_C} & \mathsf{Stack}(C). \end{array}$$

However, the pseudo-commutativity of the left square subdiagram follows from proposition 3.3.19. For the right subdiagram, it suffices to observe that $h_{\mathscr{C}}$ is cocontinuous for the sites C and $C^\wedge$ (theorem 4.4.2(i)) and invoke proposition 5.4.1(i).

(ii) follows by inspecting the definitions, and the first pseudo-natural equivalence of (iii) follows from remark 3.3.15(vi); then the second pseudo-natural equivalence of (iii) follows from the first one and from remark 2.4.28(iii). □

5.4.30. Let $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two U-sites, and $u : C' \to C$ a weak morphism of sites. We have a commutative diagram of 2-categories :

$$\mathscr{D}_u \quad : \quad \begin{array}{ccc} \mathsf{Stack}(C') & \xrightarrow{i_{C'}} & \mathsf{Fib}(\mathscr{C}') \\ {\scriptstyle \mathsf{St}(u)_*}\downarrow & & \downarrow{\scriptstyle \mathsf{Fib}(u)^*} \\ \mathsf{Stack}(C) & \xrightarrow{i_C} & \mathsf{Fib}(\mathscr{C}) \end{array}$$

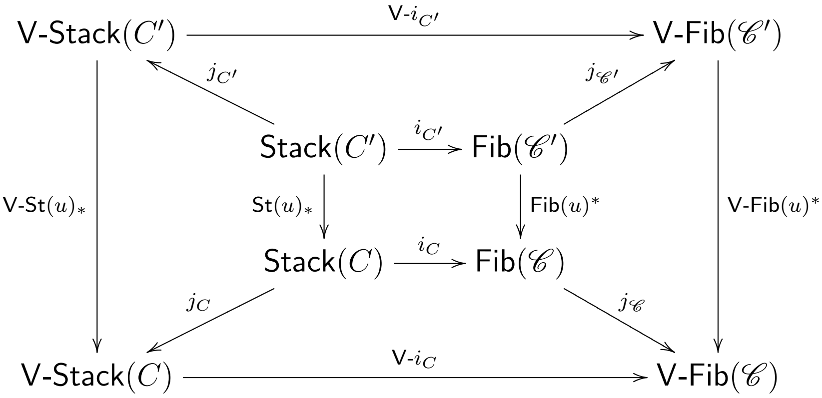
where the inclusion pseudo-functors i_C and $i_{C'}$ admit left 2-adjoints $(-)^a_C : \mathsf{Fib}(\mathscr{C}) \to \mathsf{Stack}(C)$ and $(-)^a_{C'} : \mathsf{Fib}(\mathscr{C}') \to \mathsf{Stack}(C')$ (corollary 5.4.19). After fixing an adjunction for these two pairs of 2-adjoint pseudo-functors, we may then regard $\mathscr{D}_u$ as a square of weak links as in (2.3.19), oriented by the identity pseudo-natural transformation. If we similarly fix adjunctions also for the pairs $(\mathsf{Fib}(u)_!, \mathsf{Fib}(u)^*)$ and $(\mathsf{St}(u)^*, \mathsf{St}(u)_*)$, the diagram $\mathscr{D}_u$ becomes even an oriented square of links.

Corollary 5.4.31. *In the situation of* (5.4.30)*, suppose that the functor $u : \mathscr{C} \to \mathscr{C}'$ is also cocontinuous for the topologies J and J'. Then the base change transformation*

$$\Upsilon(\mathscr{D}_u) : (-)^a_C \circ \mathsf{Fib}(u)^* \to \mathsf{St}(u)_* \circ (-)^a_{C'}$$

is a pseudo-natural equivalence.

Proof. Let V be a universe with $\mathsf{U} \subset \mathsf{V}$, and such that $\mathscr{C}$ and $\mathscr{C}'$ are V-small; we get a commutative diagram of 2-categories :



whose horizontal arrows are the inclusion pseudo-functors; since the latter all admit left 2-adjoints, we may regard this diagram as an oriented cubical diagram of weak links as in 2.3.21, whose orientations are given by identities. Especially, the lower and upper trapezoidal subdiagrams are oriented respectively by $\mathbf{1}_{j_{\mathscr{C}} \circ i_C}$ and $\mathbf{1}_{j_{\mathscr{C}'} \circ i_{C'}}$, and we remark :

Claim 5.4.32. $\Upsilon(\mathbf{1}_{j_{\mathscr{C}} \circ i_C})$ and $\Upsilon(\mathbf{1}_{j_{\mathscr{C}'} \circ i_{C'}})$ are pseudo-natural equivalences.

Proof of the claim. We show the assertion for $\Upsilon(\mathbf{1}_{j_{\mathscr{C}} \circ i_C})$: the same argument shall apply to $\Upsilon(\mathbf{1}_{j_{\mathscr{C}'} \circ i_{C'}})$ as well. Let (η, ε) (resp. $(\mathsf{V}\text{-}\eta, \mathsf{V}\text{-}\varepsilon)$) be the unit and counit of a 2-adjunction for the 2-adjoint pair $((-)^a_C, i_C)$ (resp. for the 2-adjoint pair $(\mathsf{V}\text{-}(-)^a_C, \mathsf{V}\text{-}i_C)$); since $\mathsf{V}\text{-}i_C$ is fully faithful, $\mathsf{V}\text{-}\varepsilon$ is a pseudo-natural equivalence, so it suffices to check that the same holds for $(\mathsf{V}\text{-}(-)^a_C \circ j_{\mathscr{C}}) * \eta$. But in view of the pseudo-natural equivalence $\mathsf{V}\text{-}(-)^a_C \circ j_{\mathscr{C}} \overset{\sim}{\to} j_C \circ (-)^a_C$, we are further reduced to checking that $(-)^a_C * \eta$ is a pseudo-natural equivalence; the latter follows from the triangular identities for the pair (η, ε), since ε is a pseudo-natural equivalence. ◇

Denote by $\mathsf{V}\text{-}\mathscr{D}_u$ the "front face" of the foregoing diagram (with its identity orientation); from claim 5.4.32 and remark 2.3.22(i) we see that if $\Upsilon(\mathsf{V}\text{-}\mathscr{D}_u)$ is a pseudo-natural equivalence, the same holds for $\Upsilon(\mathscr{D}_u)$. Thus, we may replace U by V, and assume from start that $\mathscr{C}$ and $\mathscr{C}'$ are small. Let now $\mathscr{F}$ be any fibration on $\mathscr{C}'$; the functor $\Upsilon(\mathscr{D}_u)_{\mathscr{F}} : (\mathsf{Fib}(u)^*\mathscr{F})^a \to \mathsf{St}(u)_*(\mathscr{F}^a)$ is obtained explicitly as follows. First, let $\eta_{\mathscr{F}} : \mathscr{F} \to \mathscr{F}^a$ be the unit of the chosen 2-adjunction for the pair $((-)^a_{C'}, i_{C'})$. Then $\Upsilon(\mathscr{D}_u)_{\mathscr{F}}$ is the composition of the induced functor

$$(\mathsf{Fib}(u)^*\eta_{\mathscr{F}})^a : (\mathsf{Fib}(u)^*\mathscr{F})^a \to (\mathsf{St}(u)_*(\mathscr{F}^a))^a$$

with the counit of adjunction $\varepsilon_{\mathscr{F}^a} : (\mathsf{St}(u)_*(\mathscr{F}^a))^a \to \mathsf{St}(u)_*(\mathscr{F}^a)$. We need to check that $\Upsilon(\mathscr{D}_u)_{\mathscr{F}}$ is an equivalence; however, $\varepsilon_{\mathscr{F}^a}$ is an equivalence, so it suffices to check that the same holds for $(\mathsf{Fib}(u)^*\eta_{\mathscr{F}})^a$. By propositions 5.2.9 and 5.2.11(iii) we are reduced to showing that $\mathsf{Fib}(u)^*(\eta_{\mathscr{F}}) : \mathsf{Fib}(u)^*\mathscr{F} \to \mathsf{St}(u)_*(\mathscr{F}^a)$ is i-covering for $i = 0, 1, 2$. Since u is cocontinuous, the latter assertion follows from propositions 5.4.1 and 5.2.11(i). □

5.5. **Sheaves of categories.** We wish next to elucidate the relationship between stacks and the related notion of sheaf of categories on a given site. We begin by recalling the following :

Definition 5.5.1. Let $C := (\mathscr{C}, J)$ be any site, and $\mathscr{A}$ any other category.

(i) A *presheaf on* $\mathscr{C}$ *with values in* $\mathscr{A}$ is any object of the category (notation of (1.1.10))

$$(\mathscr{C}, \mathscr{A})^\wedge := \mathsf{Fun}(\mathscr{C}^o, \mathscr{A}).$$

(ii) Let V be a universe such that $\mathscr{A}$ has V-small Hom-sets; following [59, Ch.0, §3.1], we say that such a presheaf $\mathscr{F}$ is a *sheaf on* C *with values in* $\mathscr{A}$ if for every $T \in \mathrm{Ob}(\mathscr{A})$, the rule :

$$U \mapsto \mathscr{F}_T(U) := \mathrm{Hom}_{\mathscr{A}}(T, \mathscr{F}(U)) \qquad \text{for every } U \in \mathrm{Ob}(\mathscr{C})$$

defines a V-sheaf (of sets) $\mathscr{F}_T$ on C. This condition is obviously independent of the choice of V. We denote by

$$(C,\mathscr{A})^\sim$$

the full subcategory of $(\mathscr{C},\mathscr{A})^\wedge$ whose objects are the sheaves on C with values in $\mathscr{A}$.

Remark 5.5.2. (i) Let $C := (\mathscr{C}, J)$ be a site and $\mathscr{F}$ a presheaf on $\mathscr{C}$ with values in a category $\mathscr{A}$. According to (4.1.6), the presheaf $\mathscr{F}$ is a sheaf on C with values in $\mathscr{A}$ if and only if, for every $T \in \mathrm{Ob}(\mathscr{A})$, every $U \in \mathrm{Ob}(\mathscr{C})$, and every sieve $\mathscr{S} \in J(U)$ the natural map

$$\mathscr{F}_T(U) \to \lim_{\mathscr{S}^o} \mathscr{F}_T \circ \mathsf{s}^o_{\mathscr{S}}$$

is bijective (where the limit is taken in a sufficiently large universe V). The latter in turns is equivalent to the following. For every U and $\mathscr{S}$ as in the foregoing, the induced cone :

$$(\mathscr{F}(f) : \mathscr{F}(U) \to \mathscr{F}(U') \mid (f : U' \to U) \in \mathrm{Ob}(\mathscr{S}))$$

is universal in $\mathscr{A}$. Especially, a sheaf on C with values in $\mathbf{Set}$ is just a usual sheaf (of sets).

In case $\mathscr{C}$ is small, $\mathscr{A}$ is complete, and all the fibre products in $\mathscr{C}$ are representable, arguing similarly we see that $\mathscr{F}$ is a sheaf on C with values in $\mathscr{A}$ if and only if, for every $U \in \mathrm{Ob}(\mathscr{C})$ and every small family $(U_i \to U \mid i \in I)$ of objects of $\mathscr{C}/U$ that generate a sieve covering U, the restriction morphisms $\mathscr{F}(U) \to \mathscr{F}(U_i)$ induce an isomorphism

$$\mathscr{F}(U) \xrightarrow{\sim} \mathrm{Equal}\Big(\prod_{i\in I} \mathscr{F}(U_i) \rightrightarrows \prod_{(i,j)\in I\times I} \mathscr{F}(U_i \times_U U_j)\Big) \qquad \text{in } \mathscr{A}.$$

(ii) Let $\mathscr{A}'$ be another category, and $F : \mathscr{A} \to \mathscr{A}'$ a functor that commutes with limits; it follows from (i) that $(\mathscr{C}, F)^\wedge := \mathsf{Fun}(\mathscr{C}^o, F) : (\mathscr{C},\mathscr{A})^\wedge \to (\mathscr{C},\mathscr{A}')^\wedge$ restricts to a functor

$$(C, F)^\sim : (C,\mathscr{A})^\sim \to (C,\mathscr{A}')^\sim.$$

(iii) Suppose that $\mathscr{A}$ is complete and V-small for a universe V such that $\mathsf{U} \subset \mathsf{V}$. Consider a functor

$$\mathscr{F}_\bullet : \Lambda \to (C,\mathscr{A})^\sim \qquad \lambda \mapsto \mathscr{F}_\lambda$$

from a small category Λ. Recall that the limit L of $\mathscr{F}_\bullet$ in $(\mathscr{C},\mathscr{A})^\wedge$ is computed argumentwise, *i.e.* $L(U)$ represents the limit of the induced functor

$$\mathscr{F}_\bullet(U) : \Lambda \to \mathscr{A} \qquad \lambda \mapsto \mathscr{F}_\lambda(U)$$

for every $U \in \mathrm{Ob}(\mathscr{C})$ (corollary 1.4.1(ii)). We claim that L is a sheaf on C with values in $\mathscr{A}$, and therefore it represents the limit of $\mathscr{F}_\bullet$ in $(C,\mathscr{A})^\sim$; especially, the latter category is complete. Indeed, for any $T \in \mathrm{Ob}(\mathscr{A})$ we have natural identifications

$$\mathrm{Hom}_{\mathscr{A}}(T, L(U)) \xrightarrow{\sim} \lim_{\lambda\in\mathrm{Ob}(\Lambda)} \mathrm{Hom}_{\mathscr{A}}(T, \mathscr{F}_\lambda(U)) = \lim_{\lambda\in\mathrm{Ob}(\Lambda)} \mathscr{F}_{\lambda,T}(U) \xrightarrow{\sim} \Big(\lim_{\lambda\in\mathrm{Ob}(\Lambda)} \mathscr{F}_{\lambda,T}\Big)(U)$$

and the limit of the functor $\mathscr{F}_{\bullet,T}$ from Λ to the category of V-presheaves (of sets) on $\mathscr{C}$ is a V-sheaf, since by assumption every $\mathscr{F}_{\lambda,T}$ is a V-sheaf (remark 4.1.19(i)). This shows that L_T is a V-sheaf on C for every $T \in \mathrm{Ob}(\mathscr{A})$, as required.

(iv) Let $C' := (\mathscr{C}', J')$ be another site, and $u : \mathscr{C} \to \mathscr{C}'$ a continuous functor for the topologies J and J'. Then u induces a functor

$$(u,\mathscr{A})^\wedge := \mathsf{Fun}(u^o,\mathscr{A}) : (\mathscr{C}',\mathscr{A})^\wedge \to (\mathscr{C},\mathscr{A})^\wedge$$

and notice that for every presheaf $\mathscr{F}'$ on $\mathscr{C}'$ with values in $\mathscr{A}$, and every $T \in \mathrm{Ob}(\mathscr{A})$ we have

$$u^\wedge(\mathscr{F}'_T) = ((u,\mathscr{A})^\wedge \mathscr{F}')_T. \tag{5.5.3}$$

It follows that $(u,\mathscr{A})^\wedge$ restricts to a functor

$$(\widetilde{u},\mathscr{A})_* : (C',\mathscr{A})^\sim \to (C,\mathscr{A})^\sim.$$

Likewise, every natural transformation $\alpha : u \Rightarrow v$ between such continuous functors $u, v : \mathscr{C} \to \mathscr{C}'$ induces a natural transformation

$$(\alpha, \mathscr{A})^\wedge := \mathsf{Fun}(\alpha^o, \mathscr{A}) : (v, \mathscr{A})^\wedge \Rightarrow (u, \mathscr{A})^\wedge$$

which yields by restriction a natural transformation

$$(\widetilde{\alpha}, \mathscr{A})_* : (v, \mathscr{A})^\sim_* \Rightarrow (u, \mathscr{A})^\sim_*.$$

(v) For every $U \in \mathrm{Ob}(\mathscr{C})$, the topology J induces a topology J_U on $\mathscr{C}/U$ (see (4.7.2)), and we let $C/U := (\mathscr{C}/U, J_U)$. The source functor $\mathsf{s}_U : \mathscr{C}/U \to \mathscr{C}$ is continuous for the topologies J and J_U, hence (iv) yields a well defined functor

$$(\widetilde{\mathsf{s}}_U, \mathscr{A})_* : (C, \mathscr{C})^\sim \to (C/U, \mathscr{C})^\sim \qquad \mathscr{F} \mapsto \mathscr{F}_{|U}.$$

Likewise, if $g : U \to V$ is any morphism of $\mathscr{C}$, the corresponding functor $g_* : \mathscr{C}/U \to \mathscr{C}/V$ is continuous for the topologies J_U and J_V, so it restricts to a functor

$$(\widetilde{g}, \mathscr{A})_* : (C/V, \mathscr{A})^\sim \to (C/U, \mathscr{A})^\sim$$

generalizing remark 4.7.3(i). We may then consider the category

$$(C/\bullet, \mathscr{A})^\sim$$

whose objects are the pairs $(U, \mathscr{F})$ consisting of objects $U \in \mathrm{Ob}(\mathscr{C})$ and $\mathscr{F} \in \mathrm{Ob}(C/U, \mathscr{A})^\sim$. A morphism $(U, \mathscr{F}) \to (V, \mathscr{G})$ is the datum of a morphism $g : U \to V$ of $\mathscr{C}$ and a morphism $\mathscr{F} \to (\widetilde{g}, \mathscr{A})_* \mathscr{G}$ in $(C/U, \mathscr{A})^\sim$. It follows easily from (5.5.3) that the resulting functor

$$(C/\bullet, \mathscr{A})^\sim \to \mathscr{C} \qquad (U, \mathscr{F}) \mapsto U$$

is a fibration. Moreover, for every $U \in \mathrm{Ob}(\mathscr{C})$, every covering family $(U_i \to U \mid i \in I)$ for J_U generates a sieve of 1-descent for this fibration, which is even of 2-descent, if $\mathscr{A}$ is complete and $\mathscr{C}$ is small.

5.5.4. In this section we are mainly interested in presheaves and sheaves with values in the category $\mathbf{Cat}$ of small categories, but the following auxiliary construction shall also be useful. For every category $\mathscr{B}$ *whose fibred products are representable* we consider the 2-category

$$\mathbf{Cat}^*(\mathscr{B})$$

of *category objects* of $\mathscr{B}$, whose objects are the data $\mathscr{C}^* := (O, M, \mathsf{s}, \mathsf{t}, \mathbb{1}, \mathsf{c})$ such that $O, M \in \mathrm{Ob}(\mathscr{B})$, and

(5.5.5) $$M \overset{\mathsf{s}}{\underset{\mathsf{t}}{\rightrightarrows}} O \qquad \mathbb{1} : O \to M \qquad M \times_{(\mathsf{t},\mathsf{s})} M \xrightarrow{\mathsf{c}} M$$

are morphisms in $\mathscr{B}$ called respectively the *source*, *target*, *identity* and *composition laws* of $\mathscr{C}^*$, fulfilling the identities :

$$\mathsf{s} \circ \mathbb{1} = \mathbf{1}_O = \mathsf{t} \circ \mathbb{1}$$

and making commute the diagrams of morphisms of $\mathscr{B}$:

$$\begin{array}{ccc} M \times_{(\mathsf{t},\mathsf{s})} M \times_{(\mathsf{t},\mathsf{s})} M & \xrightarrow{\mathbf{1}_M \times \mathsf{c}} & M \times_{(\mathsf{t},\mathsf{s})} M \\ {\scriptstyle \mathsf{c} \times \mathbf{1}_M} \downarrow & & \downarrow {\scriptstyle \mathsf{c}} \\ M \times_{(\mathsf{t},\mathsf{s})} M & \xrightarrow{\mathsf{c}} & M \end{array} \qquad \begin{array}{ccc} M & \xrightarrow{(\mathbf{1}_M, \mathbb{1} \circ \mathsf{t})} & M \times_{(\mathsf{t},\mathsf{s})} M \\ {\scriptstyle (\mathbb{1} \circ \mathsf{s}, \mathbf{1}_M)} \downarrow & \searrow^{\mathbf{1}_M} & \downarrow {\scriptstyle \mathsf{c}} \\ M \times_{(\mathsf{t},\mathsf{s})} M & \xrightarrow{\mathsf{c}} & M. \end{array}$$

Notice that the datum of c includes the choice of a representative for the fibre product $M \times_{(\mathsf{t},\mathsf{s})} M$, and we (implicitly) fix as well a universal cone $M \leftarrow M \times_{(\mathsf{t},\mathsf{s})} M \to M$ for this fibre product.

The 1-cells $(F_1, F_2) : \mathscr{C}^* := (O, M, \mathsf{s}, \mathsf{t}, \mathbb{1}, \mathsf{c}) \to \mathscr{C}'^* := (O', M', \mathsf{s}', \mathsf{t}', \mathbb{1}', \mathsf{c}')$ in $\mathbf{Cat}^*(\mathscr{B})$ are the pairs of morphisms $(F_1 : O \to O', F_2 : M \to M')$ of $\mathscr{B}$ such that

$$\mathsf{s}' \circ F_2 = F_1 \circ \mathsf{s} \qquad \mathsf{t}' \circ F_2 = F_1 \circ \mathsf{t} \qquad \mathbb{1}' \circ F_1 = F_2 \circ \mathbb{1} \qquad \mathsf{c}' \circ (F_2 \times_{(\mathsf{t},\mathsf{s})} F_2) = F_2 \circ \mathsf{c}.$$

The composition law of 1-cells is given by the obvious rule :

$(F'_1, F'_2) \circ (F_1, F_2) := (F'_1 \circ F_1, F'_2 \circ F_2)$ for every pair of 1-cells $\mathscr{C}^* \xrightarrow{(F_1,F_2)} \mathscr{C}'^* \xrightarrow{(F'_1,F'_2)} \mathscr{C}''^*$.

For every pair of category objects $\mathscr{C}^*$ and $\mathscr{C}'^*$ of $\mathscr{B}$, and every pair of 1-cells $(F_1, F_2), (G_1, G_2) : \mathscr{C}^* \to \mathscr{C}'^*$, the 2-cells $\beta : (F_1, F_2) \Rightarrow (G_1, G_2)$ are the morphisms $\beta : O \to M'$ of $\mathscr{B}$ such that

$$(5.5.6) \qquad \mathsf{s}' \circ \beta = F_1 \qquad \mathsf{t}' \circ \beta = G_1 \qquad \mathsf{c}' \circ (\beta \circ \mathsf{s}, G_2) = \mathsf{c}' \circ (G_1, \beta \circ \mathsf{t})$$

(where $(\beta \circ \mathsf{s}, G_2)$ and $(G_1, \beta \circ \mathsf{t})$ are morphisms $M \to M' \times_{(\mathsf{t}',\mathsf{s}')} M'$).

Remark 5.5.7. (i) We have a natural strict and strong 2-equivalence of 2-categories :

$$(5.5.8) \qquad \mathsf{V}\text{-}\mathbf{Cat} \xrightarrow{\sim} \mathbf{Cat}^*(\mathsf{V}\text{-}\mathbf{Set}) \qquad \text{for every universe } \mathsf{V}.$$

Namely, to each V-small category $\mathscr{C}$ we assign the object $[\mathscr{C}] := (\mathrm{Ob}(\mathscr{C}), \mathrm{Morph}(\mathscr{C}), \mathsf{s}, \mathsf{t}, \mathbb{1}, \mathsf{c})$ where $\mathsf{s}, \mathsf{t}, \mathbb{1}, \mathsf{c}$ encode the source, target, identity and composition laws for $\mathscr{C}$ in the obvious way. Then any functor $F : \mathscr{C} \to \mathscr{C}'$ induces an obvious 1-cell $[F] : [\mathscr{C}] \to [\mathscr{C}']$, and every natural transformation $\beta : F \Rightarrow F'$ induces a 2-cell $[\beta] : [F_1] \Rightarrow [F_2]$. The quasi-inverse assigns to every datum $\mathscr{C}^* := (O, M, \mathsf{s}, \mathsf{t}, \mathbb{1}, \mathsf{c})$ the category $[\mathscr{C}^*]$ with $\mathrm{Ob}([\mathscr{C}^*]) := O$ and $\mathrm{Hom}_{[\mathscr{C}^*]}(X, Y) := \mathsf{s}^{-1}(X) \cap \mathsf{t}^{-1}(Y)$ for every $X, Y \in O$, with the composition law induced by c in the obvious way, and with $\mathbf{1}_X := \mathbb{1}(X)$ for every $X \in O$. Then every 1-cell $(F_1, F_2) : \mathscr{C}^* \to \mathscr{C}'^*$ induces a functor $[F_1, F_2] : [\mathscr{C}^*] \to [\mathscr{C}'^*]$ and every 2-cell $\beta : (F_1, F_2) \Rightarrow (G_1, G_2)$ induces a natural transformation $[\beta] : [F_1, F_2] \Rightarrow [G_1, G_2]$, in the obvious fashion.

(ii) We have obvious *objects* and *morphisms* functors :

$$\mathsf{V}\text{-}\mathbf{Cat} \underset{\mathrm{Morph}}{\overset{\mathrm{Ob}}{\rightrightarrows}} \mathsf{V}\text{-}\mathbf{Set} \qquad \text{for every universe } \mathsf{V}$$

which – in terms of the 2-equivalence (5.5.8) – translate as the functors $\mathbf{Cat}^*(\mathsf{V}\text{-}\mathbf{Set}) \to \mathsf{V}\text{-}\mathbf{Set}$ that extract from each datum $(O, M, \mathsf{s}, \mathsf{t}, \mathbb{1}, \mathsf{c})$ the set O and respectively the set M, and that assign to every morphism (F_1, F_2) of $\mathbf{Cat}^*(\mathsf{V}\text{-}\mathbf{Set})$ the map F_1 and respectively the map F_2.

(iii) Notice that both Ob and Morph are representable functors. Indeed, let $\mathbb{1}$ be the category with one object and one morphism, and let $\mathbb{2}$ be the category with exactly two objects a and b, and a single morphism from a to b (and no morphisms from b to a). Then it is easily seen that $\mathbb{1}$ (resp. $\mathbb{2}$) represents the presheaf Ob (resp. Morph) on $\mathsf{V}\text{-}\mathbf{Cat}^o$: the details shall be left to the reader. Especially, Ob and Morph commute with all the limits of $\mathsf{V}\text{-}\mathbf{Cat}$ (example 1.3.15(ii)).

Moreover, obviously a functor $F : \mathscr{A} \to \mathscr{A}'$ is an isomorphism in $\mathsf{V}\text{-}\mathbf{Cat}$ if and only if both $\mathrm{Ob}(F) : \mathrm{Ob}(\mathscr{A}) \to \mathrm{Ob}(\mathscr{A}')$ and $\mathrm{Morph}(F) : \mathrm{Morph}(\mathscr{A}) \to \mathrm{Morph}(\mathscr{A}')$ are bijections.

(iv) Taking into account (iii) and remark 5.5.2(ii), it follows immediately that a presheaf of V-small categories F on $\mathscr{C}$ is a sheaf of categories on C if and only if $\mathrm{Ob}(F) := \mathrm{Ob} \circ F$ and $\mathrm{Morph}(F) := \mathrm{Morph} \circ F$ are sheaves (of sets) on C.

(v) For every site $C := (\mathscr{C}, J)$, the categories $(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge$ and $(C, \mathsf{V}\text{-}\mathbf{Cat})^\sim$ inherit from $\mathsf{V}\text{-}\mathbf{Cat}$ a natural structure of 2-category. Namely, $(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge$ can be described as the sub-2-category of of $\mathsf{PsFun}(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})$ whose objects are the strict pseudo-functors, whose 1-cells are all the strict pseudo-natural transformations (where $\mathscr{C}$ is regarded as usual, as a 2-category with trivial 2-cells), and whose 2-cells are all the modifications $\beta \rightsquigarrow \beta'$, for every pair of 1-cells $\beta, \beta' : F \Rightarrow F'$ of $(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge$. Similarly we describe $(C, \mathsf{V}\text{-}\mathbf{Cat})^\sim$ as the strong sub-2-category of $(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge$ whose objects are the sheaves of V-small categories on the site C (see definition 2.4.9(iii)). Then (5.5.8) generalizes to strict and strong 2-equivalences

$$(5.5.9) \qquad (\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge \xrightarrow{\sim} \mathbf{Cat}^*(\mathscr{C}^\wedge_{\mathsf{V}}) \qquad (C, \mathsf{V}\text{-}\mathbf{Cat})^\sim \xrightarrow{\sim} \mathbf{Cat}^*(C^\sim_{\mathsf{V}}).$$

(vi) Let $\mathscr{B}$ and $\mathscr{B}'$ be any two categories whose fibre products are representable, and $u : \mathscr{B} \to \mathscr{B}'$ any functor *that commutes with fibre products*. Then u induces a strict pseudo-functor

$$\mathbf{Cat}^*(u) : \mathbf{Cat}^*(\mathscr{B}) \to \mathbf{Cat}^*(\mathscr{B}') \qquad (O, M, \mathsf{s}, \mathsf{t}, \mathbb{1}, \mathsf{c}) \mapsto (u(0), u(M), u(\mathsf{s}), u(\mathbb{1}), u(\mathsf{c})).$$

Indeed, we can regard $u(\mathsf{c})$ as a morphism $u(M) \times_{(u(\mathsf{t}),u(\mathsf{s}))} u(M) \to u(M)$ (since u commutes with fibre products), and then it is clear that the rule defining $\mathbf{Cat}^*(u)$ takes objects of $\mathbf{Cat}^*(\mathscr{B})$ to objects of $\mathbf{Cat}^*(\mathscr{B}')$. To every 1-cell (F_1, F_2) and every 2-cell β, the pseudo-functor $\mathbf{Cat}^*(u)$ assigns likewise respectively the 1-cell $(u(F_1), u(F_2))$ and the 2-cell $u(\beta)$ of $\mathbf{Cat}^*(\mathscr{B}')$.

If $v : \mathscr{B} \to \mathscr{B}'$ is another functor commuting with fibre products, and $\alpha : u \Rightarrow v$ is any natural transformation, we get a strict pseudo-natural transformation

$$\mathbf{Cat}^*(\alpha) : \mathbf{Cat}^*(u) \Rightarrow \mathbf{Cat}^*(v) \qquad (O, M, \mathsf{s}, \mathsf{t}, \mathbb{1}, \mathsf{c}) \mapsto (\alpha_O, \alpha_M).$$

Indeed, notice that $u(M \times_{(\mathsf{t},\mathsf{s})} M)$ represents $u(M) \times_{(u(\mathsf{t}),u(\mathsf{s}))} u(M)$ since u commutes with fibre products, and likewise for $v(M \times_{(\mathsf{t},\mathsf{s})} M)$, and under these identifications, the morphism $\alpha_{M\times_{(\mathsf{t},\mathsf{s})}M}$ corresponds to $\alpha_M \times_{(u(\mathsf{t}),u(\mathsf{s}))} \alpha_M$, whence it is easily seen that (α_O, α_M) is a 1-cell of $\mathbf{Cat}^*(\mathscr{B}')$, and the strict pseudo-functoriality of $\mathbf{Cat}^*(\alpha)$ is then immediate from the definition.

(vii) Clearly the rules $u \mapsto \mathbf{Cat}^*(u)$ and $\alpha \mapsto \mathbf{Cat}^*(\alpha)$ define a strict pseudo-functor from the sub-2-category of $\mathbf{Cat}$ whose objects are all the small categories whose fibre products are representable, whose 1-cells are the functor commuting with fibre products and whose 2-cells are the natural transformations, to the 2-category whose objects are the small 2-categories, whose 1-cells are the strict pseudo-functors, and whose 2-cells are the strict pseudo-natural transformations.

5.5.10. Let now $C := (\mathscr{C}, J)$ be a U-site; then we deduce that the strongly faithful inclusion pseudo-functor $(C, \mathsf{V}\text{-}\mathbf{Cat})^\sim \to (\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge$ admits a strong left 2-adjoint :

$$(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge \to (C, \mathsf{V}\text{-}\mathbf{Cat})^\sim \qquad F \mapsto F^a \tag{5.5.11}$$

for every universe V with $\mathsf{U} \subset \mathsf{V}$. Namely, by remark 5.5.7(vi,vii), the exact left adjoint $(-)^a : \mathscr{C}^\wedge_\mathsf{V} \to C^\sim_\mathsf{V}$ provided by remark 4.1.23(ii) induces first a strong left 2-adjoint $\mathbf{Cat}^*((-)^a) : \mathbf{Cat}^*(\mathscr{C}^\wedge_\mathsf{V}) \to \mathbf{Cat}^*(C^\sim_\mathsf{V})$ to the inclusion of 2-categories $\mathbf{Cat}^*(C^\sim_\mathsf{V}) \to \mathbf{Cat}^*(C^\wedge_\mathsf{V})$. Then, combining with the strong and strict 2-equivalences (5.5.9) we get the sought strong left 2-adjoint. It is also easily seen that (5.5.11) is an exact functor on the underlying categories.

5.5.12. Let $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two U-sites, $u : \mathscr{C} \to \mathscr{C}'$ a functor, U' a universe with $\mathsf{U} \subset \mathsf{U}'$ and such that $\mathscr{C}$ and $\mathscr{C}'$ are U'-small and the functor $u^a_{\mathsf{U}'!} : \mathscr{C}^\wedge_{\mathsf{U}'} \to C'^\sim_{\mathsf{U}'}$ commutes with fibre products. Arguing as in (5.5.10), and in light of remark 4.2.18(iii), we deduce that for every universe V with $\mathsf{U} \subset \mathsf{V}$, the pseudo-functor $u^a_{\mathsf{V}!}$ induces a pseudo-functor

$$(u, \mathsf{V}\text{-}\mathbf{Cat})^a_! : (\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge \to (C', \mathsf{V}\text{-}\mathbf{Cat})^\sim.$$

In case u is continuous for the topologies J and J', corollary 4.3.19(i) and remark 5.5.7(vi,vii) easily imply that $(u, \mathsf{V}\text{-}\mathbf{Cat})^a_!$ restricts to a strong and strict left 2-adjoint

$$(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})^* : (C, \mathsf{V}\text{-}\mathbf{Cat})^\sim \to (C', \mathsf{V}\text{-}\mathbf{Cat})^\sim$$

for the strict pseudo-functor $(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})_*$ of remark 5.5.2(iv).

5.5.13. Let $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two U-sites, $u : \mathscr{C} \to \mathscr{C}'$ a cocontinuous functor, and V a universe with $\mathsf{U} \subset \mathsf{V}$. Arguing as in (5.5.10) we see that the adjoint pair of left exact functors $(\breve{u}^*_\mathsf{V}, \breve{u}_{\mathsf{V}*})$ provided by corollary 4.3.19(ii) induces a strict and strong 2-adjoint pair of strict pseudo-functors

$$(C', \mathsf{V}\text{-}\mathbf{Cat})^\sim \underset{(\breve{u}, \mathsf{V}\text{-}\mathbf{Cat})_*}{\overset{(\breve{u}, \mathsf{V}\text{-}\mathbf{Cat})^*}{\rightleftarrows}} (C, \mathsf{V}\text{-}\mathbf{Cat})^\sim.$$

Remark 5.5.14. (i) In the situation of (5.5.12), suppose that u is a continuous functor and $\widetilde{u}_{\mathsf{V}*}$ is an equivalence, so that $\widetilde{u}^*_\mathsf{V}$ is its quasi-inverse. From the explicit description of the functors $(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})_*$ and $(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})^*$, we then deduce straightforwardly that the latter are mutually quasi-inverse equivalences and strong 2-equivalences as well.

(ii) Combining with theorem 4.4.2(iii), we deduce especially that for every U-site $C := (\mathscr{C}, J)$, the Yoneda embedding $h^a_{\mathscr{C}} : \mathscr{C} \to C^{\sim}_{\mathsf{U}}$ induces a strong 2-equivalence of 2-categories :

$$(\widetilde{h}^a_{\mathscr{C}}, \mathsf{V}\text{-}\mathbf{Cat})_* : (\mathrm{Can}(C^{\sim}_{\mathsf{U}}), \mathsf{V}\text{-}\mathbf{Cat})^{\sim} \xrightarrow{\sim} (C, \mathsf{V}\text{-}\mathbf{Cat})^{\sim}.$$

(iii) Let $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two sites such that $\mathscr{C}$ is small and $\mathscr{C}'$ has small Hom-sets, and let $u : \mathscr{C} \to \mathscr{C}'$ be any continuous functor for the topologies J and J'. Recall that for every universe V with $\mathsf{U} \subset \mathsf{V}$, the functor $(u, \mathsf{V}\text{-}\mathbf{Cat})^\wedge$ admits a left adjoint

$$(u, \mathsf{V}\text{-}\mathbf{Cat})_! : (\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge \to (\mathscr{C}', \mathsf{V}\text{-}\mathbf{Cat})^\wedge$$

computed by left Kan extensions : see theorem 1.3.4. If C' is a U-site, we can compose this functor with the functor (5.5.11), to get a functor $(u, \mathsf{V}\text{-}\mathbf{Cat})^a_! : (\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge \to (C', \mathsf{V}\text{-}\mathbf{Cat})^{\sim}$, whose restriction to $(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^{\sim}$ is a left adjoint for $(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})_*$. If C is no longer a small site, but only a U-site, we can pick as usual an essentially small topologically generating full subcategory $\mathscr{G} \subset \mathscr{C}$, endowed with the topology $J_{\mathscr{G}}$ induced by J via the inclusion functor $\jmath : \mathscr{G} \to \mathscr{C}$, so that $(\widetilde{\jmath}, \mathsf{V}\text{-}\mathbf{Cat})_* : (C, \mathsf{V}\text{-}\mathbf{Cat})^{\sim} \to ((\mathscr{G}, J_{\mathscr{G}}), \mathsf{V}\text{-}\mathbf{Cat})^{\sim}$ is an equivalence, by (i); then $(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})_*$ admits the left adjoint $(\widetilde{u \circ \jmath}, \mathsf{V}\text{-}\mathbf{Cat})^* \circ (\widetilde{\jmath}, \mathsf{V}\text{-}\mathbf{Cat})_*$. This yields another construction for the functor underlying the strict pseudo-functor $(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})^*$ of (5.5.12), which is available under weaker assumptions, but is not obviously pseudo-functorial for the 2-category structures of $(C, \mathsf{V}\text{-}\mathbf{Cat})^{\sim}$ and $(C', \mathsf{V}\text{-}\mathbf{Cat})^{\sim}$.

(iv) On the other hand, in the situation of (iii), recall that the strict pseudo-functor

$$\mathsf{PsFun}(u^o, \mathsf{V}\text{-}\mathbf{Cat}) : \mathsf{PsFun}(\mathscr{C}'^o, \mathsf{V}\text{-}\mathbf{Cat}) \to \mathsf{PsFun}(\mathscr{C}^o, \mathsf{V}\text{-}\mathbf{Cat})$$

admits a left 2-adjoint that can be computed by the strong left 2-Kan extension $2\text{-}\int^{u^o}$ along u^o (remark 2.6.18(ii) and theorem 3.3.9). The latter restricts to a strict pseudo-functor

$$(u, \mathsf{V}\text{-}\mathbf{Cat})_! : (\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge \to (\mathscr{C}', \mathsf{V}\text{-}\mathbf{Cat})^\wedge.$$

Moreover, the 2-adjunction for the pair $(2\text{-}\int^{u^o}, \mathsf{PsFun}(u^o, \mathsf{V}\text{-}\mathbf{Cat}))$ restricts to a natural functor

$$(-)^\dagger_{F,G} : \mathrm{Hom}_{(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge}(G \circ u^o, F) \to \mathrm{Hom}_{(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge}\Big(G, 2\text{-}\int^{u^o} F\Big)$$

for every presheaf of categories F on $\mathscr{C}$ and G on $\mathscr{C}'$ (remark 2.6.24). But in this generality, though such functors are fully faithful, it is not clear whether they are equivalences of categories.

(v) However, *suppose now additionally that the category $X/u\mathscr{C}$ is cofiltered for every* $X \in \mathrm{Ob}(\mathscr{C}')$ (this condition is fulfilled, notably, in case *C and C' are two lex-sites, and u is a morphism of lex-sites $C' \to C$*, by virtue of example 1.3.16(i)). Recall that for every presheaf of V-small categories F on $\mathscr{C}$ and every $X \in \mathrm{Ob}(\mathscr{C}')$, the value $2\text{-}\int^{u^o} F(X)$ represents the 2-colimit of the strict pseudo-functor $F \circ \mathrm{t}^o_X : (X/u\mathscr{C})^o \to \mathsf{V}\text{-}\mathbf{Cat}$; but then such 2-colimit is represented by the colimit of the same functor, and every universal cocone for such colimit is also a universal pseudo-cocone (example 3.3.13(iv)). This means that the restriction to $(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge$ of the strong left 2-Kan extension $2\text{-}\int^{u^o}$ agrees with the left Kan extension $\int^{u^o}$ of theorem 1.3.4; moreover, a direct inspection shows that the functor $(-)^\dagger_{F,G}$ agrees on objects with the standard adjunction for the pair $(\int^{u^o}, (u, \mathsf{V}\text{-}\mathbf{Cat})^\wedge)$, provided by the proof of theorem 1.3.4. *I.e.*, under these assumptions, $(u, \mathsf{V}\text{-}\mathbf{Cat})_!$ is indeed a strong and strict left 2-adjoint for $(u, \mathsf{V}\text{-}\mathbf{Cat})^\wedge$, and we get an essentially commutative diagram of 2-categories :

$$\begin{array}{ccc}
(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge & \xrightarrow{(u, \mathsf{V}\text{-}\mathbf{Cat})_!} & (\mathscr{C}', \mathsf{V}\text{-}\mathbf{Cat})^\wedge \\
\downarrow & & \downarrow \\
\mathsf{PsFun}(\mathscr{C}^o, \mathsf{V}\text{-}\mathbf{Cat}) & \xrightarrow{2\text{-}\int^{u^o}} & \mathsf{PsFun}(\mathscr{C}'^o, \mathsf{V}\text{-}\mathbf{Cat})
\end{array}$$

whose vertical arrows are the inclusion strict pseudo-functors (with a different choice of left 2-Kan extension, this diagram is then still at least pseudo-commutative). Lastly, under these same assumptions, we obtain as well a pseudo-commutative diagram :

$$\begin{array}{ccc} (\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\wedge & \xrightarrow{(u,\mathsf{V}\text{-}\mathbf{Cat})_!} & (\mathscr{C}', \mathsf{V}\text{-}\mathbf{Cat})^\wedge \\ {\scriptstyle \mathscr{F}ib_{\mathscr{C}}}\downarrow & & \downarrow{\scriptstyle \mathscr{F}ib_{\mathscr{C}'}} \\ \mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C}) & \xrightarrow{\mathsf{V}\text{-}\mathsf{Fib}(u)_!} & \mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C}'). \end{array}$$

Arguing as in (iii), we get, again under the current assumptions, an alternative construction of the strict pseudo-functor $(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})^*$, as the restriction to $(\mathscr{C}, \mathsf{V}\text{-}\mathbf{Cat})^\sim$ of the composition of the foregoing pseudo-functor $(u, \mathsf{V}\text{-}\mathbf{Cat})_!$ with the pseudo-functor (5.5.11).

Lemma 5.5.15. *Let $C := (\mathscr{C}, J)$ be any site, and consider a presheaf of categories on $\mathscr{C}$*

$$\mathscr{A}_\bullet : \mathscr{C}^o \to \mathbf{Cat} \qquad X \mapsto \mathscr{A}_X \qquad (f : Y \to X) \mapsto (\mathscr{A}_f : \mathscr{A}_X \to \mathscr{A}_Y).$$

The following holds :

(i) *If $\mathscr{A}_\bullet$ is a sheaf on C, the associated prestack $\mathscr{F}ib(\mathscr{A}_\bullet)$ on C is 1-separated.*
(ii) *Suppose that C is a U-site, and that $\mathscr{F}ib(\mathscr{A}_\bullet)$ is a stack on C, and let $j : \mathscr{A}_\bullet \to \mathscr{A}_\bullet^a$ be the unit of adjunction (notation of (5.5.10)). Then the induced morphism of prestacks $\mathscr{F}ib(j) : \mathscr{F}ib(\mathscr{A}_\bullet) \to \mathscr{F}ib(\mathscr{A}_\bullet^a)$ is an equivalence of categories.*

Proof. (i): By lemma 5.1.9, it suffices to show that for every $X \in \mathrm{Ob}(\mathscr{C})$ and every pair of cartesian sections $\sigma, \sigma' : \mathscr{C}/X \to \mathscr{F}ib(\mathscr{A}_\bullet)$, the presheaf $\mathscr{C}art(\sigma, \sigma')$ is a sheaf on the site C/X. Set $A := \sigma(\mathbf{1}_X)$ and $A' := \sigma'(\mathbf{1}_X)$; it is easily seen that $\mathscr{C}art(\sigma, \sigma')$ is isomorphic to the presheaf

$$H_{AA'} : (\mathscr{C}/X)^o \to \mathbf{Set} \qquad (f : Y \to X) \mapsto \mathrm{Hom}_{\mathscr{A}_Y}(\mathscr{A}_f(A), \mathscr{A}_f(A'))$$

that assigns to every morphism $(h/X) : (Y \xrightarrow{f} X) \to (Y' \xrightarrow{f'} X)$ of $\mathscr{C}/X$ the induced map

$$\mathrm{Hom}_{\mathscr{A}'_Y}(\mathscr{A}_{f'}(A), \mathscr{A}_{f'}(A')) \to \mathrm{Hom}_{\mathscr{A}_Y}(\mathscr{A}_f(A), \mathscr{A}_f(A')) \qquad g \mapsto \mathscr{A}_h(g).$$

Now, let $\mathbb{1}_{\mathscr{C}/X}$ be a final object of $(\mathscr{C}/X)^\wedge$ (see example 1.2.16(v)); it is easily seen that $\mathbb{1}_{\mathscr{C}/X}$ is a sheaf on C/X. Recall that the source functor $\mathsf{s}_X : \mathscr{C}/X \to \mathscr{C}$ is continuous for the topologies of C and C/X. Denote also by $(O_{\mathscr{A}}, M_{\mathscr{A}}, \mathsf{s}_{\mathscr{A}}, \mathsf{t}_{\mathscr{A}}, \mathbb{1}_{\mathscr{A}})$ the object of $(\mathscr{C}, \mathbf{Cat}^*)^\wedge$ corresponding to $\mathscr{A}_\bullet$; by remark 5.5.7(iv), both $O_{\mathscr{A}}$ and $M_{\mathscr{A}}$ are sheaves on C, hence we get sheaves $\widetilde{\mathsf{s}}_{X*}(O_{\mathscr{A}})$ and $\widetilde{\mathsf{s}}_{X*}(M_{\mathscr{A}})$ on C/X, as well as source and target morphisms of sheaves $\widetilde{\mathsf{s}}_{X*}(\mathsf{s}_{\mathscr{A}}), \widetilde{\mathsf{s}}_{X*}(\mathsf{t}_{\mathscr{A}}) : \widetilde{\mathsf{s}}_{X*}(M_{\mathscr{A}}) \to \widetilde{\mathsf{s}}_{X*}(O_{\mathscr{A}})$. There follows a cartesian diagram of presheaves :

$$\begin{array}{ccc} H_{AA'} & \longrightarrow & \widetilde{\mathsf{s}}_{X*}(M_{\mathscr{A}}) \\ \downarrow & & \downarrow{\scriptstyle (\widetilde{\mathsf{s}}_{X*}(\mathsf{s}_{\mathscr{A}}), \widetilde{\mathsf{s}}_{X*}(\mathsf{t}_{\mathscr{A}}))} \\ \mathbb{1}_{\mathscr{C}/X} & \xrightarrow{\tau} & \widetilde{\mathsf{s}}_{X*}(O_{\mathscr{A}} \times O_{\mathscr{A}}) \end{array} \qquad \text{on } \mathscr{C}/X$$

where $\tau_f : \{\mathbb{1}\} = \mathbb{1}_{\mathscr{C}/X}(X) \to \mathrm{Ob}(\mathscr{A}_Y \times \mathscr{A}_Y)$ is the map such that $\mathbb{1} \mapsto (\mathscr{A}_f(A), \mathscr{A}_f(A'))$, for every morphism $f : Y \to X$ of $\mathscr{C}$. But then $H_{AA'}$ is a sheaf on C/X, as required.

