$$W_{n+1}C \otimes_{W_{n+1}B} \overline{\boldsymbol{\omega}}_k^* D \xrightarrow{\sim} W_{n+1}C \otimes_{W_{n+1}B} \overline{\boldsymbol{\omega}}_k^* B \otimes_{\overline{\boldsymbol{\omega}}_k^* B} \overline{\boldsymbol{\omega}}_k^* D \xrightarrow{\sim} \overline{\boldsymbol{\omega}}_k^* C \otimes_{\overline{\boldsymbol{\omega}}_k^* B} \overline{\boldsymbol{\omega}}_k^* D = \overline{\boldsymbol{\omega}}_k^*(C \otimes_B D)$$

where the second isomorphism follows from theorem 14.7.26(ii).

(iv): The proof of (i) also shows that the natural morphism

$$W_{n+2}C \otimes_{W_{n+2}B} \overline{V}_{n+1} B \to \overline{V}_{n+1} C$$

is an isomorphism. The assertion is an immediate consequence.

(ii): Let $\psi : W_{n+1}B \to B^{n+1} := \prod_{i=0}^n \overline{\boldsymbol{\omega}}_i^* B$ be the morphism of $W_{n+1}A^a$-algebras whose composition with the projection $B^{n+1} \to \overline{\boldsymbol{\omega}}_i^* B$ is the morphism $\overline{\boldsymbol{\omega}}_i$, for $i = 0, \dots, n$; denote by $R \subset B^{n+1}$ the image of ψ. Let also $\mathbf{P}$ be one of the properties : "almost finitely generated", "almost finitely presented", or "almost projective", and suppose that f enjoys $\mathbf{P}$; in view of theorem 14.7.26(i), proposition 9.3.30(i) and [75, Lemma 3.2.25], it suffices to prove that the R-module $W_{n+1}C \otimes_{W_{n+1}B} R$ enjoys property $\mathbf{P}$. Next, by proposition 9.3.30(ii) we know that

$$p^{n+1}B^{n+1} \subset R \qquad \text{and we let} \qquad R_0 := R/p^{n+1}B^{n+1} \qquad B_0^{n+1} := B^{n+1}/pB^{n+1}.$$

With this notation, it is easily seen that there exists a well defined morphism of $W_{n+1}B$-algebras

$$\varphi : B_0 \to B_0^{n+1} \qquad \text{such that} \qquad \pi_i \circ \varphi = \Phi_{B_0}^i : B_0 \to \overline{\boldsymbol{\omega}}_i^* B_0 = \Phi_{B_0}^{i*} B_0 \qquad \text{for } i = 0, \dots, n$$

where $\pi_i : B_0^{n+1} \to \overline{\boldsymbol{\omega}}_i^* B_0$ is the projection on the $(i+1)$-th factor. Arguing as in the proof of proposition 14.7.11, we get cartesian diagrams

$$\begin{array}{ccc} S & \longrightarrow & B^{n+1} \\ \downarrow & & \downarrow \\ B_0 & \xrightarrow{\varphi} & B_0^{n+1} \end{array} \qquad \begin{array}{ccc} R & \longrightarrow & R_0 \\ \downarrow & & \downarrow \\ S & \longrightarrow & S_0 := S/p^{n+1}B^{n+1}. \end{array}$$

In case $\mathbf{P}$ is "almost finitely generated" or "almost finitely presented" we may then apply [75, Rem.3.2.26(i) and Lemma 3.4.18(i)] to the second of these cartesian diagrams, and thereby reduce to checking property $\mathbf{P}$ for the $(S \times R_0)$-module $W_{n+1}C \otimes_{W_{n+1}B} (S \times R_0)$. In case $\mathbf{P}$ is the property "almost projective", we may argue as in the proof of [75, Prop.3.4.21] to achieve the same reduction. But notice as well that the restriction $R_0 \to \overline{\boldsymbol{\omega}}_0^* B_0$ of π_0 is an epimorphism (on the underlying modules), and has nilpotent kernel (see the proof of proposition 14.7.11), so the R_0-module $W_{n+1}C \otimes_{W_{n+1}B} R_0$ enjoys $\mathbf{P}$ if and only the same holds for the $\overline{\boldsymbol{\omega}}_0^* B_0$-module $W_{n+1}C \otimes_{W_{n+1}B} \overline{\boldsymbol{\omega}}_0^* B_0$. Next, by invoking again [75, Rem.3.2.26(i) and Lemma 3.4.18(i)] or the proof of [75, Prop.3.4.21] to the first of the two above diagrams we deduce that the S-module $W_{n+1}C \otimes_{W_{n+1}B} S$ enjoys $\mathbf{P}$ if and only if the same holds for the $(\overline{\boldsymbol{\omega}}_0^* B_0 \times B^{n+1})$-module $W_{n+1}C \otimes_{W_{n+1}B} (\overline{\boldsymbol{\omega}}_0^* B_0 \times B^{n+1})$. Since $\overline{\boldsymbol{\omega}}_0^* B_0$ is a quotient of B^{n+1}, we are finally reduced to checking that the B^{n+1}-module $W_{n+1}C \otimes_{W_{n+1}B} B^{n+1}$ enjoys $\mathbf{P}$; but according to theorem 14.7.26(ii), the latter is isomorphic to the B^{n+1}-module $\prod_{i=0}^n \overline{\boldsymbol{\omega}}_i^* C$, so the assertion is clear.

(iii): Suppose first that f is weakly étale, so that the multiplication morphism $\mu_{C/B} : C \otimes_B C \to C$ is flat; since it is also an epimorphism on the underlying B-modules, it follows easily that $\mu_{C/B}$ is weakly étale. Especially, $\Phi_{C/C\otimes_B C}$ is an isomorphism, by remark 14.7.25 and our assumption on $\mathfrak{m}$. Then theorem 14.7.26 says that $W_{n+1}(\mu_{C/C\otimes_B C})$ is flat. Lastly, according to (i), the multiplication morphism $\mu_{W_{n+1}C/W_{n+1}B}$ of $W_{n+1}C$ factors through $W_{n+1}(\mu_{C/C\otimes_B C})$ and an isomorphism

$$W_{n+1}C \otimes_{W_{n+1}B} W_{n+1}C \xrightarrow{\sim} W_{n+1}(C \otimes_B C). \tag{14.7.35}$$

Hence $\mu_{W_{n+1}C/W_{n+1}B}$ is flat, and combining with theorem 14.7.26, we conclude that $W_{n+1}f$ is weakly étale. In case f is étale, we deduce from (ii), the isomorphism (14.7.35), and [75, Prop.2.4.18] that $W_{n+1}f$ is étale as well. Conversely, (iv) implies that if $W_{n+1}f$ is weakly étale (resp. étale), then the same holds for f. □

Remark 14.7.36. (i) It is shown in [104, 1.5.8] that if $f : B \to C$ is a homomorphism of $\mathbb{F}_p$-algebras and $n \in \mathbb{N}$ any integer, then $W_{n+1}f$ is étale (in the usual sense of [66], which includes the condition that f is finitely presented), if and only if the same holds for f. This result can be deduced from corollary 14.7.34(iii) and extended to arbitrary rings, as follows. Resume the notation of the proof of the corollary, and suppose that $\mathfrak{m} = A$, so we are dealing with the "classical limit" for which almost rings are just usual rings; then, $W_{n+1}f$ is a weakly étale ring homomorphism, and by [75, §3.4.44] we know already that $W_{n+1}f$ is finitely presented if and only if the same holds for $W_{n+1}f \otimes_{W_{n+1}B} R$. We claim next that $W_{n+1}f \otimes_{W_{n+1}B} R$ is finitely presented if and only if the same holds for $W_{n+1}f \otimes_{W_{n+1}B} (R_0 \times S)$. For the proof, arguing as in [75, §3.4.44] we reduce to checking that the natural morphism $R \to R_0 \times S$ is of universal effective descent for the fibred category of weakly étale morphisms of rings. The latter assertion is already known by corollary 14.1.92. By the same token, $W_{n+1}f \otimes_{W_{n+1}B} S$ is finitely presented if and only if the same holds for $W_{n+1}f \otimes_{W_{n+1}B} (B^{n+1} \times B_0)$. Moreover, the surjective ring homomorphism $R_0 \to B_0$ has nilpotent kernel, so again by [75, §3.4.44] we know that $W_{n+1}f \otimes_{W_{n+1}B} R_0$ is finitely presented if and only if the same holds for $W_{n+1}f \otimes_{W_{n+1}B} B_0$. Since B_0 is a quotient of B^{n+1}, we are finally reduced to checking that $W_{n+1}f \otimes_{W_{n+1}B} B^{n+1}$ is finitely presented; but it was observed in the proof of corollary 14.7.34(ii) that the latter is isomorphic to the B^{n+1}-module $\prod_{i=0}^n \overline{\boldsymbol{\omega}}_i^* C$, so the assertion is clear.

(ii) A version of corollary 14.7.34(iii) for truncated big Witt vectors of usual rings is found in [109, Th.2.4]. Another proof and generalization is given by [31, Th.9.2].

14.8. **Complements : locally measurable algebras.** This section studies the global counterpart of the class of measurable algebras introduced in section 14.5. To begin with – and until (14.8.42) – we consider an arbitrary valued field $(K, |\cdot|)$, and we resume the notation of (11.4) and (14.5). Our first result is the following generalization of proposition 9.1.27 :

Proposition 14.8.1. *Let A be a measurable K^+-algebra, M a K^+-flat and finitely generated A-module. Then M is a finitely presented A-module.*

Proof. Let Σ be a finite system of generators for M; also let us write A as the colimit of a filtered system $(A_i \mid i \in I)$ of finitely presented K^+-algebras, with étale transition maps. For every $i \in I$, let M_i be the A_i-submodule of M generated by Σ; notice that M_i is still K^+-flat, hence it is a finitely presented A_i-module (proposition 9.1.27). We may then write M as the colimit of the filtered system $(M_i \otimes_{A_i} A \mid i \in I)$ of finitely presented A-modules, with surjective transition maps. Moreover, since $\overline{A} := A/\mathfrak{m}_K A$ is noetherian (lemma 14.5.4(i)), there exists $i \in I$ such that $M_j \otimes_{A_j} \overline{A} = M/\mathfrak{m}_K M$ for every $j \geq i$. Since the ring homomorphism $\overline{A}_j := A_j/\mathfrak{m}_K A_j \to \overline{A}$ is faithfully flat, we deduce that

$$M_i \otimes_{A_i} \overline{A}_j = M_j \otimes_{A_j} \overline{A}_j \qquad \text{for every } j \geq i. \tag{14.8.2}$$

Consider the short exact sequence

$$C \quad : \quad 0 \to N \to M_i \otimes_{A_i} A_j \to M_j \to 0.$$

Since M_i is K^+-flat, the same holds for N, and the latter is a finitely generated A_j-module, since both M_j and $M_i \otimes_{A_i} A_j$ are finitely presented; therefore, the sequence $C \otimes_{K^+} \kappa$ is still exact. Taking into account (14.8.2), we see that $N/\mathfrak{m}_K N = 0$. By Nakayama's lemma, it follows that $N = 0$, and finally, $M = M_i \otimes_{A_i} A$ is finitely presented, as stated. □

Definition 14.8.3. Let A be a K^+-algebra. Set $X := \operatorname{Spec} A$, $S := \operatorname{Spec} K^+$, and denote by $f : X \to S$ the structure morphism. We say that A is *locally measurable*, if the following holds. For every $x \in X$ and every point ξ of X localized at x, the strict henselization of A at ξ is a measurable $\mathscr{O}_{S,f(x)}$-algebra.

Remark 14.8.4. Let A be a local K^+-algebra, A^{sh} the strict henselization of A at a geometric point localized at the closed point, and M an A-module.

(i) Clearly, A is locally measurable if and only if A^{sh} is measurable.

(ii) However, if A^{sh} is measurable, it does not necessarily follow that A is measurable.

(iii) On the other hand, if A is a normal local domain, one can show that A is measurable if and only if the same holds for A^{sh}.

(iv) Suppose that A is local and locally measurable. Since the natural map $A \to A^{\mathrm{sh}}$ is faithfully flat, and since every measurable K^+-algebra is a coherent ring, it is easily seen that A is coherent. If furthermore, the structure map $K^+ \to A$ is local, lemma 14.5.4(i) implies that $A/\mathfrak{m}_K A$ is a noetherian ring.

Remark 14.8.5. Let A be a locally measurable K^+-algebra. Then, for every finitely generated ideal $I \subset A$, the K^+-algebra A/I is also locally measurable. Indeed, for every geometric point ξ of $\operatorname{Spec} A$, let A^{sh}_ξ (resp. $(A/I)^{\mathrm{sh}}_\xi$) be the strict henselization of A (resp. of A/I) at ξ. Then the natural map $A^{\mathrm{sh}}_\xi / I A^{\mathrm{sh}}_\xi \to (A/I)^{\mathrm{sh}}_\xi$ is an isomorphism for every such ξ ([66, Ch.IV, Prop.18.8.10]), so the assertion follows from lemma 14.5.4(iv).

Definition 14.8.6. Let A be a K^+-algebra, M an A-module, and $\gamma \in \log \Gamma^+$ any element.

(i) A *K^+-flattening sequence* for the A-module M is a finite sequence $\underline{b} := (b_0, \dots, b_n)$ of elements of K^+ such that
   (a) $\log |b_{i+1}| > \log |b_i|$ for every $i = 0, \dots, n-1$, $b_0 = 1$ and $b_n = 0$.
   (b) $b_i M / b_{i+1} M$ is a $K^+/b_i^{-1} b_{i+1} K^+$-flat module, for every $i = 0, \dots, n-1$.

   We say that a K^+-flattening sequence $\underline{b}$ for M is *minimal*, if no proper subsequence of $\underline{b}$ is still flattening for M.

(ii) Say that $\gamma = \log |b|$ for some $b \in K^+$, and let $b_M : M \to bM$ be the map given by the rule : $m \mapsto bm$, for every $m \in M$. We say that γ *breaks* M if the κ-linear map

$$b_M \otimes_{K^+} \kappa : M \otimes_{K^+} \kappa \to bM \otimes_{K^+} \kappa$$

is not an isomorphism.

Remark 14.8.7. Let A be a K^+-algebra, M an A-module.

(i) Suppose that $\gamma \in \log \Gamma^+$ breaks M, and say that $\gamma = \log |c|$ for some $c \in K^+$. Clearly, for every $b \in cK^+$, the map b_M factors through c_M. We deduce that every $\gamma' \in \log \Gamma^+$ with $\gamma' \geq \gamma$ also breaks M.

(ii) For given $b \in K^+$, suppose that M is a flat K^+/bK^+-module. Then we claim that no $\gamma < \log |b|$ breaks M. Indeed, for such γ pick $c \in K^+$ with $\log |c| = \gamma$, and set $W := K^+/bK^+$; notice that the map $c_W : W \to cW$ induces an isomorphism $c_W \otimes_W \mathbf{1}_\kappa : \kappa \xrightarrow{\sim} cW \otimes_W \kappa$ (notation of definition 14.8.6(ii)), whence an isomorphism

$$\mathbf{1}_M \otimes_W c_W \otimes_W \mathbf{1}_\kappa : M \otimes_W \kappa \xrightarrow{\sim} M \otimes_W (cW \otimes_W \kappa).$$

Since M is a flat W-module, the natural map $M \otimes_W cW \to cM$ is an isomorphism, and the resulting isomorphism $M \otimes_W \kappa \xrightarrow{\sim} cM \otimes_W \kappa$ is naturally identified with c_M, whence the contention.

(iii) Let $\underline{b} := (b_0, \dots, b_n)$ be a sequence of elements of K^+ fulfilling condition (a) of definition 14.8.6(i), and suppose that $\underline{b}$ admits a subsequence that is K^+-flattening for M. Then $\underline{b}$ is K^+-flattening for M as well. Indeed, an easy induction reduces the contention to the following. Let $b, c \in K^+$ be any two elements such that $\log |c| < \log |b|$, and suppose that M is K^+/bK^+-flat; then M/cM is K^+/cK^+-flat, and cM is $K^+/c^{-1}bK^+$-flat. Of this two assertion, the first is trivial; to show the second, recall that M can be written as the colimit of a filtered system of free K^+/bK^+-modules ([120, Ch.I, Th.1.2]). Then we may assume that M is free, in which case the assertion is easily verified.

Lemma 14.8.8. *Let A be a K^+-algebra, M a coherent A-module that admits a K^+-flattening sequence, and suppose that the Jacobson radical of A contains $\mathfrak{m}_K A$. Then we have :*

(i) *M admits a minimal K^+-flattening sequence, unique up to units of K^+.*

(ii) *Let $(b_0, \dots, b_n)$ be a minimal K^+-flattening sequence for M. For every $\gamma \in \log \Gamma^+$ and every $i = 0, \dots, n-1$, the following conditions are equivalent :*

(a) *γ breaks $b_i M$.*

(b) *$\gamma \geq \log |b_i^{-1} b_{i+1}|$. (As usual, we set $\log |0| := +\infty$: see (14.5).)*

Proof. It is clear that M admits a minimal K^+-flattening sequence $(1, b_1, \dots, b_{n-1}, 0)$, and (i) asserts that every other such minimal sequence is of the type $(1, u_1 b_1, \dots, u_{n-1} b_{n-1}, 0)$ for some elements $u_1, \dots, u_{n-1} \in (K^+)^\times$. However, notice that the condition of (ii) characterize uniquely such a sequence, so we only have to show that (ii) holds. We may also assume that $n > 1$; indeed, when $n = 1$, the module M is K^+-flat, and the assertion is immediate. Moreover, since M is coherent, the same holds for bM, for every $b \in K^+$. Thus, an easy induction reduces to showing the equivalence of conditions (ii.a) and (ii.b) for $i = 0$.

However, notice that if γ breaks M, then it obviously also breaks $M/b_1 M$; in light of remark 14.8.7(ii), it follows already that (a)$\Rightarrow$(b). Therefore, taking into account remark 14.8.7(i), it remains only to show that $\log |b_1|$ breaks M.

If $n = 2$, then $b_1 M$ is a flat K^+-module; let $N := \operatorname{Ker} b_{1,M}$. We have already observed that $b_1 M$ is a finitely presented A-module, hence N is a finitely generated A-module, and $N \otimes_{K^+} \kappa$ is the kernel of $b_{1,M} \otimes_{K^+} \kappa$. Suppose that $\log |b_1|$ does not break M; then $N \otimes_{K^+} \kappa$ vanishes, and then $N = 0$, by Nakayama's lemma. It follows that M is K^+-flat, which contradicts the minimality of the sequence $(1, b_1, 0)$.

Next, we consider the case where $n > 2$ and set $M' := M/b_2 M$, $b := b_1^{-1} b_2$; since $b_2 M \subset b_1 \mathfrak{m} M$, it suffices to show that $\log |b_1|$ breaks M', hence we may assume that $b_2 M = 0$, $b_1 M$ is a flat K^+/bK^+-module, and the flattening sequence is $(1, b_1, b_2, 0)$. We remark :

Claim 14.8.9. If $\log |b_1|$ does not break M, the map $b_{1,M/bM} : M/bM \to b_1 M$ is an isomorphism of K^+/bK^+-modules.

Proof of the claim. Indeed, let $N := \mathrm{Ker}\, b_{1,M/bM}$; since b_1M is K^+/bK^+-flat, $N \otimes_{K^+} \kappa$ is the kernel of $b_{1,M/bM} \otimes_{K^+} \kappa$, and the latter vanishes if $\log |b_1|$ does not break M; on the other hand, N is a finitely generated A-module, hence $N = 0$, by Nakayama's lemma. $\diamondsuit$

We shall use the following variant of the local flatness criterion :

Claim 14.8.10. Let R be a ring, $I_1, I_2 \subset A$ two ideals, and M an R-module such that :

(a) $I_1 I_2 = 0$
(b) M/I_iM is R/I_i-flat for $i = 1, 2$
(c) the natural map $I_1 \otimes_R M/I_2M \to I_1M$ is an isomorphism.

Then M is a flat R-module.

Proof of the claim. Set $I_3 := I_1 \cap I_2$; to begin with, [75, Lemma 3.4.18] and (b) imply that M/I_3M is a flat R/I_3-module. We have an obviously commutative diagram

$$\begin{array}{ccccc} I_3 \otimes_R M/I_3M & & \xrightarrow{\quad\alpha\quad} & & I_3M \\ \downarrow{\scriptstyle\beta} & & & & \downarrow{\scriptstyle\gamma} \\ I_3 \otimes_{R/I_2} M/I_2M & \xrightarrow{\delta} & I_1 \otimes_{R/I_2} M/I_2M & \xrightarrow{\tau} & I_1M \end{array}$$

of R-linear maps. From (a) we see that $I_3^2 = 0$, and it follows easily that β is an isomorphism; γ is clearly injective, and the same holds for δ, since M/I_2M is a flat R/I_2-module; by the same token, τ is an isomorphism. We conclude that α is an isomorphism, and then the local flatness criterion ([126, Th.22.3]) yields the contention. $\diamondsuit$

We shall apply claim 14.8.10 with $R := K^+/b_2K^+$, $I_1 := b_1R$, $I_2 := bR$. Indeed, condition (a) obviously holds with these choices; by assumption, M/I_1M is a R/I_1-flat module, and if $\log |b_1|$ does not break M, claim 14.8.9 implies that M/I_2M is a flat R/I_2-module. Lastly, condition (c) is equivalent to claim 14.8.9. Summing up, we have shown that if $\log |b_1|$ does not break M, then M is a flat K^+/b_2-module, contradicting again the minimality of our flattening sequence. $\square$

Proposition 14.8.11. *Let A be a K^+-algebra, M a finitely presented A-module, and suppose that either one of the following two conditions holds :*

(a) *A is an essentially finitely presented K^+-algebra.*
(b) *A is a local and locally measurable K^+-algebra.*

Then M admits a K^+-flattening sequence.

Proof. Suppose first that (b) holds, and let A^{sh} be the strict henselization of A at a geometric point localized at the closed point. Since A^{sh} is a faithfully flat A-algebra, it suffices to show that $M \otimes_A A^{\mathrm{sh}}$ admits a K^+-flattening sequence. Hence, we may assume that A is measurable, in which case we may find a finitely presented K^+-algebra A_0 with an ind-étale map $A_0 \to A$ and a finitely presented A_0-module M_0 with an isomorphism $M_0 \otimes_{A_0} A \xrightarrow{\sim} M$ of A-modules. We may then replace A by A_0, M by M_0, and therefore assume that A is finitely presented over K^+, especially, we are reduced to showing the assertion in the case where (a) holds. To this aim, let us remark :

Claim 14.8.12. Let $B := \bigoplus_{n \in \mathbb{N}} B_n$ be a $\mathbb{N}$-graded finitely presented K^+-algebra with $B_0 = K^+$, and $N := \bigoplus_{n \in \mathbb{N}} N_n$ a $\mathbb{N}$-graded finitely presented B-module. We have :

(i) The K^+-module N_n is finitely presented, for every $n \in \mathbb{N}$.
(ii) For every $n \in \mathbb{N}$, let $(\gamma_{n,i} \mid i \in \mathbb{N})$ be the sequence of elementary divisors of N_n (see (14.5.15)). Then $\Gamma(N) := \{\gamma_{n,i} \mid n, i \in \mathbb{N}\}$ is a finite set.
(iii) N admits a K^+-flattening sequence.

Proof of the claim. (i) is just a special case of proposition 7.6.11(iii).

(ii): Let $\mathscr{Q}$ be the set of all finitely presented graded quotients Q of the B-modules N, for which $\Gamma(Q)$ is infinite. We have to show that $\mathscr{Q} = \varnothing$. However, for every $Q \in \mathscr{Q}$, the $B \otimes_{K^+} \kappa$-module $\overline{Q} := Q \otimes_{K^+} \kappa$ is a quotient of $\overline{N} := N \otimes_{K^+} \kappa$; since $B \otimes_{K^+} \kappa$ is a noetherian ring, the set $\overline{\mathscr{Q}} := \{\overline{Q} \mid Q \in \mathscr{Q}\}$ admits minimal elements, if it is not empty. In the latter case, we may then replace N by any $Q_0 \in \mathscr{Q}$ such that $\overline{Q}_0$ is a minimal element of $\overline{\mathscr{Q}}$, and assume that, for every graded quotient Q of N, either $\overline{Q} = \overline{N}$, or else $\Gamma(Q)$ is a finite set. Now, for every $n \in \mathbb{N}$, let γ_n be the minimal non-zero elementary divisor of N_n, and pick $a_n \in \mathfrak{m}_K$ with $\log|a_n| = \gamma_n$ (if $N_n = 0$, set $a_n = 0$). Let $I \subset K^+$ be the ideal generated by $\{a_n \mid n \in \mathbb{N}\}$; it is easily seen that N_n/IN_n is a free K^+/I-module for every $n \in \mathbb{N}$, hence N/IN is a K^+/I-flat finitely presented B/IB-module. We may then find $a \in I$ such that N/aN is already a K^+/aK^+-flat B/aB-module ([65, Ch.IV, Cor.11.2.6.1]), so N_n/aN_n is a free K^+/aK^+-module for every $n \in \mathbb{N}$, and we easily deduce that $\log|a| \leq \gamma_n$ for every $n \in \mathbb{N}$, *i.e.* $I = aK^+$. Notice that aN is a finitely presented B-module (corollary 9.1.28); it follows that

$$\Gamma(N) = \{\gamma + \log|a| \mid \gamma \in \Gamma(aN)\} \cup \{0\}.$$

Especially, $\Gamma(aN)$ is an infinite set. On the other hand, there exists some $n \in \mathbb{N}$ such that $\dim_\kappa(aN_n) \otimes_{K^+} \kappa < \dim_\kappa N_n \otimes_{K^+} \kappa$, so $(aN) \otimes_{K^+} \kappa$ is a proper quotient of $\overline{N}$, a contradiction.

(iii): Let $|b_0|, \dots, |b_{n-1}|$ be the finitely many elements of $\Gamma(N)$ (for suitable $b_1, \dots, b_n \in K^+$), and set $b_n := 0$; after permutation, we may assume that $b_{i+1} \in b_i\mathfrak{m}_K$ for every $i = 0, \dots, n-1$, and $b_0 = 1$. Then we claim that $(b_0, \dots, b_n)$ is a K^+-flattening sequence for N, *i.e.* $b_iN_k/b_{i+1}N_k$ is $K^+/b_i^{-1}b_{i+1}K^+$-flat for every $i = 0, \dots, n$ and every $k \in \mathbb{N}$. However, say that $(\log|c_j| \mid j \in \mathbb{N})$ is the sequence of elementary divisors of N_k; we are reduced to checking that $(c_jK^+ + b_iK^+)/(c_jK^+ + b_{i+1}K^+)$ is a flat $K^+/b_i^{-1}b_{i+1}K^+$-module for every $j \in \mathbb{N}$. However, by construction we have either $c_jK^+ \subset b_{i+1}K^+$, or $b_iK^+ \subset c_jK^+$; in either case the assertion is clear. ◊

Let now A be an arbitrary essentially finitely presented K^+-algebra, and M an arbitrary finitely presented A-module. We easily reduce to the case where $A = K^+[T_1, , \dots, T_r]$ is a free polynomial K^+-algebra. In this case, we define a filtration $\mathrm{Fil}_\bullet A$ on A, by declaring that $\mathrm{Fil}_k A$ is the K^+-submodule of all polynomials of total degree $\leq k$, for every $k \in \mathbb{N}$; then $R := \mathsf{R}(A, \mathrm{Fil}_\bullet A)_\bullet$ is a free polynomial K^+-algebra as well (see example 7.9.5). Let

$$L_1 \xrightarrow{\varphi} L_0 \to M$$

be a presentation of M as quotient of free A-modules of finite rank. Let

$$\mathbf{e} := (e_1, \dots, e_n) \qquad (\text{resp. } \mathbf{f} := (f_1, \dots, f_m))$$

be a basis of L_0 (resp. of L_1); we endow L_0 with the good $(A, \mathrm{Fil}_\bullet A)$-filtration $\mathrm{Fil}_\bullet L_0$ associated with the pair $(\mathbf{e}, (1, \dots, 1))$ as in (7.9.6) (this means that $e_i \in \mathrm{Fil}_1 L_0$ for every $i = 1, \dots, n$). Also, for every $i = 1, \dots, m$, pick $j_i \in \mathbb{N}$ such that $\varphi(f_i) \in \mathrm{Fil}_{j_i} L_0$, and endow L_1 with the good $(A, \mathrm{Fil}_\bullet A)$-filtration $\mathrm{Fil}_\bullet L_1$ associated with the pair $(\mathbf{f}, (j_1, \dots, j_m))$. Set $L'_i := \mathsf{R}(L_i, \mathrm{Fil}_\bullet L_i)$, and notice that L'_i is a free R-module of finite rank, for $i = 0, 1$. With these choices, φ is a map of filtered A-modules, and there follows an R-linear map of $\mathbb{N}$-graded R-modules $\mathsf{R}(\varphi)_\bullet : L'_1 \to L'_0$, whose cokernel is a $\mathbb{N}$-graded finitely presented R-module $N_\bullet$. By inspecting the construction, it is easily seen that the inclusion $\mathrm{Fil}_k L_0 \subset \mathrm{Fil}_{k+1} L_0$ induces a K^+-linear map $N_k \to N_{k+1}$, for every $k \in \mathbb{N}$, as well as an isomorphism of K^+-modules

$$\operatorname*{colim}_{k \in \mathbb{N}} N_k \xrightarrow{\sim} M.$$

On the other hand, claim 14.8.12 ensures that $N_\bullet$ admits a K^+-flattening sequence. We easily deduce that the same sequence is also flattening for M. □

Corollary 14.8.13. *Let A be a local and locally measurable K^+-algebra, $I \subset K^+$ any ideal, M a finitely generated A/IA-module, and suppose that the structure map $K^+ \to A$ is local. Then the following conditions are equivalent :*

(a) *M is a flat K^+/I-module.*
(b) *For every $c \in K^+$ such that $I \subset c \cdot \mathfrak{m}_K$, the value $\log |c|$ does not break M.*
(c) *M is a K^+/I-flat finitely presented A/IA-module.*

Proof. (a)⇒(b): in light of remark 14.8.7(ii), it suffices to remark that $M \otimes_{K^+} /bK^+$ is a flat K^+/bK^+-module, for every $b \in K^+$ such that $I \subset K^+b$.

(b)⇒(c): Let us write M as the colimit of a filtered system $(M_\lambda \mid \lambda \in \Lambda)$ of finitely presented A-modules, with surjective transition maps. Then each M_λ is a coherent A-module, and $A/\mathfrak{m}_K A$ is noetherian (remark 14.8.4(iv)), so we may also assume that the induced maps $\varphi_\lambda : M_\lambda/\mathfrak{m}_K M_\lambda \to M/\mathfrak{m}_K M$ are isomorphisms for every $\lambda \in \Lambda$. In view of the commutative diagram

$$\begin{array}{ccc} M_\lambda \otimes_{K^+} \kappa & \xrightarrow{c_{M_\lambda}} & cM_\lambda \otimes_{K^+} \kappa \\ {\scriptstyle \varphi_\lambda}\downarrow & & \downarrow \\ M \otimes_{K^+} \kappa & \xrightarrow{c_M} & cM \otimes_{K^+} \kappa \end{array}$$

it easily follows that $\log |c|$ does not break M_λ, for any $\lambda \in \Lambda$ and any $c \in K^+$ such that $I \subset c{\cdot}\mathfrak{m}_K$. Thus, if $(b_0, \dots, b_n)$ is the minimal flattening sequence for M_λ, we see that $b_1 \in I$ (lemma 14.8.8(ii)), and therefore M_λ/IM_λ is a flat K^+/I-module for every $\lambda \in \Lambda$. Now, for $\lambda, \mu \in \Lambda$ with $\mu \geq \lambda$, let $\psi_{\lambda\mu} : M_\lambda \to M_\mu$ be the transition map, and set $N_{\lambda\mu} := \mathrm{Ker}(\psi_{\lambda\mu} \otimes_{K^+} K^+/I)$; it follows that $N_{\lambda\mu} \otimes_{K^+} \kappa$ is the kernel of $\psi_{\lambda\mu} \otimes_{K^+} \kappa$. But the latter map is an isomorphism, since the same holds for φ_λ and φ_μ. By Nakayama's lemma, we deduce that $N_{\lambda\mu} = 0$, therefore $M = M_\lambda/IM_\lambda$ for any $\lambda \in \Lambda$, whence (c).

Lastly, (c)⇒(a) is obvious. □

Proposition 14.8.14. *Let A be a locally measurable K^+-algebra. Suppose that*

(a) *$A/\mathfrak{m}_K A$ is a noetherian ring.*
(b) *The Jacobson radical of A contains $\mathfrak{m}_K A$.*

Then we have :

(i) *$A \otimes_{K^+} K$ is a noetherian ring.*
(ii) *Every finitely generated K^+-flat A-module is finitely presented.*
(iii) *If the valuation of K is discrete, A is noetherian.*

Proof. For any K^+-algebra B, and any ideal $I \subset B_K := B \otimes_{K^+} K$, let us set $I^{\mathrm{sat}} := \mathrm{Ker}(B \to B_K/I)$, and notice that $I^{\mathrm{sat}} \otimes_{K^=} K = I$. To begin with, we remark :

Claim 14.8.15. Let B be a measurable K^+-algebra, $I \subset B_K$ an ideal. Then I^{sat} is a finitely generated ideal of B.

Proof of the claim. Clearly B/I^{sat} is a K^+-flat finitely generated B-module, hence it is finitely presented, by proposition 14.8.1; now the claim follows from [75, Lemma 2.3.18(ii)]. ◊

(i): Suppose $(I_k \mid k \in \mathbb{N})$ is an increasing sequence of ideals of $A \otimes_{K^+} K$; assumption (a) implies that there exists $n \in \mathbb{N}$ such that the images of I_n^{sat} and I_m^{sat} agree in $A/\mathfrak{m}_K A$, for every $m \geq n$. This means that

$$(I_m^{\mathrm{sat}}/I_n^{\mathrm{sat}}) \otimes_{K^+} \kappa = 0 \qquad \text{for every } m \geq n. \tag{14.8.16}$$

Next, for any geometric point ξ of $\mathrm{Spec}\, A$, let A_ξ^{sh} be the strict henselization of A at ξ; since the natural map $A \to A_\xi^{\mathrm{sh}}$ is flat, $I_k \otimes_A A_\xi^{\mathrm{sh}}$ is an ideal of $A_\xi^{\mathrm{sh}} \otimes_{K^+} K$, and clearly $I_k^{\mathrm{sat}} \otimes_A A_\xi^{\mathrm{sh}} = (I_k \otimes_A A_\xi^{\mathrm{sh}})^{\mathrm{sat}}$, for every $k \in \mathbb{N}$. Especially $I_k^{\mathrm{sat}} \otimes_A A_\xi^{\mathrm{sh}}$ is a finitely generated ideal of A_ξ^{sh}, by claim 14.8.15. In view of (14.8.16), and assumption (b), Nakayama's lemma then says that $(I_m^{\rm sat}/I_n^{\rm sat}) \otimes_A A_\xi^{\rm sh} = 0$ for every $m \geq n$. Since ξ is arbitrary, we conclude that $I_m^{\rm sat}/I_n^{\rm sat} = 0$ for every $m \geq n$, therefore the sequence $(I_k \mid k \in \mathbb{N})$ is stationary.

(ii): Let M be a K^+-flat and finitely generated A-module, pick an A-linear surjection $\varphi : A^{\oplus n} \to M$, and set $N := \operatorname{Ker} \varphi$. Since M is K^+-flat, $N/\mathfrak{m}_K N$ is the kernel of $\varphi \otimes_{K^+} \kappa$, and assumption (a) implies that $N/\mathfrak{m}_K N$ is a finitely generated $A/\mathfrak{m}_K A$-module. Hence we may find a finitely generated A-submodule $N' \subset N$ such that $N = N' + \mathfrak{m}_K N$. For any geometric point ξ of $\operatorname{Spec} A$, define $A_\xi^{\rm sh}$ as in the foregoing; by proposition 14.8.1 (and by [75, Lemma 2.3.18(ii)]), $N \otimes_A A_\xi^{\rm sh}$ is a finitely generated $A_\xi^{\rm sh}$-module; then (b) and Nakayama's lemma imply that $N' \otimes_A A_\xi^{\rm sh} = N \otimes_A A_\xi^{\rm sh}$. Since ξ is arbitrary, it follows that $N = N'$; especially, M is finitely presented, as stated.

(iii): It suffices to show that every prime ideal of A is finitely generated ([126, Th.3.4]). However, let $\mathfrak{p} \subset A$ be such a prime ideal, and fix a generator t of $\mathfrak{m}_K$. Suppose first that $t \in \mathfrak{p}$; in that case (a) implies that $\mathfrak{p}/tA$ is a finitely generated ideal of A/tA, so then clearly $\mathfrak{p}$ is finitely generated as well. Next, in case $t \notin \mathfrak{p}$, the quotient $A/\mathfrak{p}$ is a K^+-flat finitely generated A-module, hence it is finitely presented (proposition 14.8.1), so again $\mathfrak{p}$ is finitely generated ([75, Lemma 2.3.18(ii)]). □

Theorem 14.8.17. *Let A be a locally measurable K^+-algebra, M a finitely presented A-module, and suppose that :*

(a) *The valuation of K has finite rank.*
(b) *For every $t \in \operatorname{Spec} K^+$, the ring $A \otimes_{K^+} \kappa(t)$ is noetherian.*

Then we have :

(i) *M admits a K^+-flattening sequence.*
(ii) *$\operatorname{Ass} M$ is a finite set.*

Proof. (i): Set $X := \operatorname{Spec} A$, $S := \operatorname{Spec} K^+$, let $f : X \to S$ be the structure morphism, and denote by $\mathscr{M}$ the quasi-coherent $\mathscr{O}_X$-module associated with M. Also, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ and every $c \in K^+$, let $c_\mathscr{F} : \mathscr{F} \to c\mathscr{F}$ be the unique $\mathscr{O}_X$-linear morphism such that $c_\mathscr{F}(U) = c_{\mathscr{F}(U)}$ for every affine open subset $U \subset X$ (notation of definition 14.8.6(ii)). For every $x \in X$, set $K^+_{f(x)} := \mathscr{O}_{S,f(x)}$; then $K^+_{f(x)}$ is a valuation ring whose valuation we denote $|\cdot|_{f(x)}$, and $\mathscr{O}_{X,x}$ is a locally K^+_x-measurable algebra. By proposition 14.8.11, the $\mathscr{O}_{X,x}$-module $\mathscr{M}_x$ admits a $K^+_{f(x)}$-flattening sequence $(b_{x,0}, \dots, b_{x,n})$; we wish to show that there exists an open neighborhood $U(x)$ of x in X, such that $(b_{x,i}\mathscr{M}/b_{x,i+1}\mathscr{M})_y$ is a $K^+/b_{x,i}^{-1}b_{x,i+1}K^+$-flat module, for every $y \in U(x)$ and every $i = 0, \dots, n-1$. To this aim, we remark :

Claim 14.8.18. Let $\mathscr{N}$ be a quasi-coherent $\mathscr{O}_X$-module of finite type, $x \in X$ a point, and $b \in K^+$ such that $\mathscr{N}_x$ is a flat K^+/bK^+-module. Then there exists an open neighborhood $U \subset X$ of x such that the map

$$c_{\mathscr{N},y} \otimes_{K^+} \kappa(f(y)) : \mathscr{N}_y \otimes_{K^+} \kappa(f(y)) \to c\mathscr{N}_y \otimes_{K^+} \kappa(f(y))$$

is an isomorphism for every $y \in U$ and every $c \in K^+$ with $\log |c|_{f(y)} < \log |b|_{f(y)}$.

Proof of the claim. Let $z \in X(x)$ be any point, and set $t := f(z)$; under our assumptions, $\mathscr{N}_z$ is a flat K^+/bK^+-module. Therefore, the sequence of $\mathscr{O}_{X,z}$-modules

$$0 \to c^{-1}b\mathscr{N}_z \xrightarrow{j} \mathscr{N}_z \xrightarrow{c_{\mathscr{N},z}} c\mathscr{N}_z \to 0$$

is exact, for every $c \in K^+$ with $\log |c| < \log |b|$, and *a fortiori*, whenever $\log |c|_t < \log |b|_t$. If the latter inequality holds, the map $j \otimes_{K^+} \kappa(t)$ vanishes, hence $c_{\mathscr{N},z} \otimes_{K^+} \kappa(t)$ is injective.

Let now $y \in X$ be any point; set $u := f(y)$, pick $c \in K^+$ with $\log |c|_u < \log |b|_u$, set $\mathscr{K}(u) := \operatorname{Ker}(c_\mathscr{N} \otimes_{K^+} \kappa(u))$, and suppose that $\mathscr{K}(u)_y \neq 0$. The foregoing shows that in this case $y \notin X(x)$. On the other hand, by assumption $f^{-1}(u)$ is a noetherian scheme, and $\mathscr{N}(u) := \mathscr{N} \otimes_{K^+} \kappa(u)$ is a coherent $\mathscr{O}_{f^{-1}(u)}$-module, therefore $\mathrm{Ass}\,\mathscr{N}(u)$ is a finite set ([126, Th.6.5(i)]). In view of proposition 10.5.6(ii), we conclude that $\mathrm{Ass}\,\mathscr{K}(u)$ is contained in the finite set $\mathrm{Ass}\,\mathscr{N}(u)\backslash X(x)$. Let Z be the topological closure in X of the (finite) set $\bigcup_{u\in S} \mathrm{Ass}\,\mathscr{N}(u)\backslash X(x)$; taking into account lemma 10.5.5(ii,iii), we see that $U := X \setminus Z$ will do. $\Diamond$

Fix $x \in X$ and $i \leq n$; taking $\mathscr{N} := b_{x,i}\mathscr{M}/b_{x,i+1}\mathscr{M}$ and $b := b_{x,i}^{-1}b_{x,i+1}$ in claim 14.8.18, and invoking the criterion of corollary 14.8.13, we obtain an open neighborhood U_i of x in X such that $\mathscr{N}_y$ is K^+/bK^+-flat for every $y \in U_i$. Clearly the subset $U(x) := U_1 \cap \cdots \cap U_n$ fulfills the sought condition. Next, pick finitely many points $x_1, \dots, x_k \in X$ and corresponding K^+-flattening sequences $\underline{b}_i$ for $\mathscr{M}_{x_i}$, for each $i = 1, \dots, k$, such that $U(x_1) \cup \cdots \cup U(x_k) = X$; after reordering, the sequence $(\underline{b}_1, \dots, \underline{b}_k)$ becomes K^+-flattening for M (see remark 14.8.7(iii)).

(ii): Let $(b_0, \dots, b_n)$ be a K^+-flattening sequence for M; in view of proposition 10.5.6(ii), it suffices to prove that $\mathrm{Ass}\, b_iM/b_{i+1}M$ is a finite set, for every $i = 0, \dots, n-1$. Taking into account remark 14.8.4(iv), we are then reduced to showing

Claim 14.8.19. Let $\mathscr{N}$ be a quasi-coherent $\mathscr{O}_X$-module, and $b \in K^+$ any element such that $\mathscr{N}_x$ is a K^+/bK^+-flat and finitely presented $\mathscr{O}_{X,x}$-module for every $x \in X$. Then $\mathrm{Ass}\,\mathscr{N}$ is finite.

Proof of the claim. For given $x \in X$ and any geometric point ξ of X localized at x, let A^{sh} be the strict henselization of A at ξ, and B a local and essentially finitely presented K^+-algebra with a local and ind-étale map $B \to A^{\mathrm{sh}}$. We may assume that $\mathscr{N}_x \otimes_A A^{\mathrm{sh}}$ descends to a finitely presented K^+/bK^+-flat B-module N_B ([65, Ch.IV, Cor.11.2.6.1(ii)]). Denote by $\overline{x}$ (resp. by x_B) the closed point of $X(\xi) = \mathrm{Spec}\, A^{\mathrm{sh}}$ (resp. of $\mathrm{Spec}\, B$); in light of corollary 10.4.37 we have

$$x \in \mathrm{Ass}\,\mathscr{N} \Leftrightarrow x \in \mathrm{Ass}_{\mathscr{O}_{X,x}}\mathscr{N}_x \Leftrightarrow \overline{x} \in \mathrm{Ass}_{A^{\mathrm{sh}}}\mathscr{N}_x \otimes_A A^{\mathrm{sh}} \Leftrightarrow x_B \in \mathrm{Ass}_B N_B. \tag{14.8.20}$$

On the other hand, it is easily seen that $\mathrm{Ass}_{K^+} K^+/bK^+$ consists of only one point, namely the maximal point t of $\mathrm{Spec}\, K^+/bK^+$. From corollary 10.5.9, we deduce :

$$x_B \in \mathrm{Ass}_B N_B \Leftrightarrow x_B \in \mathrm{Ass}_B N_B \otimes_{K^+} \kappa(t)$$

and by applying again repeatedly corollary 10.4.37 as in (14.8.20), we see that

$$x_B \in \mathrm{Ass}_B N_B \otimes_{K^+} \kappa(t) \Leftrightarrow x \in \mathrm{Ass}\,\mathscr{N} \otimes_{K^+} \kappa(t).$$

Summing up, we conclude that $\mathrm{Ass}\mathscr{N} = \mathrm{Ass}\mathscr{N} \otimes_{K^+} \kappa(t)$, and the latter is a finite set, by [126, Th.6.5(i)]. $\square$

Corollary 14.8.21. *Let $(K, |\cdot|)$ be a valued field, and A a locally measurable K^+-algebra fulfilling conditions* (a) *and* (b) *of theorem* 14.8.17. *Let also M be a finitely generated A-module, and $\mathfrak{p} \subset A$ any prime ideal such that $M_{\mathfrak{p}}$ is a finitely presented $A_{\mathfrak{p}}$-module. We have:*

(i) *There exists $f \in A\backslash\mathfrak{p}$ such that M_f is a finitely presented A_f-module.*
(ii) *A is coherent.*

Proof. (i): We may find a finitely presented A-module M' with an A-linear surjection $\varphi : M' \to M$ such that $\varphi_{\mathfrak{p}}$ is an isomorphism. Set $M'' := \mathrm{Ker}\,\varphi$; it follows that $\mathrm{Ass}\, M'' \subset \mathrm{Ass}\, M' \setminus \mathrm{Spec}\, A_{\mathfrak{p}}$. However, $\mathrm{Ass}\, M'$ is a finite set (theorem 14.8.17(ii)); therefore the support of $\mathrm{Ker}\,\varphi$ is contained in a closed subset of $X := \mathrm{Spec}\, A$ that does not contain $\mathfrak{p}$, and the assertion follows.

(ii): Let M be a finitely presented A-module, $M' \subset M$ a finitely generated submodule, and let $\mathscr{M}'$ be the quasi-coherent $\mathscr{O}_X$-module associated with M'. By remark 14.8.4(iv), we know that $\mathscr{M}'_x$ is a finitely presented $\mathscr{O}_{X,x}$-module for every $x \in X$; from (i), it follows that $\mathscr{M}'$ is a finitely presented $\mathscr{O}_X$-module, and the assertion follows easily. $\square$

In view of theorem 14.8.17 and corollary 14.8.21, it is interesting to have criteria ensuring that the fibres over $\mathrm{Spec}\, K$ of the spectrum of a locally measurable K^+-algebra are noetherian. We present two results in this direction. To state them, let us make first the following :

Definition 14.8.22. Let $f : X \to Y$ be a morphism of schemes.