(ii): By assumption, $\mathscr{F}ib(\mathscr{A}_\bullet)$ is 2-separated, and $\mathscr{F}ib(\mathscr{A}_\bullet^a)$ is 1-separated, by (i); in view of proposition 5.2.9, it then suffices to check that $\mathscr{F}ib(j)$ is i-covering for $i = 0, 1, 2$. The latter follows easily from remark 5.2.2, taking into account the explicit description of $\mathscr{A}_\bullet^a$ from (5.5.10). □

5.5.16. Fix a universe V with $\mathsf{U}\subset\mathsf{V}$, and a U-site $C := (\mathscr{C}, J_{\mathscr{C}})$. Consider the pseudo-functor

$$\mathscr{F}ib^a_C : (C, \mathsf{V}\text{-}\mathbf{Cat})^\sim \to \mathsf{V}\text{-}\mathsf{Stack}(C) \qquad \mathscr{A}_\bullet \mapsto \mathscr{F}ib(\mathscr{A}_\bullet)^a$$

composition of the restriction of the pseudo-functor $\mathscr{F}ib_{\mathscr{C}}$ of theorem 3.1.24 with $(-)^a$ of corollary 5.4.19 (where $(C, \mathsf{V}\text{-}\mathbf{Cat})^\sim$ is a 2-category as in remark 5.5.7(v)). Let also $C' := (\mathscr{C}', J_{\mathscr{C}'})$ be another U-site and $u : C' \to C$ a weak morphism of sites (definition 5.4.2); we wish to attach an orientation to the induced diagram :

$$\begin{array}{ccc} (C', \mathsf{V}\text{-}\mathbf{Cat})^\sim & \xrightarrow{(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})_*} & (C, \mathsf{V}\text{-}\mathbf{Cat})^\sim \\ {\scriptstyle \mathscr{F}ib^a_{C'}}\downarrow & & \downarrow{\scriptstyle \mathscr{F}ib^a_C} \\ \mathsf{V}\text{-}\mathsf{Stack}(C') & \xrightarrow{\mathsf{V}\text{-}\mathsf{St}(u)_*} & \mathsf{V}\text{-}\mathsf{Stack}(C) \end{array} \tag{5.5.17}$$

i.e. a pseudo-natural transformation

$$\Delta^u : \mathscr{F}ib^a_C \circ (\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})_* \Rightarrow \mathsf{V}\text{-}\mathsf{St}(u)_* \circ \mathscr{F}ib^a_{C'}.$$

To this aim, notice that remark 3.1.27(ii) yields an oriented diagram of 2-categories :

$$\begin{array}{ccc} (C', \mathsf{V}\text{-}\mathbf{Cat})^\sim & \xrightarrow{(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})_*} & (C, \mathsf{V}\text{-}\mathbf{Cat})^\sim \\ {\scriptstyle \mathscr{F}ib_{\mathscr{C}'}}\downarrow & \Downarrow \perp^u & \downarrow{\scriptstyle \mathscr{F}ib_{\mathscr{C}}} \\ \mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C}') & \xrightarrow[\mathsf{V}\text{-}\mathsf{Fib}(u)^*]{} & \mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C}) \end{array} \tag{5.5.18}$$

whose orientation $\perp^u$ is a strict pseudo-natural isomorphism of strict pseudo-functors. On the other hand, the square of links $\mathscr{D}_u$ of (5.4.30), oriented by the identity pseudo-natural transformation, yields a base change square :

$$\begin{array}{ccc} \mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C}') & \xrightarrow{\mathsf{V}\text{-}\mathsf{Fib}(u)^*} & \mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C}) \\ {\scriptstyle (-)^a_{C'}}\downarrow & \Downarrow \Upsilon(\mathscr{D}_u) & \downarrow{\scriptstyle (-)^a_C} \\ \mathsf{V}\text{-}\mathsf{Stack}(C') & \xrightarrow[\mathsf{V}\text{-}\mathsf{St}(u)_*]{} & \mathsf{V}\text{-}\mathsf{Stack}(C) \end{array} \tag{5.5.19}$$

and then we take $\Delta^u := \perp^u \boxdot \Upsilon(\mathscr{D}_u)$. In case we wish to emphasize the dependence on V, we shall also write $\mathsf{V}\text{-}\Delta^u$ for this orientation of (5.5.17).

Remark 5.5.20. In the situation of (5.5.16), suppose that u is a morphism of sites; in this case, the pseudo-functors $(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})_*$ and $\mathsf{V}\text{-}\mathsf{St}(u)_*$ admit left 2-adjoints $(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})^*$ and $\mathsf{V}\text{-}\mathsf{St}(u)^*$, and after choosing units and counits for these 2-adjoint pairs, and for the 2-adjoint pair $(\mathsf{V}\text{-}\mathsf{Fib}(u)_!, \mathsf{V}\text{-}\mathsf{Fib}(u)^*)$ we then get well defined links

$$(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat}) := ((\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})^*, (\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})_*, \eta^{(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})}, \varepsilon^{(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})}) : (C', \mathsf{V}\text{-}\mathbf{Cat})^\sim \to (C, \mathsf{V}\text{-}\mathbf{Cat})^\sim$$

$$\mathsf{V}\text{-}\mathsf{St}(u) := (\mathsf{V}\text{-}\mathsf{St}(u)^*, \mathsf{V}\text{-}\mathsf{St}(u)_*, \eta^{\mathsf{V}\text{-}\mathsf{St}(u)}, \varepsilon^{\mathsf{V}\text{-}\mathsf{St}(u)}) : \mathsf{V}\text{-}\mathsf{Stack}(C') \to \mathsf{V}\text{-}\mathsf{Stack}(C)$$

$$\mathsf{V}\text{-}\mathsf{Fib}(u) := (\mathsf{V}\text{-}\mathsf{Fib}(u)_!, \mathsf{V}\text{-}\mathsf{Fib}(u)^*, \eta^{\mathsf{V}\text{-}\mathsf{Fib}(u)}, \varepsilon^{\mathsf{V}\text{-}\mathsf{Fib}(u)}) : \mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C}') \to \mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C})$$

of the 2-category $\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}}$, and the data

$$((-)^a_{C'}, (-)^a_C, \Upsilon(\mathscr{D}_u)) \qquad \text{and} \qquad (\mathscr{F}ib_{\mathscr{C}'}, \mathscr{F}ib_{\mathscr{C}}, \perp^u)$$

can be regarded as 1-cells $\mathsf{V}\text{-}\mathsf{Fib}(u) \to \mathsf{V}\text{-}\mathsf{St}(u)$ and $(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat}) \to \mathsf{V}\text{-}\mathsf{Fib}(u)$ in the 2-category $\mathsf{wLink}(\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}})$ (see (2.3.19)) whose composition is the 1-cell

$$(\mathscr{F}ib^a_{C'}, \mathscr{F}ib^a_C, \Delta^u) : (\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat}) \to \mathsf{V}\text{-}\mathsf{St}(u).$$

5.5.21. Let V be a universe with $\mathsf{U} \in \mathsf{V}$; we shall denote by

$$(\mathsf{U}, \mathsf{V})\text{-}\mathbf{wSite}$$

the sub-2-category of (U, V)-$\mathbf{Site}$ (see definition 4.3.1(ii)) whose objects are all the V-small U-sites, whose 1-cells are the weak morphisms of sites, and whose 2-cells $g \Rightarrow g'$ are the natural transformations of functors $g' \Rightarrow g$. As in remark 4.3.2(i), we shall usually drop the mention of U and V, and write simply $\mathbf{wSite}$ for this 2-category. We have a strict pseudo-functor

$$(-, \mathsf{V}\text{-}\mathbf{Cat})^{\sim} : \mathbf{wSite} \to \mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}} \qquad C \mapsto (C, \mathsf{V}\text{-}\mathbf{Cat})^{\sim}$$

(notation of remark 2.2.16) that assigns to every morphism of U-sites u the strict pseudo-functor $(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})_*$, and to every natural transformation $\beta : u \Rightarrow v$ the 2-cell $(\widetilde{\beta}, \mathsf{V}\text{-}\mathbf{Cat})_* : (\widetilde{v}, \mathsf{V}\text{-}\mathbf{Cat})_* \Rightarrow (\widetilde{u}, \mathsf{V}\text{-}\mathbf{Cat})_*$. Likewise, we get a pseudo-functor

$$\mathsf{V}\text{-}\mathsf{Stack} : \mathbf{wSite} \to \mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}} \qquad C \mapsto \mathsf{V}\text{-}\mathsf{Stack}(C) \qquad (u : C' \to C) \mapsto \mathsf{V}\text{-}\mathsf{St}(u)_*.$$

To define the coherence constraints $(\delta^{\mathsf{V}\text{-}\mathsf{Stack}}, \gamma^{\mathsf{V}\text{-}\mathsf{Stack}})$ of V-Stack, and the action of V-Stack on natural transformations $\beta : u \Rightarrow v$ between weak morphisms of sites $u, v : C' \to C$, notice that $\mathsf{V}\text{-}\mathsf{Stack}(\mathscr{C}, J) \subset \mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C})$ for every U-site $(\mathscr{C}, J)$, and $\mathsf{V}\text{-}\mathsf{St}(u)_*$ is the restriction of $\mathsf{V}\text{-}\mathsf{Fib}(u)^*$, for every morphism of sites u; we may then simply define $(\delta^{\mathsf{V}\text{-}\mathsf{Stack}}, \gamma^{\mathsf{V}\text{-}\mathsf{Stack}})$ as the restriction of the coherence constraint $(\delta^{\mathsf{V}\text{-}\mathsf{Fib}}, \gamma^{\mathsf{V}\text{-}\mathsf{Fib}})$ of the pseudo-functor V-Fib of (3.1.29), and for any β as above, let $\mathsf{V}\text{-}\mathsf{St}(\beta)_* : \mathsf{V}\text{-}\mathsf{St}(v) \Rightarrow \mathsf{V}\text{-}\mathsf{St}(u)_*$ be the restriction of $\mathsf{V}\text{-}\mathsf{Fib}(\beta)^*$.

With this notation, it would be tempting to state that the rule : $C \mapsto \mathscr{F}ib^a_C$ of (5.5.16) defines a pseudo-natural transformation $\mathscr{F}ib^a_\bullet : (-, \mathsf{V}\text{-}\mathbf{Cat})^{\sim} \Rightarrow \mathsf{V}\text{-}\mathsf{Stack}$ whose coherence constraint is given by the orientations Δ^u. However, notice first that Δ^u points in the direction opposite to the one which is required for such a coherence constraint. This can be fixed, by stating instead that $\mathscr{F}ib^a_\bullet$ should be a pseudo-natural transformation ${}^o(-, \mathsf{V}\text{-}\mathbf{Cat})^{\sim} \Rightarrow {}^o\mathsf{V}\text{-}\mathsf{Stack}$. But since *the orientations Δ^u are not, in general, pseudo-natural equivalences*, we have rather :

Proposition 5.5.22. *There exists a lax-natural transformation*

$${}^o\mathscr{F}ib^a_\bullet : {}^o(-, \mathsf{V}\text{-}\mathbf{Cat})^{\sim} \Rightarrow {}^o\mathsf{V}\text{-}\mathsf{Stack} \qquad C \mapsto {}^o\mathscr{F}ib^a_C \qquad \textit{for every } \mathsf{U}\textit{-site } C$$

whose coherence constraint attaches to every weak morphism of U-sites $u : C' \to C$ the square ^{o}(5.5.17), with its orientation ${}^o\Delta^u$.

Proof. Consider the forgetful strict pseudo-functor

$$\Phi : \mathbf{wSite} \to {}^o\mathsf{V}\text{-}\mathbf{Cat}^o \qquad (\mathscr{C}, J) \mapsto \mathscr{C}$$

that assigns to every weak morphism of sites $u : (\mathscr{C}', J') \to (C, J)$ the functor $u : \mathscr{C} \to \mathscr{C}'$, and to every 2-cell $\beta : u \Rightarrow v$ of $\mathbf{wSite}$ the natural transformation $\beta : v \Rightarrow u$. From corollary 3.1.36 we deduce a pseudo-natural transformation of pseudo-functors :

$${}^o\mathscr{F}ib_\bullet : {}^o(-, \mathsf{V}\text{-}\mathbf{Cat})^{\sim} \Rightarrow {}^o\mathsf{V}\text{-}\mathsf{Fib} \circ {}^o\Phi \qquad (\mathscr{C}, J) \mapsto {}^o\mathscr{F}ib_{\mathscr{C}} \qquad \text{for every } \mathsf{U}\text{-site } (\mathscr{C}, J)$$

whose coherence constraint assigns to every morphism of sites u the oriented square diagram (5.5.18). It then suffices to exhibit a lax-natural transformation

$${}^o(-)^a_\bullet : {}^o\mathsf{V}\text{-}\mathsf{Fib} \circ {}^o\Phi \Rightarrow {}^o\mathsf{V}\text{-}\mathsf{Stack} \qquad C \mapsto {}^o(-)^a_C \qquad \text{for every } \mathsf{U}\text{-site } C$$

whose coherence constraint assigns to every weak morphism of U-sites $u : C' \to C$ the oriented square $\Upsilon(\mathscr{D}_u)$. Indeed, we will then define ${}^o\mathscr{F}ib^a_\bullet := {}^o(-)^a_\bullet \odot {}^o\mathscr{F}ib_\bullet$. Now, notice that the pseudo-functors V-Stack and V-Fib factor through well-defined pseudo-functors

$$\mathsf{V}\text{-}\mathsf{LStack} : \mathbf{wSite} \to \mathsf{Link}(\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}}) \qquad \mathsf{V}\text{-}\mathsf{LFib} : {}^o\mathsf{V}\text{-}\mathbf{Cat}^o \to \mathsf{Link}(\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}}).$$

Namely, V-LStack assigns to every site C the 2-category $\mathsf{V}\text{-}\mathsf{Stack}(C)$ and to every weak morphism of sites $u : C' \to C$ the link $\mathsf{V}\text{-}\mathsf{St}(u)$ defined as in remark 5.5.20; likewise, V-LFib assigns to every category $\mathscr{C}$ the 2-category $\mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C})$, and to every functor $u : \mathscr{C} \to \mathscr{C}'$ the link

$\mathsf{V}\text{-}\mathsf{Fib}(u)$. Next, let $i_C : \mathsf{V}\text{-}\mathsf{Stack}(C) \to \mathsf{V}\text{-}\mathsf{Fib}(\mathscr{C})$ be the inclusion strict pseudo-functor; notice that the rule : $C \mapsto i_C$ for every site C yields a pseudo-natural transformation

$$i_\bullet : \mathsf{V}\text{-}\mathsf{LStack} \Rightarrow \mathsf{V}\text{-}\mathsf{LFib} \circ \Phi$$

whose coherence constraints are given by the oriented diagrams $\mathscr{D}_u$ (notice that $i_\bullet$ is not strict, even though $\mathscr{D}_u$ is oriented by the identity pseudo-natural transformation). According to remark 2.2.5(ii), the pseudo-natural transformation $i_\bullet$ corresponds to a pseudo-functor $\widetilde{\imath}_\bullet : \mathbf{wSite} \to \mathscr{M} := 2\text{-}\mathsf{Morph}(\mathsf{Link}(\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}}))$, and we consider the composition :

$$\Psi : \mathbf{wSite} \xrightarrow{\widetilde{\imath}_\bullet} \mathscr{M} \xrightarrow{\Upsilon^o_{\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}}}} (2\text{-}\mathsf{Morph}(\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}}^o))^o \xrightarrow{\sim} {}^o2\text{-}\mathsf{Morph}({}^o\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}})$$

with the pseudo-functor $\Upsilon^o_{\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}}}$ of theorem 2.3.17 and the strict isomorphism of 2-categories given by example 2.1.23(i). Let $\mathsf{s}, \mathsf{t} : 2\text{-}\mathsf{Morph}({}^o\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}}) \to {}^o\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}}$ be the source and target strict pseudo-functors; by definition, ${}^o\Psi$ is a lax-natural transformation $\mathsf{s} \circ {}^o\Psi \Rightarrow \mathsf{t} \circ {}^o\Psi \Rightarrow$. Lastly, a direct inspection shows that $\mathsf{s} \circ {}^o\Psi = \mathsf{LStack}$ and $\mathsf{t} \circ {}^o\Psi \Rightarrow = \mathsf{LFib} \circ \Phi$, so we may let ${}^o(-)^a_\bullet := {}^o\Psi$. □

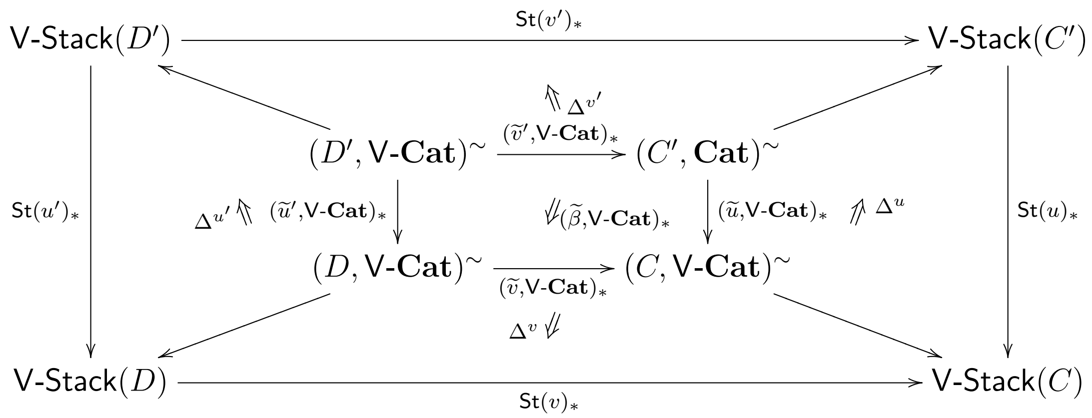
5.5.23. We consider now an oriented square :

$$\begin{array}{ccc} D' := (\mathscr{D}', J_{\mathscr{D}'}) & \xrightarrow{v'} & C' := (\mathscr{C}', J_{\mathscr{C}'}) \\ {\scriptstyle u'}\downarrow & \Downarrow \beta & \downarrow{\scriptstyle u} \\ D := (\mathscr{D}, J_{\mathscr{D}}) & \xrightarrow{v} & C := (\mathscr{C}, J_{\mathscr{C}}) \end{array}$$

where v and v' are morphisms of U-sites, and u and u' are weak morphisms of U-sites. In case also u and u' are morphisms of sites, we get an induced oriented diagram of topoi :

$$(5.5.24) \qquad \begin{array}{ccc} \widetilde{D}' & \xrightarrow{\widetilde{v}'} & \widetilde{C}' \\ {\scriptstyle \widetilde{u}'}\downarrow & \Downarrow \widetilde{\beta}_* & \downarrow{\scriptstyle \widetilde{u}} \\ \widetilde{D} & \xrightarrow{\widetilde{v}} & \widetilde{C}. \end{array}$$

Even when u and u' are only weak morphisms of sites, both $\widetilde{u}_*$ and $\widetilde{u}'_*$ admit left adjoint functors, hence (5.5.24) may still be regarded as an oriented square of links in the 2-category $\mathsf{V}\text{-}\mathbf{Cat}$. On the other hand, we deduce a diagram of 2-categories :



whose diagonal arrows are the pseudo-functors $\mathscr{F}ib^a$. We complete it by adding the orientation

$$\mathsf{St}(\beta)^\gamma_* := (\gamma^{\mathsf{Stack}}_{u',v})^{-1} \odot \mathsf{St}(\beta)_* \odot \gamma^{\mathsf{Stack}}_{v',u} : \mathsf{St}(u)_* \circ \mathsf{St}(v')_* \Rightarrow \mathsf{St}(v)_*\mathsf{St}(u')_*$$

for the external square subdiagram. In light of proposition 5.5.22, we then see that the resulting cubical diagram commutes on 2-cells, in the sense of remark 2.3.22(iii).

5.5.25. In the situation of (5.5.23), we associate with v the links $(\widetilde{v}, \mathsf{V}\text{-}\mathbf{Cat})$, $\mathsf{V}\text{-}\mathsf{St}(v)$ and $\mathsf{V}\text{-}\mathsf{Fib}(v)$ of the 2-category $\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}}$, as in remark 5.5.20, as well as 1-cells

$$((-)^a_D, (-)^a_C, \Upsilon(\mathscr{D}^v)) : \mathsf{V}\text{-}\mathsf{Fib}(v) \to \mathsf{V}\text{-}\mathsf{St}(v) \qquad (\mathscr{F}ib_{\mathscr{D}}, \mathscr{F}ib_{\mathscr{C}}, \bot^v) : (\widetilde{v}, \mathsf{V}\text{-}\mathbf{Cat}) \to \mathsf{V}\text{-}\mathsf{Fib}(v)$$

in the 2-category $\mathsf{wLink}(\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}})$, whose composition is the 1-cell :

$$(\mathscr{F}ib^a_D, \mathscr{F}ib^a_C, \Delta^v) : (\widetilde{v}, \mathsf{V}\text{-}\mathbf{Cat}) \to \mathsf{V}\text{-}\mathsf{St}(v)$$

(and likewise for v'). Additionally, we get two more 1-cells of $\mathsf{wLink}(\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}})$:

$$((\widetilde{u}', \mathbf{Cat})_*, (\widetilde{u}, \mathbf{Cat})_*, (\widetilde{\beta}, \mathbf{Cat})_*) : (\widetilde{v}', \mathbf{Cat}) \to (\widetilde{v}, \mathbf{Cat})$$
$$(\mathsf{St}(u')_*, \mathsf{St}(u)_*, \mathsf{St}(\beta)^{\gamma}_*) : \mathsf{St}(v') \to \mathsf{St}(v).$$

Corollary 5.5.26. *With the notation of* (5.5.25)*, let* $\mathscr{A}_\bullet \in \mathrm{Ob}((C', \mathbf{Cat})^\sim)$. *We have :*

(i) *If* $\mathscr{F}ib_{\mathscr{C}'}(\mathscr{A}_\bullet)$ *is a stack on* C'*, then* $\Delta^u_{\mathscr{A}_\bullet}$ *is an equivalence of categories.*
(ii) *If* u *is also cocontinuous, then* Δ^u *is a pseudo-natural equivalence.*
(iii) $\Upsilon(\mathscr{F}ib^a_D, \mathscr{F}ib^a_C, \Delta^v)$ *is a pseudo-natural equivalence.*
(iv) *In the situation of* (5.5.23)*, suppose that both* $\mathscr{F}ib_{\mathscr{C}'}(\mathscr{A}_\bullet)$ *and* $\mathscr{F}ib_{\mathscr{D}'}((\widetilde{v}', \mathbf{Cat})^*\mathscr{A}_\bullet)$ *are stacks. Then* $\mathscr{F}ib^a_D(\Upsilon((\widetilde{\beta}, \mathbf{Cat})_*)_{\mathscr{A}_\bullet})$ *is an equivalence if and only if the same holds for* $\Upsilon(\mathsf{St}(\beta)^{\gamma}_*)_{\mathscr{F}ib(\mathscr{A}_\bullet)}$.

Proof. (i): It suffices to show that $\Upsilon(\mathscr{D}^u)_{\mathscr{E}}$ is an equivalence if $\mathscr{E}$ is a stack on C'. Thus, let (η^C, ε^C) be the unit and counit for the 2-adjoint pair $(()^a_C, i_C)$ (notation of (5.4.30)) and define likewise $(\eta^{C'}, \varepsilon^{C'})$. Since i_C is fully faithful, ε^C is a pseudo-natural equivalence, and likewise for $\varepsilon^{C'}$. From the triangular identities of theorem 2.4.24(i) we deduce that also $\eta^C * i_C$ and $\eta^{C'} * i_{C'}$ are pseudo-natural equivalences; the assertion follows directly.

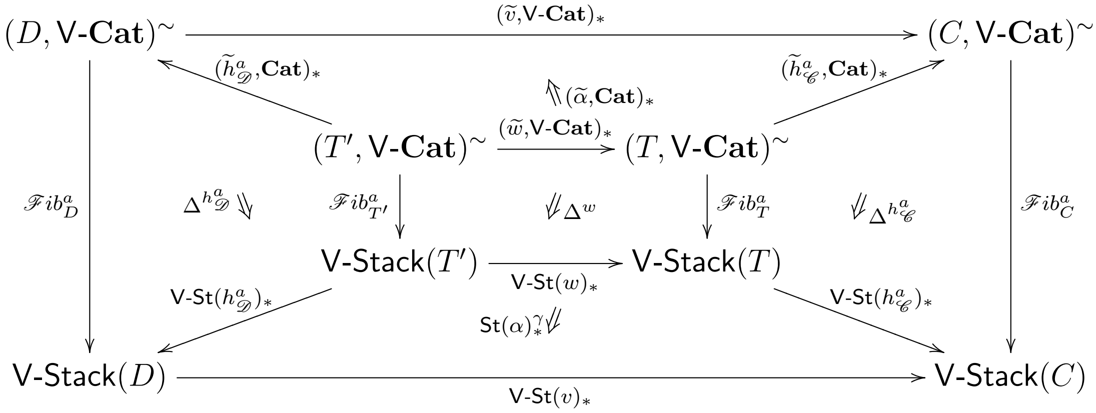
(ii): Again, it suffices to check that $\Upsilon(\mathscr{D}^u)$ is a pseudo-natural equivalence if u is cocontinuous; this is known by corollary 5.4.31.

Claim 5.5.27. In order to prove (iii), we may assume that v is a morphism of small lex-sites.

Proof of the claim. Let T (resp. T') be the site whose underlying category is $C^\sim_{\mathsf{U}}$ (resp $D^\sim_{\mathsf{U}}$), with its canonical topology. Pick a universe V' with $\mathsf{V} \subset \mathsf{V}'$, such that T and T' are V'-small. By direct inspection, we see that $\mathsf{V}\text{-}\Delta^v$ is the restriction of $\mathsf{V}'\text{-}\Delta^v$; hence if $\Upsilon(\mathsf{V}'\text{-}\Delta^v)$ is a pseudo-natural equivalence, the same holds for $\Upsilon(\mathsf{V}\text{-}\Delta^v)$. We may then replace V by V', and suppose that C, D, T, T' are V-small; notice that $w := \widetilde{u}^* : T' \to T$ is a morphism of lex-sites (remark 4.4.13(ii)). We consider the induced essentially commutative diagram of morphisms of sites :

$$\begin{array}{ccc} T' & \xrightarrow{\ w\ } & T \\ {\scriptstyle h^a_{\mathscr{D}}}\downarrow & \swarrow_{\alpha} & \downarrow{\scriptstyle h^a_{\mathscr{C}}} \\ D & \xrightarrow{\ v\ } & C \end{array}$$

(lemma 4.2.11(ii)) which, according to (5.5.23), induces a diagram :

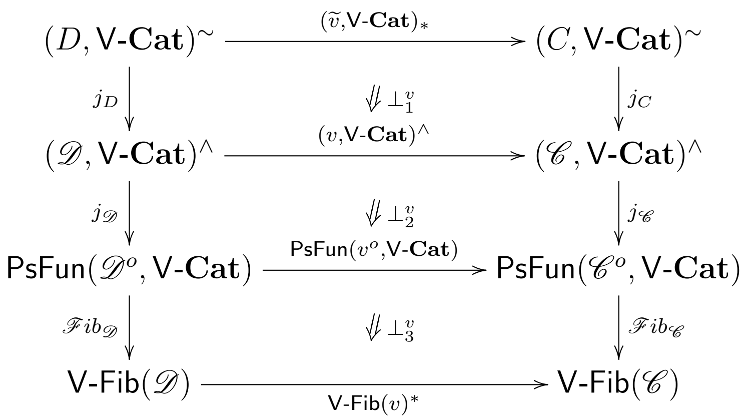


completed by adding the orientation Δ^v for the external square subdiagram. Indeed, this diagram is obtained by rotating suitably the corresponding diagram of (5.5.23), and notice that, after such rotation, the diagram still commutes on 2-cells, but now in the sense of (2.3.21). The four diagonal arrows of the diagrams are 2-equivalences, by theorem 4.4.2(iii), proposition 5.4.17(ii), and remark 5.5.14(ii). Then $\Upsilon((\widetilde{\alpha}, \mathbf{Cat})_*)$ and $\Upsilon(\mathsf{St}(\alpha)^\gamma_*)$ are pseudo-natural equivalences, by remark 2.3.11. Combining with (ii), theorem 4.4.2(iii) and remark 2.3.22(i), we conclude that if $\Upsilon(\Delta^w)$ is a pseudo-natural equivalence, the same holds for $\Upsilon(\Delta^v)$, whence the claim. ◊

(iii): By claim 5.5.27, we shall henceforth suppose that v is a morphism of small lex-sites. By remark 2.3.20 we have $\Upsilon(\Upsilon(\mathscr{D}^v)) = \mathbf{1}^\dagger_{i_C \circ \text{V-St}(v)_*}$, and since

$$\mathbf{1}_{i_C \circ \text{V-St}(v)_*} : \mathsf{Fib}(v) \circ ((-)^a_{C'}, i_{C'}, \eta^C, \varepsilon^C) \Rightarrow ((-)^a_C, i_C, \eta^C, \varepsilon^C) \circ \mathsf{St}(v)$$

is an invertible 2-cell in the category $\mathsf{Link}(\text{V-}\overline{2\text{-}\mathbf{Cat}})$, the strict isomorphisms of proposition 2.3.4 show that $\mathbf{1}^\dagger_{i_C \circ \text{V-St}(v)_*}$ is invertible as well. On the other hand, $\Upsilon(\perp^v)$ is not necessarily a pseudo-natural equivalence, but in order to conclude the proof of (iii) it will suffice to show that $(-)^a_D * \Upsilon(\perp^v)$ is a pseudo-natural equivalence. To this aim, notice that (5.5.18) (for the morphism v) can be further decomposed as a chain of three oriented squares :



where j_C, $j_{\mathscr{C}}$, j_D and $j_{\mathscr{D}}$ are the inclusion pseudo-functors, and where now $\mathscr{F}ib_{\mathscr{C}}$ and $\mathscr{F}ib_{\mathscr{D}}$ are strong 2-equivalences (theorem 3.1.24). The orientation $\perp^v_3$ is still a pseudo-natural equivalence, and both orientations $\perp^v_1$ and $\perp^v_2$ are identities. After choosing as usual a unit and counit (η, ε) for the 2-adjoint pair $((v, \text{V-}\mathbf{Cat})_!, (v, \text{V-}\mathbf{Cat})^\wedge)$ and a unit and counit (η', ε') for the 2-adjoint pair $(2\text{-}\int^{v^o}, \mathsf{PsFun}(v^o, \text{V-}\mathbf{Cat}))$, we may regard the three squares as oriented squares of weak links. Then $\Upsilon(\perp^v_3)$ is well defined, and is a pseudo-natural equivalence (remark 2.3.11). Next, let $\mathscr{A}_\bullet$ be any presheaf of categories on $\mathscr{C}$, and set $\mathscr{B}_\bullet := (v, \mathsf{V}\text{-}\mathbf{Cat})^\wedge\mathscr{A}$; by definition we have

$$\Upsilon(\perp_2^v)_{\mathscr{A}_\bullet} = \varepsilon'_{\mathscr{B}_\bullet} \odot 2\text{-}\int^{v^o} \eta_{\mathscr{A}_\bullet}.$$

But the discussion of remark 5.5.14(v) shows that

$$\varepsilon'_{\mathscr{B}_\bullet} = \varepsilon_{\mathscr{B}_\bullet} \qquad \text{and} \qquad 2\text{-}\int^{v^o} \eta_{\mathscr{A}_\bullet} = (v, \mathsf{V}\text{-}\mathbf{Cat})_!(\eta_{\mathscr{A}_\bullet}).$$

Hence, the triangular identities of (1.1.13) yield $\Upsilon(\perp_2^v)_{\mathscr{A}_\bullet} = \mathbf{1}_{\mathscr{B}_\bullet}$. Thus, we are further reduced to checking that $\mathscr{F}ib^a_D * \Upsilon(\perp_1^v)$ is a pseudo-natural equivalence, or equivalently, that the same holds for ${}^o(\mathscr{F}ib^a_D) * {}^o\Upsilon(\perp_1^v)$. However, let $[-]^a_C$ (resp. $[-]^a_D$) be the left 2-adjoint of j_C (resp. of j_D), and (η^C, ε^C) (resp. (η^D, ε^D)) the unit and counit of the 2-adjoint pair $([-]^a_C, j_C)$ (resp. $([-]^a_D, j_D)$); by proposition 2.3.10 we have

$${}^o\Upsilon(\perp_1^v) = (\Upsilon({}^o(\perp_1^v)^\dagger) = {}^o((j_D \circ (\widetilde{v}, \mathsf{V}\text{-}\mathbf{Cat})^*) * \varepsilon^C) \odot (j_D * \perp_1^{v\dagger} * j_C) \odot (\eta^D * ((v, \mathsf{V}\text{-}\mathbf{Cat})_! \circ j_C)))$$

and notice that ε^C is a pseudo-natural equivalence, since j_C is fully faithful (corollary 2.4.29). Also $\perp_1^{v\dagger}$ is a pseudo-natural equivalence, by virtue of proposition 2.3.4. Therefore, let $\mathscr{B}_\bullet$ be any sheaf of categories on C, and set $\mathscr{B}'_\bullet := (v, \mathsf{V}\text{-}\mathbf{Cat})_!\mathscr{B}_\bullet$; we are reduced to checking that the cartesian functor $\mathscr{F}ib^a_D(\eta^C_{\mathscr{B}'_\bullet})$ is an equivalence of categories. But remark 5.2.2 easily implies that $\mathscr{F}ib_{\mathscr{D}}(\eta^C_{\mathscr{B}'_\bullet})$ is t-covering for $t = 0, 1, 2$, so the assertion follows from propositions 5.2.11(iii) and 5.2.9.

(iv): Under the stated assumptions, (i) says that both $\Delta^u_{\mathscr{A}_\bullet}$ and $\Delta^{u'}_{(\widetilde{v}', \mathbf{Cat})^*\mathscr{A}}$ are equivalences, and both $\Upsilon(\Delta^v)$ and $\Upsilon(\Delta^{v'})$ are pseudo-natural equivalences, by virtue of (iii). Then the assertion follows by arguing as in remark 2.3.22(i). □

Example 5.5.28. (i) Let $C := (\mathscr{C}, J)$ be a U-site, and A any small category. The *constant presheaf of categories on* $\mathscr{C}$ *with value* A is the presheaf $A_{\mathscr{C}}$ such that $A_{\mathscr{C}}(X) := A$ for every $X \in \mathrm{Ob}(\mathscr{C})$, and $A_{\mathscr{C}}(f) := \mathbf{1}_A$ for every morphism f of $\mathscr{C}$. The associated sheaf $A^a_{\mathscr{C}}$ is then the *constant sheaf of categories on* C *with value* A. Likewise, we say that $\mathscr{F}ib(A_{\mathscr{C}})$ is the *constant fibration on* $\mathscr{C}$ *with value* A, and $\mathscr{F}ib(A_{\mathscr{C}})^a$ is the *constant stack on* C *with value* A.

(ii) Now, let $C' := (C', J')$ be another U-site, and $u : C' \to C$ a morphism of sites; we notice that $(\widetilde{u}, \mathbf{Cat})^* A_{\mathscr{C}}$ is isomorphic to the constant sheaf of categories on C' with value A. Indeed, for the proof we are easily reduced to the corresponding assertion for constant sheaves of sets, which is known by remark 4.3.2(iii).

(iii) In light of (i) and lemma 5.5.15(iii), we deduce that the stack $\mathsf{St}(u)^*(\mathscr{F}ib(A_{\mathscr{C}})^a)$ is equivalent to the constant stack on C' with value A.

5.5.29. In section (5.7) we will prove two *base change theorems*, asserting that, for suitable oriented diagrams of sites as in (5.5.23), the *base change map* $\Upsilon(\mathsf{St}(\beta)^\gamma_*)$ is a pseudo-natural equivalence. To this aim we shall apply corollary 5.5.26(iv), thereby reducing the assertion to the corresponding one for $\Upsilon((\widetilde{\beta}, \mathbf{Cat})_*)$, *i.e.* we shall deduce a base change theorem for stacks from one for sheaves of categories. The latter in turn can be reduced to the corresponding assertion for $\Upsilon(\beta^\sim_*)$, as we explain hereafter. Indeed, by remark 5.5.7(v,vi,vii) we deduce from

(5.5.23) a diagram of 2-categories whose four diagonal arrows are 2-equivalences :

$$\begin{array}{ccccccc}
(D',\mathbf{Cat})^\sim & & & \xrightarrow{\quad(\widetilde{v}',\mathbf{Cat})_*\quad} & & & (C',\mathbf{Cat})^\sim \\
 & \nwarrow & & & & \nearrow & \\
 & & \mathbf{Cat}^*(D'^\sim) & \xrightarrow{\mathbf{Cat}^*(\widetilde{v}'_*)} & \mathbf{Cat}^*(C'^\sim) & & \\
{\scriptstyle (\widetilde{u}',\mathbf{Cat})_*}\Big\downarrow & & {\scriptstyle \mathbf{Cat}^*(\widetilde{u}'_*)}\Big\downarrow & \swarrow_{\mathbf{Cat}^*(\widetilde{\beta}_*)} & \Big\downarrow{\scriptstyle \mathbf{Cat}^*(\widetilde{u}_*)} & & \Big\downarrow{\scriptstyle (\widetilde{u},\mathbf{Cat})_*} \\
 & & \mathbf{Cat}^*(D^\sim) & \xrightarrow[\mathbf{Cat}^*(\widetilde{v}_*)]{} & \mathbf{Cat}^*(C^\sim) & & \\
 & \swarrow & & & & \searrow & \\
(D,\mathbf{Cat})^\sim & & & \xrightarrow{\quad(\widetilde{v},\mathbf{Cat})_*\quad} & & & (C,\mathbf{Cat})^\sim
\end{array}$$

whose four external trapezoidal subdiagrams are strictly commutative, and can therefore be oriented by adding in the respective identity pseudo-natural transformations. We further complete the diagram by inserting the orientation

$$(\widetilde{\beta},\mathbf{Cat})_* : (\widetilde{u},\mathbf{Cat})_* \circ (\widetilde{v}',\mathbf{Cat})_* \Rightarrow (\widetilde{v},\mathbf{Cat})_* \circ (\widetilde{u}',\mathbf{Cat})_*$$

for the "front face" of the resulting cubical diagram $\mathscr{D}$. We regard $\mathscr{D}$ as a diagram of 1-cells and 2-cells in V-$\overline{2\text{-}\mathbf{Cat}}$ (for a suitable universe V); then it is clear that $\mathscr{D}$ commutes on 2-cells in the sense of (2.3.21). Moreover, all the horizontal arrows in $\mathscr{D}$ admit left 2-adjoint pseudo-functors, which we regard as left adjoint 1-cells, in the 2-category V-$\overline{2\text{-}\mathbf{Cat}}$; after fixing such a system of left adjoints, we may regard $\mathscr{D}$ as a diagram oriented squares of links in V-$\overline{2\text{-}\mathbf{Cat}}$, and especially, the 2-cells $\Upsilon((\widetilde{\beta},\mathbf{Cat})_*)$ and $\Upsilon(\mathbf{Cat}^*(\widetilde{\beta}_*))$ are then well defined. Invoking again remarks 2.3.11), and 2.3.22(i) we deduce that $\Upsilon((\widetilde{\beta},\mathbf{Cat})_*)$ is invertible if and only if the same holds for $\Upsilon(\mathbf{Cat}^*(\widetilde{\beta}_*))$ (recall that the invertible 2-cells of V-$\overline{2\text{-}\mathbf{Cat}}$ are the equivalence classes of pseudo-natural equivalences of pseudo-functors). According to proposition 2.3.24, we have $\Upsilon(\mathbf{Cat}^*(\widetilde{\beta}_*)) = \mathbf{Cat}^*(\Upsilon(\beta^\sim_*))$, where $\Upsilon(\beta^\sim_*)$ is the base change transformation associated with the oriented square of links (5.5.24); so, if $\Upsilon(\beta^\sim_*)$ is invertible, the same holds for $\Upsilon((\widetilde{\beta},\mathbf{Cat})_*)$.

5.5.30. Here is a first illustration of the method explained in (5.5.29). Consider a morphism of sites $u : C' := (\mathscr{C}', J') \to C := (\mathscr{C}, J)$; we assume that all finite products are representable in $\mathscr{C}$ and $\mathscr{C}'$, and that u commutes with such products. For every $X, Y \in \mathrm{Ob}(\mathscr{C})$ we choose a representative $X \times Y \in \mathrm{Ob}(\mathscr{C})$ for the product of X and Y, and let $X \xleftarrow{q_{X,Y}} X \times Y \xrightarrow{p_{X,Y}} Y$ be the universal projections. For every $X \in \mathrm{Ob}(\mathscr{C})$ we get a morphism of sites $p_X : C/X \to C$ that assigns to every $Y \in \mathrm{Ob}(\mathscr{C})$ the projection $p_{X,Y}$: see remark 4.7.3(iii). Likewise we define the morphism of sites $p_{uX} : C'/uX \to C'$. For every $Y \in \mathrm{Ob}(\mathscr{C})$, there is by assumption a unique isomorphism $\beta_Y : u(X \times Y) \xrightarrow{\sim} uX \times uY$ in $\mathscr{C}'$ such that $p_{uX,uY} \circ \beta_Y = u(p_{X,Y})$, and $q_{uX,uY} \circ \beta_Y = u(q_{X,Y})$, where $uX \xleftarrow{q_{uX,uY}} uX \times uY \xrightarrow{p_{uX,uY}} uY$ are likewise the universal projections. Especially, $\beta_Y/X : u_{|X}(p_{X,Y}) \xrightarrow{\sim} p_{uX,uY}$ is an isomorphism in $\mathscr{C}'/uX$ (notation of (1.1.26)). Thus, we get an oriented square diagram of sites :

$$\begin{array}{ccc}
C'/uX & \xrightarrow{p_{uX}} & C' \\
{\scriptstyle u_{|X}}\Big\downarrow & \swarrow_{\beta} & \Big\downarrow{\scriptstyle u} \\
C/X & \xrightarrow{p_X} & C.
\end{array}$$

Proposition 5.5.31. *In the situation of* (5.5.30)*, the base change transformation* $\Upsilon(\mathsf{St}(\beta)^\gamma_*)$ *is a pseudo-natural equivalence.*

Proof. To begin with, we remark :

Claim 5.5.32. Let $\mathscr{A}_\bullet \in \mathrm{Ob}((C', \mathbf{Cat})^\sim)$ such that $\mathscr{E} := \mathscr{F}ib_{\mathscr{C}'}(\mathscr{A}_\bullet)$ is a stack on C'. Then the fibration $\mathscr{F}ib_{\mathscr{C}'/uX}(\widetilde{p}_{uX}, \mathbf{Cat})^*\mathscr{A}_\bullet$ is a stack on C'/uX.

Proof of the claim. The isomorphism of functors $\widetilde{p}^*_{uX} \simeq \widetilde{\mathsf{s}}_{uX*}$ of remark 4.7.3(iii) induces an isomorphism of pseudo-functors $(\widetilde{p}_{uX}, \mathbf{Cat})^* \stackrel{\sim}{\to} (\widetilde{\mathsf{s}}_{uX}, \mathbf{Cat})_*$, hence it suffices to show that $\mathscr{F} := \mathscr{F}ib_{\mathscr{C}'/uX}(\widetilde{\mathsf{s}}_{uX}, \mathbf{Cat})_*\mathscr{A}_\bullet = \mathscr{F}ib_{\mathscr{C}'/uX}(\mathscr{A}_\bullet \circ \mathsf{s}^o_{uX}) \simeq \mathscr{C}'/uX \times_{\mathscr{C}'} \mathscr{E}$ is a stack. Thus, let $(Z \xrightarrow{h} uX) \in \mathrm{Ob}(\mathscr{C}'/uX)$ and $\mathscr{S}' \subset (\mathscr{C}'/uX)/h$ a sieve covering h for the site C'/uX; under the natural identification of categories

$$(\mathscr{C}'/uX)/h \stackrel{\sim}{\to} \mathscr{C}'/Z$$

the sieve $\mathscr{S}'$ corresponds to a sieve $\mathscr{S} \subset \mathscr{C}'/Z$ covering Z for the site C (see (4.7)). Then the restriction functor

$$\mathscr{F}(h) := \mathsf{Cart}_{\mathscr{C}'/uX}((\mathscr{C}'/uX)/h, \mathscr{F}) \to \mathsf{Cart}_{\mathscr{C}'/uX}(\mathscr{S}', \mathscr{F})$$

is naturally identified with the restriction functor

$$\mathscr{E}(Z) := \mathsf{Cart}_{\mathscr{C}'}(\mathscr{C}'/Z, \mathscr{E}) \to \mathsf{Cart}_{\mathscr{C}'}(\mathscr{S}, \mathscr{E})$$

whence the contention. ◊

By claim 5.5.32, lemma 5.5.15(ii), corollary 5.5.26(iv) and the discussion of (5.5.29), we are reduced to showing that the base change transformation $\Upsilon(\beta^\sim_*) : \widetilde{p}^*_X \circ \widetilde{u}_* \to \widetilde{u}_{|X*} \circ \widetilde{p}^*_{uX}$ is an isomorphism of functors. Now, recall that the source functor $\mathsf{s}_X : \mathscr{C}/X \to \mathscr{C}$ is continuous for the sites C and C/X, and is left adjoint to p_X; more precisely, we have an explicit adjunction :

$$\vartheta_{h,Z} : \mathrm{Hom}_{\mathscr{C}}(Y, Z) \stackrel{\sim}{\to} \mathrm{Hom}_{\mathscr{C}/X}(h, p_{X,Z}) \quad \text{for every } (Y \xrightarrow{h} X) \in \mathrm{Ob}(\mathscr{C}/X) \text{ and } Z \in \mathrm{Ob}(\mathscr{C})$$

that assigns to every morphism $f : Y \to Z$ of $\mathscr{C}$ the unique morphism $f^*/X : h \to p_{X,Z}$ of $\mathscr{C}/X$ such that $q_{X,Z} \circ f^* = f$. The adjunction $\vartheta_{h,Z}$ induces a corresponding adjunction for the pair $(\widetilde{\mathsf{s}}_{X*}, \widetilde{p}_{X*})$, as described in remark 1.1.19(iii,iv). Explicitly, the unit of this induced adjunction assigns to every sheaf $\mathscr{F}$ on C the morphism of sheaves :

$$\eta^X_{\mathscr{F}} : \mathscr{F} \to \mathscr{F} \circ \mathsf{s}^o_X \circ p^o_X \qquad Y \mapsto (\mathscr{F}(q_{X,Y}) : \mathscr{F}(Y) \to \mathscr{F}(X \times Y))$$

and the counit assigns to every sheaf $\mathscr{G}$ on C/X the morphism of sheaves :

$$\varepsilon^X_{\mathscr{G}} : \mathscr{G} \circ p^o_X \circ \mathsf{s}^o_X \to \mathscr{G} \qquad (Y \xrightarrow{h} X) \mapsto (\mathscr{G}(h^*/X) : \mathscr{G}(p_{X,Y}) \to \mathscr{G}(h)).$$

The same description applies to the adjunction for the pair $(\widetilde{\mathsf{s}}_{uX*}, \widetilde{p}_{uX*})$, and we get therefore isomorphisms of links

$$\begin{aligned} \mathscr{L}_X &:= (\widetilde{\mathsf{s}}_{X*}, \widetilde{p}_{X*}, \eta^X, \varepsilon^X) \stackrel{\sim}{\to} \widetilde{p}_X := (\widetilde{p}^*_X, \widetilde{p}_{X*}, \eta^{p_X}, \varepsilon^{p_X}) \\ \mathscr{L}_{uX} &:= (\widetilde{\mathsf{s}}_{uX*}, \widetilde{p}_{uX*}, \eta^{uX}, \varepsilon^{uX}) \stackrel{\sim}{\to} \widetilde{p}_{uX} := (\widetilde{p}^*_{uX}, \widetilde{p}_{uX*}, \eta^{p_{uX}}, \varepsilon^{p_{uX}}). \end{aligned}$$

Hence, it suffices to check that the base change transformation for the oriented diagram of links:

$$\mathscr{D} \quad : \quad \begin{array}{ccc} (C'/uX)^\sim & \xrightarrow{\mathscr{L}_{uX}} & C'^\sim \\ {\scriptstyle \widetilde{u}_{|X}}\big\downarrow & \Downarrow \widetilde{\beta}_* & \big\downarrow{\scriptstyle \widetilde{u}} \\ (C/X)^\sim & \xrightarrow[\mathscr{L}_X]{} & C^\sim \end{array}$$

is an isomorphism of functors $\Upsilon(\mathscr{D}) : \widetilde{\mathsf{s}}_{X*} \circ \widetilde{u}_* \stackrel{\sim}{\to} \widetilde{u}_{|X*} \circ \widetilde{\mathsf{s}}_{uX*}$. However, a direct computation that we leave to the reader easily shows that $\Upsilon(\mathscr{D})$ is the identity automorphism of $\widetilde{\mathsf{s}}_{X*} \circ \widetilde{u}_* = \widetilde{u}_{|X*} \circ \widetilde{\mathsf{s}}_{uX*}$ □

5.6. **Stacks in groupoids and ind-finite stacks.** Let $C := (\mathscr{C}, J)$ be any site; for every universe V denote by

$$\mathsf{V}\text{-}\mathsf{Stack}^\times(C) \qquad \text{and} \qquad \mathsf{V}\text{-}\mathsf{StGpd}(C)$$

respectively the strong 2-subcategory of $\mathsf{V}\text{-}\mathsf{Fib}^\times(\mathscr{C})$ whose objects are the V-stacks on C and the strong 2-subcategory of $\mathsf{V}\text{-}\mathsf{Stack}(C)$ whose objects are the V-*stacks in groupoids* on C, *i.e.* the V-stacks on C that are fibrations in groupoids. For every $\mathscr{C}$-fibration $F : \mathscr{E} \to \mathscr{C}$, every $X \in \mathrm{Ob}(\mathscr{C})$, and every sieve $\mathscr{S} \subset \mathscr{C}/X$, the inclusion $\mathscr{E}^\times \to \mathscr{E}$ yields a commutative diagram

$$\begin{array}{ccc} \mathscr{E}(X)^\times & \longrightarrow & \mathscr{E}^\times(X) \\ \downarrow & & \downarrow \\ \mathsf{Cart}_\mathscr{C}(\mathscr{S}, \mathscr{E})^\times & \longrightarrow & \mathsf{Cart}_\mathscr{C}(\mathscr{S}, \mathscr{E}^\times) \end{array}$$

whose horizontal arrows are isomorphisms of categories, due to remark 3.4.8(i); notice that the source functor $\mathsf{s} : \mathscr{S} \to \mathscr{C}$ is a fibration in groupoids, by remark 3.5.2(ii). Suppose now that $\mathscr{E}$ is i-separated on C for some $i \in \{0, 1, 2\}$; from remark 3.4.1(ii) we deduce that the left vertical arrow is an i-faithful functor whenever $\mathscr{S} \in J(X)$, and then the same holds for the right vertical arrow, so finally $\mathscr{E}^\times$ is also i-separated on C. Especially, the pseudo-functor $(-)^\times_\mathscr{C}$ restricts to a pseudo-functor

$$(-)^\times_C : \mathsf{V}\text{-}\mathsf{Stack}^\times(C) \to \mathsf{V}\text{-}\mathsf{StGpd}(C).$$

Next, if C is a small site, taking into account remark 3.4.1(iii) we get a natural identification:

$$(\mathscr{E}^+_X)^\times \xrightarrow{\sim} \operatorname*{colim}_{\mathscr{S} \in J(X)} \mathsf{Cart}_\mathscr{C}(\mathscr{S}, \mathscr{E})^\times \xrightarrow{\sim} \operatorname*{colim}_{\mathscr{S} \in J(X)} \mathsf{Cart}_\mathscr{C}(\mathscr{S}, \mathscr{E}^\times) = ((\mathscr{E}^\times)^+)_X$$

whence natural isomorphisms of $\mathscr{C}$-fibrations :

$$(\mathscr{E}^+)^\times \xrightarrow{\sim} (\mathscr{E}^\times)^+ \qquad (\mathscr{E}^a)^\times \xrightarrow{\sim} (\mathscr{E}^\times)^a. \tag{5.6.1}$$

If $C' := (\mathscr{C}', J')$ is another site, and $u : C \to C'$ a weak morphism of sites, it is also clear that $\mathsf{V}\text{-}\mathsf{St}(u)_*$ restricts to pseudo-functors

$$\mathsf{V}\text{-}\mathsf{St}^\times(u)_* : \mathsf{V}\text{-}\mathsf{Stack}^\times(C) \to \mathsf{V}\text{-}\mathsf{Stack}^\times(C') \qquad \mathsf{V}\text{-}\mathsf{StGpd}(u)_* : \mathsf{V}\text{-}\mathsf{StGpd}(C) \to \mathsf{V}\text{-}\mathsf{StGpd}(C')$$

that make commute the diagram of 2-categories :

$$\begin{array}{ccc} \mathsf{V}\text{-}\mathsf{Stack}^\times(C) & \xrightarrow{\mathsf{V}\text{-}\mathsf{St}^\times(u)_*} & \mathsf{V}\text{-}\mathsf{Stack}^\times(C') \\ {\scriptstyle (-)^\times_C}\downarrow & & \downarrow{\scriptstyle (-)^\times_{C'}} \\ \mathsf{V}\text{-}\mathsf{StGpd}(C) & \xrightarrow{\mathsf{V}\text{-}\mathsf{StGpd}(u)_*} & \mathsf{V}\text{-}\mathsf{StGpd}(C'). \end{array} \tag{5.6.2}$$

5.6.3. Consider any U-site $C := (\mathscr{C}, J)$, and let $j : \mathscr{T} \to \mathscr{C}$ be the inclusion functor of an essentially small subcategory whose set of objects is a topologically generating family for C; we endow as usual $\mathscr{T}$ with the topology $J_\mathscr{T}$ induced by J via j, so that j is a continuous functor for J and $J_\mathscr{T}$. Say that $\mathscr{C}$ is U'-small for some universe U', and recall that the rule : $\mathscr{A} \mapsto \mathscr{A}^a := \mathsf{U}'\text{-}\mathsf{Fib}(j)_*(\mathsf{U}'\text{-}\mathsf{Fib}(j)^*(\mathscr{A})^a)$ for every fibration $\mathscr{A}$ with small fibres on $\mathscr{C}$ yields a left 2-adjoint for the inclusion pseudo–functor $\mathsf{Stack}(C) \to \mathsf{Fib}(\mathscr{C})$ (see the proof of corollary 5.4.19). Combining with (3.4.5) and (3.4.6) we deduce a pseudo-commutative diagram :

$$\begin{array}{ccc} \mathsf{V}\text{-}\mathsf{Fib}^\times(\mathscr{C}) & \xrightarrow{(-)^a} & \mathsf{V}\text{-}\mathsf{Stack}^\times(C) \\ {\scriptstyle (-)^\times_\mathscr{C}}\downarrow & & \downarrow{\scriptstyle (-)^\times_C} \\ \mathsf{V}\text{-}\mathsf{Gpd}(\mathscr{C}) & \xrightarrow{(-)^a} & \mathsf{V}\text{-}\mathsf{StGpd}(C) \end{array}$$

for every universe V containing U.