(i) We say that f is *absolutely flat* if the following holds. For every geometric point ξ of X, the induced morphism $f_\xi : X(\xi) \to Y(f(\xi))$ is an isomorphism.
(ii) We say that f *has finite fibres* if the set $f^{-1}(y)$ is finite, for every $y \in Y$.
(iii) We say that Y *admits a geometrically unibranch stratification* if every irreducible closed subset Z of Y contains a subset $U \neq \varnothing$, open in Z, and geometrically unibranch.
(iv) We say that a ring homomorphism $\varphi : A \to B$ is *absolutely flat* if $\mathrm{Spec}\,\varphi$ is absolutely flat.

Remark 14.8.23. In practice, it is often the case that a noetherian scheme admits a geometrically unibranch stratification; for instance, this holds (essentially by definition) for the spectrum of a quasi-excellent noetherian ring (see definition 9.7.3(ii)).

Lemma 14.8.24. *Let $f : X \to Y$ be an absolutely flat morphism of schemes. Then $\mathbb{L}_{X/Y} \simeq 0$ in $\mathsf{D}(\mathscr{O}_X\text{-}\mathbf{Mod})$.*

Proof. We easily reduce to the case where both X and Y are local schemes. Let ξ be a geometric point of X localized at the closed point; then $\mathbb{L}_{X(\xi)/X} \simeq 0$ in $\mathsf{D}(\mathscr{O}_{X(\xi)}\text{-}\mathbf{Mod})$ ([75, Th.2.5.37]). Hence, by transitivity ([75, Th.2.5.33]), we are reduced to showing that $\mathbb{L}_{X(\xi)/Y} \simeq 0$ in $\mathsf{D}(\mathscr{O}_{X(\xi)}\text{-}\mathbf{Mod})$. The latter assertion assertion holds, again by virtue of [75, Th.2.5.37], since f_ξ is an isomorphism. $\square$

Proposition 14.8.25. *Let $\varphi : A \to B$ be a local and absolutely flat morphism of local rings. Assume that either one of the following two conditions holds :*

(a) *A is a normal local domain.*
(b) *B is a henselian local ring.*

Then φ is an ind-étale ring homomorphism.

Proof. Pick a geometric point ξ of $\mathrm{Spec}\, B$ localized at the closed point, and let ξ' denote the image of ξ in $\mathrm{Spec}\, A$. Let also A^{sh} (resp. B^{sh}) be the strict henselization of A at ξ' (resp. of B at ξ). Notice first that A is a normal local domain if and only if the same holds for B ([66, Ch.IV, Prop.18.8.12(i)]). In case (a) holds, let F_A (resp. F_B) be the field of fractions of A (resp. B). We remark :

Claim 14.8.26. Let R be any normal local domain, and R^{sh} the strict henselization of R at a geometric point localized at the closed point of $\mathrm{Spec}\, R$. We have :

(i) $R = R^{\mathrm{sh}} \cap \mathrm{Frac}\, R$ (where the intersection takes place in $\mathrm{Frac}\, R^{\mathrm{sh}}$).
(ii) For every field extension F of $\mathrm{Frac}\, R$ contained in $\mathrm{Frac}\, R^{\mathrm{sh}}$, the R-algebra $F \cap R^{\mathrm{sh}}$ is ind-étale.

Proof of the claim. (i): More generally, let $C \to D$ be any faithfully flat ring homomorphism, and denote by $\mathrm{Frac}\, C$ (resp. $\mathrm{Frac}\, D$) the total ring of fractions of C (resp. of D); then it is easily seen that $C = D \cap \mathrm{Frac}\, C$, where the intersection takes place in $\mathrm{Frac}\, D$: the proof shall be left as an exercise for the reader.

(ii): We easily reduce to the case where F is a finite extension of $F_R := \mathrm{Frac}\, R$. Then, let E be a finite Galois extension of F_R, contained in a fixed separable closure F^{sep} of $F_R^{\mathrm{sh}} := \mathrm{Frac}\, R^{\mathrm{sh}}$, and containing F; also, denote by R^ν (resp. R^ν_E) the integral closure of R in F^{sep} (resp. in E). Recall that there exists a unique maximal ideal $\mathfrak{p}^{\mathrm{sep}} \subset R^\nu$ lying over the maximal ideal of R, such that $R^{\mathrm{sh}} = (R^\nu)^I_{\mathfrak{p}^{\mathrm{sep}}}$, where $I \subset \mathrm{Gal}(F^{\mathrm{sep}}/F_R)$ is the inertia subgroup associated with $\mathfrak{p}^{\mathrm{sep}}$ ([141, Ch.X, §2, Th.2]); therefore, $F^{\mathrm{sh}}_R = (F^{\mathrm{sep}})^I$. On the other hand, $F = E^H$ for a subgroup $H \subset \mathrm{Gal}(E/F_R)$, and recall that the natural surjection $\mathrm{Gal}(F^{\mathrm{sep}}/F_R) \to \mathrm{Gal}(E/F_R)$ maps I onto the inertia subgroup I_E associated with the maximal ideal $\mathfrak{p}_E := \mathfrak{p}^{\mathrm{sep}} \cap E \subset R^\nu_E$. It follows that H contains I_E. Set $\mathfrak{p}_F := \mathfrak{p}_E \cap F$; then $R_F := (R^\nu_E \cap F)_{\mathfrak{p}_F}$ is a faithfully flat and essentially étale R-algebra ([141, Ch.X, §1, Th.1(1)]). Especially, R^{sh} is also a strict henselization of R_F, and notice that $\mathrm{Frac}\, R_F = F$, so the assertion follows from (i). ◇

By assumption, φ extends to an isomorphism of local domains $A^{\mathrm{sh}} \xrightarrow{\sim} B^{\mathrm{sh}}$; in view of claim 14.8.26(i), we see that $B = F_B \cap A^{\mathrm{sh}}$, and then the proposition follows from claim 14.8.26(ii).

Next, suppose assumption (b) holds. Then, φ extends uniquely to a local ring homomorphism $\varphi^{\mathrm{h}} : A^{\mathrm{h}} \to B$ from the henselization of A ([66, Ch.IV, Th.18.6.6(ii)]); clearly φ^{h} is still absolutely flat, hence we may replace A by A^{h} and assume that both A and B are henselian. Since φ is absolutely flat, the residue field extension $\kappa(A) \to \kappa(B)$ is separable and algebraic; then for every finite extension E of $\kappa(A)$ contained in $\kappa(B)$ there exists a finite étale local A-algebra A_E, unique up to isomorphism, whose residue field is E ([66, Ch.IV, Prop.18.5.15]). The natural map $\kappa(B) \to E \otimes_{\kappa(A)} \kappa(B)$ admits a well defined section, given by the multiplication in $\kappa(B)$, and the latter extends to a section s_E of the induced finite étale ring homomorphism $B \to A_E \otimes_A B$ ([66, Ch.IV, Th.18.5.11]). The composition of s_E with the natural map $A_E \to A_E \otimes_A B$ is a ring homomorphism $A_E \to B$ that extends φ. The construction is clearly compatible with inclusion of subextensions $E \subset E'$, hence let A' be the colimit of the system $(A_E \mid E \subset \kappa(B))$; summing up, φ extends to a local and absolutely flat map $A' \to B$. We may therefore replace A by A' and assume from start that $\kappa(A) = \kappa(B)$. In this case, set $B' := A^{\mathrm{sh}} \otimes_A B$, and notice that $\kappa(A^{\mathrm{sh}}) \otimes_{\kappa(A)} \kappa(B) = \kappa(A^{\mathrm{sh}})$, so that B' is a local ring, ind-étale, faithfully flat over B, and with separably closed residue field. Since B is already henselian, it follows that B' is a strict henselization of B, and therefore the induced map $A^{\mathrm{sh}} \to B'$ is an isomorphism; by faithfully flat descent, we deduce that φ is already an isomorphism, and the proof of the proposition is concluded. □

Lemma 14.8.27. *Let A be a locally measurable K^+-algebra, and set $X := \mathrm{Spec}\, A$. Let also $f : X \to Y$ be a morphism of K^+-schemes with $\Omega_{X/Y} = 0$, and Y a finitely presented K^+-scheme. Then f_ξ is a finitely presented closed immersion, for every geometric point ξ of X.*

Proof. Fix such a geometric point ξ; by definition, we may find a local K^+-scheme Z essentially finitely presented, and a pro-étale morphism $g : X(\xi) \to Z$ of K^+-schemes. We may also assume that the morphism $X(\xi) \to Y$ deduced from f factors through g, in which case the resulting morphism $h : Z \to Y$ is essentially finitely presented. Under the current assumptions, $\Omega_{X(\xi)/Y} = 0$, and then lemma 14.8.24 easily implies that $\Omega_{Z/Y}$ vanishes as well, so h is essentially unramified, and therefore it factors as the composition of a finitely presented closed immersion $Z \to Z'$ followed by an essentially étale morphism $Z' \to Y$ ([66, Ch.IV, Cor.18.4.7]). The lemma is an immediate consequence. □

Proposition 14.8.28. *Let A be a local, henselian, and locally measurable K^+-algebra, whose structure map $K^+ \to A$ is local. Then A is a measurable K^+-algebra.*

Proof. Pick a local and essentally finitely presented K^+-algebra B and a local and ind-étale map $\varphi : B \to A$ of K^+-algebras. Let ξ be a geometric point of $\mathrm{Spec}\, A$ localized at the closed point, and denote by ξ' the image of ξ in $\mathrm{Spec}\, B$; also, let A^{sh} (resp. B^{sh}) be the strict henselization of A at ξ (resp. of B at ξ'). Then $\Omega_{A/B} = 0$, hence the induced map $\varphi^{\mathrm{sh}} : B^{\mathrm{sh}} \to A^{\mathrm{sh}}$ is a finitely presented surjection (lemma 14.8.27), especially $I := \mathrm{Ker}\, \varphi^{\mathrm{sh}}$ is a finitely generated ideal, and it follows as well that the residue field extension $\kappa(B) \to \kappa(A)$ is separable and algebraic. Let B^{h} be the henselization of B, and for every field extension E of $\kappa(B)$ contained in $\kappa(A)^{\mathrm{sep}} = \kappa(B)^{\mathrm{sep}}$, let B^{h}_E denote the local ind-étale B^{h}-algebra –

determined up to isomorphism – whose residue field is E ([66, Ch.IV, Prop.18.5.15]). We may find a finite Galois extension E of $\kappa(B)$ such that I descends to a finitely generated ideal $I_E \subset B^{\mathrm{h}}_E$. For any automorphism $\sigma \in G := \mathrm{Gal}(\kappa(B)^{\mathrm{sep}}/\kappa(B))$, let $\overline{\sigma} \in G_E := \mathrm{Gal}(E/\kappa(B))$ be the image of σ. Recall that G (resp. G_E) is the group of automorphisms of the B^{h}-algebra B^{sh} (resp. B^{h}_E). With this notation, we have the identity

$$\overline{\sigma}(I_E)B^{\mathrm{sh}} = \sigma(I) = I \qquad \text{for every } \sigma \in G$$

and since B^{sh} is a faithfully flat B^{h}-algebra, it follows that I_E is invariant under the action of G_E; by Galois descent, we conclude that I descends to a finitely generated ideal $I_0 \subset B^{\mathrm{h}}$. Set $C := B^{\mathrm{h}}/I_0$, and let C^{sh} denote the strict henselization of C at (the unique lifting of) the geometric point ξ'. Since A is henselian, φ extends uniquely to a local homomorphism $\varphi^{\mathrm{h}} : B^{\mathrm{h}} \to A$ ([66, Ch.IV, Th.18.6.6(ii)]), and it is easily seen that φ^{h} factors through C. By construction, the resulting map $C \to A$ is absolutely flat, so the assertion follows from proposition 14.8.25. □

Lemma 14.8.29. *Let X be a noetherian scheme that admits a geometrically unibranch stratification, and $\mathscr{F}$ a coherent $\mathscr{O}_{X_{\mathrm{\acute{e}t}}}$-module. Then there exists a partition*

$$X = X_1 \cup \cdots \cup X_k$$

of X into finitely many disjoint irreducible locally closed subsets, such that the following holds. For every $i = 1, \dots, k$, every geometric point $\overline{x}$ of X_i, and every generization $\overline{u}$ of $\overline{x}$ in X_i, every strict specialization map

$$s_{\overline{x},\overline{u}} : \mathscr{F}_{\overline{x}} \to \mathscr{F}_{\overline{u}}$$

is injective (see (4.9.23)).

Proof. Arguing by noetherian induction, it suffices to show that every reduced and irreducible closed subscheme W of X contains a subset $U \neq \varnothing$ that is open in W, and such that every strict specialization map $s_{\overline{x},\overline{u}}$ with $\overline{x}$, $\overline{u}$ localized in U, is injective. However, W contains an open subset $U \neq \varnothing$ such that

(a) U is geometrically unibranch
(b) U is affine and irreducible
(c) $\mathscr{F}$ is normally flat along W at every point of U (see [64, Ch.IV,§6.10.1]).

Indeed, (a) holds by assumption; (b) can be easily arranged by shrinking U, since X is noetherian. Lastly, (c) follows from [64, Ch.IV, Prop.6.10.2]. We claim that such U will do. Indeed, let $i : W \to W$ be the closed immersion; set

$$\mathscr{I} := \mathrm{Ker}(\mathscr{O}_X \to i_*\mathscr{O}_W) \qquad \mathscr{R}^\bullet := \bigoplus_{n\in\mathbb{N}} \mathscr{I}^n\mathscr{F}/\mathscr{I}^{n+1}\mathscr{F}$$

and recall that condition (c) means that $\mathscr{R}^\bullet_u$ is a flat $\mathscr{O}_{W,u}$-module, for every $u \in U$. Now, for a given $s_{\overline{x},\overline{u}}$ as in the foregoing, denote by x (resp. u) the support of $\overline{x}$ (resp. of $\overline{u}$) and define descending filtrations by the rule :

$$\mathrm{Fil}^k\mathscr{F}_{\overline{x}} := \mathscr{I}^k_x \cdot \mathscr{F}_{\overline{x}} \qquad \mathrm{Fil}^k\mathscr{F}_{\overline{u}} := \mathscr{I}^k_u \cdot \mathscr{F}_{\overline{u}} \qquad \text{for every } k \in \mathbb{N}.$$

By [126, Th.8.9], both these filtrations are separated, and obviously $s_{\overline{x},\overline{u}}$ is a map of filtered modules; thus, it suffices to show that the induced maps $\mathrm{gr}^k\mathscr{F}_{\overline{x}} \to \mathrm{gr}^k\mathscr{F}_{\overline{u}}$ of associated graded modules are injective, for every $k \in \mathbb{N}$. However, notice the natural identifications :

$$\mathrm{gr}^\bullet\mathscr{F}_{\overline{x}} = \mathscr{R}^\bullet_x \otimes_{\mathscr{O}_{W,x}} \mathscr{O}_{W_{\mathrm{\acute{e}t}},\overline{x}} \qquad \mathrm{gr}^\bullet\mathscr{F}_{\overline{u}} = \mathscr{R}^\bullet_x \otimes_{\mathscr{O}_{W,x}} \mathscr{O}_{W_{\mathrm{\acute{e}t}},\overline{u}}.$$

Then, the normal flatness condition reduces to checking that the induced strict specialization map $\mathscr{O}_{W_{\mathrm{\acute{e}t}},\overline{x}} \to \mathscr{O}_{W_{\mathrm{\acute{e}t}},\overline{u}}$ is injective; the latter assertion holds by the following :

Claim 14.8.30. Let W be a reduced, irreducible scheme, $\overline{w}$ a geometric point of W, and suppose that W is unibranch at the support w of $\overline{w}$. Then, for every generization $\overline{u}$ of $\overline{w}$ in W, every strict specialization map $\mathscr{O}_{W_{\text{ét}},\overline{w}} \to \mathscr{O}_{W_{\text{ét}},\overline{u}}$ is injective.

Proof of the claim. Let W^ν be the normalization of W, and $\overline{w}^\nu$ a geometric point of W^ν whose image in X is isomorphic to $\overline{w}$, and denote by w^ν the support of $\overline{w}^\nu$. The assumption on w means that the induced morphism $W^\nu(w^\nu) \to W(w)$ is integral, and the residue field extension $\kappa(w) \to \kappa(w^\nu)$ is radicial, hence the natural morphism of $W^\nu(\overline{w}^\nu)$-schemes

$$W(\overline{w}) \times_{W(w)} W^\nu(w^\nu) \to W^\nu(\overline{w}^\nu)$$

is an isomorphism ([66, Ch.IV, Prop.18.8.10]). Since $W^\nu(\overline{w}^\nu)$ is a normal local scheme ([66, Prop.18.8.12(i)]), it follows easily that $W(\overline{w})$ is reduced and irreducible. However, any specialization map is the composition of a localization map, followed by a local ind-étale map of local rings, whence the claim. □

14.8.31. Now, consider a ring homomorphism $A \to B$, with A noetherian. Set $Y := \operatorname{Spec} A$, $X := \operatorname{Spec} B$, and denote by $f : X \to Y$ the associated morphism of affine schemes.

Lemma 14.8.32. *In the situation of* (14.8.31)*, suppose moreover that f is absolutely flat. Then the following conditions are equivalent :*

(a) *B is noetherian.*
(b) *f has finite fibres.*

Proof. Let ξ be any geometric point of X, and x (resp. y) the support of ξ (resp. of $f(\xi)$).

(a)⇒(b): $B(y) := B \otimes_A \kappa(y)$ is a noetherian ind-étale $\kappa(y)$-algebra (proposition 14.8.25), so of dimension ≤ 0, and then $\operatorname{Spec} B(y)$ is a finite set (proposition 8.1.4). Since x is arbitrary, (b) follows.

(b)⇒(a): Let $I \subset B$ be any ideal, and denote by $\mathscr{I}$ the associated quasi-coherent $\mathscr{O}_X$-module. We need to show that $\mathscr{I}$ is an $\mathscr{O}_X$-module of finite type. Since f_ξ is an isomorphism, we may find a commutative diagram of affine schemes

$$\begin{array}{ccc} X' & \xrightarrow{\ g\ } & Y' \\ {\scriptstyle h}\big\downarrow & & \big\downarrow \\ X & \xrightarrow{\ f\ } & Y \end{array}$$

whose left (resp. right) vertical arrow is an étale neighborhood of ξ (resp. of $f(\xi)$), and a quasi-coherent ideal $\mathscr{J} \subset \mathscr{O}_{Y'}$ such that $g^*\mathscr{J} \subset h^*\mathscr{I}$ and such that $(g^*\mathscr{J})_{x'} = (h^*\mathscr{I})_{x'}$ for some $x' \in h^{-1}(x)$ (notice that g is a flat morphism). Set $\mathscr{M} := \mathscr{O}_{Y'}/\mathscr{J}$, let $z' \in X'$ an arbitrary point, and set $y' := g(z')$; in light of corollary 10.4.37, we have

$$z' \in \operatorname{Ass} g^*\mathscr{M} \Leftrightarrow z' \in \operatorname{Ass} g^*\mathscr{M}_{|X'(x')} \Leftrightarrow y' \in \operatorname{Ass} \mathscr{M}_{|Y'(y')} \Leftrightarrow y' \in \operatorname{Ass} \mathscr{M}.$$

In other words, $\operatorname{Ass} g^*\mathscr{M} = g^{-1}\operatorname{Ass} \mathscr{M}$. However, $\operatorname{Ass} \mathscr{M}$ is finite ([126, Th.6.5(i)]), hence the same holds for $\operatorname{Ass} g^*\mathscr{M}$, in view of (b). Now, notice that $\operatorname{Ass} h^*\mathscr{I}/g^*\mathscr{J} \subset \operatorname{Ass} g^*\mathscr{M} \setminus X'(x')$ (proposition 10.5.6(ii)). It follows that there exists an open neighborhood U of x' in X' such that $(h^*\mathscr{I}/g^*\mathscr{J})_{|U} = 0$ (lemma 10.5.5(iii)), *i.e.* $(g^*\mathscr{J})_{|U} = h^*\mathscr{I}_{|U}$; especially, $h^*\mathscr{I}_{|U}$ is an $\mathscr{O}_U$-module of finite type. Since h is an open map, we deduce that $h(U)$ is an open neighborhood of x in X, and $\mathscr{I}_{|h(U)}$ is an $\mathscr{O}_{h(U)}$-module of finite type. Since x is arbitrary, the lemma follows. □

14.8.33. For our second criterion, keep the situation of (14.8.31), and suppose additionally that, for every geometric point ξ of X, the induced morphism $f_\xi : X(\xi) \to Y(\xi)$ is a closed immersion. Under this weaker assumption, it is not necessarily true that conditions (a) and (b) of lemma 14.8.32 are equivalent. For instance, we have :

Example 14.8.34. Take $A := k[X]$, the free polynomial algebra over a given infinite field k; also, let $(a_i \mid i \in \mathbb{N})$ be a sequence of distinct elements of k. We construct an A-algebra B, as the colimit of the inductive system $(B_i \mid i \in \mathbb{N})$ of A-algebras, such that

- $B_i := k[X] \times k^{i+1}$ (the product of $k[x]$ and $i+1$ copies of k, in the category of rings)
- the structure map $A \to B_i$ is the unique map of k-algebras given by the rule : $X \mapsto (X, a_0, \dots, a_i)$
- the transition maps $B_i \to B_{i+1}$ are given by the rule : $X \mapsto (X, 0, \dots, 0, a_{i+1})$ and $(0, e_i) \mapsto (0, e_i, 0)$ for $i = 0, \dots, i$. (Here $e_0, \dots, e_i$ is the standard basis of the k-vector space k^{i+1}.)

Then one can check that $X := \operatorname{Spec} B = \operatorname{Spec} k[X] \cup \mathbb{N}$, and $\mathbb{N}$ is an open subset of X with the discrete topology. Moreover, the induced map $\operatorname{Spec} B \to Y := \operatorname{Spec} A$ restricts to the continuous map $\mathbb{N} \to Y$ given by the rule $i \mapsto \mathfrak{p}_i$, for every $i \in \mathbb{N}$, where $\mathfrak{p}_i$ is the prime ideal generated by $X - a_i$. It follows easily that the condition of (14.8.33) is fulfilled; nevertheless, clearly X has infinitely many maximal points, hence its underlying topological space is not noetherian, and *a fortiori*, B cannot be noetherian.

However, we have the following positive result :

Proposition 14.8.35. *In the situation of* (14.8.33)*, suppose additionally that Y admits a geometrically unibranch stratification. Then the following conditions are equivalent :*

(a) *B is noetherian.*
(b) *The topological space underlying X is noetherian.*
(c) *For every geometric point ξ of X there exist a neighborhood X' of ξ in $X_{\text{ét}}$, an unramified Y-scheme Y', and an absolutely flat morphism $X' \to Y'$ of Y-schemes, with finite fibres.*

Proof. Obviously (a)⇒(b).

(c)⇒(a): Indeed, under assumption (c), we may find finitely many geometric points $\xi_1, \dots, \xi_k$ of X, and for every $i = 1, \dots, k$, a neighborhood X'_i of ξ_i in $X_{\text{ét}}$, and a Y-morphism $X'_i \to Y'_i$ with the stated properties, such that moreover, the family $(X'_i \mid i = 1, \dots, k)$ is an étale covering of X. Furthermore, we may assume that X'_i and Y'_i are affine for every $i \leq k$. In this case, lemma 14.8.32 shows that every X'_i is noetherian, and then the same holds for X.

(b)⇒(c): Fix a geometric point ξ of X, and let B^{sh}_ξ (resp. A^{sh}_ξ) denote the strict henselization of B at ξ (resp. of A at $f(\xi)$); by assumption, we may find a (finitely generated) ideal $I \subset A^{\text{sh}}_\xi$ such that f_ξ induces an isomorphism $A^{\text{sh}}_\xi/I \xrightarrow{\sim} B^{\text{sh}}_\xi$. Then we may find an affine étale neighborhood Y' of $f(\xi)$, say $Y' := \operatorname{Spec} A'$ for some étale A-algebra A', and an ideal $I' \subset A'$ such that $I'A^{\text{sh}}_\xi = I$. Next, we may find an affine étale neighborhood $X' := \operatorname{Spec} B'$ of ξ such that f_ξ extends to a morphism $g : X' \to Y'$, and we may further suppose that the corresponding ring homomorphism $A' \to B'$ factors through A'/I', so g factors through a morphism

$$h : X' \to Z := \operatorname{Spec} A'/I'$$

and the closed immersion $Z \to Y'$. By construction, ξ lifts to a geometric point ξ' of X', and $h_{\xi'} : X'(\xi') \to Z(h(\xi'))$ is an isomorphism ([66, Ch.IV, Prop.18.8.10]). To conclude the proof, it then suffices to exhibit an open subset $U \subset X'$ containing the support of ξ', and such that the restriction $U \to Z$ of h is absolutely flat with finite fibres.

Claim 14.8.36. Let $\varphi : W \to W'$ be a quasi-finite, separated, dominant and finitely presented morphism of reduced, irreducible schemes, and suppose that W' contains a non-empty geometrically unibranch open subset. Then the same holds for W.

Proof of the claim. After replacing W' by some open subset $U' \subset W'$, and W by $\varphi^{-1}U'$, may assume that W' is affine and unibranch; then we may also suppose that φ is finite ([65, Ch.IV, Th.8.12.6]), in which case W is affine as well, and φ is surjective.

Let $\eta \in W$ and $\eta' \in W'$ be the respective generic points, and denote by $E \subset \kappa(\eta)$ the maximal subfield that is separable over $\kappa(\eta')$. We may then find a reduced and irreducible scheme W'', with generic point η'', such that φ factors as the composition of finite surjective morphisms $\varphi' : W \to W''$, $\varphi'' : W'' \to W'$, and such that $\kappa(\eta'') = E$. By virtue of [65, Ch.IV, Th.8.10.5] and [66, Ch.IV, Prop.17.7.8(ii)], we may then replace W' by a non-empty open subset, and assume that φ' is radicial, and φ'' is étale. Then W'' is geometrically unibranch ([64, Ch.IV, Prop.6.15.10]); hence, we may replace W' by W'', and reduce to the case where φ is radicial. Let p be the characteristic of $\kappa(\eta')$; if $p = 0$, φ is birational, in which case the assertion follows from [64, Prop.6.15.5(ii)]. In case $p > 0$, write $W = \mathrm{Spec}\, C$, $W' = \mathrm{Spec}\, C'$; the induced ring homomorphism $C' \to C$ is finite and injective, and we have $C^{p^n} \subset C'$ for $n \in \mathbb{N}$ large enough. Denote by C^ν (resp. C'^ν) the normalization of the domain C (resp. of C'); it follows easily that $(C^\nu)^{p^n} \subset C'^\nu$, so the morphism $\mathrm{Spec}\, C^\nu \to \mathrm{Spec}\, C'^\nu$ is radicial. On the other hand, since W' is geometrically unibranch, the normalization morphism $\mathrm{Spec}\, C'^\nu \to W'$ is radicial ([63, Ch.0, Lemme 23.2.2]) and therefore the normalization map $\mathrm{Spec}\, C^\nu \to W$ is radicial as well ([64, Ch.IV, Lemme 6.15.3.1(i)]). Then W is geometrically unibranch, again by [63, Ch.0, Lemme 23.2.2]. ◊

From claim 14.8.36 and our assumption on Y, it follows easily that Z admits a geometrically unibranch stratification. The morphism h induces as usual a morphism of étale topoi

(14.8.37) $$(X')^{\sim}_{\text{ét}} \underset{h^*}{\overset{h_*}{\rightleftarrows}} Z^{\sim}_{\text{ét}}$$

as well as a morphism $h^\natural : h^* \mathscr{O}_{Z_{\text{ét}}} \to \mathscr{O}_{X'_{\text{ét}}}$ of $(X')^{\sim}_{\text{ét}}$-rings. By construction, for every geometric point τ of X', the induced map on stalks $h^\natural_\tau : \mathscr{O}_{Z_{\text{ét}}, h(\tau)} \to \mathscr{O}_{X'_{\text{ét}}, \tau}$ is surjective, and $h^\natural_{\xi'}$ is a bijection. It follows easily that $h^\natural_\tau$ is also bijective for every generization τ of ξ'. Now, choose a partition $Z = Z_1 \cup \cdots \cup Z_k$ as in lemma 14.8.29 (with $\mathscr{F} := \mathscr{O}_{Z_{\text{ét}}}$), and for given $i \leq k$, suppose that τ and η are two geometric points of $h^{-1} Z_i$, with η a generization of τ. The choice of a strict specialization morphism $X'(\eta) \to X'(\tau)$ yields a commutative diagram

(14.8.38) $$\begin{array}{ccc} \mathscr{O}_{Z_{\text{ét}}, h(\tau)} & \xrightarrow{h^\natural_\tau} & \mathscr{O}_{X'_{\text{ét}}, \tau} \\ \downarrow & & \downarrow \\ \mathscr{O}_{Z_{\text{ét}}, h(\eta)} & \xrightarrow{h^\natural_\eta} & \mathscr{O}_{X'_{\text{ét}}, \eta} \end{array}$$

whose vertical arrows are strict specialization maps (see remark 4.9.26(i)); in light of lemma 14.8.29, we deduce that $h^\natural_\tau$ is injective, whenever the same holds for $h^\natural_\eta$. Now, let $x' \in X'$ be the support of ξ', and Σ_i the set of maximal points of $h^{-1} Z_i$. Condition (b) and proposition 8.1.65 imply that $h^{-1} Z_i$ is a noetherian topological space, hence Σ_i is a finite set; it follows that the topological closure W of $\bigcup_{i=1}^k \Sigma_i \setminus X'(x')$ in X' is a closed subset that does not contain x'; by construction, $h^\natural$ restricts to a monomorphism on $U := X' \setminus W$, *i.e.* the restriction $h_U : U \to Z$ of h is absolutely flat, as required. It also follows that the fibres of h_U are noetherian topological spaces of dimension zero (cp. the proof of lemma 14.8.32), hence they are finite, and the proof is complete. □

Lemma 14.8.39. *Suppose that the valuation of K has finite rank, and let X be a finitely presented K^+-scheme, $\mathscr{F}$ a coherent $\mathscr{O}_{X_{\text{ét}}}$-module. Then there exists a partition*

$$X = X_1 \cup \cdots \cup X_k$$

of X into finitely many disjoint irreducible locally closed subsets, such that the following holds. For every $i = 1, \ldots, k$, every geometric point $\overline{x}$ of X_i, and every generization $\overline{u}$ of $\overline{x}$ in X_i, *every strict specialization map*

$$s_{\overline{x},\overline{u}} : \mathscr{F}_{\overline{x}} \to \mathscr{F}_{\overline{u}}$$

is injective (see (4.9.23)*).*

Proof. We easily reduce to the case where X is affine, say $X = \operatorname{Spec} A$, and then $\mathscr{F}$ is the coherent $\mathscr{O}_{X_{\text{ét}}}$-module arising from a finitely presented A-module M. By theorem 14.8.17(i), M admits a K^+-flattening sequence $(b_0, \dots, b_n)$. Then we are further reduced to showing the assertion for the subquotients $b_i M/b_{i+1}M$ (that are finitely presented, by corollary 14.8.21(ii)). So, we may assume from start that $f : X \to S_0 := \operatorname{Spec} K^+/bK^+$ is a finitely presented morphism for some $b \in K^+$, and $\mathscr{F}$ is f-flat. For every $t \in S_0$, let

$$i_t : X_t := f^{-1}(t) \to X$$

be the locally closed immersion; since X_t is an excellent noetherian scheme, we may apply lemma 14.8.29 and remark 14.8.23 to produce a partition $X_t = X_{t,1} \cup \dots \cup X_{t,k}$ by finitely many disjoint irreducible locally closed subsets such that, for every $i = 1, \dots, k$, every geometric point $\overline{x}$ of $X_{t,i}$ and every generization $\overline{u}$ of $\overline{x}$ in $X_{t,i}$, every specialization map

$$(i_t^* \mathscr{F})_{\overline{x}} \to (i_t^* \mathscr{F})_{\overline{u}}$$

is injective. Since $|S_0|$ is a finite set, the lemma will then follow from :

Claim 14.8.40. Let $g : Y \to T$ be any finitely presented morphism of schemes, $\mathscr{G}$ a finitely presented, quasi-coherent g-flat $\mathscr{O}_Y$-module, and $t \in T$. Let also $\overline{y}, \overline{u}$ be two geometric points of $g^{-1}(t)$, such that $\overline{u}$ is a generization of $\overline{y}$. Let $s_{\overline{y},\overline{u}} : \mathscr{G}_{\overline{y}} \to \mathscr{G}_{\overline{u}}$ be a strict specialization map, and suppose that $s_{\overline{y},\overline{u}} \otimes_{\mathscr{O}_{T,t}} \kappa(t)$ is injective. Then the same holds for $s_{\overline{y},\overline{u}}$.

Proof of the claim. Set $Y' := Y(\overline{y})$, denote by $j : Y' \to Y$ the natural morphism, and set $\mathscr{G}' := j^* \mathscr{G}$. The map $s_{\overline{y},\overline{u}}$ is deduced from a morphism $Y(\overline{u}) \to Y'$ of Y-schemes; the latter factors through a faithfully flat morphism $Y(\overline{u}) \to Y'(u)$, where $u \in Y'$ is the image of the closed point of $Y(\overline{u})$. Hence, $s_{\overline{y},\overline{u}}$ is the composition of the specialization map $s' : \mathscr{G}'_{\overline{y}} \to \mathscr{G}'_u$, and the injective map $\mathscr{G}'_u \to \mathscr{G}'_{\overline{u}}$. Our assumption implies that $s' \otimes_{\mathscr{O}_{T,t}} \kappa(t)$ is injective, and it suffices to show that the same holds for s'. However, Y' is the limit of a cofiltered system $(j_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ of local, essentially étale Y-schemes. Write $\mathscr{G}_\lambda := j_\lambda^* \mathscr{G}$ for every $\lambda \in \Lambda$, and notice that the transition morphisms $Y_\lambda \to Y_\mu$ are faithfully flat, for every $\lambda \geq \mu$; it follows that $\mathscr{G}'_{\overline{y}}$ is the filtered union of the system of modules $(G_\lambda := \Gamma(Y_\lambda, \mathscr{G}_\lambda) \mid \lambda \in \Lambda)$ (proposition 10.1.10(i)); likewise, $\mathscr{G}'_{\overline{y}} \otimes_{\mathscr{O}_{T,t}} \kappa(t)$ is the filtered union of the submodules $(G_\lambda \otimes_{\mathscr{O}_{T,t}} \kappa(t) \mid \lambda \in \Lambda)$. We are then reduced to checking that all the restrictions $s_\lambda : G_\lambda \to \mathscr{G}'_u$ of s' are injective, and we know already that $s_\lambda \otimes_{\mathscr{O}_{T,t}} \kappa(t)$ is injective for every $\lambda \in \Lambda$. For every such λ, let $u_\lambda \in Y_\lambda$ be the image of u; then s_λ factors through the injective map $\mathscr{G}_{\lambda,u_\lambda} \to \mathscr{G}'_u$ and the specialization map $s'_\lambda : G_\lambda \to \mathscr{G}_{\lambda,u_\lambda}$. Consequently, it suffices to show that s'_λ is injective, and we know already that the same holds for $s'_\lambda \otimes_{\mathscr{O}_{T,t}} \kappa(t)$. However, $\mathscr{G}_{\lambda,u_\lambda}$ is a localization $Q_\lambda^{-1} G_\lambda$, for a multiplicative set $Q_\lambda \subset \Gamma(Y_\lambda, \mathscr{O}_{Y_\lambda})$, and s'_λ is the localization map. The claim therefore boils down to the assertion that, for every $\lambda \in \Lambda$ and every $q \in Q_\lambda$, the endomorphism $q \cdot \mathbf{1}_{G_\lambda}$ is injective on G_λ, and our assumption already ensures that $(q \cdot \mathbf{1}_{G_\lambda}) \otimes_{\mathscr{O}_{T,t}} \kappa(t)$ is injective on $G_\lambda \otimes_{\mathscr{O}_{T,t}} \kappa(t)$. However, let $g_\lambda : Y_\lambda \to T$ be the morphism induced by g; by construction, $\mathscr{G}_\lambda$ is a g_λ-flat $\mathscr{O}_{Y_\lambda}$-module, hence the contention follows from [65, Prop.11.3.7]. □

Proposition 14.8.41. *Let* $(K, |\cdot|)$ *be a valued field, and* A *a locally measurable* K^+*-algebra fulfilling conditions* (a) *and* (b) *of theorem* 14.8.17. *The following conditions are equivalent:*

- (c) *For every geometric point* ξ *of* $X := \operatorname{Spec} A$ *there exist a neighborhood* U *of* ξ *in* $X_{\text{ét}}$*, and a finitely presented* K^+*-scheme* Z *with an absolutely flat morphism of* K^+*-schemes* $X' \to Z$.
- (d) Ω_{A/K^+} *is an* A*-module of finite type.*

Proof. (c)⇒(d) follows easily from lemma 14.8.24.

(d)⇒(c): Let $a_1, \dots, a_k \in A$ be a finite system of elements such that $da_1, \dots, da_k$ generate the A-module Ω_{A/K^+}. We define a map of K^+-algebras $A_0 := K^+[T_1, \dots, T_k] \to A$ by the rule: $T_i \mapsto a_i$ for $i = 1, \dots, k$. Clearly $\Omega_{A/A_0} = 0$. Let $Z_0 := \mathrm{Spec}\, A_0$, and denote by $f : X \to Z_0$ the induced morphism of schemes. Let A^{sh}_ξ (resp. $A^{\mathrm{sh}}_{0,\xi}$) be the strict henselization of A at ξ (resp. of A_0 at $f(\xi)$). According to lemma 14.8.27, the induced map $A^{\mathrm{sh}}_{0,\xi} \to A^{\mathrm{sh}}_\xi$ is surjective, and its kernel is a finitely generated ideal $I \subset A^{\mathrm{sh}}_{0,\xi}$. In this situation, we may argue as in the proof of proposition 14.8.35, to produce an affine étale neighborhood X' of ξ, a finitely presented affine unramified Z_0-scheme Z, and a morphism of Z_0-schemes $h : X' \to Z$ such that $h_\tau : X'(\tau) \to Z(h(\tau))$ is a closed immersion for every geometric point τ of X', and $h_{\xi'}$ is an isomorphism for some lifting ξ' of ξ.

Then we consider the associated morphism of étale topoi as in (14.8.37) and the morphism $h^\natural : h^*\mathscr{O}_{Z_{\mathrm{\acute{e}t}}} \to \mathscr{O}_{X'_{\mathrm{\acute{e}t}}}$ of $(X')^\sim_{\mathrm{\acute{e}t}}$-rings. Again, the induced map on stalks $h^\natural_\tau$ is surjective for every geometric point τ of X', and is bijective if τ is a generization of ξ'. We pick a finite partition $Z = Z_1 \cup \dots \cup Z_k$ as in lemma 14.8.39 (for $\mathscr{F} := \mathscr{O}_Z$). For any $i \leq k$, let τ, η be two geometric points of $h^{-1}Z_i$, such that η is a generization of τ; by considering the commutative diagram (14.8.38), we see again that $h^\natural_\tau$ is injective whenever the same holds for $h^\natural_\eta$.

Now, condition (b) of theorem 14.8.17 easily implies that $h^{-1}Z_i$ is a noetherian topological space, hence its set Σ_i of maximal points is finite. Again we let $x' \in X'$ be the support of ξ', and W the topological closure of $\bigcup_{i=1}^k \Sigma_i \setminus X'(x')$ in X', and it is easily seen that the restriction $U \to Z$ of h is absolutely flat, so (c) holds. □

14.8.42. Henceforth we restrict to the case where the value group Γ of K is not discrete and of rank one. As usual, we consider the almost structure attached to the standard setup attached to $(K, |\cdot|)$.

Definition 14.8.43. In the situation of (14.8.42), let A be a K^{+a}-algebra and M an A-module.

(i) We say M is an *almost noetherian* A-module, if every A-submodule of M is almost finitely generated.

(ii) We say that A is an *almost noetherian* K^{+a}-algebra, if A is an almost noetherian A-module.

Remark 14.8.44. (i) In the situation of (14.8.42), suppose that A is an almost noetherian K^{+a}-algebra. Then the same argument as in the "classical limit" case shows that every almost finitely generated A-module M is almost noetherian. The details shall be left to the reader.

(ii) The notion of almost noetherian module goes back to the appendix of Kiehl's article [117]; in our language, he proved in Satz 5.1 that for a rank 1 complete valuation ring V with dense value group, every finitely generated module over a ring of restricted formal series $V\langle X_1, ..., X_n\rangle$ (or more generally, over V-algebras of topologically finite type) is almost noetherian.

Theorem 14.8.45. *Let A be a locally measurable K^+-algebra. Suppose that both $A \otimes_{K^+} \kappa$ and $A \otimes_{K^+} K$ are noetherian rings. Then A^a is an almost noetherian K^{+a}-algebra.*

Proof. If the valuation of K is discrete, the assertion is proposition 14.8.14(iii). Hence, we may assume that the valuation of K is not discrete. Moreover, let $\mathscr{Q}$ be the set of all locally measurable K^+-algebras B that are quotients of A, and such that B^a is not almost noetherian. We have to show that $\mathscr{Q} = \varnothing$. However, for every $B \in \mathscr{Q}$ the κ-algebra $\overline{B} := B \otimes_{K^+} \kappa$ is a quotient of the noetherian κ-algebra $\overline{A} := A \otimes_{K^+} \kappa$; it follows that the set $\overline{\mathscr{Q}} := \{\overline{B} \mid B \in \mathscr{Q}\}$ admits minimal elements, if it is not empty. In the latter case, we may then replace A by any quotient $B \in \mathscr{Q}$ such that $\overline{B}$ is minimal in $\overline{\mathscr{Q}}$, and therefore assume that for every locally measurable quotient B of A, either $\overline{B} = \overline{A}$, or else B^a is almost noetherian.

Let $I \subset A$ be any ideal; we have to show that I^a is almost finitely generated. By assumption, the image $\overline{I}$ of I in $\overline{A}$ is finitely generated, and the same holds for the ideal $I_K := I \otimes_{K^+} K$ of $A_K := A \otimes_{K^+} K$. Thus, we may find a finitely generated subideal $I_0 \subset I$ whose image in $\overline{A}$ agrees with $\overline{I}$, and such that $I_0 \otimes_{K^+} K = I_K$. After replacing A by A/I_0 and I by I/I_0, we are then reduced to the case where both $\overline{I}$ and I_K vanish. Let $J \subset A$ denote the kernel of the localization map $A \to A_K$, set $S := 1 + \mathfrak{m}_K A$, and let $B := S^{-1}A \times A_K$. Clearly B is a faithfully flat A-algebra, and A/J is a K^+-flat A-module; therefore $(A/J) \otimes_A B$ is a K^+-flat B-module of finite type, and since A_K is noetherian, proposition 14.8.14(ii) implies that $(A/J) \otimes_A B$ is finitely presented. Then A/J is finitely presented as well, and therefore J is a finitely generated ideal. We conclude that there exists $c \in \mathfrak{m}_K$ such that $cJ = 0$. Then notice that $J \cap cA = 0$: indeed, if $a \in J \cap cA$, we have $a = cx$ for some $x \in A$, and $ca = 0$, therefore $c^2 x = 0$, so $x \in J$, and consequently $a = cx = 0$. Now, fix $b \in \mathfrak{m}_K$; since the valuation of K has rank one, and since $I \subset J$, it follows that there exists $n \in \mathbb{N}$ large enough, so that

$$I \cap b^n A = 0.$$

Let $i_0 := \max\{i \in \mathbb{N} \mid I \subset b^i A\}$, and set

$$N := b^{i_0}A/(I + b^{i_0+1}A) \qquad N' := b^{i_0}A/b^{i_0+1}A.$$

Let $\varphi : N' \to N$ be the natural surjection, and set $c^*_N := c_N \circ \varphi : N' \to cN$ for every $c \in K^+$ (notation of definition 14.8.6(ii)).

Claim 14.8.46. There exists $c \in K^+$ with $\log |c| < \log |b|$ such that $c^*_N \otimes_{K^+} \kappa$ is not an isomorphism.

Proof of the claim. Suppose that the claim fails; then it is easily seen that no $\gamma \in \log \Gamma^+$ with $\gamma < \log |b|$ breaks N. For every geometric point ξ of $\operatorname{Spec} A$, let A^{sh}_ξ denote the strict henselization of A at ξ; since A^{sh}_ξ is a flat A-algebra, we have a natural identification

$$cN \otimes_A A^{\mathrm{sh}}_\xi = c(N \otimes_A A^{\mathrm{sh}})$$

of A^{sh}-modules; therefore, no $\gamma < \log |b|$ breaks $N \otimes_A A^{\mathrm{sh}}_\xi$. By corollary 14.8.13, we deduce that $N \otimes_A A^{\mathrm{sh}}_\xi$ is a K^+/bK^+-flat and finitely presented A^{sh}_ξ-module, for every geometric point ξ. Hence, $C_\xi := \operatorname{Ker} \varphi \otimes_A A^{\mathrm{sh}}_\xi$ is a finitely generated A^{sh}_ξ-module, and $C_\xi \otimes_{K^+} \kappa = 0$, for every geometric point ξ. By Nakayama's lemma, it follows that $C_\xi = 0$ for every such ξ, so finally $\operatorname{Ker} \varphi = 0$, which means that $I \subset b^{i_0+1}A$, contradicting the choice of i_0. ◊

Let c be as in claim 14.8.46, and set $d := cb^{i_0}$; notice the natural isomorphism of $\overline{A}$-modules

$$cN \otimes_{K^+} \kappa \xrightarrow{\sim} \frac{dA}{I \cap dA} \otimes_{K^+} \kappa.$$

Let $\varphi : A \to dA/(I \cap dA)$ be the composition of $d_A : A \to dA$ and the projection $dA \to dA/(I \cap dA)$ (notation of definition 14.8.6(ii)); by construction, $\varphi \otimes_{K^+} \kappa$ is not an isomorphism, hence there exists $x \in I \cap dA$ such that the composition $\varphi_x : A \to dA/xA$ of d_A and the projection $dA \to dA/xA$ induces a map $\varphi_x \otimes_{K^+} \kappa$ with non-trivial kernel. In other words, dA/xA is a cyclic module over a locally measurable quotient B of A such that the projection $\overline{A} \to \overline{B}$ is not an isomorphism, so B^a is almost noetherian. Set $I_0 := (I \cap dA)/xA$; then I_0 is a submodule of dA/xA, and consequently I^a_0 is an almost finitely generated B^a-module (remark 14.8.44(i)). Then clearly $(I \cap dA)^a$ is an almost finitely generated ideal of A^a. But by construction, $cI \subset I \cap dA$, and b annihilates $(I \cap dA)/cI$. Since b is arbitrary, this easily implies that I^a is almost finitely generated, as required. □

Corollary 14.8.47. *In the situation of theorem* 14.8.45*, the following holds :*

(i) *Every almost finitely generated A^a-module is almost finitely presented.*
(ii) *Every flat almost finitely generated A^a-module is almost projective of finite rank.*

Proof. Assertion (i) is an easy consequence of theorem 14.8.45 and remark 14.8.44(i) : the details shall be left to the reader.

(ii): Let M be a flat and almost finitely generated A^a-module; by (i) and [75, Prop.2.4.18(ii)], M is almost projective. It remains to show that there exists $n \in \mathbb{N}$ such that $\Lambda^n_{A^a} M = 0$, or equivalently, that $(\Lambda^n_A M_!)^a = 0$. However, $M_!$ is a flat A-module, so $\mathrm{Ass}\, M_! \subset \mathrm{Ass}\, A$; in view of theorem 14.8.17(ii), we may argue by induction on the cardinality c of $\mathrm{Ass}\, A$, and it suffices to check that, for every $\mathfrak{p} \in \mathrm{Ass}\, A$ there exists $n \in \mathbb{N}$ such that $\Lambda^n_{A_\mathfrak{p}}(M_!)_\mathfrak{p} = 0$. If $c = 0$, we have $A = 0$, and there is nothing to prove. Suppose that $c > 0$ and the assertion is known for every locally measurable K^+-algebra B such that $B \otimes_{K^+} K$ and $B \otimes_{K^+} \kappa$ are noetherian, and such that $\mathrm{Ass}\, B$ has cardinality $< c$. Especially, for a fixed $\mathfrak{p} \in \mathrm{Ass}\, A$, we can cover $\mathrm{Spec}\, A_\mathfrak{p} \setminus \{\mathfrak{p}\}$ by finitely many affine open subsets $\mathrm{Spec}\, B_1, \dots, \mathrm{Spec}\, B_k$, and then the inductive assumption yields $n \in \mathbb{N}$ such that $\Lambda^n_{B_i}(M_! \otimes_A B_i) = \Lambda^n_{B_i}(M \otimes_{A^a} B_i^a)_! = 0$ for every $i = 1, \dots, k$. In other words, $N := \Lambda^n_{A_\mathfrak{p}}(M_\mathfrak{p})$ is a flat $A^a_\mathfrak{p}$-module with $\mathrm{Supp}\, N_! \subset \{\mathfrak{p}\}$.

Let $A^{\mathrm{sh}}_\mathfrak{p}$ denote the strict henselization of A at some geometric point localized at $\mathfrak{p}$; on the one hand, the $A_\mathfrak{p}$-algebra $A^{\mathrm{sh}}_\mathfrak{p}$ is faithfully flat, and $M_! \otimes_A A^{\mathrm{sh}}_\mathfrak{p} = (M \otimes_{A^a} (A^{\mathrm{sh}}_\mathfrak{p})^a)_!$. On the other hand, exterior powers commute with arbitrary base change; thus, we are reduced to showing :

Claim 14.8.48. Let B be a measurable K^+-algebra, and N a flat almost finitely generated B^a-module whose support is contained in $\{s(B)\}$ (notation of (14.5.36)). Then $\Lambda^n_B N_! = 0$ for every sufficiently large $n \in \mathbb{N}$.

Proof of the claim. By assumption, we may find an essentially finitely presented K^+-algebra B_0 and an ind-étale and faithfully flat map $B_0 \to B$ of K^+-algebras. Set $X_0 := \mathrm{Spec}\, B_0$ and $X := \mathrm{Spec}\, B$; since $\{s(B_0)\}$ is a constructible subset of X_0, the natural map

$$B \otimes_{B_0} \Gamma_{\{s(B_0)\}} \mathscr{O}_{X_0} \to \Gamma_{\{s(B)\}} \mathscr{O}_X$$

is an isomorphism (lemma 10.4.17(iii)). On the other hand, there exists a finitely generated $s(B_0)$-primary ideal $J \subset B_0$ such that the natural map $\Gamma_{\{s(B_0)\}} \mathscr{O}_{X_0} \to B_0/J$ is injective (lemma 10.5.15 and theorem 11.4.37(i)). It follows that the natural map $\Gamma_{\{s(B)\}} \mathscr{O}_X \to B/JB$ is injective as well. Now, $N_!$ can be written as the colimit of a filtered system $(L_\lambda \mid \lambda \in \Lambda)$ of free B-modules of finite rank; for each $\lambda \in \Lambda$, let $L^\sim_\lambda$ be the quasi-coherent $\mathscr{O}_X$-module arising from L_λ, and define likewise $N^\sim_!$; taking into account lemma 10.4.4(iii.b) we deduce that the natural map

$$N_! = \Gamma_{\{s(B)\}} N^\sim_! = \operatorname*{colim}_{\lambda \in \Lambda} \Gamma_{\{s(B)\}} L^\sim_\lambda \to \operatorname*{colim}_{\lambda \in \Lambda} L_\lambda / J L_\lambda = N_!/JN_!$$

is injective. In other words, N is a B^a/JB^a-module. We may then replace B by B/JB, and assume from start that B has Krull dimension zero. In this situation, we may find a nilpotent ideal $I \subset B$, a valuation ring V that is a measurable K^+-algebra, and a finitely presented surjection $V \to B/I$ (lemma 14.5.42). It suffices to find $n \in \mathbb{N}$ such that $(\Lambda^n_B N_!) \otimes_B B/I = 0$; hence, we may replace N by N/IN and B by B/I, and assume as well that $B = V/bV$ for some $b \in V$. In this case, the assertion follows easily from corollary 14.5.33. ☐

15. Continuous valuations and adic spaces

In this chapter we present Huber's theory of adic spaces.

15.1. **Formal schemes.** In this section we define a category of topologically ringed spaces that generalize the usual formal schemes from [59]. This generalization was crucial for the previous releases of this work, that followed closely Faltings's original method for proving the almost purity theorem. In the current release, where we have switched to the new approach invented by Scholze, and based on his theory of perfectoid spaces, formal schemes are still useful, but they play a rather different role : we will employ them to establish some foundational properties of adic spaces (and later, of perfectoid spaces); for such purposes, the standard adic formal schemes of [59] would already suffice, but the generalization that we worked out in the previous releases might be interesting in its own right, and for other applications. Besides, our former treatment included some complements on the cohomology of formal schemes that do not appear explicitly in [61], which will come in handy in section 15.5.

15.1.1. In this section we shall deal with topological rings whose topology is linear, so that $0 \in A$ admits a fundamental system of open neighborhoods $I_\bullet := (I_\lambda \mid \lambda \in \Lambda)$ consisting of ideals of A (see definition 8.3.1(v)). Then the separated completion $A^\wedge$ of A is also a topological ring of this type : namely, its topology is linear, defined by the system $I^\wedge_\bullet := (I^\wedge_\lambda \mid \lambda \in \Lambda)$, where $I^\wedge_\lambda$ denotes the topological closure of I_λ in $A^\wedge$, for every $\lambda \in \Lambda$.

15.1.2. Keep the notation of (15.1.1). We shall consider topological A-modules $(M, \mathscr{T}_M)$ whose topology is A-linear (see definition 8.3.1(iv)); additionally, we shall assume that $\mathscr{T}_M$ *is coarser than the* $I_\bullet$*-adic topology*, *i.e.* for every open submodule $N \subset M$, there exists $\lambda \in \Lambda$ such that $I_\lambda M \subset N$ (see remark 8.3.2(ii)). (Notice that [59, Ch.0, §7.7.1] is slightly ambiguous: it is not clear whether all the topological modules considered there are supposed to satisfy the foregoing additional condition.) Then, the topology of the separated completion $(M^\wedge, \mathscr{T}^\wedge_M)$ is $A^\wedge$-linear and coarser than the $I^\wedge_\bullet$-adic topology. Let N be any other topological A-module of this type; notice that the topology $\mathscr{T}^\otimes_{M,N}$ on $M \otimes_A N$ (see (8.3.7)) is also coarser than the $I_\bullet$-adic topology, so the topology of $M \widehat{\otimes}_A N$ is coarser than the $I^\wedge_\bullet$-adic topology. We also denote

$$\mathrm{top.Hom}_A(M, N)$$

the A-module of all continuous A-linear maps $M \to N$. Notice the natural identification :

$$\mathrm{top.Hom}_A(M, N^\wedge) \simeq \lim_{N' \subset N} \operatorname*{colim}_{M' \subset M} \mathrm{Hom}_A(M/M', N/N') \tag{15.1.3}$$

where N' (resp. M') ranges over the family of open submodules of N (resp. of M).

Definition 15.1.4. Let $X := (\mathscr{X}, J)$ be any site, and $\mathscr{C}$ any other category.

(i) A *sheaf of topological spaces on* X, any sheaf on X with values in the category **Top** of topological spaces (see definition 5.5.1(ii)). Likewise, a *sheaf of topological groups* (resp. *of topological rings*) on X is a sheaf $\mathscr{A}$ on X with values in the category of topological groups (resp. topological rings).

(ii) Let $\mathscr{A}$ be a sheaf of topological rings on X. A *sheaf of topological* $\mathscr{A}$*-modules* – or briefly, a *topological* $\mathscr{A}$*-module* – is the datum of an $\mathscr{A}$-module $\mathscr{F}$, and for every $U \in \mathrm{Ob}(\mathscr{X})$, a topology $\mathscr{T}_U$ on $\mathscr{F}(U)$, such that $\underline{\mathscr{F}}(U) := (\mathscr{F}(U), \mathscr{T}_U)$ is a topological $\mathscr{A}(U)$-module, and the rule $U \mapsto \underline{\mathscr{F}}(U)$ defines a sheaf of topological groups on X.

(iii) An $\mathscr{A}$-linear map $\varphi : \mathscr{F} \to \mathscr{G}$ between topological $\mathscr{A}$-modules is said to be *continuous* if it is a morphism of sheaves of topological groups, *i.e.* if $\varphi_U : \mathscr{F}(U) \to \mathscr{G}(U)$ is a continuous map for every $U \in \mathrm{Ob}(\mathscr{X})$. We denote by :

$$\mathrm{top.Hom}_{\mathscr{A}}(\mathscr{F}, \mathscr{G})$$

the A-module of all continuous $\mathscr{A}$-linear morphisms $\mathscr{F} \to \mathscr{G}$.

Remark 15.1.5. Keep the notation of definition 15.1.4.

(i) Since the forgetful functor **Top** $\to$ **Set** commutes with all limits, remark 5.5.2(i,ii) implies that the presheaf (of sets) underlying any sheaf of topological spaces on X is a sheaf (of sets). Likewise, the presheaf underlying any sheaf of topological groups or topological rings is also a sheaf of sets.

(ii) For any sheaf $\mathscr{A}$ of topological rings on X, and any topological $\mathscr{A}$-modules $\mathscr{F}$ and $\mathscr{G}$, consider the presheaf on X defined by the rule :

$$U \mapsto \mathrm{top.Hom}_{\mathscr{A}_{|U}}(\mathscr{F}_{|U}, \mathscr{G}_{|U}). \tag{15.1.6}$$

From the discussion of remark 5.5.2(v) we deduce that (15.1.6) is a sheaf on X, which we denote by :

$$top.\mathscr{H}om_{\mathscr{A}}(\mathscr{F},\mathscr{G}).$$

15.1.7. In the situation of (15.1.1), set $X_\lambda := \operatorname{Spec} A/I_\lambda$ for every $\lambda \in \Lambda$; we define the *formal spectrum* of A as the colimit of topological spaces :

$$\operatorname{Spf} A := \operatorname*{colim}_{\lambda\in\Lambda} X_\lambda.$$

Hence, the set underlying $\operatorname{Spf} A$ is the filtered union of the X_λ, and a subset $U \subset \operatorname{Spf} A$ is open (resp. closed) in $\operatorname{Spf} A$ if and only if $U \cap X_\lambda$ is open (resp. closed) in X_λ for every $\lambda \in \Lambda$.

Let $I \subset A$ be any open ideal of A; then I contains an ideal I_λ, and therefore $\operatorname{Spec} A/I$ is a closed subset of $\operatorname{Spec} A/I_\lambda$, hence also a closed subset of $\operatorname{Spf} A$.

15.1.8. We endow $\operatorname{Spf} A$ with a sheaf of topological rings as follows. For every $\lambda \in \Lambda$, the structure sheaf $\mathscr{O}_{X_\lambda}$ carries a natural *pseudo-discrete topology* that makes it a sheaf of topological rings (see [59, Ch.0, §3.8]). Let $j_\lambda : X_\lambda \to \operatorname{Spf} A$ be the closed immersion; we set

$$\mathscr{O}_{\operatorname{Spf} A} := \lim_{\lambda\in\Lambda} j_{\lambda *}\mathscr{O}_{X_\lambda}$$

where the limit is taken in the category of sheaves of topological rings ([59, Ch.0, §3.2.6]). By remark 5.5.2(iii), it follows that :

$$\mathscr{O}_{\operatorname{Spf} A}(U) = \lim_{\lambda\in\Lambda} \mathscr{O}_{X_\lambda}(U \cap X_\lambda) \tag{15.1.9}$$

for every open subset $U \subset \operatorname{Spf} A$. In this equality, the right-hand side is endowed with the topology of the (projective) limit, and the identification with the left-hand side is a homeomorphism. Set $X := \operatorname{Spf} A$; directly from the definitions we get natural maps of locally ringed spaces :

$$(X_\lambda, \mathscr{O}_{X_\lambda}) \xrightarrow{j_\lambda} (X, \mathscr{O}_X) \xrightarrow{i_X} (\operatorname{Spec} A^\wedge, \mathscr{O}_{\operatorname{Spec} A^\wedge}) \qquad \text{for every } \lambda \in \Lambda \tag{15.1.10}$$

where $A^\wedge := \mathscr{O}_X(X)$ is the (separated) completion of A, and i_X is given by the universal property [58, Ch.I, Prop.1.6.3] of the spectrum of a ring. Clearly the composition $i_X \circ j_\lambda$ is the map of affine schemes induced by the surjection $A^\wedge \to A/I_\lambda$. Therefore i_X identifies the set underlying X with the subset $\bigcup_{\lambda\in\Lambda} X_\lambda \subset \operatorname{Spec} A^\wedge$. However, the topology of X is usually strictly finer than the subspace topology on the image of i_X. For any $f \in A^\wedge$ we let:

$$\mathfrak{D}(f) := i_X^{-1} D(f)$$

where as usual, $D(f) \subset \operatorname{Spec} A^\wedge$ is the open subset consisting of all prime ideals that do not contain f.

15.1.11. Let $f : A \to B$ be a continuous map of topological rings whose topologies are linear. For every open ideal $J \subset B$, we have an induced map $A/f^{-1}J \to B/J$, and after taking colimits, a natural continuous map of topologically ringed spaces :

$$\operatorname{Spf} f : (\operatorname{Spf} B, \mathscr{O}_{\operatorname{Spf} B}) \to (\operatorname{Spf} A, \mathscr{O}_{\operatorname{Spf} A}).$$

Lemma 15.1.12. *In the situation of* (15.1.11)*, we have :*

(i) $\operatorname{Spf} A$ *is a locally and topologically ringed space.*

(ii) $\varphi := \operatorname{Spf} f : \operatorname{Spf} B \to \operatorname{Spf} A$ *is a morphism of locally and topologically ringed spaces; in particular, the induced map on stalks* $\mathscr{O}_{\operatorname{Spf} A,\varphi(x)} \to \mathscr{O}_{\operatorname{Spf} B,x}$ *is a local ring homomorphism, for every* $x \in \operatorname{Spf} B$.

(iii) *Let* $I \subset A$ *be any open ideal,* $x \in \operatorname{Spec} A/I \subset \operatorname{Spf} A$ *any point. The induced map :*

$$\mathscr{O}_{\operatorname{Spf} A,x} \to \mathscr{O}_{\operatorname{Spec} A/I,x} \tag{15.1.13}$$

is a surjection.

Proof. (i): We need to show that the stalk $\mathscr{O}_{X,x}$ is a local ring, for every $x \in X := \mathrm{Spf}\, A$. Let $(I_\lambda \mid \lambda \in \Lambda)$ be a cofiltered fundamental system of open ideals. Then $x \in X_\mu := \mathrm{Spec}\, A/I_\mu$ for some $\mu \in \Lambda$; let $\kappa(x)$ be the residue field of the stalk $\mathscr{O}_{X_\mu,x}$; there follows a ring homomorphism

$$\mathscr{O}_{X,x} \to (j_{\mu*}\mathscr{O}_{X_\mu})_x = \mathscr{O}_{X_\mu,x} \to \kappa(x). \tag{15.1.14}$$

Moreover, for every $\lambda \geq \mu$, the closed immersion $X_\mu \to X_\lambda$ induces an identification of $\kappa(x)$ with the residue field of $\mathscr{O}_{X_\lambda,x}$, so (15.1.14) is independent of μ.

Suppose now that $g \in \mathscr{O}_{X,x}$ is mapped to a non-zero element in $\kappa(x)$; according to (15.1.9) we may find an open subset $U \subset X$, such that g is represented as a compatible system $(g_\lambda \mid \lambda \geq \mu)$ of sections $g_\lambda \in \mathscr{O}_{X_\lambda}(U \cap X_\lambda)$. For every $\lambda \geq \mu$, let $V_\lambda \subset X_\lambda$ denote the open subset of all $y \in X_\lambda$ such that $g_\lambda(y) \neq 0$ in $\kappa(y)$. Then $V_\eta \cap X_\lambda = V_\lambda$ whenever $\eta \geq \lambda \geq \mu$. It follows that $V := \bigcup_{\lambda \geq \mu} V_\lambda$ is an open subset of X, and clearly g is invertible at every point of V, hence g is invertible in $\mathscr{O}_{X,x}$, which implies the contention.

(ii): The assertion is easily reduced to the corresponding statement for the induced morphisms of schemes : $\mathrm{Spec}\, B/J \to \mathrm{Spec}\, A/f^{-1}J$, for any open ideal $J \subset B$. The details shall be left to the reader.

(iii): Indeed, using (15.1.10) with $X := \mathrm{Spf}\, A$ and $I_\lambda := I$, we see that the natural surjection $\mathscr{O}_{\mathrm{Spec}\, A^\wedge,x} \to \mathscr{O}_{\mathrm{Spec}\, A/I,x}$ factors through (15.1.13). □

15.1.15. Let A and M be as in (15.1.2), and fix a (cofiltered) fundamental system $(M_\lambda \mid \lambda \in \Lambda)$ of open submodules $M_\lambda \subset M$. For every $\lambda \in \Lambda$ we may find an open ideal $I_\lambda \subset A$ such that M/M_λ is an A/I_λ-module. Let $j_\lambda : X_\lambda := \mathrm{Spec}\, A/I_\lambda \to X := \mathrm{Spf}\, A$ be the natural closed immersion (of ringed spaces). We define the topological $\mathscr{O}_X$-module :

$$M^\sim := \lim_{\lambda \in \Lambda} j_{\lambda*}(M/M_\lambda)^\sim$$

where, as usual, $(M/M_\lambda)^\sim$ denotes the quasi-coherent pseudo-discrete $\mathscr{O}_{X_\lambda}$-module associated with M/M_λ, and the limit is formed in the category of sheaves of topological $\mathscr{O}_X$-modules ([59, Ch.0, §3.2.6]). Thus, for every open subset $U \subset X$ one has the identity of topological modules

$$M^\sim(U) = \lim_{\lambda \in \Lambda} (M/M_\lambda)^\sim(U \cap X_\lambda) \tag{15.1.16}$$

that generalizes (15.1.9), and follows likewise from remark 5.5.2(iii).

To proceed beyond these simple generalities, we need to add further assumptions. The following definition covers all the situations that we shall find in the sequel.

Definition 15.1.17. Let A be a topological ring whose topology is linear.

(i) We say that A is *ω-admissible* if A is separated and complete, and $0 \in A$ admits a countable fundamental system of open neighborhoods.
(ii) We say that an open subset $U \subset \mathrm{Spf}\, A$ is *affine* if there exist an ω-admissible topological ring B and an isomorphism $(\mathrm{Spf}\, B, \mathscr{O}_{\mathrm{Spf}\, B}) \xrightarrow{\sim} (U, \mathscr{O}_{\mathrm{Spf}\, A|U})$ of topologically ringed spaces.
(iii) We say that an open subset $U \subset \mathrm{Spf}\, A$ is *truly affine* if $U \cap \mathrm{Spec}\, A/I$ is an affine open subset of $\mathrm{Spec}\, A/I$ for every open ideal $I \subset A$.
(iv) An *affine ω-formal scheme* is a topologically and locally ringed space $(X, \mathscr{O}_X)$ that is isomorphic to the formal spectrum of an ω-admissible topological ring.
(v) An *ω-formal scheme* is a topologically and locally ringed space $(X, \mathscr{O}_X)$ that admits an open covering $X = \bigcup_{i \in I} U_i$ such that, for every $i \in I$, the restriction $(U_i, \mathscr{O}_{X|U_i})$ is an affine ω-formal scheme.
(vi) A *morphism of ω-formal schemes* $f : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ is a map of topologically and locally ringed spaces, *i.e.* a morphism of locally ringed spaces such that the corresponding map $\mathscr{O}_Y \to f_*\mathscr{O}_X$ induces continuous ring homomorphisms $\mathscr{O}_Y(U) \to \mathscr{O}_X(f^{-1}U)$, for every open subset $U \subset Y$.

Remark 15.1.18. (i) Let X be any ω-formal scheme, and $U \subset X$ any open subset. Using the condition of definition 5.5.1(ii), it is easily seen that :

(a) $\mathscr{O}_X(U)$ is a complete and separated topological ring.
(b) If additionally, $U = \bigcup_{i\in I} U_i$ for a countable family $(U_i \mid i \in I)$ of open subsets, such that $(U_i, \mathscr{O}_{X|U_i})$ is an affine ω-formal scheme for every $i \in I$ (briefly, each U_i is an *affine open subset* of X), then $\mathscr{O}_X(U)$ is ω-admissible.

(ii) In [58] one finds a notion of *admissible topological ring*, and to any such ring A it is assigned an affine formal scheme $\mathrm{Spf}\, A$. These notions relate to ours as follows. Let us say that a topological ring is c-admissible if it is admissible in the sense of [58, Ch.0, Déf.7.1.2] and $0 \in A$ admits a countable fundamental system of open neighborhoods. Then, an admissible topological ring A is ω-admissible if and only if it is c-admissible. Likewise, if A is admissible, then the formal scheme $\mathrm{Spf}\, A$ defined in [58, Ch.I, Déf.10.1.2] is an ω-formal scheme if and only if A is c-admissible. Indeed, if A is c-admissible, obviously $\mathrm{Spf}\, A$ coincides with the affine ω-formal scheme attached to A as in (15.1.7) and (15.1.8). For the converse, notice that $\mathrm{Spf}\, A$ (in the sense of [58]) is quasi-compact, so if it is an ω-formal scheme we may cover it by finitely many of its affine open subsets $U_1, \dots, U_n$; say that $U_i = \mathrm{Spf}\, B_i$ for $i = 1, \dots, n$, where $B_1, \dots, B_n$ are ω-admissible. There follows a natural continuous map $\rho : A \to B := \prod_{i=1}^n B_i$, and the topology of A agrees with the topology induced by B via ρ (remark 5.5.2(i)); however, clearly $0 \in B$ admits a countable fundamental system of open neighborhoods, so the same holds for A.

(iii) In the same vein, if A is ω-admissible, then $\mathrm{Spf}\, A$ as defined in (15.1.7) and (15.1.8) is a quasi-compact formal scheme in the sense of [58] if and only if A is c-admissible. Indeed, the condition is obviously sufficient; conversely, if $\mathrm{Spf}\, A$ is a quasi-compact formal scheme in the sense of [58], we may cover it by finitely many open subsets $U_1, \dots, U_n$ such that, for every $i = 1, \dots, n$ we have $U_i = \mathrm{Spf}\, B_i$ for some topological ring that is admissible in the sense of [58], and the topology of A is induced by the natural inclusion map into $B := \prod_{i=1}^n B_i$. For each such B_i, pick an open and nilpotent ideal $I_i \subset B_i$; then $I := \prod_{i=1}^n I_i$ is an open and nilpotent ideal of B, and $I \cap A$ is open and nilpotent in A, so the latter is c-admissible.

Proposition 15.1.19. *Suppose that A is an ω-admissible topological ring. Then :*

(i) *The truly affine open subsets form a basis for the topology of $X := \mathrm{Spf}\, A$.*
(ii) *Let $I \subset A$ be an open ideal, $U \subset X$ a truly affine open subset. Then :*
   (a) *The natural map $\rho_U : A \to A_U := \mathscr{O}_X(U)$ induces an isomorphism :*
$$(\mathrm{Spf}\, A_U, \mathscr{O}_{\mathrm{Spf}\, A_U}) \xrightarrow{\sim} (U, \mathscr{O}_{X|U}).$$
   (b) *The topological closure I_U of IA_U in A_U is an open ideal, and the natural map : $\mathrm{Spec}\, A_U/I_U \to \mathrm{Spec}\, A/I$ is an open immersion.*
   (c) *U is affine.*
   (d) *Every open covering of U admits a countable subcovering.*

Proof. (i): By assumption, we may find a countable fundamental system $(I_n \mid n \in \mathbb{N})$ of open ideals of A, and clearly we may assume that this system is ordered under inclusion (so that $I_n \subset I_m$ whenever $n \geq m$). Let $x \in \mathrm{Spf}\, A$ be any point, and $U \subset \mathrm{Spf}\, A$ an open neighborhood of x. Then $x \in X_n := \mathrm{Spec}\, A/I_n$ for sufficiently large $n \in \mathbb{N}$. We are going to exhibit, by induction on $m \in \mathbb{N}$, a sequence $(f_m \mid m \geq n)$ of elements of A, such that :

$$x \in \mathfrak{D}(f_p) \cap X_m = \mathfrak{D}(f_m) \cap X_m \subset U \qquad \text{whenever } p \geq m \geq n \tag{15.1.20}$$

To start out, we may find $f_n \in A/I_n$ such that $x \in \mathfrak{D}(f_n) \cap X_n \subset U \cap X_n$. Next, let $m \geq n$ and suppose that f_m has already been found; we may write

$$U \cap X_{m+1} = X_{m+1} \setminus V(J) \qquad \text{for some ideal } J \subset A/I_{m+1}.$$

Let $\overline{J} \subset A/I_m$ and $\overline{f}_m \in A/I_m$ be the images of J and f_m; then $V(\overline{J}) \subset V(\overline{f}_m)$, hence there exists $k \in \mathbb{N}$ such that $\overline{f}_m^k \in \overline{J}$. Pick $\overline{f}_{m+1} \in J$ such that the image of $\overline{f}_{m+1}$ in A/I_m agrees with $\overline{f}_m^k$, and let $f_{m+1} \in A$ be any lifting of $\overline{f}_{m+1}$; with this choice, one verifies easily that (15.1.20) holds for $p := m+1$. Finally, the subset :

$$U' := \bigcup_{m \geq n} \mathfrak{D}(f_m) \cap X_m$$

is an admissible affine open neighborhood of x contained in U.

(ii.a): For every $n, m \in \mathbb{N}$ with $n \geq m$, we have a closed immersion of affine schemes: $U \cap X_m \subset U \cap X_n$; whence induced surjections :

$$A_{U,n} := \mathscr{O}_{X_n}(U \cap X_n) \to A_{U,m} := \mathscr{O}_{X_m}(U \cap X_m).$$

By [59, Ch.0, §3.8.1], $A_{U,n}$ is a discrete topological ring, for every $n \in \mathbb{N}$, hence $A_U \simeq \lim_{n \in \mathbb{N}} A_{U,n}$ carries the linear topology that admits the fundamental system of open ideals $(\mathrm{Ker}\,(A_U \to A_{U,n}) \mid n \in \mathbb{N})$, especially A_U is ω-admissible. It follows that the topological space underlying $\mathrm{Spf}\,A_U$ is $\mathrm{colim}_{n \in \mathbb{N}}(U \cap X_n)$, which is naturally identified with U, under $\mathrm{Spf}\,\rho_U$. Likewise, let $i : U \to X$ be the open immersion; one verifies easily (*e.g.* using (15.1.9)) that the natural map :

$$i^* \lim_{n \in \mathbb{N}} j_{n*}\mathscr{O}_{X_n} \to \lim_{n \in \mathbb{N}} i^* j_{n*}\mathscr{O}_{X_n}$$

is an isomorphism of topological sheaves, which implies the assertion.

(ii.b): We may assume that $I_0 = I$. Since $U \cap X_n$ is affine for every $n \in \mathbb{N}$, we deduce short exact sequences :

$$\mathscr{E}_n := (0 \to I \cdot \mathscr{O}_{X_n}(X_n \cap U) \to \mathscr{O}_{X_n}(U \cap X_n) \to \mathscr{O}_{X_0}(U \cap X_0) \to 0)$$

and $\lim_{n \in \mathbb{N}} \mathscr{E}_n$ is the exact sequence :

$$0 \to I_U \to A_U \to \mathscr{O}_{X_0}(U \cap X_0) \to 0.$$

Since $U \cap X_0$ is an open subset of X_0, both assertions follow easily.

(ii.c): It has already been remarked that A_U is ω-admissible. More precisely, for every $n \in \mathbb{N}$ let $(I_n A_U)^c$ be the topological closure of $I_n A_U$ in A_U; then the proof of (ii.b) shows that the family of ideals $((I_n A_U)^c \mid n \in \mathbb{N})$ is a fundamental system of open neighborhoods of $0 \in A_U$. Hence the assertion follows from (ii.a).

(ii.d): By definition, U is a countable union of quasi-compact subsets, so the assertion is immediate. □

Corollary 15.1.21. *Let X be an ω-formal scheme, $U \subset X$ any open subset. Then $(U, \mathscr{O}_{X|U})$ is an ω-formal scheme.* □

Proposition 15.1.22. *Let X be an ω-formal scheme, A an ω-admissible topological ring. Then the rule :*

$$(f : X \to \mathrm{Spf}\,A) \mapsto (f^\natural : A \to \Gamma(X, \mathscr{O}_X)) \qquad (15.1.23)$$

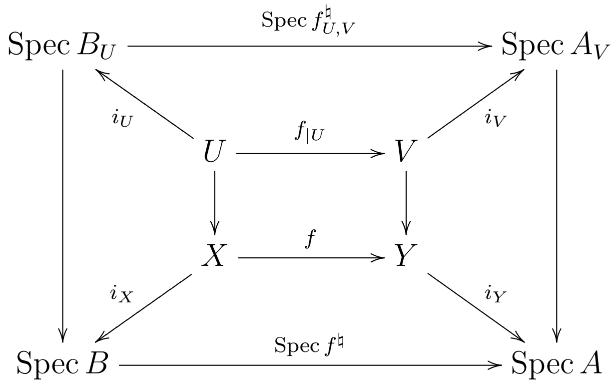
establishes a natural bijection between the set of morphisms of ω-formal schemes $X \to \mathrm{Spf}\,A$ and the set of continuous ring homomorphisms $A \to \Gamma(X, \mathscr{O}_X)$.

Proof. We reduce easily to the case where $X = \mathrm{Spf}\,B$ for some ω-admissible topological ring B. Let $f : X \to Y := \mathrm{Spf}\,A$ be a morphism of ω-formal schemes; we have to show that $f = \mathrm{Spf}\,f^\natural$, where $f^\natural : A \to B$ is the map on global sections induced by the morphism of sheaves $\mathscr{O}_Y \to f^*\mathscr{O}_X$ that defines f. Let $U \subset X$ and $V \subset Y$ be two truly affine open subsets, such that $f(U) \subset V$, and let likewise :

$$f^\natural_{U,V} : A_V := \mathscr{O}_Y(V) \to B_U := \mathscr{O}_X(U)$$

be the map induced by $f_{|U}$. Using the universal property of [58, Ch.I, Prop.1.6.3], we obtain a commutative diagram of morphisms of locally ringed spaces:

(15.1.24)



where i_X, i_Y, i_U and i_V are the morphisms of (15.1.10). Since i_X and i_Y are injective on the underlying sets, it follows already that f and $\mathrm{Spf}\, f^\natural$ induce the same continuous map of topological spaces. Let now $J \subset B$ be any open ideal, $I \subset f^{\natural -1}(J)$ an open ideal of A, and let J_U (resp. I_V) be the topological closure of JB_U in B_U (resp. of IA_V in A_V). Since the map $f^\natural_{U,V}$ is continuous, we derive a commutative diagram of schemes :

$$\begin{array}{ccc} \mathrm{Spec}\, B_U/J_U & \xrightarrow{\varphi} & \mathrm{Spec}\, A_V/I_V \\ {\scriptstyle\alpha}\downarrow & & \downarrow{\scriptstyle\beta} \\ \mathrm{Spec}\, B/J & \xrightarrow{\psi} & \mathrm{Spec}\, A/I \end{array}$$

where α and β are open immersions, by proposition 15.1.19(ii.b), and φ (resp. ψ) is induced by $f^\natural_{U,V}$ (resp. by $f^\natural$). Let $\mathscr{I}$ be a fundamental system of open neighborhoods of $0 \in A$ consisting of ideals, and for every $I \in \mathscr{I}$ denote by $(IA_V)^c$ the topological closure of IA_V in A_V; from proposition 15.1.19(ii.b) (and its proof) it follows as well that $A_V \simeq \lim_{I\in\mathscr{I}} A_V/(IA_V)^c$. Summing up, this shows that $f^\natural_{U,V}$ is determined by $f^\natural$, whence the contention. □

Corollary 15.1.25. *Let A be an ω-admissible topological ring, $U \subset \mathrm{Spf}\, A$ an affine open subset, $V \subset U$ a truly affine open subset of X. Then V is a truly affine open subset of U.*

Proof. Say that $U = \mathrm{Spf}\, B$, for some ω-admissible topological ring B; by proposition 15.1.22, the immersion $j : U \to X$ is of the form $j = \mathrm{Spf}\,\varphi$ for a unique map $\varphi : A \to B$. Let now $J \subset B$ be any open ideal, and set $I := \varphi^{-1}J$; there follows a commutative diagram of locally ringed spaces :

$$\begin{array}{ccc} U_0 := \mathrm{Spec}\, B/J & \longrightarrow & X_0 := \mathrm{Spec}\, A/I \\ \downarrow & & \downarrow \\ U & \xrightarrow{\ j\ } & X. \end{array}$$

By assumption, $V \cap X_0 = \mathrm{Spec}\, C$ for some A/I-algebra C; it follows that :

$$V \cap U_0 = \mathrm{Spec}\, B/J \otimes_{A/I} C$$

and since J is arbitrary, the claim follows. □

Remark 15.1.26. (i) Let A be an ω-admissible topological ring, and B, C two topological A-algebras whose topologies are linear (and the structure maps $A \to B$, $A \to C$ are continuous). Recall that $B \widehat{\otimes}_A C$ represents the product of B and C in the category of ω-admissible A-algebras (see (8.3.7)). By standard arguments, we deduce from proposition 15.1.22 that $\mathrm{Spf}\, B \widehat{\otimes}_A C$ represents the product of $\mathrm{Spf}\, B$ and $\mathrm{Spf}\, C$ in the category of ω-formal $\mathrm{Spf}\, A$-schemes; especially, the category of ω-formal schemes admits arbitrary fibre products.

(ii) We shall say that a topological A-module M is *ω-admissible* if M is complete and separated, and admits a countable fundamental system of open neighborhoods of $0 \in M$. Notice that the completion functor $N \mapsto N^\wedge$ on topological A-modules is not always "right exact", in the following sense. Suppose $N \to N'$ is a quotient map; then the induced map $N^\wedge \to N'^\wedge$ is not necessarily onto. However, this is the case if $N^\wedge$ is ω-admissible (see proposition 8.2.13(v)). For such A-modules, we have moreover the following :

Lemma 15.1.27. *Let A be a topological ring, M, M', N three ω-admissible topological A-modules, and $f : M \to M'$ a quotient map. Then :*

(i) *The homomorphism $f \widehat{\otimes}_A \mathbf{1}_N : M \widehat{\otimes}_A N \to M' \widehat{\otimes}_A N$ is a quotient map.*

(ii) *Let us endow $\mathrm{Ker}\, f$ with the subspace topology induced from M, and suppose additionally that, for every open ideal $I \subset A$:*

(a) *The topological closure $(IN)^c$ of IN in N is an open submodule of N.*

(b) *$N/(IN)^c$ is a flat A/I-module.*

Then the complex :

$$0 \to (\mathrm{Ker}\, f) \widehat{\otimes}_A N \to M \widehat{\otimes}_A N \to M' \widehat{\otimes}_A N \to 0$$

is an admissible short exact sequence of topological $A^\wedge$-modules.

Proof. By assumption, we may find an inverse system of discrete A-modules, with surjective transition maps $(M_n \mid n \in \mathbb{N})$ (resp. $(N_n \mid n \in \mathbb{N})$), and an isomorphism of topological A-modules : $M \simeq \lim_{n\in\mathbb{N}} M_n$ (resp. $N \simeq \lim_{n\in\mathbb{N}} N_n$); let us define $M'_n := M' \amalg_M M_n$ for every $n \in \mathbb{N}$ (the cofibred sum of M' and M_n over M). Since f is a quotient map, M'_n is a discrete A-module for every $n \in \mathbb{N}$, and the natural map : $M' \to \lim_{n\in\mathbb{N}} M'_n$ is a topological isomorphism. We deduce an inverse system of short exact sequences of discrete A-modules :

$$0 \to K_n \to M_n \otimes_A N_n \to M'_n \otimes_A N_n \to 0$$

where K_n is naturally a quotient of $\mathrm{Ker}(M_n \to M'_n) \otimes_A N_n$, for every $n \in \mathbb{N}$; especially, the transition maps $K_j \to K_i$ are surjective whenever $j \geq i$. Then assertion (i) follows from lemma 8.6.2.

(ii): We may find open ideals $I_n \subset A$ such that $I_n N_n = I_n M_n = 0$ for every $n \in \mathbb{N}$, hence $(I_n N)^c \subset \mathrm{Ker}(N \to N_n)$, and from (a) we deduce that $((I_n N)^c \mid n \in \mathbb{N})$ is a fundamental system of open neighborhoods of $0 \in N$. Due to (b), we obtain short exact sequences :

$$0 \to \mathrm{Ker}(M_n \to M'_n) \otimes_A N/(I_n N)^c \to M_n \otimes_A N/(I_n N)^c \to M'_n \otimes_A N/(I_n N)^c \to 0$$

for every $n \in \mathbb{N}$. Then it suffices to invoke again lemma 8.6.2. □

Lemma 15.1.28. *Let A be an ω-admissible topological ring, M a topological A-module, and $U \subset X := \mathrm{Spf}\, A$ any affine open subset. Then the following holds :*

(i) *There is a natural isomorphism of topological $\mathscr{O}_X(U)$-modules :*

$$M^\sim(U) \simeq M \widehat{\otimes}_A \mathscr{O}_X(U).$$

(ii) *If L is any other topological A-module, the natural map :*

$$\mathrm{top.Hom}_A(L, M^\wedge) \to \mathrm{top.Hom}_{\mathscr{O}_X}(L^\sim, M^\sim) \quad \varphi \mapsto \varphi^\sim$$

is an isomorphism.

(iii) *The functor $M \mapsto M^\sim$ on topological A-modules, is left adjoint to the global sections functor $\mathscr{F} \mapsto \mathscr{F}(X)$, defined on the category of complete and separated topological $\mathscr{O}_X$-modules and continuous maps.*

Proof. (i): First we remark that the assertion holds whenever U is a truly affine open subset of X; the easy verification shall be left to the reader. For a general U, set $M_U := M \widehat{\otimes}_A \mathscr{O}_X(U)$, and denote by $M_U^\sim$ the associated $\mathscr{O}_U$-module. Let $V \subset U$ be any open subset which is truly affine in X; by corollary 15.1.25, V is truly affine in U as well. We deduce natural isomorphisms:

$$M^\sim(V) \simeq M_U \widehat{\otimes}_{\mathscr{O}_X(U)} \mathscr{O}_X(V) \simeq M_U^\sim(V)$$

which – in view of proposition 15.1.19(i) – amount to a natural isomorphism of topological $\mathscr{O}_U$-modules : $(M^\sim)_{|U} \xrightarrow{\sim} M_U^\sim$. Assertion (i) follows easily.

(iii): Given a continuous map $M^\sim \to \mathscr{F}$, we get a map of global sections $M = M^\sim(X) \to \mathscr{F}(X)$. Conversely, suppose $f : M \to \mathscr{F}(X)$ is a given continuous map; let $U \subset X$ be any affine open subset, and $f_U : M \to \mathscr{F}(U)$ the composition of f and the restriction map $\mathscr{F}(X) \to \mathscr{F}(U)$. Then f_U extends first – by linearity – to a map $M \otimes_A \mathscr{O}_X(U) \to \mathscr{F}(U)$, and second – by continuity – to a map $M \widehat{\otimes}_A \mathscr{O}_X(U) \to \mathscr{F}(U)$; the latter, in view of (i), is the same as a map $f_U^\sim : M^\sim(U) \to \mathscr{F}(U)$. Clearly the rule $U \mapsto f_U^\sim$ thus defined is functorial for inclusion of open subsets $U \subset U'$, whence (iii).

(ii) is a straightforward consequence of (iii). □

Proposition 15.1.29. *Let A be an ω-admissible topological ring, M an ω-admissible topological A-module, $N \subset M$ a submodule, and $U \subset X := \mathrm{Spf}\, A$ an affine open subset. Then:*

(i) *If we endow M/N with the quotient topology, the sequence of $\mathscr{O}_X$-modules :*

$$0 \to N^\sim \to M^\sim \to (M/N)^\sim \to 0$$

is short exact.

(ii) *The induced sequence*

$$0 \to N^\sim(U) \to M^\sim(U) \to (M/N)^\sim(U) \to 0$$

is short exact and admissible in the sense of (8.6).

Proof. (i): We recall the following :

Claim 15.1.30. Let $j : Z' := \mathrm{Spec}\, R' \to Z := \mathrm{Spec}\, R$ be an open immersion of affine schemes. Then R' is a flat R-algebra.

Proof of the claim. The assertion can be checked on the localizations at the prime ideals of R'; however, the induced maps $\mathscr{O}_{Z,j(z)} \to \mathscr{O}_{Z',z}$ are isomorphisms for every $z \in Z'$, so the claim is clear. ◊

Let $V \subset X$ be any truly affine open subset. It follows easily from proposition 15.1.19(ii.b) and claim 15.1.30 that $\mathscr{O}_X(V)$ fulfills conditions (a) and (b) of lemma 15.1.27(ii). In light of lemma 15.1.28(i), we deduce that the sequence :

$$0 \to N^\sim(V) \to M^\sim(V) \to (M/N)^\sim(V) \to 0$$

is admissible short exact, whence the contention.

(ii): Clearly the sequence is left exact; using lemmata 15.1.27(i) and 15.1.28(i), we see that it is also right exact, and moreover $M^\sim(U) \to (M/N)^\sim(U)$ is a quotient map. It remains only to show that the topology on $N^\sim(U)$ is induced from $M^\sim(U)$, and to this aim we may assume – thanks to the condition of definition 5.5.1(ii) – that U is a truly affine open subset of X, in which case the assertion has already been observed in the proof of (i). □

Definition 15.1.31. Let X be an ω-formal scheme, and $\mathscr{F}$ a topological $\mathscr{O}_X$-module $\mathscr{F}$.

(i) We say that $\mathscr{F}$ is *quasi-coherent* if there exist a covering $\mathfrak{U} := (U_i \mid i \in I)$ of X consisting of affine open subsets, and for every $i \in I$, an ω-admissible topological $\mathscr{O}_X(U_i)$-module M_i with an isomorphism $\mathscr{F}_{|U_i} \xrightarrow{\sim} M_i^\sim$ of topological $\mathscr{O}_{U_i}$-modules (in the sense of definition 15.1.4(ii,iii)).

(ii) We denote by $\mathscr{O}_X\text{-}\mathbf{Mod}_{\mathrm{qcoh}}$ the category of quasi-coherent $\mathscr{O}_X$-modules and continuous $\mathscr{O}_X$-linear morphisms.

(iii) We say that a continuous morphism $f : \mathscr{F} \to \mathscr{G}$ of quasi-coherent $\mathscr{O}_X$-modules is a *quotient map* if the induced map $f(U) : \mathscr{F}(U) \to \mathscr{G}(U)$ is a quotient map of topological $\mathscr{O}_X(U)$-modules, for every affine open subset $U \subset X$.

Remark 15.1.32. (i) The category $\mathscr{O}_X$-$\mathbf{Mod}_{\mathrm{qcoh}}$ is usually not abelian (see (8.6)); more than that, the kernel (in the category of abelian sheaves) of a continuous map $f : \mathscr{F} \to \mathscr{G}$ of quasi-coherent $\mathscr{O}_X$-modules may fail to be quasi-coherent. However, using proposition 15.1.29 one may show that $\mathrm{Ker}\, f$ is quasi-coherent whenever f is a quotient map, and in this case $\mathrm{Ker}\, f$ is also the kernel of f in the category $\mathscr{O}_X$-$\mathbf{Mod}_{\mathrm{qcoh}}$.

(ii) Furthermore, any (continuous) morphism f in $\mathscr{O}_X$-$\mathbf{Mod}_{\mathrm{qcoh}}$ admits a cokernel. This can be exhibited as follows. To start out, let us define presheaves $\mathscr{I}$ and $\mathscr{L}$ by declaring that $\mathscr{I}(U) \subset \mathscr{G}(U)$ is the topological closure of the $\mathscr{O}_X(U)$-submodule $\mathrm{Im}(f(U) : \mathscr{F}(U) \to \mathscr{G}(U))$, and $\mathscr{L}(U) := \mathscr{G}(U)/\mathscr{I}(U)$, which we endow with its natural quotient topology, for every open subset $U \subset X$. Now, suppose that $V \subset U$ is an inclusion of sufficiently small affine open subsets of X (so that $\mathscr{F}_{|U}$ and $\mathscr{G}_{|U}$ are of the form $M^\sim$ for some topological $\mathscr{O}_X(U)$-module M); since $\mathscr{F}(U)\widehat{\otimes}_{\mathscr{O}_X(U)}\mathscr{O}_X(V) = \mathscr{F}(V)$, we see that the image of $\mathscr{I}(U)$ in $\mathscr{I}(V)$ generates a dense $\mathscr{O}_X(V)$-submodule. On the other hand, by construction the exact sequence $\mathscr{E} := (0 \to \mathscr{I}(U) \to \mathscr{G}(U) \to \mathscr{L}(U) \to 0)$ is admissible, hence the same holds for the sequence $\mathscr{E}\widehat{\otimes}_{\mathscr{O}_X(U)}\mathscr{O}_X(V)$ (lemma 15.1.28(i) and proposition 15.1.29(ii)). It follows that $\mathscr{I}(V) = \mathscr{I}(U)\widehat{\otimes}_{\mathscr{O}_X(U)}\mathscr{O}_X(V)$ and $\mathscr{L}(V) = \mathscr{L}(U)\widehat{\otimes}_{\mathscr{O}_X(U)}\mathscr{O}_X(V)$. Thus $\mathscr{I}$ and $\mathscr{L}$ are sheaves of topological $\mathscr{O}_X$-modules on the site C of all sufficiently small affine open subsets of X, and their sheafifications $\mathscr{I}'$ and $\mathscr{L}'$ are the topological $\mathscr{O}_X$-modules obtained as in [59, Ch.0, §3.2.1], by extension of $\mathscr{I}$ and $\mathscr{L}$ from the site C to the whole topology of X. It follow that $\mathscr{I}'$ and $\mathscr{L}'$ are quasi-coherent $\mathscr{O}_X$-modules; then it is easy to check that $\mathscr{L}'$ is the cokernel of f in the category $\mathscr{O}_X$-$\mathbf{Mod}_{\mathrm{qcoh}}$ (briefly : the *topological cokernel of* f), and shall be denoted

$$\mathrm{top.Coker}\, f.$$

The sheaf $\mathscr{I}'$ shall be called *the topological closure of the image of* f, and denoted

$$\overline{\mathrm{Im}}(f).$$

A morphism f with $\mathrm{top.Coker}\, f = 0$ shall be called a *topological epimorphism.*

(iii) Notice also that the natural map $\mathrm{Coker}\, f \to \mathrm{top.Coker}\, f$ is an epimorphism of abelian sheaves, hence a continuous morphism of quasi-coherent $\mathscr{O}_X$-modules which is an epimorphism of $\mathscr{O}_X$-modules, is also a topological epimorphism.