Proposition 5.6.4. *For every morphism of* U*-sites* $u : C' := (\mathscr{C}', J') \to C := (\mathscr{C}, J)$*, and every universe* V *containing* U*, the pseudo-functor* $\mathsf{V}\text{-}\mathsf{St}(u)^*$ *restricts to pseudo-functors*

$$\mathsf{V}\text{-}\mathsf{St}^\times(u)^* : \mathsf{V}\text{-}\mathsf{Stack}^\times(C) \to \mathsf{V}\text{-}\mathsf{Stack}^\times(C') \qquad \mathsf{V}\text{-}\mathsf{StGpd}(u)^* : \mathsf{V}\text{-}\mathsf{StGpd}(C) \to \mathsf{V}\text{-}\mathsf{StGpd}(C')$$

and we have a pseudo-commutative diagram :

$$\begin{array}{ccc} \mathsf{V}\text{-}\mathsf{Stack}^\times(C) & \xrightarrow{\mathsf{V}\text{-}\mathsf{St}^\times(u)^*} & \mathsf{V}\text{-}\mathsf{Stack}^\times(C') \\ {\scriptstyle (-)^\times_C}\downarrow & & \downarrow{\scriptstyle (-)^\times_{C'}} \\ \mathsf{V}\text{-}\mathsf{StGpd}(C) & \xrightarrow{\mathsf{V}\text{-}\mathsf{StGpd}(u)^*} & \mathsf{V}\text{-}\mathsf{StGpd}(C'). \end{array}$$

Proof. Endow the topoi $T := C^\sim_{\mathsf{U}}$ and $T' := C'^\sim_{\mathsf{U}}$ with their canonical topologies; we get an essentially commutative diagram of morphisms of sites :

$$\begin{array}{ccc} T' & \xrightarrow{u'} & T \\ {\scriptstyle h^a_{C'}}\downarrow & & \downarrow{\scriptstyle h^a_C} \\ C' & \xrightarrow{u} & C \end{array} \qquad \text{with } u' := \widetilde{u}^*$$

(lemma 4.2.11(ii)). After replacing U by a larger universe, we may assume that T and T' are small; notice also that u' is a morphism of lex-sites (remark 4.4.13(ii)). Especially, the proposition is already known for u', by virtue of (3.4.7) and (5.6.1).

Claim 5.6.5. The proposition holds for h^a_C and $h^a_{C'}$.

Proof of the claim. It suffices to check the assertion for h^a_C, since the same argument will work for $h^a_{C'}$. Now, let $\mathscr{A}$ be a stack in groupoids on C; we need to check that $\mathsf{St}(h^a_C)^*(\mathscr{A})$ is a stack of groupoids on T. However, since $\mathsf{St}(h^a_C)_*$ is a 2-equivalence (proposition 5.4.17(ii)), we may assume that $\mathscr{A} = \mathsf{St}(h^a_C)_*\mathscr{B}$ for a stack $\mathscr{B}$ on T, and we may moreover assume that $\mathscr{B}$ is a stack in groupoids, by (5.6.1). But since $\mathsf{St}(h^a_C)^*(\mathscr{A})$ is equivalent to $\mathscr{B}$, the assertion follows. This shows that the pseudo-functor $\mathsf{StGpd}(h^a_C)^*$ is well defined, and then it is clearly a pseudo-inverse for $\mathsf{StGpd}(h^a_C)_*$. But then the required pseudo-commutativity of the resulting diagram follows easily from the commutativity of (5.6.2) : details left to the reader. ◊

Now, let $\mathscr{A}$ be a stack in groupoids on C; we need to check that $\mathscr{B} := \mathsf{St}(u)^*(\mathscr{A})$ is a stack in groupoids on C', and by claim 5.6.5 it suffices to show that $\mathsf{St}(h^a_{C'})^*(\mathscr{B})$ is a stack in groupoids on T'; but the latter is equivalent to $\mathsf{St}(u')^* \circ \mathsf{St}(h^a_C)^*(\mathscr{A})$, and the proposition is already known for both u' and h^a_C. This shows that $\mathsf{StGpd}(u)^*$ is well defined.

Lastly, we consider the diagram of 2-categories :

$$\begin{array}{ccccccc} \mathsf{StGpd}(T) & & & \xrightarrow{\mathsf{StGpd}(u')^*} & & & \mathsf{StGpd}(T') \\ & \nwarrow{\scriptstyle (-)^\times_T} & & & & \nearrow{\scriptstyle (-)^\times_{T'}} & \\ & & \mathsf{Stack}^\times(T) & \xrightarrow{\mathsf{St}^\times(u')^*} & \mathsf{Stack}^\times(T') & & \\ {\scriptstyle \mathsf{StGpd}(h^a_C)^*}\downarrow & & {\scriptstyle \mathsf{St}^\times(h^a_C)^*}\downarrow & & \downarrow{\scriptstyle \mathsf{St}^\times(h^a_{C'})^*} & & \downarrow{\scriptstyle \mathsf{StGpd}(h^a_{C'})^*} \\ & & \mathsf{Stack}^\times(C) & \xrightarrow{\mathsf{St}^\times(u)^*} & \mathsf{Stack}^\times(C') & & \\ & \swarrow{\scriptstyle (-)^\times_C} & & & & \searrow{\scriptstyle (-)^\times_{C'}} & \\ \mathsf{StGpd}(C) & & & \xrightarrow{\mathsf{StGpd}(u)^*} & & & \mathsf{StGpd}(C') \end{array}$$

whose inner and outer square subdiagrams are pseudo-commutative. Moreover, by the foregoing, we know that also the left, the right, and the top trapezoidal subdiagrams pseudo-commute.

Since $\mathsf{St}^\times(h^a_C)$ is a 2-equivalence, a little diagram chase shows easily that the bottom trapezoidal subdiagram pseudo-commutes as well, whence the proposition. □

5.6.6. Let $C := (\mathscr{C}, J)$ be any U-site; according to example 5.1.2, for every universe V containing U, the pseudo-functor $\mathscr{F}ib_{\mathscr{C}}$ of (3.4.9) restricts to a (strict) pseudo-functor :

$$\mathscr{F}ib_C : C^\sim_{\mathsf{V}} \to \mathsf{V}\text{-}\mathsf{StGpd}(C)$$

and then it is clear that $\pi_0^{\mathscr{C}}$ induces a left 2-adjoint pseudo-functor

$$\pi_0^C : \mathsf{V}\text{-}\mathsf{StGpd}(C) \to C^\sim_{\mathsf{V}} \qquad \mathscr{E} \mapsto (\pi_0^{\mathscr{C}}(\mathscr{E}))^a.$$

Lemma 5.6.7. *In the situation of* (5.6.6)*, let* $\varphi : \mathscr{E} \to \mathscr{F}$ *be a cartesian functor of fibrations in groupoids over* $\mathscr{C}$*. The following holds :*

(i) φ *is* 0*-covering (for the topology of* C*) if and only if* $\pi_0^{\mathscr{C}}(\varphi)^a : \pi_0^{\mathscr{C}}(\mathscr{E})^a \to \pi_0^{\mathscr{C}}(\mathscr{F})^a$ *is an epimorphism of sheaves on* C*.*

(ii) *If* φ *is* i*-covering for* $i = 0, 1$*, then* $\pi_0^{\mathscr{C}}(\varphi)^a$ *is an isomorphism.*

Proof. Both assertions follow by direct inspection of the definitions, taking into account corollary 4.1.30 and remark 4.1.29(ii,iii). □

5.6.8. Let $u : C' := (\mathscr{C}', J') \to C := (\mathscr{C}, J)$ be a morphism of U-sites; then for every universe V containing U the induced diagram of 2-categories

$$\begin{array}{ccc}
\mathsf{V}\text{-}\mathsf{StGpd}(C) & \xrightarrow{\mathsf{V}\text{-}\mathsf{StGpd}(u)^*} & \mathsf{V}\text{-}\mathsf{StGpd}(C') \\
{\scriptstyle \pi_0^C}\downarrow & & \downarrow{\scriptstyle \pi_0^{C'}} \\
C^\sim & \xrightarrow{\quad \widetilde{u}^* \quad} & C'^\sim
\end{array}$$

is essentially commutative. Indeed, lemma 5.6.7(ii) and proposition 5.2.11(i) imply that for every fibration $\mathscr{E}$ over $\mathscr{C}'$, the unit of adjunction $\mathscr{E} \to \mathscr{E}^a$ induces an isomorphism $\pi_0^{\mathscr{C}'}(\mathscr{E})^a \xrightarrow{\sim} \pi_0^{C'}(\mathscr{E}^a)$ of sheaves on C'. The assertion follows easily, taking into account the essential commutativity of (3.4.10) : the details are left to the reader.

5.6.9. *Ind-finite stacks.* It is easy to say when a sheaf of groups G on a topological space $\mathscr{T}$ is ind-finite, when $\mathscr{T}$ admits a basis of quasi-compact open subsets : in which case, one simply asks that the group of U-sections $G(U)$ is a filtered union of finite groups, for every quasi-compact open subset U of $\mathscr{T}$. This definition is however not suitable for more general topological spaces, nor of course for arbitrary sites. Before we explain a definition that is appropriate for the general case, let us introduce a notion of quasi-compactness for such context:

Definition 5.6.10. Let $(\mathscr{C}, J)$ be any site, and $X \in \mathrm{Ob}(\mathscr{C})$. We say that X is *quasi-compact for the topology* J, if for every covering sieve $\mathscr{S} \in J(X)$ there exists a finite subset $S \subset \mathscr{S}$ that generates a sieve covering X.

Obviously this definition recovers the standard one, in the case of the site of open subsets of any topological space.

Definition 5.6.11. Let $C := (\mathscr{C}, J)$ be a site, and G a sheaf of groups on C. We say that G is *ind-finite* if the following holds. For every $X \in \mathrm{Ob}(\mathscr{C})$ and every finite subset $\Sigma \subset GX$, there exists a covering family $(f_i : X_i \to X \mid i \in I)$ for the topology J such that the set $Gf_i(\Sigma) := \{Gf_i(\sigma) \mid \sigma \in \Sigma\}$ generates a finite subgroup of GX_i, for every $i \in I$.

Remark 5.6.12. The first observation is that if G is ind-finite on the site $(\mathscr{C}, J)$, then for every quasi-compact $X \in \mathrm{Ob}(\mathscr{C})$ the group GX is *ind-finite*, *i.e.* it is a filtered union of finite groups. Indeed, let $\Sigma \subset GX$ be any finite subset; by assumption we have a covering family $(X_i \to X \mid i \in I)$ such that $Gf_i(\Sigma)$ generates a finite group H_i for every $i \in I$, and since X is quasi-compact, we may assume that I is a finite set. But the natural map $GX \to \prod_{i\in I} GX_i$ is injective, and maps the subgroup H generated by Σ into the finite group $\prod_{i\in I} H_i$, so H is finite, whence the claim.

5.6.13. For every group G and every subset $\Sigma \subset G$, let us write $\langle\Sigma\rangle \subset G$ for the subgroup generated by Σ. Definition 5.6.11 prompts the following construction. Let $C := (\mathscr{C}, J)$ be any site, and H any presheaf of groups on $\mathscr{C}$. For every $n \in \mathbb{N}$ and every $X \in \mathrm{Ob}(\mathscr{C})$ we set :

$$(H^n)_{\mathsf{f}}(X) := \{(\sigma_1, \dots, \sigma_n) \in H^n(X) \mid \langle\sigma_1, \dots, \sigma_n\rangle \text{ is a finite group}\}.$$

Clearly the rule : $X \mapsto (H^n)_{\mathsf{f}}(X)$ yields a sub-presheaf H^n_{f} of the *presheaf of sets* H^n, for every $n \in \mathbb{N}$. If H is a sheaf on C, $(H^n)_{\mathsf{f}}$ is not necessarily a sheaf, hence we consider the sheaf

$$(H^n)_{\mathsf{lf}}$$

defined as the smallest subsheaf of sets of H^n containing $(H^n)_{\mathsf{f}}$. The latter is also (naturally isomorphic to) the sheaf of sets $(H^n)^a_{\mathsf{f}}$ on C associated with the presheaf $(H^n)_{\mathsf{f}}$. Clearly every morphism $\varphi : H \to K$ of presheaves of groups on $\mathscr{C}$ induces a morphism of presheaves of sets

$$(\varphi^n)_{\mathsf{f}} : (H^n)_{\mathsf{f}} \to (K^n)_{\mathsf{f}} \qquad \text{for every } n \in \mathbb{N}.$$

If H and K are sheaves of groups on C, we get also an induced morphism of sheaves of sets

$$(\varphi^n)_{\mathsf{lf}} : (H^n)_{\mathsf{lf}} \to (K^n)_{\mathsf{lf}} \qquad \text{for every } n \in \mathbb{N}.$$

Thus, in the notation of definition 5.5.1, we get by these rules two well defined functors

$$(-)^n_{\mathsf{f}} : (\mathscr{C}, \mathsf{V}\text{-}\mathbf{Grp})^\wedge \to \mathscr{C}^\wedge_{\mathsf{V}} \qquad (-)^n_{\mathsf{lf}} : (C, \mathsf{V}\text{-}\mathbf{Grp})^\sim \to C^\sim_{\mathsf{V}} \qquad \text{for every } n \in \mathbb{N}$$

for every universe V.

Remark 5.6.14. Let $C := (\mathscr{C}, J)$ be a site, and H a sheaf of groups on C.

(i) Notice that $(H^n)_{\mathsf{f}}$ is a separated presheaf for every $n \in \mathbb{N}$, since it is a sub-presheaf of the sheaf H^n; hence $(H^n)_{\mathsf{lf}} = (H^n)^+_{\mathsf{f}}$ (claim 4.1.16(ii)). This means that for every $X \in \mathrm{Ob}(\mathscr{C})$, the set $(H^n)_{\mathsf{lf}}(X)$ consists of all $(\sigma_1, \dots, \sigma_n) \in H^n(X)$ for which there exists a covering family $(f_i : X_i \to X \mid i \in I)$ for the topology J such that $\langle Gf_i(\sigma_1), \dots, Gf_i(\sigma_n)\rangle$ is a finite subgroup of GX_i, for every $i \in I$.

(ii) We deduce easily from (i) that H is ind-finite if and only if $H^n = (H^n)_{\mathsf{lf}}$ for every $n \in \mathbb{N}$.

(iii) It also follows from (i) that $(H^n)_{\mathsf{f}}(X) = (H^n)_{\mathsf{lf}}(X)$ for every quasi-compact object X of $\mathscr{C}$. Indeed, let $\underline{\sigma} := (\sigma_1, \dots, \sigma_n) \in (H^n)_{\mathsf{lf}}(X)$, and pick a covering family $(f_i : X_i \to X \mid i \in I)$ verifying the condition of (i) relative to $\underline{\sigma}$; since X is quasi-compact, we may assume that I is a finite set, and then arguing as in remark 5.6.12 we deduce that $\underline{\sigma} \in (H^n)_{\mathsf{f}}(X)$.

Lemma 5.6.15. *Let $(\mathscr{C}, J)$ be a site, and $\varphi : H \to K$ a bicovering morphism of presheaves of groups on $\mathscr{C}$. Then $(\varphi^n)_{\mathsf{f}} : (H^n)_{\mathsf{f}} \to (K^n)_{\mathsf{f}}$ is bicovering for every $n \in \mathbb{N}$.*

Proof. Let $X \in \mathrm{Ob}(\mathscr{C})$ and $\underline{\sigma} := (\sigma_1, \dots, \sigma_n) \in (K^n)_{\mathsf{f}}(X)$; according to remark 4.1.29(ii) we have to exhibit a covering family $(f_i : X_i \to X \mid i \in I)$ such that $(Kf_i(\sigma_1), \dots, Kf_i(\sigma_n))$ lies in the image of the map $(\varphi^n)_{\mathsf{f},X_i} : (H^n)_{\mathsf{f}}(X_i) \to (H^n)_{\mathsf{f}}(X_i)$ for every $i \in I$. But by assumption, for every $j = 1, \dots, n$ there exists a covering sieve $\mathscr{S}_j \subset \mathscr{C}/X$ such that $Kf(\sigma_j)$ lies in the image of the map $\varphi_Y : HY \to KY$ for every $f : Y \to X$ in $\mathscr{S}_j$. Then the sieve $\mathscr{S} := \mathscr{S}_1 \cap \dots \cap \mathscr{S}_n$ still covers X (remark 4.1.3(i)), and for every $g : Y \to X$ in $\mathscr{S}$ we see that $K^n g(\underline{\sigma}) = \varphi^n_Y(\underline{\tau})$ for some $\underline{\tau} := (\tau_1, \dots, \tau_n) \in H^n(Y)$. To conclude, it then suffices to exhibit for every such g and τ a covering sieve $\mathscr{S}' \subset \mathscr{S}/Y$ such that $H^n g'(\underline{\tau}) \in (H^n)_{\mathsf{f}}(Y')$ for every $g' : Y' \to Y$ in $\mathscr{S}'$. However, by construction we have $\varphi^n_Y(\underline{\tau}) \in (K^n)_{\mathsf{f}}(Y)$; the latter means that the subgroup $\langle\varphi_Y(\tau_1), \dots, \varphi_Y(\tau_n)\rangle \subset KY$ is finite. This in turn means that there exists an integer $N \geq 2$, such that for every $\underline{j} \in \{1, \dots, n\}^N$ we may find an integer $M(\underline{j}) < N$ and $\underline{j}' \in \{1, \dots, n\}^{M(\underline{j})}$ with $\prod_{k=1}^N \varphi_Y(\tau_{j_k}) = \prod_{k=1}^{M(\underline{j})} \varphi_Y(\tau_{j'_k})$. By remark 4.1.29(iii), this implies that there exists a covering sieve $\mathscr{S}'_{\underline{j}} \subset \mathscr{C}/Y$ such that $\prod_{k=1}^{N} Hf(\tau_{j_k}) = \prod_{k=1}^{M(\underline{j})} Hf(\tau_{j'_k})$ for every $f : Y' \to Y$ in $\mathscr{S}'_{\underline{j}}$. Then the sieve $\mathscr{S}' := \bigcap_{\underline{j}\in\{1,\dots,n\}^N} \mathscr{S}'_{\underline{j}}$ covers Y, and we deduce that the sequence $H^n f(\underline{\tau})$ generates a finite subgroup of $H^n Y'$, for every $f : Y' \to Y$ in $\mathscr{S}'$; *i.e.* $H^n f(\underline{\tau}) \in (H^n)_{\mathsf{f}}(Y')$, as required.

Lastly, let $\underline{\sigma}, \underline{\sigma}' \in (H^n)_{\mathsf{f}}(X)$ be two sections such that $\varphi^n_X(\underline{\sigma}) = \varphi^n_X(\underline{\sigma}')$; according to remark 4.1.29(iii) we need to exhibit a covering sieve $\mathscr{S} \subset \mathscr{C}/X$ such that $H^n f(\underline{\sigma}) = H^n f(\underline{\sigma}')$ for every $f : Y \to X$ in $\mathscr{S}$. But by assumption, for $i = 1, \dots, n$ there exists a sieve $\mathscr{S}_i$ such that $Hf(\sigma_i) = Hf(\sigma'_i)$ for every f in $\mathscr{S}_i$; clearly $\mathscr{S} := \mathscr{S}_1 \cap \cdots \cap \mathscr{S}_n$ will do. $\square$

5.6.16. Let now $C := (\mathscr{C}, J)$ and $C' := (\mathscr{C}', J')$ be two sites, $u : \mathscr{C}' \to \mathscr{C}$ a functor, and H a presheaf of groups on $\mathscr{C}$. Clearly $u^\wedge H$ is a presheaf of groups on $\mathscr{C}'$, and we have :

$$u^\wedge((H^n)_{\mathsf{f}}) = ((u^\wedge H)^n)_{\mathsf{f}} \qquad \text{for every } n \in \mathbb{N}.$$

Proposition 5.6.17. *In the situation of* (5.6.16)*, suppose that u is cocontinuous for the topologies J and J', and H is a sheaf of groups on C. Then the following holds :*

(i) *$\breve{u}^* H$ is a sheaf of groups on C', and $\breve{u}^*((H^n)_{\mathsf{lf}}) = ((\breve{u}^* H)^n)_{\mathsf{lf}}$ for every $n \in \mathbb{N}$.*
(ii) *If H is ind-finite, the same holds for $\breve{u}^* H$.*

Proof. (i): Since the functor $(-)^a$ is exact, it is clear that the group law $K \times K \to K$ of every presheaf of groups K on $\mathscr{C}'$ yields a group law $K^a \times K^a \to K^a$ for the sheaf K^a : details left to the reader; the first assertion of the proposition is an immediate consequence.

To check the sought identity, recall that by definition $\breve{u}^*((H^n)_{\mathsf{lf}}) = (u^\wedge((H^n)^a_{\mathsf{f}}))^a$, and

$$(u^\wedge((H^n)^a_{\mathsf{f}}))^a = (u^\wedge((H^n)_{\mathsf{f}}))^a$$

by lemma 4.2.9 and corollary 4.1.30(iii). Next, $(u^\wedge((H^n)_{\mathsf{f}}))^a = (((u^\wedge H)^n)_{\mathsf{f}})^a$, by (5.6.16). Lastly, $(((u^\wedge H)^n)_{\mathsf{f}})^a = ((((u^\wedge H)^a)^n)_{\mathsf{f}})^a$, by lemma 5.6.15, whence the contention.

(ii) follows immediately from (i) and remark 5.6.14(ii). $\square$

Lemma 5.6.18. *In the situation of* (5.6.16)*, suppose that the category $X/u\mathscr{C}'$ is cofiltered for every $X \in \mathrm{Ob}(\mathscr{C})$, and let K be a presheaf of groups on $\mathscr{C}'$. Then $u_!K$ is a presheaf of groups on $\mathscr{C}$, and we have a natural isomorphism of presheaves :*

$$u_!((K^n)_{\mathsf{f}}) \xrightarrow{\sim} ((u_!K)^n)_{\mathsf{f}} \qquad \textit{for every } n \in \mathbb{N}.$$

Proof. Under the stated assumption, the functor $u_!$ is exact (*cp.* the proof of corollary 1.5.19(i)), so we easily deduce that $u_!K$ is a presheaf of groups, as in the proof of proposition 5.6.17(i).

Next, we get a natural morphism of presheaves $\omega : u_!((K^n)_{\mathsf{f}}) \to ((u_!K)^n)_{\mathsf{f}}$ as follows. First, the unit of adjunction is a morphism $\eta_K : K \to u^\wedge u_! K$, which induces a morphism $(\eta^n_K)_{\mathsf{f}} : (K^n)_{\mathsf{f}} \to ((u^\wedge u_! K)^n)_{\mathsf{f}}$. Then, by (5.6.16) we have $((u^\wedge u_! K)^n)_{\mathsf{f}} = u^\wedge(((u_!K)^n)_{\mathsf{f}})$, and the resulting morphism $(K^n)_{\mathsf{f}} \to u^\wedge(((u_!K)^n)_{\mathsf{f}})$ yields by adjunction the sought morphism.

Explicitly, for every $X \in \mathrm{Ob}(\mathscr{C})$, every element of $u_!((K^n)_{\mathsf{f}})(X)$ is the class $[\underline{\sigma}]$ of some $\underline{\sigma} := (\sigma_1, \dots, \sigma_n) \in K^n(Y)$, for an object $f : X \to uY$ of $X/u\mathscr{C}'$, and $\omega_X([\underline{\sigma}])$ is the section $([\sigma_1], \dots, [\sigma_n]) \in ((u_!K)^n)_{\mathsf{f}}(X)$, where $[\sigma_i] \in u_!K(X)$ is the class of σ_i, for $i = 1, \dots, n$.

To show the injectivity of ω_X, let $[\underline{\sigma}], [\underline{\tau}] \in u_!((K^n)_{\mathsf{f}})(X)$ such that $\omega_X([\underline{\sigma}]) = \omega_X([\underline{\tau}])$; we may assume that $\underline{\sigma}, \underline{\tau} \in K^n Y$ for some morphism $f : X \to uY$ of $\mathscr{C}'$, and the assumption means that for $i = 1, \dots, n$ there exists a morphism $X/h_i : (g_i : X \to uY_i) \to f$ in $X/u\mathscr{C}'$ such that $Kh_i(\sigma_i) = Kh_i(\tau_i)$ in KY_i. Since $X/u\mathscr{C}'$ is cofiltered, we may then find an object $g' : X \to uY'$ of $X/u\mathscr{C}'$ and morphisms $X/h'_i : g' \to g_i$ of $X/u\mathscr{C}'$ with $(X/h_i) \circ (X/h'_i) = (X/h_j) \circ (X/h'_j)$ for every $i, j = 1, \dots, n$. Recall that $h_i : Y_i \to Y$ and $h'_i : Y' \to Y_i$ are morphisms in $\mathscr{C}'$, and the foregoing identity means that $h := h_i \circ h'_i = h_j \circ h'_j$ for every such i, j. We conclude that $Kh(\sigma_i) = Kh(\tau_i)$ for $i = 1, \dots, n$, whence $[\underline{\sigma}] = [\underline{\tau}]$, as required.

To check the surjectivity of ω_X, let $([\sigma_1],\dots,[\sigma_n]) \in ((u_!K)^n)_{\mathfrak{f}}(X)$; hence, for $i=1,\dots,n$ there exists an object $f_i : X \to uY_i$ of $X/u\mathscr{C}'$ such that $\sigma_i \in KY_i$. Arguing as in the foregoing, we easily reduce to the case where $Y := Y_1 = \cdots = Y_n$ and $f := f_1 = \cdots = f_n$. For every morphism $X/h : (g : X \to uY') \to f$ in $X/u\mathscr{C}'$, let $G_h := \langle Kh(\sigma_1),\dots,Kh(\sigma_n)\rangle \subset KY'$, and set $G := \langle[\sigma_1],\dots,[\sigma_n]\rangle \subset u_!K(X)$. The source morphism $(X/u\mathscr{C}')/f \to X/u\mathscr{C}'$ is coinitial (example 1.5.9(i)), and a direct inspection shows that the group G is the colimit of the functor

$$G_\bullet : ((X/u\mathscr{C}')/f)^o \to \mathbf{Grp} \qquad h \mapsto G_h.$$

To every pair of objects $X/h : (g : X \to uY') \to f$ and $X/h : (g : X \to uY'') \to f$ of $(X/u\mathscr{C}')/f$, and every morphism $(X/l)/f : (X/h') \to (X/h)$ in $(X/u\mathscr{C}')/f$, the functor $G_\bullet$ assigns the group homomorphism $G_h \to G_{h'}$ given by the restriction of $Kh : KY' \to KY''$. By assumption, G is a finite group; let us then remark more generally :

Claim 5.6.19. Let $\Gamma_\bullet : I \to \mathbf{Grp}$ be a functor from a filtered category I, such that :

(a) Γ_i is a finitely generated group for every $i \in \mathrm{Ob}(I)$
(b) Γ_φ is a surjective group homomorphism for every morphism φ of I
(c) The colimit G of $\Gamma_\bullet$ is a finite group.

Let also $\tau_\bullet : \Gamma_\bullet \Rightarrow c_G$ be a universal cocone. Then there exists a cofinal functor $\psi : J \to I$ such that $\tau * \psi$ is an isomorphism of functors $\Gamma_\bullet \circ \psi \xrightarrow{\sim} c_G$.

Proof of the claim. By virtue of proposition 1.5.21(ii) we may assume that $(I,\leq)$ is a filtered partially ordered set. Since I is filtered, the colimit of $\Gamma_\bullet$ commutes with the forgetful functor $\Phi : \mathbf{Grp} \to \mathbf{Set}$. Especially, for every $x \in G$ we may find $i(x) \in \mathrm{Ob}(I)$ and $x' \in \Gamma_{i(x)}$ such that $\tau_{i(x)}(x') = x$. Since I is filtered and G is finite, we may then find $i \in \mathrm{Ob}(I)$ with $i \geq i(x)$ for every $x \in G$. Hence the rule : $x \mapsto \Gamma_{i(x),i}(x')$ defines a set-theoretic section $\sigma_i : G \to \Gamma_i$ of τ_i. Then for every $j \geq i$, the composition $\sigma_j := \Gamma_{ij} \circ \sigma_i$ is a set-theoretic section of τ_j. After replacing I by the cofinal subset $\{j \in I \mid j \geq i\}$ we may therefore assume that there exists a cone $\sigma_\bullet : c_G \Rightarrow \Phi \circ \Gamma_\bullet$ such that $\tau_i \circ \sigma_i = \mathbf{1}_G$ for every $i \in I$. Next, for every $x, y \in G$ we may find $i(x,y) \in I$ such that

$$\sigma_{i(x,y)}(xy) = \sigma_{i(x,y)}(x) \cdot \sigma_{i(x,y)}(y)$$

(details left to the reader). Again, we may then pick $i_0 \in I$ such that $i_0 \geq i(x,y)$ for every $x, y \in G$, in which case it is easily seen that $\sigma_{i_0}(xy) = \sigma_{i_0}(x) \cdot \sigma_{i_0}(y)$ for every $x, y \in G$, *i.e.* σ_{i_0} is a group homomorphism. Then clearly σ_j is a group homomorphism for every $j \geq i_0$, so after replacing I by the cofinal subset of elements $\geq i_0$, we may assume that $\sigma_\bullet$ is even a cone $c_G \Rightarrow \Gamma_\bullet$, and that I admits an initial element i_0. Now, let $g_1,\dots,g_k$ be a finite system of generators for Γ_{i_0}. For $t = 1,\dots,k$ and every $l \in I$ we have $\tau_l \circ \sigma_l \circ \tau_l(g_t) = \tau_l \circ \Gamma_{i_0,l}(g_t)$; hence we may find $j_t \in I$ such that

$$\sigma_{j_t} \circ \tau_{j_t}(g_t) = \Gamma_{i_0,j_t}(g_t).$$

Then pick again $j \in I$ such that $j \geq j_t$ for every $t = 1,\dots,k$, and set $g'_t := \Gamma_{i_0,j}(g_t)$ for every such t. It follows that for every $t = 1,\dots,k$ we have :

$$\begin{aligned} \sigma_j \circ \tau_j(g'_t) &= \sigma_j \circ \tau_j \circ \Gamma_{i_0,j}(g_t) \\ &= \sigma_j \circ \tau_{j_t} \circ \Gamma_{i_0,j_t}(g_t) \\ &= \Gamma_{j_t,j} \circ \sigma_{j_t} \circ \tau_{j_t} \circ \Gamma_{i_0,j_t}(g_t) \\ &= \Gamma_{j_t,j} \circ \Gamma_{i_0,j_t}(g_t) \\ &= g'_t. \end{aligned}$$

Notice that $g'_1,\dots,g'_k$ is a generating system for Γ_j, since $\Gamma_{i_0,j}$ is a surjective map. We conclude that $\sigma_j \circ \tau_j = \mathbf{1}_{\Gamma_j}$, so τ_j and σ_j are mutually inverse group isomorphisms. After replacing I

by the cofinal subset $\{l \in I \mid l \geq j\}$, we may then assume that $j = i_0$ is the initial element of I. Then, for every $i \in I$ the map $\sigma_i = \Gamma_{i_0,i} \circ \sigma_{i_0}$ is surjective; but σ_i is also injective by construction, so σ_i is an isomorphism for every $i \in I$, and finally, the same follows for τ_i. $\lozenge$

From claim 5.6.19 we deduce that there exists a morphism $X/h : (X \to uY') \to f$ in $X/u\mathscr{C}'$ such that G_h is a finite group, and therefore $\underline{\sigma}' := K^n h(\sigma_1, \dots, \sigma_n) \in (K^n)_{\mathsf{f}}(Y')$. Then the class $[\underline{\sigma}'] \in u_!(K^n)(X)$ lies in $u_!((K^n)_{\mathsf{f}})(X)$ and $\omega_X([\underline{\sigma}']) = ([\sigma_1], \dots, [\sigma_n])$ as required. $\square$

Theorem 5.6.20. *In the situation of* (5.6.16)*, suppose that* $u : C \to C'$ *is a morphism of sites, and let* K *be a sheaf of groups* K *on* C'*. Then* $\widetilde{u}^* K$ *is a sheaf of groups on* C*, and we have a natural isomorphism of sheaves :*

$$\omega^{(n)}_{u,K} : \widetilde{u}^*((K^n)_{\mathsf{lf}}) \xrightarrow{\sim} ((\widetilde{u}^* K)^n)_{\mathsf{lf}} \qquad \text{for every } n \in \mathbb{N}.$$

Proof. By assumption, for every universe V such that C and C' are V-small, the functor $\widetilde{u}^* : C'^{\sim} \to C^{\sim}$ is exact; as in the proof of proposition 5.6.17(i), we deduce that $\widetilde{u}^* K$ is a sheaf of groups. We get therefore for every such V a well defined functor

$$(\widetilde{u}, \mathsf{V}\text{-}\mathbf{Grp})^* : (C', \mathbf{Grp})^{\sim} \to (C, \mathsf{V}\text{-}\mathbf{Grp})^{\sim} \qquad K \mapsto \widetilde{u}^* K.$$

Next, the unit of adjunction $\eta_K : K \to \widetilde{u}_* \widetilde{u}^* K$ induces a morphism of presheaves $(\eta^n_K)_{\mathsf{f}} : (K^n)_{\mathsf{f}} \to ((\widetilde{u}_* \widetilde{u}^* K)^n)_{\mathsf{f}}$. By (5.6.16), we have $((\widetilde{u}_* \widetilde{u}^* K)^n)_{\mathsf{f}} = u^\wedge(((\widetilde{u}^* K)^n)_{\mathsf{f}})$, so by adjunction $(\eta^n_K)_{\mathsf{f}}$ corresponds to a morphism of presheaves $u_!((K^n)_{\mathsf{f}}) \to ((\widetilde{u}^* K)^n)_{\mathsf{f}}$. After taking associated sheaves, we get a morphism of sheaves $\omega : (u_!((K^n)_{\mathsf{f}}))^a \to ((\widetilde{u}^* K)^n)_{\mathsf{lf}}$. Lastly, the inclusion of presheaves $(K^n)_{\mathsf{f}} \to (K^n)_{\mathsf{lf}}$ induces an isomorphism $(u_!((K^n)_{\mathsf{f}}))^a \xrightarrow{\sim} \widetilde{u}^*((K^n)_{\mathsf{lf}})$, by lemma 4.2.11(ii), and $\omega^{(n)}_{u,K}$ is the composition of ω with the inverse of this isomorphism. With the notation of (5.6.13), we have therefore a natural transformation :

$$\omega^{(n)}_{u,\bullet} : \widetilde{u}^* \circ (-)^n_{\mathsf{lf}} \Rightarrow (-)^n_{\mathsf{lf}} \circ (\widetilde{u}, \mathbf{Grp})^* \qquad K \mapsto \omega^{(n)}_{u,K}$$

and it remains to check that $\omega^{(n)}_{u,K}$ is an isomorphism. We begin with the following more explicit description of the map $(\omega^{(n)}_{u,K})_X : \widetilde{u}^*((K^n)_{\mathsf{lf}})(X) \to ((\widetilde{u}^* K)^n)_{\mathsf{lf}}(X)$, for every $X \in \mathrm{Ob}(\mathscr{C})$. First, by definition every element of $\widetilde{u}^*((K^n)_{\mathsf{lf}})(X)$ is the equivalence classes $[\underline{\sigma}]_f$ of a sequence $\underline{\sigma} := (\sigma_1, \dots, \sigma_n) \in K^n Y$, for a morphism $f : X \to uY$ in $\mathscr{C}$, such that for some covering sieve $\mathscr{S} \subset \mathscr{C}'/Y$, the subgroup $\langle Kg(\sigma_1), \dots, Kg(\sigma_n) \rangle \subset KY'$ is finite for every $(g : Y' \to Y) \in \mathrm{Ob}(\mathscr{S})$. Likewise, every element of $((\widetilde{u}^* K)^n)_{\mathsf{lf}}(X)$ is a sequence $([\tau_1]_{f_1}, \dots, [\tau_n]_{f_n})$ such that $[\tau_i]_{f_i} \in \widetilde{u}^* K(X)$ for every $i = 1, \dots, n$ is the equivalence class of a section $\tau_i \in KY_i$, for a morphism $f_i : X \to uY_i$ in $\mathscr{C}$, and there exists a covering sieve $\mathscr{T} \subset \mathscr{C}/X$ such that the subgroup $\langle [\tau_1]_{f_1 \circ h}, \cdots, [\tau_n]_{f_n \circ h} \rangle \subset (\widetilde{u}^* K)(X')$ is finite for every $(h : X' \to X) \in \mathrm{Ob}(\mathscr{T})$.

Now, given such class $[\underline{\sigma}]_f$ and covering sieve $\mathscr{S}$, the sieve $u(\mathscr{S}) \subset \mathscr{C}/uY$ generated by $\{u(g) \mid g \in \mathrm{Ob}(\mathscr{S})\}$ covers uY (lemma 4.2.4), and $\mathscr{T} := f \times_{uY} u(\mathscr{S})$ covers X for the topology J. For every $(h : X' \to X) \in \mathrm{Ob}(\mathscr{T})$ there exist $(g : Y' \to Y) \in \mathrm{Ob}(\mathscr{S})$ and a morphism $f' : X' \to uY'$ in $\mathscr{C}$ with $f \circ h = u(g) \circ f'$. It follows that

$$[\sigma_i]_{f \circ h} = [\sigma_i]_{u(g) \circ f'} = [Kg(\sigma_i)]_{f'} \qquad \text{for } i = 1, \dots, n$$

and therefore $\langle [\sigma_1]_{f \circ h}, \dots, [\sigma_n]_{f \circ h} \rangle$ is a finite subgroup of $(\widetilde{u}^* K)(X')$. Then, by unwinding the definition, we find that $(\omega^{(n)}_{u,K})_X$ is given by the rule :

$$[\underline{\sigma}]_f \mapsto ([\sigma_1]_f, \dots, [\sigma_n]_f).$$

Next, endow $T := C^\sim$ and $T' := C'^\sim$ with their canonical topologies, and consider the essentially commutative diagram of sites provided by lemma 4.2.11(ii) :

$$\begin{array}{ccc} T & \xrightarrow{u'} & T' \\ {\scriptstyle v}\downarrow & \not\swarrow_\beta & \downarrow{\scriptstyle v'} \\ C & \xrightarrow[u]{} & C' \end{array} \qquad \text{with } u' := \widetilde{u}^*, \ \ v' := h^a_{C'} \text{ and } v := h^a_C.$$

After replacing U by a larger universe, we may assume that T and T' are small; we notice :

Claim 5.6.21. The theorem holds for u' and every sheaf H on T'.

Proof of the claim. Recall that u' is a morphism of lex-sites (remark 4.4.13(ii)), and in particular u' fulfills the condition of lemma 5.6.18, so we get an isomorphism of presheaves $\omega : u'_!((H^n)_{\mathsf{f}}) \xrightarrow{\sim} ((u'_! H)^n)_{\mathsf{f}}$. Taking into account lemma 4.2.11(ii), we deduce an isomorphism of sheaves $\omega^a : \widetilde{u}'^*((H^n)_{\mathsf{lf}}) \xrightarrow{\sim} ((\widetilde{u}'^* H)^n)_{\mathsf{lf}}$. But a direct inspection of the construction shows that the latter agrees with $\omega^{(n)}_{u',H}$. ◊

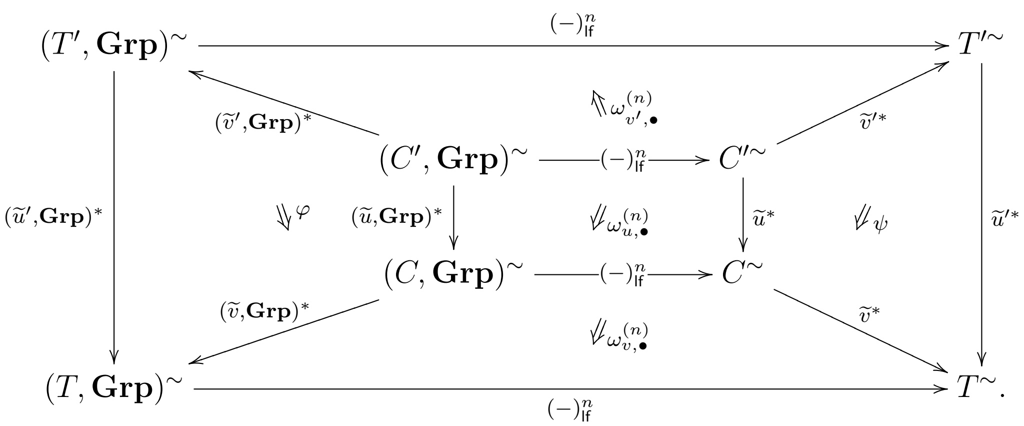
Claim 5.6.22. The theorem holds as well for v and v'.