Proposition 15.1.33. *Let X be an affine ω-formal scheme, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module. Then $\mathscr{F}(X)$ is an ω-admissible $\mathscr{O}_X(X)$-module, and the natural map*

$$\mathscr{F}(X)^\sim \to \mathscr{F}$$

is an isomorphism of topological $\mathscr{O}_X$-modules.

Proof. By assumption we may find an affine open covering $\mathfrak{U} := (U_i \mid i \in I)$ of X such that, for every $i \in I$, $\mathscr{F}_{|U_i} \simeq M_i^\sim$ for some $\mathscr{O}_X(U_i)$-module M_i. In view of lemma 15.1.28(i) we may assume – up to replacing $\mathfrak{U}$ by a refinement – that U_i is a truly affine subset of X for every $i \in I$. Furthermore, we may write $X = \bigcup_{n\in\mathbb{N}} X_n$ for an increasing countable family of quasi-compact subsets; for each $n \in \mathbb{N}$ we may then find a finite subset $I(n) \subset I$ such that $X_n \subset \bigcup_{i\in I(n)} U_i$, and therefore we may replace I by $\bigcup_{n\in\mathbb{N}} I_n$, which allows to assume that I is countable.

Next, for every $i \in I$ we may find a countable fundamental system of open submodules $(M_{i,n} \mid n \in \mathbb{N})$ of M_i, and for every $n \in \mathbb{N}$ an open ideal $J_{i,n} \subset A_i := \mathscr{O}_X(U_i)$ such that $N_{i,n} := M_i/M_{i,n}$ is an $A_i/J_{i,n}$-module. Let $j_{i,n} : U_{i,n} := \mathrm{Spec}\, A_i/J_{i,n} \to U_i$ be the natural closed immersion; we may write :

$$\mathscr{F}_{|U_i} \simeq \lim_{n\in\mathbb{N}} j_{i,n*}N_{i,n}^\sim. \qquad (15.1.34)$$

Let also $\iota_{i,n} : U_{i,n} \to X$ be the locally closed immersion obtained as the composition of $j_{i,n}$ and the open immersion $j_i : U_i \to X$; we deduce natural maps of $\mathscr{O}_X$-modules :

$$\varphi_{i,n} : \mathscr{F} \to j_{i*}\mathscr{F}_{|U_i} \to \mathscr{G}_{i,n} := \iota_{i,n*}N^{\sim}_{i,n}.$$

Claim 15.1.35. (i) There exists $m \in \mathbb{N}$ such that $\mathscr{G}_{i,n}$ is the extension by zero of a quasi-coherent $\mathscr{O}_{X_m}$-module.

(ii) $\varphi_{i,n}$ is continuous for the pseudo-discrete topology on $\mathscr{G}_{i,n}$.

Proof of the claim. (i): It is easy to see that $U_{i,n} \subset X_m$ for $m \in \mathbb{N}$ large enough; then the assertion follows from ([59, Ch.I, Cor.9.2.2]).

(ii): We need to check that the map $\varphi_{i,n,V} : \mathscr{F}(V) \to \mathscr{G}_{i,n}(V)$ is continuous for every open subset $V \subset X$. However, the condition of definition 5.5.1(ii) implies that the assertion is local on X, hence we may assume that V is a truly affine open subset of X, in which case $\mathscr{G}_{i,n}(V)$ is a discrete space. We may factor $\varphi_{i,n,V}$ as a composition :

$$\mathscr{F}(V) \xrightarrow{\alpha} \mathscr{F}(V \cap U_i) \xrightarrow{\beta} N^{\sim}_{i,n}(U_{i,n} \cap V)$$

where the restriction map α is continuous, and β is continuous for the pseudo-discrete topology on $N^{\sim}_{i,n}(U_{i,n} \cap V)$. However, $U_i \cap V$ is a truly affine open subset of U_i; therefore $U_{i,n} \cap V$ is quasi-compact, and the pseudo-discrete topology on $N^{\sim}_{i,n}$ induces the discrete topology on $N^{\sim}_{i,n}(U_{i,n} \cap V)$. The claim follows. ◊

For every finite subset $S \subset I \times \mathbb{N}$, let $\varphi_S : \mathscr{F} \to \mathscr{G}_S := \prod_{(i,n)\in S} \mathscr{G}_{i,n}$ be the product of the maps $\varphi_{i,n}$; according to claim 15.1.35(ii), φ_S is continuous for the pseudo-discrete topology on $\mathscr{G}_S$. Hence, for every $i \in I$, the restriction $\varphi_{S|U_i} : \mathscr{F}_{|U_i} \to \mathscr{G}_{S|U_i}$ is of the form $f^{\sim}_{i,S}$, for some continuous map $f_{i,S} : M_i \to \mathscr{G}_S(U_i)$ (lemma 15.1.28(ii)). It follows easily that $(\mathrm{Im}\,\varphi_S)_{|U_i}$ is the quasi-coherent $\mathscr{O}_{U_i}$-module $(\mathrm{Im}\, f_{i,S})^{\sim}$, especially $\mathrm{Im}\,\varphi_S$ is quasi-coherent. Notice that $\mathscr{G}_S$ is already a quasi-coherent $\mathscr{O}_{X_m}$-module for $m \in \mathbb{N}$ large enough, hence the same holds for $\mathrm{Im}\,\varphi_S$; we may therefore find an $\mathscr{O}_{X_m}(X_m)$-module G_S such that $G^{\sim}_S \simeq \mathrm{Im}\,\varphi_S$. Furthermore, for every other finite subset $S' \subset I \times \mathbb{N}$ containing S, we deduce a natural $\mathscr{O}_X(X)$-linear surjection $G_{S'} \to G_S$, compatible with compositions of inclusions $S \subset S' \subset S''$. Let $(S_n \mid n \in \mathbb{N})$ be a countable increasing family of finite subsets, whose union is $I \times \mathbb{N}$; we endow $G := \lim_{n\in\mathbb{N}} G_{S_n}$ with the pro-discrete topology. It is then easy to check that G is an ω-admissible $\mathscr{O}_X(X)$-module; furthermore, by construction we get a unique continuous map $\varphi : \mathscr{F} \to G^{\sim}$ whose composition with the projection onto $G^{\sim}_{S_n}$ agrees with φ_{S_n} for every $n \in \mathbb{N}$. In light of (15.1.34) we see easily that $\varphi_{|U_i}$ is an isomorphism of topological $\mathscr{O}_{U_i}$-modules for every $i \in I$, hence the same holds for φ. Then φ necessarily induces an isomorphism $\mathscr{F}(X) \xrightarrow{\sim} G$. □

Corollary 15.1.36. *Let X be an ω-formal scheme, $(\mathscr{F}_n \mid n \in \mathbb{N})$ an inverse system of quasi-coherent $\mathscr{O}_X$-modules, whose transition maps are topological epimorphisms. Then $\lim_{n\in\mathbb{N}} \mathscr{F}_n$ (with its inverse limit topology) is a quasi-coherent $\mathscr{O}_X$-module.*

Proof. We may assume that X is affine; then, for every $n \in \mathbb{N}$ we have $\mathscr{F}_n = M^{\sim}_n$ for some complete and separated $\mathscr{O}_X(X)$-module M_n (by proposition 15.1.33), and the transition maps $\mathscr{F}_{n+1} \to \mathscr{F}_n$ come from corresponding continuous linear maps $f_n : M_{n+1} \to M_n$. We choose inductively, for every $n \in \mathbb{N}$, a descending fundamental system of open submodules $(N_{n,k} \mid k \in \mathbb{N})$ of M_n, such that $f_n(N_{n+1,k}) \subset N_{n,k}$ for every $n, k \in \mathbb{N}$. Set $M_{n,k} := M_n/N_{n,k}$ for every $n, k \in \mathbb{N}$. By assumption, $\mathrm{top.Coker}\, f^{\sim}_n = 0$; hence the induced maps $M^{\sim}_{n+1,k} \to M^{\sim}_{n,k}$ are topological epimorphisms; since $M^{\sim}_{n,k}$ is pseudo-discrete (on the closure of its support), it follows that the latter maps are even epimorphisms (of abelian sheaves) so the corresponding maps $M_{n+1,k} \to M_{n,k}$ are onto for every $n, k \in \mathbb{N}$. Thus :

$$\lim_{n\in\mathbb{N}} \mathscr{F}_n \simeq \lim_{n\in\mathbb{N}} \lim_{k\in\mathbb{N}} M^{\sim}_{n,k} \simeq \lim_{n\in\mathbb{N}} M^{\sim}_{n,n} \simeq (\lim_{n\in\mathbb{N}} M_{n,n})^{\sim}$$

and it is clear that the $\mathscr{O}_X(X)$-module $\lim_{n\in\mathbb{N}} M_{n,n}$ is ω-admissible. $\square$

Theorem 15.1.37. *Let X be an ω-formal scheme, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module, $\mathfrak{U} := (U_i \mid i \in I)$ an open covering of X, such that the intersection $U_{t_0} \cap \cdots \cap U_{t_n}$ is affine for every $n \in \mathbb{N}$ and every $(t_0, \dots, t_n) \in I^{n+1}$. Then :*

(i) *There is a natural isomorphism (notation of* (10.2.18)*)*

$$H^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}) \xrightarrow{\sim} H^\bullet(X, \mathscr{F}).$$

(ii) *If moreover X is affine, we have $H^i(X, \mathscr{F}) = 0$ for every $i > 0$.*

Proof. (The statements refer to the cohomology of the abelian sheaf underlying $\mathscr{F}$, in other words, we forget the topology of the modules $\mathscr{F}(U)$.)

(ii): Say that $X = \operatorname{Spf} A$ for an ω-admissible topological ring A. Let $U \subset X$ be any truly affine open subset, and $\mathfrak{U} := (U_i \mid i \in I)$ a covering of U consisting of truly affine open subsets. By proposition 15.1.33 we have $\mathscr{F}_{|U} \simeq M^\sim$, where $M := \mathscr{F}(U)$.

Claim 15.1.38. The augmented alternating Čech complex $C^\bullet_{\mathrm{alt}}(\mathfrak{U}, M^\sim)$ is acyclic.

Proof of the claim. Let $(M_n \mid n \in \mathbb{N})$ be a fundamental system of neighborhoods of $0 \in M$, consisting of open submodules, and for every $n \in \mathbb{N}$, choose an open ideal $I_n \subset A$ such that $I_n M \subset M_n$. Set $X_n := \operatorname{Spec} A/I_n$ and $\mathfrak{U}_n := (U_i \cap X_n \mid i \in I)$ for every $n \in \mathbb{N}$. For every $n \in \mathbb{N}$ we may consider the augmented alternating Čech complex $C^\bullet_{\mathrm{alt}}(\mathfrak{U}_n, (M/M_n)^\sim)$, and in view of (15.1.16) we obtain a natural isomorphism of complexes :

$$C^\bullet_{\mathrm{alt}}(\mathfrak{U}, M^\sim) \xrightarrow{\sim} \lim_{n\in\mathbb{N}} C^\bullet_{\mathrm{alt}}(\mathfrak{U}_n, (M/M_n)^\sim).$$

We may view the double complex $C^\bullet_{\mathrm{alt}}(\mathfrak{U}_\bullet, (M/M_\bullet)^\sim)$ also as a complex of inverse systems of modules, whose term in degree $i \in \mathbb{N}$ is $C^i_{\mathrm{alt}}(\mathfrak{U}_\bullet, (M/M_\bullet)^\sim)$. Notice that, for every $i \in \mathbb{N}$, all the transition maps of this latter inverse system are surjective. Hence ([163, Lemma 3.5.3]) :

$$\lim_{n\in\mathbb{N}}{}^q\, C^i_{\mathrm{alt}}(\mathfrak{U}_n, (M/M_n)^\sim) = 0 \qquad \text{for every } q > 0.$$

In other words, these inverse systems are acyclic for the inverse limit functor. It follows (*e.g.* by means of [163, Th.10.5.9]) that :

$$R\lim_{n\in\mathbb{N}} C^\bullet_{\mathrm{alt}}(\mathfrak{U}_\bullet, (M/M_\bullet)^\sim) \simeq C^\bullet_{\mathrm{alt}}(\mathfrak{U}, M^\sim).$$

On the other hand, the complexes $C^\bullet_{\mathrm{alt}}(\mathfrak{U}_n, (M/M_n)^\sim)$ are acyclic for every $n \in \mathbb{N}$ ([61, Ch.III, Th.1.3.1 and Prop.1.4.1]), hence $C^\bullet_{\mathrm{alt}}(\mathfrak{U}_\bullet, (M/M_\bullet)^\sim)$ is acyclic, when viewed as a cochain complex of inverse systems of modules. The claim follows. $\diamondsuit$

Assertion (ii) follows from claim 15.1.38, proposition 15.1.19(i) and theorem 10.2.24(i).
Assertion (i) follows from (ii) and corollary 10.2.21(ii). $\square$

Corollary 15.1.39. *In the situation of* (15.1.15)*, suppose that A and M are ω-admissible. Then:*

$$\lim_{\lambda\in\Lambda}{}^q\, j_{\lambda *}(M/M_\lambda)^\sim = 0 \qquad \textit{for every } q > 0.$$

Proof. For every truly affine open subset $U \subset X$, we have a topos U^Λ defined as in [75, §7.3.4], and the cofiltered system $\mathscr{M} := (j_{\lambda *}(M/M_\lambda)^\sim \mid \lambda \in \Lambda)$ defines an abelian sheaf on U^Λ. According to *loc.cit.* there are two spectral sequences :

$$E_2^{pq} := R^p\Gamma(U, \lim_{\lambda\in\Lambda}{}^q\, j_{\lambda *}(M/M_\lambda)^\sim) \Rightarrow H^{p+q}(U^\Lambda, \mathscr{M})$$

$$F_2^{pq} := \lim_{\lambda\in\Lambda}{}^q\, R^p\Gamma(U, j_{\lambda *}(M/M_\lambda)^\sim) \Rightarrow H^{p+q}(U^\Lambda, \mathscr{M})$$

and we notice that $F_2^{pq} = 0$ whenever $p > 0$ (since $U \cap X_\lambda$ is affine for every $\lambda \in \Lambda$) and whenever $q > 0$, since the cofiltered system $(\Gamma(U, j_{\lambda *}(M/M_\lambda)^\sim) \mid \lambda \in \Lambda)$ has surjective transition maps. One can then argue as in the proof of [75, Lemma 7.3.5] : the sheaf $L^q := \lim^q_{\lambda \in \Lambda} j_{\lambda *}(M/M_\lambda)^\sim$ is the sheafification of the presheaf : $U \mapsto H^q(U^\Lambda, \mathscr{M})$ and the latter vanishes by the foregoing. We supply an alternative argument. Since the truly affine open subsets form a basis of X, it suffices to show that $E_2^{0q} = 0$ whenever $q > 0$. We proceed by induction on q. For $q = 1$, we look at the differential $d_2^{01} : E_2^{0,1} \to E_2^{2,0}$; by theorem 15.1.37 we have $E_2^{2,0} = 0$, hence $E_2^{0,1} = E_\infty^{0,1}$, and the latter vanishes by the foregoing. Next, suppose that $q > 1$, and that we have shown the vanishing of L^j for $1 \leq j < q$. It follows that $E_2^{pj} = 0$ whenever $1 \leq j < q$, hence $E_r^{pj} = 0$ for every $r \geq 2$ and the same values of j. Consequently :

$$0 = E_\infty^{0q} \simeq \mathrm{Ker}(d_{q+1}^{0q} : E_2^{0q} = E_{q+1}^{0q} \to E_{q+1}^{q+1,0}).$$

However, theorem 15.1.37 implies that $E_r^{p0} = 0$ whenever $p > 0$ and $r \geq 2$, therefore $E_2^{0q} = E_\infty^{0q}$, *i.e.* $E_2^{0q} = 0$, which completes the inductive step. □

15.1.40. Let X be an ω-formal scheme, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module. For every affine open subset $U \subset X$, we let $\mathrm{Cl}_\mathscr{F}(U)$ be the set consisting of all closed $\mathscr{O}_X(U)$-submodules of $\mathscr{F}(U)$. It follows from proposition 15.1.29(ii) that the rule

$$U \mapsto \mathrm{Cl}_\mathscr{F}(U)$$

defines a presheaf on the site of all affine open subsets of X. Namely, for an inclusion $U' \subset U$ of affine open subsets, the restriction map $\mathrm{Cl}_\mathscr{F}(U) \to \mathrm{Cl}_\mathscr{F}(U')$ assigns to $N \subset \mathscr{F}(U)$ the submodule $N^\sim(U') \subset \mathscr{F}(U')$ (here $N^\sim$ is a quasi-coherent $\mathscr{O}_U$-module).

Proposition 15.1.41. *With the notation of* (15.1.40)*, the presheaf* $\mathrm{Cl}_\mathscr{F}$ *is a sheaf on the site of affine open subsets of* X.

Proof. Let $U \subset X$ be an affine open subset, and $U = \bigcup_{i \in I} U_i$ a covering of U by affine open subsets $U_i \subset X$. For every $i, j \in I$ we let $U_{ij} := U_i \cap U_j$. Suppose there is given, for every $i \in I$, a closed $\mathscr{O}_X(U_i)$-submodule $N_i \subset \mathscr{F}(U_i)$, with the property that :

$$N_{ij} := N_i^\sim(U_{ij}) = N_j^\sim(U_{ij}) \qquad \text{for every } i, j \in I$$

(an equality of topological $\mathscr{O}_X(U_{ij})$-submodules of $\mathscr{F}(U_{ij})$). Then $(N_i^\sim)_{|U_{ij}} = (N_j^\sim)_{|U_{ij}}$, by proposition 15.1.33, hence there exist a quasi-coherent $\mathscr{O}_U$-module $\mathscr{N}$, and isomorphisms $\mathscr{N}_{|U_i} \xrightarrow{\sim} N_i^\sim$, for every $i \in I$, such that the induced $\mathscr{O}_{U_i}$-linear maps $N_i^\sim \to \mathscr{F}_{|U_i}$ assemble into a continuous $\mathscr{O}_U$-linear morphism $\varphi : \mathscr{N} \to \mathscr{F}_{|U}$. By construction, we have a commutative diagram of continuous maps with exact rows :

$$\begin{array}{ccccccc}
0 \longrightarrow & \mathscr{N}(U) & \xrightarrow{\rho_\mathscr{N}} & \prod_{i \in I} N_i & \longrightarrow & \prod_{i,j \in I} N_{ij} \\
& \downarrow & & \downarrow & & \downarrow \\
0 \longrightarrow & \mathscr{F}(U) & \xrightarrow{\rho_\mathscr{F}} & \prod_{i \in I} \mathscr{F}(U_i) & \longrightarrow & \prod_{i,j \in I} \mathscr{F}(U_{ij})
\end{array}$$

where the central vertical arrow is a closed immersion. However, the condition of definition 5.5.1(ii) implies that both $\rho_\mathscr{N}$ and $\rho_\mathscr{F}$ are admissible monomorphisms (in the sense of (8.6)), and moreover the image of $\rho_\mathscr{N}$ is a closed submodule, since each N_{ij} is a separated module. Hence also the left-most vertical arrow is a closed immersion, and the assertion follows. □

Definition 15.1.42. Let $f : X \to Y$ be a morphism of ω-formal schemes. We say that f is *affine* (resp. a *closed immersion*) if there exists a covering $Y = \bigcup_{i \in I} U_i$ by affine open subsets, such that for every $i \in I$, the open subset $f^{-1}U_i \subset X$ is an affine ω-formal scheme (resp. is isomorphic, as a U_i-scheme, to an ω-formal scheme of the form $\mathrm{Spf}\, A_i/J_i$, where $A_i := \mathscr{O}_Y(U_i)$ and $J_i \subset A_i$ is a closed ideal).

Corollary 15.1.43. *Let $f : X \to Y$ be a morphism of ω-formal schemes. The following conditions are equivalent :*

(i) *f is an affine morphism (resp. a closed immersion).*
(ii) *For every affine open subset $U \subset Y$, the preimage $f^{-1}U$ is an affine ω-formal scheme (resp. is isomorphic, as a U-scheme, to the ω-formal scheme $\mathrm{Spf}\, A/J$, where $A := \mathscr{O}_Y(U)$, and $J := \mathrm{Ker}(A \to \mathscr{O}_X(f^{-1}U)) \subset A$ is a closed ideal).*

Proof. Of course, it suffices to show that (i)⇒(ii). Hence, suppose that f is an affine morphism, and choose an affine open covering $Y = \bigcup_{i\in I} U_i$ such that $f^{-1}U_i$ is an affine ω-formal scheme for every $i \in I$. We may find an affine open covering $U = \bigcup_{j\in J} V_j$ such that, for every $j \in J$ there exists $i \in I$ with $V_j \subset I_i$; moreover, we may assume that J is countable, by proposition 15.1.19(ii.d). The assumption implies that $f^{-1}V_j$ is affine for every $j \in J$, and then remark 15.1.18(i.b) says that $A := \mathscr{O}_X(f^{-1}U)$ is an ω-admissible topological ring, so there exists a unique morphism $g : f^{-1}U \to \mathrm{Spf}\, A$ such that $g^\natural : A \to \mathscr{O}_X(f^{-1}U)$ is the identity (proposition 15.1.22), and $f_{|f^{-1}U}$ factors as the composition of g and the morphism $h : \mathrm{Spf}\, A \to U$ induced by the natural map $B := \mathscr{O}_Y(U) \to A$. It remains to check that g is an isomorphism. To this aim, it suffices to verify that the restriction $g_{|V_j} : f^{-1}V_j \to h^{-1}V_j$ is an isomorphism for every $j \in J$. However, it is clear that $f_*\mathscr{O}_X$ is a quasi-coherent $\mathscr{O}_Y$-module, whence a natural isomorphism of A-algebras :

$$\mathscr{O}_X(f^{-1}V_j) = f_*\mathscr{O}_X(V_j) \xrightarrow{\sim} A_j := A\widehat{\otimes}_B \mathscr{O}_Y(V_j)$$

(proposition 15.1.33) as well as an isomorphism $f^{-1}V_j \xrightarrow{\sim} \mathrm{Spf}\, A_j$. On the other hand, $h^{-1}V_j = \mathrm{Spf}\, A_j$, and by construction $g_{|V_j}$ is the unique morphism such that $(g_{|V_j})^\natural$ is the identity map of A_j. The assertion follows.

Next, suppose that f is a closed immersion, and choose an affine open covering $Y = \bigcup_{i\in I} U_i$, and closed ideals $J_i \subset A_i := \mathscr{O}_Y(U_i)$ such that we have isomorphisms $f^{-1}U_i \xrightarrow{\sim} \mathrm{Spf}\, A_i/J_i$ for every $i \in I$. Set $U_{ij} := U_i \cap U_j$ for every $i, j \in I$. Clearly, $J_i^\sim(U_{ij}) = J_j^\sim(U_{ij})$ for every $i, j \in I$, hence there exists a unique closed ideal $J \subset A := \mathscr{O}_Y(U)$ such that :

$$J^\sim(U_i) = J_i \qquad \text{for every } i \in I \tag{15.1.44}$$

(proposition 15.1.41). Especially, we have $J\mathscr{O}_Y(U_i) \subset J_i$, whence a unique morphism of U-schemes : $g_i : f^{-1}U_i \to Z := \mathrm{Spf}\, A/J$, for every $i \in I$. The uniqueness of g_i implies in particular that $g_{i|U_{ij}} = g_{j|U_{ij}}$ for every $i, j \in I$, whence a unique morphism $g : f^{-1}U \to Z$ of U-schemes. It remains to verify that g is an isomorphism, and to this aim it suffices to check that the restriction $g^{-1}(U_i \cap Z) \to U_i \cap Z$ is an isomorphism for every $i \in I$. The latter assertion is clear, in view of (15.1.44). □

Corollary 15.1.45. *Let A be an ω-admissible topological ring, $U \subset X := \mathrm{Spf}\, A$ an affine open subset. We have :*

(i) *The following conditions are equivalent :*
  (a) *U is truly affine.*
  (b) *$U \cap \mathrm{Spec}\, A/I$ is quasi-compact, for every open ideal $I \subset A$.*
(ii) *Especially, every quasi-compact affine open subset of X is truly affine.*

Proof. (i): Obviously (i.a)⇒(i.b). Conversely, let $j : Y := \mathrm{Spf}\, A/I \to X$ be the closed immersion, and set $A_U := \mathscr{O}_X(U)$. On the one hand, we have $j_*\mathscr{O}_Y = (A/I)^\sim$; on the other hand, proposition 15.1.29(ii) gives an admissible short exact sequence of topological A_U-modules $0 \to I^\sim(U) \to A_U \to B := (A/I)^\sim(U) \to 0$, and notice that the topology of B is discrete, since U is quasi-compact. Thus, $(Y \cap U, (\mathscr{O}_Y)_{|U}) = \mathrm{Spf}\, B = \mathrm{Spec}\, B$, by corollary 15.1.43(ii).

(ii) is an immediate consequence of (i). □

Remark 15.1.46. (i) Let A be an ω-admissible topological ring. Then $\mathrm{Spf}\, A$ may well contain affine subsets that are not truly affine. As an example, consider the one point compactification $X := \mathbb{N} \cup \{\infty\}$ of the discrete topological space $\mathbb{N}$ (this is the space which induces the discrete topology on its subset $\mathbb{N}$, and such that the open neighborhoods of ∞ are the complements of the finite subsets of $\mathbb{N}$). We choose any field F, which we endow with the discrete topology, and let A be the ring of all continuous functions $X \to F$. We endow A with the discrete topology, in which case $\mathrm{Spf}\, A = \mathrm{Spec}\, A$, and one can exhibit a natural homeomorphism $\mathrm{Spec}\, A \stackrel{\sim}{\to} X$ (exercise for the reader). On the other hand, we have an isomorphism of topological rings :

$$\mathscr{O}_{\mathrm{Spf}\, A}(\mathbb{N}) = \lim_{b \in \mathbb{N}} \mathscr{O}_{\mathrm{Spec}\, A}(\{0, \dots, b\}) \simeq k^{\mathbb{N}}$$

where $k^{\mathbb{N}}$ is endowed with the product topology. A verification that we leave to the reader, shows that the natural injective ring homomorphism $A \to k^{\mathbb{N}}$ induces an isomorphism of ringed spaces

$$\mathrm{Spf}\, k^{\mathbb{N}} \stackrel{\sim}{\to} (\mathbb{N}, \mathscr{O}_{\mathrm{Spf}\, A|\mathbb{N}})$$

hence $\mathbb{N} \subset \mathrm{Spf}\, A$ is an affine subset. However, $\mathbb{N}$ is not an affine subset of $\mathrm{Spec}\, A$, hence $\mathbb{N}$ is not a truly affine open subset of $\mathrm{Spf}\, A$.

(ii) On the other hand, suppose that A is c-admissible, in the sense of remark 15.1.18(ii), and let $U \subset \mathrm{Spf}\, A$ be any open subset. Combining corollary 15.1.45(ii) and remark 15.1.18, we see that U is an affine formal scheme in the sense of [58] if and only if it is an affine and quasi-compact ω-formal scheme, if and only if it is truly affine.

We conclude this section by reviewing briefly a standard method for getting formal schemes out of usual schemes.

15.1.47. Let X be a scheme, $\mathscr{I} \subset \mathscr{O}_X$ a quasi-coherent sheaf of ideals of finite type, and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module. Let also $i : X_0 := \mathrm{Spec}\, \mathscr{O}_X/\mathscr{I} \to X$ be the closed immersion. For every $n \in \mathbb{N}$, set $\mathscr{F}_n := \mathscr{F}/\mathscr{I}^{n+1}\mathscr{F}$; we endow the $i^{-1}\mathscr{O}_X$-module $i^{-1}(\mathscr{F}_n)$ with its pseudo-discrete topology. Following [58, Ch.I, Déf.10.8.2], we define the *completion of $\mathscr{F}$ along X_0*

$$\mathscr{F}^\wedge := \lim_{n \in \mathbb{N}} i^{-1}\mathscr{F}_n$$

where the limit is taken in the category of sheaves of topological abelian groups. Especially, we may consider the completion $\mathscr{O}_{X^\wedge} := \mathscr{O}_X^\wedge$ which is naturally a sheaf of topological rings on X_0, and clearly $\mathscr{F}^\wedge$ is naturally an $\mathscr{O}_{X^\wedge}$-module. For every open subset $U \subset X$, set $U_0 := U \cap X_0$; notice that, if $U \subset U'$ are two such open subsets with $U_0 = U'_0$, then the restriction map $\mathscr{F}_n(U') \to \mathscr{F}_n(U)$ is an isomorphism for every $n \in \mathbb{N}$, since the support of $\mathscr{F}_n$ lies in X_0. There follows a natural identification

$$i^{-1}\mathscr{F}_n(U_0) \stackrel{\sim}{\to} \mathscr{F}_n(U) \qquad \text{for every } n \in \mathbb{N} \text{ and every open subset } U \subset X$$

whence, by virtue of remark 5.5.2(iii) a natural isomorphism of topological groups

$$\mathscr{F}^\wedge(U_0) \stackrel{\sim}{\to} \lim_{n \in \mathbb{N}} \mathscr{F}_n(U) \qquad \text{for every open subset } U \subset X.$$

If moreover U is quasi-compact, then $\mathscr{F}_n(U)$ is a discrete topological group for every $n \in \mathbb{N}$. If U is affine, and $A_U := \mathscr{O}_X(U)$, $I_U := \mathscr{I}(U)$, we have $\mathscr{F}_n(U) = A_U/I_U^n \otimes_{A_U} \mathscr{F}(U)$ for every $n \in \mathbb{N}$, so that

$$\mathscr{F}^\wedge(U_0) = \mathscr{F}(U)^\wedge$$

where $\mathscr{F}(U)^\wedge$ denotes the I_U-adic completion of $\mathscr{F}(U)$. Especially, the ringed space

$$(U_0, (\mathscr{O}_{X^\wedge})_{|U_0})$$

is an affine ω-formal scheme (see definition 15.1.17(iv)), isomorphic to $\mathrm{Spf}\, \mathscr{O}_X(U)^\wedge$. Thus

$$X^\wedge := (X_0, \mathscr{O}_{X^\wedge})$$

is an ω-formal scheme called the *completion of* X *along* X_0, and $\mathscr{F}^\wedge$ is a quasi-coherent $\mathscr{O}_{X^\wedge}$-module (see definition 15.1.31(i)). Furthermore, the system of projections $(i^{-1}\mathscr{F} \to \mathscr{F}_n)$ yields a morphism of $i^{-1}\mathscr{O}_X$-modules

$$i^{-1}\mathscr{F} \to \mathscr{F}^\wedge.$$

Especially, the map $\vartheta : i^{-1}\mathscr{O}_X \to \mathscr{O}_{X^\wedge}$ is a morphism of sheaves of rings, and the pair

$$\pi_X := (i, \vartheta) : X^\wedge \to X$$

is a natural morphism of ringed spaces. By inspecting the proof of lemma 15.1.12(i), we see more precisely that π_X is a morphism of locally ringed spaces.

Remark 15.1.48. In the situation of (15.1.47), let $U \subset X^\wedge$ be any quasi-compact open subset. Then the topology of $\mathscr{F}(U)$ is the linear topology defined by the system of submodules

$$(\Gamma(U, (\mathscr{I}^n\mathscr{F})^\wedge) \mid n \in \mathbb{N}).$$

Indeed, the assertion is clear if U is affine, since in this case the ideal I_U is finitely generated (see remark 8.3.3(ii,iv)). For the general case, let $(U_\lambda \mid \lambda \in \Lambda)$ be a finite affine covering of U, and endow $M := \prod_{\lambda\in\Lambda} \mathscr{F}(U_\lambda)$ with the product topology; according to remark 5.5.2(i), the topology of $\mathscr{F}(U)$ agrees with the topology induced by M via the natural injection $\mathscr{F}(U) \to M$. However, the topology of M is I_U-adic, and we have $\mathscr{F}(U) \cap I_U^n M = \Gamma(U, (\mathscr{I}^n\mathscr{F})^\wedge)$ for every $n \in \mathbb{N}$, whence the contention.

15.1.49. Keep the notation of (15.1.47), and let Y be another scheme, $\mathscr{J} \subset \mathscr{O}_Y$ another quasi-coherent sheaf of ideals, and $f : X \to Y$ a morphism of schemes such that the associated map of sheaves $\mathscr{O}_Y \to f_*\mathscr{O}_X$ restricts to a morphism $\mathscr{J} \to f_*\mathscr{I}$. We may then consider the completion $Y^\wedge$ of Y along $Y_0 := \mathrm{Spec}\mathscr{O}_Y/\mathscr{J}$. Let also $U \subset X$ and $V \subset Y$ be two affine open subsets with $f(U) \subset V$, set $I_U := \mathscr{I}(U) \subset A_U := \mathscr{O}_X(U)$, $J_V := \mathscr{J}(V) \subset B_V := \mathscr{O}_Y(V)$, and endow A_U (resp. B_V) with its I_U-adic (resp. J_V-adic) topology; it follows that the resulting map $B_V \to A_U$ is continuous, and therefore we get an induced morphism

$$f^\wedge_{U,V} : (U_0, (\mathscr{O}_{X^\wedge})_{|U_0}) \to (V_0, (\mathscr{O}_{Y^\wedge})_{|V_0}).$$

If moreover, $U' \subset U$ and $V' \subset V$ is another pair of affine open subsets such that $f(U') \subset V'$, it is clear that $f^\wedge_{U',V'}$ agrees with the restriction of $f^\wedge_{U,V}$. We deduce a well defined morphism of formal schemes

$$f^\wedge : X^\wedge \to Y^\wedge$$

that makes commute the diagram

$$\begin{array}{ccc} X^\wedge & \xrightarrow{f^\wedge} & Y^\wedge \\ {\scriptstyle \pi_X}\downarrow & & \downarrow{\scriptstyle \pi_Y} \\ X & \xrightarrow{f} & Y. \end{array}$$

Especially, if f is an open immersion and $\mathscr{I} = f^{-1}\mathscr{J}$, then clearly $f^\wedge$ is an open immersion.

15.2. **Analytically noetherian rings.**

Definition 15.2.1. Let A be an adic topological ring with a finitely generated ideal I of adic definition.

(i) We say that A is *analytically noetherian* if the following two conditions hold :

  (a) The analytic locus of $\mathrm{Spec}\, A$ is a noetherian scheme (see definition 8.3.28).

  (b) For every finitely generated A-module M, the increasing sequence of submodules

$$(\mathrm{Ann}_M(I^n) \mid n \in \mathbb{N})$$

  is stationary.

(ii) We say that A is *universally analytically noetherian* if, for every $n \in \mathbb{N}$, the polynomial A-algebra $A[X_1, \dots, X_n]$, endowed with its I-adic topology, is analytically noetherian.

(iii) We say that A *satisfies the topological Artin-Rees condition*, if the following holds. For every A-module M of finite type, and every submodule $N \subset M$, the I-adic topology on N agrees with the topology induced by the I-adic topology of M.

(iv) We say that an A-module M is *analytically of finite type*, if there exists a submodule $N \subset M$ of finite type and an integer $n \in \mathbb{N}$ such that $I^n M \subset N$.

Remark 15.2.2. (i) It is easily seen that condition (b) of definition 15.2.1(i) does not depend on the chosen finitely generated ideal I of adic definition of A. Likewise, the class of A-modules of analytically finite type is determined solely by the topology of A.

(ii) Obviously, every noetherian ring is analytically noetherian when endowed with the adic topology defined by any of its ideals.

(iii) Let A be an analytically noetherian ring, and M an A-module of analytically finite type; then the sequence $(\mathrm{Ann}_M(I^k) \mid k \in \mathbb{N})$ is stationary. Indeed, pick a finitely generated submodule $N \subset M$ such that $I^n M \subset N$ for some $n \in \mathbb{N}$; by assumption, there exists $t \in \mathbb{N}$ such that $\mathrm{Ann}_N(I^t) = \mathrm{Ann}_N(I^s)$ for every $s \geq t$. It follows easily that $\mathrm{Ann}_M(I^k) = \mathrm{Ann}_M(I^{t+n})$ for every $k \geq t+n$.

Lemma 15.2.3. *Let A be an adic topological ring that admits a finitely generated ideal I of adic definition. Then we have :*

(i) *The following conditions are equivalent :*
  (a) *A satisfies the topological Artin-Rees condition.*
  (b) *For every A-module M of finite type, every $n \in \mathbb{N}$, and every submodule $N \subset M$ such that $I^n N = 0$, there exists $m \in \mathbb{N}$ such that $N \cap I^m M = 0$.*

(ii) *Suppose that the equivalent conditions of* (i) *hold for A, let M be any A-module of analytically finite type, and $N \subset M$ any submodule. Then the I-adic topology on N agrees with the topology induced by the I-adic topology of M.*

Proof. (i): Clearly (a)⇒(b). Conversely, let M be an A-module of finite type, $N \subset M$ a submodule, and $n \in \mathbb{N}$ any integer. Set $M' := M/I^n N$ and $N' := N/I^n N$; clearly $I^n N' = 0$, so (b) implies that $N' \cap I^m M' = 0$ for some $m \in \mathbb{N}$, and the latter means that $N \cap I^m M \subset I^n N$, whence (a).

(ii): By assumption, there exist $n \in \mathbb{N}$ and a submodule $M' \subset M$ of finite type such that $I^n M \subset M'$; set $N' := M' \cap N$. Then, for every $t \in \mathbb{N}$ there exists $s \in \mathbb{N}$ such that $I^s M' \cap N = I^s M' \cap N' \subset I^t N' \subset I^t N$. We conclude that $I^{s+n} M \cap N \subset I^t N$, whence the assertion. □

Lemma 15.2.4. *Let A be any analytically noetherian (resp. universally analytically noetherian) topological ring, and $I \subset A$ any ideal of adic definition. We have :*

(i) *For every multiplicative subset $S \subset A$, the localization $S^{-1}A$ is analytically noetherian (resp. universally analytically noetherian) for its $S^{-1}I$-adic topology.*

(ii) *Let $f : A \to B$ be a ring homomorphism, and $\mathscr{T}_B$ the IB-adic topology on B. If f is finite (resp. of finite type) Then $(B, \mathscr{T}_B)$ is analytically noetherian (resp. universally analytically noetherian).*

Proof. (i): Suppose that A is analytically noetherian. Clearly the analytic locus of $\mathrm{Spec}\, S^{-1}A$ is noetherian. Next, let M be any $S^{-1}A$-module of finite type; pick a finite system of generators $x_\bullet := (x_1, \dots, x_k)$ for M, and let N be the A-submodule of M generated by $x_\bullet$. Then $S^{-1}N = M$, and $\mathrm{Ann}_M(S^{-1}I^n) = S^{-1}\mathrm{Ann}_N(I^n)$ for every $n \in \mathbb{N}$, whence the assertion. The assertion for the case where A is universally analytically noetherian case follows immediately,

(ii): Again, suppose first that A is analytically noetherian, and f is finite. The analytic locus of $\mathrm{Spec}\, B$ is finite over the analytic locus of $\mathrm{Spec}\, A$, hence it is noetherian. Next, if M is a B-module of finite type, then it is also an A-module of finite type, and $\mathrm{Ann}_M(I^n B) = \mathrm{Ann}_M(I^n)$

for every $n \in \mathbb{N}$, whence the assertion. Lastly, suppose that A is universally analytically noetherian and f is of finite type. For every $n \in \mathbb{N}$, the A-algebra $B[T_1, \dots, T_n]$ is a quotient of a free polynomial A-algebra of finite type, so it is analytically noetherian, by the foregoing case, whence the assertion. □

Proposition 15.2.5. *Let A be a ring, $I, J \subset A$ two finitely generated ideals, and denote by $\mathscr{T}_I$ (resp. $\mathscr{T}_J$, resp. $\mathscr{T}_{I+J}$) the I-adic (resp. J-adic, resp. $(I+J)$-adic) topology on A. We have :*

(i) *If $(A, \mathscr{T}_I)$ is analytically noetherian, and $\mathscr{T}_J$ is finer than $\mathscr{T}_I$, then $(A, \mathscr{T}_J)$ is analytically noetherian.*
(ii) *If $(A, \mathscr{T}_I)$ and $(A, \mathscr{T}_J)$ are analytically noetherian, then the same holds for $(A, \mathscr{T}_{I+J})$.*
(iii) *If $(A, \mathscr{T}_I)$ and $(A, \mathscr{T}_J)$ satisfy the topological Artin-Rees condition, the same holds for $(A, \mathscr{T}_{I+J})$.*

Proof. (i): After replacing J by J^n for a suitable $n \in \mathbb{N}$, we may assume that $J \subset I$, in which case it is clear that the analytic locus $U_I \subset X := \operatorname{Spec} A$ of $(A, \mathscr{T}_I)$ contains the analytic locus U_J of $(A, \mathscr{T}_J)$. Since by assumption U_I is noetherian, the same holds for the scheme U_J. Next, let M be any A-module of finite type, and for every $n \in \mathbb{N}$, denote by $\mathscr{M}_n$ the quasi-coherent $\mathscr{O}_X$-module associated with $M_n := \operatorname{Ann}_M(J^n)$. Since U_I is noetherian, there exists $t \in \mathbb{N}$ such that $\mathscr{M}_{n|U_I} = \mathscr{M}_{t|U_I}$ for every $n \geq t$. Set $M' := M/M_t$, and $M'_n := \operatorname{Ann}_{M'}(J^n)$ for every $n \in \mathbb{N}$. It is easily seen that

$$M'_n = M_{n+t}/M_t \qquad \text{for every } n \in \mathbb{N}. \tag{15.2.6}$$

On the other hand, since $(\mathscr{M}_{n+t}/\mathscr{M}_t)_{|U_I} = 0$ for every $n \in \mathbb{N}$, we get

$$\bigcup_{n\in\mathbb{N}} M'_n = N := \bigcup_{n\in\mathbb{N}} \operatorname{Ann}_{M'}(I^n).$$

By assumption, there exists $s \in \mathbb{N}$ such that $N = \operatorname{Ann}_{M'}(I^s)$, and therefore $N \subset M'_s \subset N$. Combining with (15.2.6) we conclude that $M_n = M_{s+t}$ for every $n \geq s+t$, whence the assertion.

(ii): Let U_I and U_J be as in the foregoing, and define U_{I+J} likewise as the analytic locus of $(A, \mathscr{T}_{I+J})$. Then $U_{I+J} = U_I \cup U_J$; since by assumption U_I and U_J are noetherian, the same then holds for U_{I+J}. Next, let M be as in the foregoing; by assumption, there exists $t \in \mathbb{N}$ such that $\operatorname{Ann}_M(I^n) = \operatorname{Ann}_M(I^t)$ and $\operatorname{Ann}_M(J^n) = \operatorname{Ann}_M(J^t)$ for every $n \geq t$. It then follows easily that $\operatorname{Ann}_M((I+J)^n) = \operatorname{Ann}_M((I+J)^{2t-1})$ for every $n \geq 2t-1$, whence the assertion.

(iii): Let M be any A-module of finite type, $N \subset M$ a submodule such that $(I+J)^n N = 0$ for some $n \in \mathbb{N}$; in light of lemma 15.2.3(i), it suffices to show that there exists $m \in \mathbb{N}$ such that $N \cap (I+J)^m M = 0$. However, again by lemma 15.2.3(i), our assumption on $(A, \mathscr{T}_I)$ implies that $N \cap I^t M = 0$ for some $t \in \mathbb{N}$; set $M' := M/I^t M$ and let $N' \subset M'$ be the image of N. Notice that $J^n N' = 0$; invoking again lemma 15.2.3(i), our assumption on $(A, \mathscr{T}_J)$ implies that $N' \cap J^s M' = 0$ for some $s \in \mathbb{N}$. We conclude that $N \cap (I^t + J^s) M = 0$, and then $m := t+s-1$ will do. □

As a corollary, we get the following weak form of the Artin-Rees lemma :

Corollary 15.2.7. *Let $(A, \mathscr{T})$ be an analytically noetherian topological ring, $\mathbf{f} := (f_1, \dots, f_n)$ a finite sequence of elements of A that generates an ideal of adic definition. We have :*

(i) *A satisfies the topological Artin-Rees condition.*
(ii) *A satisfies condition $(\mathrm{d})_{\mathbf{f}}$ of (7.8.21).*

Proof. For every $i = 1, \dots, n$, let $\mathscr{T}_i$ be the $f_i A$-adic topology on A; by proposition 15.2.5(i), $(A, \mathscr{T}_i)$ is analytically noetherian for every $i = 1, \dots, n$. Taking into account lemma 15.2.4(ii), we see that A fulfills the assumptions of lemma 7.8.44, whence (ii).

Next, if the topological Artin-Rees condition holds for each $(A, \mathscr{T}_i)$, proposition 15.2.5(iii) and a simple induction show that the same holds for $(A, \mathscr{T})$. Thus, we may assume from start that $n = 1$ and A admits a principal ideal $I = fA$ of adic definition.

Now, let M be any A-module of finite type, $N \subset M$ a submodule, and set $M' := M/N$. Pick $t \in \mathbb{N}$ such that $\mathrm{Ann}_{M'}(f^n) = \mathrm{Ann}_{M'}(f^t)$ for every $n \geq t$; it follows easily that

$$N \cap f^{n+t}M = f^n(N \cap f^t M) \qquad \text{for every } n \in \mathbb{N}$$

whence the contention. □

Corollary 15.2.8. *Let A be an analytically noetherian ring, $I \subset A$ a finitely generated ideal of adic definition, and*

$$0 \to M_1 \to M_2 \to M_3 \to 0$$

a short exact sequence of A-modules, which we endow with their I-adic topologies. We have :

(i) *M_2 is analytically of finite type if and only if the same holds for both M_1 and M_3.*

(ii) *Suppose that M_2 is analytically of finite type. Then the induced sequence of separated completions*

$$0 \to M_1^\wedge \to M_2^\wedge \to M_3^\wedge \to 0 \tag{15.2.9}$$

is short exact.

Proof. (i): Suppose that M_2 is analytically of finite type. Then it is easily seen that the same holds for M_3. Next, set $X := \mathrm{Spec}\, A$, so that $U := X \setminus \mathrm{Spec}\, A/I$ is the analytic locus of X. Let also $\mathscr{M}_1$ and $\mathscr{M}_2$ be the quasi-coherent $\mathscr{O}_X$-modules associated with M_1 and respectively M_2. Then $\mathscr{M}_{2|U}$ is a quasi-coherent $\mathscr{O}_U$-module of finite type, and since U is noetherian, the same then holds for its submodule $\mathscr{M}_{1|U}$. Hence, we may find a quasi-coherent $\mathscr{O}_X$-submodule $\mathscr{P} \subset \mathscr{M}_1$ of finite type such that $\mathscr{P}_{|U} = \mathscr{M}_{1|U}$, and we denote by $P \subset M_1$ the submodule corresponding to $\mathscr{P}$. Set $M_1' := M_1/P$ and $M_2' := M_2/P$; by construction, the support of M_1' lies in $\mathrm{Spec}\, A/I$, and since A is analytically noetherian and M_2' is analytically of finite type, it follows that $I^n M_1' = 0$ for some $n \in \mathbb{N}$ (remark 15.2.2(iii)). Thus, $I^n M_1 \subset P$, which shows that M_1 is analytically of finite type.

Lastly, suppose that M_1 and M_3 are analytically of finite type, and pick $n \in \mathbb{N}$ and finitely generated submodules $N_i \subset M_i$ such that $I^n M_i \subset N_i$ for $i = 1, 3$. Then we may find a submodule $P \subset M_2$ of finite type whose image in M_3 equals N_3, and it is easily seen that $I^{2n} M_2 \subset P + N_1$.

(ii): This follows from corollary 15.2.7(i), lemma 15.2.3(ii) and proposition 8.2.13(v). □

Proposition 15.2.10. *Let A and I be as in corollary* 15.2.8*, and M any A-module of analytically finite type. Endow M with its I-adic topology, and denote by $A^\wedge$ and $M^\wedge$ the separated completions of A and M. We have :*

(i) *The natural map $\varphi_M : A^\wedge \otimes_A M \to M^\wedge$ is an isomorphism.*

(ii) *The completion map $A \to A^\wedge$ is flat.*

Proof. (i): We consider first the case where M is of finite type. Pick any surjective A-linear map $\psi : L \to M$, from a finitely presented A-module L, and endow $K := \mathrm{Ker}\, \psi$ with its I-adic topology. We consider the induced commutative diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A^\wedge \otimes_A K & \longrightarrow & A^\wedge \otimes_A L & \longrightarrow & A^\wedge \otimes_A M & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \varphi_K} & & \downarrow{\scriptstyle \varphi_L} & & \downarrow{\scriptstyle \varphi_M} & & \\ 0 & \longrightarrow & K^\wedge & \longrightarrow & L^\wedge & \longrightarrow & M^\wedge & \longrightarrow & 0 \end{array}$$

whose bottom row is short exact, by corollary 15.2.8. If L is free of finite rank, φ_L is an isomorphism; then φ_M is surjective and φ_K is injective. Since we can always find such a surjection φ with L free of finite rank, we conclude already that φ_M is surjective for every finitely generated A-module M.

Next, suppose that M is finitely presented and L is still free of finite rank; in this case, K is an A-module of finite type ([75, Lemma 2.3.18(iii)]), so φ_K is also surjective, by the foregoing, hence φ_K is an isomorphism and therefore the same holds for φ_M.

For a general M of finite type, in view of corollary 15.2.8(i) we may find a submodule $K' \subset K$ of finite type such that $I^n K \subset K'$. Set $L' := L/K'$, and let $\psi' : L' \to M$ be the surjective map induced by ψ; then L' is still finitely presented, so we may replace L by L' and ψ by ψ', and assume from start that the I-adic topology is discrete on K, in which case the completion map $K \to K^\wedge$ is an isomorphism, consequently φ_K is again surjective, and we conclude as in the foregoing that φ_M is an isomorphism, as required.

Lastly, suppose that M is of analytically finite type, and pick a submodule $N \subset M$ of finite type such that $I^n(M/N) = 0$ for some $n \in \mathbb{N}$. We consider the analogous commutative diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A^\wedge \otimes_A N & \longrightarrow & A^\wedge \otimes_A M & \longrightarrow & A^\wedge \otimes_A (M/N) & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \varphi_N} & & \downarrow{\scriptstyle \varphi_M} & & \downarrow{\scriptstyle \varphi_{M/N}} & & \\ 0 & \longrightarrow & N^\wedge & \longrightarrow & M^\wedge & \longrightarrow & (M/N)^\wedge & \longrightarrow & 0 \end{array}$$

and it is easily seen that both $\varphi_{M/N}$ and the completion map $M/N \to (M/N)^\wedge$ are isomorphisms. The same holds for φ_N, by the foregoing, so finally φ_M is an isomorphism.

(ii): Let $N \to M$ be any injective homomorphism of A-modules; we need to check that the induced map $A^\wedge \otimes_A N \to A^\wedge \otimes_A M$ is still injective. Since the tensor product commutes with all colimits, we are easily reduced to the case where M and N are A-modules of finite type. In this case, endow M and N with their I-adic topologies; by corollary 15.2.8, the induced map on I-adic completions $N^\wedge \to M^\wedge$ is injective. Then it suffices to apply (i) to conclude. □

15.2.11. Let $(A, \mathscr{T})$ be a complete and separated adic topological ring that admits a principal ideal $I = Aa$ of adic definition. Let also M be an A-module whose I-adic topology $\mathscr{T}_M$ is complete and separated. For a submodule $N \subset M$ let N^c be the topological closure of N in M, and for every $k \in \mathbb{N}$ denote by $N_k \subset M$ the submodule of all $x \in M$ such that $a^k x \in N$. Set

$$N^s := \bigcup_{k \in \mathbb{N}} N_k.$$

Lemma 15.2.12. *In the situation of* (15.2.11)*, let $N' \subset N \subset M$ be two submodules, such that N' is dense in N (for the topology $\mathscr{T}_M$) and $N = N^s$. The following holds :*

(i) *The I-adic topology on N agrees with the topology induced by $\mathscr{T}_M$.*
(ii) $N^c = (N^c)^s$.
(iii) *If $N = N^c$ as well, and $N[a^{-1}]$ is an $A[a^{-1}]$-module of finite type, then N is analytically of finite type, and $N' = N$.*

Proof. (i): Since $N = N^s$ we have $a^m N = a^m M \cap N$ for every $m \in \mathbb{N}$, whence the assertion.

(ii): If $x \in M$ and $ax \in N^c$, then for every $n \in \mathbb{N}$ there exists $z_n \in M$ such that $ax - a^n z_n \in N$, and therefore $x - a^{n-1} z_n \in N$ for every $n \geq 1$, whence $x \in N^c$.

(iii): By assumption, there exists a finitely generated submodule $L \subset N$ with

$$N = L^s = \bigcup_{k \in \mathbb{N}} (L_k)^c$$

(indeed, the first identity holds if we choose L such that $N[a^{-1}] = L[a^{-1}]$, and the second follows, since $N = N^c$). Notice next that we may regard M as a complete metric space, with the metric defined by the rule

$$d(x,y) := \begin{cases} 0 & \text{if } x = y \\ 2^{-b} & \text{if } x \neq y \text{, where } b := \max(n \in \mathbb{N} \mid x - y \in a^n M). \end{cases}$$

By Baire's category theorem ([41, Ch.IX, §5, n.3, Th.1]), it follows that $(L_k)^c$ is open in N for some $k \in \mathbb{N}$ (for the topology of N induced by $\mathscr{T}_M$), and therefore it contains $a^m N$ for some $m \in \mathbb{N}$; thus $a^{k+m}N \subset a^k(L_k)^c \subset L^c$. Combining with (i) we deduce that the I-adic topology of L^c agrees with the topology induced by $\mathscr{T}_M$; then by lemma 8.3.22(i) we conclude that $L = L^c$, so $a^{k+m}N \subset L$, which shows that N is analytically of finite type.

Lastly, since N' is dense in N, from (i) we see that $N = N' + a^{m+k+1}N \subset N' + aL$. It follows that $L = (N' \cap L) + aL$, and by Nakayama's lemma we get $L = N' \cap L$, *i.e.* $L \subset N'$, so N' is open in N and thus $N = N'$. □

Theorem 15.2.13. *Let $(A, \mathscr{T})$ be a complete and separated adic topological ring that admits a finitely generated ideal I of adic definition, and suppose that the analytic locus of* Spec A *is noetherian. Then A is analytically noetherian.*

Proof. (This is [71, Th.5.1.2].) Let $a_1, \dots, a_k$ be a finite system of elements of A that generates I, and for every $i = 1, \dots, k$ denote by $\mathscr{T}_i$ that Aa_i-adic topology on A; taking into account proposition 15.2.5(ii), it suffices to show that $(A, \mathscr{T}_i)$ is analytically noetherian for $i = 1, \dots, k$. However, since the analytic locus of $(A, \mathscr{T})$ is noetherian, the same holds for the analytic locus of $(A, \mathscr{T}_i)$, and the topology $\mathscr{T}_i$ is also complete and separated for every $i = 1, \dots, k$, by virtue of lemma 8.3.12. We are then reduced to the case where $I = Aa$ is a principal ideal.

Now, let M be an A-module of finite type; we need to show that the sequence of submodules $(\mathrm{Ann}_M(a^n) \mid n \in \mathbb{N})$ is stationary. Let us write $M = L/Q$ for a free A-module L of finite rank, and a submodule $Q \subset L$, and set $N := Q^s$ (notation of (15.2.11)). Notice that

$$N/Q = \bigcup_{n \in \mathbb{N}} \mathrm{Ann}_M(a^n)$$

so it suffices to show that $a^k N \subset Q$ for some $k \in \mathbb{N}$. Now, obviously $N^s = N$, so $N^c = (N^c)^s$ as well, by lemma 15.2.12(ii). Moreover, since $A[a^{-1}]$ is noetherian, $N^c[a^{-1}]$ is an $A[a^{-1}]$-module of finite type, and consequently N^c is analytically of finite type, and $N = N^c$, by lemma 15.2.12(iii). It follows that N/Q is also analytically of finite type; so, pick a submodule $N' \subset N/Q$ of finite type and an integer $k \in \mathbb{N}$ such that $a^k(N/Q) \subset N'$; since N' is finitely generated, there exists as well $n \in \mathbb{N}$ such that $a^n N' = 0$, so finally $a^{k+n}(N/Q) = 0$, as required. □

Next, we globalize definition 15.2.1 to schemes as follows.

Definition 15.2.14. Let A be an adic topological ring that has a finitely generated ideal I of adic definition, X an A-scheme, and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module.

(i) We say that X is *locally analytically noetherian* if every point of X admits an affine open neighborhood U such that the following holds. Endow $A_U := \mathscr{O}_X(U)$ with the I-adic topology $\mathscr{T}_U$; then $(A_U, \mathscr{T}_U)$ is analytically noetherian.

(ii) We say that X is *analytically noetherian* if it is quasi-compact, quasi-separated and locally analytically noetherian.

(iii) We say that $\mathscr{F}$ is *analytically of finite type* if every point of X admits an affine open neighborhood U such that $\mathscr{F}(U)$ is an $(A_U, \mathscr{T}_U)$-module of analytically finite type.

Remark 15.2.15. If A is a universally analytically noetherian ring, then every A-scheme of finite type is analytically noetherian, by virtue of lemma 15.2.4.

Lemma 15.2.16. *Let A and I be as in definition* 15.2.14. *Let also X be a quasi-compact and quasi-separated A-scheme, and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module. We have :*

(i) *If $\mathscr{F}$ is analytically of finite type, there exist an integer $n \in \mathbb{N}$ and a quasi-coherent $\mathscr{O}_X$-submodule of finite type $\mathscr{G} \subset \mathscr{F}$ such that $I^n\mathscr{F} \subset \mathscr{G}$.*

(ii) *If $\mathscr{F}$ is analytically of finite type and X is analytically noetherian, there exists $p \in \mathbb{N}$ such that $\mathrm{Ann}_{\mathscr{F}}(I^q) = \mathrm{Ann}_{\mathscr{F}}(I^p)$ for every integer $q \geq p$.*

(iii) *If $\mathscr{F}$ is of finite type and X is analytically noetherian, there exist a finitely presented $\mathscr{O}_X$-module $\mathscr{G}$, an epimorphism $\varphi : \mathscr{G} \to \mathscr{F}$ of $\mathscr{O}_X$-modules, and an integer $n \in \mathbb{N}$ such that $I^n\mathrm{Ker}\,\varphi = 0$.*

Proof. (i): By assumption, we may find a finite affine open covering $(U_\lambda \mid \lambda \in \Lambda)$ of X, and for every $\lambda \in \Lambda$ a quasi-coherent $\mathscr{O}_{U_\lambda}$-submodule $\mathscr{H}_\lambda$ of finite type of $\mathscr{F}_\lambda := \mathscr{F}_{|U_\lambda}$ and an integer $n_\lambda \in \mathbb{N}$ such that $I^{n_\lambda}\mathscr{F}_\lambda \subset \mathscr{H}_\lambda$. We may also find, for every $\lambda \in \Lambda$, a finitely presented quasi-coherent $\mathscr{O}_{U_\lambda}$-module $\mathscr{H}'_\lambda$ with an $\mathscr{O}_{U_\lambda}$-linear morphism $\varphi_\lambda : \mathscr{H}'_\lambda \to \mathscr{F}_\lambda$ whose image is $\mathscr{H}_\lambda$. According to lemma 10.3.27(i) there exist a finitely presented quasi-coherent $\mathscr{O}_X$-module $\mathscr{G}_\lambda$ with $\mathscr{G}_{\lambda|U_\lambda} = \mathscr{H}'_\lambda$ and a morphism $\psi_\lambda : \mathscr{G}_\lambda \to \mathscr{F}_\lambda$ of $\mathscr{O}_X$-modules such that $\psi_{\lambda|U_\lambda} = \varphi_\lambda$. Then we may take $\mathscr{G} := \sum_{\lambda\in\Lambda} \mathrm{Im}\,\psi_\lambda$.

(ii): Suppose that for every $\lambda \in \Lambda$ there exists $p_\lambda \in \mathbb{N}$ such that $\mathrm{Ann}_{\mathscr{F}_\lambda}(I^q) = \mathrm{Ann}_{\mathscr{F}_\lambda}(I^{p_\lambda})$ for every $q \geq p_\lambda$. Then $p := \max(p_\lambda \mid \lambda \in \Lambda)$ fulfills the stated condition. Thus, we may suppose that $X = \mathrm{Spec}\,A$ for an analytically noetherian ring A, in which case the assertion follows from remark 15.2.2(iii).

(iii): By assumption, we may find a finite affine covering $(U_\lambda \mid \lambda \in \Lambda)$ of X such that $A_\lambda := \mathscr{O}_X(U_\lambda)$ is analytically noetherian relative to its IA_λ-adic topology, for every $\lambda \in \Lambda$. Pick a finitely presented quasi-coherent $\mathscr{O}_{U_\lambda}$-module $\mathscr{H}_\lambda$ and an epimorphism $\psi_\lambda : \mathscr{H}_\lambda \to \mathscr{F}_{|U_\lambda}$ for every $\lambda \in \Lambda$. By lemma 10.3.27(i) there exist a finitely presented quasi-coherent $\mathscr{O}_X$-module $\mathscr{H}'_\lambda$ with $\mathscr{H}'_{\lambda|U_\lambda} = \mathscr{H}_\lambda$ and a morphism of $\mathscr{O}_X$-modules $\psi'_\lambda : \mathscr{H}'_\lambda \to \mathscr{F}$ such that $\psi'_{\lambda|U_\lambda} = \psi_\lambda$, for every $\lambda \in \Lambda$. Set $\mathscr{H} := \bigoplus_{\lambda\in\Lambda} \mathscr{H}'_\lambda$; the sum of the morphisms ψ'_λ is an epimorphism $\psi : \mathscr{H} \to \mathscr{F}$, and $\mathscr{H}$ is clearly finitely presented. For every $\lambda \in \Lambda$, let also $V_\lambda \subset U_\lambda$ be the analytic locus; then $V := \bigcup_{\lambda\in\Lambda} V_\lambda$ is locally noetherian, quasi-compact and quasi-separated, and therefore $\mathscr{K} := \mathrm{Ker}\,\psi$ restricts to a finitely presented quasi-coherent $\mathscr{O}_V$-module $\mathscr{K}_{|V}$. Then, invoking again lemma 10.3.27(i) we find a quasi-coherent finitely presented $\mathscr{O}_X$-module $\mathscr{K}'$ and an $\mathscr{O}_X$-linear morphism $\mathscr{K}' \to \mathscr{K}$ that restricts to an isomorphism on V. Let $\mathscr{K}'' \subset \mathscr{K}$ be the image of $\mathscr{K}'$, and set $\mathscr{G} := \mathscr{H}/\mathscr{K}''$. Clearly ψ factors through an epimorphism $\varphi : \mathscr{G} \to \mathscr{F}$, and the support of $\mathrm{Ker}\,\varphi$ lies in $X \setminus V$. Lastly, since A_λ is analytically noetherian, we may find an integer $n_\lambda \in \mathbb{N}$ such that $I^{n_\lambda} \cdot (\mathrm{Ker}\,\varphi)_{|V_\lambda} = 0$, for every $\lambda \in \Lambda$. The assertion then holds with $n := \max(n_\lambda \mid \lambda \in \Lambda)$. ☐

Proposition 15.2.17. *Let A be an adic topological ring with a finitely generated ideal I of adic definition, B an A-algebra, that we endow with its IB-adic topology $\mathscr{T}_B$. Let also F be any B-module, and denote by $\mathscr{F}$ the quasi-coherent $\mathscr{O}_{\mathrm{Spec}\,B}$-module arising from F. We have :*

(i) *The following conditions are equivalent :*
   (a) *$(B, \mathscr{T}_B)$ is analytically noetherian.*
   (b) *$\mathrm{Spec}\,B$ is an analytically noetherian A-scheme.*

(ii) *The following conditions are equivalent :*
   (a) *F is a B-module of analytically finite type.*
   (b) *$\mathscr{F}$ is an $\mathscr{O}_{\mathrm{Spec}\,B}$-module of analytically finite type.*

Proof. (i): Clearly (a)⇒(b). Hence, suppose that $X := \mathrm{Spec}\,B$ is analytically noetherian, and let $(U_i \mid i = 1, \dots, k)$ be a finite affine covering of X such that $B_i := \mathscr{O}_X(U_i)$ is analytically noetherian for its IB_i-adic topology for every $i = 1, \dots, k$. By virtue of lemma 15.2.4, we may assume that for every $i = 1, \dots, k$ there exists $b_i \in B$ such that $B_i = B[b_i^{-1}]$. Clearly the analytic locus U of X is the union of the analytic loci of $\mathrm{Spec}\,B_1, \dots, \mathrm{Spec}\,B_k$, so U is noetherian. Next, let M be any B-module of finite type, and for every $i = 1, \dots, k$, set $M_i :=$

$B_i \otimes_B M$; choose $n \in \mathbb{N}$ such that $\mathrm{Ann}_{M_i}(I^r B_i) = \mathrm{Ann}_{M_i}(I^n B_i)$ for every $i = 1, \dots, n$ and every $r \geq n$. It follows that $\mathrm{Ann}_M(I^r) = \mathrm{Ann}_M(I^n)$ for every $r \geq n$, whence the contention.

(ii) follows easily from lemma 15.2.16(i). □

15.2.18. Let A be a universally analytically noetherian ring, $I \subset A$ a finitely generated ideal of adic definition, X a quasi-separated A-scheme locally of finite type, and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module. According to (15.1.47) we may consider the completions $X^\wedge$ and $\mathscr{F}^\wedge$ of X and $\mathscr{F}$ along the closed subscheme $X_0 := \mathrm{Spec}\,\mathscr{O}_X/I\mathscr{O}_X = \mathrm{Spec}\,A/I \times_{\mathrm{Spec}\,A} X$, which are respectively a formal scheme endowed with a natural morphism of locally ringed spaces

$$\pi : X^\wedge \to X$$

and a quasi-coherent $\mathscr{O}_{X^\wedge}$-module with a natural map of $\mathscr{O}_{X^\wedge}$-modules

$$\pi^*\mathscr{F} \to \mathscr{F}^\wedge. \tag{15.2.19}$$

Proposition 15.2.20. *With the notation of* (15.2.18), *the following holds :*

(i) *If $\mathscr{F}$ is analytically of finite type, the map* (15.2.19) *is an isomorphism.*

(ii) *We have $H^i(U, \pi^*\mathscr{F}) = 0$ for every affine quasi-compact open subset $U \subset X^\wedge$ and every $i > 0$.*

(iii) *If X is affine, the natural map*

$$\mathscr{O}_{X^\wedge}(X^\wedge) \otimes_{\mathscr{O}_X(X)} H^0(X, \mathscr{F}) \to H^0(X^\wedge, \pi^*\mathscr{F})$$

is an isomorphism.

(iv) *Let $\mathfrak{U} := (U_i \mid i \in I)$ be an open covering of $X^\wedge$, and suppose that $U_i \cap U_j$ is affine for every $i, j \in I$. Then there is a natural isomorphism (notation of* (10.2.18)*) :*

$$H^\bullet_{\mathrm{alt}}(\mathfrak{U}, \pi^*\mathscr{F}) \xrightarrow{\sim} H^\bullet(X^\wedge, \pi^*\mathscr{F}).$$

Proof. (i): The assertion is local on X, hence we may assume that X is local, say $X = \mathrm{Spec}\,B$, and $\mathscr{F}$ is the quasi-coherent $\mathscr{O}_X$-module attached to the module $F := \mathscr{F}(X)$. Let T be any final object in the category of topological spaces (*i.e.* T is the unique topology over a set that has only one point), and endow T with a structure sheaf $\mathscr{O}_T$ by declaring that $\mathscr{O}_T(T) := B$ and $\mathscr{O}_T(\varnothing) := 0$. The module F defines an $\mathscr{O}_T$-module F_T by the rule : $F_T(T) := F$ and $F_T(\varnothing) := 0$. The system of restriction maps $B \to \mathscr{O}_X(U)$ for U ranging over the open subsets of X, may be viewed as a morphism of ringed spaces

$$\varepsilon : X \to T$$

and with this notation we then have $\mathscr{F} = \varepsilon^* F_T$. Set as well $\varepsilon^\wedge := \varepsilon \circ \pi$; there follows a natural isomorphism of $\mathscr{O}_{X^\wedge}$-modules

$$\pi^*\mathscr{F} \xrightarrow{\sim} \varepsilon^{\wedge *} F_T.$$

In other words, $\pi^*\mathscr{F}$ is the sheaf associated to the presheaf given by the rule :

$$U_0 \mapsto \mathscr{O}_{X^\wedge}(U_0) \otimes_B F \qquad \text{for every open subset } U_0 \subset X^\wedge = X_0$$

and the discussion of (15.1.47) shows that (15.2.19) is the morphism associated to the morphism of presheaves given, on every affine open subset $U_0 \subset X_0$, by the natural map

$$\mathscr{O}_X(U)^\wedge \otimes_B F \to \mathscr{F}(U)^\wedge \tag{15.2.21}$$

where $U \subset X$ is any affine open subset such that $U_0 = U \cap X_0$, and where $\mathscr{O}_X(U)^\wedge$ and $\mathscr{F}(U)^\wedge$ denote the I-adic completions of $\mathscr{O}_X(U)$ and respectively $\mathscr{F}(U)$. However, since $\mathscr{F}$ is quasi-coherent, we have $\mathscr{F}(U) = \mathscr{O}_X(U) \otimes_B F$; taking into account remark 15.2.15 and propositions 15.2.10 and 15.2.17(ii) we deduce that (15.2.21) is an isomorphism for every such U_0. Since the affine open subsets are a basis of the topology of $X^\wedge$ that is closed under finite intersections, the assertion follows.

(ii): Since U is quasi-compact, $\pi(U)$ is contained in a quasi-compact open subset $V \subset X$; we may then replace X by V, and assume from start that X is quasi-compact and quasi-separated. In this case, $\mathscr{F}$ is the colimit of the filtered family $(\mathscr{F}_\lambda \mid \lambda \in \Lambda)$ of its quasi-coherent $\mathscr{O}_X$-submodules of finite type (proposition 10.3.31), hence $\pi^*\mathscr{F}$ is the colimit of the system $(\pi^*\mathscr{F}_\lambda \mid \lambda \in \Lambda)$. Since U is a spectral topological space, proposition 10.1.10 then reduces to showing that $H^i(U, \pi^*\mathscr{F}_\lambda) = 0$ for every $\lambda \in \Lambda$. Hence, we may assume from start that $\mathscr{F}$ is of finite type, in which case $\pi^*\mathscr{F}$ is a quasi-coherent $\mathscr{O}_{X^\wedge}$-module, by (i), and then the assertion follows from theorem 15.1.37(ii).

(iii): Arguing as in the proof of (ii), we reduce to the case where $\mathscr{F}$ is analytically of finite type; then $\mathscr{F}(X)$ is an $\mathscr{O}_X(X)$-module of analytically finite type (proposition 15.2.17(ii)), and the discussion of (15.1.47) says that $\mathscr{O}_{X^\wedge}(X^\wedge)$ (resp. $\mathscr{F}^\wedge(X^\wedge)$) is the I-adic completion of $\mathscr{O}_X(X)$ (resp. of $\mathscr{F}(X)$). Then the assertion follows from (i), lemma 15.1.28(i) and proposition 15.2.10(i).

(iv) follows from (ii), together corollary 10.2.21(ii) and [58, Ch.I, Prop.10.7.2]. □

Theorem 15.2.22. *Let A be a universally analytically noetherian ring, X a proper and finitely presented A-scheme, and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module of analytically finite type. Then the A-module $H^i(X, \mathscr{F})$ is analytically of finite type for every $i \in \mathbb{N}$.*

Proof. Let $I \subset A$ be any ideal of adic definition. The first observation is the following :

Claim 15.2.23. Let $i \in \mathbb{N}$ be any integer, and suppose that $H^i(X, \mathscr{F}')$ is analytically of finite type for every finitely presented $\mathscr{O}_X$-module $\mathscr{F}'$. Then $H^i(X, \mathscr{F})$ is analytically of finite type for every $\mathscr{O}_X$-module $\mathscr{F}$ of analytically finite type.

Proof of the claim. Let $\mathscr{G} \subset \mathscr{F}$ be an $\mathscr{O}_X$-submodule as in lemma 15.2.16(i), so that $I^n\mathscr{F} \subset \mathscr{G}$ for some $n \in \mathbb{N}$, and denote by $j : \mathscr{G} \to \mathscr{F}$ the inclusion morphism. Then, for every $a \in I^n$ the endomorphism $a \cdot \mathbf{1}_\mathscr{F}$ factors through an $\mathscr{O}_X$-linear morphism $\varphi_a : \mathscr{F} \to \mathscr{G}$. Set $H^i := H^i(X, \mathscr{F})$; we deduce that $a \cdot \mathbf{1}_{H^i} = H^i(X, j) \circ H^i(X, \varphi_a)$. Especially, $I^n H^i$ is contained in the image of $H^i(X, j)$. Hence, if $H^i(X, \mathscr{G})$ is analytically of finite type, the same follows for H^i. We may then replace $\mathscr{F}$ by $\mathscr{G}$, and assume from start that $\mathscr{F}$ is quasi-coherent of finite type. Next, by lemma 15.2.16(iii) and remark 15.2.15 we may find a short exact sequence of quasi-coherent $\mathscr{O}_X$-modules $0 \to \mathscr{K} \to \mathscr{F}' \to \mathscr{F} \to 0$ such that $\mathscr{F}'$ is finitely presented and $I^n\mathscr{K} = 0$ for some $n \in \mathbb{N}$. It follows easily that I^n annihilates the cokernel of the induced map $H^i(X, \mathscr{F}') \to H^i$, whence the claim. ◊

Thus, suppose henceforth that $\mathscr{F}$ is finitely presented, and set $S := \operatorname{Spec} A$; according to [65, Ch.IV, Prop.8.9.1(i,ii)] we may assume that there exist a noetherian subring $A_0 \subset A$, a finitely presented morphism of schemes $X_0 \to S_0 := \operatorname{Spec} A_0$ and a coherent $\mathscr{O}_{X_0}$-module $\mathscr{F}_0$ such that $X = S \times_{S_0} X_0$ and $\mathscr{F} = \pi^*\mathscr{F}_0$, where $\pi : X \to X_0$ is the projection. By [65, Ch.IV, Th.8.10.5], we may moreover assume that X_0 is a proper A_0-scheme.

Claim 15.2.24. The $\mathscr{O}_X$-module $\mathscr{T}or_q^{S_0}(\mathscr{O}_S, \mathscr{F}_0)$ is analytically of finite type for every $q \in \mathbb{N}$.

Proof of the claim. The assertion is local on X_0, so we may assume that X_0 is and affine and finitely presented S_0-scheme; then we may find an integer $n \in \mathbb{N}$ and a closed immersion $i : X_0 \to \mathbb{A}^n_{S_0}$. Set $i_S := S \times_{S_0} i : X \to \mathbb{A}^n_S$; according to [62, Ch.III, Prop.6.5.11] there is a natural isomorphism of $\mathscr{O}_X$-modules :

$$i_{S*}\mathscr{T}or_q^{S_0}(\mathscr{O}_S, \mathscr{F}_0) \xrightarrow{\sim} \mathscr{T}or_q^{S_0}(\mathscr{O}_S, i_*\mathscr{F}_0)$$

so we may replace X_0 by $\mathbb{A}^n_{S_0}$ and $\mathscr{F}_0$ by $i_*\mathscr{F}_0$, and assume from start that X_0 is a flat and affine S_0-scheme. In this situation, there exists as well a natural isomorphism of $\mathscr{O}_X$-modules :

$$\mathscr{T}or_q^{S_0}(\mathscr{O}_S, \mathscr{F}_0) \xrightarrow{\sim} \mathscr{T}_q := \mathscr{T}or_q^{X_0}(\mathscr{O}_X, \mathscr{F}_0) \qquad \text{for every } n \in \mathbb{N}.$$

Indeed, for every V_0, V and U as in the foregoing condition (a) we have an isomorphism

$$\gamma_{V,U} : \mathrm{Tor}_q^{\mathscr{O}_{S_0}(V_0)}(\mathscr{O}_S(V), \mathscr{F}_0(U)) \xrightarrow{\sim} \mathrm{Tor}_q^{\mathscr{O}_{X_0}(U)}(\mathscr{O}_X(V \times_{S_0} U), \mathscr{F}_0(U))$$

of $\mathscr{O}_X(V \times_{S_0} U)$-modules, such that for every inclusion of open subsets $V'_0 \subset V_0$, $V' \subset V \cap (S \times_{S_0} V'_0)$ and $U' \subset U \cap (S \times_{S_0} V'_0)$ the resulting diagram commutes :

$$\begin{array}{ccc} \mathrm{Tor}_q^{\mathscr{O}_{S_0}(V_0)}(\mathscr{O}_S(V), \mathscr{F}_0(U)) & \xrightarrow{\gamma_{V,U}} & \mathrm{Tor}_q^{\mathscr{O}_{X_0}(U)}(\mathscr{O}_X(V \times_{S_0} U), \mathscr{F}_0(U)) \\ \downarrow & & \downarrow \\ \mathrm{Tor}_q^{\mathscr{O}_{S_0}(V'_0)}(\mathscr{O}_S(V'), \mathscr{F}_0(U')) & \xrightarrow{\gamma_{V',U'}} & \mathrm{Tor}_q^{\mathscr{O}_{X_0}(U')}(\mathscr{O}_X(V' \times_{S_0} U'), \mathscr{F}_0(U')) \end{array}$$

([163, Prop.3.2.9]) whence the assertion. Thus, it suffices to check that $\mathscr{T}_q$ is analytically of finite type; however, since X_0 is affine, $\mathscr{F}_0$ admits a resolution $\mathscr{P}_\bullet \xrightarrow{\sim} \mathscr{F}[0]$ consisting of free $\mathscr{O}_{X_0}$-modules of finite type, and $\mathscr{T}_q$ is isomorphic to $H_q(\mathscr{O}_X \otimes_{\mathscr{O}_{X_0}} \mathscr{P}_\bullet)$. The claim then follows easily from corollary 15.2.8(i). ◊

Let $\mathfrak{U} := (U_i \mid i = 1, \dots, n)$ be a finite affine covering of X_0; we have natural isomorphisms in $\mathsf{D}(A_0\text{-}\mathbf{Mod})$ and respectively $\mathsf{D}(A\text{-}\mathbf{Mod})$

$$R\Gamma(X_0, \mathscr{F}_0) \xrightarrow{\sim} \overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}_0) \qquad R\Gamma(X, \mathscr{F}) \xrightarrow{\sim} A \otimes_{A_0} \overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}_0)$$

where $\overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U}, -)$ denotes the truncated alternating Čech complex associated with the covering $\mathfrak{U}$ (theorem 10.2.28(ii)). Let us choose a Cartan-Eilenberg projective resolution $P^{\bullet\bullet} \xrightarrow{\sim} \overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}_0)[0]$ such that $P^{pq} = 0$ whenever $q > 0$ (see [163, Lemma 5.7.2]); the double complex $A \otimes_{A_0} P^{\bullet\bullet}$ gives rise to a spectral sequence

$$E_2^{p,-q} := \mathrm{Tor}_q^{A_0}(A, H^p\overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}_0)) \Rightarrow M_{p-q} := H_{p-q}(A \overset{\mathbf{L}}{\otimes}_{A_0} \overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}_0))$$

as well as a spectral sequence

$$F_1^{p,-q} := \mathrm{Tor}_q^{A_0}(A, \overline{C}^p_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}_0)) \Rightarrow M_{p-q}$$

whose differentials $d_1^{pq} : F_1^{pq} \to F_1^{p+1,q}$ are induced by those of $\overline{C}^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{F}_0)$, whence natural isomorphisms for every $p, q \in \mathbb{N}$:

$$(15.2.25) \qquad E_2^{p,-q} \xrightarrow{\sim} \mathrm{Tor}_q^{A_0}(A, H^p(X_0, \mathscr{F}_0)) \qquad F_2^{p,-q} \xrightarrow{\sim} H^p(X, \mathscr{T}\!or_q^{S_0}(\mathscr{O}_S, \mathscr{F}_0))$$

and especially, we have natural isomorphisms

$$(15.2.26) \qquad F_2^{i,0} \xrightarrow{\sim} H^i \qquad \text{for every } i \in \mathbb{N}.$$

Claim 15.2.27. M_{p-q} is analytically of finite type, for every $p, q \in \mathbb{N}$.

Proof of the claim. The A_0-module $H^p(X_0, \mathscr{F}_0)$ is finitely generated for every $p \in \mathbb{N}$, because X_0 is a proper A_0-scheme ([61, Ch.III, Th.3.2.1]); since A_0 is noetherian, we may then find a resolution $P_\bullet$ of $H^p(X_0, \mathscr{F}_0)$ consisting of free A_0-modules of finite type, and there are natural isomorphisms $E_2^{p,-q} \xrightarrow{\sim} H_q(A \otimes_{A_0} P_\bullet)$; taking into account corollary 15.2.8(i), we conclude that $E_2^{p,-q}$ is an A-module of analytically finite type, for every $p, q \in \mathbb{N}$. Then, again by corollary 15.2.8(i), a simple induction on $r \in \mathbb{N}$ shows that $E_r^{p,-q}$ is analytically of finite type, for every $p, q, r \in \mathbb{N}$. We deduce that the A-module M_{p-q} admits a finite filtration whose subquotients are analytically of finite type, and to conclude it suffices to invoke again corollary 15.2.8(i). ◊

Now the theorem is a special case of the following more general

Claim 15.2.28. $F_{r+2}^{p,-q}$ is an A-module of analytically finite type, for every $p, q, r \in \mathbb{N}$.

Proof of the claim. We argue by descending induction on p, and notice that $F_1^{p,-q} = 0$ for every $p \geq n-1$, so the assertion is clear for $p \geq n-1$. Next, let $t \leq n-1$, and suppose that the claim has already been shown for every $p, q, r \in \mathbb{N}$ with $r \geq 2$ and $p \geq t$. First we prove, by descending induction on $r \geq 2$, that $F_r^{t-1,0}$ is analytically of finite type. Indeed, there exists $s \in \mathbb{N}$ large enough, such that $F_r^{t-1,0}$ is a subquotient of M_{t-1} for every $r \geq s$, whence the assertion for every $r \geq s$, by virtue of claim 15.2.27 and corollary 15.2.8(i). Thus, suppose that $2 < r \leq s$, and we know already that $F_r^{t-1,0}$ is analytically of finite type; we have an exact sequence

$$0 \to F_r^{t-1,0} \to F_{r-1}^{t-1,0} \to F_{r-1}^{t-2+r,2-r}$$

and by inductive assumption we also know that $F_{r-1}^{t-2+r,2-r}$ is analytically of finite type. From corollary 15.2.8(i), it follows that the same holds for $F_{r-1}^{t-1,0}$, as required. Especially, in light of (15.2.26), the foregoing implies that $H^{t-1}(X, \mathscr{F})$ is analytically of finite type, for every finitely presented $\mathscr{O}_X$-module $\mathscr{F}$, hence the same holds more generally whenever $\mathscr{F}$ is analytically of finite type, by virtue of claim 15.2.23. Taking into account claim 15.2.24 and (15.2.25), we deduce that $F_2^{t-1,-q}$ is analytically of finite type for every $q \in \mathbb{N}$, and finally, the same follows for $F_r^{t-1,-q}$, whenever $q, r \in \mathbb{N}$ and $r \geq 2$, after invoking once more corollary 15.2.8(i). □

15.2.29. In the situation of theorem 15.2.22, let $I \subset A$ be any finitely generated ideal of adic definition; we notice that $I^n\mathscr{F}$ is a quasi-coherent $\mathscr{O}_X$-module of analytically finite type for every $\in \mathbb{N}$, and we define a descending filtration $\mathrm{Fil}_I^\bullet H^i$ on $H^i := H^i(X, \mathscr{F})$ by setting

$$\mathrm{Fil}_I^n H^i := \mathrm{Im}(\psi_{i,n} : H^i(X, I^n\mathscr{F}) \to H^i) \qquad \text{for every } i, n \in \mathbb{N}.$$

Corollary 15.2.30. *With the notation of* (15.2.29)*, the following holds for every $i \in \mathbb{N}$:*

(i) *The linear topology on H^i defined by the descending filtration $\mathrm{Fil}_I^\bullet H^i$ agrees with the I-adic topology.*
(ii) *The system* $(\mathrm{Ker}\,\psi_{i,n} \mid n \in \mathbb{N})$ *is essentially zero.*

Proof. Let us show first that (i)⇒(ii). To ease notation, set $K_n^i := \mathrm{Ker}\,\psi_{i,n}$ for every $i, n \in \mathbb{N}$. For every $a \in I^n$, the endomorphism $a \cdot \mathbf{1}_\mathscr{F}$ is the composition of the inclusion map $j_n : I^n\mathscr{F} \to \mathscr{F}$ and a morphism $\varphi_{a,n} : \mathscr{F} \to I^n\mathscr{F}$ of $\mathscr{O}_X$-modules, and we have as well

$$\varphi_{a,n} \circ j_n = a \cdot \mathbf{1}_{I^n\mathscr{F}}$$

whence $H^i(X, \varphi_{a,n}) \circ \psi_{i,n} = a \cdot \mathbf{1}_{H^i(X, I^n\mathscr{F})}$. We deduce immediately that

$$I^n K_n^i = 0 \qquad \text{for every } p, n \in \mathbb{N}. \tag{15.2.31}$$

Next, notice that

$$\mathrm{Im}(K_p^i \to K_n^i) = K_n^i \cap \mathrm{Im}(H^i(X, I^p\mathscr{F}) \to H^i(X, I^n\mathscr{F})) \qquad \text{for all integers } p \geq n \geq 0.$$

Suppose now that (i) holds for every $\mathscr{O}_X$-module $\mathscr{F}$ of analytically finite type; especially, it applies to $I^n\mathscr{F}$, and therefore for every $k \in \mathbb{N}$ we may find an integer $p \geq n$ such that $\mathrm{Im}(H^i(X, I^p\mathscr{F}) \to H^i(X, I^n\mathscr{F})) \subset I^k H^i(X, I^n\mathscr{F})$, whence

$$\mathrm{Im}(K_p^i \to K_n^i) \subset K_n^i \cap I^k H^i(X, I^n\mathscr{F}).$$

By theorem 15.2.22, we know that $H^i(X, I^n\mathscr{F})$ is analytically of finite type; by corollary 15.2.7 and lemma 15.2.3(ii), it follows that there exists $k \in \mathbb{N}$ large enough, such that $K_n^i \cap I^k H^i(X, I^n\mathscr{F}) \subset I^n K_n^i$, and then the assertion follows from (15.2.31).

(i): Let $a_1, \dots, a_k$ be a finite system of generators for I; we argue by induction on k. If $k = 1$, let $p \in \mathbb{N}$ such that $\mathrm{Ann}_\mathscr{F}(a_1^q) = \mathrm{Ann}_\mathscr{F}(a_1^p)$ for every $q \geq p$ (lemma 15.2.16(ii)); there follows a commutative diagram of $\mathscr{O}_X$-modules

$$\begin{array}{ccc} a_1^p \mathscr{F} & \longrightarrow & a_1^q \mathscr{F} \\ \downarrow & & \downarrow \\ \mathscr{F} & \xrightarrow{a_1^{q-p} \cdot \mathbf{1}_{\mathscr{F}}} & \mathscr{F} \end{array}$$

whose top horizontal arrow is an isomorphism, and whose vertical arrows are the inclusion maps. We deduce easily that $\mathrm{Fil}^q_I H^i = a_1^{q-p} \cdot \mathrm{Fil}^p_I H^i$ for every $q \geq p$, whence

$$a_1^q H^i \subset \mathrm{Fil}^q_I H^i \subset a_1^{q-p} H^i$$

as required. Next, let $k > 1$, and set $J := Aa_1 + \cdots + Aa_{k-1}$ and $L := Aa_k$. Denote by $\mathscr{T}_I$, $\mathscr{T}_J$ and $\mathscr{T}_L$ respectively the I-adic, J-adic and L-adic topologies on A.

Fix $p \in \mathbb{N}$; it is easily seen that $I^p H^i \subset \mathrm{Fil}^p H^i$, so it remains only to check that there exists $n \in \mathbb{N}$ such that $\mathrm{Fil}^n H^i \subset I^p H^i$. To this aim, notice first that X is also an analytically noetherian $(A, \mathscr{T}_L)$-scheme (proposition 15.2.5(i)), and $\mathscr{F}$ is also analytically of finite type relative to the topology $\mathscr{T}_L$; since L is principal, it follows that we may find $t \in \mathbb{N}$ such that

$$\mathrm{Fil}^t_L H^i \subset L^p H^i. \tag{15.2.32}$$

Notice also that

$$J^{r+t} \subset I^{r+t} \subset J^r + L^t \qquad \text{for every } r, t \in \mathbb{N}$$

which implies that the I-adic topology on any A/L^t-module agrees with the J-adic topology. By the same token, an A/L^t-module is an $(A, \mathscr{T}_I)$-module of analytically finite type if and only if it is an $(A, \mathscr{T}_J)$-module of analytically finite type. Taking into account proposition 15.2.5(i) we deduce that X is also an analytically noetherian $(A, \mathscr{T}_J)$-scheme and $\mathscr{F}/L^t\mathscr{F}$ is analytically of finite type relative to the topology $\mathscr{T}_J$ as well, for every $t \in \mathbb{N}$. Then, theorem 15.2.22 says that $H^i_t := H^i(X, \mathscr{F}/L^t\mathscr{F})$ is an A-module analytically of finite type relative to the topology $\mathscr{T}_J$, hence also relative to the topology $\mathscr{T}_I$, since it is an A/L^tA-module. Moreover, by inductive assumption the linear topology on H^i_t defined by the filtration $\mathrm{Fil}^\bullet_J H^i_t$ agrees with the J-adic topology, hence the linear topology on H^i_t defined by the filtration $\mathrm{Fil}^\bullet_I H^i_t$ agrees with the I-adic topology, by the foregoing observation.

Now, the image of $\mathrm{Fil}^n_I H^i$ in H^i_t lies in the intersection of $\mathrm{Fil}^n_I H^i_t$ with the submodule $H^i/\mathrm{Fil}^t_L H^i \subset H^i_t$, and the I-adic topology on the latter agrees with the one induced by the I-adic topology of H^i_t (corollary 15.2.7 and lemma 15.2.3(ii)), so

$$\mathrm{Im}(\mathrm{Fil}^n_I H^i \to H^i/\mathrm{Fil}^t_L H^i) \subset I^p(H^i/\mathrm{Fil}^t_L H^i) \qquad \text{for some } n \in \mathbb{N}$$

i.e. $\mathrm{Fil}^n_I H^i \subset I^p H^i + \mathrm{Fil}^t_L H^i$, and combining with (15.2.32), the assertion follows. □

15.2.33. Keep the notation of (15.2.29), and define $\pi : X^\wedge \to X$ and $\mathscr{F}^\wedge$ as in (15.2.18). Moreover, for every $i, n \in \mathbb{N}$ endow $H^i(X, \mathscr{F})$ with its I-adic topology and $H^i(X, \mathscr{F}/I^n\mathscr{F})$ with the discrete topology, and denote by $A^\wedge$ and $H^i(X, \mathscr{F})^\wedge$ the separated completions of A and respectively $H^i(X, \mathscr{F})$.

Corollary 15.2.34. *In the situation of* (15.2.33)*, the following holds :*

(i) *There exist natural $A^\wedge$-linear isomorphisms*

$$H^i(X^\wedge, \mathscr{F}^\wedge) \xrightarrow{\sim} \lim_{n \in \mathbb{N}} H^i(X, \mathscr{F}/I^n\mathscr{F}) \xleftarrow{\sim} H^i(X, \mathscr{F})^\wedge \qquad \textit{for every } i \in \mathbb{N}.$$

(ii) *For $i = 0$, the maps of* (i) *are even isomorphisms of topological $A^\wedge$-modules.*

(iii) *For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{G}$, there exists a natural isomorphism*

$$H^i(X^\wedge, \pi^*\mathscr{G}) \xrightarrow{\sim} A^\wedge \otimes_A H^i(X, \mathscr{G}) \qquad \textit{for every } i \in \mathbb{N}.$$

Proof. (i): Fix a finite affine covering $U_\bullet := (U_\lambda \mid \lambda \in \Lambda)$ of X, and for every $\lambda \in \Lambda$ let $U_\lambda^\wedge$ be the completion of U_λ along its closed subscheme $\mathrm{Spec}\, A/I \times_{\mathrm{Spec}\, A} U$, . In light of lemma 15.1.28(i) we have a natural identification of complexes of topological $A^\wedge$-modules

$$\overline{C}^\bullet_{\mathrm{alt}}(U^\wedge_\bullet, \mathscr{F}^\wedge) \xrightarrow{\sim} \lim_{n\in\mathbb{N}} \overline{C}^\bullet_{\mathrm{alt}}(U_\bullet, \mathscr{F}/I^n\mathscr{F})$$

(where $\overline{C}^q_{\mathrm{alt}}(U_\bullet, \mathscr{F}/I^n\mathscr{F})$ is endowed with the discrete topology, for every $n, q \in \mathbb{N}$). On the other hand, by theorems 15.1.37(i) and 10.2.28(ii), we have natural isomorphisms

$$H^i(X, \mathscr{F}/I^n\mathscr{F}) \xrightarrow{\sim} H^i\overline{C}^\bullet_{\mathrm{alt}}(U_\bullet, \mathscr{F}/I^n\mathscr{F}) \qquad H^i(X^\wedge, \mathscr{F}^\wedge) \xrightarrow{\sim} H^i\overline{C}^\bullet_{\mathrm{alt}}(U^\wedge_\bullet, \mathscr{F}^\wedge)$$

for every $i, n \in \mathbb{N}$. Taking into account [163, Th.3.5.8] there follows a short exact sequence

$$(15.2.35) \qquad 0 \to \lim_{n\in\mathbb{N}}{}^1 H^{i-1}(X, \mathscr{F}/I^n\mathscr{F}) \to H^i(X^\wedge, \mathscr{F}^\wedge) \to \lim_{n\in\mathbb{N}} H^i(X, \mathscr{F}/I^n\mathscr{F}) \to 0$$

of $A^\wedge$-modules, for every $i \in \mathbb{N}$. Set also

$$F^i_k := \mathrm{Im}(H^i(X, \mathscr{F}) \to H^i(X, \mathscr{F}/I^k\mathscr{F})) \qquad \text{for every } i, k \in \mathbb{N}.$$

We notice :

Claim 15.2.36. $\lim_{n\in\mathbb{N}}{}^1 H^{i-1}(X, \mathscr{F}/I^n\mathscr{F}) = 0$ for every $i \in \mathbb{N}$.