Proof of the claim. It suffices to show the claim for v, since the same argument will work for v' as well. Recall now that $\breve{v}^* = \widetilde{v}_* : C^\sim \to T^\sim$ is an equivalence (theorem 4.4.2(iii)), and $\widetilde{v}^*$ is its quasi-inverse. It follows that $(\widetilde{v}, \mathbf{Grp})_* : (C, \mathbf{Grp})^\sim \to (T, \mathbf{Grp})^\sim$ is also an equivalence, and its inverse is $(\widetilde{v}, \mathbf{Grp})^*$. Then, let H be any sheaf of groups on C; in order to check that $\omega_{v,H}$ is an isomorphism, we may assume that $H = \widetilde{v}_* L$ for a sheaf of groups L on T, and it suffices to check the commutativity of the diagram :

$$\begin{array}{ccc} \widetilde{v}^*((\widetilde{v}_* L^n)_{\mathsf{lf}}) & \xrightarrow{\omega^{(n)}_{v,\widetilde{v}_* L}} & ((\widetilde{v}^*\widetilde{v}_* L)^n)_{\mathsf{lf}} \\ \Vert & & \downarrow{\scriptstyle ((\varepsilon_L)^n)_{\mathsf{lf}}} \\ \widetilde{v}^*\widetilde{v}_*((L^n)_{\mathsf{lf}}) & \xrightarrow{\varepsilon_{(L^n)_{\mathsf{lf}}}} & (L^n)_{\mathsf{lf}} \end{array}$$

where $\varepsilon_\bullet : \widetilde{v}^*\widetilde{v}_* \xrightarrow{\sim} \mathbf{1}_{T^\sim}$ is the counit for the adjoint $(\widetilde{v}^*, \widetilde{v}_*)$. However, for every sheaf F on T, and every $X \in \mathrm{Ob}(T)$ the elements of $\widetilde{v}^*\widetilde{v}_* F(X)$ are the equivalence classes $[\sigma]_f$, where $f : X \to vY$ is a morphism in T, and $\sigma \in \widetilde{v}_* F(Y) = F(vY)$; with this notation, the map $\varepsilon_{F,X} : \widetilde{v}^*\widetilde{v}_* F(X) \xrightarrow{\sim} FX$ is given by the rule : $[\sigma]_f \mapsto Ff(\sigma)$. Then the assertion follows after simple inspection, by combining with the foregoing explicit description of $\omega^{(n)}_{v,\widetilde{v}_* L}$. ◊

We deduce an oriented diagram of categories :



which we complete by adding the orientation $\omega^{(n)}_{u',\bullet}$ for the "front face". Here φ and ψ denote the identifications induced by β :

$$(\widetilde{u}', \mathbf{Grp})^* \circ (\widetilde{v}', \mathbf{Grp})^* \stackrel{\sim}{\to} (\widetilde{v}, \mathbf{Grp})^* \circ (\widetilde{u}, \mathbf{Grp})^* \qquad \text{and} \qquad \widetilde{u}'^* \circ \widetilde{v}'^* \stackrel{\sim}{\to} \widetilde{v}^* \circ \widetilde{u}^*.$$

Explicitly, for every sheaf F' on C' and every $X \in \mathrm{Ob}(T)$, the elements of $\widetilde{u}'^* \circ \widetilde{v}'^* F(X)$ are the equivalences classes $[[\tau]_g]_f$, where $f : X \to u'Y$ is a morphism of T, $g : Y \to v'Z$ is a morphism of T', and $\tau \in FZ$; likewise one describes the elements of $\widetilde{v}^* \circ \widetilde{u}^* F(X)$, and notice that $\beta_Z \circ u'(g) \circ f$ is a morphism $X \to vuZ$ in T. Then $\psi_{F,X} : \widetilde{u}'^* \circ \widetilde{v}'^* F(X) \stackrel{\sim}{\to} \widetilde{v}^* \circ \widetilde{u}^* F(X)$ is given by the rule :

$$[[\tau]_g]_f \mapsto [[\tau]_{\beta_Z \circ u'(g) \circ f}]_{\mathbf{1}_{uZ}}.$$

If F is a sheaf of groups on T, the same rule defines the group isomorphism $\varphi_{F,X}$. Now, a simple inspection shows that this oriented diagram commutes on 2-cells, in the sense of (2.3.21). By claims 5.6.21 and 5.6.22 we know that $\omega^{(n)}_{u',\bullet}$, $\omega^{(n)}_{v,\bullet}$ and $\omega^{(n)}_{v',\bullet}$ are isomorphisms; we conclude that the same holds for $\omega^{(n)}_{u,\bullet}$, as stated. □

Corollary 5.6.23. *In the situation of theorem* 5.6.20*, the following holds :*

(i) *If K is ind-finite, the same holds for $\widetilde{u}^* K$.*
(ii) *If $\widetilde{u}^*$ is a conservative functor and $\widetilde{u}^* K$ is ind-finite, then K is ind-finite.*

Proof. The assertions are immediate consequences of theorem 5.6.20 and remark 5.6.14(ii). □

Proposition 5.6.24. *In the situation of* (5.6.16)*, suppose that u is continuous and there exists a topologically generating family $G \subset \mathrm{Ob}(\mathscr{C}')$ such that uY is quasi-compact for the topology J, for every $Y \in G$. Then, if H is an ind-finite sheaf on C, the sheaf $\widetilde{u}_* H$ is ind-finite on C'.*

Proof. Let $X \in \mathrm{Ob}(\mathscr{C}')$ be any object, and $\Sigma \subset \widetilde{u}_* H(X) = H(uX)$ any finite set. Pick a covering family $(f_i : Y_i \to X \mid i \in I)$ with $Y_i \in G$ for every $i \in I$; by remark 5.6.12, the group $\widetilde{u}_* H(Y_i) = H(uY_i)$ is ind-finite, hence $Hf_i(\Sigma)$ generates a finite subgroup of $H(uY_i)$ for every $i \in I$, whence the assertion. □

5.6.25. $C := (\mathscr{C}, J)$ be a site, and $\mathscr{A} \to \mathscr{C}$ a fibration; for every $X \in \mathrm{Ob}(\mathscr{C})$ and every cartesian section $\sigma \in \mathrm{Ob}(\mathscr{A}(X))$ we define the presheaf on $\mathscr{C}/X$:

$$\mathscr{C}art^\times(\sigma) := \mathscr{C}art(\sigma^\times, \sigma^\times)$$

(notation of (3.4.2)). Clearly, for every $f \in \mathrm{Ob}(\mathscr{C}/X)$, the set $\mathscr{C}art^\times(\sigma)(f)$ carries a natural group structure, given by composition of automorphisms of the cartesian section $(\sigma \circ f_*)^\times$ of $\mathscr{A}^\times$, so $\mathscr{C}art^\times(\sigma)$ is a presheaf of groups on $\mathscr{C}/X$.

Definition 5.6.26. With the notation of (5.6.25), we say that $\mathscr{A}$ is an *ind-finite prestack* on C, if $\mathscr{C}art^\times(\sigma)$ an ind-finite sheaf of groups on C/X, for every $X \in \mathrm{Ob}(\mathscr{C})$, and every $\sigma \in \mathrm{Ob}(\mathscr{A}(X))$ (notation of (4.7)). We say that $\mathscr{A}$ is an *ind-finite stack* on C, if it is both an ind-finite prestack and a stack on C.

5.6.27. Let $u : C := (\mathscr{C}, J) \to C' := (\mathscr{C}', J')$ be a morphism of small sites, $\mathscr{E}$ a stack on C'; let also $X \in \mathrm{Ob}(\mathscr{C}')$, and $\sigma, \tau \in \mathrm{Ob}(\mathscr{E}(X))$. Set $\mathscr{E}' := \mathsf{St}(u)^* \mathscr{E}$, and denote

$$\eta_{\mathscr{E}} : \mathscr{E} \to \mathsf{St}(u)_* \mathscr{E}'$$

the unit of the 2-adjunction for the 2-adjoint pair $(\mathsf{St}(u)^*, \mathsf{St}(u)_*)$. According to (5.4.7), the natural projection $\pi : \mathsf{St}(u)_* \mathscr{E}' \to \mathscr{E}'$ induces an equivalence of categories :

$$u^*_{|X} : \mathscr{E}'(uX) \stackrel{\sim}{\to} \mathsf{St}(u)_* \mathscr{E}'(X).$$

We may then find $\sigma', \tau' \in \mathrm{Ob}(\mathscr{E}'(uX))$ and isomorphisms

$$\omega_1 : \eta_{\mathscr{E}} \circ \sigma \stackrel{\sim}{\to} u^*_{|X}(\sigma') \qquad \omega_2 : \eta_{\mathscr{E}} \circ \tau \stackrel{\sim}{\to} u^*_{|X}(\tau').$$

Taking into account lemma 5.1.9 we deduce isomorphisms of sheaves on C'/X :

$$\mathscr{C}art(\eta_{\mathscr{E}} \circ \sigma, \eta_{\mathscr{E}} \circ \tau) \xrightarrow{\sim} \mathscr{C}art(u^*_{|X}\sigma', u^*_{|X}\tau') \xrightarrow{\sim} \widetilde{u}_{|X*}\mathscr{C}art(\sigma', \tau')$$

namely the composition of the isomorphism (5.1.7) induced by ω_1 and ω_2, with the isomorphism of presheaves given in (5.4.7). Then (5.1.8) yields as well a morphism of sheaves :

$$\mathscr{C}art(\sigma, \tau) \to \mathscr{C}art(\eta_{\mathscr{E}} \circ \sigma, \eta_{\mathscr{E}} \circ \tau) \qquad \beta \mapsto \eta_{\mathscr{E}} * \beta.$$

By adjunction, the composition of these morphisms induces a morphism of sheaves on C/uX :

$$\widetilde{u}^*_{|X}\mathscr{C}art(\sigma, \tau) \to \mathscr{C}art(\sigma', \tau'). \tag{5.6.28}$$

Remark 5.6.29. (i) Let $(f : Y \to uX) \in \mathrm{Ob}(\mathscr{C}/uX)$. The evaluation at f of the morphism (5.6.28) can be described explicitly as follows. For every element $[\alpha] \in \widetilde{u}^*_{|X}\mathscr{C}art(\sigma, \tau)(f)$ we may find a covering family $(k_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ and for every $\lambda \in \Lambda$ a morphism $h_\lambda : Y_\lambda \to uZ_\lambda$ in $\mathscr{C}$ and a morphism $g_\lambda : Z_\lambda \to X$ in $\mathscr{C}'$ with $f \circ k_\lambda = u(g_\lambda) \circ h_\lambda$, such that $[\alpha]$ is represented by a system of morphisms of cartesian sections $(\alpha_\lambda : \sigma \circ g_{\lambda*} \Rightarrow \tau \circ g_{\lambda*})$. Set

$$\alpha^*_\lambda := \pi(\omega_{2,g_\lambda} \circ \eta_{\mathscr{E}}(\alpha_{\lambda,\mathbf{1}_{Z_\lambda}}) \circ \omega^{-1}_{1,g_\lambda}) : \sigma'(ug_\lambda) \to \tau'(ug_\lambda) \qquad \text{for every } \lambda \in \Lambda.$$

Then for every $\lambda \in \Lambda$ there exists a unique morphism $\alpha^{**}_\lambda : \sigma'(f \circ k_\lambda) \to \tau'(f \circ k_\lambda)$ in $\mathscr{E}'_{Y_\lambda}$ that makes commute the following diagram in $\mathscr{E}'$:

$$\begin{array}{ccc} \sigma'(f \circ k_\lambda) & \xrightarrow{\alpha^{**}_\lambda} & \tau'(f \circ k_\lambda) \\ {\scriptstyle \sigma'(h_\lambda/uX)} \downarrow & & \downarrow {\scriptstyle \tau'(h_\lambda/uX)} \\ \sigma'(ug_\lambda) & \xrightarrow{\alpha^*_\lambda} & \tau'(ug_\lambda) \end{array}$$

and there exists a unique morphism of cartesian sections $\alpha^{**} : \sigma' \circ f_* \Rightarrow \tau' \circ f*$ such that $\alpha^{**}_{k_\lambda} = \alpha^{**}_\lambda$ for every $\lambda \in \Lambda$. Then the map (5.6.28) is given by the rule : $[\alpha] \mapsto \alpha^{**}$.

(ii) The morphism (5.6.28) depends obviously on the choice of σ', τ', ω_1 and ω_2. However, say that $\sigma'', \tau'' \in \mathrm{Ob}(\mathscr{E}'(uX))$ are two other cartesian sections with isomorphisms $\omega'_1 : \eta_{\mathscr{E}} \circ \sigma \xrightarrow{\sim} u^*_{|X}(\sigma'')$ and $\omega'_2 : \eta_{\mathscr{E}} \circ \tau \xrightarrow{\sim} u^*_{|X}(\tau'')$. Then there exists unique isomorphisms $\rho_1 : \sigma' \xrightarrow{\sim} \sigma''$ and $\rho_2 : \tau' \xrightarrow{\sim} \tau''$ in $\mathscr{E}'(uX)$ such that

$$\omega'_i = u^*_{|X}(\rho_i) \circ \omega_i \qquad \text{for } i = 1, 2$$

and in light of (i) it is easily seen that we get a commutative diagram :

$$\begin{array}{ccc} & \mathscr{C}art(\sigma, \tau) & \\ \swarrow & & \searrow \\ \mathscr{C}art(\sigma', \tau') & \xrightarrow{\sim} & \mathscr{C}art(\sigma'', \tau'') \end{array}$$

whose downward arrows are the morphisms (5.6.28) relative to the choices (ω_1, ω_2) and respectively (ω'_1, ω'_2), and whose horizontal arrow is the isomorphism (5.1.7) induced by (ρ_1, ρ_2).

Proposition 5.6.30. *The morphism* (5.6.28) *is an isomorphism.*

Proof. Let us check that (5.6.28) is a monomorphism. Thus, let $(f : Y \to uX) \in \mathrm{Ob}(\mathscr{C}/uX)$, and $[\alpha], [\beta] \in \widetilde{u}^*_{|X}\mathscr{C}art(\sigma, \tau)(f)$ whose images agree in $\mathscr{C}art(\sigma', \tau')(f)$; we need to show that $[\alpha] = [\beta]$. We may find a covering family $(k_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ such that the restrictions $[\alpha_\lambda], [\beta_\lambda] \in \widetilde{u}^*_{|X}\mathscr{C}art(\sigma, \tau)(f \circ k_\lambda)$ of $[\alpha]$ and $[\beta]$ are in the image of the natural map $u_{|X!}\mathscr{C}art(\sigma, \tau)(f \circ k_\lambda) \to \widetilde{u}^*_{|X}\mathscr{C}art(\sigma, \tau)(f \circ k_\lambda)$, for every $\lambda \in \Lambda$. Then the images of

$[\alpha_\lambda]$ and $[\beta_\lambda]$ agree in $\mathscr{C}art(\sigma', \tau')(f \circ k_\lambda)$, and it suffices to check that $[\alpha_\lambda] = [\beta_\lambda]$ for every such λ. Thus, we may assume from start that $[\alpha], [\beta]$ are in the image of the natural map $u_{|X!}\mathscr{C}art(\sigma, \tau)(f) \to \widetilde{u}^*_{|X}\mathscr{C}art(\sigma, \tau)(f)$. This means that there exists a commutative diagram

$$\begin{array}{ccccc} uZ' & \xleftarrow{h'} & Y & \xrightarrow{h} & uZ \\ & {\scriptstyle u(g')}\searrow & \downarrow{\scriptstyle f} & \swarrow{\scriptstyle u(g)} & \\ & & uX & & \end{array}$$

in $\mathscr{C}$ such that $[\alpha]$ and $[\beta]$ are represented by natural $\mathscr{C}$-transformations

$$\alpha : \sigma \circ g_* \Rightarrow \tau \circ g_* \qquad \beta : \sigma \circ g'_* \Rightarrow \tau \circ g'_*.$$

By proposition 4.3.9, the fibration $\mathsf{s} : \mathscr{C}/u\mathscr{C}' \to \mathscr{C}$ is locally cofiltered relative to the topology J of C, hence there exist a covering family $(k_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ and for every $\lambda \in \Lambda$ a morphism $h''_\lambda : Y_\lambda \to uZ_\lambda$ in $\mathscr{C}$, and two morphisms $l_\lambda : Z_\lambda \to Z$, $l'_\lambda : Z_\lambda \to Z'$ such that

$$h \circ k_\lambda = u(l_\lambda) \circ h''_\lambda \qquad \text{and} \qquad h' \circ k_\lambda = u(l'_\lambda) \circ h''_\lambda \qquad \text{for every } \lambda \in \Lambda.$$

It suffices to check that the images of $[\beta]$ and $[\alpha]$ in $\mathscr{C}art(\sigma, \tau)(f \circ k_\lambda)$ coincide for every $\lambda \in \Lambda$; but these images are the classes of $[\alpha * l_\lambda]$ and respectively $[\beta * l'_\lambda]$. Hence, we may assume from start that $Z = Z'$, $h = h'$ and $g = g'$. With the notation of (5.4.7), the condition on $[\alpha]$ and $[\beta]$ amounts then to the identity :

$$u^*_{|Z}(\eta_{\mathscr{E}} * \alpha) * h_* = u^*_{|Z}(\eta_{\mathscr{E}} * \beta) * h_* \qquad \text{in } \mathscr{E}'(Y). \tag{5.6.31}$$

Recall that the evaluation functor $\mathsf{ev}^{\mathscr{E}}_Z : \mathscr{E}(Z) \to \mathscr{E}_Z$ is an equivalence of categories for every $Z \in \mathrm{Ob}(\mathscr{C})$, natural with respect to morphism in $\mathscr{C}$ (claim 3.2.8); this equivalence assigns to the cartesian sections $\sigma \circ g_*$ and $\tau \circ g_*$ their evaluations $\sigma_g := \sigma(g)$ and $\tau_g := \tau(g)$ in c_X, and to α and β the morphisms $\alpha_0 := \alpha_{\mathbf{1}_Z} : \sigma_g \to \tau_g$ and $\beta_0 := \beta_{\mathbf{1}_Z} : \sigma_g \to \tau_g$ in $\mathscr{E}_Z$. We wish next to similarly interpret the identity (5.6.31) as an equality of morphisms in the fibre category $\mathscr{E}'_Y$. To this aim, let us pick a unital cleavage for $\mathscr{E}$, and let c be its associated unital pseudo-functor; denote also by γ^{c} the coherence constraint of c. Recall that for every $Y \in \mathrm{Ob}(\mathscr{C})$, the fibre category $\mathsf{Fib}(u)_!\mathscr{E}_Y$ of the $\mathscr{C}$-fibration $\mathsf{Fib}(u)_!\mathscr{E}$ represents the 2-colimit of the pseudo-functor

$$F_Y := \mathsf{c} \circ \mathsf{t}^o_Y : (Y/u\mathscr{C}')^o \to \mathbf{Cat} \qquad (g : Y \to uZ) \mapsto \mathsf{c}_Z = \mathscr{E}_Z.$$

The latter is realized by the localization $\mathscr{F}ib(F_Y)[\Sigma^{-1}_Y]$, where Σ_Y denotes the set of cartesian morphisms of $\mathscr{F}ib(F_Y)$. Recall that the objects of $\mathscr{F}ib(F_Y)[\Sigma^{-1}_Y]$ are the data

$$(Z, h : Y \to uZ, T) \qquad \text{with } (Z, h) \in \mathrm{Ob}(Y/u\mathscr{C}') \text{ and } T \in \mathrm{Ob}(\mathscr{E}_Z).$$

The morphisms are the pairs $[Y/g, t] : (Z, h, T) \to (Z', h', T')$ where $Y/g : h \to h'$ is a morphism in $Y/u\mathscr{C}'$ and $t : T \to \mathsf{c}_g T'$ is a morphism in $\mathscr{E}_Z$. Moreover, every morphism $k : Y \to Y'$ in $\mathscr{C}$ induces a $\mathscr{C}$-cartesian functor

$$k^* : \mathscr{F}ib(F_{Y'}) \to \mathscr{F}ib(F_Y) \qquad (Z, h, T) \mapsto (Z, h \circ k, T) \qquad [Y'/g, t] \mapsto [Y/g, t]$$

which therefore extends uniquely to a functor

$$\mathscr{F}ib(F_{Y'})[\Sigma^{-1}_{Y'}] \to \mathscr{F}ib(F_Y)[\Sigma^{-1}_Y]$$

and the system of such functors provides a natural split cleavage for $\mathsf{Fib}(u)_!\mathscr{E}$. Notice then the rules : $Y \mapsto \mathscr{F}ib(F_Y)$ and $k \mapsto k^*$ for every $Y \in \mathrm{Ob}(\mathscr{C})$ and every morphism k of $\mathscr{C}$, define a pseudo-functor $\mathsf{d} : \mathscr{C}^o \to \mathbf{Cat}$, and the foregoing description amounts to saying that $\mathsf{Fib}(u)_!\mathscr{E}$ is represented by the fibration which in the proof of proposition 5.3.1 is denoted

$$\mathscr{F}ib(\mathsf{d})[\Sigma^{-1}_\bullet] \to \mathscr{C}.$$

By proposition 5.3.1, the natural functor $j : \mathsf{Fib}(u)_!\mathscr{E} \to \mathscr{E}'$ factors then as a composition

$$\mathsf{Fib}(u)_!\mathscr{E} \xrightarrow{L_{\{\Sigma\}}} \mathscr{F}ib(\mathsf{d})\{\Sigma_\bullet^{-1}\} \xrightarrow{j'} \mathscr{E}'.$$

Furthermore, for every $Z \in \mathrm{Ob}(\mathscr{C}')$ we have a natural identification $u^*_{|uZ} : \mathsf{St}(u)_*\mathscr{E}'_Z \xrightarrow{\sim} \mathscr{E}'_{uZ}$. Hence, $\eta_\mathscr{E}$ restricts to a functor of fibre categories $\eta_{\mathscr{E},Z} : \mathscr{E}_Z \to \mathscr{E}'_{uZ}$ for every such Z. However, $\mathscr{E}_Z$ is also the fibre category over $\mathbf{1}_{uZ} \in \mathrm{Ob}(uZ/u\mathscr{C}')$ of the $(uZ/u\mathscr{C}')$-fibration $\mathscr{F}ib(F_{uZ})$; in terms of the foregoing realization of $\mathsf{Fib}(u)_!\mathscr{E}_{uZ}$, the functor $\eta_{\mathscr{E},Z}$ is then just given by the rule :

$$\mathscr{E}_Z \to \mathscr{F}ib(F_{uZ})[\Sigma^{-1}_{uZ}] \xrightarrow{j_{uZ}} \mathscr{E}'_{uZ} \qquad T \mapsto j_{uZ}(Z, \mathbf{1}_{uZ}, T)$$

where j_{uZ} is the restriction of j. Summing up, we find that the objects $\eta_\mathscr{E}(\sigma_g)$ and $\eta_\mathscr{E}(\tau_g)$ of $\mathscr{E}'_{uZ}$ are respectively $j_{uZ}(Z, \mathbf{1}_{uZ}, \sigma_g)$ and $j_{uZ}(Z, \mathbf{1}_{uZ}, \tau_g)$, and (5.6.31) translates as the identity:

$$j_{uZ}[Y/\mathbf{1}_Z, \alpha_0] = j_{uZ}[Y/\mathbf{1}_Z, \beta_0].$$

But since j is 2-covering (proposition 5.2.11(i)), we deduce that there exists a covering family $(k_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ in $\mathscr{C}$ such that $[Y_\lambda/\mathbf{1}_Z, \alpha_0] = [Y_\lambda/\mathbf{1}_Z, \beta_0]$ in $\mathscr{F}ib(F_{Y_\lambda})[\Sigma^{-1}_{Y_\lambda}]$ for every $\lambda \in \Lambda$. Since it suffices to check that the images of $[\alpha]$ and $[\beta]$ coincide in $\mathscr{C}art(\sigma, \tau)(f \circ k_\lambda)$ for every λ, we may then assume from start that $[Y/\mathbf{1}_Z, \alpha_0] = [Y/\mathbf{1}_Z, \beta_0]$ in $\mathscr{F}ib(F_Y)[\Sigma_Y^{-1}]$.

Claim 5.6.32. The system $\Sigma_\bullet := (\Sigma_Y \mid Y \in \mathrm{Ob}(\mathscr{C}))$ admits a right local calculus of fractions.

Proof of the claim. Conditions (LCF1) and (LCF2) of definition 5.3.2 obviously hold for $\Sigma_\bullet$. Next, let $(Y/k', l) : (h', T') \to (h, T)$ be a morphism in $\mathscr{F}ib(F_Y)$ and $(Y/k'', t) : (h'', T'') \to (h, T)$ an element of Σ_Y; *i.e.* we have a commutative diagram of morphisms of $\mathscr{C}$:

$$\begin{array}{ccccc} uZ' & \xleftarrow{h'} & Y & \xrightarrow{h''} & uZ'' \\ & {\scriptstyle u(k')}\searrow & \downarrow{\scriptstyle h} & \swarrow{\scriptstyle u(k'')} & \\ & & uZ & & \end{array}$$

together with a morphism $l : T' \to \mathsf{c}_{k'}T$ and an isomorphism $t : T'' \xrightarrow{\sim} \mathsf{c}_{k''}T$ in $\mathscr{A}_Y$. By proposition 4.3.9, the fibration $\mathsf{s} : \mathscr{C}/u\mathscr{C}' \to \mathscr{C}$ is locally cofiltered relative to the topology J of C, hence there exist a covering family $(g_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ and for every $\lambda \in \Lambda$ a morphism $h_\lambda : Y_\lambda \to uZ_\lambda$ in $\mathscr{C}$, and two morphisms $k'_\lambda : Z_\lambda \to Z'$, $k''_\lambda : Z_\lambda \to Z''$ such that

$$h' \circ g_\lambda = u(k'_\lambda) \circ h_\lambda \qquad h'' \circ g_\lambda = u(k''_\lambda) \circ h_\lambda \qquad k' \circ k'_\lambda = k'' \circ k''_\lambda \qquad \text{for every } \lambda \in \Lambda$$

whence a well defined morphism in $\mathscr{A}_{Y_\lambda}$, for every $\lambda \in \Lambda$:

$$l_\lambda : \mathsf{c}_{k'_\lambda}T' \xrightarrow{\mathsf{c}_{k'_\lambda}l} \mathsf{c}_{k'_\lambda}\mathsf{c}_{k'}T \xrightarrow{\gamma^{\mathsf{c}}_{(k'_\lambda,k'),T}} \mathsf{c}_{k'\circ k'_\lambda}T \xrightarrow{\gamma^{\mathsf{c}\,-1}_{(k''_\lambda,k''),T}} \mathsf{c}_{k''_\lambda}\mathsf{c}_{k''}T \xrightarrow{(\mathsf{c}_{k''_\lambda}t)^{-1}} \mathsf{c}_{k''_\lambda}T''$$

which then yield a commutative diagram in $\mathscr{F}ib(F_{Y_\lambda})$ for every such λ :

$$\begin{array}{ccc} (h_\lambda, \mathsf{c}_{k'_\lambda}T') & \xrightarrow{(Y_\lambda/k'_\lambda, t_\lambda)} & g^*_\lambda(h', T') \\ {\scriptstyle (Y_\lambda/k''_\lambda, l_\lambda)}\downarrow & & \downarrow{\scriptstyle g^*_\lambda(Y/k', l)} \\ g^*_\lambda(h'', T'') & \xrightarrow{g^*_\lambda(Y/k'', t)} & g^*_\lambda(Y/h, T) \end{array}$$

where we take for t_λ the identity of $\mathsf{c}_{k'_\lambda}T'$. This shows that condition (LCF3) holds for $\Sigma_\bullet$. Lastly, suppose that we have a commutative diagram in $\mathscr{F}ib(\mathscr{A}_Y)$:

$$(h, T) \overset{(Y/k,l)}{\underset{(Y/k',l')}{\rightrightarrows}} (h', T') \xrightarrow{(Y/k'', t)} (h'', T'')$$

with $(Y/k'', t) \in \Sigma_Y$. This means that we have a commutative diagram in $\mathscr{C}$:

$$\begin{array}{ccccc} & & Y & & \\ & \swarrow^{h} & \downarrow{\scriptstyle h'} & {}^{h''}\searrow & \\ uZ & \underset{u(k')}{\overset{u(k)}{\rightrightarrows}} & uZ' & \xrightarrow{u(k'')} & uZ'' \end{array}$$

and morphisms $l : T \to \mathsf{c}_k T'$, $l' : T \to \mathsf{c}_{k'} T'$ and an isomorphism $t : T' \xrightarrow{\sim} \mathsf{c}_{k''} T''$ in $\mathscr{A}_Y$ with

$$k'' \circ k = k'' \circ k' \qquad \text{and} \qquad \gamma^{\mathsf{c}}_{(k,k''),T''} \circ \mathsf{c}_k(t) \circ l = \gamma^{\mathsf{c}}_{(k',k''),T''} \circ \mathsf{c}_{k'}(t) \circ l'.$$

Since the fibration $\mathsf{s} : \mathscr{C}/u\mathscr{C}' \to \mathscr{C}$ is locally cofiltered, there exist a covering family $(g_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ and for every $\lambda \in \Lambda$, morphisms $h_\lambda : Y_\lambda \to uZ_\lambda$ in $\mathscr{C}$ and $k_\lambda : Z_\lambda \to Z$ in $\mathscr{C}'$ such that $h \circ g_\lambda = u(k_\lambda) \circ h_\lambda$ in $\mathscr{C}$ and $k \circ k_\lambda = k' \circ k_\lambda$ in $\mathscr{C}'$. We compute :

$$\begin{aligned}
\gamma^{\mathsf{c}}_{(k\circ k_\lambda,k''),T''} \circ \mathsf{c}_{k\circ k_\lambda}(t) \circ \gamma^{\mathsf{c}}_{(k,k_\lambda),T'} \circ \mathsf{c}_{k_\lambda}(l) &= \gamma^{\mathsf{c}}_{(k\circ k_\lambda,k''),T''} \circ \gamma^{\mathsf{c}}_{(k,k_\lambda),\mathsf{c}_{k''}T''} \circ \mathsf{c}_{k_\lambda}\mathsf{c}_k(t) \circ \mathsf{c}_{k_\lambda}(l) \\
&= \gamma^{\mathsf{c}}_{(k_\lambda,k''\circ k),T''} \circ \mathsf{c}_{k_\lambda}(\gamma^{\mathsf{c}}_{(k,k''),T''}) \circ \mathsf{c}_{k_\lambda}\mathsf{c}_k(t) \circ \mathsf{c}_{k_\lambda}(l) \\
&= \gamma^{\mathsf{c}}_{(k_\lambda,k''\circ k'),T''} \circ \mathsf{c}_{k_\lambda}(\gamma^{\mathsf{c}}_{(k,k''),T''} \circ \mathsf{c}_k(t) \circ l) \\
&= \gamma^{\mathsf{c}}_{(k_\lambda,k''\circ k'),T''} \circ \mathsf{c}_{k_\lambda}(\gamma^{\mathsf{c}}_{(k',k''),T''} \circ \mathsf{c}_{k'}(t) \circ l') \\
&= \gamma^{\mathsf{c}}_{(k_\lambda,k''\circ k'),T''} \circ \mathsf{c}_{k_\lambda}(\gamma^{\mathsf{c}}_{(k',k''),T''}) \circ \mathsf{c}_{k_\lambda}\mathsf{c}_{k'}(t) \circ \mathsf{c}_{k_\lambda}(l') \\
&= \gamma^{\mathsf{c}}_{(k'\circ k_\lambda,k''),T''} \circ \gamma^{\mathsf{c}}_{(k',k_\lambda),\mathsf{c}_{k''}T''} \circ \mathsf{c}_{k_\lambda}\mathsf{c}_{k'}(t) \circ \mathsf{c}_{k_\lambda}(l') \\
&= \gamma^{\mathsf{c}}_{(k'\circ k_\lambda,k''),T''} \circ \mathsf{c}_{k'\circ k_\lambda}(t) \circ \gamma^{\mathsf{c}}_{(k',k_\lambda),T'} \circ \mathsf{c}_{k_\lambda}(l')
\end{aligned}$$

whence $\gamma^{\mathsf{c}}_{(k,k_\lambda),T'} \circ \mathsf{c}_{k_\lambda}(l) = \gamma^{\mathsf{c}}_{(k',k_\lambda),T'} \circ \mathsf{c}_{k_\lambda}(l')$. We deduce a commutative diagram in $\mathscr{F}ib(F_{Y_\lambda})$

$$(h_\lambda, \mathsf{c}_{k_\lambda}T) \xrightarrow{(Y/k_\lambda,t_\lambda)} g^*_\lambda(h,T) \underset{g^*_\lambda(Y/k',l')}{\overset{g^*_\lambda(Y/k,l)}{\rightrightarrows}} g^*_\lambda(h',T') \qquad \text{for every } \lambda \in \Lambda$$

where t_λ is the identity of $\mathsf{c}_{k_\lambda}T$. This shows that (LFC4) holds for $\Sigma_\bullet$. ◊

To ease notation, set $A := L_{\{\Sigma\}}(Z, h, \sigma_g)$ and $B := L_{\{\Sigma\}}(Z, h, \tau_g)$, and define the presheaf $M_{A,B}$ on $\mathscr{C}/uZ$ and the sheaf $H_{A,B}$ on C/uZ as in (5.3.5). Then

$$L_{\{\Sigma\}}[Y/\mathbf{1}_Z, \alpha] = L_{\{\Sigma\}}[Y/\mathbf{1}_Z, \beta] \in H_{A,B}(h)$$

so there exists a covering family $(k_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ such that the images of $[Y_\lambda/\mathbf{1}_Z, \alpha]$ and $[Y_\lambda/\mathbf{1}_Z, \beta]$ agree in $M_{A,B}(h \circ g_\lambda)$. Hence as usual we may assume from start that the images of $[Y/\mathbf{1}_Z, \alpha_0]$ and $[Y/\mathbf{1}_Z, \beta_0]$ agree in $M_{A,B}(h)$. Then, in view of claim 5.6.32, condition (b) of (5.3.5) tells us that there exist a covering family $(k_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$, and for every $\lambda \in \Lambda$ a morphism $h_\lambda : Y_\lambda \to uZ_\lambda$ in $\mathscr{C}$ and a morphism $l_\lambda : Z_\lambda \to Z$ in $\mathscr{C}'$ such that $h \circ k_\lambda = u(l_\lambda) \circ h_\lambda$ and with $\mathsf{c}_{l_\lambda}(\alpha_0) = \mathsf{c}_{l_\lambda}(\beta_0)$. This means that the images of $[\alpha]$ and $[\beta]$ agree in $\widetilde{u}^*_{|X}\mathscr{C}art(\sigma, \tau)(f \circ k_\lambda)$ for every $\lambda \in \Lambda$, so $[\alpha] = [\beta]$, as required.

Next, let us check that (5.6.28) is an epimorphism. To this aim, set $\mathscr{E}'' := \mathsf{Fib}(u)_!\mathscr{E}$, and let $\eta'_{\mathscr{E}} : \mathscr{E} \to \mathsf{Fib}(u)^*\mathscr{E}''$ be the unit of the 2-adjunction for the 2-adjoint pair $(\mathsf{Fib}(u)_!, \mathsf{Fib}(u)^*)$; as in(5.6.27), the projection $\pi' : \mathsf{Fib}(u)^*\mathscr{E}'' \to \mathscr{E}''$ induces an equivalence of categories

$$u^*_{|X} : \mathscr{E}''(uX) \xrightarrow{\sim} \mathsf{Fib}(u)^*\mathscr{E}''(X)$$

so we may find $\sigma'', \tau'' \in \mathrm{Ob}(\mathscr{E}''(uX))$ with isomorphisms :

$$\eta'_{\mathscr{E}} \circ \sigma \xrightarrow{\sim} u^*_{|X}(\sigma'') \qquad \eta'_{\mathscr{E}} \circ \tau \xrightarrow{\sim} u^*_{|X}(\tau'').$$

Since $\mathsf{Fib}(u)^*(j) \circ \eta'_{\mathscr{E}} : \mathscr{E} \to \mathsf{St}(u)_*\mathscr{E}'$ is isomorphic to $\eta_{\mathscr{E}}$, we deduce isomorphisms

$$\sigma' \xrightarrow{\sim} j \circ \sigma'' \qquad \tau' \xrightarrow{\sim} j \circ \tau''$$

and it suffices to show that the corresponding morphism of sheaves on C/uX

$$\widetilde{u}^*_{|X}\mathscr{C}art(\sigma,\tau) \to \mathscr{C}art(j \circ \sigma'', j \circ \tau'')$$

is an epimorphism. Thus, let $(f : Y \to X) \in \mathrm{Ob}(\mathscr{C}/X)$ and $\mu' \in \mathscr{C}art(j \circ \sigma'', j \circ \tau'')(f)$; we need to show that $\mu' : j \circ \sigma'' \circ f_* \Rightarrow j \circ \tau'' \circ f_*$ is the image of some $[\mu] \in \widetilde{u}^*_{|X}\mathscr{C}art(\sigma,\tau)(f)$. Set $\sigma''_0 := \sigma''(f)$, $\tau''_0 := \tau''(f)$, and recall that μ' is determined by its evaluation

$$\mu'_0 := \mu'_{\mathbf{1}_Y} : j(\sigma''_0) \to j(\tau''_0).$$

Since j is 1-covering (proposition 5.2.11(i)), there exist a covering family $(k_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$, and for every $\lambda \in \Lambda$ a morphism $\mu''_\lambda : \sigma''(f \circ k_\lambda) \to \tau''(f \circ k_\lambda)$ in $\mathscr{E}''_{Y_\lambda}$ such that $\mu'_{k_\lambda} = j(\mu''_\lambda)$. Now, suppose that for every $\lambda \in \Lambda$ there exists $\mu_\lambda \in \widetilde{u}^*_{|X}\mathscr{C}art(\sigma,\tau)(f \circ k_\lambda)$ whose image in $\mathscr{C}art(\sigma',\tau')(f \circ k_\lambda)$ equals $\mu' * k_\lambda$. Then, for every $\lambda, \lambda' \in \Lambda$, and every pair of morphisms $Y_{\lambda'} \xleftarrow{k''_{\lambda\lambda'}} Y_{\lambda\lambda'} \xrightarrow{k'_{\lambda\lambda'}} Y_\lambda$ in $\mathscr{C}$ such that $k_{\lambda\lambda'} := k_\lambda \circ k'_{\lambda\lambda'} = k_{\lambda'} \circ k''_{\lambda\lambda'}$, let $\mu_{\lambda\lambda'}$ and $\mu_{\lambda'\lambda}$ be the images of μ_λ and respectively $\mu_{\lambda'}$ in $\widetilde{u}^*_{|X}\mathscr{C}art(\sigma,\tau)(k_{\lambda\lambda'} \circ f)$; it follows that $\mu_{\lambda\lambda'}$ and $\mu_{\lambda'\lambda}$ are both mapped to $\mu' * k_{\lambda\lambda'}$ by the morphism (5.6.28). Since we already know that the latter is a monomorphism, we deduce that $\mu_{\lambda\lambda'} = \mu_{\lambda'\lambda}$ for every such pair of morphisms $k'_{\lambda\lambda'}, k''_{\lambda\lambda'}$. Then the system $(\mu_\lambda \mid \lambda \in \Lambda)$ determines a unique $\mu \in \widetilde{u}^*_{|X}\mathscr{C}art(\sigma,\tau)(f)$ whose image in $\mathscr{C}art(\sigma',\tau')(f)$ equals μ', as sought. Thus, we may replace μ by $\mu * k_\lambda$ for every $\lambda \in \Lambda$, and assume from start that there exists a morphism

$$\mu''_0 : L_{\{\Sigma\}}\sigma''_0 \to L_{\{\Sigma\}}\tau''_0 \qquad \text{in } \mathscr{F}ib(\mathsf{d})\{\Sigma^{-1}_\bullet\}_Y \text{ such that} \qquad \mu'_0 = j'(\mu''_0).$$

Set $\sigma''' := L_{\{\Sigma\}}\sigma''$ and $\tau''' := L_{\{\Sigma\}}\tau''$; then μ''_0 corresponds to a unique morphism of cartesian sections $\mu'' : \sigma''' \circ f_* \Rightarrow \tau''' \circ f_*$ with $j' * \mu'' = \mu'$. Recall that σ''_0 (resp. τ''_0) is a datum (Z, h, T) (resp. (Z', h', T')). Now, according to condition (a) of (5.3.5), we may find a covering family $(k_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$, and for every $\lambda \in \Lambda$, an object $(Z_\lambda, h_\lambda : Y_\lambda \to uZ_\lambda, T_\lambda)$ of $\mathscr{F}ib(F_{Y_\lambda})$, and morphisms $(Z, h \circ k_\lambda, T) \xleftarrow{(Y_\lambda/l_\lambda, s_\lambda)} (Z_\lambda, h_\lambda, T_\lambda) \xrightarrow{(Y_\lambda/l'_\lambda, t_\lambda)} (Z', h' \circ k_\lambda, T')$ in $\mathscr{F}ib(F_{Y_\lambda})$, where $s_\lambda : T_\lambda \to \mathsf{c}_{l_\lambda}T$ is an isomorphism in $\mathscr{E}_{Z_\lambda}$, and such that we have a commutative diagram in $\mathscr{F}ib(\mathsf{d})\{\Sigma^{-1}_\bullet\}_{Y_\lambda}$:

$$\begin{array}{ccc}
(Z, h \circ k_\lambda, T) & \xrightarrow{L_{\{\Sigma\}}(Y_\lambda/l'_\lambda, t_\lambda) \circ L_{\{\Sigma\}}(Y_\lambda/l_\lambda, s_\lambda)^{-1}} & (Z', h' \circ k_\lambda, T) \\
\downarrow & & \downarrow \\
\sigma'''(f \circ k_\lambda) & \xrightarrow{\quad \mu''_{k_\lambda} \quad} & \tau'''(f \circ k_\lambda)
\end{array}$$

whose vertical arrows are isomorphisms. The latter is equivalent to a commutative diagram :

$$\begin{array}{ccc}
(Z_\lambda, h_\lambda, \mathsf{c}_{l_\lambda}T) & \xrightarrow{L_{\{\Sigma\}}(Y_\lambda/\mathbf{1}_{Z_\lambda}, t_\lambda \circ s_\lambda^{-1})} & (Z_\lambda, h_\lambda, \mathsf{c}_{l'_\lambda}T') \\
\downarrow & & \downarrow \\
\sigma'''(f \circ k_\lambda) & \xrightarrow{\quad \mu''_{k_\lambda} \quad} & \tau'''(f \circ k_\lambda)
\end{array}$$

whose vertical arrows are again isomorphisms. After replacing σ''' and τ''' by isomorphic cartesian sections, we may therefore assume that $\mu''_{k_\lambda} = L_{\{\Sigma\}}(Y_\lambda/\mathbf{1}_{Z_\lambda}, t_\lambda \circ s_\lambda^{-1})$ for every $\lambda \in \Lambda$.

Arguing as in the foregoing, we may then assume that there exist a morphism $h : Y \to uZ$ in $\mathscr{C}$ and a morphism $t : T \to T'$ in $\mathscr{E}_Z$ such that $\mu'_0 = j(Y/\mathbf{1}_Z, t) : j(Z, h, T) \to j(Z, h, T')$.

Next, since the fibration $\mathsf{s} : \mathscr{C}/u\mathscr{C}' \to \mathscr{C}$ is locally cofiltered over the site C, we may find a covering family $(k_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$, and for every $\lambda \in \Lambda$ a morphism $h_\lambda : Y_\lambda \to uZ_\lambda$ in $\mathscr{C}$ and two morphisms $X \xleftarrow{g_\lambda} Z_\lambda \xrightarrow{g'_\lambda} Z$ such that $f \circ k_\lambda = g_\lambda \circ h_\lambda$ and $h'' \circ k_\lambda = g'_\lambda \circ h_\lambda$. Then again, we may replace σ' and τ' by isomorphic cartesian sections, and assume that $\mu'_{k_\lambda} =$

$j(Y_\lambda/\mathbf{1}_{Z_\lambda}, \mathsf{c}_{g'_\lambda}t) : (Z_\lambda, h_\lambda, \mathsf{c}_{g'_\lambda}T) \to (Z_\lambda, h_\lambda, \mathsf{c}_{g'_\lambda}T')$. Arguing once again as in the foregoing, we may finally assume that we have still $\mu'_0 = j(Y/\mathbf{1}_Z, t) : j(Z, h, T) \to j(Z, h, T')$, and moreover there exists a morphism $g : Z \to X$ in $\mathscr{C}$ such that $u(g) \circ h = f$. But then, t corresponds to a morphism of cartesian sections $\mu : \sigma \circ f_* \to \tau \circ f_*$, and the pair $(Y/g : f \to h, \mu)$ yields the sought section $[\mu]$. □

Theorem 5.6.33. *In the situation of* (5.6.27)*, the following holds :*

(i) *If $\mathscr{E}$ is ind-finite, then the same holds for $\mathscr{E}'$.*
(ii) *If $\widetilde{u}^*$ is a conservative functor and $\mathscr{E}'$ is ind-finite, then $\mathscr{E}$ is ind-finite.*

Proof. (i): In view of proposition 5.6.4, we may replace $\mathscr{E}$ by $\mathscr{E}^\times$, and assume from start that $\mathscr{E}$ is a stack in groupoids, in which case we need to show that for every $Y \in \mathrm{Ob}(\mathscr{C})$ and every $\sigma' \in \mathrm{Ob}(\mathscr{E}'(Y))$, the sheaf of groups $\mathscr{C}\!art(\sigma', \sigma')$ is ind-finite on C/Y.

Since the natural functor $j : \mathscr{E}'' := \mathsf{Fib}(u)_!\mathscr{E} \to \mathscr{E}'$ is 0-covering (proposition 5.2.11(i)), there exist a covering family $(\varphi_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$, and for every $\lambda \in \Lambda$ a cartesian section $\sigma''_\lambda \in \mathrm{Ob}(\mathscr{E}''(Y_\lambda))$ with an isomorphism $j \circ \sigma''_\lambda \xrightarrow{\sim} \sigma' \circ \varphi_{\lambda*}$. Clearly it suffices to show that $\mathscr{C}\!art(\sigma' \circ \varphi_{\lambda*}, \sigma' \circ \varphi_{\lambda*})$ is ind-finite for every $\lambda \in \Lambda$. We may thus replace Y by Y_λ for every such λ, and assume from start that $\sigma' = j \circ \sigma''$ for some $\sigma'' \in \mathrm{Ob}(\mathscr{E}''(Y))$. Recall that $\sigma''(\mathbf{1}_Y) \in \mathrm{Ob}(\mathscr{E}''_Y)$ is a datum $(X, f : Y \to uX, T)$ where $(X, f) \in \mathrm{Ob}(Y/u\mathscr{C}')$ and $T \in \mathrm{Ob}(\mathscr{E}_X)$. Let then $\tau : \mathscr{C}'/X \to \mathscr{E}$ and $\tau' : \mathscr{C}/uX \to \mathscr{E}''$ be cartesian sections with $\tau_{\mathbf{1}_X} = T$ and $\tau'(\mathbf{1}_{uX}) := (X, \mathbf{1}_{uX}, T)$. As explained in the proof of of proposition 5.6.30, we have an isomorphism :

$$\eta'_{\mathscr{E}} \circ \tau \xrightarrow{\sim} u^*_{|X}(\tau')$$

where $\eta'_{\mathscr{E}} : \mathscr{E} \to \mathsf{Fib}(u)^*\mathscr{E}''$ is the unit of a 2-adjunction for the 2-adjoint pair $(\mathsf{Fib}(u)_!, \mathsf{Fib}(u)^*)$. Since $\mathsf{Fib}(u)^*(j) \circ \eta'_{\mathscr{E}} : \mathscr{E} \to \mathsf{St}(u)_*\mathscr{E}'$ is isomorphic to the unit $\eta_{\mathscr{E}} : \mathscr{E} \to \mathsf{St}(u)_*\mathscr{E}'$ of a 2-adjunction for the 2-adjoint pair $(\mathsf{Fib}(u)_!, \mathsf{Fib}(u)^*)$, there follows an isomorphism

$$\eta_{\mathscr{E}} \circ \tau \xrightarrow{\sim} u^*_{|X}(j \circ \tau').$$

From proposition 5.6.30 and corollary 5.6.23(i) we conclude that $\mathscr{C}\!art(j \circ \tau', j \circ \tau')$ is ind-finite on C/uX. On the other hand, we have $\tau' \circ f_* \simeq \sigma''$, whence $j \circ \tau' \circ f_* \simeq \sigma'$. Combining with (5.1.5), there follows an isomorphism of sheaves $\mathscr{C}\!art(\sigma', \sigma') \xrightarrow{\sim} (f_*)^\sim_*\mathscr{C}\!art(j \circ \tau', j \circ \tau')$. But recall that f_* is both continuous and cocontinuous for the topologies of the sites C/Y and C/uX (remark 4.7.3(i)); then the assertion follows from proposition 5.6.17(ii) and lemma 4.2.15(i).

(ii): We may reduce as in (i) to the case where $\mathscr{E}$ is a stack in groupoids. Next notice that if $\widetilde{u}^*$ is conservative, $\widetilde{u}^*_{|X}$ is conservative for every $X \in \mathrm{Ob}(\mathscr{C}')$, by virtue of proposition 4.7.7(ii). Then the assertion follows immediately from proposition 5.6.30 and corollary 5.6.23(ii). □

Proposition 5.6.34. *In the situation of* (5.6.16)*, suppose that u is a weak morphism of sites, and moreover there exists a topologically generating family $G \subset \mathrm{Ob}(\mathscr{C}')$ such that uY is quasi-compact for the topology J, for every $Y \in G$. Then, for every ind-finite stack $\mathscr{E}$ on C, the stack $\mathsf{St}(u)_*\mathscr{E}$ is ind-finite on C'.*

Proof. In view of the pseudo-commutative diagram (5.6.2) we may assume that $\mathscr{E}$ is a stack in groupoids, in which case the same holds for $\mathscr{E}' := \mathsf{St}(u)_*\mathscr{E}$. Now, let $X \in \mathrm{Ob}(\mathscr{C}')$ and $\sigma, \tau \in \mathscr{E}'(X)$. Recall that u induces a continuous functor $u_{|X} : \mathscr{C}'/X \to \mathscr{C}/uX$ (proposition 4.7.7(i)), and moreover $G/X \subset \mathrm{Ob}(\mathscr{C}'/X)$ is a topologically generating family, according to (4.7.2); then it is easily seen that for every $(Y \xrightarrow{g} X) \in \mathrm{Ob}(G/X)$ the object $uY \xrightarrow{u(g)} uX$ of $\mathscr{C}/uX$ is quasi-compact. On the other hand, arguing as in the proof of proposition 5.4.8(i), we find $\sigma', \tau' \in \mathscr{E}(uX)$ and isomorphisms of sheaves

$$\mathscr{C}\!art(\sigma, \tau) \xrightarrow{\sim} \widetilde{u}_{|X*}\mathscr{C}\!art(\sigma', \tau').$$

The assertion then follows from proposition 5.6.24. □

5.6.35. *Stalk of a stack over a T-point.* Let T be a topos, and $\xi := (\xi^*, \xi_*) : \mathbf{Set} \to T$ a T-point (see definition 4.7.11(i)). For every stack $\mathscr{E}$ on the canonical site $\mathrm{Can}(T)$ we set

$$\mathscr{E}_\xi := \mathsf{St}(\xi^*)^*\mathscr{E}.$$

Likewise, for every morphism $\varphi : \mathscr{E} \to \mathscr{F}$ of stacks on $\mathrm{Can}(T)$, we let

$$\varphi_\xi := \mathsf{St}(\xi^*)^*(\varphi) : \mathscr{E}_\xi \to \mathscr{F}_\xi.$$

Remark 5.6.36. (i) Recall that $\mathbf{Set}$ is equivalent to $(\mathbb{1}, J)^\sim$, where $\mathbb{1}$ is the category with one object and one morphism, and J is the unique topology on $\mathbb{1}$. It follows easily that a stack on the canonical site $\mathrm{Can}(\mathbf{Set})$ of $\mathbf{Set}$ amounts to the datum of a category, and a morphism of stacks on $\mathrm{Can}(\mathbf{Set})$ is just an arbitrary functor.