Proof of the claim. By virtue of [163, Prop.3.5.7], it suffices to check that the descending system of submodules

$$(M^{i-1}_{k,k+n} := \mathrm{Im}(H^{i-1}(X, \mathscr{F}/I^{k+n}\mathscr{F}) \to H^{i-1}(X, \mathscr{F}/I^k\mathscr{F})) \mid n \in \mathbb{N})$$

is stationary, for every $i, k \in \mathbb{N}$. However, the short exact sequence of $\mathscr{O}_X$-modules

$$0 \to I^n\mathscr{F} \to \mathscr{F} \to \mathscr{F}/I^n\mathscr{F} \to 0$$

induces a commutative diagram of A-modules with exact rows

$$\begin{array}{ccccccc} H^{i-1}(X, \mathscr{F}) & \longrightarrow & H^{i-1}(X, \mathscr{F}/I^{n+k}\mathscr{F}) & \longrightarrow & H^i(X, I^{n+k}\mathscr{F}) & \longrightarrow & H^i(X, \mathscr{F}) \\ \| & & \downarrow & & \downarrow & & \| \\ H^{i-1}(X, \mathscr{F}) & \longrightarrow & H^{i-1}(X, \mathscr{F}/I^k\mathscr{F}) & \longrightarrow & H^i(X, I^k\mathscr{F}) & \longrightarrow & H^i(X, \mathscr{F}) \end{array}$$

which shows that

$$F^{i-1}_k \subset M^{i-1}_{k,k+n} \qquad \text{for every } i, k, n \in \mathbb{N}.$$

On the other hand, corollary 15.2.30(ii) implies that

$$M^{i-1}_{k,k+n} \subset \mathrm{Ker}(H^{i-1}(X, \mathscr{F}/I^k\mathscr{F}) \to H^i(X, I^k\mathscr{F})) = F^{i-1}_k$$

for every $k \in \mathbb{N}$ and every sufficiently large $n \in \mathbb{N}$. The claim follows. ◊

From (15.2.35) and claim 15.2.36, we already get the first stated isomorphism. Next, the proof of claim 15.2.36 shows that the system of inclusion maps $(F^i_n \to H^i(X, \mathscr{F}/I^n\mathscr{F}) \mid n \in \mathbb{N})$ induces an isomorphism of $A^\wedge$-modules

$$\lim_{n\in\mathbb{N}} F^i_n \xrightarrow{\sim} \lim_{n\in\mathbb{N}} H^i(X, \mathscr{F}/I^n\mathscr{F}) \qquad \text{for every } i \in \mathbb{N}.$$

But the system $(F^i_n \mid n \in \mathbb{N})$ is also isomorphic to the system $(H^i/\mathrm{Fil}^n_I H^i \mid n \in \mathbb{N})$ (notation of (15.2.29)), and lastly, from corollary 15.2.30(i) we obtain a natural isomorphism

$$\lim_{n\in\mathbb{N}} H^i/\mathrm{Fil}^n_I H^i \xrightarrow{\sim} H^i(X, \mathscr{F})^\wedge$$

whence the second stated isomorphism.

(ii): The topology of $H^0(X,\mathscr{F})^\wedge$ is I-adic, by remark 8.3.3(ii,iv). On the other hand, the topology of $H^0(X^\wedge,\mathscr{F}^\wedge)$ is the linear topology given by the system of submodules

$$(H^0(X^\wedge,(I^n\mathscr{F})^\wedge) \mid n \in \mathbb{N})$$

by remark 15.1.48. Denote $H^0(X, I^n\mathscr{F})^\wedge$ the I-adic completion of $H^0(X, I^n\mathscr{F})$, for every $n \in \mathbb{N}$; by (i) we get a commutative diagram of $A^\wedge$-modules

$$\begin{array}{ccc} H^0(X^\wedge,(I^n\mathscr{F})^\wedge) & \longrightarrow & H^0(X, I^n\mathscr{F})^\wedge \\ \downarrow & & \downarrow \\ H^0(X^\wedge,\mathscr{F}^\wedge) & \longrightarrow & H^0(X,\mathscr{F})^\wedge \end{array} \tag{15.2.37}$$

whose horizontal arrows are isomorphisms, and whose left (resp. right) vertical arrow is induced by the inclusion $(I^n\mathscr{F})^\wedge \subset \mathscr{F}^\wedge$ (resp. is the I-adic completion of the natural map $H^0(X, I^n\mathscr{F}) \to H^0(X,\mathscr{F})$). By corollary 15.2.30(i), the topology on $H^0(X,\mathscr{F})^\wedge$ given by the filtration $(H^0(X, I^n\mathscr{F})^\wedge \mid n \in \mathbb{N})$ agrees with the topology given by the filtration $((I^n H^0(X,\mathscr{F}))^\wedge \mid n \in \mathbb{N})$, and the latter is none else than the I-adic filtration, again by remark 8.3.3(ii,iv). We conclude already that the bottom horizontal arrow of (15.2.37) is an isomorphism of topological $A^\wedge$-modules. The same holds for the natural map $H^0(X^\wedge,\mathscr{F}^\wedge) \to \lim_{n\in\mathbb{N}} H^0(X,\mathscr{F}/I^n\mathscr{F})$, by the discussion of (15.1.47).

(iii): Since X is quasi-compact and quasi-separated, $\mathscr{G}$ is the colimit of the filtered family $(\mathscr{G}_\lambda \mid \lambda \in \Lambda)$ of its quasi-coherent $\mathscr{O}_X$-submodules of finite type (proposition 10.3.31), hence $\pi^*\mathscr{G}$ is the colimit of the system $(\pi^*\mathscr{G}_\lambda \mid \lambda \in \Lambda)$. Since $X^\wedge$ is a spectral topological space, proposition 10.1.10 then reduces to showing the assertion for each $\mathscr{G}_\lambda$, so we may assume from start that $\mathscr{G}$ is analytically of finite type, in which case it suffices to apply (i), propositions 15.2.10(i) and 15.2.20(i), and theorem 15.2.22. □

Remark 15.2.38. (i) The assertions of theorem 15.2.22 and of its corollaries 15.2.30 and 15.2.34 hold also in case X is projective but not necessarily finitely presented : indeed, if $i : X \to \mathbb{P}^n_A$ is a closed immersion in a projective space over $\operatorname{Spec} A$, then $H^\bullet(X,\mathscr{F}) = H^\bullet(\mathbb{P}^n_A, i_*\mathscr{F})$, and $i_*\mathscr{F}$ is clearly an $\mathscr{O}_{\mathbb{P}^n_A}$-module of analytically finite type, so we are reduced to the case where $X = \mathbb{P}^n_A$, which is covered by theorem 15.2.22.

(ii) More generally, theorem 15.2.22 and its two corollaries hold for any proper A-scheme X (and any $\mathscr{O}_X$-module $\mathscr{F}$ of analytically finite type) : indeed, according to [49, Th.4.1 and Th.4.3] there exists a locally closed immersion $i : X \to X'$ of A-scheme, with X' proper and finitely presented over $\operatorname{Spec} A$. Since X is proper, i is even a closed immersion ([60, Ch.II, Cor.5.4.3]), so again it suffices to apply the theorem to the $\mathscr{O}_{X'}$-module $i_*\mathscr{F}$.

(iii) Theorem 15.2.22 and corollary 15.2.34 have also been announced, respectively as theorem C.3.1 and theorem C.3.3 of Chapter 1, in K.Fujiwara and F.Kato's treatise [72]; however, their proofs have been postponed to a forthcoming article, which has not appeared yet.

Corollary 15.2.39. *Let A be a universally analytically noetherian ring, $\mathbf{f} := (f_1, \dots, f_r)$ a sequence of elements of A that generates an ideal of adic definition. Then A satisfies condition* $(\mathrm{a})^{\mathrm{un}}_{\mathbf{f}}$ *of* (7.8.21).

Proof. Let $X := \operatorname{Spec} A$, denote by $I \subset A$ the ideal generated by $\mathbf{f}$, and by $\mathscr{I} \subset \mathscr{O}_X$ the quasi-coherent ideal arising from I. Let also $\pi : Y \to X$ be the blowing up morphism of $\mathscr{I}$. It follows easily from remark 10.6.39(iii) that the support of the A-module $H^p := H^p(Y,\mathscr{O}_Y)$ is contained in $\operatorname{Spec} A/I$, for every $p > 0$, and the same holds for the kernel and cokernel of the natural map $\varphi : A \to H^0(Y,\mathscr{O}_Y)$. Combining with theorem 15.2.22 and remark 15.2.2(iii), we deduce that there exists $n \in \mathbb{N}$ such that $I^n \cdot H^p = 0$ for every $p > 0$, and $I^n \cdot \operatorname{Ker}\varphi = I^n \cdot \operatorname{Coker}\varphi = 0$. Then it suffices to invoke theorem 10.6.50. □

15.3. **Continuous valuations.** As already mentioned in (8.1.54), the study of the valuation spectrum of a topological ring A will lead us to consider certain subsets of $\mathrm{Spv}\, A$ that are not pro-constructible, but nevertheless are spectral spaces, with the topology induced via the inclusion map into $\mathrm{Spv}\, A$.

15.3.1. As a first step, let A be any ring, $I \subset A$ a finitely generated ideal; we attach to I a set of specializations S_I of $\mathrm{Spv}\, A$ (see (8.1.54)), by declaring that $(v, w) \in S_I$ if and only if :

- either, $w(I) \neq \{0\}$ and w is a primary specialization of v
- or else, $v = w$.

The S_I-admissible specializations in $\mathrm{Spv}\, A$ will be simply called *I-admissible*, and the S_I-closed subsets of $\mathrm{Spv}\, A$ shall be called *I-closed.* It is clear that the set of I-admissible specializations of $\mathrm{Spv}\, A$ is transitive, and it satisfies condition (S3) of corollary 8.1.57, by lemma 9.2.15(i). We shall show hereafter that it fulfills also conditions (S1) and (S2) of proposition 8.1.55. This shall be achieved in several steps; to start out, for any abelian ordered group Δ, let us say that an element $\delta \in \Delta_\circ$ is *final in* Δ if the following holds. For every $\gamma \in \Delta$ there exists $n \in \mathbb{N}$ such that $\delta^n < \gamma$. We remark :

Lemma 15.3.2. *In the situation of* (15.3.1)*, let v be a valuation of A with*

$$v(I) \neq \{0\} \qquad \textit{and} \qquad v(I) \cap c\Gamma_v = \varnothing.$$

Then we have :

(i) *There exists a smallest convex subgroup Δ of Γ_v with $v(I) \cap \Delta \neq \varnothing$.*
(ii) $c\Gamma_v \subset \Delta$.
(iii) *For every $i \in I$, either $v(i) < \delta$ for every $\delta \in \Delta$, or else $v(i)$ is final in Δ.*

Proof. (i): Let $a_1, \dots, a_n$ be a finite system of generators of I; the stated assumptions on v imply that $v(a_i) < 1$ for every $i = 1, \dots, n$, and $v(a_k) > 0$ for at least one index $k \leq n$. Let Δ be the convex hull of the subgroup Δ_0 of Γ_v generated by $\max\{v(a_i) \mid i = 1, \dots, n\}$. It remains only to check that $\Delta \subset \Delta'$ for every convex subgroup $\Delta' \subset \Gamma_v$ with $\Delta' \cap v(I) \neq \varnothing$. To this aim, notice first that $c\Gamma_v \subset \Delta'$ for every such Δ' : indeed, otherwise there exists $\gamma \in c\Gamma_v$ such that $\gamma < \delta$ for every $\delta \in \Delta'$. Then, pick $i \in I$ with $v(i) \in \Delta'$; it follows that $1 > v(i) > \gamma$, so $v(i) \in c\Gamma_v$, contradicting our assumptions. Now, let $i \in I$ be any element with $v(i) \in \Delta'$, and write $i = a_1 b_1 + \cdots + a_n b_n$ for some $b_1, \dots, b_n \in A$; since $c\Gamma_v \subset \Delta'$ and $v(i) \leq \max\{v(a_i) \cdot v(b_i) \mid i = 1, \dots, n\}$, it follows that $v(a_k) \in T$ for some $k \leq n$ (details left to the reader). Then clearly $\Delta_0 \subset \Delta'$, and the contention follows. Moreover, the argument also shows (ii).

(iii): Let $a_0 \in I$ be any element; the sequence $a_0, a_1, \dots, a_n$ is also a system of generators for I, and the foregoing shows that Δ is the convex hull of the subgroup generated by $\max\{v(a_i) \mid i = 0, \dots, n\}$. The assertion follows immediately. □

Definition 15.3.3. Keep the situation of (15.3.1). To every $v \in \mathrm{Spv}\, A$ we attach a convex subgroup

$$c\Gamma_v(I) \subset \Gamma_v$$

as follows :

- If $v(I) = \{0\}$, we set $c\Gamma_v(I) := \Gamma_v$.
- If $v(I) \cap c\Gamma_v \neq \varnothing$, we set $c\Gamma_v(I) := c\Gamma_v$.
- Otherwise, v fulfills the conditions of lemma 15.3.2, and we let $c\Gamma_v(I)$ be the smallest of the convex subgroups Δ such that $v(I) \cap \Delta \neq \varnothing$.

Lemma 15.3.4. *Keep the notation of definition* 15.3.3*, and let $a_1, \dots, a_n$ be a system of generators for the ideal I. We have :*

(i) *The following conditions are equivalent :*

(a) $\Gamma_v = c\Gamma_v(I)$.
(b) $\Gamma_v = c\Gamma_v$*, or else* $v(a)$ *is final in* Γ_v *for every* $a \in I$.
(c) $\Gamma_v = c\Gamma_v$*, or else* $v(a_i)$ *is final in* Γ_v*, for every* $i = 1, \dots, n$.

(ii) *An element* $w \in \mathrm{Spv}\, A$ *is an* I*-admissible specialization of* v *if and only if* $w = v^\Delta$ *for a convex subgroup* Δ *of* Γ_v *with* $c\Gamma_v(I) \subset \Delta$.

(iii) v *has no proper* I*-admissible specializations if and only if* $\Gamma_v = c\Gamma_v(I)$.

Proof. (i): The equivalence of (a) and (b) follows directly from the definitions and lemma 15.3.2(iii). The equivalence of (b) and (c) follows by remarking that the set

$$\{a \in A \mid v(a) = 0 \text{ or else } v(a) \text{ is final in } \Gamma_v\}$$

is an ideal in A, provided $\Gamma_v \neq c\Gamma_v$ (details left to the reader).

(ii) and (iii) are immediate from the definitions. □

Lemma 15.3.5. *Let* A *be a ring,* $I \subset A$ *a finitely generated ideal. We have :*

(i) *Let also* $f_\bullet := (f_0, f_1, \dots, f_n)$ *be a finite sequence of elements of* A*, and* $J \subset A$ *the ideal generated by* $f_\bullet$*. Suppose that the radical of* J *contains* I*. Then the rational subset* $R_A\big(\frac{f_1}{f_0}, \dots, \frac{f_n}{f_0}\big)$ *is* I*-closed.*

(ii) *Let* v *be any valuation of* A *such that* $\Gamma_v = c\Gamma_v(I)$*. Then for every open neighborhood* U *of* v *in* $\mathrm{Spv}\, A$ *there exists a finite sequence* $f_\bullet := (f_0, f_1, \dots, f_n)$ *of elements of* A *such that :*
(a) $v \in R_A\big(\frac{f_1}{f_0}, \dots, \frac{f_n}{f_0}\big) \subset U$.
(b) I *is contained in the radical of the ideal generated by* $f_\bullet$.

Proof. (i): Let $w \in \mathrm{Spv}\, A$ be an I-admissible specialization of some $v \in R := R_A\big(\frac{f_1}{f_0}, \dots, \frac{f_n}{f_0}\big)$. If $v(I) = \{0\}$, then $v = w$, and there is nothing to prove. Thus, we may assume $v(I) \neq \{0\}$, in which case $w(I) \neq \{0\}$ as well. Since w is a primary specialization of v, we have $w(f_i) \leq w(f_0)$ for every $i = 1, \dots, n$. Suppose, by way of contradiction, that $w \notin R$; then we must have $w(f_0) = 0$, and consequently $w(f_i) = 0$ for every $i \leq n$ as well. Thus, $J \subset \mathrm{Ker}\, w$, and since the support of w is a prime ideal, it contains also the radical of J; hence, $I \subset \mathrm{Ker}\, w$, a contradiction.

(ii): We may assume that $U = R_A\big(\frac{g_1}{g_0}, \dots, \frac{g_k}{g_0}\big)$ for some $g_0, g_1, \dots, g_k \in A$. Pick also a finite system $a_1, \dots, a_n$ of generators of I. We distinguish two cases :

• Suppose first that $\Gamma_v = c\Gamma_v$. In this case, since $v(g_0) \neq 0$, there exists $d \in A$ such that $v(g_0) \cdot v(d) = v(g_0 d) > 1$. Then $v \in R_A\big(\frac{1}{g_0 d}\big) \cap U$, and we may take $f_\bullet := (g_0 d, \dots, g_k d, 1)$.

• Lastly, suppose that $\Gamma_v \neq c\Gamma_v$. In this case, since $v(g_0) \neq 0$, lemma 15.3.4(i) implies that there exists $r \in \mathbb{N}$ with $v(g_0) \geq v(a_i^r)$ for every $i = 1, \dots, n$. Then $v \in R_A\big(\frac{a_1^r}{g_0}, \dots, \frac{a_n^r}{g_0}\big) \cap U$, and the sequence $f_\bullet := (g_0, \dots, g_k, a_1^r, \dots, a_n^r)$ will do. □

Definition 15.3.6. Let A be any ring and $I \subset A$ any finitely generated ideal.

(i) We set

$$\mathrm{Spv}(A, I) := \{v \in \mathrm{Spv}\, A \mid \Gamma_v = c\Gamma_v(I)\}$$

and we endow $\mathrm{Spv}(A, I)$ with the topology induced by $\mathrm{Spv}\, A$ via the inclusion map.

(ii) The *rational subsets* of $\mathrm{Spv}(A, I)$ are the subsets of the form

$$\mathrm{Spv}(A, I) \cap R_A\Big(\frac{f_1}{f_0}, \dots, \frac{f_n}{f_0}\Big)$$

where $f_\bullet := (f_0, f_1, \dots, f_n)$ is any sequence of elements of A such that I is contained in the radical of the ideal generated by $f_\bullet$.

Theorem 15.3.7. *With the notation of definition* 15.3.6*, we have :*

(i) *The topological space* $\mathrm{Spv}(A,I)$ *is spectral, and the retraction*

$$r_I : \mathrm{Spv}\, A \to \mathrm{Spv}(A,I) \qquad v \mapsto v^{c\Gamma_v(I)}$$

is spectral.

(ii) *The rational subsets of* $\mathrm{Spv}(A,I)$ *are constructible in* $\mathrm{Spv}(A,I)$*, and form a basis of the topology of* $\mathrm{Spv}(A,I)$ *that is closed under finite intersections.*

(iii) *A subset* $T \subset \mathrm{Spv}(A,I)$ *is constructible in* $\mathrm{Spv}(A,I)$ *if and only if* $r_I^{-1}T$ *is constructible in* $\mathrm{Spv}\, A$.

Proof. (i): From lemma 15.3.5 we see that the set of I-admissible specializations of $\mathrm{Spv}\, A$ fulfills conditions (S1) and (S2) of proposition 8.1.55, whence the assertion.

(ii): Lemma 15.3.5 already shows that the rational subsets form a basis $\mathscr{B}$ of the topology of $\mathrm{Spv}(A,I)$. If $R_A\big(\frac{f_1}{f_0},\dots,\frac{f_n}{f_0}\big)$ and $R_A\big(\frac{g_1}{g_0},\dots,\frac{g_m}{g_0}\big)$ are any two rational open subset of $\mathrm{Spv}\, A$ such that the radicals of the ideals J and J' generated respectively by $f_\bullet$ and $g_\bullet$ contain I, then the same holds for the radical of the ideal JJ'; taking into account remark 9.2.4(i), it follows that $\mathscr{B}$ is closed under finite intersections.

Lastly, let $f_\bullet$ and J be as in the foregoing, with I contained in the radical of J, and set $R := R_A\big(\frac{f_1}{f_0},\dots,\frac{f_n}{f_0}\big)$. By lemma 15.3.5, the set R is I-closed, so $r_I(R) = R\cap\mathrm{Spv}(A,I)$; since R is quasi-compact in $\mathrm{Spv}\, A$, the subset $r_I(R)$ is quasi-compact in $\mathrm{Spv}(A,I)$, so $R\cap\mathrm{Spv}(A,I)$ is a constructible open subset of $\mathrm{Spv}(A,I)$.

(iii) follows from proposition 8.1.55(iii). □

Example 15.3.8. Let A be any ring.

(i) We may take $I = 0$, in which case $c\Gamma_v(I) = \Gamma_v$ for every $v \in \mathrm{Spv}\, A$, so that $\mathrm{Spv}(A,0) = \mathrm{Spv}\, A$. Also, the rational subsets of $\mathrm{Spv}(A,0)$ are the same as the rational subsets of $\mathrm{Spv}\, A$.

(ii) We may also take $I = A$, in which case $c\Gamma_v(I) = c\Gamma_v$ for every $v \in \mathrm{Spv}\, A$, so that $\mathrm{Spv}(A,A) = \{v \in \mathrm{Spv}\, A \mid \Gamma_v = c\Gamma_v\}$. The rational subsets of $\mathrm{Spv}(A,A)$ can be described as the sets of the form

$$\mathrm{Spv}(A,A) \cap \{v \in \mathrm{Spv}\, A \mid v(f_1) \le v(f_0),\dots,v(f_n) \le v(f_0)\}$$

where $f_0, f_1, \dots, f_n$ is any sequence of elements with $\sum_{i=1}^n f_iA = A$ (details left to the reader).

Lemma 15.3.9. *Let* A *be any ring, and* $I, J \subset A$ *two finitely generated ideals. We have :*

(i) *If* I *is contained in the radical of* J*, then* $\mathrm{Spv}(A,J) \subset \mathrm{Spv}(A,I)$*. The inclusion map* $\mathrm{Spv}(A,J) \to \mathrm{Spv}(A,I)$ *is not spectral in general. On the other hand, there is a spectral retraction*

$$r_{I,J} : \mathrm{Spv}(A,I) \to \mathrm{Spv}(A,J) \qquad \textit{such that} \qquad r_{I,J}\circ r_I = r_J.$$

(ii) *Especially, the spectral map* $r_{I,I+J}$ *is well defined, and it coincides with the restriction of* r_J *to* $\mathrm{Spv}(A,I)$.

(iii) $\mathrm{Spv}(A, I\cdot J) = \mathrm{Spv}(A,I) \cup \mathrm{Spv}(A,J)$.

(iv) $\mathrm{Spv}(A, I+J) = \mathrm{Spv}(A,I) \cap \mathrm{Spv}(A,J)$.

Proof. (i): Indeed, the assumption easily implies that $c\Gamma_v(J) \subset c\Gamma_v(I)$ for every $v \in \mathrm{Spv}\, A$, from which the assertion follows immediately.

(ii): Let $v \in \mathrm{Spv}\, A$ be any element, and set $w := r_I(v)$, $u := r_J(w)$; then u does not have proper J-admissible specializations, nor any proper I-admissible specialization, because any I-admissible specialization of u would be also an I-admissible specialization of w. It follows easily that u is a primary specialization of v that does not have any proper $(I+J)$-specialization, whence the assertion.

Claim 15.3.10. For every $v \in \mathrm{Spv}\, A$ we have :

$$c\Gamma_v(I+J) = c\Gamma_v(I) \cap c\Gamma_v(J) \qquad \text{and} \qquad c\Gamma_v(I\cdot J) = c\Gamma_v(I) \cup c\Gamma_v(J).$$

Proof of the claim. We consider first the assertion for $c\Gamma_v(I \cdot J)$: it is easily seen that $v(IJ) = \{0\}$ if and only if either $v(I) = \{0\}$ or $v(J) = \{0\}$, so the assertion holds in case $v(IJ) = \{0\}$. Similarly, $v(IJ) \cap c\Gamma_v \neq \varnothing$ if and only if both $v(I)$ and $v(J)$ intersect $c\Gamma_v$, so the assertion holds also in case $v(IJ)$ intersects $c\Gamma_v$. Lastly, suppose that $v(IJ) \neq \{0\}$ and $v(IJ) \cap c\Gamma_v = \varnothing$, and pick a finite system of generators $a_1, \dots, a_n$ (resp. $b_1, \dots, b_m$) for I (resp. for J), with

$$v(a_1) = \max(v(a_i) \mid i = 1, \dots, n) \qquad \text{and} \qquad v(b_1) = \max(v(b_i) \mid i = 1, \dots, m).$$

Then the system $(a_i b_j \mid i \leq n,\ j \leq m)$ generates IJ, and $v(ab) = \max(v(a_i b_j) \mid i \leq n,\ j \leq m)$. Hence $v(a_1)$ (resp. $v(b_1)$, resp. $v(a_1 b_1)$) is final in $c\Gamma_v(I)$ (resp. in $c\Gamma_v(J)$, resp. in $c\Gamma_v(IJ)$) by lemma 15.3.2(iii). Without loss of generality we may assume that $c\Gamma_v(J) \subset c\Gamma_w(I)$, in which case there exists $n \in \mathbb{N}$ such that $v(a_1^n) \leq v(b_1)$, hence $v(a_1 b_1)^n \geq v(a_1)^{2N}$, which shows that $c\Gamma_v(IJ) \subset c\Gamma_v(I)$, and the converse inclusion is clear.

We argue similarly for the calculation of $c\Gamma_v(I + J)$: first, it is clear that $v(I + J) = \{0\}$ if and only if $v(I) = v(J) = \{0\}$. Next, we have $v(I + J) \cap c\Gamma_v \neq \varnothing$ if and only if $(v(I) \cup v(J)) \cap c\Gamma_v \neq \varnothing$ (details left to the reader). Lastly, if $v(IJ) \neq \{0\}$ and $v(IJ) \cap c\Gamma_v = \varnothing$, pick $a_1, \dots, a_n$ and $b_1, \dots, b_m$ as in the foregoing; without loss of generality we may assume that $v(a_1) \geq v(b_1)$. Since the system $a_1, \dots, a_n, b_1, \dots, b_m$ generates $I + J$, we deduce that $v(a_1)$ is final in $c\Gamma_v(I + J)$ (lemma 15.3.2(iii)), whence the contention. ◊

Assertion (iii) and (iv) follow immediately from claim 15.3.10 : details left to the reader. □

Example 15.3.11. Let A be any ring, $I \subset A$ a finitely generated ideal.

(i) Every element of the subset $L := \{v \in \mathrm{Spv}\, A \mid v(I) = \{0\}\}$ has no proper I-admissible specializations, so L lies in $\mathrm{Spv}(A, I)$. Clearly, L is constructible in $\mathrm{Spv}\, A$, and $r_I^{-1}(L) = L$, so L is constructible in $\mathrm{Spv}(A, I)$, by theorem 15.3.7(iii).

(ii) Let $(\mathrm{Spv}\, A)_0$ be the set of trivial valuations of A; from remark 9.2.4(iii) we know already that $(\mathrm{Spv}\, A)_0$ is a spectral space, with the topology induced by the inclusion into $\mathrm{Spv}\, A$. Moreover, if $R := R_A\big(\frac{f_1}{f_0}, \dots, \frac{f_n}{f_0}\big)$ is any rational subset of $\mathrm{Spv}(A, I)$, then $R \cap (\mathrm{Spv}\, A)_0 = \{v \in (\mathrm{Spv}\, A)_0 \mid v(f_0) = 1\}$, which is a constructible (open) subset of $(\mathrm{Spv}\, A)_0$. Hence, the inclusion map $(\mathrm{Spv}\, A)_0 \to \mathrm{Spv}(A, I)$ is spectral.

(iii) Pick a finite system $a_1, \dots, a_n$ of generators for I, and set

$$E_0 := \{v \in (\mathrm{Spv}\, A)_0 \mid v(I) = \{0\}\}$$
$$E_i := \{v \in \mathrm{Spv}\, A \mid v(a_i) = 1 \text{ and } v(a) \leq 1 \text{ for every } a \in A\} \quad \text{for every } i = 1, \dots, n.$$

Then $E_0, \dots, E_n$ are pro-constructible subsets of $\mathrm{Spv}\, A$ that are closed under I-admissible specializations and generizations. We have $(\mathrm{Spv}\, A)_0 = \mathrm{Spv}(A, I) \cap \bigcup_{i=0}^n E_i$, and therefore $r_I^{-1}(\mathrm{Spv}\, A)_0 = \bigcup_{i=0}^n E_i$, by corollary 8.1.57.

We are now ready to introduce the *spectrum of continuous valuations* of a topological ring.

Definition 15.3.12. Let $(A, \mathscr{T}_A)$ be any topological ring, and v a valuation of A.

(i) We endow $\Gamma_{v\circ}$ with a topology $\mathscr{T}_{\Gamma_v}$, by ruling that a subset $U \subset \Gamma_{v\circ}$ is open if either $0 \notin U$, or else there exists $\delta \in \Gamma_v$ such that $\{\gamma \in \Gamma_{v\circ} \mid \gamma < \delta\} \subset U$. Then, we say that v is *continuous* if it is a continuous map $(A, \mathscr{T}_A) \to (\Gamma_{v\circ}, \mathscr{T}_{\Gamma_v})$.

(ii) We set

$$\mathrm{Cont}(A) := \{v \in \mathrm{Spv}\, A \mid v \text{ is continuous}\} \qquad \mathrm{Cont}^+(A) := \mathrm{Cont}(A) \cap \mathrm{Spv}^+(A)$$

and we endow $\mathrm{Cont}(A)$ and $\mathrm{Cont}^+(A)$ with the topology induced by $\mathrm{Spv}\, A$.

Remark 15.3.13. Let A be any topological ring, any v any valuation of A.

(i) Endow $\kappa(v)$ with its valuation topology $\mathscr{T}_v$ (see definition 9.1.14(i)). A simple inspection of the definitions shows that the residual valuation $\overline{v} : (\kappa(v), \mathscr{T}_v) \to \Gamma_{v\circ}$ of v is continuous. Moreover, v is continuous if and only if the same holds for the natural map $\pi_v : A \to (\kappa(v), \mathscr{T}_v)$.

Indeed, clearly if π_v is continuous, the same holds for $v = \overline{v} \circ \pi_v$. Conversely, suppose that v is continuous; it suffices to check that π_v is continuous at the point $0 \in A$. However, for every $\delta \in \Gamma_v$ let $U_\delta := \{\gamma \in \Gamma_{v\circ} \mid \gamma < \delta\}$; then the family $(U_\delta \mid \delta \in \Gamma_v)$ is a fundamental system of open neighborhoods of $0 \in \Gamma_{v\circ}$, and $(\overline{v}^{-1} U_\delta \mid \delta \in \Gamma_v)$ is a fundamental system of open neighborhoods of $0 \in \kappa(v)$, whence the contention.

(ii) It follows easily from (i) that the valuation v is continuous if and only if it is continuous at the point $0 \in A$.

(iii) Let $\varphi : \Gamma \to \Gamma'$ be a morphism of ordered groups, and endow $\Gamma_\circ$ and $\Gamma'_\circ$ with the topologies $\mathscr{T}_\Gamma$ and $\mathscr{T}_{\Gamma'}$ described in definition 15.3.12(i). In general, the induced map $\varphi_\circ : \Gamma_\circ \to \Gamma'_\circ$ is *not* necessarily continuous for these topologies; for instance :

- If Γ is a subgroup of Γ', and φ is the inclusion map, then $\varphi_\circ$ is continuous if and only if the convex hull of Γ equals Γ' (see remark 9.1.2(iii)), and if the latter condition holds, then the topology $\mathscr{T}_\Gamma$ agrees with the topology induced by $\mathscr{T}_{\Gamma'}$.
- If $\Gamma' = \Gamma/\Delta$ for a proper convex subgroup $\Delta \subset \Gamma$, and φ is the projection, then $\varphi_\circ$ is continuous.
- If $\Gamma \neq \{1\}$ and $\Gamma' = \{1\}$, then $\varphi_\circ$ is not continuous.

Especially, a secondary generization w of v is continuous if either $v = w$ or else $\Gamma_w \neq \{1\}$, but w may fail to be continuous in case $\Gamma_v \neq \{1\}$ and $\Gamma_w = \{1\}$. On the other hand, if $\varphi_\circ \circ v$ is a continuous map, then it is easily seen that v is continuous as well.

(iv) Let $\Delta \subset \Gamma_v$ be any convex subgroup containing $c\Gamma_v$, denote by $\Gamma^+_{v\circ} \cdot \Delta$ the smallest submonoid of $\Gamma_{v\circ}$ containing $\Gamma^+_{v\circ}$ and Δ, and endow $\Gamma^+_{v\circ} \cdot \Delta$ with the topology $\mathscr{T}_{\Gamma^+_{v\circ}\cdot\Delta}$ induced by $\mathscr{T}_{\Gamma_v}$ via the inclusion map. Let also $\mathscr{T}_\Delta$ be the topology on $\Delta_\circ$ described in definition 15.3.12(i). Then the inclusion map $\Delta_\circ \to \Gamma^+_{v\circ} \cdot \Delta$ admits a unique continuous retraction

$$\rho : (\Gamma^+_{v\circ} \cdot \Delta, \mathscr{T}_{\Gamma^+_{v\circ}\cdot\Delta}) \to (\Delta_\circ, \mathscr{T}_\Delta) \qquad \text{such that } \rho(\gamma) = 0 \text{ whenever } \gamma \notin \Delta_\circ.$$

On the other hand, since $c\Gamma_v \subset \Delta$, the map v factors through a (unique) mapping $v' : A \to \Gamma^+_{v\circ} \cdot \Delta$, and if v is continuous, the same holds for v'. Clearly $\rho \circ v' = v^\Delta$, so the latter is continuous as well. Combining with (iii) and proposition 9.2.24, we conclude that every specialization of a continuous valuation is continuous. However, in general $\mathrm{Cont}(A)$ is not a closed subset (not even a pro-constructible subset) of $\mathrm{Spv}\, A$.

(v) Since $\mathrm{Spv}\, A$ is a T_0 topological space, the same holds for $\mathrm{Cont}(A)$. Especially, the specializations in $\mathrm{Cont}(A)$ define a partial ordering on $\mathrm{Cont}(A)$: see remark 8.1.45(ii).

(vi) It follows also from (ii) that if $\mathrm{Ker}\, v$ is an open prime ideal, then v is continuous. We shall say that v is *non-analytic* if $\mathrm{Ker}\, v$ is an open prime ideal. If v is continuous and its support is not an open prime ideal, we shall say that v is *analytic*. We denote by

$$\mathrm{Cont}(A)_{\mathrm{a}} \qquad \text{and} \qquad \mathrm{Cont}(A)_{\mathrm{na}}$$

the sets of all analytic and respectively non-analytic valuations of A.

(vii) Let $f : A \to B$ be any continuous ring homomorphism of topological rings. Then $\mathrm{Spv}(f)$ restricts to continuous maps

$$\mathrm{Cont}(f) : \mathrm{Cont}(B) \to \mathrm{Cont}(A) \qquad \mathrm{Cont}^+(f) : \mathrm{Cont}^+(B) \to \mathrm{Cont}^+(A).$$

Indeed, let w be a continuous valuation of B; obviously $v := w \circ f : A \to \Gamma_{w\circ}$ is a continuous map. The value group Γ_v of v is a subgroup of Γ_w, and v factors uniquely through a valuation $v' : A \to \Gamma_v$ that is obviously equivalent to v; by (iii), the continuity of w implies the continuity of v', whence the claim. It is then also clear that $\mathrm{Cont}(f)$ in turns restricts to a mapping

$$\mathrm{Cont}(f)_{\mathrm{na}} : \mathrm{Cont}(B)_{\mathrm{na}} \to \mathrm{Cont}(A)_{\mathrm{na}}.$$

Lemma 15.3.14. *Let A be any f-adic topological ring, and $v \in \mathrm{Cont}(A)$. We have :*

(i) $\mathrm{Cont}(A) = \{w \in \mathrm{Spv}\, A \mid w(a)$ *is final in* Γ_w*, for every* $a \in A^{\circ\circ}\}$.

(ii) *Suppose that v is analytic, and endow $\kappa(v)$ with its valuation topology $\mathscr{T}_v$. Then v is a Tate valuation (see definition* 9.1.14(iv)*), and the natural map*

$$\pi_v : A \to (\kappa(v), \mathscr{T}_v)$$

is an f-adic continuous ring homomorphism.

(iii) *Let $w \in \mathrm{Cont}(A)$ be any proper primary specialization of v. Then w is non-analytic.*

(iv) *Let $w \in \mathrm{Cont}(A)_{\mathrm{a}}$ be a specialization of v. Then $v \in \mathrm{Cont}(A)_{\mathrm{a}}$ and w is a secondary specialization of v.*

(v) *If v is analytic, the totally ordered set of continuous generizations of v admits a maximal element, which is a rank one analytic valuation.*

Proof. Let $A_0 \subset A$ be a subring of definition, $I \subset A_0$ a finitely generated ideal of adic definition, and $a_1, \dots, a_n$ a finite system of generators of I; for every $w \in \mathrm{Spv}\, A$ we set $\gamma_w := \max(w(a_1), \dots, w(a_n))$

(i): The condition is clearly necessary. Conversely, suppose that $w \in \mathrm{Spv}\, A$ fulfills this condition; by remark 15.3.13(ii), it suffices to check that, for every $\delta \in \Gamma_w$ there exists an open neighborhood U_δ of 0 in A such that $w(a) < \delta$ for every $a \in U_\delta$. However, we have $w(a) < 1$ for every $a \in I$, since $I \subset A^{\circ\circ}$, and we may find $k \in \mathbb{N}$ such that $\delta > \gamma_w^k$. Hence $U_\delta := I^{k+1}$ will do.

(ii): Denote by $\overline{v}$ the residual valuation of v; if v is analytic, the value γ_v lies in Γ_v, and if $x \in \kappa(v)^+$ is any element with $\overline{v}(x) = \gamma$, it follows easily that the valuation topology on $\kappa(v)^+$ agrees with the x-adic topology, so v is a Tate valuation. Next, after replacing A_0 by the smallest $\mathbb{Z}$-subalgebra of A_0 containing I, we may assume that $\pi_v(A_0) \subset \kappa(v)^+$, and notice that $\pi_v(I^n)$ generates $x^n \cdot \kappa(v)^+$ for every $n \in \mathbb{N}$, so that π_v is continuous and f-adic (details left to the reader).

(iii): Say that $w = v^\Delta$ for some convex subgroup Δ strictly contained in Γ_v. Then the value γ_v cannot lie in Δ, so $w(I) = 0$, whence the assertion.

(iv): Proposition 9.2.24 says that w is a primary specialization of a secondary specialization u of v, and u is a continuous valuation of A, by remark 15.3.13(iv). In light of (iii), it follows that $u = w$, whence the contention.

(v): First, from (iv) we see that every continuous generization of v must be a secondary generization and must be analytic; hence, let $\Delta \subset \Gamma_v$ be the largest convex subgroup that does not contain γ_v, and set $w := v_\Delta$. It is easily seen that the image $\overline{\gamma}_v$ of γ_v in $\Gamma_w = \Gamma_v/\Delta$ is still final, and by definition $\gamma_w = \overline{\gamma}_v$, so w is continuous, by (i). It remains only to check that w does not admit any proper (secondary) generization; however, by construction, every non-trivial convex subgroup $\Delta' \subset \Gamma_w$ contains γ_w, and on the other hand, γ_w cannot lie in any proper convex subgroup of Γ_w. Thus, the only convex subgroups of Γ_w are $\{1\}$ and Γ_w, whence the assertion. □

Theorem 15.3.15. *Let A be any f-adic ring, and $J \subset A$ any finitely generated ideal such that* $\mathrm{Spec}\, A/J$ *is the non-analytic locus of* $\mathrm{Spec}\, A$. *Then we have :*

(i) $\mathrm{Cont}(A) = \{v \in \mathrm{Spv}(A, J) \mid v(a) < 1$ *for every* $a \in A^{\circ\circ}\}$.

(ii) $\mathrm{Cont}(A)$ *is a closed (in particular, pro-constructible) subset of* $\mathrm{Spv}(A, J)$. *Especially,* $\mathrm{Cont}(A)$ *is a spectral topological space.*

Proof. (i): Let $A_0 \subset A$ be a subring of definition, and $I \subset A_0$ an ideal of adic definition; by lemma 8.3.29(i) we have $\mathrm{Spec}\, A/IA = \mathrm{Spec}\, A/J$, so that the ideals J and IA have the same radical; from lemma 15.3.9(i) we deduce that $\mathrm{Spv}(A, J) = \mathrm{Spv}(A, IA)$, so we may assume from start that $J = IA$. Since I is an open subset of A, for every $a \in A^{\circ\circ}$ we may find $n \in \mathbb{N}$ such that $a^n \in I$; combining with lemma 15.3.14(i) we easily deduce that

$$\mathrm{Cont}(A) = \{v \in \mathrm{Spv}\, A \mid v(a) \text{ is final in } \Gamma_v, \text{for every } a \in I\}.$$

In light of lemma 15.3.4(i) we then see that

$$\mathrm{Cont}(A) \subset \{v \in \mathrm{Spv}(A, J) \mid v(a) < 1 \text{ for every } a \in I\}$$

and to conclude, it suffices to prove the converse inclusion. Hence, let $v \in \mathrm{Spv}(A, J)$ be any valuation such that $v(a) < 1$ for every $a \in I$. If $\Gamma_v \neq c\Gamma_v$, lemma 15.3.4(i) implies that either $v(a) = 0$ or $v(a)$ is final in Γ_v for every $a \in J$, and then $v \in \mathrm{Cont}(A)$, by the foregoing.

Lastly, suppose that $\Gamma_v = c\Gamma_v$, and let $a \in I$ be any element; in this case, it suffices to show that, for every $b \in A$ with $v(b) \neq 0$, there exists $n \in \mathbb{N}$ such that $v(a)^n < v(b)^{-1}$. However, we may find $n \in \mathbb{N}$ such that $a^n b \in I$, so $v(a^n b) < 1$ by assumption, whence the contention.

(ii): From (i) we see that $\mathrm{Cont}(A) = \bigcap_{a \in A^{\circ\circ}} \big(\mathrm{Spv}(A, J) \backslash R_A\big(\frac{1}{a}\big)\big)$. Combining with corollary 8.1.42, we obtain the assertion. □

15.3.16. Let A be and J be as in theorem 15.3.15. We say that a subset of $\mathrm{Cont}(A)$ is *rational*, if it can be written as an intersection $\mathrm{Cont}(A) \cap R$, where R is a rational subset of $\mathrm{Spv}(A, J)$ (see definition 15.3.6(ii)). Hence, a rational subset is of the form $\mathrm{Cont}(A) \cap R_A\big(\frac{f_1}{f_0}, \dots, \frac{f_n}{f_0}\big)$, where $(f_0, f_1, \dots, f_n)$ is any sequence of elements of A that generates an open ideal. Especially, the class of rational subsets of $\mathrm{Cont}(A)$ does not depend on the choice of the ideal J, and provides a basis of quasi-compact open subsets of $\mathrm{Cont}(A)$ that is closed under finite intersections (theorem 15.3.7(ii)).

Corollary 15.3.17. *Let $f : A \to B$ be an f-adic morphism of f-adic topological rings. We have:*

(i) $\mathrm{Cont}(f)$ *is a spectral map. More precisely, if R is a rational subset of* $\mathrm{Cont}(A)$*, then* $\mathrm{Cont}(f)^{-1}(R)$ *is a rational subset of* $\mathrm{Cont}(B)$.

(ii) $\mathrm{Cont}(f)$ *restricts to maps* $\mathrm{Cont}(B)_{\mathrm{a}} \to \mathrm{Cont}(A)_{\mathrm{a}}$ *and* $\mathrm{Cont}(B)_{\mathrm{na}} \to \mathrm{Cont}(A)_{\mathrm{na}}$.

Proof. (i): Indeed, if $R = \mathrm{Cont}(A) \cap R_A\big(\frac{a_1}{a_0}, \dots, \frac{a_n}{a_0}\big)$ for a sequence $a_0, a_1, \dots, a_n$ that generates an open ideal of A, then $\mathrm{Cont}(f)^{-1}(R) = \mathrm{Cont}(B) \cap R_A\big(\frac{f(a_1)}{f(a_0)}, \dots, \frac{f(a_n)}{f(a_0)}\big)$, and since f is adic, it is easily seen that the sequence $f(a_0), f(a_1), \dots, f(a_n)$ generates an open ideal of B.

(ii) is clear. □

Proposition 15.3.18. *Let A be an f-adic ring, $B \subset A$ an open subring, and denote by $i : B \to A$ the inclusion map. Then we have :*

(i) $\mathrm{Cont}(A) = \mathrm{Spv}(i)^{-1}\mathrm{Cont}(B)$.

(ii) $\mathrm{Cont}(i)$ *restricts to a homeomorphism* $\mathrm{Cont}(A)_{\mathrm{a}} \xrightarrow{\sim} \mathrm{Cont}(B)_{\mathrm{a}}$.

Proof. (i): Let v be a valuation of A such that $w := \mathrm{Spv}(i)(v) = v_{|B}$ is a continuous valuation of B; we have to show that v is a continuous valuation of A, and by remark 15.3.13(vi), we may assume that $\mathrm{Ker}\, v$ is not open. In this case, lemma 8.3.29(iii) implies that $\kappa(v) = \kappa(w)$, and therefore v and w have the same value group; the assertion follows immediately.

(ii): Define X_A and $X_A^{\circ\circ}$ as in definition 8.3.28; we have

$$\mathrm{Cont}(A)_{\mathrm{a}} = \mathrm{Spv}(X_A \setminus X_A^{\circ\circ}) \cap \mathrm{Cont}(A)$$

and likewise for $\mathrm{Cont}(B)_{\mathrm{a}}$, so the assertion follows from (i) and lemma 8.3.29(iii). □

Proposition 15.3.19. *Let A be a topological ring, $A^\wedge$ the separated completion of A. We have:*

(i) *The completion map $i : A \to A^\wedge$ induces a bijective and continuous map*

$$\mathrm{Cont}(i) : \mathrm{Cont}(A^\wedge) \to \mathrm{Cont}(A).$$

(ii) *Moreover, with the ordering given by specializations on* $\mathrm{Cont}(A)$ *and* $\mathrm{Cont}(A^\wedge)$*, the map* $\mathrm{Cont}(i)$ *is also an isomorphism of partially ordered sets (see remark* 15.3.13(v)*)*

$$(\mathrm{Cont}(A^\wedge), \leq) \xrightarrow{\sim} (\mathrm{Cont}(A), \leq).$$

(iii) *Furthermore,* $\mathrm{Cont}(i)$ *restricts to bijections*

$$\mathrm{Cont}(A^\wedge)_{\mathrm{a}} \xrightarrow{\sim} \mathrm{Cont}(A)_{\mathrm{a}} \qquad \textit{and} \qquad \mathrm{Cont}(A^\wedge)_{\mathrm{na}} \xrightarrow{\sim} \mathrm{Cont}(A)_{\mathrm{na}}.$$

(iv) *If A is f-adic,* $\mathrm{Cont}(i)$ *is a homeomorphism.*

Proof. (i): For the injectivity of $\mathrm{Cont}(i)$ we show the following more precise :

Claim 15.3.20. Let $w \in \mathrm{Cont}(A^\wedge)$ be any element, and set $v := \mathrm{Cont}(i)(w)$. Let Γ_w and Γ_v be the value groups of w and respectively v. Then we have:

(i) $\Gamma_w = \Gamma_v$ and $c\Gamma_w = c\Gamma_v$.
(ii) The induced map of residue fields $\kappa(v) \to \kappa(w)$ has dense image, for the valuation topology of $\kappa(w)$ (notation of remark 9.1.4(v)).