(ii) Likewise, a functor $F : \mathscr{A} \to \mathscr{B}$ between categories is 0-covering (resp. 1-covering, resp. 2-covering) when regarded as a morphism of stacks on $\mathrm{Can}(\mathbf{Set})$, if and only if it is essentially surjective (resp. full, resp. faithful) : the details shall be left to the reader.

Proposition 5.6.37. *With the notation of* (5.6.35)*, let Ω be a conservative set of T-points (see definition* 4.7.11(iv)*). Then for every $i = 0, 1, 2$ the following conditions are equivalent :*

(a) *φ is i-covering.*
(b) *The morphism φ_ξ is i-covering for every $\xi \in \Omega$.*

Proof. (a)⇒(b) follows from proposition 5.4.22(ii).

(b)⇒(a): For $i = 1$ and $i = 2$, the assertion follows easily from lemma 5.2.7 and proposition 5.6.30. Suppose then that φ_ξ is 0-covering for every $\xi \in \Omega$; by lemma 5.6.7(i), it follows that $\pi_0(\varphi_\xi) : \pi_0(\mathscr{E}_\xi) \to \pi_0(\mathscr{F}_\xi)$ is a surjection. But according to (5.6.8), $\pi_0(\mathscr{E}_\xi)$ is naturally identified with the stalk $\pi_0^T(\mathscr{E})_\xi$ of the sheaf $\pi_0^T(\mathscr{E})$ on $\mathrm{Can}(T)$, and likewise for $\pi_0(\mathscr{F}_\xi)$. Thus, the morphism of sheaves $\pi_0^T(\varphi) : \pi_0^T(\mathscr{E}) \to \pi_0^T(\mathscr{F})$ is an epimorphism, and therefore φ is 0-covering, again by lemma 5.6.7(i). □

5.7. **Stacks on fibred sites and fibred topoi.** Let $\mathscr{C}$ and $\mathscr{C}'$ be two categories, $u : \mathscr{C}' \to \mathscr{C}$ any functor, $(\mathscr{A}, p, J_\bullet)$ a fibred site over $\mathscr{C}$, and $(\mathscr{A}', p'_\bullet, J'_\bullet) := \mathscr{C}' \times_{\mathscr{C}} (\mathscr{A}, p, J_\bullet)$ the induced fibred site as in (4.5.11); denote also by $(\mathscr{A}, J_{\mathscr{A}})$ and $(\mathscr{A}', J_{\mathscr{A}'})$ the respective fibred sites. Then it follows easily from proposition 4.5.5(ii,iv) that the projection $\pi : \mathscr{A}' \to \mathscr{A}$ fulfills condition (C2) of (5.4.5), relative to the topologies $J_{\mathscr{A}}$ and $J_{\mathscr{A}'}$, so it is a weak morphism of sites $\pi : (\mathscr{A}, J_{\mathscr{A}}) \to (\mathscr{A}', J_{\mathscr{A}'})$, and we get a well defined pseudo-functor

$$\mathsf{St}(\pi)_* : \mathsf{Stack}(\mathscr{A}, J_{\mathscr{A}}) \to \mathsf{Stack}(\mathscr{A}', J_{\mathscr{A}'}).$$

If $\mathscr{C}$ and $\mathscr{C}'$ are small and $(\mathscr{A}_X, J_X)$ is a U-site for every $X \in \mathrm{Ob}(\mathscr{C})$, then $(\mathscr{A}, J_{\mathscr{A}})$ and $(\mathscr{A}', J_{\mathscr{A}'})$ are also U-sites (remark 4.5.2(iii)), and in this case also the left 2-adjoint $\mathsf{St}(\pi)^*$ of $\mathsf{St}(\pi)_*$ is well defined; moreover, π is cocontinuous (see (4.5.11)), so we have a pseudo-natural equivalence $\mathsf{St}(\pi)_* \xrightarrow{\sim} \mathsf{St}(\breve{\pi})^*$ (proposition 5.4.29(ii)).

As a special case, for every $X \in \mathrm{Ob}(\mathscr{C})$ the inclusion functor $i_X : \mathscr{A}_X \to \mathscr{A}$ is a weak morphism of sites $(\mathscr{A}, J_{\mathscr{A}}) \to (\mathscr{A}_X, J_X)$, and we get a well defined pseudo-functor

$$\mathsf{St}(i_X)_* : \mathsf{Stack}(\mathscr{A}, J_{\mathscr{A}}) \to \mathsf{Stack}(\mathscr{A}_X, J_X).$$

If $\mathscr{C}$ is small and $(\mathscr{A}_X, J_X)$ is a U-site for every $X \in \mathrm{Ob}(\mathscr{C})$, also $\mathsf{St}(i_X)^*$ is well defined.

Proposition 5.7.1. *In the situation of* (5.7)*, we have :*

(i) *Let $\varphi : \mathscr{E} \to \mathscr{E}'$ be a cartesian functor of fibrations over $\mathscr{A}$, and $i \in \{0, 1, 2\}$. The following conditions are equivalent :*
   (a) *φ is i-covering for the topology $J_{\mathscr{A}}$.*
   (b) *$\mathsf{Fib}(i_X)^*(\varphi)$ is i-covering for the topology J_X, for every $X \in \mathrm{Ob}(\mathscr{C})$.*

(ii) *Suppose that $\mathscr{C}$ is small, and $(\mathscr{A}_X, J_X)$ is a* U*-site for every $X \in \mathrm{Ob}(\mathscr{C})$. Then the following diagram of 2-categories is pseudo-commutative :*

$$\begin{array}{ccc} \mathsf{Fib}(\mathscr{A}) & \xrightarrow{\mathsf{Fib}(i_X)^*} & \mathsf{Fib}(\mathscr{A}_X) \\ {\scriptstyle (-)^a}\downarrow & & \downarrow{\scriptstyle (-)^a} \\ \mathsf{Stack}(\mathscr{A}, J_{\mathscr{A}}) & \xrightarrow{\mathsf{St}(i_X)_*} & \mathsf{Stack}(\mathscr{A}_X, J_X) \end{array} \qquad \textit{for every } X \in \mathrm{Ob}(\mathscr{C}).$$

Proof. (i.a)⇒(i.b): This follows directly from propositions 5.4.1(i) and 4.5.5(iii).

(i.b)⇒(i.a): Suppose first that $i = 0$, and let $X \in \mathrm{Ob}(\mathscr{A})$ and $E' \in \mathrm{Ob}(\mathscr{E}'_X)$; pick cleavages for $\mathscr{E}$ and $\mathscr{E}'$, and let c and c' be the corresponding associated pseudo-functors. By assumption, there exist a covering family $f_\bullet : (f_i : X_i \to X \mid i \in I)$ for the topology J_{pX}, and for every $i \in I$ an object $E_i \in \mathrm{Ob}(\mathscr{E}_{X_i})$ such that φE_i is isomorphic to $\mathsf{c}'_{f_i} E'$ in $\mathscr{E}'_{X_i}$. Since $f_\bullet$ is also a covering family for the topology $J_{\mathscr{A}}$, this shows that φ is 0-covering, as required. The cases where $i = 1, 2$ are similar : the details shall be left to the reader.

(ii): The assertion is a special case of corollary 5.4.31. □

Corollary 5.7.2. *Let $j \leq 2$ be any integer. The following holds :*

(i) *In the situation of* (4.3.24)*, let $\mathscr{E}$ be a fibration on $\mathscr{C}$. Then $\mathscr{E}$ is a j-separated prestack on C if and only if* $\mathsf{Fib}(\pi_i)^*(\mathscr{E})$ *is a j-separated prestack on C_i for every $i \in \mathrm{Ob}(I)$.*

(ii) *In the situation of* (5.7)*, let $\mathscr{E}$ be a fibration on $\mathscr{A}$. Then $\mathscr{E}$ is a j-separated prestack on $(\mathscr{A}, J_{\mathscr{A}})$ if and only if* $\mathsf{Fib}(i_X)^*(\mathscr{E})$ *is j-separated on $(\mathscr{A}_X, J_X)$ for every $X \in \mathrm{Ob}(\mathscr{C})$.*

Proof. (i): The condition is necessary, by virtue of corollary 5.4.15 and proposition 5.4.8(i,ii). For the converse, we argue as in the proof of proposition 4.3.25(ii). Indeed, suppose that $\mathsf{Fib}(\pi_i)^*(\mathscr{E})$ is a j-separated prestack on C_i for every $i \in \mathrm{Ob}(I)$; according to remark 4.1.8(ii) there exists a topology J' on $\mathscr{C}$ such that, for every $X \in \mathrm{Ob}(\mathscr{C})$, the set $J'(X)$ consists of the sieves $\mathscr{S} \subset \mathscr{C}/X$ of universal $\mathscr{E}$-j-descent. It then suffices to prove that $J \subset J'$. We come down to checking the following. For every $i \in \mathrm{Ob}(I)$, every $X \in \mathrm{Ob}(\mathscr{C}_i)$, every covering family $g_\bullet := (g_\lambda : X_\lambda \to X \mid \lambda \in \Lambda)$ for the topology J_i, and every morphism $f : Y \to \pi_i X$ in $\mathscr{C}$, the family $(Y \times_{\pi_i X} \pi_i(g_\lambda) : Y \times_{\pi_i X} \pi_i X_\lambda \to Y \mid \lambda \in \Lambda)$ generates a sieve of $\mathscr{E}$-j-descent. Arguing as in the proof of proposition 4.3.25(ii), we are first reduced to the case where $Y = \pi_i Y'$ for some $Y' \in \mathrm{Ob}(\mathscr{C}_i)$ and $f = \pi_i(t)$ for some morphism $t : Y' \to X$ of $\mathscr{C}_i$, and then we may even replace the family $g_\bullet$ by $(Y' \times_X g_\lambda \mid \lambda \in \Lambda)$ and reduce further to the case where $t = \mathbf{1}_X$. Finally, pick a cleavage c for $\mathscr{E}$; we need to show that the natural functor

$$\mathscr{E}(\pi_i X) \to \mathsf{Desc}(\mathscr{E}, \pi_i(g_\bullet), \mathsf{c})$$

is j-faithful (notation of (3.5.22)). But since π_i is left exact, this functor is naturally identified with the corresponding functor for $\mathscr{E}_i := \mathsf{Fib}(\pi_i)^*(\mathscr{E})$:

$$\mathscr{E}_i(X) \to \mathsf{Desc}(\mathscr{E}_i, g_\bullet, \mathsf{c} \circ \pi_i^o)$$

and the latter is j-faithful, since $\mathscr{E}_i$ is a j-separated prestack on C_i.

(ii): Again, the condition is necessary, by corollary 5.4.15 and proposition 5.4.8(i,ii). For the converse we argue as in the proof of proposition 4.5.5. Namely, we let J' be the topology on $\mathscr{A}$ such that for every $A \in \mathrm{Ob}(\mathscr{A})$ the set $J'(A)$ consists of the sieves $\mathscr{S} \subset \mathscr{A}/A$ of universal $\mathscr{E}$-j-descent, and we check that $J_{\mathscr{A}} \subset J'$, assuming that $\mathscr{E}_X := \mathsf{Fib}(i_X)^*(\mathscr{E})$ is a j-separated prestack on $(\mathscr{A}_X, J_X)$ for every $X \in \mathrm{Ob}(\mathscr{C})$. To this aim, we consider any morphism $f : A' \to A$ in $\mathscr{A}$ and any family $(g_\lambda : B_\lambda \to A \mid \lambda \in \Lambda)$ of morphisms in $\mathscr{A}_{pA}$ covering A for the topology J_{pA}; after choosing a cleavage for $\mathscr{A}$, we then construct the family $g'_\bullet := (g'_\lambda : B'_\lambda \to A' \mid \lambda \in \Lambda)$ of morphisms of $\mathscr{A}_{pA'}$ as in the proof of proposition 4.5.5. Let $i_{pA'} : \mathscr{A}_{pA'} \to \mathscr{A}$ be the inclusion functor; taking into account lemma 3.5.35(ii), we reduce to checking that the sieve of $\mathscr{A}/A'$

generated by the family $i_{pA'}(g'_\bullet) := (i_{pA'}(g_\lambda) \mid \lambda \in \Lambda)$ is of $\mathscr{E}$-j-descent. Now, choose a cleavage c for $\mathscr{E}$, and set

$$B'_{\lambda\mu} := B'_\lambda \times_{A'} B'_\mu \qquad \text{and} \qquad B'_{\lambda\mu\nu} := B'_{\lambda\mu} \times_{A'} B'_\nu \qquad \text{for every } \lambda, \mu, \nu \in \Lambda$$

and notice that $i_{pA'}B'_{\lambda\mu}$ represents the fibre product $i_{pA'}B'_\lambda \times_{i_{pA'}A'} B'_\mu$, and likewise $i_{pA'}B'_{\lambda\mu\nu}$ represents $i_{pA'}B'_{\lambda\mu} \times_{i_{pA'}A'} i_{pA'}B'_\nu$ (remark 4.5.2(ii)), so that the category $\mathsf{Desc}(\mathscr{E}, i_{pA'}(g'_\bullet), \mathsf{c})$ is well defined, and we are reduced to checking that the induced map

$$\mathscr{E}(i_{pA'}A') \to \mathsf{Desc}(\mathscr{E}, i_{pA'}(g'_\bullet), \mathsf{c})$$

is j-faithful. But the latter is naturally identified with the analogous map

$$\mathscr{E}_{pA'}(A') \to \mathsf{Desc}(\mathscr{E}_{pA'}, g'_\bullet, \mathsf{c} \circ i^o_{pA'})$$

which is j-faithful by assumption. □

Proposition 5.7.3. *In the situation of* (4.5.13)*, suppose that* $(\mathscr{A}_{i,X}, J_{i,X})$ *is a* U*-site for every* $X \in \mathrm{Ob}(\mathscr{C})$ *and* $i = 0, 1$. *Then the induced base change transformation :*

$$\Upsilon(\mathsf{St}(\mathbf{1}_{u\circ\pi_1})^\gamma_*) : \mathsf{St}(v)^* \circ \mathsf{St}(\pi_1)_* \to \mathsf{St}(\pi_0)_* \circ \mathsf{St}(u)^*$$

is a pseudo-natural equivalence.

Proof. Recall that the projections π_0 and π_1 satisfy condition (C2) from (5.4.5) : see (5.7); in particular, they are weak morphisms of sites, and moreover they are cocontinuous (see (4.5.11)). We are then in the situation contemplated in (5.5.23), and by corollary 5.5.26(ii), both Δ^{π_0} and Δ^{π_1} are pseudo-natural equivalences, and the same holds for $\Upsilon(\Delta^u)$ and $\Upsilon(\Delta^v)$, by virtue of corollary 5.5.26(iii). Hence, arguing as in remark 2.3.22(i), we are reduced to checking that $\Upsilon((\mathbf{1}^\sim_{u\circ\pi_1}, \mathbf{Cat})_*)$ is a pseudo-natural equivalence. The latter assertion follows from proposition 4.5.14 and the discussion of (5.5.29). □

Definition 5.7.4. Let $(\mathscr{A}, p, J_\bullet)$ and $(\mathscr{A}', p', J'_\bullet)$ be two fibred sites over a category $\mathscr{C}$. A *weak morphism of fibred sites* $\varphi : (\mathscr{A}, p, J_\bullet) \to (\mathscr{A}', p', J'_\bullet)$ is a functor $\varphi : \mathscr{A}' \to \mathscr{A}$ with $p \circ \varphi = p'$, whose restriction $\varphi_X : \mathscr{A}'_X \to \mathscr{A}_X$ is a weak morphism of sites $(\mathscr{A}_X, J_X) \to (\mathscr{A}'_X, J'_X)$, for every $X \in \mathrm{Ob}(\mathscr{C})$.

Proposition 5.7.5. *Let* $(\mathscr{A}, p, J_\bullet)$ *and* $(\mathscr{A}', p', J'_\bullet)$ *be two fibred lex-sites over a category* $\mathscr{C}$, *and* $\varphi : (\mathscr{A}, p, J_\bullet) \to (\mathscr{A}', p', J'_\bullet)$ *a weak morphism of fibred sites. Then* φ *is a weak morphism of the respective total sites* $(\mathscr{A}, J_\mathscr{A}) \to (\mathscr{A}', J_{\mathscr{A}'})$.

Proof. For every $X \in \mathrm{Ob}(\mathscr{C})$, let $i_x : \mathscr{A}_X \to \mathscr{A}$ and $i'_X : \mathscr{A}'_X \to \mathscr{A}'$ be the inclusion functors, and $\varphi_X : \mathscr{A}'_X \to \mathscr{A}_X$ the restriction of φ; in light of corollary 5.7.2(ii), it suffices to check that for every stack $\mathscr{E}$ over $(\mathscr{A}, J_\mathscr{A})$, the fibration $\mathscr{F} := \mathsf{Fib}(i'_X)^* \circ \mathsf{Fib}(\varphi)^*(\mathscr{E})$ is a stack on $(\mathscr{A}'_X, J'_X)$. But we have a natural identification $\mathscr{F} \xrightarrow{\sim} \mathsf{Fib}(\varphi_X)^* \circ \mathsf{Fib}(i_X)^*(\mathscr{E})$, and $\mathsf{Fib}(i_X)^*(\mathscr{E})$ is a stack on $(\mathscr{A}_X, J_X)$, again by corollary 5.7.2(ii), whence the contention. □

5.7.6. Let $(\mathscr{A}, p, J_\bullet)$ be a small fibred lex-site over a small category $\mathscr{C}$; pick a unital cleavage $\boldsymbol{\lambda}$ for p, and let $\mathsf{c} : \mathscr{C}^o \to \mathbf{Cat}$ be the associated pseudo-functor. Clearly c^o factors through a pseudo-functor

$$\widetilde{\mathsf{c}} : \mathscr{C} \to \mathsf{lex}.\mathbf{Site} \qquad X \mapsto (\mathscr{A}_X, J_X)$$

and the forgetful functor $\mathsf{lex}.\mathbf{Site} \to \mathbf{Cat}^o$. Let $\Sigma_\mathscr{A}$ be the set of cartesian morphisms of $\mathscr{A}$. By remark 3.3.13(i), we know that $\mathscr{A}[\Sigma^{-1}_\mathscr{A}]$ represents the strong 2-colimit of c :

$$\text{2-}\operatorname*{colim}_{\mathscr{C}^o} \mathsf{c} \xrightarrow{\sim} \mathscr{A}[\Sigma^{-1}_\mathscr{A}].$$

Suppose now that $\mathscr{C}$ *is cofiltered.* Then, the construction of (4.3.24) endows $\mathscr{A}[\Sigma^{-1}_\mathscr{A}]$ with a natural topology $J^*_\mathscr{A}$ such that $(\mathscr{A}[\Sigma^{-1}_\mathscr{A}], J^*_\mathscr{A})$ is a strong 2-limit of $\widetilde{\mathsf{c}}$, and again by direct inspection we see that the localization functor $L_{\mathscr{A}} : \mathscr{A} \to \mathscr{A}[\Sigma_{\mathscr{A}}^{-1}]$ is continuous for the topology $J^*_{\mathscr{A}}$ and the topology $J_{\mathscr{A}}$ of the total site $(\mathscr{A}, J_{\mathscr{A}})$. Moreover, for every $X \in \mathrm{Ob}(X)$, the composition $\mathscr{A}_X \to \mathscr{A}[\Sigma_{\mathscr{A}}^{-1}]$ of the inclusion functor $i_X : \mathscr{A}_X \to \mathscr{A}$ and $F_{\mathscr{A}}$, is a morphism of sites

$$L_{\mathscr{A}} \circ i_X : (\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}], J^*_{\mathscr{A}}) \to (\mathscr{A}_X, J_X)$$

and the rule : $X \mapsto L_{\mathscr{A}} \circ i_X$ defines both a universal pseudo-cone $\widetilde{\tau} : \mathsf{F}_{(\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}], J^*_{\mathscr{A}})} \Rightarrow \widetilde{\mathsf{c}}$ and a universal pseudo-cocone $\tau : \mathsf{c} \Rightarrow \mathsf{F}_{\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}]}$. Recall as well that $\Sigma_{\mathscr{A}}$ admits a right calculus of fraction (example 3.3.13(ii)), so that the category $X/L_{\mathscr{A}}\mathscr{A}$ is cofiltered for every $X \in \mathrm{Ob}(\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}])$ (proposition 1.6.25(i)). Then the source fibration $\mathsf{s} : \mathscr{A}[\Sigma_{\mathscr{A}}^{-1}]/L_{\mathscr{A}}\mathscr{A} \to \mathscr{A}[\Sigma_{\mathscr{A}}^{-1}]$ is trivially locally cofiltered, and from proposition 4.3.9 we see that $L_{\mathscr{A}}$ is a morphism of sites

$$L_{\mathscr{A}} : (\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}], J^*_{\mathscr{A}}) \to (\mathscr{A}, J_{\mathscr{A}}).$$

Proposition 5.7.7. *In the situation of* (5.7.6)*, the following holds :*

(i) *The functor $L^{\sim}_{\mathscr{A}*} : (\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}], J^*_{\mathscr{A}})^{\sim} \to (\mathscr{A}, J_{\mathscr{A}})^{\sim}$ is fully faithful.*

(ii) *Suppose that every object of $\mathscr{A}$ is quasi-compact for the topology $J_{\mathscr{A}}$ (see definition* 5.6.10*), and let F and $\mathscr{E}$ be respectively a sheaf and a stack on $(\mathscr{A}, J_{\mathscr{A}})$. Then:*

(a) *$L_{\mathscr{A}!}F$ is a sheaf on $(\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}], J^*_{\mathscr{A}})$.*

(b) *$\mathsf{Fib}(L_{\mathscr{A}})_!\mathscr{E}$ is a stack on $(\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}], J^*_{\mathscr{A}})$.*

Proof. (i) follows easily from corollary 1.6.11.

Next, let $F \in \mathrm{Ob}(\mathscr{A}^\wedge)$ and $A \in \mathrm{Ob}(\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}])$; recall that $L_{\mathscr{A}!}F(A)$ represents the colimit of

$$F \circ \mathsf{t}^o_A : (A/L_{\mathscr{A}}\mathscr{A})^o \to \mathbf{Set} \qquad (A \to L_{\mathscr{A}}B) \mapsto FB.$$

We define as follows a functor $\Phi_A : \mathscr{C}/pA \to A/L_{\mathscr{A}}\mathscr{A}$. For every $\varphi \in \mathrm{Ob}(\mathscr{C}/pA)$ we let

$$\Phi_A(\varphi) := (\mathsf{c}_\varphi A, (L_{\mathscr{A}}\boldsymbol{\lambda}(A, \varphi))^{-1} : A \to L_{\mathscr{A}}(\mathsf{c}_\varphi A))$$

(see (3.1.6)). For every morphism $\psi/pA : \varphi \to \varphi'$ of $\mathscr{C}/pA$ we have $\varphi = \varphi' \circ \psi$, and we set

$$\Phi_A(\psi/pA) := A/L_{\mathscr{A}}(\lambda(\mathbf{1}_A, \psi)) : \Phi_A(\varphi) \to \Phi_A(\varphi').$$

Claim 5.7.8. The functor Φ_A is coinitial.

Proof of the claim. Since $\mathscr{C}$ is cofiltered, the same holds for $\mathscr{C}/A$ (example 1.5.9(i)), hence we may apply the criterion of (the dual of) lemma 1.5.7(i). First, for every object $(B, f : A \to L_{\mathscr{A}}B)$ of $A/L_{\mathscr{A}}\mathscr{A}$ we may find a morphism $\varphi : pB \to pA$ of $\mathscr{C}$ and a morphism $f' : \mathsf{c}_\varphi A \to B$ in $p^{-1}(pB)$ such that $f = L_{\mathscr{A}}(f') \circ L_{\mathscr{A}}(\lambda(A, \varphi))^{-1}$ (details left to the reader), so that f' yields a morphism $\Phi_A(\varphi) \to (B, f)$ in $A/L_{\mathscr{A}}\mathscr{A}$. Next, let $\varphi : X \to pA$ be any object of $\mathscr{C}/pA$ and $A/g, A/h : \Phi_A(\varphi) \to (B, f : A \to L_{\mathscr{A}}B)$ two morphisms of $A/L_{\mathscr{A}}\mathscr{A}$; by definition, we have $g = f \circ L_{\mathscr{A}}(\lambda(A, \varphi)) = h$, so condition (b) of lemma 1.5.7(i) is trivially verified. ◊

By claim 5.7.8, the set $L_{\mathscr{A}!}F(A)$ also represents the colimit of the functor

$$F \circ (\mathsf{t}_A \circ \Phi_A)^o : (\mathscr{C}/pA)^o \to \mathbf{Set} \qquad (\varphi : X \to pA) \mapsto F(\mathsf{c}_\varphi A).$$

(ii.a): Notice first that, under the stated assumptions, for every $X \in \mathrm{Ob}(\mathscr{C})$, every $B \in \mathrm{Ob}(\mathscr{A}_X)$ is quasi-compact for the topology J_X : indeed, if $\mathscr{S} \in J_X(B)$, let $\mathscr{S}'$ be the sieve of $\mathscr{A}/B$ generated by $\mathscr{S}$; we have $\mathscr{S}' \in J_{\mathscr{A}}(B)$, so by assumption, there exists a finite subset $\{f_i : B_i \to B \mid i \in I\} \subset \mathscr{S}'$ that generates a sieve $\mathscr{S}''$ covering B in $(\mathscr{A}, J_{\mathscr{A}})$. But for every $i \in I$ there exist $(f'_i : C_i \to B) \in \mathscr{S}$ and a morphism $g_i : B_i \to C_i$ in $\mathscr{A}$ such that $f_i = f'_i \circ g_i$; the family $(f'_i \mid i \in I)$ still generates a covering sieve for $J_{\mathscr{A}}$, and then the same family covers B also in the site $(\mathscr{A}_X, J_X)$. Next we remark :

Claim 5.7.9. Let $A \in \mathrm{Ob}(\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}]) = \mathrm{Ob}(\mathscr{A})$, and $\mathscr{S}$ a sieve of $\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}]/A$. Then $\mathscr{S} \in J^*_{\mathscr{A}}(A)$ if and only if there exist a cartesian morphism $h : A' \to A$ in $\mathscr{A}$ and a finite covering family $(f_i : A'_i \to A')$ in $(\mathscr{A}_{pA'}, J_{pA'})$ with $L_{\mathscr{A}}(h \circ f_i) \in \mathscr{S}$ for every $i \in I$.

Proof of the claim. Since $L_{\mathscr{A}}$ is continuous and $L_{\mathscr{A}}h$ is an isomorphism in $\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}]$, the stated condition implies that $\mathscr{S} \in J^*_{\mathscr{A}}(A)$. For the converse, recall that $J^*_{\mathscr{A}}$ is the coarsest topology such that $L_{\mathscr{A}} \circ i_X$ is a continuous functor for the topology J_X and $J^*_{\mathscr{A}}$, for every $X \in \mathrm{Ob}(\mathscr{C})$. Thus, for every $B \in \mathrm{Ob}(\mathscr{A})$, denote by $J^{**}_{\mathscr{A}}(B)$ the set of all sieves of $\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}]/B$ fulfilling the condition of the claim; it suffices then to check that $J^{**}_{\mathscr{A}} := (J^{**}_{\mathscr{A}}(B) \mid B \in \mathrm{Ob}(A))$ is a topology on $\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}]$, and that $L_{\mathscr{A}} \circ i_X$ is a continuous functor for the topologies J_X and $J^{**}_{\mathscr{A}}$, for every $X \in \mathrm{Ob}(\mathscr{C})$. To check stability under base change for $J^{**}_{\mathscr{A}}$ (see definition 4.1.1(i)), consider any morphism $g : B \to A$ in $\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}]$; we need to show that $\mathscr{S} \times_A g \in J^{**}_{\mathscr{A}}(B)$. However, since $\Sigma_{\mathscr{A}}$ admits a right calculus of fraction, there exist a cartesian morphism $h' : B' \to B$ in $\mathscr{A}$ and a morphism $k : B' \to A$ in $\mathscr{A}$ such that $g = L_{\mathscr{A}}(k) \circ L_{\mathscr{A}}(h')^{-1}$. Suppose now that $\mathscr{S}' := \mathscr{S} \times_A L_{\mathscr{A}}(k) \in J^{**}_{B'}$; this means that there exist a cartesian morphism $h'' : B'' \to B'$ and a finite covering family $(f'_i : B''_i \to B')$ in $(\mathscr{A}_{pB'}, J_{pB'})$ such that $L_{\mathscr{A}}(h'' \circ f'_i) \in \mathscr{S}'$ for every $i \in I$. Therefore $L_{\mathscr{A}}(h' \circ h'' \circ f'_i) \in \mathscr{S}' \times_{B'} L_{\mathscr{A}}(h')^{-1} = \mathscr{S} \times_A g$, and since $h' \circ h''$ is cartesian, we get $\mathscr{S} \times_A g \in J^{**}_{\mathscr{A}}$. Thus, we may replace B by B', and assume from start that $g = L_{\mathscr{A}}(k)$ for some morphism $k : B \to A$ in $\mathscr{A}$. In this case, since $\mathscr{C}$ is cofiltered, we can find $X \in \mathrm{Ob}(\mathscr{C})$ with morphisms $\varphi : X \to pB$ and $\psi : X \to pA'$ such that $p(g) \circ \varphi = p(h) \circ \psi$; then we may also find a morphism $k' : B' \to A''$ in $p^{-1}X$, and cartesian morphisms $h' : B' \to B$ and $h'' : A'' \to A'$ in $\mathscr{A}$ such that $p(h') = \varphi$, $p(h'') = \psi$, and $k \circ h' = h \circ h'' \circ k'$ in $\mathscr{A}$. For every $i \in I$ there exist a morphism $f'_i : A''_i \to A''$ in $p^{-1}X$ and a cartesian morphism $h''_i : A''_i \to A'_i$ such that $f_i \circ h''_i = h'' \circ f'_i$. Since c_ψ is continuous for the topologies $J_{pA'}$ and J_X, it follows easily that $(f'_i \mid i \in I)$ is a covering family in $(\mathscr{A}_X, J_X)$ (details left to the reader), and by construction $L_{\mathscr{A}}(h \circ h'' \circ f'_i) \in \mathscr{S}$ for every $i \in I$. Since $h \circ h''$ is cartesian, we may therefore replace A' by A'', h by $h \circ h''$ and the family $(f_i \mid i \in I)$ by $(f'_i \mid i \in I)$, and assume from start that there exist a morphism $k' : B' \to A'$ in $\mathscr{A}_{pA'}$ and a cartesian morphism $h' : B' \to B$ in $\mathscr{A}$ such that $h \circ k' = k \circ h'$. Let $(f'_i : A'_i \times_{A'} B' \to B' \mid i \in I)$ be the induced finite covering family of B' in $\mathscr{A}_{pA'}$, and for every $i \in I$ let also $k'_i : A'_i \times_{A'} B'' \to A'_i$ be the second projection. It suffices to check that $L_{\mathscr{A}}(h' \circ f'_i) \in \mathscr{S} \times_A g$ for every $i \in I$, *i.e.* that $L_{\mathscr{A}}(k \circ h' \circ f'_i) \in \mathscr{S}$ for every such i. However, $L_{\mathscr{A}}(k \circ h' \circ f'_i) = L_{\mathscr{A}}(h \circ k' \circ f'_i) = L_{\mathscr{A}}(h \circ f_i \circ k'_i)$, whence the contention. To check the local character of $J^{**}_{\mathscr{A}}$, suppose that $\mathscr{T}$ is another sieve of $\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}]/A$ such that for every $(t : A' \to A) \in \mathscr{S}$ we have $\mathscr{T} \times_A t \in J^{**}_{\mathscr{A}}(A')$; we need to show that $\mathscr{T} \in J^{**}(A)$. In particular, for every $i \in I$ there exist a cartesian morphism $h_i : B_i \to A'_i$ in $\mathscr{A}$ and a finite covering family $(g_{i\lambda} : B_{i\lambda} \to B_i \mid \lambda \in \Lambda_i)$ in $(\mathscr{A}_{pB_i}, J_{pB_i})$ such that $L_{\mathscr{A}}(h_i \circ g_{i\lambda}) \in \mathscr{T} \times_A L_{\mathscr{A}}(h \circ f_i)$ for every $\lambda \in \Lambda_i$, *i.e.* $L_{\mathscr{A}}(h \circ f_i \circ h_i \circ g_{i\lambda}) \in \mathscr{T}$ for every such λ. Now, since $\mathscr{C}$ is cofiltered, we may find a morphism $\varphi : Y \to pA'$ in $\mathscr{C}$ such that for every $i \in I$ there exists a morphism $\varphi_i : Y \to pB_i$ with $\varphi = p(h_i) \circ \varphi_i$. Pick then any cartesian morphism $k : C \to A'$ with $p(k) = \varphi$, and a cartesian morphism $k_i : C_i \to B_i$ such that $p(k_i) = \varphi_i$, for every $i \in I$. With this notation, for every $i \in I$ there exists a unique morphism $f'_i : C_i \to C$ in $\mathscr{A}_Y$ such that $k \circ f'_i = f_i \circ h_i \circ k_i$. Since c_φ is continuous for the topologies J_Y and $J_{pA'}$, it follows easily that $(f'_i : C_i \to C \mid i \in I)$ is a finite covering family in $(\mathscr{A}_Y, J_Y)$ (details left to the reader). Lastly, for every $i \in I$ and $\lambda \in \Lambda_i$ pick a cartesian morphism $k_{i\lambda} : C_{i\lambda} \to B_{i\lambda}$ with $p(k_{i\lambda}) = \varphi_i$. Then for every such i and λ there exists a unique morphism $g'_{i\lambda} : C_{i\lambda} \to C_i$ in $\mathscr{A}_Y$ such that $g_{i\lambda} \circ k_{i\lambda} = k_i \circ g'_{i\lambda}$, and arguing as in the foregoing, we easily see that $(g'_{i\lambda} \mid \lambda \in \Lambda_i)$ is a finite covering family in $(\mathscr{A}_Y, J_Y)$, for every $i \in I$. We conclude that $(f'_{i\lambda} := f'_i \circ g'_{i,\lambda} : C_{i\lambda} \to C \mid i \in I, \lambda \in \Lambda_i)$ is a finite covering family in $(\mathscr{A}_Y, J_Y)$ as well. But we have $k \circ f'_{i\lambda} = f_i \circ h_i \circ g_{i\lambda} \circ k_{i\lambda}$ for every $i \in I$ and $\lambda \in \Lambda_i$; since $h \circ k$ is a cartesian morphism, the assertion follows. Thus, $J^{**}_{\mathscr{A}}$ is indeed a topology on $\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}]$. In order to prove that $L_{\mathscr{A}} \circ i_X$ is continuous for $J^{**}_{\mathscr{A}}$ and J_X, it suffices now to check that for every covering family $(f_\lambda : B_\lambda \to B \mid \lambda \in \Lambda)$ in $\mathscr{A}_X$, the family $(L_{\mathscr{A}}(f_\lambda) \mid \lambda \in \Lambda)$ covers B for the topology $J^{**}_{\mathscr{A}}$ (lemma 4.2.4). Since, as we have already observed, B is quasi-compact for the topology J_X, we are easily reduced to the case where Λ is a finite set (details left to the reader); but then the assertion follows immediately from the definition of $J^{**}_{\mathscr{A}}(B)$. $\Diamond$

We shall show that the natural morphism of presheaves $L_{\mathscr{A}!}F \to (L_{\mathscr{A}!}F)^+$ is an isomorphism (notation of (4.1.11)); the lemma will follow immediately. To this aim, claim 5.7.9 reduces to checking the following assertion. For every $A \in \mathrm{Ob}(\mathscr{A})$ and every finite covering family $(f_i : A_i \to A \mid i \in I)$ in $(\mathscr{A}_{pA}, J_{pA})$, the natural map :

$$L_{\mathscr{A}!}FA \to E := \mathrm{Equal}\Big(\prod_{i\in I} L_{\mathscr{A}!}F(A_i) \rightrightarrows \prod_{(i,j)\in I\times I} L_{\mathscr{A}!}F(A_i \times_A A_j)\Big)$$

is bijective. Thus, let $\mathscr{I}$ be the finite category whose set of objects is the disjoint union of I and $I\times I$, and with two morphisms $i \leftarrow (i,j) \to j$ for every $(i,j) \in I\times I$ (and of course, the identity morphism of each object); the covering family $(f_i \mid i \in I)$ induces a functor $A_\bullet : \mathscr{I}^o \to \mathscr{A}_{pA}$ given by the rule : $i \mapsto A_i$ and $(i,j) \mapsto A_{ij} := A_i \times_A A_j$ for every $i,j \in I$, and which assigns to every morphism $l : (i,j) \to k$ of $\mathscr{I}$ the projection $\pi_l : A_{ij} \to A_k$. We consider the functor

$$\Psi : \mathscr{I} \times (\mathscr{C}/pA) \to \mathscr{A}$$

that assigns to every pair $(t, \varphi/pA) \in \mathrm{Ob}(\mathscr{I}) \times \mathrm{Ob}(\mathscr{C}/pA)$ the object $\mathsf{c}_\varphi(A_t)$, and to every morphism $(l,\psi) : (t,\varphi/pA) \to (t',\varphi'/pA)$ the composition :

$$\mathsf{c}_\varphi(A_t) \xrightarrow{\boldsymbol{\lambda}(\mathbf{1}_{A_t},\psi)} \mathsf{c}_{\varphi'}(A_t) \xrightarrow{\mathsf{c}_{\varphi'}(\pi_l)} \mathsf{c}_{\varphi'}(A_{t'}).$$

For every $(t,\varphi) \in \mathrm{Ob}(\mathscr{I} \times (\mathscr{C}/pA))$, let also $[t]$ (resp. $[\varphi]$) be the subcategory of $\mathscr{I}$ (resp. of $\mathscr{C}/pA$) with $\mathrm{Ob}([t]) := \{t\}$ (resp. with $\mathrm{Ob}([\varphi]) = \{\varphi\}$), and denote by $\Psi_t : \mathscr{C}/pA \to \mathscr{A}$ (resp $\Psi^\varphi : \mathscr{I} \to \mathscr{A}$) the restriction of Ψ to $[t] \times (\mathscr{C}/pA) \xrightarrow{\sim} \mathscr{C}/pA$ (resp. to $\mathscr{I} \times [\varphi] \xrightarrow{\sim} \mathscr{I}$). With this notation, $L_{\mathscr{A}!}F(A_t)$ represents the colimit of $F \circ \Psi_t^o$, for every $t \in \mathrm{Ob}(\mathscr{I})$, and since $\mathscr{I}$ is finite and $(\mathscr{C}/pA)^o$ is filtered, we get natural identifications :

$$E = \lim_{t\in\mathrm{Ob}(\mathscr{I})} \operatorname*{colim}_{(\mathscr{C}/pA)^o} F \circ \Psi_t^o \xrightarrow{\sim} \operatorname*{colim}_{\varphi\in\mathrm{Ob}(\mathscr{C}/pA)} \lim_{\mathscr{I}} F \circ (\Psi^\varphi)^o.$$

But since c_φ is left exact and continuous for the topologies J_X and J_Y, for every morphism $\varphi : X \to Y$ of $\mathscr{C}$, and since the restriction of F to $\mathscr{A}_X$ is a sheaf for the topology J_X, for every $X \in \mathrm{Ob}(\mathscr{C})$, we see that $F(\mathsf{c}_\varphi A)$ represents the limit of the functor $F \circ (\Psi^\varphi)^o$, for every such φ, so the functor $(\mathscr{C}/pA)^o \to \mathbf{Set}$ given by the rule $\varphi \mapsto \lim_{\mathscr{I}} F \circ (\Psi^\varphi)^o$ is naturally identified with $F \circ (\mathsf{t}_A \circ \Phi_A)^o$. Summing up, we conclude that E represents the colimit of $F \circ (\mathsf{t}_A \circ \Phi_A)^o$, whence (i).

(ii.b): By claim 3.2.8, we may assume that $\mathscr{E} = \mathscr{F}ib(E_\bullet)$ for a presheaf of categories $E_\bullet$ on $\mathscr{A}$. Then recall that $\mathscr{F} := \mathsf{Fib}(L_{\mathscr{A}})_!\mathscr{E}$ is the fibration associated with the strict pseudo-functor computed by the strong left 2-Kan extension :

$$F_\bullet := 2\text{-}\!\int^{L^o_{\mathscr{A}}} E_\bullet \qquad A \mapsto F_A := \operatorname*{2\text{-}colim}_{(A/L_{\mathscr{A}}\mathscr{A})^o} E_\bullet \circ \mathsf{t}^o_A.$$

However, since $(A/L_{\mathscr{A}}\mathscr{A})^o$ is filtered, the 2-colimit of $E_\bullet \circ \mathsf{t}^o_A$ is represented by the colimit of the same functor, for every $A \in \mathrm{Ob}(\mathscr{A})$ (example 3.3.13(iv)), and in view of claim 5.7.8, this is also the colimit of the functor $E_\bullet \circ (\mathsf{t}_A \circ \Phi_A)^o : (\mathscr{C}/pA)^o \to \mathbf{Cat}$, for every such A.

It suffices to show that the natural functor $\mathsf{C}(\mathscr{F}) \to \mathscr{F}^+$ (see (5.1.17)) is an equivalence of categories, and in view of claim 5.7.9 (and of corollary 3.1.28(i)) we are reduced to checking the following assertion. For every $A \in \mathrm{Ob}(\mathscr{A})$ and every finite covering family $f_\bullet := (f_i : A_i \to A \mid i \in I)$ in $(\mathscr{A}_{pA}, J_{pA})$, the natural functor

$$F_A \xrightarrow{\sim} \mathscr{F}(A) \to \mathsf{Desc}(\mathscr{F}, L_{\mathscr{A}}(f_\bullet))$$

is an equivalence. Now, every morphism $\psi/A : \varphi \to \varphi'$ of $\mathscr{C}/pA$ induces a functor

$$\delta_{\psi/A} : \mathsf{Desc}(\mathscr{E}, \mathsf{c}_{\varphi'}(f_\bullet)) \to \mathsf{Desc}(\mathscr{E}, \mathsf{c}_\varphi(f_\bullet))$$

as follows. Notice that, since c_φ is left exact, a descent datum for $\mathscr{E}$ relative to the covering $\mathsf{c}_\varphi(f_\bullet) := (\mathsf{c}_\varphi(f_i) \mid i \in I)$ is a pair $(e_\bullet, \omega_{\bullet\bullet})$, where $e_\bullet := (e_i \mid i \in I)$ is a system of objects $e_i \in \mathrm{Ob}(E_{\mathsf{c}_\varphi A})$ for every $i \in I$, and $\omega_{\bullet\bullet}$ is a system of isomorphisms $\omega_{ij} : E_{\mathsf{c}_\varphi(\pi_{ij})}(e_i) \xrightarrow{\sim} E_{\mathsf{c}_\varphi(\pi_{ji})}(e_j)$ fulfilling the usual cocycle condition (here we denote by $\pi_{ij} : A_{ij} \to A_i$ and $\pi_{ji} : A_{ij} \to A_j$ the projections). A morphism $h_\bullet : (e_\bullet, \omega_{\bullet\bullet}) \to (e_\bullet, \omega_{\bullet\bullet})$ of such descent data is a system of morphisms $(h_i : e_i \to e'_i \mid i \in I)$ compatible in the obvious fashion with ω_{ij} and ω'_{ij}. Then $\delta_{\psi/A}$ is given by the rules :

$$\begin{aligned}(e_\bullet, \omega_{\bullet\bullet}) &\mapsto ((E_{\boldsymbol{\lambda}(\mathbf{1}_{A_i}, \psi)}(e_i) \mid i \in I), (E_{\boldsymbol{\lambda}(\mathbf{1}_{A_{ij}}, \psi)}(\omega_{ij}) \mid i, j \in I)) \\ h_\bullet &\mapsto ((E_{\boldsymbol{\lambda}(\mathbf{1}_{A_i}, \psi)}(h_i) \mid i \in I)\end{aligned}$$

for every object $(e_\bullet, \omega_{\bullet\bullet})$ and every morphism $h_\bullet$ of $\mathsf{Desc}(\mathscr{E}, \mathsf{c}_{\varphi'}(f_\bullet))$. We thus obtain a functor $\delta : (\mathscr{C}/pA)^o \to \mathbf{Cat}$ that assigns to every $\varphi \in \mathrm{Ob}(\mathscr{C}/pA)$ the category $\mathsf{Desc}(\mathscr{E}, \mathsf{c}_\varphi(f_\bullet))$, and to every morphism ψ/A the functor $\delta_{\psi/A}$, and a direct inspection of the definitions yields a natural identification

$$\mathsf{Desc}(\mathscr{F}, L_\mathscr{A}(f_\bullet)) \xrightarrow{\sim} \operatorname*{colim}_{(\mathscr{C}/pA)^o} \delta.$$

Lastly, since $\mathscr{E}$ is a stack on $(\mathscr{A}[\Sigma_\mathscr{A}^{-1}], J^*_\mathscr{A})$, the natural functor $E_{\mathsf{c}_\varphi A} \to \mathsf{Desc}(\mathscr{E}, \mathsf{c}_\varphi(f_\bullet))$ is an equivalence for every $\varphi \in \mathrm{Ob}(\mathscr{C}/pA)$, and we get an induced equivalence

$$\operatorname*{2\text{-}colim}_{(\mathscr{C}/pA)^o} E_\bullet \circ (\mathsf{t} \circ \Phi_A)^o \xrightarrow{\sim} \operatorname*{2\text{-}colim}_{(\mathscr{C}/pA)^o} \delta.$$

But again, these 2-colimits are represented by the colimits of the same functors, whence the contention. □

5.7.10. Keep the notation of (5.7.6), and let now $\varphi : (\mathscr{A}, p, J_\bullet) \to (\mathscr{A}', p', J'_\bullet)$ be a morphism of small fibred lex-sites over the small category $\mathscr{C}$. We have $\varphi(\Sigma_{\mathscr{A}'}) \subset \Sigma_\mathscr{A}$, whence a commutative diagram of categories, for every $X \in \mathrm{Ob}(\mathscr{C})$:

$$\begin{array}{ccccc}\mathscr{A}'_X & \xrightarrow{i'_X} & \mathscr{A}' & \xrightarrow{L_{\mathscr{A}'}} & \mathscr{A}'[\Sigma_{\mathscr{A}'}^{-1}] \\ \downarrow{\scriptstyle \varphi_X} & & \downarrow{\scriptstyle \varphi} & & \downarrow{\scriptstyle \varphi_\Sigma} \\ \mathscr{A}_X & \xrightarrow{i_X} & \mathscr{A} & \xrightarrow{L_\mathscr{A}} & \mathscr{A}[\Sigma_\mathscr{A}^{-1}]\end{array}$$

where i_X and i'_X are the inclusion functors. Let as well $\boldsymbol{\lambda}'$ be a unital cleavage for p', and c' its associated pseudo-functor, which factors likewise through a pseudo-functor $\widetilde{\mathsf{c}}' : \mathscr{C} \to \mathsf{lex}.\mathbf{Site}$; then φ corresponds to a unique pseudo-natural transformation $\omega : \mathsf{c}' \Rightarrow \mathsf{c}$, and the latter in turn can also be regarded as a 2-cell $\widetilde{\omega} : \widetilde{\mathsf{c}} \Rightarrow \widetilde{\mathsf{c}}'$ of $\mathsf{lex}.\mathbf{Site}$. Now, since $\mathscr{A}[\Sigma_\mathscr{A}^{-1}]$ is a strong 2-colimit for c, there exists a unique functor $\psi : \mathscr{A}'[\Sigma_{\mathscr{A}'}^{-1}] \to \mathscr{A}[\Sigma_\mathscr{A}^{-1}]$ such that $\tau \odot \mathsf{F}_\psi = \omega$; clearly we must then have $\psi = \varphi_\Sigma$. On the other hand, since $\mathscr{A}[\Sigma_\mathscr{A}^{-1}]$ is a strong 2-limit for $\widetilde{\mathsf{c}}$, there exists a unique morphism of sites $\widetilde{\psi} : (\mathscr{A}[\Sigma_\mathscr{A}^{-1}], J^*_\mathscr{A}) \to (\mathscr{A}'[\Sigma_{\mathscr{A}'}^{-1}], J^*_{\mathscr{A}'})$ such that $\mathsf{F}_{\widetilde{\psi}} \odot \widetilde{\tau} = \widetilde{\omega}$; thus, we must have $\widetilde{\psi} = \psi$, and this shows that φ_Σ is a morphism of sites as well, so we get a commutative diagram of morphisms of sites :

$$\begin{array}{ccc}(\mathscr{A}[\Sigma_\mathscr{A}^{-1}], J^*_\mathscr{A}) & \xrightarrow{L_\mathscr{A}} & (\mathscr{A}, J_\mathscr{A}) \\ \downarrow{\scriptstyle \varphi_\Sigma} & & \downarrow{\scriptstyle \varphi} \\ (\mathscr{A}'[\Sigma_{\mathscr{A}'}^{-1}], J^*_{\mathscr{A}'}) & \xrightarrow{L_{\mathscr{A}'}} & (\mathscr{A}', J_{\mathscr{A}'})\end{array}$$

which we orient by the identity transformation $\mathbf{1}_{\varphi\circ L_{\mathscr{A}}}$. Following (5.5.23), the resulting oriented diagram then induces an oriented square of 2-categories :

$$\begin{array}{ccc} \mathsf{Stack}(\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}], J^*_{\mathscr{A}}) & \xrightarrow{\mathsf{St}(L_{\mathscr{A}})_*} & \mathsf{Stack}(\mathscr{A}, J_{\mathscr{A}}) \\ {\scriptstyle \mathsf{St}(\varphi_\Sigma)_*}\downarrow & \Downarrow \mathsf{St}(\mathbf{1}_{\varphi\circ L_{\mathscr{A}}})^{\gamma}_* & \downarrow{\scriptstyle \mathsf{St}(\varphi)_*} \\ \mathsf{Stack}(\mathscr{A}'[\Sigma_{\mathscr{A}'}^{-1}], J^*_{\mathscr{A}'}) & \xrightarrow[\mathsf{St}(L_{\mathscr{A}'})_*]{} & \mathsf{Stack}(\mathscr{A}', J_{\mathscr{A}'}) \end{array}$$

which in turn can be regarded as an oriented square of links of the 2-category $\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}}$, for a suitable universe V : see (5.5.25).

Proposition 5.7.11. *In the situation of* (5.7.10)*, suppose that every object of* $\mathscr{A}$ *is quasi-compact for the topology* $J_{\mathscr{A}}$*. Then* $\Upsilon(\mathsf{St}(\mathbf{1}_{\varphi\circ L_{\mathscr{A}}})^{\gamma}_*)$ *is a pseudo-natural equivalence.*

Proof. Let $\mathscr{E}$ be any stack on $(\mathscr{A}, J_{\mathscr{A}})$; as usual, we may assume that $\mathscr{E} = \mathscr{F}ib(E_\bullet)$ for a presheaf of categories $E_\bullet$ on $\mathscr{A}$, and by virtue of lemma 5.5.15(ii) we may also assume that $E_\bullet$ is a sheaf of categories on $(\mathscr{A}, J_{\mathscr{A}})$. According to corollary 5.5.26(iv), and the discussion of (5.5.29), we are then reduced to checking :

Claim 5.7.12. (i) $\mathscr{F}ib((L^{\sim}_{\mathscr{A}}, \mathbf{Cat})^* E_\bullet)$ is a stack on $(\mathscr{A}[\Sigma_{\mathscr{A}}^{-1}], J^*_{\mathscr{A}})$.
(ii) $\Upsilon((\mathbf{1}_{\varphi\circ L_{\mathscr{A}}})^{\sim}_*)$ is an isomorphism of functors.

Proof of the claim. (i): On one hand the natural morphism $(L_{\mathscr{A}}, \mathbf{Cat})_! E_\bullet \to (L^{\sim}_{\mathscr{A}}, \mathbf{Cat})^* E_\bullet$ is an isomorphism, by proposition 5.7.7(ii.a); on the other hand, from claim 5.7.8 and lemma 1.5.7(ii) we see that the category $A/L_{\mathscr{A}}\mathscr{A}$ is cofiltered for every $A \in \mathrm{Ob}(\mathscr{A})$, hence remark 5.5.14(v) yields an equivalence of categories $\mathscr{F}ib((L_{\mathscr{A}}, \mathbf{Cat})_! E_\bullet) \overset{\sim}{\to} \mathsf{Fib}(L_{\mathscr{A}})_!(\mathscr{E})$. Lastly, $\mathsf{Fib}(L_{\mathscr{A}})_!(\mathscr{E})$ is a stack, by proposition 5.7.7(ii.b), whence the assertion.

(ii): By definition, we have :

$$\Upsilon((\mathbf{1}_{\varphi\circ L_{\mathscr{A}}})^{\sim}_*) = (\varepsilon^{L_{\mathscr{A}'}} * \widetilde{\varphi}_{\Sigma *}\widetilde{L}^*_{\mathscr{A}}) \odot (\widetilde{L}^*_{\mathscr{A}'}\widetilde{\varphi}_* * \eta^{L_{\mathscr{A}}})$$

where $\eta^{L_{\mathscr{A}}}$ (resp. $\varepsilon^{L_{\mathscr{A}'}}$) is the unit (resp. the counit) of an adjunction for the pair $(\widetilde{L}^*_{\mathscr{A}}, \widetilde{L}_{\mathscr{A}*})$ (resp. $(\widetilde{L}^*_{\mathscr{A}'}, \widetilde{L}_{\mathscr{A}'*})$). However, $\widetilde{L}_{\mathscr{A}'*}$ is fully faithful (proposition 5.7.7(i)), hence $\varepsilon^{L_{\mathscr{A}'}}$ is an isomorphism (proposition 1.1.20(iii)). Thus, we are reduced to checking that $\widetilde{L}^*_{\mathscr{A}'}\widetilde{\varphi}_* * \eta^{L_{\mathscr{A}}}$ is an isomorphism. However, since also $\varepsilon^{L_{\mathscr{A}}}$ is an isomorphism, we know already that $\widetilde{L}^*_{\mathscr{A}} * \eta^{L_{\mathscr{A}}}$ is an isomorphism, due to the triangular identities of (1.1.13). Thus, we are further reduced to exhibiting an *arbitrary* isomorphism of functors :

$$\widetilde{L}^*_{\mathscr{A}'} \circ \widetilde{\varphi}_* \overset{\sim}{\to} \widetilde{\varphi}_{\Sigma *} \circ \widetilde{L}^*_{\mathscr{A}}.$$

Hence, let F be any sheaf on $(\mathscr{A}, J_{\mathscr{A}})$, and $A' \in \mathrm{Ob}(\mathscr{A}')$; from the proof of proposition 5.7.7(i) we see that $\widetilde{L}^*_{\mathscr{A}'} \circ \widetilde{\varphi}_* F(A')$ represents the colimit of the functor

$$\Psi : (\mathscr{C}/p'A')^o \to \mathbf{Set} \qquad (X \xrightarrow{f} p'A') \mapsto F\varphi(\mathsf{c}'_f A') \qquad (f \xrightarrow{g/p'A'} f') \mapsto F\varphi(\boldsymbol{\lambda}'(\mathbf{1}_{A'}, g))$$

whereas $\widetilde{\varphi}_{\Sigma *} \circ \widetilde{L}^*_{\mathscr{A}} F(A')$ represents the colimit of the functor

$$\Psi' : (\mathscr{C}/p'A')^o \to \mathbf{Set} \qquad (X \xrightarrow{f} p'A') \mapsto F\mathsf{c}_f(\varphi A') \qquad (f \xrightarrow{g/p'A'} f') \mapsto F(\boldsymbol{\lambda}'(\mathbf{1}_{\varphi A'}, g)).$$

Now, let τ^ω denote the coherence constraint of the pseudo-natural transformation ω associated with φ as in (5.7.10), so that $\omega_X : \mathscr{A}_X \to \mathscr{A}'_X$ is the restriction of φ, for every $X \in \mathrm{Ob}(\mathscr{C})$; we claim that the following system of maps yields an isomorphism of functors $\Psi \overset{\sim}{\to} \Psi'$:

(5.7.13) $$(F(\tau^\omega_{f,A'}) : F\varphi(\mathsf{c}'_f A') \overset{\sim}{\to} F\mathsf{c}_f(\varphi A') \mid f \in \mathrm{Ob}(\mathscr{C}/p'A')).$$

More precisely, we show that for every two objects $f : X \to p'A'$ and $f' : X' \to p'A'$ and every morphism $g/p'A' : f \to f'$ of $\mathscr{C}/p'A'$ the following diagram commutes :

$$\begin{array}{ccc} \mathsf{c}_f(\varphi A') & \xrightarrow{\tau^\omega_{f,A'}} & \varphi(\mathsf{c}'_f A') \\ {\scriptstyle \boldsymbol{\lambda}(\mathbf{1}_{\varphi A'}, g/p'A')} \downarrow & & \downarrow {\scriptstyle \varphi(\boldsymbol{\lambda}'(\mathbf{1}_{A'}, g/p'A'))} \\ \mathsf{c}_{f'}(\varphi A') & \xrightarrow{\tau^\omega_{f',A'}} & \varphi(\mathsf{c}'_{f'} A'). \end{array} \tag{5.7.14}$$

To this aim, denote by $\gamma^{\mathsf{c}'}$ the coherence constraint of c', and recall that, under the natural identification $\mathscr{A}' \xrightarrow{\sim} \mathscr{F}ib(\mathsf{c}')$, the morphism $\boldsymbol{\lambda}'(\mathbf{1}_{A'}, g/p'A')$ of $\mathscr{A}'$ corresponds to the morphism

$$(g, \gamma^{\mathsf{c}'\,-1}_{(g,f'),A'} : \mathsf{c}'_f A' \to \mathsf{c}'_g \mathsf{c}'_{f'} A') : (X, \mathsf{c}'_f A') \to (X', \mathsf{c}'_{f'} A').$$

Likewise we describe $\boldsymbol{\lambda}(\mathbf{1}_{\varphi A'}, g)$ in terms of the coherence constraint γ^{c} of c; since $\boldsymbol{\lambda}$ and $\boldsymbol{\lambda}'$ are unital, the assertion comes down to the commutativity of the diagram :

$$\begin{array}{ccccc} \mathsf{c}_g \mathsf{c}_{f'}(\varphi A') & & \xrightarrow{\gamma^{\mathsf{c}}_{(g,f'),\varphi A'}} & & \mathsf{c}_f(\varphi A') \\ {\scriptstyle \mathsf{c}_g(\tau^\omega_{f',A'})} \downarrow & & & & \downarrow {\scriptstyle \tau^\omega_{f,A'}} \\ \mathsf{c}_g \circ \varphi(\mathsf{c}'_{f'} A') & \xrightarrow{\tau^\omega_{g,\mathsf{c}'_{f'}A'}} & \varphi(\mathsf{c}'_g \mathsf{c}'_{f'} A') & \xrightarrow{\omega_X(\gamma^{\mathsf{c}'}_{(g,f'),A'})} & \varphi(\mathsf{c}'_f A') \end{array}$$

which in turn follows from the coherence axiom for τ^ω. So finally, the colimit of the system (5.7.13) yields a bijection $t_{F,A'} : \widetilde{L}^*_{\mathscr{A}'} \circ \widetilde{\varphi}_* F(A') \xrightarrow{\sim} \widetilde{\varphi}_{\Sigma *} \circ \widetilde{L}^*_{\mathscr{A}} F(A')$ for every $A' \in \mathrm{Ob}(\mathscr{A}')$, and we need to check that the rule : $A' \mapsto t_{F,A'}$ defines a morphism of sheaves t_F. Thus, let

$$(\beta^A_{F,f} : F(\mathsf{c}_f A) \to \widetilde{L}^*_{\mathscr{A}} F(A) \mid f \in \mathrm{Ob}(\mathscr{C}/pA)) \qquad \text{for every } A \in \mathrm{Ob}(\mathscr{A})$$

be a fixed system of universal cocones, and $h : B \to A$ any morphism in $\mathscr{A}[\Sigma^{-1}_{\mathscr{A}}]$; for a given object $f : X \to pA$ of $\mathscr{C}/pA$, we may find a morphism $g : Y \to pB$ in $\mathscr{C}$ and a morphism $h_{g,f} : \mathsf{c}_g B \to \mathsf{c}_f A$ in $\mathscr{A}$ such that $L_{\mathscr{A}}(\boldsymbol{\lambda}(A, f))^{-1} \circ h = L_{\mathscr{A}}(h_{g,f}) \circ L_{\mathscr{A}}(\boldsymbol{\lambda}(B, g))^{-1}$, and by unraveling the definitions, it is easily seen that :

$$\widetilde{L}^*_{\mathscr{A}} F(h) \circ \beta^A_{F,f} = \beta^B_{F,g} \circ F h_{g,f}.$$

Likewise, fix a system of universal cocones :

$$(\beta'^{A'}_{F,f} : F\varphi(\mathsf{c}'_f A') \to \widetilde{L}^*_{\mathscr{A}'} \widetilde{\varphi}_* F(A') \mid f \in \mathrm{Ob}(\mathscr{C}/p'A')) \qquad \text{for every } A' \in \mathrm{Ob}(\mathscr{A}').$$

If $h' : B' \to A'$ is any morphism of $\mathscr{A}'[\Sigma^{-1}_{\mathscr{A}'}]$, and $f : X \to p'A'$ any object of $\mathscr{C}/p'A'$, we may find a morphism $g : Y \to p'B'$ in $\mathscr{C}$ and a morphism $h'_{g,f} : \mathsf{c}'_g B' \to \mathsf{c}'_f A'$ of $\mathscr{A}'$ such that $L_{\mathscr{A}'}(\boldsymbol{\lambda}'(A, f))^{-1} \circ h' = L_{\mathscr{A}'}(h'_{g,f}) \circ L_{\mathscr{A}'}(\boldsymbol{\lambda}'(B, g))^{-1}$, and again it is easily seen that :

$$\widetilde{L}^*_{\mathscr{A}'} \widetilde{\varphi}_* F(h') \circ \beta'^{A'}_{F,f} = \beta'^{B'}_{F,g} \circ F\varphi(h'_{g,f}).$$

Now, for every such h' we need to check the identity :

$$t_{F,B'} \circ \widetilde{L}^*_{\mathscr{A}'} \widetilde{\varphi}_* F(h') = \widetilde{\varphi}_{\Sigma *} \widetilde{L}^*_{\mathscr{A}} F(h') \circ t_{F,A'} \tag{5.7.15}$$

and it suffices to check that the sides of (5.7.15) agree after composition with $\beta'^{A'}_{F,f}$, for every $f \in \mathrm{Ob}(\mathscr{C}/p'A')$. Notice that if $g : Y \to p'B'$ is a suitable choice for constructing $h'_{g,f}$, then the same choice can be used for constructing $(\varphi_\Sigma h')_{g,f}$ (details left to the reader). We compute:

$$t_{F,B'} \circ \widetilde{L}^*_{\mathscr{A}'} \widetilde{\varphi}_* F(h') \circ \beta'^{A'}_{F,f} = t_{F,B'} \circ \beta'^{B'}_{F,g} \circ F\varphi(h'_{g,f}) = \beta^{\varphi B'}_{F,g} \circ F(\tau^\omega_{g,B'}) \circ F\varphi(h'_{g,f})$$
$$\widetilde{\varphi}_{\Sigma *} \widetilde{L}^*_{\mathscr{A}} F(h') \circ t_{F,A'} \circ \beta'^{A'}_{F,f} = \widetilde{\varphi}_{\Sigma *} \widetilde{L}^*_{\mathscr{A}} F(h') \circ \beta^{\varphi A'}_{F,f} \circ F(\tau^\omega_{f,A'}) = \beta^{\varphi B'}_{F,g} \circ F(\varphi_\Sigma h')_{g,f} \circ F(\tau^\omega_{f,A'}).$$

Thus, we are reduced to checking that we may choose $(\varphi_\Sigma h')_{g,f}$ such that :

$$\varphi(h'_{g,f}) \circ \tau^\omega_{g,B'} = \tau^\omega_{f,A'} \circ (\varphi_\Sigma h')_{g,f}.$$

In other words, we have to check the identity :

$$(5.7.16) \quad L_{\mathscr{A}}((\tau^\omega_{f,A'})^{-1} \circ \varphi(h'_{g,f}) \circ \tau^\omega_{g,B'}) \circ L_{\mathscr{A}}(\boldsymbol{\lambda}(\varphi B', g))^{-1} = L_{\mathscr{A}}(\boldsymbol{\lambda}(\varphi A', f))^{-1} \circ (\varphi_\Sigma h').$$

However, if we regard g as a morphism $g/p'B' : g \to \mathbf{1}_{p'B'}$ of $\mathscr{C}/p'B'$, we get

$$\boldsymbol{\lambda}'(\mathbf{1}_{B'}, g/p'B') = \boldsymbol{\lambda}'(B', g) \qquad \text{and} \qquad \boldsymbol{\lambda}(\mathbf{1}_{\varphi B'}, g/p'B') = \boldsymbol{\lambda}(\varphi B', g).$$

Likewise, we have corresponding identities for $\boldsymbol{\lambda}'(A', g)$ and $\boldsymbol{\lambda}(\varphi A', g)$, by regarding f as a morphism $f/p'A' : f \to \mathbf{1}_{p'A'}$ of $\mathscr{C}/p'A'$. Then (5.7.14) yields the identities

$$\varphi(\boldsymbol{\lambda}'(A', f)) \circ \tau^\omega_{f,A'} = \boldsymbol{\lambda}(\varphi A', f) \qquad \varphi(\boldsymbol{\lambda}'(B', g)) \circ \tau^\omega_{g,B'} = \boldsymbol{\lambda}(\varphi B', g).$$

(notice that $\tau^\omega_{\mathbf{1}_{A'},A'} = \mathbf{1}_{\varphi A'}$ and $\tau^\omega_{\mathbf{1}_{B'},B'} = \mathbf{1}_{\varphi B'}$, since c and c' are unital : see remark 2.4.2(ii)). Summing up, we deduce that (5.7.16) is equivalent to the identity :

$$L_{\mathscr{A}}(\varphi(\boldsymbol{\lambda}'(A', f)) \circ \varphi(h'_{g,f})) \circ L_{\mathscr{A}}(\varphi(\boldsymbol{\lambda}'(B', g)))^{-1} = \varphi_\Sigma h'$$

which follows immediately from the definition of $h'_{g,f}$ and the identity $\varphi_\Sigma \circ L_{\mathscr{A}'} = L_{\mathscr{A}} \circ \varphi$.

This conclude the construction of the morphism of sheaves $t_F : \widetilde{L}^*_{\mathscr{A}'} \circ \widetilde{\varphi}_* F \xrightarrow{\sim} \widetilde{\varphi}_{\Sigma *} \circ \widetilde{L}^*_{\mathscr{A}} F$. To conclude the proof, it remains to check that the rule $F \mapsto t_F$ yields the sought isomorphism of functors. Thus, let $\nu : F \to G$ be a morphism of sheaves on $(\mathscr{A}, J_{\mathscr{A}})$; we come down to checking the identity :

$$(5.7.17) \qquad \widetilde{\varphi}_{\Sigma *} \widetilde{L}^*_{\mathscr{A}}(\nu)_{A'} \circ t_{F,A'} = t_{G,A'} \circ \widetilde{L}^*_{\mathscr{A}} \widetilde{\varphi}_*(\nu) \qquad \text{for every } A' \in \mathrm{Ob}(\mathscr{A}')$$

and again, it suffices to check that the two sides of (5.7.17) agree after composition with $\beta'^{A'}_{F,f}$, for every $f \in \mathrm{Ob}(\mathscr{C}/p'A')$. We compute :

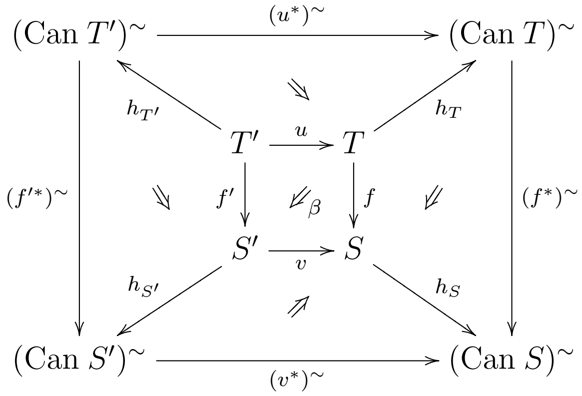
$$\begin{aligned} \widetilde{\varphi}_{\Sigma *} \widetilde{L}^*_{\mathscr{A}}(\nu)_{A'} \circ t_{F,A'} \circ \beta'^{A'}_{F,f} &= \widetilde{\varphi}_{\Sigma *} \widetilde{L}^*_{\mathscr{A}}(\nu)_{A'} \circ \beta^{\varphi A'}_{F,f} \circ F(\tau^\omega_{f,A'}) = \beta^{\varphi A'}_{G,f} \circ \nu_{\mathsf{c}_f(\varphi A')} \circ F(\tau^\omega_{f,A'}) \\ t_{G,A'} \circ \widetilde{L}^*_{\mathscr{A}} \widetilde{\varphi}_*(\nu) \circ \beta'^{A'}_{F,f} &= t_{G,A'} \circ \beta'^{A'}_{G,f} \circ \nu_{\varphi(\mathsf{c}'_f A')} = \beta^{\varphi A'}_{G,f} \circ G(\tau^\omega_{f,A'}) \circ \nu_{\varphi(\mathsf{c}'_f A')}. \end{aligned}$$

So we come down to showing that $\nu_{\mathsf{c}_f(\varphi A')} \circ F(\tau^\omega_{f,A'}) = G(\tau^\omega_{f,A'}) \circ \nu_{\varphi(\mathsf{c}'_f A')}$. The latter is clear, since ν is a morphism of sheaves. □

5.7.18. *Stacks on fibred topoi.* Recall that the pseudo-functor T of (4.4.15) assigns to every site C a topos $\mathsf{T}(C)$ with an isomorphism $\omega_C : C^\sim \xrightarrow{\sim} \mathsf{T}(C)$, and the unit of the 2-adjoint pair $(\mathrm{Can}, \mathsf{T})$ exhibited in the proof of theorem 4.4.17 assigns to every topos T an equivalence $\mathsf{h}_{T*} :\xrightarrow{\sim} \mathsf{T} \circ \mathrm{Can}(T)$ whose composition with $\omega^{-1}_{\mathrm{Can}(T)}$ equals the Yoneda imbedding $h_T : T \xrightarrow{\sim} T^\sim$. Also, for every natural transformation $\beta : u \Rightarrow v$ of morphisms of topoi $u, v : T' \to T$, the isomorphisms $\omega_{\mathrm{Can}(T)}$ and $\omega_{\mathrm{Can}(T')}$ identify $\mathsf{T} \circ \mathrm{Can}(\beta)$ with $(\beta^\dagger)^\sim_*$, where $\beta^\dagger$ is the adjoint transformation to β. Now, consider any oriented square of morphisms of topoi :

$$\begin{array}{ccc} T' & \xrightarrow{u} & T \\ {\scriptstyle f'}\downarrow & \swarrow_\beta & \downarrow{\scriptstyle f} \\ S' & \xrightarrow[v]{} & S \end{array}$$

(*i.e.* β is a natural transformation $f_* \circ u_* \Rightarrow v_* \circ f'_*$). There follows a diagram of oriented squares of topoi :



whose unmarked orientations are identified, via the isomorphisms $\omega_\bullet$, with the coherence constraints of the pseudo-natural transformation $\mathsf{h}_{\bullet *}$. We complete it by inserting the orientation $(\beta^\dagger)^\sim_*$ for the external square. Then the resulting cubical diagram commutes on 2-cells, in the sense of (2.3.21). Since the four diagonal arrows are equivalences (theorem 4.4.2(iv)) it follows that $\Upsilon(\beta)$ is an isomorphism of functors if and only if the same holds for $\Upsilon((\beta^\dagger)^\sim_*)$ (remark 2.3.22(ii)).

5.7.19. Let $\omega : T \to S$ be a morphism of fibred topoi over a small category I; let also $t \in \mathrm{Ob}(I)$ be any object, and define the functor $\rho^t : \mathbb{1} \to I$ as in remark 4.6.22(ii). By direct inspection, we see that :

$$\Psi^*_t := \mathsf{Top}(T/\rho^t)^* \circ \mathsf{Top}(\omega)^* = \omega^*_t \circ \mathsf{Top}(S/\rho^t)^*.$$

Indeed, both functors attach to every object $E_\bullet : I \to \mathscr{F}ib(S^*)$ of $\mathsf{Top}(S)$ the object $\omega^*_t(E_t) \in \mathrm{Ob}(T_t)$, and to every morphism $\beta_\bullet : E_\bullet \to E'_\bullet$, the morphism $\omega^*_t(\beta_t)$. Similarly, we get :

$$\Phi_t := \mathsf{Top}(S/\rho^t)^* \circ \mathsf{Top}(\omega)_* = \omega_{t*} \circ \mathsf{Top}(T/\rho^t)^*.$$

The adjoint of $\mathbf{1}_{\Psi^*_t}$ yields therefore an orientation for the following diagram of topoi :

$$\begin{array}{ccc} T_t & \xrightarrow{\mathsf{Top}(T/\rho^t)} & \mathsf{Top}(T) \\ {\scriptstyle \omega_t}\downarrow & \swarrow \mathbf{1}^\dagger_{\Psi^*_t} & \downarrow{\scriptstyle \mathsf{Top}(\omega)} \\ S_t & \xrightarrow[\mathsf{Top}(S/\rho^t)]{} & \mathsf{Top}(S) \end{array}$$

which we regard as an oriented square of links in the 2-category of categories (see (2.3.8)).

Lemma 5.7.20. *With the notation of* (5.7.19)*, we have :* $\Upsilon(\mathbf{1}^\dagger_{\Psi^*_t}) = \mathbf{1}_{\Phi_t}$.

Proof. We may as usual assume that T and S are unital; then we may replace $\mathsf{Top}(S)$ by the isomorphic category $\mathsf{Top}(S)_*$, and $\mathsf{Top}(\omega)$ by the adjunction $\Omega := (\Omega^*, \Omega_*, \eta^\Omega)$ described in the proof of proposition 4.6.10. Then $\mathsf{Top}(S/\rho^t)^*$ is replaced by $\Sigma(\mathscr{F}ib(S_*)/\rho^{to})^*$ (see the proof of corollary 4.6.21), and we come down to considering the oriented square of links :

$$\begin{array}{ccc} T_t & \xrightarrow{\mathsf{Top}(T/\rho^t)} & \mathsf{Top}(T) \\ {\scriptstyle \omega_t}\downarrow & \swarrow \mathbf{1}^\dagger_{\Lambda^*_t} & \downarrow{\scriptstyle \Omega} \\ S_t & \xrightarrow[\Sigma(\mathscr{F}ib(S_*)/\rho^{to})]{} & \mathsf{Top}(S)_* \end{array} \qquad \text{where } \Lambda^*_t := \mathbf{Top}(T/\rho^t)^* \circ \Omega^*$$

whose bottom horizontal arrow is given by $\Sigma(\mathscr{F}ib(S_*)/\rho^{to})^*$, its right adjoint, and a unit for this adjoint pair. Set $\Phi'_t := \Sigma(\mathscr{F}ib(S_*)/\rho^{to})^* \circ \Omega_*$; by proposition 2.3.10, it suffices to show that $\Upsilon({}^o\mathbf{1}_{\Lambda_t^*}) = {}^o\mathbf{1}_{\Phi_t'}$. However, let $(\eta^{\omega_i}, \varepsilon^{\omega_i})$ be the unit and counit of the adjunction for the pair $(\omega_i^*, \omega_{i*})$ defining the morphism of topoi ω_i, for every $i \in \mathrm{Ob}(I)$; by definition we have :

$$\Upsilon({}^o\mathbf{1}_{\Lambda_t^*}) = (\varepsilon^{{}^o\omega_t} * {}^o\Sigma(\mathscr{F}ib(S_*)/\rho^{to})^* * {}^o\Omega_*) \odot ({}^o\omega_{t*} * {}^o\mathsf{Top}(T/\rho^t)^* * \eta^{{}^o\Omega})$$

and recall that $\varepsilon^{{}^o\omega_t} = {}^o\eta^{\omega_t}$; likewise, $\eta^{{}^o\Omega} = {}^o\varepsilon^{\Omega}$, where ε^{Ω} denotes the counit for the adjoint pair Ω. Thus, we get :

$${}^o\Upsilon({}^o\mathbf{1}_{\Lambda_t^*}) = (\omega_{t*} * \mathsf{Top}(T/\rho^t)^* * \varepsilon^{\Omega}) \odot (\eta^{\omega_t} * \Sigma(\mathscr{F}ib(S_*)/\rho^{to})^* * \Omega_*) = (\Phi_t * \varepsilon^{\Omega}) \odot (\eta^{\omega_t} * \Phi_t).$$

But by inspecting the proof of proposition 4.6.10 we see that ε^{Ω} is the natural transformation that assigns to every object $E_\bullet : I \to \mathscr{F}ib(T^*)$ of $\mathsf{Top}(T)$ the system of morphisms $(\varepsilon^{\omega_i} : \omega_i^* \circ \omega_{i*}E_i \to E_i \mid i \in \mathrm{Ob}(I))$. Thus, finally, the natural transformation $(\Phi_t * \varepsilon^{\Omega}) \odot (\eta^{\omega_t} * \Phi_t)$ attaches to every such $E_\bullet$ the morphism $(\omega_{t*} * \varepsilon^{\omega_t}) \odot (\eta^{\omega_t} * \omega_{t*})$, which is indeed $\mathbf{1}_{\omega_{t*}E_t}$, by the triangular identities of (1.1.13). □

5.7.21. Keep the situation of (5.7.19), and to ease notation set

$$v_t := \mathsf{Top}(S/\rho^t)^* \qquad v_t' := \mathsf{Top}(T/\rho^t)^* \qquad \mathsf{S} := \mathrm{Can} \circ \mathsf{Top} : \mathsf{PsFun}(I, \mathbf{Topos}) \to \mathbf{Site}.$$

Arguing as in (5.5.23), we deduce an essentially commutative diagram :

$$\begin{array}{ccc} \mathsf{Stack}(\mathrm{Can}\, T_t) & \xrightarrow{\mathsf{St}(v_t')_*} & \mathsf{Stack}(\mathsf{S}(T)) \\ {\scriptstyle \mathsf{St}(\omega_t^*)_*}\downarrow & \Downarrow \mathsf{St}(\mathbf{1}_{\Psi_t^*})_*^{\gamma} & \downarrow{\scriptstyle \mathsf{St}(\mathsf{Top}(\omega)^*)_*} \\ \mathsf{Stack}(\mathrm{Can}\, S_t) & \xrightarrow[\mathsf{St}(v_t)_*]{} & \mathsf{Stack}(\mathsf{S}(S)) \end{array}$$

which we regard as an oriented square in $\mathsf{Link}(\mathsf{V}\text{-}\overline{2\text{-}\mathbf{Cat}})$ (see (5.5.25)); then we may state :

Proposition 5.7.22. $\Upsilon(\mathsf{St}(\mathbf{1}_{\Psi_t^*})_*^{\gamma})$ *is a pseudo-natural equivalence.*

Proof. Let $\mathscr{E}$ be any stack on the canonical site of $\mathsf{Top}(T)$; we need to check that $\Upsilon(\mathsf{St}(\mathbf{1}_{\Psi_t^*})_*^{\gamma})_{\mathscr{E}}$ is an equivalence of categories. To this aim, in view of claim 3.2.8 we may replace $\mathscr{E}$ by the split fibration $\mathsf{C}(\mathscr{E})$, so that $\mathscr{E} = \mathscr{F}ib(\mathscr{A}_\bullet)$ for a presheaf of categories $\mathscr{A}_\bullet$ on $\mathsf{Top}(T)$; then by lemma 5.5.15(ii) we may as well replace $\mathscr{A}_\bullet$ by $\mathscr{A}_\bullet^a$, and assume that $\mathscr{A}_\bullet$ is a sheaf of categories on $\mathsf{Top}(T)$.

Claim 5.7.23. $\Upsilon((\mathbf{1}_{\Psi_t^*}^{\sim}, \mathbf{Cat})_*)$ is a pseudo-natural equivalence.

Proof of the claim. As explained in (5.5.29), it suffices to check that $\Upsilon((\mathbf{1}_{\Psi_t^*})_*^{\sim})$ is an isomorphism of functors. By (5.7.18), the latter holds if and only if $\Upsilon(\mathbf{1}_{\Psi_t^*}^{\dagger})$ is an isomorphism of functors. This in turn is clear from lemma 5.7.20. ◊

In light of claim 5.7.23 and corollary 5.5.26(iv), it suffices to check that $\mathscr{F}ib((\widetilde{v}_t', \mathbf{Cat})^*\mathscr{A}_\bullet)$ is a stack on the canonical site of T_t. For every site C, let

$$\omega_C : \mathbf{Cat}^*(C^{\sim}) \xrightarrow{\sim} (C, \mathbf{Cat})^{\sim}$$

be the strict and strong 2-equivalence of (5.5.9). We may assume that $\mathscr{A}_\bullet = \omega_{\mathsf{Top}(T)}(\mathscr{A}^*)$ for a category object $\mathscr{A}^*$ of $\mathrm{Can}(\mathsf{Top}(T))^{\sim}$ and then we need to check that $\mathscr{F}ib(\omega_{T_t} \circ \mathbf{Cat}^*(\widetilde{v}_t'^*)(\mathscr{A}^*))$ is a stack on $\mathrm{Can}(T_t)$. Since $h_{\mathsf{Top}(T)} : \mathsf{Top}(T) \to \mathrm{Can}(\mathsf{Top}(T))^{\sim}$ is an equivalence, we may assume that $\mathscr{A}^* = \mathbf{Cat}^*(h_{\mathsf{Top}(T)})(\mathscr{B}^*)$ for some $\mathscr{B}^* \in \mathrm{Ob}(\mathbf{Cat}^*(\mathsf{Top}(T)))$; by corollary 4.3.19(i.b), it then suffices to check that $\mathscr{F}ib(\omega_{T_t} \circ \mathbf{Cat}^*(h_{T_t}) \circ \mathbf{Cat}^*(v_t')(\mathscr{B}^*))$ is a stack. However, theorem 4.6.24(i) yields an equivalence of categories $a : \mathsf{Top}(T) \xrightarrow{\sim} (\mathrm{Can}(T), J)^{\sim}$ and a morphism of sites $b : \mathrm{Can}(\mathsf{Top}(T)) \to (\mathrm{Can}(T), J)$ with isomorphisms of functors :

$$h_{T_t} \circ v_t' \xrightarrow{\sim} \widetilde{\imath}_{t*} \circ a \qquad a \xrightarrow{\sim} \widetilde{b}_* \circ h_{\mathsf{Top}(T)}$$

where $i_t : T_t \to \mathrm{Can}(T)$ is the inclusion functor. There follow isomorphisms of fibrations :

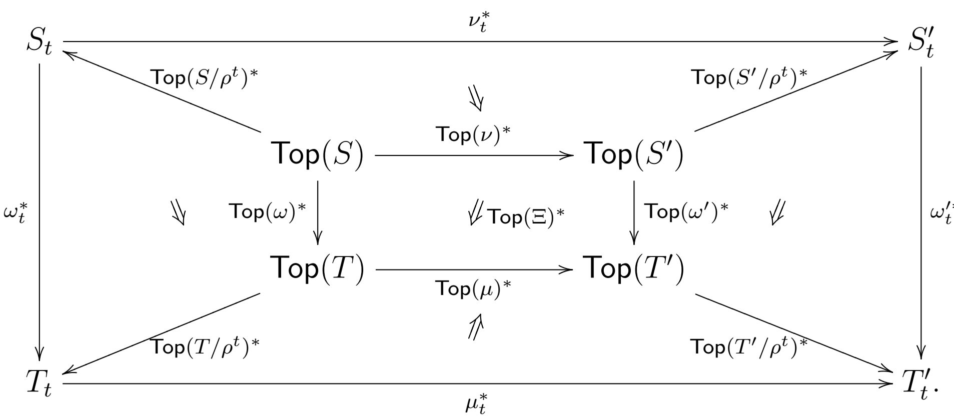
$$\begin{aligned}\mathscr{F}ib(\omega_{T_t} \circ \mathbf{Cat}^*(h_{T_t}) \circ \mathbf{Cat}^*(v'_t)\mathscr{B}^*) &\xrightarrow{\sim} \mathscr{F}ib(\omega_{T_t} \circ \mathbf{Cat}^*(\widetilde{\imath}_{t*}) \circ \mathbf{Cat}^*(a)\mathscr{B}^*) \\ &\xrightarrow{\sim} \mathscr{F}ib((\widetilde{\imath}_t, \mathbf{Cat})_* \circ \omega_{(\mathrm{Can}(T),J)} \circ \mathbf{Cat}^*(a)\mathscr{B}^*) \\ &\xrightarrow{\sim} \mathsf{Fib}(i_t)^*(\mathscr{F}ib(\omega_{(\mathrm{Can}(T),J)} \circ \mathbf{Cat}^*(a)\mathscr{B}^*))\end{aligned}$$

and by corollary 5.7.2, it then suffices to check that $\mathscr{F}ib(\omega_{(\mathrm{Can}(T),J)} \circ \mathbf{Cat}^*(a)\mathscr{B}^*)$ is a stack on $(\mathrm{Can}(T), J)$. We are then further reduced to showing that $\mathscr{F}ib((\widetilde{b}, \mathbf{Cat})_*\mathscr{A}_\bullet)$ is a stack on $(\mathrm{Can}(T), J)$, or equivalently, that the same holds for $\mathsf{Fib}(b)^*(\mathscr{F}ib(\mathscr{A}_\bullet)) = \mathsf{Fib}(b)^*(\mathscr{E})$. The latter holds, by corollary 5.4.15. $\square$

5.7.24. Consider now an oriented diagram of fibred topoi over a small category I :

$$\begin{CD} T' @>{\mu}>> T \\ @V{\omega'}VV \swarrow_{\Xi} @VV{\omega}V \\ S' @>>{\nu}> S \end{CD}$$

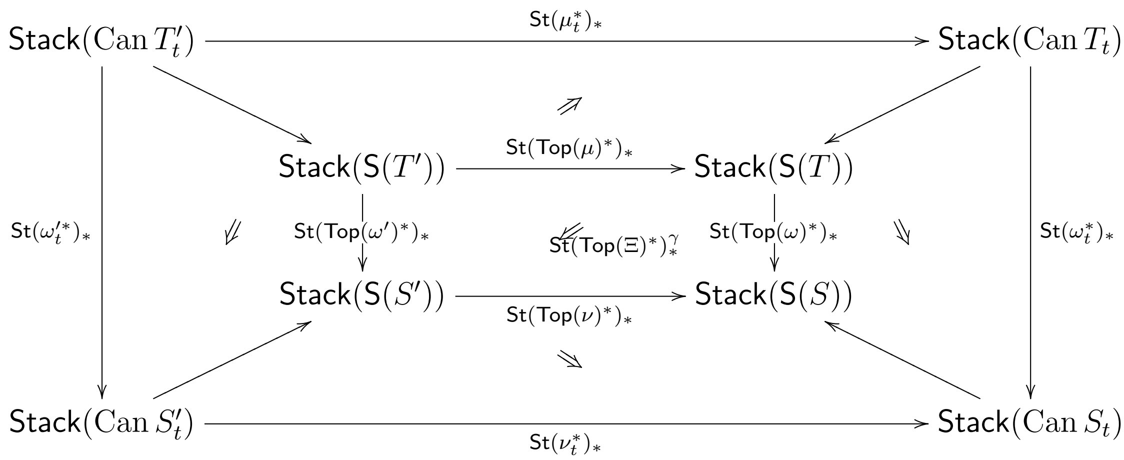
i.e. $\Xi : \omega \circ \mu \rightsquigarrow \nu \circ \omega'$ is a modification. For every $t \in \mathrm{Ob}(I)$ we get an oriented diagram :



whose four unmarked 2-cells are identities. We complete it by adding the orientation

$$\Xi_t^\dagger := (\Xi_t, \eta^{(\omega\circ\mu)_t}, \eta^{(\nu\circ\omega')_t})^\dagger : (\nu \circ \omega')_t^* \Rightarrow (\omega \circ \mu)_t^*$$

for the front face (notation of remark 1.1.17(ii)). Then a direct inspection shows that the resulting cubical diagram commutes both on 1-cells and 2-cells. As in (5.7.21), there follows an essentially commutative oriented diagram of 2-categories :



whose four unmarked 2-cells are defined as in the diagram of (5.7.21), and which we complete to a cubical diagram that commutes on 2-cells, by adding the orientation for the front face

$$\mathsf{St}(\Xi_t^\dagger)_*^\gamma : \mathsf{St}(\omega_t^*)_* \circ \mathsf{St}(\mu_t^*)_* \Rightarrow \mathsf{St}(\nu_t^*)_* \circ \mathsf{St}(\omega_t'^*)_*.$$

Thus, let $\mathscr{E}$ be any stack on the site $\mathrm{Can}(\mathsf{Top}(T))$, and set $\mathscr{E}_t := \mathsf{St}(\mathsf{Top}(T/\rho^t)^*)^*\mathscr{E}$; in light of proposition 5.7.22 and remark 2.3.22(i), we conclude that :

$$\mathsf{St}(\mathsf{Top}(S'/\rho^t)^*)^* * \Upsilon(\mathsf{St}(\mathsf{Top}(\Xi)^*)_*^\gamma)_{\mathscr{E}} \text{ is an equivalence} \Leftrightarrow \Upsilon(\mathsf{St}(\Xi_t^\dagger)_*^\gamma)_{\mathscr{E}_t} \text{ is an equivalence.}$$

5.7.25. Next, consider an oriented diagram of fibred lex-sites over I :

$$\mathscr{D} \quad : \quad \begin{array}{ccc} \underline{\mathscr{A}} & \xrightarrow{\varphi'} & \underline{\mathscr{A}}' \\ {\scriptstyle\psi'}\downarrow & \swarrow_\beta & \downarrow{\scriptstyle\psi} \\ \underline{\mathscr{B}} & \xrightarrow[\varphi]{} & \underline{\mathscr{B}}'. \end{array}$$

For every $t \in \mathrm{Ob}(I)$ the restriction $\mathscr{D}_t$ of the diagram $\mathscr{D}$ to the fibre categories over t yields another oriented square of 2-categories

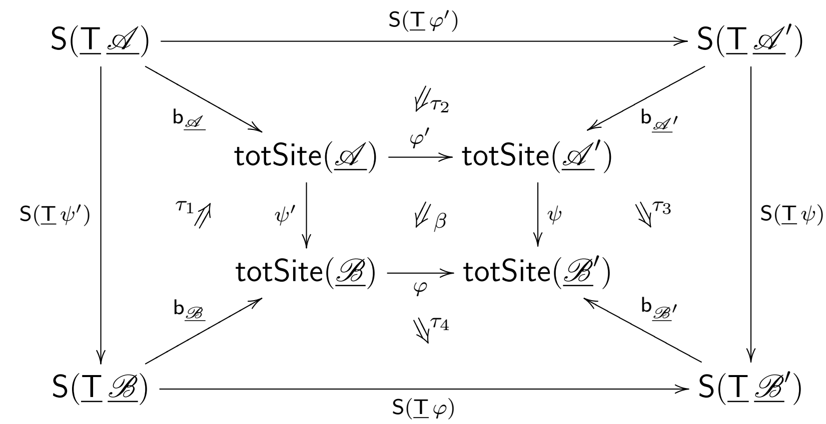
$$\mathsf{St}(\mathscr{D}_t)_* \quad : \quad \begin{array}{ccc} \mathsf{Stack}(\mathscr{A}_t) & \xrightarrow{\mathsf{St}(\varphi_t')_*} & \mathsf{Stack}(\mathscr{A}_t') \\ {\scriptstyle\mathsf{St}(\psi_t')_*}\downarrow & \Downarrow \mathsf{St}(\beta_t)_*^\gamma & \downarrow{\scriptstyle\mathsf{St}(\psi_t)_*} \\ \mathsf{Stack}(\mathscr{B}_t) & \xrightarrow[\mathsf{St}(\varphi_t)_*]{} & \mathsf{Stack}(\mathscr{B}_t'). \end{array}$$

For every fibred site $\underline{\mathscr{A}} := (\mathscr{A}, p, J_\bullet)$ over I, let also $i_{\mathscr{A},t} : \mathscr{A}_t \to \mathscr{A}$ be the inclusion functor.

Corollary 5.7.26. *In the situation of* (5.7.25)*, let $\mathscr{E}$ be any stack on the total site of $\underline{\mathscr{A}}'$, and set $\mathscr{E}_t := \mathsf{St}(i_{\mathscr{A}',t})_*\mathscr{E}$ for every $t \in \mathrm{Ob}(I)$. The following conditions are equivalent :*

(a) $\Upsilon(\mathsf{St}(\beta)_*^\gamma)_{\mathscr{E}}$ *is an equivalence.*
(b) $\Upsilon(\mathsf{St}(\beta_t)_*^\gamma)_{\mathscr{E}_t}$ *is an equivalence for every $t \in \mathrm{Ob}(I)$.*

Proof. By invoking the pseudo-natural transformation $\mathsf{b}_\bullet : \mathsf{S} \circ \underline{\mathsf{lex.T}} \to \mathsf{totSite}$ of remark 4.6.29(ii), we get an oriented cubical diagram of fibred sites :



whose front face is oriented by $\mathsf{S}(\underline{\mathsf{T}}\beta) = \mathsf{Top}(\underline{\mathsf{T}}\beta)^*$, and where the orientations $\tau_1, \dots, \tau_4$ are given by the coherence constraints of $\mathsf{b}_\bullet$; again, this cubical diagram commutes on 2-cells. After applying termwise as usual the pseudo-functor $\mathsf{St}(-)_*$, we deduce a similar cubical diagram whose front and back faces are oriented by $\mathsf{St}(\mathsf{Top}(\underline{\mathsf{T}}\beta)^*)_*^\gamma$ and respectively $\mathsf{St}(\beta)_*^\gamma$, and whose other four faces are oriented by $\mathsf{St}(\tau_i)_*^\gamma$ for $i = 1, \dots, 4$.

Claim 5.7.27. $\mathsf{St}(\mathsf{b}_{\underline{\mathscr{A}}})_*$ is a 2-equivalence for every fibred lex-site $\underline{\mathscr{A}}$ over I.

Proof of the claim. By construction, $\mathsf{b}_{\underline{\mathscr{A}}}$ is the composition of an isomorphism of canonical sites $\mathsf{S}(\underline{\mathsf{T}}\,\underline{\mathscr{A}}) \xrightarrow{\sim} \mathrm{Can} \circ \mathsf{T}(\mathsf{totSite}\,\underline{\mathscr{A}})$ with the counit $\varepsilon_{\mathsf{totSite}(\underline{\mathscr{A}})} : \mathrm{Can} \circ \mathsf{T}(\mathsf{totSite}\,\underline{\mathscr{A}}) \to \mathsf{totSite}(\underline{\mathscr{A}})$. Thus, it suffices to check that $\mathsf{St}(\varepsilon_{\mathsf{totSite}(\underline{\mathscr{A}})})_*$ is a 2-equivalence. But the natural isomorphism $\mathsf{T}(\mathsf{totSite}\,\underline{\mathscr{A}}) \xrightarrow{\sim} \mathsf{totSite}(\underline{\mathscr{A}})^\sim$ identifies $\varepsilon_{\mathsf{totSite}(\underline{\mathscr{A}})}$ with the Yoneda morphism $h^a_{\mathsf{totSite}(\underline{\mathscr{A}})} : \mathsf{totSite}(\underline{\mathscr{A}})^\sim \to \mathsf{totSite}(\underline{\mathscr{A}})$, so the assertion follows from theorem 5.4.12. ◊

Claim 5.7.28. For every fibred lex-site $\underline{\mathscr{A}}$ over I we have pseudo-natural equivalences :

$$\mathsf{St}(\omega^*_{\mathscr{A}_t})^* \circ \mathsf{St}(\mathsf{Top}(\underline{\mathsf{T}}(\underline{\mathscr{A}})/\rho^t)^*)^* \circ \mathsf{St}(\mathsf{b}_{\underline{\mathscr{A}}})^* \xrightarrow{\sim} \mathsf{St}(h^a_{\mathscr{A}_t})^* \circ \mathsf{St}(i_{\mathscr{A},t})_* \qquad \text{for every } t \in \mathrm{Ob}(I)$$

where $\omega_{\mathscr{A}_t} : \mathscr{A}_t^\sim \xrightarrow{\sim} \mathsf{T}(\mathscr{A}_t)$ is the isomorphism of topoi as in (4.4.15).