Proof of the claim. (i): Let $a \in A^\wedge$ be any element such that $\gamma := w(a) \in \Gamma_w$; by assumption, there exists an open neighborhood U_γ of 0 in $A^\wedge$ such that $w(x) < \gamma$ for every $x \in U_\gamma$, hence $w(a + U_\gamma) = \{\gamma\}$, and since $a + U_\gamma$ intersects the image of A in $A^\wedge$, we deduce that $\gamma \in \Gamma_v$, whence the claim.

(ii): According to remark 15.3.13(i), the natural map $\pi_v : A \to \kappa(v)$ is continuous for the valuation topology $\mathscr{T}_v$ of $\kappa(v)$, hence it extends uniquely to a continuous ring homomorphism $\pi_v^\wedge : A^\wedge \to \kappa(v)^\wedge$, where $(\kappa(v)^\wedge, \mathscr{T}_v^\wedge)$ denotes the completion of $(\kappa(v), \mathscr{T}_v)$. However, v extends uniquely to a valuation $v^\wedge : \kappa(v)^\wedge \to \Gamma_{v\circ}$ and $\mathscr{T}_v^\wedge$ agrees with the corresponding valuation topology of $\kappa(v)^\wedge$ (proposition 9.1.16(iv,v)). It follows that $v^\wedge \circ \pi_v^\wedge : A^\wedge \to \Gamma_{v\circ}$ is the unique continuous valuation whose composition with i agrees with v. Consequently, there exists as well a unique inclusion of fields $j : \kappa(w) \to \kappa(v)^\wedge$ whose composition with the projection $\pi_w : A^\wedge \to \kappa(w)$ agrees with $\pi_v^\wedge$, and $v^\wedge \circ j$ is the residual valuation $\mathscr{T}_w$ of $\kappa(w)$. Especially, $\mathscr{T}_w$ agrees with the topology induced by $\mathscr{T}_v^\wedge$ via j; since the image of $\kappa(v)$ is dense in $\kappa(v)^\wedge$ relative to the topology $\mathscr{T}_v^\wedge$ (theorem 8.2.8(ii)), the assertion follows. ◊

Now, let $w, w' \in \mathrm{Cont}(A^\wedge)$ be two valuations such that $w \circ i$ is equivalent to $w' \circ i$, and denote by Γ_w (resp. $\Gamma_{w'}$) the value group of w (resp. of w'). From claim 15.3.20 we may assume that $\Gamma_w = \Gamma_{w'}$ and $w \circ i = w' \circ i$. Since the image of A is dense in $A^\wedge$ and the topology of Γ_w is separated, we conclude that $w = w'$, as required.

Next, we show that $\mathrm{Cont}(i)$ is surjective. Indeed, let v be any continuous valuation of A with value group Γ, so that, for every $\gamma \in \Gamma$ there exists an open neighborhood U_γ of 0 in A such that $v(x) < \gamma$ for every $x \in U_\gamma$; we need to show that there exists a valuation $v^\wedge : A^\wedge \to \Gamma_\circ$ such that $v = v^\wedge \circ i$. We define $v^\wedge$ as follows. Let $\mathscr{C} := (a_i \mid i \in I)$ be any Cauchy net in A (indexed by some filtered ordered set I); for every $\gamma \in \Gamma$, we may then find $i(\gamma) \in I$ such that $a_j - a_k \in U_\gamma$ for every $j, k \in I$ with $j, k \geq i(\gamma)$. We let $\mathscr{C}_\gamma$ be the Cauchy net $(a_j \mid j \in I,\ j \geq i(\gamma))$ for every such γ. Now, suppose that there exists $\gamma \in \Gamma$ and $a \in \mathscr{C}_\gamma$ with $\delta := v(a) \geq \gamma$; then $v(b) = \delta$ for every $b \in \mathscr{C}_\gamma$, and in this case we set $v^\wedge(\mathscr{C}) := \delta$. Otherwise, we set $v^\wedge(\mathscr{C}) := 0$. It is easily seen that this definition depends only on the equivalence class of $\mathscr{C}$ in $A^\wedge$, so it yields a well defined map $v^\wedge : A^\wedge \to \Gamma_\circ$, and it is clear that $v^\wedge \circ i = v$. We leave to the reader the verification that $v^\wedge$ is indeed a continuous valuation on $A^\wedge$.

(ii): Let $u \in \mathrm{Cont}(A^\wedge)$ be any element, and w' a specialization of $u' := \mathrm{Cont}(i)(u)$ in $\mathrm{Cont}(A)$. By proposition 9.2.24 there exists $v' \in \mathrm{Spv}\,A$ that is both a secondary specialization of u' and a primary generization of w' in $\mathrm{Spv}\,A$. By lemma 9.2.25(iii) we may find a secondary specialization v of u in $\mathrm{Spv}\,A^\wedge$ with $\mathrm{Spv}(i)(v) = v'$; then $v \in \mathrm{Cont}(A^\wedge)$ and $v' \in \mathrm{Cont}(A)$ (remark 15.3.13(iv)). By claim 15.3.20, we know that v and v' have the same value groups and the same characteristic subgroups; hence, we may find a primary specialization w of v in $\mathrm{Spv}\,A$ with $w' = \mathrm{Spv}(i)(w)$, and $w \in \mathrm{Cont}(A)$ (remark 15.3.13(iv)), as required.

(iii): We have already observed that $\mathrm{Cont}(i)$ restricts to a map $\mathrm{Cont}(A^\wedge)_{\mathrm{na}} \to \mathrm{Cont}(A)_{\mathrm{na}}$ (remark 15.3.13(vii)); in light of (i), it then suffices to show that $\mathrm{Cont}(i)$ restricts as well to a map $\mathrm{Cont}(A^\wedge)_\mathrm{a} \to \mathrm{Cont}(A)_\mathrm{a}$. Thus, let $v : A^\wedge \to \Gamma_\circ$ be any continuous analytic valuation, and suppose that $\mathfrak{p} := \mathrm{Ker}\, v \circ i$ is open in A; by continuity, the topological closure $i(\mathfrak{p})^c$ of $i(\mathfrak{p})$ in $A^\wedge$ lies in $\mathrm{Ker}\, v$. However, $i(\mathfrak{p})^c$ contains an open subset of $A^\wedge$ (claim 8.2.11(ii)), and therefore it is open, a contradiction.

(iv): From (i), we know already that $\mathrm{Cont}(i)$ is continuous and bijective. It then suffices to show that $\mathrm{Cont}(i)$ is a closed map, if A is f-adic. However, in this case $\mathrm{Cont}(A)$ and $\mathrm{Cont}(A^\wedge)$ are spectral topological spaces (theorem 15.3.15(ii)) and $\mathrm{Cont}(i)$ is a spectral map (corollary 15.3.17(i) and proposition 8.3.33(ii)), so it suffices to check that $\mathrm{Cont}(i)$ is specializing (proposition 8.1.47(i) and corollary 8.1.50(i)). The latter follows immediately from (ii). □

Corollary 15.3.21. *Let $f : A \to B$ be a continuous ring homomorphism of f-adic rings. Suppose that B is topologically local, and denote by $B^\wedge$ the separated completion of B. Then the following conditions are equivalent :*

(a) *f is an f-adic map.*
(b) *The composition $A \to B^\wedge$ of f with the completion map $B \to B^\wedge$ is f-adic.*
(c) *$\mathrm{Cont}(f)$ restricts to a map $\mathrm{Cont}(B)_\mathrm{a} \to \mathrm{Cont}(A)_\mathrm{a}$.*

Proof. (a)⇒(b) since the completion map $B \to B^\wedge$ is f-adic (proposition 8.3.33(i,ii)).

(b)⇒(c) by corollary 15.3.17(ii) and proposition 15.3.19(i).

(c)⇒(a): Let B_0 be a subring of definition of B, and A_0 a subring of definition of A such that $A_0 \subset f^{-1}B_0$ (corollary 8.3.19(ii)), and let $f_0 : A_0 \to B_0$ be the restriction of f. From (c) and proposition 15.3.18(ii) we deduce that $\mathrm{Cont}(f_0)$ restricts to a map $\mathrm{Cont}(B_0)_\mathrm{a} \to \mathrm{Cont}(A_0)_\mathrm{a}$, and it suffices to check that f_0 is f-adic. Moreover, B_0 is still topologically local (proposition 8.4.2(i)). Thus, we may replace f by f_0, and assume from start that $B = B^\circ$, so that $B^{\circ\circ}$ lies in the Jacobson radical of B. Now, define X_A and $X_A^{\circ\circ}$ as in definition 8.3.28, and likewise for the ring B; also, set $\varphi := \mathrm{Spec}\, f$. By lemma 8.3.29(iv), it suffices to show that $\varphi^{-1}X_A^{\circ\circ} = X_B^{\circ\circ}$. However, suppose that the latter fails; then there exists a prime ideal $\mathfrak{p} \in X_B \setminus X_B^{\circ\circ}$ with $\varphi(\mathfrak{p}) \in X_A^{\circ\circ}$, and we pick any maximal ideal $\mathfrak{m}$ of B containing $\mathfrak{p}$. Set $C := (B/\mathfrak{p})_\mathfrak{m}$, and choose a valuation ring V of $\mathrm{Frac}\, C$ that dominates C (corollary 9.1.25). The valuation ring V corresponds to a point $v \in \mathrm{Spv}\, B$; next, pick any finitely generated ideal of definition I of B, and set $w := v^{\mathrm{c}\Gamma_v(I)}$. Since $B^{\circ\circ} \subset \mathfrak{m}$, theorem 15.3.15(i) implies that w is a continuous valuation of B. Since $\mathfrak{p} = \mathrm{Ker}\, v$ and I is not contained in $\mathfrak{p}$, it follows that I is not contained in the support of w, therefore $w \in \mathrm{Cont}(B)_\mathrm{a}$. However, $w' := \mathrm{Cont}(f)(w)$ is a primary specialization of $\mathrm{Spv}\, f(v)$, and the support of the latter is an open ideal of A, by construction, so $w' \in \mathrm{Cont}(A)_\mathrm{na}$, which contradicts our assumptions. □

Proposition 15.3.22. *Let A be any f-adic topological ring, and denote by A^sep the maximal separated quotient of A. The following holds :*

(i) *$\mathrm{Spv}\, A = \varnothing$ if and only if $A = 0$.*
(ii) *$\mathrm{Cont}(A) = \varnothing$ if and only if $A^\mathrm{sep} = 0$.*
(iii) *$\mathrm{Cont}(A)_\mathrm{a} = \varnothing$ if and only if the topology of A^sep is discrete.*

Proof. (i): Indeed, if $A \neq 0$, it has a prime ideal $\mathfrak{p}$, and the trivial valuation on $A/\mathfrak{p}$ yields an element of $\mathrm{Spv}\, A$.

(iii): Let $A^\wedge$ be the separated completion of A; if $\mathrm{Cont}(A)_\mathrm{a} = \varnothing$, we have $\mathrm{Cont}(A^\wedge)_\mathrm{a} = \varnothing$ as well, by proposition 15.3.19(iii), and it suffices to show that the topology of $A^\wedge$ is discrete. Let $B \subset A^\wedge$ be a subring of definition, and $I \subset B$ a finitely generated ideal of adic definition (proposition 8.3.33(i)); then

$$\mathrm{Cont}(B)_\mathrm{a} = \varnothing \qquad (15.3.23)$$

as well (proposition 15.3.18(ii)), and we remark :

Claim 15.3.24. I is a nilpotent ideal.

Proof of the claim. Let $\mathfrak{p} \subset B$ be any prime ideal, and suppose by way of contradiction, that I is not contained in $\mathfrak{p}$. Choose a maximal ideal $\mathfrak{m}$ of $C := B/\mathfrak{p}$, and pick a valuation ring V of $\mathrm{Frac}\, C$ that dominates $C_\mathfrak{m}$ (corollary 9.1.25). Let $\mathfrak{n} \subset B$ be the maximal ideal such that $\mathfrak{n}/\mathfrak{p} = \mathfrak{m}$; then V corresponds to a valuation v of B with support equal to $\mathfrak{p}$, and such that $v(a) < 1$ for every $a \in \mathfrak{n}$. Since B is I-adically complete, we have $I \subset \mathfrak{n}$ (remark 8.3.10(v)), so it follows easily that $v(a) < 1$ for every $a \in B^{\circ\circ}$. Let Γ_v be the value group of v, and set $w := v^{c\Gamma_v(I)}$ (notation of definition 15.3.3). Then $w \in \mathrm{Spv}(B, I)$ and $w(a) < 1$ for every $a \in B^{\circ\circ}$, so w is continuous (theorem 15.3.15(i)). Lastly, since $v(I) \neq \{0\}$ by construction, we have $w(I) \neq \{0\}$ as well, since w is an I-admissible specialization of v. Therefore $w \in \mathrm{Cont}(B)_\mathrm{a}$, which contradicts (15.3.23). ◊

Claim 15.3.24 means that the topology of B is discrete, hence the same holds for the topology of $A^\wedge$, as required.

(ii): From (iii) we know that the topological closure $\{0\}^c$ of the ideal $\{0\}$ of A is open in A; hence, every prime ideal containing $\{0\}^c$ is open as well, and therefore every valuation with support equal to such a prime ideal would be continuous (remark 15.3.13(vi)); since $\mathrm{Cont}(A) = \varnothing$, we conclude that no prime ideal of A contains $\{0\}^c$, *i.e.* $\{0\}^c = A$, whence the assertion. □

Lemma 15.3.25. *Let A be a topologically local f-adic ring, $J \subset A$ an ideal. The following conditions are equivalent :*

(a) *J is an open ideal.*
(b) *For every $v \in \mathrm{Cont}(A)_\mathrm{a}$ we have $J \not\subset \mathrm{Ker}\, v$.*
(c) *For every $v \in \mathrm{Cont}(A)_\mathrm{a}$ of rank one, we have $J \not\subset \mathrm{Ker}\, v$.*

Proof. Clearly (a)⇒(b)⇒(c).

Next, suppose that J is not open; to conclude, it suffices to exhibit a rank one continuous analytic valuation on A whose support contains J. Now, let $B \subset A$ be a subring of definition, and set $J_B := B \cap J$; since J is not open in A, the ideal J_B cannot be open in B. Moreover, B is also topologically local, by proposition 8.4.2(i).

Claim 15.3.26. It suffices to exhibit a rank one continuous analytic valuation on B whose support contains J_B.

Proof of the claim. Indeed, let $v : B \to \Gamma_\circ$ be such a valuation, and denote by $\mathfrak{p} \subset B$ the support of v; with the notation of definition 8.3.28, we have $\mathfrak{p} \in X_B \setminus X_B^{\circ\circ}$, and by lemma 8.3.29(iii) the inclusion map $i : B \to A$ induces an isomorphism of schemes $\varphi : X_A \setminus X_A^{\circ\circ} \xrightarrow{\sim} X_B \setminus X_B^{\circ\circ}$. Set $\mathfrak{q} := \varphi^{-1}(\mathfrak{p})$; it follows that i extends to a ring isomorphism $i_\mathfrak{p} : B_\mathfrak{p} \xrightarrow{\sim} A_\mathfrak{q}$. Let also $j : A \to A_\mathfrak{q}$ be the localization map; v extends uniquely to a valuation $\overline{v} : B_\mathfrak{p} \to \Gamma_\circ$, and composing with $i_\mathfrak{p}^{-1} \circ j$ we deduce a valuation $w : A \to \Gamma_\circ$. Moreover, $\mathrm{Cont}(i) : \mathrm{Cont}(A) \to \mathrm{Cont}(B)$ is a homeomorphism (proposition 15.3.18(ii)), and a direct inspection of the definitions yields

$$\mathrm{Cont}(i)^{-1}(v) = w.$$

Especially, w is continuous, analytic and of rank one. Lastly, the support of $\overline{v}$ contains $J_{B,\mathfrak{p}} = i_\mathfrak{p}^{-1} J_\mathfrak{q}$, so the support of w contains J. ◊

Due to claim 15.3.26, we may replace A by B and J by J_B, and assume from start that $A = A^\circ$; especially, $A^{\circ\circ}$ lies in the Jacobson radical of A. By lemma 8.3.29(v), there exists $x \in \mathrm{Spec}\, A/J \setminus X_A^{\circ\circ}$; according to remark 8.1.45(ii) we may find a minimal specialization y of x in $\mathrm{Spec}\, A/J \setminus X_A^{\circ\circ}$, and if $\{y\}^c$ denotes the topological closure of $\{y\}$ in $\mathrm{Spec}\, A/J$, the closed subset $Z := \{y\}^c \cap X_A^{\circ\circ}$ of $\mathrm{Spec}\, A/J$ is non-empty, since $X_A^{\circ\circ}$ contains all the maximal ideals of A. We let $\mathfrak{p} \subset A$ be any maximal point of Z, and we notice that the image C of $A_\mathfrak{p}$ in $\kappa(y)$ is a one-dimensional local domain.

Claim 15.3.27. For any one-dimensional local domain $(R, \mathfrak{m}_R)$ there exists a one-dimensional valuation ring of $\mathrm{Frac}\, R$ that dominates R.

Proof of the claim. By corollary 9.1.25 we may find a valuation ring V of $\mathrm{Frac}\, R$ that dominates R. Let $\mathscr{F}$ be the set of all prime ideals $\mathfrak{q}$ of V such that $\mathfrak{q} \cap R = \mathfrak{m}_R$; then $\mathscr{F}$ is non-empty, and it admits a minimal element $\mathfrak{r} := \bigcap_{\mathfrak{q} \in \mathscr{F}} \mathfrak{q}$. It then suffices to check that the localization $V_\mathfrak{r}$ is one-dimensional. However, let $\mathfrak{p} \subset V_\mathfrak{r}$ be any non-zero prime ideal, and pick any $a \in \mathfrak{p} \setminus \{0\}$; we may write $a := b/b'$ for some $b, b' \in R$, and then $b \in \mathfrak{p}$ as well, so $\mathfrak{p} \cap R = \mathfrak{m}_R$, in which case $\mathfrak{p}$ must be the maximal ideal of $V_\mathfrak{r}$, and the assertion follows. ◊

By claim 15.3.27, we may find a one-dimensional valuation ring V of $\kappa(y)$ that dominates C, and denote by $v \in \mathrm{Spv}\, A$ the corresponding valuation. Let also $I \subset A$ be any finitely generated ideal of adic definition; by construction, the support of v contains J and is not an open ideal, and v does not admit any proper I-admissible specializations (see (15.3.1)), so $v \in \mathrm{Spv}(A, I)$. Moreover $A^{\circ\circ} \subset \mathfrak{p}$, so that $v(b) < 1$ for every $b \in A^{\circ\circ}$, and consequently $v \in \mathrm{Cont}(A)_\mathrm{a}$. □

15.4. **Affinoid rings and affinoid schemes.** In this section we present an extension and refinement of Huber's theory of affinoid rings.

Definition 15.4.1. (i) Let A be any f-adic ring. An open subring $B \subset A$ is called a *ring of integral elements of* A, if $B \subset A^\circ$ and B is integrally closed in A.

(ii) An *affinoid ring* is a datum (A, A^+) consisting of an f-adic ring A and a ring A^+ of integral elements of A. A *morphism of affinoid rings* $f : (A, A^+) \to (B, B^+)$ is a continuous ring homomorphism $f : A \to B$ such that $f(A^+) \subset B^+$. Then we say that f is *f-adic*, if the same holds for the underlying map $A \to B$.

(iii) A *quasi-affinoid ring* is a datum (A, A^+, U) consisting of an affinoid ring (A, A^+) and a constructible open subset $U \subset X_A$ that contains the analytic locus (see definition 8.3.28). A *morphism of quasi-affinoid rings* $f : (A, A^+, U) \to (B, B^+, V)$ is a morphism $f : (A, A^+) \to (B, B^+)$ of affinoid rings such that $\mathrm{Spec}\, f$ restricts to a morphism of schemes $V \to U$. We say that such f is *f-adic*, if the same holds for the underlying map $A \to B$.

(iv) A *quasi-affinoid scheme* is a datum $\underline{X} := (X, \mathscr{T}_X, A^+_X)$ consisting of a (quasi-compact) quasi-affine scheme X (see [60, Ch.II, Déf.5.1.1]), an f-adic topology $\mathscr{T}_X$ on $A_X := \mathscr{O}_X(X)$, and a subring $A^+_X \subset A_X$ such that the following holds :

- (A_X, A^+_X) is an affinoid ring.
- For every $s \in A^{\circ\circ}_X$, the open subscheme $X_s := X \times_{\mathrm{Spec}\, A_X} \mathrm{Spec}\, A_X[s^{-1}]$ is affine.

A *morphism of quasi-affinoid schemes* $\varphi : (X, \mathscr{T}_X, A^+_X) \to (Y, \mathscr{T}_Y, A^+_Y)$ is a morphism of schemes $\varphi : X \to Y$ whose associated morphism of sheaves of rings $\varphi^\flat : \mathscr{O}_Y \to \varphi_*\mathscr{O}_X$ induces a morphism of affinoid rings $\varphi^\flat_Y : (\mathscr{O}_Y(Y), A^+_Y) \to (\mathscr{O}_X(X), A^+_X)$. We say that φ is *f-adic* if $\varphi^\flat_Y$ is f-adic. We say that $\underline{X}$ is an *affinoid scheme* if X is an affine scheme.

(v) Let $\underline{A} := (A, A^+, U)$ (resp. $\underline{X} := (X, \mathscr{T}_X, A^+_X)$) be any quasi-affinoid ring (resp. quasi-affinoid scheme). We say that $\underline{A}$ (resp. $\underline{X}$) is *topologically local* (resp. *topologically henselian*, resp. *complete*, resp. *separated*) if the underlying f-adic ring A (resp. $\mathscr{O}_X(X)$) enjoys the corresponding property.

Remark 15.4.2. (i) Clearly the affinoid rings, the quasi-affinoid rings, the affinoid schemes and the quasi-affinoid schemes with their morphisms as in definition 15.4.1 form categories denoted respectively :

$$\mathsf{Afd.Ring} \qquad \mathsf{q.Afd.Ring} \qquad \mathsf{Afd.Sch} \qquad \mathsf{q.Afd.Sch}$$

(Afd.Sch is a full subcategory of q.Afd.Sch). Also, we have a natural fully faithful functor

$$\mathsf{Afd.Ring} \to \mathsf{q.Afd.Ring} \qquad (A, A^+) \mapsto (A, A^+, \mathrm{Spec}\, A)$$

so we may regard Afd.Ring as a full subcategory of q.Afd.Ring.

(ii) By virtue of [60, Ch.II, Prop.5.1.2], we have a natural fully faithful functor

$$\Gamma : \mathsf{q.Afd.Sch}^o \to \mathsf{q.Afd.Ring} \qquad (X, \mathscr{T}_X, A^+_X) \mapsto (A_X, A^+_X, X)$$

(where $A_X := \mathscr{O}_X(X)$ and X is naturally identified with the image of the open immersion $X \to \mathrm{Spec}\, A_X$). Indeed, let $s \in A_X^{\circ\circ}$ be any element, and define the open subscheme $X_s \subset X$ as in definition 15.4.1(iv); by assumption, X_s is affine, and on the other hand we have a natural isomorphism of A_X-algebras

$$\Gamma(X_s, \mathscr{O}_X) \xrightarrow{\sim} A_X[s^{-1}]$$

by [59, Ch.I, Cor.9.2.2]. Therefore the image of the open immersion $\mathrm{Spec}\, A_X[s^{-1}] \to \mathrm{Spec}\, A_X$ equals X_s; especially, $\mathrm{Spec}\, A_X[s^{-1}] \subset X$ for every $s \in A_X^{\circ\circ}$, so (A_X, A_X^+, X) is indeed a quasi-affinoid ring. Especially, the analytic locus of $\mathrm{Spec}\, A_X$ lies in X, and shall also be called the *analytic locus of* $\underline{X}$.

(iii) Let (A, A^+) be any affinoid ring, $B \subset A$ an open subring, and endow B with the topology induced by the inclusion map $B \to A$. Then corollary 8.3.20(i) implies that the pair $(B, A^+ \cap B)$ is an affinoid ring.

(iv) Let A be any f-adic ring, and endow $R := \mathbb{Z} \oplus A^{\circ\circ}$ with the multiplication map given by the rule : $(n, a) \cdot (m, b) := (nm, ma + nb + ab)$ for every $n, m \in \mathbb{Z}$ and $a, b \in A^{\circ\circ}$. Then R is a ring, and we have a unique ring homomorphism $f : R \to A$ that restricts to the inclusion map on $A^{\circ\circ}$. The integral closure B of the image of f is the smallest ring of integral elements of A. On the other hand, A° is the largest subring of integral elements of A.

Proposition 15.4.3. (i) *The functor* Γ *of remark* 15.4.2(ii) *admits a left adjoint :*

$$\mathsf{Spec} : \mathsf{q.Afd.Ring} \to \mathsf{q.Afd.Sch}^o \qquad (A, A^+, U) \mapsto (U, \mathscr{T}_U, A_U^+)$$

(ii) *If* $f : \underline{A} \to \underline{B}$ *is an f-adic morphism of quasi-affinoid rings, then* $\mathsf{Spec}(f) : \mathsf{Spec}(\underline{B}) \to \mathsf{Spec}(\underline{A})$ *is an f-adic morphism of quasi-affinoid rings.*

(iii) *The functor* Spec *is not fully faithful, but it restricts to an equivalence of categories*

$$\mathsf{Spec} : \mathsf{Afd.Ring} \to \mathsf{Afd.Sch}^o.$$

Proof. (i): For a quasi-affinoid ring $\underline{A} := (A, A^+, U)$, we let $\mathscr{T}_U$ be the f-adic topology on $A_U := \mathscr{O}_U(U)$ provided by proposition 8.3.30(i), and let A_U^+ be the integral closure of A^+ in A_U. Indeed, notice that the restriction map $A \to A_U$ sends A° into A_U° (lemma 8.3.24(iii.a)); since $A^+ \subset A^\circ$, remark 8.3.10(iii) easily implies that $A_U^+ \subset A_U^\circ$. Next, let $\overline{A} := \mathrm{Im}(A \to A_U)$ and endow $\overline{A}$ with the topology induced by A_U via the open inclusion map $\overline{A} \to A_U$; since $A^{\circ\circ}$ is an open subgroup of A, for every $s \in A_U^{\circ\circ}$ we may find $n \in \mathbb{N}$ and $t \in A^{\circ\circ}$ such that s^n equals the image of t in $\overline{A}$. Notice that t annihilates the kernel of the projection $\pi : A \to \overline{A}$, so $\mathrm{Spec}\,\pi$ restricts to an isomorphism of schemes $\mathrm{Spec}\,\overline{A}[s^{-n}] \xrightarrow{\sim} \mathrm{Spec}\, A[t^{-1}] \subset U$. It follows that

$$U \times_{\mathrm{Spec}\, A_U} \mathrm{Spec}\, A_U[s^{-1}] = U \times_{\mathrm{Spec}\, A} \mathrm{Spec}\, A[t^{-1}] = \mathrm{Spec}\, A[t^{-1}]$$

so the construction of $\mathsf{Spec}(\underline{A})$ is achieved. Next, let $f : \underline{A} \to \underline{B} := (B, B^+, V)$ be any morphism of quasi-affinoid rings; set $(V, \mathscr{T}_V, B_V^+) := \mathsf{Spec}(\underline{B})$ and denote by $\overline{B}$ the image of B in $B_V := \mathscr{O}_V(V)$. We deduce easily from proposition 8.3.30(i) that (a) the subrings $\overline{A}$ and $\overline{B}$ are open in A_U and B_V, so the induced map $\varphi : A_U \to B_V$ is continuous if and only the same holds for its restriction $\overline{f} : \overline{A} \to \overline{B}$, and (b) the topologies of $\overline{A}$ and $\overline{B}$ are induced from the surjections $A \to \overline{A}$ and $B \to \overline{B}$, so the continuity of $\overline{f}$ follows from that of f. Thus, φ is continuous, and clearly $\varphi(A_U^+) \subset B_V^+$, so $\varphi : \mathsf{Spec}(\underline{B}) \to \mathsf{Spec}(\underline{A})$ is a well defined morphism of quasi-affinoid schemes, and we let $\mathsf{Spec}(f) := \varphi$.

Now, a simple inspection shows that $\mathsf{Spec} \circ \Gamma$ is the identity automorphism of the category $\mathsf{q.Afd.Sch}^o$; on the other hand, for every quasi-affinoid ring $\underline{A} := (A, A^+, U)$, the restriction map $A \to A_U$ determines a natural morphism $\eta_{\underline{A}} : \underline{A} \to \Gamma \circ \mathsf{Spec}(\underline{A})$. Lastly, it is easily seen that the pair of natural transformations $(\varepsilon := \mathbf{1}_{\mathsf{Spec}\circ\Gamma}, \eta)$ fulfills the triangular identities of (1.1.13), so the assertion follows from proposition 1.1.15(i).

(ii): Indeed, set $A_U := \mathscr{O}_U(U)$ and $B_V := \mathscr{O}_V(V)$; by assumption there exist open and bounded subrings $A_0 \subset A$ and $B_0 \subset B$ such that $f(A_0) \subset B_0$, and f restricts to an adic ring homomorphism $A_0 \to B_0$. Then, let $\overline{A}_0$ be the image of A_0 in A_U, and define likewise $\overline{B}_0 \subset B_V$; we know that $\overline{A}_0$ and $\overline{B}_0$ are open and bounded subrings of A_U and respectively B_V, for the topologies induced by the latter topological rings, and the image of every ideal of adic definition of A_0 (resp. of B_0) is an ideal of adic definition of $\overline{A}_0$ (resp. of $\overline{B}_0$) (proposition 8.3.30(i)). It follows easily that the continuous map $A_U \to B_V$ restricts to an adic ring homomorphism $\overline{A}_0 \to \overline{B}_0$, whence the contention.

(iii) follows easily from the definitions. □

Example 15.4.4. Let $\underline{X} := (X, \mathscr{T}_X, A^+_X)$ be any quasi-affinoid scheme, set $A_X := \mathscr{O}_X(X)$, and let $U \subset X$ be any quasi-compact open subset containing the analytic locus of $\mathrm{Spec}\, A_X$. Let us denote by F_U the presheaf on the category $\mathsf{q.Afd.Sch}$ such that

$$F_U(\underline{Z}) := \{\varphi : \underline{Z} \to \underline{X} \mid \varphi(Z) \subset U\} \qquad \text{for every quasi-affinoid scheme } \underline{Z} := (Z, \mathscr{T}_Z, A^+_Z)$$

so that F_U is a sub-presheaf of the presheaf $h_{\underline{X}}$ represented by $\underline{X}$. Let $\underline{A}$ be the quasi-affinoid ring (A_X, A^+_X, U); we claim that F_U is representable by the quasi-affinoid scheme

$$U \times_X \underline{X} := \mathsf{Spec}\, \underline{A}.$$

Indeed, the identity map of A_X yields a morphism of quasi-affinoid rings $i : \Gamma(\underline{X}) \to \underline{A}$; now, for every quasi-affinoid scheme $\underline{Z} := (Z, \mathscr{T}_Z, A^+_Z)$, the datum of a morphism $\psi : \underline{Z} \to U \times_X \underline{X}$ of quasi-affinoid schemes is equivalent, by adjunction, to that of a morphism $g : \underline{A} \to \Gamma(\underline{Z})$ of quasi-affinoid rings, and the composition $f := g \circ i : \Gamma(\underline{X}) \to \Gamma(\underline{Z})$ is a morphism such that $\mathrm{Spec}(f)(Z) \subset U$, whence the morphism $\varphi := \mathsf{Spec}(f) : \underline{Z} \to \underline{X}$ with $\varphi(Z) \subset U$. Conversely, any morphism $\varphi : \underline{Z} \to \underline{X}$ with $\varphi(Z) \subset U$ yields a morphism $\Gamma(\varphi) : \Gamma(\underline{X}) \to \Gamma(\underline{Z})$ that factors uniquely through $\underline{A}$, whence the contention.

Example 15.4.5. (i) Consider two f-adic morphisms of affinoid rings

$$\underline{B}' := (B', B'^+) \xleftarrow{g} \underline{B} := (B, B^+) \xrightarrow{f} \underline{A} := (A, A^+)$$

and endow $A' := B' \otimes_B A$ with the f-adic topology $\mathscr{T}_{A'}$ characterized by proposition 8.3.34(i), so that the natural maps $f' : B' \to A'$ and $g_A : A \to A'$ are both f-adic. Let also $R \subset A'$ be the image of $B'^+ \otimes_{B^+} A^+$, and denote by A'^+ the integral closure of R in A'. Then the datum

$$\underline{B}' \otimes_{\underline{B}} \underline{A} := (A', A'^+)$$

is an affinoid ring. Indeed, a simple inspection of the definition of $\mathscr{T}_{A'}$ shows that R is open in A', and we have $g_A(A^+), f(B^+) \subset A'^\circ$ by lemma 8.3.24(iii), so also $R \subset A'^\circ$, and then $A'^+ \subset A'^\circ$ as well, by remark 8.3.10(iv).

(ii) In the situation of (i), let also $U_B \subset X_B := \mathrm{Spec}\, B$, $U_A \subset X_A := \mathrm{Spec}\, A$ and $U_{B'} \subset X_{B'} := \mathrm{Spec}\, B'$ be three open subsets, such that f and g are morphisms of quasi-affinoid rings

$$(\underline{B}', U_{B'}) \xleftarrow{g} (\underline{B}, U_B) \xrightarrow{f} (\underline{A}, U_A)$$

and set $U_{A'} := U_{B'} \times_{U_B} U_A$. Then the datum

$$(\underline{B}', U_{B'}) \otimes_{(\underline{B}, U_B)} (\underline{A}, U_A) := (\underline{B}' \otimes_{\underline{B}} \underline{A}, U_{A'})$$

is a quasi-affinoid ring as well. Indeed, let $B_0 \subset B$ be a ring of definition, and $I_0 \subset B_0$ an ideal of adic definition; we need to show that $\mathrm{Spec}\, A' \setminus \mathrm{Spec}\, A'/I_0A' \subset U_{A'}$. Set $Z_{B'} := X_{B'} \setminus U_{B'}$ and $Z_A := X_A \setminus U_A$; the assertion is equivalent to $(Z_{B'} \times_{X_B} X_A) \cup (X_{B'} \times_{X_B} Z_A) \subset \mathrm{Spec}\, A'/I_0A'$. The latter is clear, since by assumption $Z_{B'} \subset \mathrm{Spec}\, B'/I_0B'$ and $Z_A \subset \mathrm{Spec}\, A/I_0A$.

Lemma 15.4.6. *With the notation of example* 15.4.5*, the resulting commutative diagrams*

$$\begin{array}{ccc} \underline{B} & \xrightarrow{\ f\ } & \underline{A} \\ {\scriptstyle g}\big\downarrow & & \big\downarrow{\scriptstyle g_A} \\ \underline{B}' & \xrightarrow{\ f'\ } & \underline{B}'\otimes_{\underline{B}}\underline{A} \end{array} \qquad\qquad \begin{array}{ccc} (\underline{B},U_B) & \xrightarrow{\qquad f\qquad} & (\underline{A},U_A) \\ {\scriptstyle g}\big\downarrow & & \big\downarrow{\scriptstyle g_A} \\ (\underline{B}',U_{B'}) & \xrightarrow{\ f'\ } & (\underline{B}',U_{B'})\otimes_{(\underline{B},U_B)}(\underline{A},U_A) \end{array}$$

are cocartesian in the categories $\mathsf{Afd.Ring}$ *and respectively* $\mathsf{q.Afd.Ring}$.

Proof. Indeed, consider any two morphisms $h:(A,A^+)\to(C,C^+)$, $k:(B,B^+)\to(C,C^+)$ of affinoid rings such that $h\circ f=k\circ g$; by proposition 8.3.34(i) there exists a unique continuous ring homomorphism $l:A'\to C$ such that $l\circ g_A=h$ and $l\circ f'=k$, and it is easily seen that $l(A'^+)\subset C^+$, *i.e.* $l:(A',A'^+)\to(C,C^+)$ is a morphism of affinoid rings, whence the assertion for the left diagram. The assertion for the right diagram is an immediate consequence. $\square$

Example 15.4.7. Consider a quasi-affinoid ring $\underline{A}:=(A,A^+)$ and any two f-adic morphisms $f:B\to A$, $g:B\to B'$ of f-adic rings.

(i) As a special case of example 15.4.5(i), take for B^+ and B'^+ the smallest subrings of integral elements of B and respectively B' (see remark 15.4.2(iv)) and set $\underline{B}:=(B,B^+)$ and $\underline{B}':=(B',B'^+)$; we may regard f and g as morphisms $\underline{B}\to\underline{A}$ and $\underline{B}\to\underline{B}'$ respectively. The resulting tensor product $\underline{B}'\otimes_{\underline{B}}\underline{A}$ shall be simply denoted

$$B'\otimes_B\underline{A}.$$

By lemma 15.4.6, the resulting morphisms $\underline{A}\xrightarrow{g_A}B'\otimes_B\underline{A}\xleftarrow{f'}\underline{B}'$ enjoy the following universal property. Let (h,k) be any pair consisting of a morphism $h:\underline{A}\to(C,C^+)$ of affinoid rings, and a continuous ring homomorphism $k:B'\to C$ such that $h\circ f=k\circ g$; then there exists a unique morphism $l:B'\otimes_B\underline{A}\to(C,C^+)$ of affinoid rings such that $l\circ g_A=h$ and $l\circ f'=k$.

(ii) Likewise, let $(\underline{A},U)$ be a quasi-affinoid ring. As a special case of example 15.4.5(ii), we may define $\underline{B}$ and $\underline{B}'$ as in (i), and take $U_B:=\operatorname{Spec}B$, $U_{B'}:=\operatorname{Spec}B'$. There follow morphisms of quasi-affinoid rings $f:(\underline{B},U_B)\to(\underline{A},U)$ and $f:(\underline{B},U_B)\to(\underline{B}',U_{B'})$. The resulting tensor product $(B'\otimes_B\underline{A},U_{B'})$ will be denoted simply

$$B'\otimes_B(\underline{A},U)$$

and notice that $U_{B'}=\operatorname{Spec}A'\times_{\operatorname{Spec}A}U$. It follows easily from lemma 8.3.29(iv) that this quasi-affinoid ring enjoys the corresponding universal property as in (i). Namely, let (h,k) be any pair consisting of a morphism $h:(\underline{A},U)\to(C,C^+,V)$ of quasi-affinoid rings, and $k:B'\to C$ a continuous ring homomorphism such that $h\circ f=k\circ g$; then there exists a unique morphism $l:B'\otimes_B(\underline{A},U)\to(C,C^+,V)$ of quasi-affinoid rings such that $l\circ g_A=h$ and $l\circ f'=k$.

Example 15.4.8. Let $\underline{Y}\to\underline{X}$ and $\underline{Y}'\to\underline{X}$ be two f-adic morphisms of quasi-affinoid schemes. Then the fibre product $\underline{Y}\times_{\underline{X}}\underline{Y}'$ is representable in the category $\mathsf{q.Afd.Sch}$. Indeed, the induced morphisms of quasi-affinoid rings $\Gamma(\underline{X})\to\Gamma(\underline{Y})$ and $\Gamma(\underline{X})\to\Gamma(\underline{Y}')$ are f-adic, hence we may form the tensor product $\underline{A}:=\Gamma(\underline{Y})\otimes_{\Gamma(\underline{X})}\Gamma(\underline{Y}')$ as in example 15.4.5(ii), and in view of lemma 15.4.6, the quasi-affinoid scheme $\mathsf{Spec}\,\underline{A}$ represents the sought fibre product (details left to the reader).

Example 15.4.9. (i) Let (A,A^+) be an affinoid ring and B a finite A-algebra. According to remark 8.3.43(iii), the canonical topology $\mathscr{T}_B^A$ on B is f-adic, and the structure map $\varphi:A\to B$ is f-adic and restricts to a finite map $A_0\to B_0$ of suitable subrings of definition. Let B^+ be the integral closure of $\varphi(A^+)$ in B. We claim that B^+ is a ring of integral elements of B. Indeed, $B^+\subset B^\circ$ by lemma 8.3.24(iii.a) and remark 8.3.10(iv). To check that B^+ is open in B, pick a finite system $b_1,\dots,b_n$ of generators of the A_0-module B_0; for every $i=1,\dots,n$ there exist $m_i\in\mathbb{N}$ and a polynomial $P_i=X^{m_i}+\sum_{j=0}^{m_i-1}a_{ij}X^j\in A_0[X]$ with $P_i(b_i)=0$. Let $I_0\subset A_0$

be an ideal of adic definition; since A^+ is open, there exists $k \in \mathbb{N}$ such that $I_0^k a_{ij} \in A^+$ for $i = 1, \dots, n$ and $j = 0, \dots, m_i - 1$. Thus, for every $c \in I_0^k$ and $i = 1, \dots, n$ we have

$$0 = c^{m_i} P_i(b_i) = Q_i(cb_i) \qquad \text{where } Q_i := X^{m_i} + \sum_{j=0}^{m_i-1} c^{m_i - j} a_{ij} X^j \in A^+[X].$$

This shows that $I_0^k B_0 \subset B^+$, whence the contention. We call (B, B^+) *the affinoid ring associated with the finite A-algebra B*, and we denote it by

$$B \otimes_A (A, A^+).$$

(ii) Thus, we get an f-adic morphism $\varphi : (A, A^+) \to B \otimes_A (A, A^+)$ of affinoid rings. We claim that the morphism of affinoid rings φ enjoys the following universal property. For every morphism $f : (A, A^+) \to (C, C^+)$ of affinoid rings, every ring homomorphism $g : B \to C$ such that $g \circ \varphi = f$ is a morphism $g : (B, B^+) \to (C, C^+)$ of affinoid rings. Indeed, a simple inspection shows that $g(B^+) \subset C^+$, and g is continuous by virtue of proposition 8.3.41(ii).

(iii) As usual, the universal property determines the pair $(B \otimes_A (A, A^+), \varphi)$ up to unique isomorphism of affinoid rings. Especially, if $\psi : B \to B'$ is any finite ring homomorphism, then $\psi \circ \varphi : A \to B'$ is also finite, and it follows easily that

$$B' \otimes_B (B \otimes_A (A, A^+)) = B' \otimes_A (A, A^+).$$

(iv) Likewise, if $\underline{A} := (A, A^+, U)$ is any quasi-affinoid ring, and $\varphi : A \to B$ is as in (i), let us set $U_B := \mathrm{Spec}\, B \times_{\mathrm{Spec}\, A} U$. According to example 15.4.7(ii) we get a quasi-affinoid ring

$$B \otimes_A \underline{A} := (B, B^+, U_B)$$

(for the topology $\mathscr{T}_B^A$ on B) and φ is an f-adic morphism of quasi-affinoid rings $\underline{A} \to B \otimes_A \underline{A}$ enjoying a corresponding universal property that the reader may spell out.

(v) In the same vein, let $\underline{X} := (X, \mathscr{T}_X, A_X^+)$ be a quasi-affinoid scheme and $f : X' \to X$ a finite morphism of schemes; set $A_X := \mathscr{O}_X(X)$, $Y := \mathrm{Spec}\, A_X$ and let $i : X \to Y$ be the open immersion and $g := i \circ f : X' \to Y$. We have natural morphisms of quasi-coherent $\mathscr{O}_Y$-algebras $i^\flat : \mathscr{O}_Y \to i_*\mathscr{O}_X$ and $g^\flat : i_*\mathscr{O}_X \to g_*\mathscr{O}_{X'}$, and we let $\mathscr{A}$ be the integral closure of the image of $i_*\mathscr{O}_X$ in $g_*\mathscr{O}_{X'}$. Notice that $i^\flat$ is an isomorphism, and $\mathscr{A}$ is a quasi-coherent $\mathscr{O}_Y$-algebra; hence $\mathscr{A}$ is the filtered union of its finite quasi-coherent $\mathscr{O}_Y$-subalgebras. Clearly $\mathscr{A}_{|X} = f_*\mathscr{O}_{X'}$ is a finite $\mathscr{O}_X$-algebra; since X is quasi-compact, it follows that there exists a finite quasi-coherent $\mathscr{O}_Y$-subalgebra $\mathscr{B} \subset \mathscr{A}$ such that $\mathscr{B}_{|X} = f_*\mathscr{O}_{X'}$, and $B := \mathscr{B}(Y)$ is a finite A_X-algebra. We claim that the quasi-affinoid scheme

$$X' \times_X \underline{X} := \mathsf{Spec}\,(B \otimes_{A_X} \Gamma(\underline{X})).$$

is independent, up to unique isomorphism, of the choice of $\mathscr{B}$ and enjoys the following universal property. For every morphism of quasi-affinoid schemes $h : \underline{Z} := (Z, \mathscr{T}_Z, A_Z^+) \to \underline{X}$, every morphism $k : Z \to X'$ of schemes such that $f \circ k = h$ is a morphism of quasi-affinoid schemes $\underline{Z} \to X' \times_X \underline{X}$. Indeed notice that, by construction, the commutative diagram of schemes

$$\begin{array}{ccc} X' & \xrightarrow{\ j\ } & \mathrm{Spec}\, B \\ {\scriptstyle f}\big\downarrow & & \big\downarrow \\ X & \xrightarrow{\ i\ } & Y \end{array}$$

is cartesian, hence X' is the scheme underlying $X' \times_X \underline{X}$. The morphisms k and j induce homomorphisms of A_X-algebras $\mathscr{O}_{X'} \to \mathscr{O}_Z(Z)$ and $B \to \mathscr{O}_{X'}$; their composition is a homomorphism of A_X-algebras $u : B \to \mathscr{O}_Z(Z)$, and since $\mathscr{O}_Z(Z)$ is a topological $(A_X, \mathscr{T}_X)$-algebra, (iv) implies that u is a morphism of quasi-affinoid rings $B \otimes_{A_X} \Gamma(\underline{X}) \to \Gamma(\underline{Z})$. By adjunction, u induces a morphism of quasi-affinoid schemes $\underline{Z} \to X' \times_X \underline{X}$, and a simple inspection shows that this morphism is precisely given by k. Then the universal property implies as usual the stated independence of the choice of $\mathscr{B}$. By the same token, we also deduce that if $X'' \to X'$ is another finite morphism of schemes, we have a natural identification of quasi-affinoid schemes

$$X'' \times_{X'} (X' \times_X \underline{X}) \xrightarrow{\sim} X'' \times_X \underline{X}$$

(details left to the reader). Lastly, notice that the induced projection $X' \times_X \underline{X} \to \underline{X}$ is f-adic, by proposition 15.4.3(ii).

(vi) In the situation of (i) (resp. of (iv), resp. of (v)), suppose that (A, A^+) (resp. $\underline{A}$, resp. $\underline{X}$) is topologically henselian; combining with proposition 8.4.2(iv) we deduce that the same holds for $B \otimes_A (A, A^+)$ (resp. for $B \otimes_A \underline{A}$, resp. for $X' \times_X \underline{X}$).