Proof of the claim. Recall that $\mathsf{St}(h^a_{\mathscr{A}_t})^*$ and its 2-adjoint $\mathsf{St}(h^a_{\mathscr{A}_t})_*$ are 2-equivalences (theorem 5.4.12); then, from proposition 5.4.29(i,ii) we get pseudo-natural equivalences :

$$\mathsf{St}(h^a_{\mathscr{A}_t})^* \circ \mathsf{St}(i_{\mathscr{A},t})_* \xrightarrow{\sim} \mathsf{St}(h^a_{\mathscr{A}_t})^* \circ \mathsf{St}(\breve{\imath}_{\mathscr{A},t})^* \xrightarrow{\sim} \mathsf{St}(\breve{\imath}^*_{\mathscr{A},t})^* \circ \mathsf{St}(h^a_{\mathsf{totSite}(\underline{\mathscr{A}})})^*.$$

We are thus reduced to checking the essential commutativity of the following diagram of sites :

$$\begin{array}{ccc}
\mathrm{Can}(\mathscr{A}_t^\sim) & \xrightarrow{\ \breve{\imath}^*_{\underline{\mathscr{A}},t}\ } & \mathrm{Can}(\mathsf{totSite}\,\underline{\mathscr{A}})^\sim \\
{\scriptstyle \mathsf{Top}(\underline{\mathsf{T}}(\underline{\mathscr{A}})/\rho^t)^*\circ\omega^*_{\mathscr{A}_t}}\big\downarrow & & \big\downarrow{\scriptstyle h^a_{\mathsf{totSite}(\underline{\mathscr{A}})}} \\
\mathrm{Can} \circ \mathsf{Top}(\underline{\mathsf{T}}\,\underline{\mathscr{A}}) & \xrightarrow{\ \mathsf{b}_{\underline{\mathscr{A}}}\ } & \mathsf{totSite}(\underline{\mathscr{A}}).
\end{array}$$

The latter follows by direct inspection. ◊

Now, on the one hand, it is clear that condition (a) holds if and only if $\mathsf{St}(i_{\mathscr{B},t})_* * \Upsilon(\mathsf{St}(\beta)^\gamma_*)_{\mathscr{E}}$ is an equivalence for every $t \in \mathrm{Ob}(I)$. By claim 5.7.28, the latter holds if and only if :

(c) $(\mathsf{St}(\mathsf{Top}(\underline{\mathsf{T}}(\underline{\mathscr{B}})/\rho^t)^*)^* \circ \mathsf{St}(\mathsf{b}_{\underline{\mathscr{B}}})^*) * \Upsilon(\mathsf{St}(\beta)^\gamma_*)_{\mathscr{E}}$ is an equivalence for every $t \in \mathrm{Ob}(I)$.

Set $\mathscr{E}' := \mathsf{St}(\mathsf{b}_{\underline{\mathscr{A}}'})^*(\mathscr{E})$. By claim 5.7.27 and remarks 2.3.11 and 2.3.22(i), condition (c) in turn holds if and only if :

(d) $\mathsf{St}(\mathsf{Top}(\underline{\mathsf{T}}(\underline{\mathscr{B}})/\rho^t)^*)^* * \Upsilon(\mathsf{St}(\mathsf{Top}(\underline{\mathsf{T}}\beta)^*)^\gamma_*)_{\mathscr{E}'}$ is an equivalence for every $t \in \mathrm{Ob}(I)$.

Then, the discussion of (5.7.24) shows that (d) holds if and only if :

(e) $\Upsilon(\mathsf{St}((\mathsf{T}\beta_t)^\dagger)^\gamma_*)_{\mathsf{St}(\mathsf{Top}(\underline{\mathsf{T}}(\underline{\mathscr{A}}')/\rho^t)^*)^*\mathscr{E}'}$ is an equivalence for every $t \in \mathrm{Ob}(I)$.

By invoking again claim 5.7.28, we see that (e) in turn holds if and only if :

(f) $\Upsilon(\mathsf{St}((\beta_t^\sim)^\dagger)^\gamma_*)_{\mathsf{St}(h^a_{\mathscr{A}'_t})^*\mathscr{E}_t}$ is an equivalence for every $t \in \mathrm{Ob}(I)$.

However, from the counit $\varepsilon : \mathrm{Can} \circ \mathsf{T} \Rightarrow \mathbf{1}_{\mathbf{Site}}$ of the 2-adjoint pair $(\mathrm{Can}, \mathsf{T})$ and the system of isomorphisms $\omega_C : C^\sim \xrightarrow{\sim} \mathsf{T}(C)$ of (4.4.15) we get as usual an oriented cubical diagram

$$\begin{array}{ccccccc}
\mathsf{Stack}(\mathrm{Can}\,\mathscr{A}_t^\sim) & & & \xrightarrow{\ \mathsf{St}(\widetilde{\varphi}'^*_t)_*\ } & & & \mathsf{Stack}(\mathrm{Can}\,\mathscr{A}'^\sim_t) \\
& \searrow^{\mathsf{St}(h^a_{\mathscr{A}_t})_*} & & \Uparrow & & {}^{\mathsf{St}(h^a_{\mathscr{A}'_t})_*}\swarrow & \\
& & \mathsf{Stack}(\mathscr{A}_t) & \xrightarrow{\ \mathsf{St}(\varphi'_t)_*\ } & \mathsf{Stack}(\mathscr{A}'_t) & & \\
{\scriptstyle \mathsf{St}(\widetilde{\psi}'^*_t)_*}\big\downarrow & \Downarrow & {\scriptstyle \mathsf{St}(\psi'_t)_*}\big\downarrow & \Downarrow{\scriptstyle \mathsf{St}(\beta_t)^\gamma_*} & \big\downarrow{\scriptstyle \mathsf{St}(\psi_t)_*} & \Downarrow & \big\downarrow{\scriptstyle \mathsf{St}(\widetilde{\psi}^*_t)_*} \\
& & \mathsf{Stack}(\mathscr{B}_t) & \xrightarrow[\ \mathsf{St}(\varphi_t)_*\ ]{} & \mathsf{Stack}(\mathscr{B}'_t) & & \\
& \nearrow^{\mathsf{St}(h^a_{\mathscr{B}_t})_*} & & \Downarrow & & {}^{\mathsf{St}(h^a_{\mathscr{B}'_t})_*}\nwarrow & \\
\mathsf{Stack}(\mathrm{Can}\,\mathscr{B}_t^\sim) & & & \xrightarrow[\ \mathsf{St}(\widetilde{\varphi}^*_t)_*\ ]{} & & & \mathsf{Stack}(\mathrm{Can}\,\mathscr{B}'^\sim_t).
\end{array}$$

commuting on 2-cells, whose four unmarked orientations are pseudo-natural equivalences, and whose front face is oriented by $\mathsf{St}((\beta_t^\sim)^\dagger)^\gamma_*$. Combining with remarks 2.3.11 and 2.3.22(i) we finally conclude that (f)⇔(b). □

Example 5.7.29. Let $u : C' := (\mathscr{C}', J') \to C := (\mathscr{C}, J)$ be a morphism of lex-sites.

(i) Recall that the target functor $\mathsf{t}_\mathscr{C} : \mathsf{Morph}(\mathscr{C}) \to \mathscr{C}$ is a fibration whose fibre category $\mathsf{t}_\mathscr{C}^{-1}X$ is naturally identified with $\mathscr{C}/X$, for every $X \in \mathrm{Ob}(\mathscr{C})$ (example 3.1.3(iii)). Fix a unital cleavage for this fibration, and let c be the associated pseudo-functor; it is easily seen that for every morphism $\varphi : X \to Y$ in $\mathscr{C}$, the functor $\mathsf{c}_\varphi : \mathscr{C}/Y \to \mathscr{C}/X$ is right adjoint to $\varphi_* : \mathscr{C}/X \to \mathscr{C}/Y$, hence it is left exact : explicitly, c_φ assigns to every object $Z \xrightarrow{h} Y$ of $\mathscr{C}/Y$ the induced projection $(X \times_Y Z \to X) \in \mathrm{Ob}(\mathscr{C}/X)$, where $X \times_Y Z$ is a choice of representative for the fibre product of X and Z over Y (detail left to the reader). This description implies easily that c_φ is a morphism of lex-sites $C/X \to C/Y$, for every such φ (notation of (4.7)). The collection of sites $(C/X \mid X \in \mathrm{Ob}(\mathscr{C}))$ then endows the fibration $\mathsf{t}_\mathscr{C}$ with a well defined structure of fibred lex-site $(\mathsf{Morph}(\mathscr{C}), \mathsf{t}_\mathscr{C}, J^\mathscr{C}_\bullet)$.

(ii) The functor $u : \mathscr{C} \to \mathscr{C}'$ induces a commutative diagram of categories :

$$\begin{array}{ccc} \mathsf{Morph}(\mathscr{C}) & \xrightarrow{\mathsf{Morph}(u)} & \mathsf{Morph}(\mathscr{C}') \\ {\scriptstyle \mathsf{t}_\mathscr{C}}\downarrow & & \downarrow{\scriptstyle \mathsf{t}_{\mathscr{C}'}} \\ \mathscr{C} & \xrightarrow{\quad u \quad} & \mathscr{C}'. \end{array}$$

Let now $\mathscr{B}$ be any category, and $F : \mathscr{B} \to \mathscr{C}$ a given functor; we set

$$\mathscr{A} := \mathsf{Fib}(F)^*(\mathsf{Morph}(\mathscr{C})) \qquad \mathscr{A}' := \mathsf{Fib}(F \circ u)^*(\mathsf{Morph}(\mathscr{C}'))$$

and let

$$\mathsf{Morph}(\mathscr{C}) \xleftarrow{\pi} \mathscr{A} \xrightarrow{\varphi} \mathscr{B} \xleftarrow{\varphi'} \mathscr{A}' \xrightarrow{\pi'} \mathsf{Morph}(\mathscr{C}')$$

be the natural projections. There is a unique functor

$$g : \mathscr{A} \to \mathscr{A}' \qquad \text{such that } \varphi' \circ g = \varphi \text{ and } \pi' \circ g = \mathsf{Morph}(u) \circ \pi$$

and since u is left exact, it is easily seen that g is cartesian (details left to the reader). Moreover, the restriction $\varphi^{-1}B \to \varphi'^{-1}B$ of g is naturally identified with $u_{|FB} : \mathscr{C}/FB \to \mathscr{C}'/uFB$, which is a morphism of lex-sites $C'/uFB \to C/FB$. Thus, g is a morphism of fibred lex-sites

$$\mathscr{B} \times_{\mathscr{C}'} (\mathsf{Morph}(\mathscr{C}'), \mathsf{t}_{\mathscr{C}'}, J^{\mathscr{C}'}_\bullet) \to \mathscr{B} \times_\mathscr{C} (\mathsf{Morph}(\mathscr{C}), \mathsf{t}_\mathscr{C}, J^\mathscr{C}_\bullet)$$

and therefore, g is also a morphism of the induced total sites (proposition 4.5.9)

$$g : (\mathscr{A}', J_{\mathscr{A}'}) \to (\mathscr{A}, J_\mathscr{A}).$$

(iii) Suppose moreover that $\mathscr{B}$ is cofiltered, in which case the pseudo-functor c^o factors through a pseudo-functor $\widetilde{\mathsf{c}} : \mathscr{B} \to \mathsf{lex}.\mathbf{Site}$ as in (5.7.6), whose strong 2-limit is represented by the localization $\mathscr{A}[\Sigma_\mathscr{A}^{-1}]$, endowed with a certain topology $J^*_\mathscr{A}$, where $\Sigma_\mathscr{A}$ denotes the set of cartesian morphisms of $\mathscr{A}$. Likewise, the corresponding localization $\mathscr{A}'[\Sigma_{\mathscr{A}'}^{-1}]$ of $\mathscr{A}'$ carries a natural topology $J^*_{\mathscr{A}'}$, and for every $B \in \mathrm{Ob}(\mathscr{B})$ the composition of the inclusion functor $i_{FB} : \mathscr{C}/FB \to \mathscr{A}$ (resp. $i_{uFB} : \mathscr{C}'/uFB \to \mathscr{A}'$) with the localization functor $L_\mathscr{A} : \mathscr{A} \to \mathscr{A}[\Sigma_\mathscr{A}^{-1}]$ (resp. $L_{\mathscr{A}'} : \mathscr{A}' \to \mathscr{A}'[\Sigma_{\mathscr{A}'}^{-1}]$) is a morphism of sites

$$l_{FB} : (\mathscr{A}[\Sigma_\mathscr{A}^{-1}], J^*_\mathscr{A}) \to C/FB \qquad (\text{resp. } l_{uFB} : (\mathscr{A}'[\Sigma_{\mathscr{A}'}^{-1}], J^*_{\mathscr{A}'}) \to C'/uFB\ ).$$

Hence, for every $B \in \mathrm{Ob}(\mathscr{B})$ we get an oriented square of sites :

$$\begin{array}{ccc} (\mathscr{A}'[\Sigma^{-1}_{\mathscr{A}'}], J^*_{\mathscr{A}'}) & \xrightarrow{l_{uFB}} & C'/uFB \\ {\scriptstyle g_\Sigma}\downarrow & \Downarrow & \downarrow{\scriptstyle u_{|FB}} \\ (\mathscr{A}[\Sigma^{-1}_{\mathscr{A}}], J^*_{\mathscr{A}}) & \xrightarrow{l_{FB}} & C/FB \end{array}$$

whose orientation is the identity $\mathbf{1}_{l_{FB} \circ g_\Sigma}$, and where g_Σ is the localization of g (see (5.7.10)). With this notation, we have the following :

Corollary 5.7.30. *In the situation of example* 5.7.29(iii)*, suppose furthermore that $\mathscr{B}$ admits a final object B_0, and that every object of $\mathscr{C}'$ is quasi-compact for the topology J'. Then the base change transformation*

$$\Upsilon(\mathsf{St}(\mathbf{1}_{l_{FB_0} \circ g_\Sigma})^\gamma_*) : \mathsf{St}(l_{FB_0})^* \circ \mathsf{St}(u_{|FB_0})_* \to \mathsf{St}(g_\Sigma)_* \circ \mathsf{St}(l_{uFB_0})^*$$

is a pseudo-natural equivalence.

Proof. We regard C/FB_0 as a fibred lex-site over the category $\mathbb{1}$ with one object and one morphism; then we may define the fibred lex-site $\mathscr{B} \times_{\mathbb{1}} C/FB_0$ over $\mathscr{B}$, as in (4.5.11) : its underlying category is $\mathscr{B} \times \mathscr{C}/FB_0$, and its fibre categories are all naturally identified with $\mathscr{C}/FB_0$, and endowed with the topology of C/FB_0. Likewise we define the fibred lex-site $\mathscr{B} \times_{\mathbb{1}} C'/uFB_0$, and we endow as well the underlying categories with their respective total site topologies. According to example 4.5.8, the inclusion functors $i_{FB_0} : \mathscr{C}/FB_0 \to \mathscr{B} \times \mathscr{C}/FB_0$ and $i_{uFB_0} : \mathscr{C}'/uFB_0 \to \mathscr{B} \times \mathscr{C}'/uFB_0$ are then morphisms of sites :

$$i_{FB_0} : \mathscr{B} \times_{\mathbb{1}} C/FB_0 \to C/FB_0 \qquad i_{uFB_0} : \mathscr{B} \times_{\mathbb{1}} C'/uFB_0 \to C'/uFB_0.$$

For every $B \in \mathrm{Ob}(\mathscr{B})$, let $t_B : B \to B_0$ be the unique morphism in $\mathscr{B}$; we have a natural isomorphism of categories

$$(\mathscr{C}/FB_0)/Ft_B \xrightarrow{\sim} \mathscr{C}/FB$$

that identifies the source functor $\mathsf{s}_{Ft_B} : (\mathscr{C}/FB_0)/Ft_B \to \mathscr{C}/FB_0$ with the functor $(Ft_B)_* : \mathscr{C}/FB \to \mathscr{C}/FB_0$, and likewise for the category $(\mathscr{C}'/uFB_0)/uFt_B$. According to (5.5.30), for every such B we have then an oriented square of sites :

$$\begin{array}{ccc} C'/uFB & \xrightarrow{p_{uFt_B}} & C'/uFB_0 \\ {\scriptstyle u_{|FB}}\downarrow & \Downarrow \beta_B & \downarrow{\scriptstyle u_{|FB_0}} \\ C/FB & \xrightarrow{p_{Ft_b}} & C/FB_0. \end{array}$$

It is easily seen that the system of orientations $(\beta_B \mid B \in \mathrm{Ob}(\mathscr{B}))$ amounts to an orientation β for the central square subdiagram in the following diagram of oriented squares of sites :

$$\begin{array}{ccccccc} (\mathscr{A}'[\Sigma^{-1}_{\mathscr{A}'}], J^*_{\mathscr{A}'}) & \xrightarrow{L_{\mathscr{A}'}} & (\mathscr{A}', J_{\mathscr{A}'}) & \xrightarrow{p_{\mathscr{A}'}} & \mathscr{B} \times_{\mathbb{1}} C'/uFB_0 & \xrightarrow{i_{uFB_0}} & C'/uFB_0 \\ {\scriptstyle g_\Sigma}\downarrow & \Downarrow & \downarrow{\scriptstyle g} & \Downarrow \beta & \downarrow{\scriptstyle \mathscr{B} \times u_{|FB_0}} & \Downarrow & \downarrow{\scriptstyle u_{|FB_0}} \\ (\mathscr{A}[\Sigma^{-1}_{\mathscr{A}}], J^*_{\mathscr{A}}) & \xrightarrow{L_{\mathscr{A}}} & (\mathscr{A}, J_{\mathscr{A}}) & \xrightarrow{p_{\mathscr{A}}} & \mathscr{B} \times_{\mathbb{1}} C/FB_0 & \xrightarrow{i_{FB_0}} & C/FB_0. \end{array}$$

Here $p_{\mathscr{A}}$ is the cartesian functor whose restriction to fibre categories $\mathscr{C}/FB_0 \to \mathscr{C}/FB$ agrees with p_{Ft_B}, for every $B \in \mathrm{Ob}(\mathscr{B})$, and the orientations of the left and right square are identities. Under our assumptions, it is easily seen that every object of $\mathscr{A}$ is quasi-compact for the topology $J_{\mathscr{A}'}$; then the base change transformation associated with the left square subdiagram is a pseudo-natural equivalence, by virtue of proposition 5.7.11. The same holds for the base change transformation associated with the central square, by proposition 5.5.31 and corollary

5.7.26. A simple inspection shows that the composition of the three top (resp. bottom) horizontal arrows equals l_{uFB_0} (resp. l_{FB_0}). It remains therefore only to check that the base change transformation

$$\mathsf{St}(i_{FB_0})^*\mathsf{St}(u_{|FB_0})_* \to \mathsf{St}(\mathscr{B} \times u_{|FB_0})_*\mathsf{St}(i_{uFB_0})^*$$

associated with the right square is a pseudo-natural equivalence. To this aim, we remark :

Claim 5.7.31. Let $\mathscr{F}_\bullet$ be any sheaf of categories on C'/uFB_0 such that $\mathscr{F}ib(\mathscr{F}_\bullet)$ is a stack on C'/uFB_0. Then $\mathscr{F}ib((\widetilde{\imath}^*_{uFB_0}, \mathbf{Cat})^*\mathscr{F}_\bullet)$ is a stack on $\mathscr{B} \times_{\mathbb{1}} C'/uFB_0$.

Proof of the claim. notice first that, since B_0 is a final object in $\mathscr{B}$, the projection $q_{uFB_0} : \mathscr{B} \times \mathscr{C}'/uFB_0 \to \mathscr{C}'/uFB_0$ is a left adjoint for the functor i_{uFB_0}. On the other hand, proposition 4.5.5(iv) easily implies that q_{uFB_0} is continuous for the sites C'/uFB_0 and $\mathscr{B} \times_{\mathbb{1}} C'/uFB_0$. Combining with lemma 4.2.14(ii), we deduce a natural isomorphism of functors :

$$\widetilde{\imath}^*_{uFB_0} \xrightarrow{\sim} \widetilde{q}_{uFB_0*}. \tag{5.7.32}$$

Thus, it suffices to check that $\mathscr{F}ib((\widetilde{q}_{uFB_0*}, \mathbf{Cat})_*\mathscr{F}_\bullet)$ is a stack. The latter follows easily from corollary 5.7.2(ii). ◊

In light of claim 5.7.31, corollary 5.5.26(iv), and the discussion of (5.5.29), we are then reduced to checking that the base change transformation

$$\widetilde{\imath}^*_{FB_0} \circ (u_{|FB_0})^\sim_* \to (\mathscr{B} \times u_{|FB_0})^\sim_* \circ \widetilde{\imath}^*_{uFB_0}$$

is an isomorphism of functors. But notice that i_{uFB_0} is fully faithful, and it is both continuous and cocontinuous (proposition 4.5.5(iii)); it follows that $\widetilde{\imath}^*_{uFB_0}$ is fully faithful (lemma 4.2.15(iv)), hence the unit of the adjoint pair $(\widetilde{\imath}^*_{uFB_0}, \widetilde{\imath}_{uFB_0*})$ is an isomorphism. Thus, let η and ε be the unit and counit for the adjoint pair $(\widetilde{\imath}^*_{FB_0}, \widetilde{\imath}_{FB_0*})$; we are reduced to checking that $\varepsilon * ((\mathscr{B} \times u_{|FB_0})^\sim_* \circ \widetilde{\imath}^*_{uFB_0})$ is an isomorphism. However, let $q_{FB_0} : \mathscr{B} \times \mathscr{C}/FB_0 \to \mathscr{C}/FB_0$ be the projection; arguing as in the proof of claim 5.7.31 we get an isomorphism of functors

$$\widetilde{\imath}^*_{FB_0} \xrightarrow{\sim} \widetilde{q}_{FB_0*}. \tag{5.7.33}$$

From (5.7.32) and (5.7.33) there follow isomorphisms of functors :

$$(\mathscr{B} \times u_{|FB_0})^\sim_* \circ \widetilde{\imath}^*_{uFB_0} \xrightarrow{\sim} (\mathscr{B} \times u_{|FB_0})^\sim_* \circ \widetilde{q}_{uFB_0*} \xrightarrow{\sim} \widetilde{q}_{FB_0*} \circ (u_{|FB_0})^\sim_* \xrightarrow{\sim} \widetilde{\imath}^*_{FB_0} \circ (u_{|FB_0})^\sim_*.$$

So it suffices to check that $\varepsilon * (\widetilde{\imath}^*_{FB_0} \circ (u_{|FB_0})^\sim_*)$ is an isomorphism; but again, arguing as in the foregoing we see that $\widetilde{\imath}^*_{FB_0}$ is fully faithful, so η is an isomorphism, and finally the assertion follows, taking into account the triangular identities of (1.1.13). □

Remark 5.7.34. In the situation of example 5.7.29(ii), the functors $\varphi : \mathscr{A} \to \mathscr{B}$ and $\mathsf{s}_{\mathscr{C}} \circ \pi : \mathscr{A} \to \mathscr{C}$ induce a functor

$$s : \mathscr{A} \to \mathscr{B} \times \mathscr{C} \qquad (B, f : X \to Y) \mapsto (B, X)$$

(namely, s is the unique functor whose composition with the projections $\mathscr{B} \leftarrow \mathscr{B} \times \mathscr{C} \to \mathscr{C}$ equals respectively φ and $\mathsf{s}_{\mathscr{C}} \circ \pi$). The functor s admits a right adjoint :

$$q : \mathscr{B} \times \mathscr{C} \to \mathscr{A}$$

that assigns to every $(B, X) \in \mathrm{Ob}(\mathscr{B} \times \mathscr{C})$ the object $(B, p_{X,B} : X \times FB \to FB) \in \mathrm{Ob}(\mathscr{A})$, where $p_{X,B}$ is the natural projection. To every morphism $(\beta, f) : (B, X) \to (B', X')$ of $\mathscr{B} \times \mathscr{C}$, the functor q assigns the morphism $q(\beta, f) := (\beta, \mathscr{D})$ of $\mathscr{A}$, with $\mathscr{D}$ the commutative square :

$$\begin{array}{ccc} X \times FB & \xrightarrow{p_{X,B}} & FB \\ {\scriptstyle f \times F\beta}\downarrow & & \downarrow{\scriptstyle F\beta} \\ X' \times FB' & \xrightarrow{p_{X',B'}} & FB'. \end{array}$$

Let us regard $(\mathscr{C}, J)$ as a fibred site over the category $\mathbb{1}$ with one object and one morphism; then $\mathscr{B} \times_{\mathbb{1}} (\mathscr{C}, J)$ is a fibred category over $\mathscr{B}$, and taking into account remark 4.7.3(iii), it is easily seen that q is a morphism of fibred sites

$$q : \mathscr{B} \times_{\mathscr{C}} (\mathsf{Morph}(\mathscr{C}), \mathsf{t}_{\mathscr{C}}, J_{\bullet}^{\mathscr{C}}) \to \mathscr{B} \times_{\mathbb{1}} (\mathscr{C}, J)$$

and therefore it is as well a morphism of the respective total sites

$$q : (\mathscr{A}, J_{\mathscr{A}}) \to (\mathscr{B} \times \mathscr{C}, J_{\mathscr{B}\times\mathscr{C}}).$$

It follows that s is cocontinuous for the topologies $J_{\mathscr{A}}$ and $J_{\mathscr{B}\times\mathscr{C}}$ (lemma 4.2.14(i)); moreover, we easily deduce from example 5.4.16 that s is a weak morphism of fibred sites

$$s : \mathscr{B} \times_{\mathbb{1}} (\mathscr{C}, J) \to \mathscr{B} \times_{\mathscr{C}} (\mathsf{Morph}(\mathscr{C}), \mathsf{t}_{\mathscr{C}}, J_{\bullet}^{\mathscr{C}})$$

(see definition 5.7.4); therefore it is as well a weak morphism of the respective total sites

$$s : (\mathscr{B} \times \mathscr{C}, J_{\mathscr{B}\times\mathscr{C}}) \to (\mathscr{A}, J_{\mathscr{A}})$$

(proposition 5.7.5). Combining with proposition 5.4.29(ii,iii), we deduce a pseudo-natural equivalence of pseudo-functors :

$$\mathsf{St}(s)_* \xrightarrow{\sim} \mathsf{St}(q)^*.$$

6. Monoids and polyhedra

Unless explicitly stated otherwise, *every monoid encountered in this chapter shall be commutative*. For this reason, we shall usually economize adjectives, and write just "monoid" when referring to commutative monoids.

6.1. **Monoids.** If M is any monoid, we shall usually denote the composition law of M by multiplicative notation: $(x, y) \mapsto x \cdot y$ (so 1 is the neutral element). However, sometimes it is convenient to be able to switch to an additive notation; to allow for that, we shall denote by $(\log M, +)$ the monoid with additive composition law, whose underlying set is the same as for the given monoid $(M, \cdot)$, and such that the identity map is an isomorphism of monoids (then, the neutral element of $\log M$ is denoted by 0). For emphasis, we may sometimes denote by $\log : M \xrightarrow{\sim} \log M$ the identity map, so that one has the tautological identities :

$$\log 1 = 0 \qquad \text{and} \qquad \log(x \cdot y) = \log x + \log y \quad \text{for every } x, y \in M.$$

Conversely, if $(M, +)$ is a given monoid with additive composition law, we may switch to a multiplicative notation by writing $(\exp M, \cdot)$, in the same way.

6.1.1. For any monoid M, and any two subsets $S, S' \subset M$, we let :

$$S \cdot S' := \{s \cdot s' \mid s \in S, s' \in S'\}$$

and S^a is defined recursively for every $a \in \mathbb{N}$, by the rule :

$$S^0 := \{1\} \qquad \text{and} \qquad S^a := S \cdot S^{a-1} \quad \text{if } a > 0.$$

Notice that the pair $(\mathscr{P}(M), \cdot)$ consisting of the set of all subsets of M, together with the composition law just defined, is itself a monoid : the neutral element is the subset $\{1\}$. In the same vein, the exponential notation for subsets of M becomes a multiplicative notation in the monoid $(\log \mathscr{P}(M), +) = (\mathscr{P}(\log M), +)$, *i.e.* we have the tautological identity : $\log S^a = a \cdot \log S$, for every $S \in \mathscr{P}(M)$ and every $a \in \mathbb{N}$.

Furthermore, for any two monoids M and N, the set $\mathrm{Hom}_{\mathbf{Mnd}}(M, N)$ is naturally a monoid. The composition law assigns to any two morphisms $\varphi, \psi : M \to N$ their product $\varphi \cdot \psi$, given by the rule : $\varphi \cdot \psi(m) := \varphi(m) \cdot \psi(m)$ for every $m \in M$.

Basic examples of monoids are the set $(\mathbb{N}, +)$ of natural numbers, and the non-negative real (resp. rational) numbers $(\mathbb{R}_+, +)$ (resp. $(\mathbb{Q}_+, +)$), with their standard addition laws.

6.1.2. Given a surjection $X \to Y$ of monoids, it may not be possible to express Y as a quotient of X – a problem relevant to the construction of *presentations* for given monoids, in terms of free monoids. For instance, consider the monoid $(\mathbb{Z}, \odot)$ consisting of the set $\mathbb{Z}$ with the composition law $\odot$ such that :

$$x \odot y := \begin{cases} x + y & \text{if either } x, y \geq 0 \text{ or } x, y \leq 0 \\ \max(x, y) & \text{otherwise} \end{cases}$$

for every $x, y \in \mathbb{Z}$. Define a surjective map $\varphi : \mathbb{N}^{\oplus 2} \to (\mathbb{Z}, \odot)$ by the rule $(n, m) \mapsto n \odot -m$, for every $n \in \mathbb{N}$. Then one verifies easily that $\operatorname{Ker} \varphi = \{0\}$, and nevertheless φ is not an isomorphism. The right way to proceed is indicated by the following :

Lemma 6.1.3. *Every surjective map of monoids is an effective epimorphism (in the category* $\mathbf{Mnd}$*).*

Proof. (See example 4.1.9(v) for the notion of effective epimorphism.) Let $\pi : M \to N$ be a surjection of monoids. For every monoid X, we have a natural diagram of sets :

$$\operatorname{Hom}_{\mathbf{Mnd}}(N, X) \xrightarrow{j} \operatorname{Hom}_{\mathbf{Mnd}}(M, X) \overset{p_1^*}{\underset{p_2^*}{\rightrightarrows}} \operatorname{Hom}_{\mathbf{Mnd}}(M \times_N M, X)$$

where $p_1, p_2 : M \times_N M \to M$ are the two natural projections, and we have to show that the map j identifies $\operatorname{Hom}_{\mathbf{Mnd}}(N, X)$ with the equalizer of p_1^* and p_2^*. First of all, the surjectivity of π easily implies that j is injective. Hence, let $\varphi : M \to X$ be any map such that $\varphi \circ p_1 = \varphi \circ p_2$; we have to show that φ factors through π. To this aim, it suffices to show that the map of sets underlying φ factors as a composition $\varphi' \circ \pi$, for some map of sets $\varphi' : N \to X$, since φ' will then be necessarily a morphism of monoids. However, the forgetful functor $F : \mathbf{Mnd} \to \mathbf{Set}$ commutes with fibre products (lemma 4.8.29(iii)), and $F(\pi)$ is an effective epimorphism, since in the category $\mathbf{Set}$ all surjections are effective epimorphisms. The assertion follows. □

6.1.4. Lemma 6.1.3 allows to construct presentations for an arbitrary monoid M, as follows. First, we choose a surjective map of monoids $F := \mathbb{N}^{(S)} \to M$, for some set S. Then we choose another set T and a surjection of monoids $\mathbb{N}^{(T)} \to F \times_M F$. Composing with the natural projections $p_1, p_2 : F \times_M F \to F$, we obtain a diagram :

$$\mathbb{N}^{(T)} \overset{q_1}{\underset{q_2}{\rightrightarrows}} \mathbb{N}^{(S)} \longrightarrow M \qquad (6.1.5)$$

which, in view of lemma 6.1.3, identifies M to the coequalizer of q_1 and q_2.

Definition 6.1.6. Let M be a monoid, $\Sigma \subset M$ a subset.

(i) Let $(e_\sigma \mid \sigma \in \Sigma)$ be the natural basis of the free monoid $\mathbb{N}^{(\Sigma)}$. We say that Σ is a *system of generators* for M, if the map of monoids $\mathbb{N}^{(\Sigma)} \to M$ such that $e_\sigma \mapsto \sigma$ for every $\sigma \in \Sigma$, is a surjection.
(ii) M is said to be *finitely generated* if it admits a finite system of generators.
(iii) M is said to be *fine* if it is integral and finitely generated.
(iv) A *finite presentation* for M is a diagram such as (6.1.5) that identifies M to the coequalizer of q_1 and q_2, and such that, moreover, S and T are finite sets.
(v) We say that a morphism of monoids $\varphi : M \to N$ is *finite*, if N is a finitely generated M-module, for the M-module structure induced by φ.

Lemma 6.1.7. (i) *Every finitely generated monoid admits a finite presentation.*

(ii) *Let M be a finitely generated monoid, and $(N_i \mid i \in I)$ a filtered family of monoids. Then the natural map :*

$$\operatorname*{colim}_{i \in I} \operatorname{Hom}_{\mathbf{Mnd}}(M, N_i) \to \operatorname{Hom}_{\mathbf{Mnd}}(M, \operatorname*{colim}_{i \in I} N_i)$$

is a bijection.

Proof. (i): Let M be a finitely generated monoid, and choose a surjection $\pi : \mathbb{N}^{(S)} \to M$ with S a finite set. We have seen that M is the coequalizer of the two projections $p_1, p_2 : P := \mathbb{N}^{(S)} \times_M \mathbb{N}^{(S)} \to \mathbb{N}^{(S)}$. For every finitely generated submonoid $N \subset P$, let $p_{1,N}, p_{2,N} : N \to \mathbb{N}^{(S)}$ be the restrictions of p_1 and p_2, and denote by C_N the coequalizer of $p_{1,N}$ and $p_{2,N}$. By the universal property of C_N, the map π factors through a map of monoids $\pi_N : C_N \to M$, and since π is surjective, the same holds for π_N. It remains to show that π_N is an isomorphism, for N large enough. We apply the functor $M \mapsto \mathbb{Z}[M]$ of (4.8.50), and we derive that $\mathbb{Z}[M]$ is the coequalizer of the two maps $\mathbb{Z}[p_1], \mathbb{Z}[p_2] : \mathbb{Z}[P] \to \mathbb{Z}[S]$, *i.e.* $\mathbb{Z}[M] \simeq \mathbb{Z}[S]/I$, where I is the ideal generated by $\mathrm{Im}(\mathbb{Z}[p_1] - \mathbb{Z}[p_2])$. Clearly I is the colimit of the filtered system of analogous ideals I_N generated by $\mathrm{Im}(\mathbb{Z}[p_{1,N}] - \mathbb{Z}[p_{2,N}])$, for N ranging over the filtered family $\mathscr{F}$ of finitely generated submonoids of P. By noetherianity, there exists $N \in \mathscr{F}$ such that $I = I_N$, therefore $\mathbb{Z}[M]$ is the coequalizer of $\mathbb{Z}[p_{1,N}]$ and $\mathbb{Z}[p_{2,N}]$. But the latter coequalizer is also the same as $\mathbb{Z}[C_N]$, whence the contention.

(ii): This is a standard consequence of (i). Indeed, say that $f_1, f_2 : M \to N_i$ are two morphisms whose compositions with the natural map $N_i \to N := \mathrm{colim}_{i \in I} N_i$ agree, and pick a finite set of generators $x_1, \dots, x_n$ for M. For any morphism $\varphi : i \to j$ in the filtered category I, denote by $g_\varphi : N_i \to N_j$ the corresponding morphism; then we may find such a morphism φ, so that $g_\varphi \circ f_1(x_k) = g_\varphi \circ f_2(x_k)$ for every $k \leq n$, whence the injectivity of the map in (ii). Next, let $f : M \to N$ be a given morphism, and pick a finite presentation (6.1.5); we deduce a morphism $g : \mathbb{N}^{(S)} \to N$, and since S is finite, it is clear that g factors through a morphism $g_i : \mathbb{N}^{(S)} \to N_i$ for some $i \in I$. Set $g'_i := g_i \circ q_1$ and $g''_i := g_i \circ q_2$; by assumption, after composing g'_i and of g''_i with the natural map $N_i \to N$, we obtain the same map, so by the foregoing there exists a morphism $\varphi : i \to j$ in I such that $g_\varphi \circ g'_i = g_\varphi \circ g''_i$. It follows that $g_\varphi \circ g_i$ factors through M, whence the surjectivity of the map in (ii). □

Definition 6.1.8. Let M be a monoid, $I \subset M$ an ideal.

(i) We say that I is *principal*, if it is cyclic, when regarded as an M-module.
(ii) The *radical* of I is the ideal $\mathrm{rad}(I)$ consisting of all $x \in M$ such that $x^n \in I$ for every sufficiently large $n \in \mathbb{N}$. If $I = \mathrm{rad}(I)$, we also say that I is a *radical ideal*.
(iii) A *face* of M is a submonoid $F \subset M$ with the following property. If $x, y \in M$ are any two elements, and $xy \in F$, then $x, y \in F$.
(iv) Notice that the complement of a face is always an ideal. We say that I is a *prime ideal* of M, if $M \backslash I$ is a face of M.

Proposition 6.1.9. *Let M be a finitely generated monoid, and S a finitely generated M-module. Then we have :*

(i) *Every submodule of S is finitely generated.*
(ii) *Especially, every ideal of M is finitely generated.*

Proof. Of course, (ii) is a special case of (i). To show (i), let $S' \subset S$ be an M-submodule, $\Sigma \subset S'$ any system of generators. Let $\mathscr{P}'(\Sigma)$ be the set of all finite subsets of Σ, and for every $A \in \mathscr{P}'(\Sigma)$, denote by $S'_A \subset S'$ the submodule generated by A; clearly S' is the filtered union of the family $(S'_A \mid A \in \mathscr{P}'(\Sigma))$, hence $\mathbb{Z}[S']$ is the filtered union of the family of $\mathbb{Z}[M]$-submodules $(\mathbb{Z}[S'] \mid S \in \mathscr{P}'(\Sigma))$. Since $\mathbb{Z}[M]$ is noetherian and $\mathbb{Z}[S]$ is a finitely generated $\mathbb{Z}[M]$-module, it follows that $\mathbb{Z}[S'_A] = \mathbb{Z}[S']$ for some finite subset $A \subset \Sigma$, whence the contention. □

Definition 6.1.10. (i) Let M be a monoid. The *spectrum* of M is the set :

$$\mathrm{Spec}\, M$$

consisting of all prime ideals of M. It has a natural partial ordering, given by inclusion of prime ideals; the minimal element of $\mathrm{Spec}\, M$ is the empty ideal $\varnothing \subset M$, and the maximal element is:

$$\mathfrak{m}_M := M \backslash M^\times.$$

(ii) The *dimension* of M, denoted $\dim M \in \mathbb{N} \cup \{+\infty\}$, is defined as the supremum of all $r \in \mathbb{N}$ such that there exists a chain of strict inclusions of prime ideals of M :

$$\mathfrak{p}_0 \subset \mathfrak{p}_1 \subset \cdots \subset \mathfrak{p}_r.$$

(iii) The *height* of a prime ideal $\mathfrak{p} \in \mathrm{Spec}\, M$ is defined as $\mathrm{ht}\, \mathfrak{p} := \dim M_\mathfrak{p}$.

(iv) A *facet* of M is the complement of a prime ideal of M of height one.

(v) Any morphism $\varphi : M \to N$ of monoids induces a natural map :

$$\varphi^* : \mathrm{Spec}\, N \to \mathrm{Spec}\, M \qquad \mathfrak{p} \mapsto \varphi^{-1}\mathfrak{p}$$

of partially ordered sets. We say that φ is *local*, if $\varphi(\mathfrak{m}_M) \subset \mathfrak{m}_N$.

Remark 6.1.11. Let M be any monoid.

(i) It is clear from definition 6.1.10(i) that $\dim M = 0$ if and only if $M = M^\times$.

(ii) Moreover, if $(I_\lambda \mid \lambda \in \Lambda)$ is any collection of ideals of M then it is easily seen that both $\bigcup_{\lambda\in\Lambda} I_\lambda$ and $\bigcap_{\lambda\in\Lambda} I_\lambda$ are ideals of M. If $(\mathfrak{p}_\lambda \mid \lambda \in \Lambda)$ is any family of prime ideals of M, then $\bigcup_{\lambda\in\Lambda} \mathfrak{p}_\lambda$ is a prime ideal of M.

Corollary 6.1.12. *Let M be any fine and sharp monoid. The set $\mathfrak{m}_M \backslash \mathfrak{m}_M^2$ is finite, and is the unique minimal system of generators of M.*

Proof. It is easily seen that any system of generators of M must contain $\Sigma := \mathfrak{m}_M \backslash \mathfrak{m}_M^2$, hence the latter must be a finite set. On the other hand, suppose that there exists an element $x_0 \in M$ which is not contained in the submonoid M' generated by Σ. Then we may write $x_0 = x_1 y_1$ for some $x_1, y_1 \in \mathfrak{m}_M$, with $x_1 \notin M'$, so x_1 admits a similar decomposition. Proceeding in this way, we obtain a sequence of elements $(x_n \mid n \in \mathbb{N})$ with the property that $Mx_n \subset Mx_{n+1}$ for every $n \in \mathbb{N}$. We claim that $Mx_n \neq Mx_{n+1}$ for every $n \in \mathbb{N}$. Indeed, if the inequality fails for some $n \in \mathbb{N}$, we may write $x_{n+1} = ax_n$ for some $a \in M$, and on the other hand, we have by construction $x_n = yx_{n+1}$ for some $y \in \mathfrak{m}_M$; summing up, we get $x_n = yax_n$, whence $ya = 1$, since M is integral, therefore $y \in M^\times$, a contradiction.

Thus, from the given x_0, we have produced an infinite strictly ascending chain of ideals of M, which is ruled out by virtue of proposition 6.1.9(ii). This means that x_0 cannot exist, and the corollary follows. □

Lemma 6.1.13. *Let $f_1 : M \to N_1$ and $f_2 : M \to N_2$ be two local morphisms of monoids. If N_1 and N_2 are sharp, then $N_1 \amalg_M N_2$ is sharp.*

Proof. Let $(a, b) \in N_1 \times N_2$, and suppose there exist $c \in M$, $a' \in N_1$, $b' \in N_2$ such that $(a, b) = (a' f_1(c), b')$ and $(1, 1) = (a', f_2(c)b')$; since N_2 is sharp, we deduce $f_2(c) = b' = 1$, so $b = 1$. Then, since f_2 is local, we get $c \in M^\times$, hence $f_1(c) = 1$ and $a = a' = 1$. One argues symmetrically in case $(1, 1) = (a' f_1(c), b')$ and $(a, b) = (a', f_2(c)b')$. We conclude that (a, b) represents the unit class in $N_1 \amalg_M N_2$ if and only if $a = b = 1$. Now, suppose that the class of (a, b) is invertible in $N_1 \amalg_M N_2$; it follows that there exists (c, d) such that $ac = 1$ and $bd = 1$, which implies that $a = 1$ and $b = 1$, whence the contention. □

Lemma 6.1.14. *Let $S \subset M$ be any submonoid. The localization $j : M \to S^{-1}M$ induces an injective map $j^* : \mathrm{Spec}\, S^{-1}M \to \mathrm{Spec}\, M$ which identifies $\mathrm{Spec}\, S^{-1}M$ with the subset of $\mathrm{Spec}\, M$ consisting of all prime ideals $\mathfrak{p}$ such that $\mathfrak{p} \cap S = \varnothing$.*

Proof. For every $\mathfrak{p} \in \mathrm{Spec}\, M$, denote by $S^{-1}\mathfrak{p}$ the ideal of $S^{-1}M$ generated by the image of $\mathfrak{p}$. We claim that $\mathfrak{p} = j^*(S^{-1}\mathfrak{p})$ for every $\mathfrak{p} \in \mathrm{Spec}\, M$ such that $\mathfrak{p} \cap S = \varnothing$. Indeed, clearly

$\mathfrak{p} \subset j^*(S^{-1}\mathfrak{p})$; next, if $f \in j^*(S^{-1}\mathfrak{p})$, there exist $s \in S$ and $g \in \mathfrak{p}$ such that $s^{-1}g = f$ in $S^{-1}M$; therefore there exists $t \in S$ such that $tg = tsf$ in M, especially $tsf \in \mathfrak{p}$, hence $f \in \mathfrak{p}$, since $t, s \notin \mathfrak{p}$. Likewise, one checks easily that $S^{-1}\mathfrak{p}$ is a prime ideal if $\mathfrak{p} \cap S = \varnothing$, and $\mathfrak{q} = S^{-1}(j^*\mathfrak{q})$ for every $\mathfrak{q} \in \operatorname{Spec} S^{-1}M$, whence the contention. □

Remark 6.1.15. (i) If we take $S_\mathfrak{p} := M \backslash \mathfrak{p}$, the complement of a prime ideal $\mathfrak{p}$ of M, we obtain the monoid

$$M_\mathfrak{p} := S_\mathfrak{p}^{-1} M$$

and $\operatorname{Spec} M_\mathfrak{p} \subset \operatorname{Spec} M$ is the subset consisting of all prime ideals $\mathfrak{q}$ of M contained in $\mathfrak{p}$.

(ii) Likewise, if $\mathfrak{p} \subset M$ is any prime ideal, the spectrum $\operatorname{Spec}(M \backslash \mathfrak{p})$ is naturally identified with the subset of $\operatorname{Spec} M$ consisting of all prime ideals $\mathfrak{q}$ containing $\mathfrak{p}$ (details left to the reader).

(iii) Let $S \subset M$ be any submonoid. Then there exists a smallest face F of M containing S (namely, the intersection of all the faces that contain S). It is easily seen that F is the subset of all $x \in M$ such that $xM \cap S \neq \varnothing$. From this characterization, it is clear that $S^{-1}M = F^{-1}M$. In other words, every localization of M is of the type $M_\mathfrak{p}$ for some $\mathfrak{p} \in \operatorname{Spec} M$.

Lemma 6.1.16. *Let M be a monoid, and $I \subset M$ any ideal. Then $\operatorname{rad}(I)$ is the intersection of all the prime ideals of M containing I.*

Proof. It is easily seen that a prime ideal containing I also contains $\operatorname{rad}(I)$. Conversely, say that $f \in M \setminus \operatorname{rad}(I)$; let $\varphi : M \to M_f$ be the localization map. Denote by $\mathfrak{m}$ the maximal ideal of M_f. We claim that $I \subset \varphi^{-1}\mathfrak{m}$, Indeed, otherwise there exist $g \in I$, $h \in M$ and $n \in \mathbb{N}$ such that $g^{-1} = f^{-n}h$ in M_f; this means that there exists $m \in \mathbb{N}$ such that $f^{m+n} = f^m gh$ in M, hence $f^{m+n} \in I$, which contradicts the assumption on f. On the other hand, obviously $f \notin \varphi^{-1}\mathfrak{m}$. □

Lemma 6.1.17. (i) *Let M be a monoid, and $G \subset M^\times$ a subgroup.*

(a) *The map given by the rule : $I \mapsto I/G$ establishes a natural bijection from the set of ideals of M onto the set of ideals of M/G.*

(b) *Especially, the natural projection $\pi : M \to M/G$ induces a bijection :*

$$\pi^* : \operatorname{Spec} M/G \to \operatorname{Spec} M$$

(ii) *Let $(M_i \mid i \in I)$ be any finite family of monoids, and for each $j \in I$, denote by $\pi_j : \prod_{i\in I} M_i \to M_j$ the natural projection. The induced map*

$$\prod_{i\in I} \operatorname{Spec} M_i \to \operatorname{Spec} \prod_{i\in I} M_i \quad : \quad (\mathfrak{p}_i \mid i \in I) \mapsto \bigcup_{i\in I} \pi_i^* \mathfrak{p}_i$$

is a bijection.

(iii) *Let $(M_i \mid i \in I)$ be any filtered system of monoids. The natural map*

$$\operatorname{Spec} \operatorname*{colim}_{i\in I} M_i \to \lim_{i\in I} \operatorname{Spec} M_i$$

is a bijection.

Proof. (i): By lemma 4.8.31(iii), M/G is the set-theoretic quotient of M by the translation action of G. By definition, any ideal I of M is stable under the G-action, hence the quotient I/G is well defined, and one checks easily that it is an ideal of M/G. Moreover, if $\mathfrak{p} \subset M$ is a prime ideal, it is easily seen that $\mathfrak{p}/G$ is a prime ideal of M/G. Assertions (a) and (b) are straightforward consequences.

(ii): The assertion can be rephrased by saying that every face F of $\prod_{i\in I} M_i$ is a product of faces $F_i \subset M_i$. However, if $\underline{m} := (m_i \mid i \in I) \in F$, then, for each $i \in I$ we can write $\underline{m} = \underline{m}(i) \cdot \underline{n}(i)$, where, for each $j \in I$, the j-th-component of $\underline{m}(i)$ (resp. of $\underline{n}(i)$) equals 1 (resp. m_j), unless $j = i$, in which case it equals m_i (resp. 1). Thus, $\underline{m}(i) \in F$ for every $i \in I$, and the contention follows easily.

(iii): Denote by M the colimit of the system $(M_i \mid i \in I)$, and $\varphi_i : M_i \to M$ the natural morphisms of monoids, as well as $\varphi_f : M_i \to M_j$ the transition maps, for every morphism $f : i \to j$ in I. Recall that the set underlying M is the colimit of the system of sets $(M_i \mid i \in I)$ (lemma 4.8.29(iii)). Let now $\mathfrak{p}_\bullet := (\mathfrak{p}_i \mid \ \in I)$ be a compatible system of prime ideals, *i.e.* such that $\mathfrak{p}_i \in \operatorname{Spec} M_i$ for every $i \in I$, and $\varphi_f^{-1}\mathfrak{p}_j = \mathfrak{p}_i$ for every $f : i \to j$. We let $\beta(\mathfrak{p}_\bullet) := \bigcup_{i\in I} \varphi_i(\mathfrak{p}_i)$. We claim that $\beta(\mathfrak{p}_\bullet)$ is a prime ideal of M. Indeed, suppose that $x, y \in M$ and $xy \in \beta(\mathfrak{p}_\bullet)$; since I is filtered, we may find $i \in I$, $x_i, y_i \in M_i$, and $z_i \in \mathfrak{p}_i$, such that $x = \varphi_i(x_i)$, $y = \varphi_i(y_i)$, and $xy = \varphi_i(z_i)$. Especially, $\varphi_i(z_i) = \varphi_i(x_i y_i)$, so there exists a morphism $f : i \to j$ such that $\varphi_f(z_i) = \varphi_f(x_i y_i)$. But $\varphi_f(z_i) \in \mathfrak{p}_j$, so either $\varphi_f(x_i) \in \mathfrak{p}_j$ or $\varphi_f(y_i) \in \mathfrak{p}_j$, and finally either $x \in \mathfrak{p}$ or $y \in \mathfrak{p}$, as required.

Let $\mathfrak{p} \subset M$ be any prime ideal; it is easily seen that $\beta(\varphi_i^{-1}\mathfrak{p} \mid i \in I) = \mathfrak{p}$. To conclude, it suffices to show that $\mathfrak{p}_i = \varphi_i^{-1}\beta(\mathfrak{p}_\bullet)$, for every compatible system $\mathfrak{p}_\bullet$ as above, and every $i \in I$. Hence, fix $i \in I$ and pick $x_i \in M_i$ such that $\varphi_i(x_i) \in \beta(\mathfrak{p}_\bullet)$; then there exist $j \in I$ and $x_j \in \mathfrak{p}_j$ such that $\varphi_i(x_i) = \varphi_j(x_j)$. Since I is filtered, we may find $k \in I$ and morphisms $f : i \to k$ and $g : j \to k$ such that $\varphi_f(x_i) = \varphi_g(x_j)$, so $\varphi_f(x_i) \in \mathfrak{p}_k$, and finally $x_i \in \mathfrak{p}_i$, as sought. □

Remark 6.1.18. In case $(M_i \mid i \in I)$ is an infinite family of monoids, the natural map of lemma 6.1.17(ii) is still injective, but it is not necessarily surjective. For instance, let I be any infinite set, and let $\mathscr{U} \subset \mathscr{P}(I)$ be a non-principal ultrafilter; denote by ${}^*\mathbb{N}$ the quotient of $\mathbb{N}^I$ under the equivalence relation $\sim_{\mathscr{U}}$ such that $(a_i \mid i \in I) \sim_{\mathscr{U}} (b_i \mid i \in I)$ if and only if there exists $U \in \mathscr{U}$ such that $a_i = b_i$ for every $i \in U$. It is clear that the composition law on $\mathbb{N}^I$ descends to ${}^*\mathbb{N}$; the resulting structure $({}^*\mathbb{N}, +)$ is called the monoid of hypernatural numbers. Denote by $\pi : \mathbb{N}^I \to {}^*\mathbb{N}$ the projection, and let $\underline{0} \in \mathbb{N}^I$ be the unit; then it is easily seen that $\{\pi(0)\}$ is a face of ${}^*\mathbb{N}$, but $\pi^{-1}(\pi(0))$ is not a product of faces $F_i \subset \mathbb{N}$.

Remark 6.1.19. (i) Notice that not all epimorphisms in **Mnd** are surjections on the underlying sets; for instance, every localization map $M \to S^{-1}M$ is an epimorphism.

(ii) If $\varphi : N \to M$ is a map of fine monoids (see definition 6.1.6(vi)), then it will follow from corollary 6.4.2 that $N \times_M N$ is also finitely generated. If M is not integral, then this fails in general : a counter-example is provided by the morphism φ constructed in (6.1.2).

(iii) Let Σ be any set; it is easily seen that a free monoid $M \simeq \mathbb{N}^{(\Sigma)}$ admits a unique minimal system of generators, in natural bijection with Σ. Especially, the cardinality of Σ is determined by the isomorphism class of M; this invariant is called the *rank* of the free monoid M. This is the same as the rank of M as an $\mathbb{N}$-module (see example 3.7.27).

(iv) A submonoid of a finitely generated monoid is not necessarily finitely generated. For instance, consider the submonoid $M \subset \mathbb{N}^{\oplus 2}$, with $M := \{(0,0)\} \cup \{(a,b) \mid a > 0\}$. However, the following result shows that a face of a finitely generated monoid is again finitely generated.

Lemma 6.1.20. *Let $f : M \to N$ be a map of monoids, $F \subset N$ a face of N, and $\Sigma \subset N$ a system of generators for N. Then :*

(i) *$N^\times$ is a face of N, and $f^{-1}F$ is a face of M.*
(ii) *$\Sigma \cap F$ is a system of generators for F.*
(iii) *If N is finitely generated,* $\operatorname{Spec} N$ *is a finite set, and* $\dim N$ *is finite.*
(iv) *If N is finitely generated (resp. fine) then the same holds for $F^{-1}N$.*

Proof. (i) and (ii) are left to the reader, and (iii) is an immediate consequence of (ii). To show (iv), notice that – in view of (ii) – the set $\Sigma \cup \{f^{-1} \mid f \in F \cap \Sigma\}$ is a system of generators of $F^{-1}N$. □

Definition 6.1.21. (i) If M is a pointed or not pointed monoid (see remark 4.8.14(ii)), and S is a pointed M-module, we say that S is *integral*, if for every $x, y \in M$ and every $s \in S$ such that

$xs = ys \neq 0$, we have $x = y$. The *annihilator ideal* of S is the ideal

$$\mathrm{Ann}_M(S) := \{m \in M \mid ms = 0 \text{ for every } s \in S\}.$$

If $s \in S$ is any element, we also write $\mathrm{Ass}_M(s) := \mathrm{Ass}_M(Ms)$. The *support* of S is the subset :

$$\mathrm{Supp}\, S := \{\mathfrak{p} \in \mathrm{Spec}\, M \mid S_\mathfrak{p} \neq 0\}.$$

(ii) A pointed monoid $(M, 0_M)$ is called *integral*, if it is integral when regarded as a pointed M-module; it is called *fine*, if it is finitely generated and integral in the above sense.

(iii) The forgetful functor $\mathbf{Mnd}_\circ \to \mathbf{Set}$ (notation of (4.8.28)) admits a left adjoint, which assigns to any set Σ the *free pointed monoid* $\mathbb{N}^{(\Sigma)}_\circ := (\mathbb{N}^{(\Sigma)})_\circ$.

(iv) A morphism $\varphi : M \to N$ of pointed monoids is *local*, if both $M, N \neq 0$, and φ is local when regarded as a morphism of non-pointed monoids.

Remark 6.1.22. (i) Quite generally, a (non-pointed) monoid M is finitely generated (resp. free, resp. integral, resp. fine) if and only if $M_\circ$ has the corresponding property for pointed monoids. However, there exist integral pointed monoids which are not of the form $M_\circ$ for any non-pointed monoid M.

(ii) Let $(M, 0_M)$ be a pointed monoid. An *ideal* of $(M, 0_M)$ is a pointed submodule $I \subset M$. Just as for non-pointed monoids, we say that I is a *prime ideal*, if $M \setminus I$ is a (non-pointed) submonoid of M, and a non-pointed submonoid which is the complement of a prime ideal, is called a *face* of M. Hence the smallest ideal is $\{0\}$. Notice though, that $\{0\}$ is not necessarily a prime ideal, hence the spectrum $\mathrm{Spec}\,(M, 0_M)$ does not always admit a least element. However, if $M = N_\circ$ for some non-pointed monoid N, the natural morphism of monoids $N \to N_\circ$ induces a bijection :

$$\mathrm{Spec}\,(N_\circ, 0_{N_\circ}) \to \mathrm{Spec}\, N.$$

(iii) Let $I \subset M$ be any ideal; the inclusion map $I \to M$ can be regarded as a morphism of pointed M-modules (if M is not pointed, this is achieved via the faithful embedding (4.8.15)), whence a pointed M-module M/I, with a natural morphism $M \to M/I$. The latter map is also a morphism of monoids, for the obvious monoid structure on M/I. One checks easily that if M is integral, M/I is an integral pointed monoid.

(iv) Let M be a (pointed or not pointed) monoid, $\mathfrak{p} \subset M$ a prime ideal. Then the natural morphism of monoids $M \to M/\mathfrak{p}$ induces a bijection :

$$\mathrm{Spec}\, M/\mathfrak{p} \xrightarrow{\sim} \{\mathfrak{q} \in \mathrm{Spec}\, M \mid \mathfrak{p} \subset \mathfrak{q}\} = \mathrm{Spec}\, M \backslash \mathfrak{p}.$$

(v) Let M be a (pointed or not pointed) monoid, and $S \neq 0$ a pointed M-module. Then the support of S contains at least the maximal ideal of M. This trivial observation shows that a pointed M-module is 0 if and only if its support is empty.

(vi) Let M be a pointed monoid, and $\Sigma \subset M$ a *non-pointed* submonoid. The localization $\Sigma^{-1}M$ (defined in the category of monoids, as in (4.8.33)) is actually a pointed monoid : its zero element $0_{\Sigma^{-1}M}$ is the image of 0_M.

(vii) If M is a (pointed or not pointed) monoid, $\Sigma \subset M$ any *non-pointed* submonoid, and S a pointed M-module, we let as usual $\Sigma^{-1}S := \Sigma^{-1}M \otimes_M S$ (see remark 4.8.21(i), if M is not pointed). The resulting functor $M\text{-}\mathbf{Mod}_\circ \to \Sigma^{-1}M\text{-}\mathbf{Mod}_\circ$ is exact. Indeed, it is right exact, since it is left adjoint to the restriction of scalars arising from the localization map $M \to \Sigma^{-1}M$ (see (3.7.26)), and one verifies directly that it commutes with finite limits. Also, it is clear that

$$\mathrm{Supp}\, \Sigma^{-1}S = \mathrm{Supp}\, S \cap \mathrm{Spec}\, \Sigma^{-1}M.$$

(viii) Let M be a pointed monoid, and $N \subset M$ a pointed submonoid. Since the final object 1 of the category of pointed monoids is not isomorphic to the initial object $1_\circ$, the push-out of the diagram $1 \leftarrow N \to M$ is not an interesting object (it is always isomorphic to 1). Even if we form the quotient M/N in the category of non-pointed monoids, we still get always 1, since $0_M \in N$, and therefore in the quotient M/N the images of 0_M and of the unit of M coincide.

The only case that may give rise to a non-trivial quotient, is when N is *non-pointed*; in this situation we may form M/N *in the category of non-pointed monoids*, and then remark that the image of 0_M yields a zero element $0_{M/N}$ for M/N, so the latter is a pointed monoid.

Example 6.1.23. (i) Let M be a (pointed or not pointed) monoid, $G \subset M^\times$ a subgroup, and S a pointed M-module. Then $M/G \otimes_M S = S/G$ is the set of orbits of S under the induced G-action.

(ii) In the situation of (i), notice that the functor

$$M\text{-}\mathbf{Mod} \to M/G\text{-}\mathbf{Mod} \quad : \quad S \mapsto S/G$$

is exact, hence M/G is a flat M-module. (See definition 4.8.22(i).)

(iii) Likewise, if $\Sigma \subset M$ is a non-pointed submonoid, then the localization $\Sigma^{-1}M$ is a flat M-module, due to remark 6.1.22(vii).

(iv) Suppose that S is an integral pointed M-module (with M either pointed or not pointed), and let $\Sigma \subset M$ be a non-pointed submonoid. Then $\Sigma^{-1}S$ is also an integral pointed $\Sigma^{-1}M$-module. Indeed, suppose that the identity

$$(s^{-1}a) \cdot (s'^{-1}b) = (s^{-1}a) \cdot (s''^{-1}c) \neq 0 \tag{6.1.24}$$

holds for some $a, b, c \in S$ and $s, s', s'' \in \Sigma$; we need to check that $s'^{-1}b = s''^{-1}c$, or equivalently, that $s''b = s'c$ in $\Sigma^{-1}S$. However, (6.1.24) is equivalent to $s''ab = s'ac$ in $\Sigma^{-1}S$, and the latter holds if and only if there exists $t \in \Sigma$ such that $ts''ab = ts'ac$ in S. The two sides in the latter identity are $\neq 0$, as the same holds for the two sides of the identity (6.1.24); therefore $s''b = s'c$ holds already in S, and the contention follows.

(v) Likewise, in the situation of (iv), $S/\Sigma := S \otimes_M M/\Sigma$ is an integral pointed M/Σ-module. Indeed, notice the natural identification $S/\Sigma = \Sigma^{-1}S \otimes_{\Sigma^{-1}M} (\Sigma^{-1}M)/\Sigma^{\mathrm{gp}}$ which – in view of (iv) – reduces the proof to the case where Σ is a subgroup of $M^\times$. Then the assertion is easily verified, taking into account (i).

Especially, if M is an integral pointed monoid, and $\Sigma \subset M$ is any non-pointed submonoid, then both $\Sigma^{-1}M$ and M/Σ are integral pointed monoids (this generalizes lemma 4.8.38).

(vi) Let G be any abelian group, $\varphi : M \to G$ a morphism of non-pointed monoids. Then $G_\circ$ is a flat $M_\circ$-module. For the proof, we may – in light of (iii) – replace M by M^{gp}, thereby reducing to the case where M is a group. Next, by (ii), we may assume that φ is injective, in which case G is a free M-module with basis G/M.

Remark 6.1.25. (i) Let $M \to N$ and $M \to N'$ be morphisms of pointed monoids; N and N' can be regarded as pointed M-modules in an obvious way, hence we may form the tensor product $N'' := N \otimes_M N'$; the latter is endowed with a unique monoid structure such that the maps $e : N \to N''$ and $e' : N' \to N''$ given by the rule $n \mapsto n \otimes 1$ for all $n \in N$ (resp. $n' \mapsto 1 \otimes n'$ for all $n' \in N'$) are morphisms of monoids. Just as for usual ring homomorphisms, the monoid N'' is a coproduct of N and N' over M, *i.e.* there is a unique isomorphism of pointed monoids:

$$N \otimes_M N' \xrightarrow{\sim} N \amalg_M N' \tag{6.1.26}$$

that identifies e and e' to the natural morphisms $N \to N \amalg_M N'$ and $N' \to N \amalg_M N'$. As usual all this extends to non-pointed monoids. (Details left to the reader.)

(ii) Especially, if we take $M = \{1\}_\circ$, the initial object in $\mathbf{Mnd}_\circ$, we obtain an explicit description of the pointed monoid $N \oplus N'$: it is the quotient $(N \times N')/\!\sim$, where $\sim$ denotes the minimal equivalence relation such that $(x, 0) \sim (0, x')$ for every $x \in N$, $x' \in N'$. From this, a direct calculation shows that a direct sum of pointed integral monoids is again a pointed integral monoid.

Remark 6.1.27. (i) Clearly every pointed M-module S is the colimit of the filtered family of its finitely generated submodules. Moreover, S is the colimit of a filtered family of finitely presented pointed M-modules. Recall the standard argument : pick a countable set I, and let $\mathscr{C}$ be the (small) full subcategory of the category $M\text{-}\mathbf{Mod}_\circ$ whose objects are the coequalizers of every pair of maps of pointed M-modules $p, q : M^{(I_1)} \to M^{(I_2)}$, for every finite sets $I_1, I_2 \subset I$ (this means that, for every such pair p, q we pick one representative for this coequalizer). Then there is a natural isomorphism of pointed M-modules :

$$\operatorname*{colim}_{i\mathscr{C}/S} \iota_S \xrightarrow{\sim} S$$

where $i : \mathscr{C} \to M\text{-}\mathbf{Mod}_\circ$ is the inclusion functor, and ι_S is the functor as in (1.1.27).

(ii) If S is finitely generated, we may find a finite filtration of S by submodules $0 = S_0 \subset S_1 \subset \cdots \subset S_n = S$ such that S_{i+1}/S_i is a cyclic M-module, for every $i = 1, \dots, n$.

(iii) Notice that if S is integral and $S' \subset S$ is any submodule, then S/S' is again integral. Moreover, if S is integral and cyclic, we have a natural isomorphism of M-modules :

$$S \xrightarrow{\sim} M/\mathrm{Ann}_M(S).$$

(Details left to the reader.)

(iv) Suppose furthermore, that $M^\sharp$ is finitely generated, and S is any pointed M-module. Lemma 6.1.17(i.a) and proposition 6.1.9(ii) easily imply that every ascending chain

$$I_0 \subset I_1 \subset I_2 \subset \cdots$$

of ideals of M is stationary; especially, the set $\{\mathrm{Ann}_M(s) \mid s \in S\setminus\{0\}\}$ admits maximal elements. Let I be a maximal element in this set; a standard argument as in commutative algebra shows that I is a prime ideal : indeed, say that $xy \in I = \mathrm{Ann}_M(s)$ and $x \notin I$; then $xs \neq 0$, hence $y \in \mathrm{Ann}_M(xs) = I$, by the maximality of I. Now, if S is also finitely generated, it follows that we may find a finite filtration of S as in (ii) such that, additionally, each quotient S_{i+1}/S_i is of the form $M/\mathfrak{p}$, for some prime ideal $\mathfrak{p} \subset M$.

These properties make the class of integral pointed modules especially well behaved : essentially, the full subcategory $M\text{-}\mathbf{Int}.\mathbf{Mod}_\circ$ of $M\text{-}\mathbf{Mod}_o$ consisting of these modules mimics closely a category of A-modules for a ring A, familiar from standard linear algebra. This shall be amply demonstrated henceforth. For instance, we point out the following combinatorial version of Nakayama's lemma :

Proposition 6.1.28. *Let M be a (pointed or not pointed) monoid, S a finitely generated integral pointed M-module, and $S' \subset S$ a pointed submodule, such that*

$$S = S' \cup \mathfrak{m}_M \cdot S.$$

Then $S = S'$.

Proof. After replacing S by S/S', we may assume that $\mathfrak{m}_M S = S$, in which case we have to check that $S = 0$. Suppose then, that $S \neq 0$; from remark 6.1.27(ii,iii) it follows that S admits a (pointed) submodule $T \subset S$ such that $S/T \simeq M/\mathfrak{m}_M$. Especially, $\mathfrak{m}_M \cdot (S/T) = 0$, *i.e.* $\mathfrak{m}_M S \subset T$, and therefore $S = T$, which contradicts the choice of T. The contention follows. □

Remark 6.1.29. (i) The integrality assumption cannot be omitted in proposition 6.1.28. Indeed, take $M := \mathbb{N}$ and $S := 0_\circ$, where 0 denotes the final $\mathbb{N}$-module. Then $S \neq 0$, but $\mathfrak{m}_M S = S$.

(ii) Let us say that an element of the M-module S is *primitive*, if it does not lie in $\mathfrak{m}_M S$. We deduce from proposition 6.1.28, the following :

Corollary 6.1.30. *Let M be a sharp (pointed or not pointed) monoid, S a finitely generated integral pointed monoid. Then the set $S \setminus \mathfrak{m}_M S$ of primitive elements of S is finite, and is the unique minimal system of generators of S.*

Proof. Indeed, it is easily seen that every system of generators of S must contain all the primitive elements, so $S \setminus \mathfrak{m}_M S$ must be finite. On the other hand, let $S' \subset S$ be the submodule generated by the primitive elements; clearly $S' \cup \mathfrak{m}_M S = S$, hence $S' = S$, by proposition 6.1.28. □

6.1.31. Let R be any ring, M a non-pointed monoid. Notice that the M-module underlying any $R[M]$-module is naturally pointed, whence a forgetful functor $R[M]\text{-}\mathbf{Mod} \to M\text{-}\mathbf{Mod}_\circ$. The latter admits a left adjoint

$$M\text{-}\mathbf{Mod}_\circ \to R[M]\text{-}\mathbf{Mod} \quad : \quad (S, 0_S) \mapsto R\langle S\rangle := \mathrm{Coker}\, R[0_S].$$

Likewise, the monoid $(A, \cdot)$ underlying any (commutative unital) R-algebra A is naturally pointed, whence a forgetful functor $R\text{-}\mathsf{Alg} \to \mathbf{Mnd}_\circ$, which again admits a left adjoint

$$\mathbf{Mnd}_\circ \to R\text{-}\mathsf{Alg} \quad : \quad (M, 0_M) \mapsto R\langle M\rangle := R[M]/(0_M)$$

where $(0_M) \subset R[M]$ denotes the ideal generated by the image of 0_M.

If $(M, 0_M)$ is a pointed monoid, and S is a pointed $(M, 0_M)$-module, then notice that $R\langle S\rangle$ is actually a $R\langle M\rangle$-module, so we have as well a natural functor

$$(M, 0_M)\text{-}\mathbf{Mod}_\circ \to R\langle M\rangle\text{-}\mathbf{Mod} \qquad S \mapsto R\langle S\rangle$$

which is again left adjoint to the forgetful functor.

For instance, let $I \subset M$ be an ideal; from the foregoing, it follows that $R\langle M/I\rangle$ is naturally an $R[M]$-algebra, and we have a natural isomorphism :

$$R\langle M/I\rangle \xrightarrow{\sim} R[M]/IR[M].$$

Explicitly, for any $x \in F := M\setminus I$, let $\overline{x} \in R\langle M/I\rangle$ be the image of x; then $R\langle M/I\rangle$ is a free R-module, with basis $(\overline{x} \mid x \in F)$. The multiplication law of $R\langle M/I\rangle$ is determined as follows. Given $x, y \in F$, then $\overline{x} \cdot \overline{y} = \overline{xy}$ if $xy \in F$, and otherwise it equals zero.

Notice that if I_1 and I_2 are two ideals of M, we have a natural identification :

$$R\langle M/(I_1 \cap I_2)\rangle \xrightarrow{\sim} R\langle M/I_1\rangle \times_{R\langle M/(I_1\cup I_2)\rangle} R\langle M/I_2\rangle.$$

These algebras will play an important role in section 12.5. As a special case, suppose that $\mathfrak{p} \subset M$ is a prime ideal; then the inclusion $M\setminus\mathfrak{p} \subset M$ induces an isomorphism of R-algebras :

$$R[M\setminus\mathfrak{p}] \xrightarrow{\sim} R\langle M/\mathfrak{p}\rangle.$$

Furthermore, general nonsense yields a natural isomorphism of R-modules :

$$R\langle S \otimes_M S'\rangle \xrightarrow{\sim} R\langle S\rangle \otimes_{R\langle M\rangle} R\langle S'\rangle \qquad \text{for all pointed } M\text{-modules } S \text{ and } S'. \tag{6.1.32}$$

6.1.33. Let A be a commutative ring with unit, and $f : M \to (A, \cdot)$ a morphism of pointed monoids. Then f induces (forgetful) functors :

$$A\text{-}\mathbf{Mod} \to M\text{-}\mathbf{Mod}_\circ \qquad A\text{-}\mathsf{Alg} \to M/\mathbf{Mnd}_\circ$$

(notation of (1.1.24)) which admit left adjoints :

$$\begin{aligned} M\text{-}\mathbf{Mod}_\circ &\to A\text{-}\mathbf{Mod} & S &\mapsto S \otimes_M A := \mathbb{Z}\langle S\rangle \otimes_{\mathbb{Z}\langle M\rangle} A \\ M/\mathbf{Mnd}_\circ &\to A\text{-}\mathsf{Alg} & N &\mapsto N \otimes_M A := \mathbb{Z}\langle N\rangle \otimes_{\mathbb{Z}\langle M\rangle} A. \end{aligned}$$

Sometimes we may also use the notation :

$$S \otimes_M N := \mathbb{Z}\langle S\rangle \otimes_{\mathbb{Z}\langle M\rangle} N \quad \text{and} \quad S \overset{\mathbf{L}}{\otimes}_M K_\bullet := \mathbb{Z}\langle S\rangle \overset{\mathbf{L}}{\otimes}_{\mathbb{Z}\langle M\rangle} K_\bullet$$

for any pointed M-module S, any A-module N and any object $K_\bullet$ of $\mathsf{D}^-(A\text{-}\mathbf{Mod})$. The latter derived tensor product is obtained by tensoring with a flat $\mathbb{Z}\langle M\rangle$-flat resolution of $\mathbb{Z}\langle S\rangle$. (Such resolutions can be constructed combinatorially, starting from a simplicial resolution of S.) All the verifications are standard, and shall be left to the reader.

Moreover, for any ideal $I \subset M$ and any A-module N, we shall write $f(I)N$, or sometimes just IN, for the A-submodule of N generated by the system $(f(x) \cdot y \mid x \in I,\ y \in N)$.

Definition 6.1.34. Let M be a pointed monoid, A a commutative ring with unit, $\varphi : M \to (A, \cdot)$ a morphism of pointed monoids, N an A-module. We say that N is *φ-flat* (or just M-flat, if no ambiguity is likely to arise), if the functor

$$M\text{-}\mathbf{Int.Mod}_\circ \to A\text{-}\mathbf{Mod} \quad : \quad S \mapsto S \otimes_M N$$

is *exact*, in the sense that it sends exact sequences of pointed integral M-modules, to exact sequences of A-modules. We say that N is *faithfully φ-flat* if this functor is exact in the above sense, and we have $S \otimes_M N = 0$ if and only if $S = 0$.

Remark 6.1.35. (i) Notice that the functor $S \mapsto S \otimes_M N$ of definition 6.1.34 is right exact in the categorical sense (*i.e.* it commutes with finite colimits), since it is a right adjoint. However, even when N is faithfully flat, this functor is not always left exact in the categorical sense : it does not commute with finite products, nor with equalizers, in general.

(ii) Let M and S be as in definition 6.1.34, and let R be any non-zero commutative unital ring. Denote by $\varphi : M \to (R\langle M \rangle, \cdot)$ the natural morphism of pointed monoids. In light of (6.1.32), it is clear that if $R\langle S \rangle$ is a flat $R\langle M \rangle$-module, then S is a flat pointed M-module, and the latter condition implies that $R\langle S \rangle$ is φ-flat.

(iii) Let P be a pointed monoid, A a ring, $\varphi : P \to (A, \cdot)$ a morphism of monoids, $f : A \to B$ a ring homomorphism. If A is φ-flat and f is flat, then B is $(f \circ \varphi)$-flat. Conversely, if B is $(f \circ \varphi)$-flat and f is faithfully flat, then A is φ-flat : the verifications are standard, and shall be left to the reader.

Lemma 6.1.36. *Let M be a monoid, A a ring, $\varphi : M \to (A, \cdot)$ a morphism of monoids, and assume that φ is local and A is φ-flat. Then A is faithfully φ-flat.*

Proof. Let S be an integral pointed M-module, and suppose that $S \otimes_M A = \{0\}$; we have to show that $S = \{0\}$. Say that $s \in S$, and let $Ms \subset S$ be the M-submodule generated by s. Since A is φ-flat, it follows easily that $Ms \otimes_M A = \{0\}$, hence we are reduced to the case where S is cyclic. By remark 6.1.27(iii), we may then assume that $S = M/I$ for some ideal $I \subset M$. It follows that $S \otimes_M A = A/\varphi(I)A$, so that $\varphi(I)$ generates A. Since φ is local, this implies that $I = M$, whence the contention. □

Lemma 6.1.37. *Let M be an integral pointed monoid, $I, J \subset M$ two ideals, A a ring, $\alpha : M \to (A, \cdot)$ a morphism of monoids, N an α-flat A-module, and S a flat M-module. Then :*

$$IS \cap JS = (I \cap J)S$$
$$\alpha(I)N \cap \alpha(J)N = \alpha(I \cap J)N.$$

Proof. We consider the commutative ladder of pointed M-modules, with exact rows and injective vertical arrows :

$$\begin{array}{ccccccccc} 0 & \longrightarrow & I \cap J & \longrightarrow & I & \longrightarrow & I/(I \cap J) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & J & \longrightarrow & M & \longrightarrow & M/(I \cup J) & \longrightarrow & 0 \end{array} \tag{6.1.38}$$

By assumption, the ladder of A-modules (6.1.38)$\otimes_M N$ has still exact rows and injective vertical arrows. Then, the snake lemma gives the following short exact sequence involving the cokernels of the vertical arrows :

$$0 \to JN/(I \cap J)N \to N/IN \xrightarrow{p} N/(IN + JN) \to 0$$

(where we have written JN instead of $\alpha(J)N$, and likewise for the other terms). However $\mathrm{Ker}\, p = JN/(IN \cap JN)$, whence the second stated identity. The first stated identity can be deduced from the second, by virtue of remark 6.1.35(ii). □

Remark 6.1.39. By inspection of the proof, we see that the first identity of lemma 6.1.37 holds, more generally, whenever $\mathbb{Z}\langle S\rangle$ is φ-flat, where $\varphi : M \to \mathbb{Z}\langle M\rangle$ is the natural morphism of pointed monoids.

Proposition 6.1.40. *Let M be a pointed integral monoid, A a ring, $\varphi : M \to (A, \cdot)$ a morphism of monoids, N an A-module. Then we have :*

- (i) *The following conditions are equivalent :*
  - (a) *N is φ-flat.*
  - (b) $\mathrm{Tor}_i^{\mathbb{Z}\langle M\rangle}(\mathbb{Z}\langle T\rangle, N) = 0$ *for every $i > 0$ and every pointed integral M-module T.*
  - (c) $\mathrm{Tor}_1^{\mathbb{Z}\langle M\rangle}(\mathbb{Z}\langle M/I\rangle, N) = 0$ *for every ideal $I \subset M$.*
  - (d) *The natural map $I \otimes_M N \to N$ is injective for every ideal $I \subset M$.*
- (ii) *If moreover, $M^\sharp$ is finitely generated, then the conditions* (a)-(d) *of* (i) *are equivalent to either of the following two conditions :*
  - (e) $\mathrm{Tor}_1^{\mathbb{Z}\langle M\rangle}(\mathbb{Z}\langle M/\mathfrak{p}\rangle, N) = 0$ *for every prime ideal $\mathfrak{p} \subset M$.*
  - (f) *The natural map $\mathfrak{p} \otimes_M N \to N$ is injective for every prime ideal $\mathfrak{p} \subset M$.*

Proof. Clearly (a)⇒(b)⇒(c)⇒(e). Next, by considering the short exact sequence of pointed integral M-modules $0 \to I \to M \to M/I \to 0$ we easily see that (c)⇔(d) and (e)⇔(f).

(c)⇒(a) : Let $\Sigma := (0 \to S' \to S \to S'' \to 0)$ be a short exact sequence of pointed integral M-modules; we need to show that the induced map $S' \otimes_M N \to S \otimes_M N$ is injective. Since the sequence $\mathbb{Z}\langle\Sigma\rangle$ is still exact, the long Tor-exact sequence reduces to showing that $\mathrm{Tor}_1^{\mathbb{Z}\langle M\rangle}(\mathbb{Z}\langle T\rangle, N) = 0$ for every pointed integral M-module T. In view of remark 6.1.27(i), we are easily reduced to the case where T is finitely generated; next, using remark 6.1.27(ii,iii), the long exact Tor-sequence, and an easy induction on the number of generators of T, we may assume that $T = M/I$, whence the contention.

Lastly, if $M^\sharp$ is finitely generated, then remark 6.1.27(iv) shows that, in the foregoing argument, we may further reduce to the case where $T = M/\mathfrak{p}$ for a prime ideal $\mathfrak{p} \subset M$; this shows that (e)⇒(a). □

Lemma 6.1.41. *Let M be a pointed monoid, S a pointed M-module, and suppose that the following conditions hold for S :*

- (F1) *If $s \in S$ and $a \in \mathrm{Ann}_M(s)$, then there exists $b \in \mathrm{Ann}_M(a)$ such that $s \in bS$.*
- (F2) *If $a_1, a_2 \in M$ and $s_1, s_2 \in S$ satisfy the identity $a_1 s_1 = a_2 s_2 \neq 0$, then there exist $b_1, b_2 \in M$ and $t \in S$ such that $s_i = b_i t$ for $i = 1, 2$ and $a_1 b_1 = a_2 b_2$.*

Then the natural map $I \otimes_M S \to S$ is injective for every ideal $I \subset M$.

Proof. Let I be an ideal, and suppose that two elements $a_1 \otimes s_1$ and $a_2 \otimes s_2$ of $I \otimes_M S$ are mapped to the same element of S. If $a_i s_i = 0$ for $i = 1, 2$, then (F1) says that there exist $b_1, b_2 \in M$ and $t_1, t_2 \in S$ such that $a_i b_i = 0$ and $s_i = b_i t_i$ for $i = 1, 2$; thus $a_i \otimes s_i = a_i \otimes b_i t_i = a_i b_i \otimes s_i = 0$ in $I \otimes_M S$. In case $a_i s_i \neq 0$, pick $b_1, b_2 \in M$ and $t \in S$ as in (F2); we conclude that $a_1 \otimes s_1 = a_1 \otimes b_1 t = a_1 b_1 \otimes t = a_2 b_2 \otimes t = a_2 \otimes s_2$ in $I \otimes_M S$, whence the contention. □

Theorem 6.1.42. *Let M be an integral pointed monoid, S a pointed M-module. The following conditions are equivalent :*

- (a) *S is M-flat.*
- (b) *For every morphism $M \to P$ of pointed monoids, $P \otimes_M S$ is P-flat.*
- (c) *For every short exact sequence Σ of integral pointed M-modules, the sequence $\Sigma \otimes_M S$ is again short exact.*

(d) *Conditions* (F1) *and* (F2) *of lemma* 6.1.41 *hold for* S.

Proof. Clearly (b)⇒(a)⇒(c).

(c)⇒(d): To show (F1), set $I := Ma$, and denote by $i : I \to M$ the inclusion; (c) implies that the induced map $i \otimes_M S : I \otimes_M S \to S$ is injective. However, we have a natural isomorphism $I \stackrel{\sim}{\to} M/\mathrm{Ann}_M(a)$ of M-modules (remark 6.1.27(iii)), whence an isomorphism : $I \otimes_M S \stackrel{\sim}{\to} S/\mathrm{Ann}_M(a)S$, and under this identification, $i \otimes_M S$ is induced by the map $S \to S : s \mapsto as$. Thus, multiplication by a maps the subset $S \setminus \mathrm{Ann}_M(a)S$ injectively into itself, which is the claim.

For (F2), notice that $\mathbb{Z}\langle S\rangle$ is φ-flat under condition (c), for $\varphi : M \to \mathbb{Z}\langle M\rangle$ the natural morphism. Now, say that $a_1s_1 = a_2s_2 \neq 0$ in S; set $I := Ma_1$, $J := Ma_2$; the assumption means that $a_1s_1 \in IS \cap JS$, in which case remark 6.1.39 shows that there exist $t \in S$ and $b_1, b_2 \in M$ such that $a_1b_1 = a_2b_2$, and $a_1s_1 = a_1b_1t$, hence $a_2s_2 = a_2b_2t$. Since we have seen that multiplication by a_1 maps $S \setminus \mathrm{Ann}_M(a_1)S$ injectively into itself, we deduce that $s_1 = b_1t$, and likewise we get $s_2 = b_2t$.

To prove that (d)⇒(b), we observe :

Claim 6.1.43. Let P be a pointed monoid, Λ a small locally directed category (see definition 1.2.19(iv)), and $S_\bullet : \Lambda \to P\text{-}\mathbf{Mod}_\circ$ a functor, such that S_λ fulfills conditions (F1) and (F2), for every $\lambda \in \mathrm{Ob}(\Lambda)$. Then the colimit of $S_\bullet$ also fulfills conditions (F1) and (F2).

Proof of the claim. In light of remark 1.2.21(ii), we may assume that Λ is either discrete or connected. Suppose first that Λ is connected; then remark 4.8.17(ii) allows to check directly that conditions (F1) and (F2) hold for the colimit of $S_\bullet$, since they hold for every S_λ. If Λ is discrete, the assertion is that conditions (F1) and (F2) are preserved by arbitrary (small) direct sums, which we leave as an exercise for the reader. ◊

To a given pointed M-module S, we attach the small category S^*, such that :

$$\mathrm{Ob}(S^*) = S\setminus\{0\} \qquad \text{and} \qquad \mathrm{Hom}_{S^*}(s', s) = \{a \in M \mid as = s'\}.$$

The composition of morphisms is induced by the composition law of M, in the obvious way. Notice that S^* is locally directed if and only if S satisfies condition (F2).

We define a functor $F : S^* \to M\text{-}\mathbf{Mod}_\circ$ as follows. For every $s \in \mathrm{Ob}(S^*)$ we let $F(s) := M$, and for every morphism $a : s' \to s$ we let $F(a) := a \cdot \mathbf{1}_M$. We have a natural transformation $\tau : F \Rightarrow c_S$, where $c_S : S^* \to M\text{-}\mathbf{Mod}_\circ$ is the constant functor associated with S; namely, for every $s \in \mathrm{Ob}(S^*)$, we let $\tau_s : M \to S$ be the map given by the rule $a \mapsto as$ for all $a \in M$. There follows a morphism of pointed M-modules :

$$\operatorname*{colim}_{S^*} F \to S \tag{6.1.44}$$

Claim 6.1.45. If S fulfills conditions (F1), the map (6.1.44) is an isomorphism.

Proof of the claim. Indeed, we have a natural decomposition of S^* as coproduct of a family $(S^*_i \mid i \in I)$ of connected subcategories (for some small set I : see remark 1.2.21(ii)); especially we have $\mathrm{Hom}_{S^*}(s, s') = \varnothing$ if $s \in \mathrm{Ob}(S^*_i)$ and $s' \in \mathrm{Ob}(S^*_j)$ for some $i \neq j$ in I.

For each $i \in I$, let $F_i : S^*_i \to M\text{-}\mathbf{Mod}_\circ$ be the restriction of F. There follows a natural isomorphism :

$$\bigoplus_{i\in I} \operatorname*{colim}_{S^*_i} F_i \stackrel{\sim}{\to} \operatorname*{colim}_{S^*} F.$$

Since the colimit of F_i commutes with the forgetful functor to sets, an inspection of the definitions yields the following explicit description of the colimit T_i of F_i. Every element of T_i is represented by some pair (s, a) where $s \in \mathrm{Ob}(S^*_i) \subset S\setminus\{0\}$ and $a \in M$; such pair is mapped to as by (6.1.44), and two such pairs (s, a), (s', a') are identified in T_i if there exists $b \in M$ such that $bs = s'$ and $ba' = a$.

Hence, denote by S_i the image under (6.1.44) of T_i; we deduce first, that $S_i \cap S_j = \{0\}$ if $i \neq j$. Indeed, say that $t \in S_i \cap S_j$; by the foregoing, there exist $s_i \in \mathrm{Ob}(S^*_i)$, $s_j \in \mathrm{Ob}(S^*_j)$, and $a_i, a_j \in M$, such that $a_i s_i = t = a_j s_j$. If $t \neq 0$, we get morphisms $a_i : t \to s_i$ and $a_j : t \to s_j$ in S^*; say that $t \in S^*_k$ for some $k \in I$; it then follows that $S^*_i = S^*_k = S^*_j$, a contradiction. Next, it is clear that (6.1.44) is surjective. It remains therefore only to show that each T_i maps injectively onto S_i. Hence, say that (s_1, a_1) and (s_2, a_2) represent two elements of T_i with $t := a_1 s_1 = a_2 s_2$. If $t \neq 0$, we get, as before, morphisms $a_1 : t \to s_1$ and $a_2 : t \to s_2$ in S^*_i, and the two pairs are identified in T_i to the pair $(t, 1)$. Lastly, if $t = 0$, condition (F1) yields $b \in M$ and $s' \in S$ such that $a_1 b = 0$ and $s_1 = bs'$, whence a morphism $b : s_1 \to s'$ in S^*_i, and $F_i(b)(a_1, s_1) = (0, s')$ which represents the zero element of T_i. The same argument applies as well to (a_2, s_2), and the claim follows. ♢

Claim 6.1.46. Let $M \to P$ be any morphism of pointed monoids, and S a pointed M-module fulfilling conditions (F1) and (F2). Then the natural map $I \otimes_M S \to P \otimes_M S$ is injective, for every ideal $I \subset P$.

Proof of the claim. From claim 6.1.45 we deduce that $P \otimes_M S$ is the locally directed colimit of the functor $P \otimes_M F$, and notice that the pointed P-module P fulfills conditions (F1) and (F2); by claim 6.1.43 we deduce that $P \otimes_M S$ also fulfills the same conditions, so the claim follows from lemma 6.1.41. ♢

After these preliminaries, suppose that conditions (F1) and (F2) hold for S, and let $\Sigma := (0 \to T' \to T \to T'' \to 0)$ be a short exact sequence of pointed M-modules. We wish to show that $\Sigma \otimes_M S$ is still short exact. However, if $U'' \subset T''$ is any M-submodule, let $U \subset T$ be the preimage of U'', and notice that the induced sequence $0 \to T' \to U \to U'' \to 0$ is still short exact. Since a filtered colimit of short exact sequences is short exact, remark 6.1.27(i) allows to reduce to the case where T'' is finitely generated.

We shall argue by induction on the number n of generators of T''. Hence, suppose first that T'' is cyclic, and let $t \in T$ be any element whose image in T'' is a generator. Set $C := Mt \subset T$, and let $C' \subset T'$ be the preimage of C. We obtain a cocartesian (and cartesian) diagram of pointed M-modules :

$$\mathscr{D} \quad : \quad \begin{array}{ccc} C' & \longrightarrow & C \\ \downarrow & & \downarrow \\ T' & \longrightarrow & T. \end{array}$$

The induced diagram $\mathscr{D} \otimes_M S$ is still cocartesian, hence the same holds for the diagram of sets underlying $\mathscr{D} \otimes_M S$ (remark 4.8.17(ii)). Especially, if the induced map $C' \otimes_M S \to C \otimes_M S$ is injective, the same will hold for the map $T' \otimes_M S \to T \otimes_M S$. We may thus replace T' and T by respectively C' and C, which allows to assume that also T is cyclic. In this case, pick a generator $u \in T$; we claim that there exists a unique multiplication law μ_T on T, such that the surjection $p : M \to T : a \mapsto au$ is a morphism of pointed monoids. Indeed, for every $t, t' \in T$, write $t = au$ for some $a \in M$, and set $\mu_T(t, t') := at'$. Using the linearity of p we easily check that $\mu_T(t, t')$ does not depend on the choice of a, and the resulting composition law μ_T is commutative and associative. Then T' is an ideal of T, so claim 6.1.46 tells us that the map $T' \otimes_M S \to T \otimes_M S$ is injective, as required.

Lastly, suppose that $n > 1$, and the assertion is already known whenever T'' is generated by at most $n - 1$ elements. Let $U'' \subset T''$ be a pointed M-submodule, such that U'' is generated by at most $n - 1$ elements, and T''/U'' is cyclic. Denote by $U \subset T$ the preimage of U''; we deduce short exact sequences $\Sigma' := (0 \to T' \to U \to U'' \to 0)$ and $\Sigma'' := (0 \to U \to T \to T''/U'' \to 0)$, and by inductive assumption, both $\Sigma' \otimes_M S$ and $\Sigma'' \otimes_M S$ are short exact. Therefore the natural map $T' \otimes_M S \to T \otimes_M S$ is the composition of two injective maps, hence it is injective, as stated. □

Remark 6.1.47. In the situation of remark 6.1.35(ii), suppose that M is pointed integral. Then theorem 6.1.42 implies that S is a flat pointed M-module if and only if $R\langle S\rangle$ is φ-flat.

Corollary 6.1.48. *Let M be an integral pointed monoid, S a pointed M-module. Then*

(i) *The following conditions are equivalent :*
  (a) *S is M-flat.*
  (b) *For every ideal $I \subset M$, the induced map $I \otimes_M S \to S$ is injective.*

(ii) *If moreover $M^\sharp$ is finitely generated, then these conditions are equivalent to :*
  (c) *For every prime ideal $\mathfrak{p} \subset M$, the induced map $\mathfrak{p} \otimes_M S \to S$ is injective.*

Proof. (i): Indeed, by remark 6.1.47 and proposition 6.1.40(i) (together with (6.1.32)), both (a) and (b) hold if and only if $\mathbb{Z}\langle S\rangle$ is φ-flat, for $\varphi : M \to \mathbb{Z}\langle M\rangle$ the natural morphism.

(ii): This follows likewise from proposition 6.1.40(ii). □

Corollary 6.1.49. *Let $\varphi : M \to N$ be a morphism of pointed monoids, $G \subset M^\times$, $H \subset N^\times$ two subgroups such that $\varphi(G) \subset H$, and denote by $\overline{\varphi} : M/G \to N/H$ the induced morphism. Let also S be any N-module. We have :*

(i) *If $S_{(\varphi)}$ is a flat M-module, then $S/H_{(\overline{\varphi})}$ is a flat M/G-module (notation of* (3.7.26)*).*

(ii) *If moreover, M is a pointed integral monoid and S is a pointed integral H-module, then also the converse of* (i) *holds.*

Proof. (i): We have a natural isomorphism

$$(S/H)_{(\overline{\varphi})} \xrightarrow{\sim} N/H \otimes_{N/\varphi G} S_{(\varphi)}/\varphi G.$$

However, by example 6.1.23(ii), N/H is a flat $N/\varphi G$-module, and $S_{(\varphi)}/\varphi G$ is a flat M/G-module, whence the contention.

(ii): By theorem 6.1.42, it suffices to check that conditions (F1) and (F2) of lemma 6.1.41 hold in $S_{(\varphi)}$, and notice that, by the same token, both conditions hold for the M/G-module $S/H_{(\overline{\varphi})} = S_{(\varphi)}/G$, since M/G is pointed integral (example 6.1.23(v)).

Hence, say that $\varphi(a)s = 0$ for some $a \in M$ and $s \in S$; we may then find $b \in M$, $t' \in S$ and $g \in G$ such that $\varphi(gb)t = s$ and $ab = 0$. Setting $t := \varphi(g)t'$, we deduce that (F1) holds.

Next, say that $\varphi(a_1)s_1 = \varphi(a_2)s_2 \neq 0$ for some $a_1, a_2 \in M$ and $s_1, s_2 \in S$; then we may find $g \in G$, $h_1, h_2 \in H$, $b_1, b_2 \in M$ and $t' \in S$ such that $ga_1b_1 = a_2b_2$ and

$$\varphi(b_i)h_it' = s_i \qquad \text{for } i = 1, 2. \tag{6.1.50}$$

After replacing b_1 by gb_1 and h_1 by $h_1\varphi(g^{-1})$, we reduce to the case where $a_1b_1 = a_2b_2$. From (6.1.50) we deduce that