Remark 15.4.10. (i) Denote by $\mathsf{Afd.Ring}_{\mathrm{comp}}$ (resp. $\mathsf{q.Afd.Ring}_{\mathrm{comp}}$) the full subcategory of $\mathsf{Afd.Ring}$ (resp. of $\mathsf{q.Afd.Ring}$) whose objects are the complete and separated affinoid (resp. quasi-affinoid) rings. Then the inclusion functor

$$\mathsf{Afd.Ring}_{\mathrm{comp}} \to \mathsf{Afd.Ring} \qquad (\text{resp. } \mathsf{q.Afd.Ring}_{\mathrm{comp}} \to \mathsf{q.Afd.Ring})$$

admits a left adjoint, that assigns to every affinoid ring (A, A^+) (resp. quasi-affinoid ring (A, A^+, U)) its *completion*, which is the datum

$$(A, A^+)^\wedge := (A^\wedge, (A^+)^\wedge) \qquad (\text{resp. } (A, A^+, U)^\wedge := (A^\wedge, (A^+)^\wedge, U^\wedge))$$

consisting of the separated completions of A and A^+ (resp. and of the open subset $U^\wedge := U \times_{\mathrm{Spec}\, A} \mathrm{Spec}\, A^\wedge$). Indeed, taking into account proposition 8.3.33(i,iii) and lemma 8.3.6 we see that $(A, A^+)^\wedge = A^\wedge \otimes_A (A, A^+)$ and $(A, A^+, U)^\wedge = A^\wedge \otimes_A (A, A^+, U)$, so the sought adjunctions follow from example 15.4.7(i,ii).

(ii) Let $\mathsf{Afd.Ring}_{\mathrm{hens}}$ (resp. $\mathsf{q.Afd.Ring}_{\mathrm{hens}}$) be the full subcategory of $\mathsf{Afd.Ring}$ (resp. of $\mathsf{q.Afd.Ring}$) whose objects are the topologically henselian affinoid (resp. quasi-affinoid) rings. Then the inclusion functor

$$\mathsf{Afd.Ring}_{\mathrm{hens}} \to \mathsf{Afd.Ring} \qquad (\text{resp. } \mathsf{q.Afd.Ring}_{\mathrm{hens}} \to \mathsf{q.Afd.Ring})$$

admits a left adjoint, that assigns to every affinoid ring (A, A^+) (resp. quasi-affinoid ring (A, A^+, U)) its *topological henselization*, which is the datum

$$(A, A^+)^{\mathrm{h}} := (A^{\mathrm{h}}, A^{+\mathrm{h}}) \qquad (\text{resp. } (A^{\mathrm{h}}, A^{+\mathrm{h}}, U^{\mathrm{h}}))$$

consisting of the topological henselizations of A and A^+ (resp. and of the open subset $U^{\mathrm{h}} := U \times_{\mathrm{Spec}\, A} \mathrm{Spec}\, A^{\mathrm{h}}$: see definition 8.4.13). Indeed, by inspecting the construction of (8.4.9) it is easily seen that $A^{+\mathrm{h}}$ identifies naturally with an open subring of A^{h} contained in $(A^{\mathrm{h}})^\circ$. Moreover, $A^{+\mathrm{h}}$ is integrally closed in A^{h}, by corollary 9.8.6(ii). Hence $(A, A^+)^{\mathrm{h}}$ is a topologically henselian affinoid ring, and theorem 8.4.10(ii) easily implies that every morphism $(A, A^+) \to (B, B^+)$ of affinoid rings with (B, B^+) topologically henselian, factors uniquely through a morphism $(A, A^+)^{\mathrm{h}} \to (B, B^+)$. By the same token, we deduce that

$$(A, A^+)^{\mathrm{h}} = A^{\mathrm{h}} \otimes_A (A, A^+)$$

from which it follows that $(A, A^+, U)^{\mathrm{h}} = A^{\mathrm{h}} \otimes_A (A, A^+, U)$, whence also the second sought adjunction.

(iii) In the same vein, if (A, A^+) (resp. (A, A^+, U)) is any affinoid (resp. quasi-affinoid) ring, we may define its *topological localization* by considering the datum $(A, A^+)_{\mathrm{loc}}$ (resp. $(A, A^+, U)_{\mathrm{loc}}$) consisting of the topological localizations A_{loc} and A^+_{loc} of A and respectively A^+, defined as in (8.4.8) (resp. and of the open subset $U \times_{\mathrm{Spec}\, A} \mathrm{Spec}\, A_{\mathrm{loc}}$). Then it is easily seen that the rule $(A, A^+) \mapsto (A, A^+)_{\mathrm{loc}}$ (resp. $(A, A^+, U) \mapsto (A, A^+, U)_{\mathrm{loc}}$) yields a left adjoint to the inclusion functor

$$\mathsf{Afd.Ring}_{\mathrm{loc}} \to \mathsf{Afd.Ring} \qquad (\text{resp. } \mathsf{q.Afd.Ring}_{\mathrm{loc}} \to \mathsf{q.Afd.Ring})$$

from the full subcategory of Afd.Ring (resp. of q.Afd.Ring) whose objects are the topologically local affinoid (resp. quasi-affinoid) rings. Notice also that $(A, A^+)_{\mathrm{loc}} = A_{\mathrm{loc}} \otimes_A (A, A^+)$, and likewise for $(A, A^+, U)_{\mathrm{loc}}$.

(iv) Let $\underline{X}$ be any quasi-affinoid scheme; by definition, $\underline{X}$ is topologically local (resp. topologically henselian) if and only if the same holds for the quasi-affinoid ring $\Gamma(\underline{X})$. On the other hand, let $\underline{A} := (A, A^+, U)$ be any quasi-affinoid ring; then $\underline{A}$ is topologically local (resp. topologically henselian) if and only if the same holds for the quasi-affinoid scheme $\mathsf{Spec}\, \underline{A}$ (notation of proposition 15.4.3). Indeed, set $A_U := \mathscr{O}_U(U)$, and recall that the image B of A in A_U is open in the f-adic topology $\mathscr{T}_U$ of A_U (proposition 8.3.30(i)). In light of proposition 8.4.2(i,iii), we are then reduced to showing that A is topologically local (resp. topologically henselian) if and only if the same holds for B, where the latter is endowed with the f-adic topology induced by the inclusion map into A_U, which is the same as the topology induced by A via the surjection $\pi : A \to B$. Let U_A and U_B be the analytic loci of $\mathrm{Spec}\, A$ and respectively $\mathrm{Spec}\, B$; since U contains U_A, it is easily seen that $\mathrm{Spec}\, \pi$ induces a homeomorphism $U_B \xrightarrow{\sim} U_A$ (details left to the reader). On the other hand, notice that $B^{\circ\circ}$ is the radical of the ideal $A^{\circ\circ}B$; then the assertion follows from claim 8.4.4 and [75, Rem.5.1.10(i)].

(v) For every quasi-affinoid scheme $\underline{X}$, set

$$\underline{X}_{\mathrm{loc}} := \mathsf{Spec}(\Gamma(\underline{X})_{\mathrm{loc}}) \qquad \underline{X}^{\mathrm{h}} := \mathsf{Spec}(\Gamma(\underline{X})^{\mathrm{h}}).$$

It follows easily from (iii),(iv), remark 15.4.2(ii) and proposition 15.4.3(i) that $\underline{X}_{\mathrm{loc}}$ is a topologically local quasi-affinoid scheme endowed with a natural morphism $j_{\underline{X}} : \underline{X}_{\mathrm{loc}} \to \underline{X}$ with the following property. Every morphism of quasi-affinoid schemes $\underline{Y} \to \underline{X}$ with $\underline{Y}$ topologically local, factors uniquely through $j_{\underline{X}}$. In other words, the rule $\underline{X} \mapsto \underline{X}_{\mathrm{loc}}$ yields a right adjoint

$$\mathsf{q.Afd.Sch} \to \mathsf{q.Afd.Sch}_{\mathrm{loc}}$$

to the inclusion functor of the full subcategory $\mathsf{q.Afd.Sch}_{\mathrm{loc}}$ of topologically local quasi-affinoid schemes. Likewise, $\underline{X}^{\mathrm{h}}$ is a topologically henselian quasi-affinoid scheme endowed with a universal morphism $h_{\underline{X}} : \underline{X}^{\mathrm{h}} \to \underline{X}$, so the rule $\underline{X} \mapsto \underline{X}^{\mathrm{h}}$ yields a right adjoint

$$\mathsf{q.Afd.Sch} \to \mathsf{q.Afd.Sch}_{\mathrm{hens}}$$

to the inclusion functor of the full subcategory $\mathsf{q.Afd.Sch}_{\mathrm{hens}}$ of topologically henselian quasi-affinoid schemes.

(vi) From (iv), we deduce that the adjunction (Spec, Γ) of proposition 15.4.3(i) restricts to two adjoint pairs of functors

$$\mathsf{q.Afd.Ring}_{\mathrm{loc}} \underset{\Gamma}{\overset{\mathsf{Spec}}{\rightleftarrows}} \mathsf{q.Afd.Sch}^o_{\mathrm{loc}} \qquad \mathsf{q.Afd.Ring}_{\mathrm{hens}} \underset{\Gamma}{\overset{\mathsf{Spec}}{\rightleftarrows}} \mathsf{q.Afd.Sch}^o_{\mathrm{hens}}.$$

Taking into account (v) and remark 1.1.17(i), we then obtain natural isomorphisms

$$\mathsf{Spec}(\underline{A}_{\mathrm{loc}}) \xrightarrow{\sim} (\mathsf{Spec}\, \underline{A})_{\mathrm{loc}} \qquad \mathsf{Spec}(\underline{A}_{\mathrm{hens}}) \xrightarrow{\sim} (\mathsf{Spec}\, \underline{A})_{\mathrm{hens}}$$

of quasi-affinoid schemes, for every quasi-affinoid ring $\underline{A}$. On the other hand, we have as well natural identifications

$$\Gamma(\underline{X}_{\mathrm{loc}}) \xrightarrow{\sim} \Gamma(\underline{X})_{\mathrm{loc}} \qquad \Gamma(\underline{X}^{\mathrm{h}}) \xrightarrow{\sim} \Gamma(\underline{X})^{\mathrm{h}} \tag{15.4.11}$$

for every quasi-affinoid scheme $\underline{X}$. Indeed, if $\Gamma(\underline{X}) = (A, A^+, U)$, we have $\Gamma(\underline{X})_{\mathrm{loc}} = (A_{\mathrm{loc}}, A^+_{\mathrm{loc}}, U_{\mathrm{loc}})$, where $U_{\mathrm{loc}} = U \times_{\mathrm{Spec}\, A} \mathrm{Spec}\, A_{\mathrm{loc}}$. Therefore $\Gamma(\underline{X}_{\mathrm{loc}}) = (B, B^+, U_{\mathrm{loc}})$, where $B := \mathscr{O}_{U_{\mathrm{loc}}}(U_{\mathrm{loc}})$, and with B^+ equal to the integral closure of A^+_{loc} in B. Since the localization map is flat, and since $A = \mathscr{O}_U(U)$, the assertion for $\Gamma(\underline{X}_{\mathrm{loc}})$ then follows from corollary 10.3.8. The same argument applies to $\Gamma(\underline{X}^{\mathrm{h}})$.

(vii) On the other hand, if $\underline{A} := (A, A^+, U)$ is a complete and separated quasi-affinoid ring, the quasi-affinoid scheme $\mathsf{Spec}\, \underline{A}$ is not necessarily complete and separated (essentially, this is because the completion map $A \to A^\wedge$ is not necessarily flat, in this generality). Thus, in order to produce a completion functor for quasi-affinoid schemes, we have to proceed more carefully, as explained in the following proposition.

Proposition 15.4.12. *Let* $\mathsf{q.Afd.Sch}_{\mathrm{comp}}$ *be the full subcategory of* $\mathsf{q.Afd.Sch}$ *whose objects are the complete and separated quasi-affinoid schemes* $(X, \mathscr{T}_X, A^+_X)$*. Then the inclusion functor*

$$\mathsf{q.Afd.Sch}_{\mathrm{comp}} \to \mathsf{q.Afd.Sch}$$

admits a right adjoint, called the completion functor *:*

$$\mathsf{q.Afd.Sch} \to \mathsf{q.Afd.Sch}_{\mathrm{comp}} \qquad (X, \mathscr{T}_X, A^+_X) \mapsto (X, \mathscr{T}_X, A^+_X)^\wedge.$$

Proof. For any given quasi-affinoid scheme $(X, \mathscr{T}_X, A^+_X)$, set $A_X := \mathscr{O}_X(X)$, and denote by $(A^\wedge_X, \mathscr{T}^\wedge_X)$ the completion of $(A_X, \mathscr{T}_X)$. For every ideal $I \subset A^\wedge_X$, set as well

$$V(I) := \mathrm{Spec}\, A^\wedge_X/I \qquad \text{and} \qquad X^\wedge_I := X \times_{\mathrm{Spec}\, A_X} V(I).$$

We let $\mathscr{F}$ be the family of all topologically closed ideals $I \subset A^\wedge_X$ such that the induced map $\rho_I : A^\wedge_X/I \to \mathscr{O}_{V(I)}(X^\wedge_I)$ is injective. Set $J := \bigcap_{I \in \mathscr{F}} I$, so that the natural map $i : A^\wedge_X/J \to \prod_{I \in \mathscr{F}} A^\wedge_X/I$ is injective, and notice that $(\prod_{I \in \mathscr{F}} \rho_I) \circ i$ factors naturally through ρ_J, therefore the latter is injective, and thus $J \in \mathscr{F}$. We endow $A' := A^\wedge_X/J$ with the quotient topology induced by the projection $\pi : A^\wedge_X \to A'$; it is clear that A' is a complete and separated f-adic ring, and π is f-adic (lemma 8.3.24(iv)), so we may define

$$(X, \mathscr{T}_X, A^+_X)^\wedge := \mathsf{Spec}\,(A' \otimes_{A^\wedge_X} (A_X, A^+_X, X)^\wedge).$$

Since the restriction map $A' \to A'_X := \mathscr{O}_{V(J)}(X^\wedge_J)$ is injective and open, the topology of A'_X is complete and separated, so the datum $(X, \mathscr{T}_X, A^+_X)^\wedge$ is indeed an object of $\mathsf{q.Afd.Sch}_{\mathrm{comp}}$.

On the other hand, let $(Y, \mathscr{T}_Y, A^+_Y)$ be any complete and separated quasi-affinoid scheme, and $f : (Y, \mathscr{T}_Y, A^+_Y) \to (X, \mathscr{T}_X, A^+_X)$ any morphism of quasi-affinoid schemes; by adjunction, $\Gamma(f)$ factors uniquely through a morphism of complete quasi-affinoid rings

$$\Gamma(f)^\wedge : (A_X, A^+_X, X)^\wedge \to \Gamma(Y, \mathscr{T}_Y, A^+_Y)$$

and we let K be the kernel of the underlying continuous ring homomorphism $h : A^\wedge_X \to A_Y$. Clearly K is a closed ideal of A_X, and $\mathrm{Spec}\, h$ restricts to a morphism of schemes $g : Y \to V(K)$; then, the pair (f, g) determines a unique morphism of X-schemes $Y \to X^\wedge_K$. Therefore, the resulting map $\overline{h} : A^\wedge_X/K \to A_Y$ is injective by construction, and it factors through ρ_K; so ρ_K is injective as well, and thus $K \in \mathscr{F}$. Hence, h factors uniquely through a continuous ring homomorphism $A' \to A_Y$, so in turns $\Gamma(f)^\wedge$ factors uniquely through a morphism of quasi-affinoid rings

$$\varphi : A' \otimes_{A_X} (A_X, A^+_X, X)^\wedge \to \Gamma(Y, \mathscr{T}_Y, A^+_Y).$$

and $\mathsf{Spec}(\varphi) : (Y, \mathscr{T}_Y, A^+_Y) \to (X, \mathscr{T}_X, A^+_X)^\wedge$ is the unique morphism of complete quasi-affinoid schemes that lifts f, whence the proposition. □

Remark 15.4.13. (i) Let $\underline{X} := (X, \mathscr{T}_X, A^+_X)$ be any quasi-affinoid scheme, set $(A_X, A^+_X, X) := \Gamma(\underline{X})$, and let $A^\wedge_X$ be the separated completion of A_X. Let also $I \subset A_X$ be any finitely generated ideal such that $\mathrm{Spec}\, A_X/I = \mathrm{Spec}\, A_X \setminus X$. By inspecting the proof of proposition 15.4.12 we obtain a natural morphism of quasi-affinoid schemes

$$\underline{X}^\wedge \to \mathsf{Spec}(\Gamma(\underline{X})^\wedge)$$

which is an isomorphism if and only if $\mathrm{depth}_I A^\wedge_X > 0$ (notation of (10.4.29)).

(ii) The morphism of (i) induces by adjunction a morphism of quasi-affinoid rings

$$\Gamma(\underline{X})^\wedge \to \Gamma(\underline{X}^\wedge)$$

which is an isomorphism if and only if $\mathrm{depth}_I A^\wedge_X > 1$.

Definition 15.4.14. Let $\underline{A} := (A, A^+, U)$ be any quasi-affinoid ring, and $\underline{X} := (X, \mathscr{T}_X, A^+_X)$ any quasi-affinoid scheme.

(i) The *adic spectrum* of the affinoid ring (A, A^+) is the set

$$\mathrm{Spa}(A, A^+) := \{v \in \mathrm{Cont}(A) \mid v(a) \leq 1 \text{ for every } a \in A^+\}$$

(notation of definition 15.3.12). Hence, $\mathrm{Spa}(A, A^+)$ is a pro-constructible subset of $\mathrm{Cont}(A)$, and we endow $\mathrm{Spa}(A, A^+)$ with the topology induced by $\mathrm{Cont}(A)$. We also let

$$\mathrm{Spa}(A, A^+)_{\mathrm{a}} := \mathrm{Spa}(A, A^+) \cap \mathrm{Cont}(A)_{\mathrm{a}} \qquad \mathrm{Spa}(A, A^+)_{\mathrm{na}} := \mathrm{Spa}(A, A^+) \cap \mathrm{Cont}(A)_{\mathrm{na}}$$

(notation of remark 15.3.13(vi)).

(ii) The *adic spectrum* of $\underline{A}$ is the set

$$\mathrm{Spa}\,\underline{A} := \mathrm{Spa}(A, A^+) \cap \mathrm{Spv}\,U.$$

We endow this subset with the topology induced by $\mathrm{Spa}(A, A^+)$.

(iii) The *adic spectrum* of $\underline{X}$ is the topological space

$$\mathrm{Spa}\,\underline{X} := \mathrm{Spa}\,\Gamma(\underline{X})$$

and we set as well

$$\mathrm{Spa}\,(\underline{X})_{\mathrm{a}} := \mathrm{Spa}\,\Gamma(\underline{X})_{\mathrm{a}} \qquad \text{and} \qquad \mathrm{Spa}\,(\underline{X})_{\mathrm{na}} := \mathrm{Spa}\,\Gamma(\underline{X})_{\mathrm{na}}.$$

(iv) A *rational subset* of $\mathrm{Spa}(A, A^+, U)$ is a subset of the form $R \cap \mathrm{Spa}(A, A^+, U)$, where R is a rational subset of $\mathrm{Cont}(A)$ (see (15.3.16)). Likewise, a *rational subset* of $\mathrm{Spa}\,\underline{X}$ is a subset of the form $R \cap \mathrm{Spa}\,\underline{X}$, where R is a rational subset of $\mathrm{Cont}(\mathscr{O}_X(X), \mathscr{T}_X)$.

Remark 15.4.15. (i) Let $f : (A, A^+) \to (B, B^+)$ be any morphism of affinoid rings. A simple inspection of definition 15.4.14(i) shows that the map $\mathrm{Cont}(f)$ restricts to a continuous map

$$\mathrm{Spa}\,f : \mathrm{Spa}(B, B^+) \to \mathrm{Spa}(A, A^+).$$

(ii) More generally, a morphism $g : (A, A^+, U) \to (B, B^+, V)$ of quasi-affinoid rings induces a continuous map

$$\mathrm{Spa}\,g : \mathrm{Spa}(B, B^+, V) \to \mathrm{Spa}(A, A^+, U)$$

that agrees with the restriction of the map $\mathrm{Spa}(B, B^+) \to \mathrm{Spa}(A, A^+)$ attached to g as in (i).

(iii) Likewise, any morphism $\varphi : (X, \mathscr{T}_X, A^+_X) \to (Y, \mathscr{T}_Y, A^+_Y)$ of quasi-affinoid schemes induces a continuous map

$$\mathrm{Spa}\,\varphi := \mathrm{Spa}\,\Gamma(\varphi) : \mathrm{Spa}(X, \mathscr{T}_X, A^+_X) \to \mathrm{Spa}(Y, \mathscr{T}_Y, A^+_Y).$$

(iv) In light of theorem 15.3.15(i), it is easily seen that $v(x) \leq 1$ for every $x \in A^\circ$ and every $v \in \mathrm{Cont}(A)$ of rank ≤ 1. Especially, the subset of $\mathrm{Spa}(A, A^+, U)$ consisting of rank one valuations is independent of the ring of integral elements A^+.

Example 15.4.16. For any f-adic ring A, let $A' \subset A$ be the smallest subring of integral elements (see remark 15.4.2(iv)). It is easily seen that $\mathrm{Spa}(A, A') = \mathrm{Cont}(A)$. Also, every continuous map $f : A \to B$ of f-adic rings yields a morphism of affinoid rings $f : (A, A') \to (B, B')$, and clearly $\mathrm{Spa}\,\varphi = \mathrm{Cont}(f)$.

(ii) On the other hand, every f-adic map $f : A \to B$ of f-adic rings induces a continuous map $\mathrm{Spa}\,f : \mathrm{Spa}(B, B^\circ) \to \mathrm{Spa}(A, A^\circ)$ (lemma 8.3.24(iii.a)).

Lemma 15.4.17. *Let $\underline{A} := (A, A^+, U)$ be any quasi-affinoid ring.*

(i) *The natural morphisms $\underline{A} \to \underline{A}_{\mathrm{loc}} \to \underline{A}^{\mathrm{h}} \to \underline{A}^\wedge$ (notation of remark 15.4.10(ii,iii)) induce homeomorphisms*

$$\mathrm{Spa}\,\underline{A}^\wedge \xrightarrow{\sim} \mathrm{Spa}\,\underline{A}^{\mathrm{h}} \xrightarrow{\sim} \mathrm{Spa}\,\underline{A}_{\mathrm{loc}} \xrightarrow{\sim} \mathrm{Spa}\,\underline{A}.$$

(ii) *The unit of the adjunction* (Spec, Γ) *of proposition* 15.4.3(i) *induces a homeomorphism*

$$\mathrm{Spa}(\mathsf{Spec}\,\underline{A}) \xrightarrow{\sim} \mathrm{Spa}\,\underline{A}.$$

(iii) *Let* $\underline{X} := (X, \mathscr{T}_X, A^+_X)$ *be any quasi-affinoid scheme, and* $\underline{X}^\wedge$ *the completion of* $\underline{X}$ *(see proposition* 15.4.12*). The completion map* $\underline{X} \to \underline{X}^\wedge$ *induces a homeomorphism*

$$\mathrm{Spa}\,\underline{X}^\wedge \xrightarrow{\sim} \mathrm{Spa}\,\underline{X}.$$

(iv) *Let* $\varphi : \mathrm{Spa}\,\underline{A}^\wedge \xrightarrow{\sim} \mathrm{Spa}\,\underline{A}$ *be the homeomorphism of* (i)*, and* $R \subset \mathrm{Spa}\,\underline{A}^\wedge$ *any rational subset. Then* $\varphi(R)$ *is a rational subset of* $\mathrm{Spa}\,\underline{A}$*.*

Proof. (i): Let A_{loc} (resp. A^{h}) be the topological localization (resp. henselization) of A; from corollary 8.4.15(i) and proposition 15.3.19(iv), we deduce that the natural maps $A \to A_{\mathrm{loc}} \to A^{\mathrm{h}} \to A^\wedge$ induce homeomorphisms

$$\mathrm{Cont}(A^\wedge) \xrightarrow{\sim} \mathrm{Cont}(A^{\mathrm{h}}) \xrightarrow{\sim} \mathrm{Cont}(A_{\mathrm{loc}}) \xrightarrow{\sim} \mathrm{Cont}(A).$$

Moreover, it was already remarked that the localization map induces a natural identification $\underline{A}_{\mathrm{loc}} \xrightarrow{\sim} A_{\mathrm{loc}} \otimes_A (A, A^+)$, and likewise for the topological henselization and the completion of $\underline{A}$; the assertion follows easily (details left to the reader).

(ii): Set $(U, \mathscr{T}_U, A^+_U) := \mathsf{Spec}\,\underline{A}$ and $A_U := \mathscr{O}_U(U)$; the assertion boils down to the following:

Claim 15.4.18. The natural morphism of quasi-affinoid rings $\rho : (A, A^+, U) \to (A_U, A^+_U, U)$ induces a homeomorphism $\mathrm{Spa}\,\rho : \mathrm{Spa}(A_U, A^+_U, U) \xrightarrow{\sim} \mathrm{Spa}(A, A^+, U)$.

Proof of the claim. Let us first check that ρ induces a homeomorphism

$$\mathrm{Cont}(A_U) \cap \mathrm{Spv}\,U \xrightarrow{\sim} \mathrm{Cont}(A) \cap \mathrm{Spv}\,U. \tag{15.4.19}$$

Indeed, since the topology of both of these spaces are induced from the inclusion into $\mathrm{Spv}\,U$, it suffices to check that (15.4.19) is surjective. Hence, let $v : A \to \Gamma_{v\circ}$ be any continuous valuation with support given by a prime ideal $\mathfrak{p} \subset A$, and suppose that $\mathfrak{p} \in U$; then there exists a unique prime ideal $\mathfrak{p}' \subset A_U$ such that $\rho^{-1}\mathfrak{p}' = \mathfrak{p}$. Set $B := A/\mathfrak{p}$ and $C := A_U/\mathfrak{p}'$; the map v factors through a continuous valuation $\overline{v} : B \to \Gamma_{v\circ}$ (for the quotient topology on B induced by the projection $A \to B$) and C is naturally identified with a subring of $\mathrm{Frac}\,B$, so $\overline{v}$ extends uniquely to a valuation $w : C \to \Gamma_{v\circ}$. It remains only to show that w is continuous, for the quotient topology on C induced by the projection $A_U \to C$. By remark 15.3.13(ii) it suffices to prove the continuity of w at the point $0 \in C$; however, ρ is an open map (proposition 8.3.30(i)), so the same holds for the induced injective map $B \to C$, and the assertion follows.

Since A^+_U is the integral closure of the image of A^+ in A_U, the claim is an immediate consequence of the foregoing : details left to the reader. ◊

(iii): Let $A_X := \mathscr{O}_X(X)$, and set $(A^\wedge_X, A^{+\wedge}_X, X^\wedge) := (A_X, A^+_X, X)^\wedge$. Define the family $\mathscr{F}$ of ideals of $A^\wedge_X$ as in the proof of proposition 15.4.12, and denote by J the minimal element of $\mathscr{F}$; also, endow $A' := A^\wedge_X/J$ with the quotient topology induced via the projection $A^\wedge_X \to A'$. Then $\underline{X}^\wedge = \mathsf{Spec}(A' \otimes_{A^\wedge_X} (A^\wedge_X, A^{+\wedge}_X, X^\wedge))$. Taking into account (i) and (ii), we are then reduced to checking that the natural projection $\pi : (A^\wedge_X, A^{+\wedge}_X, X^\wedge) \to A' \otimes_{A^\wedge_X} (A^\wedge_X, A^{+\wedge}_X, X^\wedge)$ induces a homeomorphism

$$\mathrm{Spa}\,\pi : \mathrm{Spa}(A' \otimes_{A^\wedge_X} (A^\wedge_X, A^{+\wedge}_X, X^\wedge)) \xrightarrow{\sim} \mathrm{Spa}(A^\wedge_X, A^{+\wedge}_X, X^\wedge).$$

However, $\mathrm{Spa}\,\pi$ is a closed immersion, so it suffices to show that it is a bijection. To this aim, let $v : A^\wedge_X \to \Gamma_{v\circ}$ be any continuous valuation whose support $\mathfrak{p}$ lies in $X^\wedge$; we come down to checking that $\mathfrak{p} \in \mathscr{F}$. However, $\mathfrak{p}$ is obviously a topologically closed ideal of $A^\wedge_X$. Next, set $B := A^\wedge_X/\mathfrak{p}$ and $X^\wedge_{\mathfrak{p}} := X \times_{\mathrm{Spec}\,A_X} \mathrm{Spec}\,B$; since B is a domain and $X^\wedge_{\mathfrak{p}} \neq \varnothing$, the restriction map $B \to \mathscr{O}_{\mathrm{Spec}\,B}(X^\wedge_{\mathfrak{p}})$ is injective, whence the contention.

(iv): Say that $R = R_{A^\wedge}\big(\frac{a_1}{a_0},\dots,\frac{a_n}{a_0}\big) \cap \mathrm{Spa}\,\underline{A}^\wedge$ for a sequence of elements $a_0,\dots,a_n \in A^\wedge$ that generates an open ideal J. Let also B be a ring of definition of A, and $I \subset B$ an ideal of adic definition. To begin with, we remark :

Claim 15.4.20. (i) Let T be a quasi-compact subset of $\mathrm{Spa}\,\underline{A}$, and t an element of $A^{\circ\circ}$ such that $v(t) \neq 0$ for every $v \in T$. Then there exists $k \in \mathbb{N}$ such that $v(x) < v(t)$ for every $v \in T$ and every $x \in I^k$.

(ii) There exists $q \in \mathbb{N}$ such that every sequence $b_0,\dots,b_n$ with $b_i \in a_i + I^q B^\wedge$ for $i = 0,\dots,n$, generates an open ideal of $A^\wedge$, and $R' := R_{A^\wedge}\big(\frac{b_1}{b_0},\dots,\frac{b_n}{b_0}\big) \cap \mathrm{Spa}\,\underline{A}^\wedge = R$.

Proof of the claim. (i): Let $x_1,\dots,x_m$ be a finite system of generators of I. For every $r \in \mathbb{N}$ set

$$T_r := \{v \in \mathrm{Spa}\,\underline{A} \mid v(x_i^r) \leq v(t) \text{ for every } i = 1,\dots,m\}.$$

Then T_r is open in $\mathrm{Spa}\,\underline{A}$ for every $r \in \mathbb{N}$, and $T \subset \bigcup_{r\in\mathbb{N}} T_r$. Thus, $T \subset T_r$ for some $r \in \mathbb{N}$, and the assertion holds with $k := r + 1$.

(ii): Pick elements $c_1,\dots,c_m \in J \cap B^\wedge$ that generate an open ideal J_0 of $B^\wedge$, and $r \in \mathbb{N}$ such that $I^r \subset J_0$. Then, every sequence $d_1,\dots,d_m$ of elements of $B^\wedge$ with $d_i \in c_i + I^r B^\wedge$ for $i = 1,\dots,m$, also generates J_0 ([126, Th.8.4]). Next, for every $i = 1,\dots,m$ pick $x_{i0},\dots,x_{in} \in A^\wedge$ such that $c_i = \sum_{j=0}^n a_j x_{ij}$, and let $p \in \mathbb{N}$ be large enough so that $I^p x_{ij} \subset I^r B^\wedge$ for every $i = 1,\dots,m$ and every $j = 0,\dots,n$; it follows already that every sequence $b_0,\dots,b_n$ of elements of $A^\wedge$ with $b_i \in a_i + I^p B^\wedge$ for $i = 0,\dots,n$ generates an open ideal of $A^\wedge$.

Next, we apply part (i) of the claim to the rational subsets $R_i := R_{A^\wedge}\big(\frac{a_1}{a_i},\dots,\frac{a_n}{a_i}\big) \cap \mathrm{Spa}\,\underline{A}^\wedge$, to find an integer $q \geq p$ such that $v(x) < v(a_i)$ for every $x \in I^q B^\wedge$, every $i = 0,\dots,n$ and every $v \in R_i$. We claim that this q will do. Indeed, let $v \in \mathrm{Spa}\,\underline{A}^\wedge$, and say that $v \in R = R_0$; since $b_i - a_i \in I^q B^\wedge$, we have $v(b_i - a_i) < v(a_0)$ for $i = 0,\dots,n$. This implies that

$$v(b_i) = v(a_i + (b_i - a_i)) \leq \max(v(a_i), v(b_i - a_i)) \leq v(a_0) = v(a_0 + (b_0 - a_0)) = v(b_0)$$

for every $i = 0,\dots,n$, which shows that $R \subset R'$. Next, suppose $v \notin R$, and consider first the case where $v(a_i) = 0$ for every $i = 0,\dots,n$. Then v is non-analytic, so that $v(b_0 - a_0) = 0$, whence $v(b_0) = 0$, and finally $v \notin R'$. Lastly, suppose that $v(a_i) \neq 0$ for some $i \leq n$, and choose $j \leq n$ so that $v \in R_j$. We must have $v(a_0) < v(a_j)$, since $v \notin R$; also, by construction $v(b_i - a_i) < v(a_j)$ for every $i = 0,\dots,n$. Then

$$v(b_0) = v(a_0 + (b_0 - a_0)) \leq \max(v(a_0), v(b_0 - a_0)) < v(a_j) = v(a_j + (b_j - a_j)) = v(b_j)$$

which yields again $v \notin R'$, and the claim follows. ◊

Now, by claim 15.4.20(ii) there exist $b_0,\dots,b_n$ in A such that $R = R_{A^\wedge}\big(\frac{b_1}{b_0},\dots,\frac{b_n}{b_0}\big) \cap \mathrm{Spa}\,\underline{A}^\wedge$. Also, by claim 15.4.20(i) there exists $k \in \mathbb{N}$ such that $v(x) < v(b_0)$ for every $v \in R$ and every $x \in I^k$. Pick a finite system $b_{n+1},\dots,b_p$ of generators of I^k; it follows that $\varphi(R) = R_A\big(\frac{b_1}{b_0},\dots,\frac{b_p}{b_0}\big)$ whence the contention. □

Remark 15.4.21. By combining lemma 15.4.17(iv) and proposition 15.3.19(i) one may obtain another, more constructive, proof of lemma 15.4.17(i) (and of proposition 15.3.19(iv)). This is the route followed in [99].

Proposition 15.4.22. *Let (A, A^+, U) be any quasi-affinoid ring. The following holds :*

(i) $\mathrm{Spa}(A, A^+, U)$ *is a constructible open subset of* $\mathrm{Spa}(A, A^+)$*, and both these topological spaces are spectral.*

(ii) *The rational subsets are a basis of quasi-compact open subsets of* $\mathrm{Spa}(A, A^+)$ *that is closed under finite intersections.*

(iii) *For any morphism $f : (A, A^+, U) \to (B, B^+, V)$ of quasi-affinoid rings, we have :*

(a) *If f is f-adic,* $\mathrm{Spa}\,f$ *is a spectral map. More precisely, if R is a rational subset of* $\mathrm{Spa}(A, A^+, U)$*, then* $(\mathrm{Spa}\,f)^{-1}(R)$ *is a rational subset of* $\mathrm{Spa}(B, B^+, V)$.

(b) *Suppose that B is topologically local. Then f is f-adic if and only if* $\mathrm{Spa}\, f$ *restricts to a map* $\mathrm{Spa}(B, B^+)_{\mathrm{a}} \to \mathrm{Spa}(A, A^+)_{\mathrm{a}}$.

(iv) *For any quasi-affinoid scheme* $(X, \mathscr{T}_X, A^+_X)$*, the topological space* $\mathrm{Spa}(X, \mathscr{T}_X, A^+_X)$ *is spectral.*

(v) *For any f-adic morphism* $\varphi : (X, \mathscr{T}_X, A^+_X) \to (Y, \mathscr{T}_Y, A^+_Y)$ *of quasi-affinoid schemes, the induced map* $\mathrm{Spa}\,\varphi$ *is spectral.*

Proof. Assertion (i) for $\mathrm{Spa}(A, A^+)$ follows from theorem 15.3.15(ii) and corollary 8.1.42. According to (15.3.16), the rational subsets of $\mathrm{Cont}(A)$ form a basis of quasi-compact open subsets for the latter space; invoking again corollary 8.1.42, we obtain (ii) as well.

Next, let $I \subset A$ be any finitely generated ideal such that $\mathrm{Spec}\, A/I = \mathrm{Spec}\, A \setminus U$, and pick a finite system of generators $a_1, \dots, a_n$ for I. Then

$$\mathrm{Spa}(A, A^+, U) = \mathrm{Spa}(A, A^+) \cap \bigcup_{i=1}^{n} R_A\Big(\frac{a_1}{a_i}, \dots, \frac{a_n}{a_i}\Big).$$

Since I is open in A, this identity presents $\mathrm{Spa}(A, A^+, U)$ as a finite union of rational subsets of $\mathrm{Spa}(A, A^+)$, and the latter are open and quasi-compact, by (ii), so the proof of (i) is complete.

(iii.a) follows immediately from corollary 15.3.17(i). The proofs of (iv) and (v) are similar, and the details shall be left to the reader.

(iii.b): Set $\varphi := \mathrm{Spec}\, f$; in light of lemma 8.3.29(iv) and corollary 15.3.21, we need only check that $\varphi^{-1} X^{\circ\circ}_A = X^{\circ\circ}_B$, if $\mathrm{Spa}\, f$ restricts to a map $\mathrm{Spa}(B, B^+)_{\mathrm{a}} \to \mathrm{Spa}(A, A^+)_{\mathrm{a}}$.

Thus, suppose that there exists $\mathfrak{p} \in X_B \setminus X^{\circ\circ}_B$ with $\varphi(\mathfrak{p}) \in X^{\circ\circ}_A$. Then $\mathfrak{p}$ is a non-open ideal of B, so there exists a rank one continuous analytic valuation v of B whose support contains $\mathfrak{p}$ (lemma 15.3.25); clearly the support of $\mathrm{Cont}(f)(v)$ contains $\varphi(\mathfrak{p})$, and it is therefore open, *i.e.* $\mathrm{Cont}(f)(v) \in \mathrm{Cont}(A)_{\mathrm{na}}$. To conclude it suffices to remark :

Claim 15.4.23. Let R be any f-adic ring, $v \in \mathrm{Cont}(R)_{\mathrm{a}}$ any element such that Γ_v has rank one. Then $v \in \mathrm{Spa}(R, R^\circ)$.

Proof of the claim. Since v is analytic, there exists $a \in R$ such that $0 < v(a) < 1$. Let $b \in R^\circ$ be any element, and suppose that $v(b) > 1$; then there exists $n \in \mathbb{N}$ large enough, such that $v(b^n a) > 1$, which is absurd, since $b^n a \in R^{\circ\circ}$ (remark 8.3.10(iv)). ☐

Proposition 15.4.24. *Let (A, A^+, U) be any quasi-affinoid ring, $I \subset A^+$ an ideal, $g_\bullet := (g_i \mid i \in \Sigma)$ and $h_\bullet := (h_j \mid j \in \Sigma')$ two systems of elements of A such that :*

(a) *The system $(g_\bullet, h_\bullet)$ generates an open ideal of A.*

(b) $\mathrm{Spec}\, A/IA$ *is the set of open prime ideals of A.*

(c) *U is dense in* $\mathrm{Spec}\, A$.

Then for every $f \in A$ the following conditions are equivalent :

(d) *For every $v \in \mathrm{Spa}(A, A^+, U)$ with $v(f) \neq 0$ there exists either $i \in \Sigma$ such that $v(f) \leq v(g_i)$ or else $j \in \Sigma'$ such that $v(f) < v(h_j)$.*

(e) *There exists a polynomial $P \in \mathscr{P}_I$ such that $P(f, g_\bullet, h_\bullet) = 0$ (notation of* (9.2.39)*).*

Proof. From theorem 15.3.15(i) and lemmata 15.4.17(i), 9.2.40 we already see that (e)⇒(d).

(d)⇒(e): Let (A', A'^+, U') be the topological localization of (A, A^+, U), and set $I' := IA'^+$. Notice that U' is dense in $\mathrm{Spec}\, A'$ (proposition 8.1.47(iii)), and $\mathrm{Spec}\, A'/I'A'$ is the set of open prime ideals of A', since the localization map $A \to A'$ is f-adic (lemma 8.3.29(iv)). We may then consider also the set $\mathscr{P}_{I'} \subset A'^+[Z, X_\bullet, Y_\bullet]$ defined as in (9.2.39), and we remark

Claim 15.4.25. Condition (e) is equivalent to :

(f) There exists a polynomial $Q \in \mathscr{P}_{I'}$ such that $Q(f, g_\bullet, h_\bullet) = 0$ in A'^+.

Proof of the claim. Obviously (e)⇒(f). Conversely, let $A_0 \subset A^+$ be a subring of definition, and J any ideal of adic definition of A_0, so that $A'^+ = (1+J)^{-1}A^+$ and $I' = (1+J)^{-1}I$. If (f) holds, we deduce that there exists a polynomial $G \in A^+[Z, X_\bullet, Y_\bullet]$ of the form

$$G(Z, X_\bullet, Y_\bullet) = (1-a) \cdot Z^n + \sum_{k=1}^{n} Z^{n-k} P_k(X_\bullet, Y_\bullet)$$

for some $a \in J$ and some $P_1, \dots, P_n \in A^+[X_\bullet, Y_\bullet]$ fulfilling the conditions of (9.2.39), and such that $G(f, g_\bullet, h_\bullet) = 0$ in A. Since A is f-adic, condition (a) implies that the system $(g_i^n, h_j^n \mid i \in \Sigma,\ j \in \Sigma')$ generates an open ideal of A (details left to the reader); then we may find $N \in \mathbb{N}$ large enough, finite subsets $\Sigma_0 \subset \Sigma'$, $\Sigma'_0 \subset \Sigma'$, and systems $(b_i \mid i \in \Sigma_0)$, $(c_j \mid j \in \Sigma'_0)$ of elements of A such that

$$a^N f^n = \sum_{i \in \Sigma_0} b_i g_i^n + \sum_{j \in \Sigma'_0} c_j h_j^n.$$

In light of (b), we may next find $M \in \mathbb{N}$ sufficiently large, so that $a^M b_i \in A^+$ and $a^M c_j \in I$ for every $i \in \Sigma_0$ and $j \in \Sigma'_0$. Summing up, we see that $a^{M+N} f^n = H(g_\bullet, h_\bullet)$ in A for some homogeneous polynomial $H(X_\bullet, Y_\bullet) \in A^+[X_\bullet, Y_\bullet]$ of degree n and with $H(0, Y_\bullet) \in I[Y_\bullet]$. Then set $u := 1 + a + \cdots + a^{M+N-1}$, so that $u \cdot (1-a) = 1 - a^{M+N}$; it follows that the polynomial

$$P := u \cdot G + a^{M+N} Z^n - H$$

fulfills condition (e). ◊

Now, if (e) fails for some $f \in A$, claim 15.4.25 and lemma 9.2.40 show that there exists $w \in \mathrm{Spv}\, A'$ whose support is a minimal prime ideal of A', and with $w(f) \neq 0$ and

$$w(a) \leq 1 \qquad w(b) < 1 \qquad \text{for every } a \in A'^+ \text{ and } b \in A'^{\circ\circ}$$
$$w(g_i) < w(f) \qquad w(h_j) \leq w(f) \qquad \text{for every } i \in \Sigma \text{ and } j \in \Sigma'.$$

Since U' is dense in $\mathrm{Spec}\, A'$, we have $w \in \mathrm{Spv}\, U'$ (proposition 8.1.47(iii)); if w is continuous, it follows that $w \in \mathrm{Spa}(A', A'^+, U') = \mathrm{Spa}(A, A^+, U)$ (lemma 15.4.17(i)), and (d) fails for w. In case w is not continuous, set $L := IA$ and $v := w^{c\Gamma_v(L)}$ (notation of definition 15.3.3).

Claim 15.4.26. (i) $v(L) \neq \{0\}$.
(ii) $v(f) \neq 0$.

Proof of the claim. (i): Since v is an L-admissible specialization of w, it suffices to show that $w(L) \neq \{0\}$. But if the latter fails, then the support of w is an open prime ideal, so w is continuous (remark 15.3.13(vi)), contradicting our assumption.

(ii): Suppose that $v(f) = 0$; then $v(g_i) = v(h_j) = 0$ as well, for every $i \in \Sigma$ and $j \in \Sigma'$. Hence the support of v is an open ideal of A, and especially, it contains L, contradicting (i). ◊

Claim 15.4.26(ii), theorem 15.3.15(i) and lemma 15.4.17(i) imply that v is an analytic point of $\mathrm{Spa}(A, A^+)$ and condition (d) fails for v; lastly, notice that $\mathrm{Cont}(A)_{\mathrm{a}} \subset \mathrm{Spv}\, U$, so $v \in \mathrm{Spa}(A, A^+, U)$ whence the proposition. □

Corollary 15.4.27. *Let* $\underline{A} := (A, A^+, U)$ *be any quasi-affinoid ring such that* U *is dense in* $\mathrm{Spec}\, A$, *and* $f \in A$ *any element. We have :*

(i) $f \in A^+$ *if and only if* $v(f) \leq 1$ *for every* $v \in \mathrm{Spa}\, \underline{A}$.
(ii) $f \in A^{\circ\circ}$ *if and only if* $v(f) < 1$ *for every* $v \in \mathrm{Spa}\, \underline{A}$.
(iii) *Let also* $J \subset A^+$ *be any finitely generated ideal whose radical is* $A^{\circ\circ}$. *Then the following conditions are equivalent :*
  (a) $|f|_J^* = 0$ *(notation of example* 9.1.9*).*
  (b) $v(f) = 0$ *for every* $v \in \mathrm{Spa}\, \underline{A}$.

Proof. (i): We may assume that $v(f) \leq 1$ for every $v \in \mathrm{Spa}\,\underline{A}$, and we show that $f \in A^+$. To this aim, we apply proposition 15.4.24 with $g_\bullet = \{1\}$, $h_\bullet$ the empty subset and $I := A^{\circ\circ}$; we deduce that there exists a monic polynomial $P(Z) \in A^+[Z]$ with $P(f) = 0$, *i.e.* f is integral over A^+, whence the contention, since A^+ is integrally closed in A.

(ii): Again, we may assume that $v(f) < 1$ for every $v \in \mathrm{Spa}\,\underline{A}$, and we check that $f \in A^{\circ\circ}$. To this aim, we apply proposition 15.4.24 with $h_\bullet = \{1\}$, $g_\bullet$ the empty subset and $I := A^{\circ\circ}$; we deduce that there exist $n \in \mathbb{N}$ and $a_1, \dots, a_n \in A^{\circ\circ}$ with $f^n + f^{n-1}a_1 + \cdots + a_n = 0$. By (i), we know already that $f \in A^+$, so that $f^{n-1}a_1 + \cdots + a_n \in A^{\circ\circ}$, and combining with remark 8.3.10(iv), the claim follows.

(iii.a)⇒(iii.b): Let $a_1, \dots, a_r$ be any finite system of generators of J, and set

$$\gamma_v := \max(v(a_1), \dots, v(a_r)) \in \Gamma_{v\circ} \qquad \text{for every } v \in \mathrm{Spa}(A, A^+, U).$$

The assumption implies that for every $n \in \mathbb{N}$ there exists $k \in \mathbb{N}$ such that $f^k \in J^{kn}$, hence $v(f^k) \leq \gamma_v^{kn}$, and therefore $v(f) \leq \gamma_v^n$ for every $n \in \mathbb{N}$ and every $v \in \mathrm{Spa}\,\underline{A}$ (details left to the reader). However γ_v is final in Γ_v for every such v (lemma 15.3.14(i)), whence the assertion.

(iii.b)⇒(iii.a): For every $n \in \mathbb{N}$, we apply the criterion of proposition 15.4.24 with $g_\bullet$ equal to the empty set, $h_\bullet^{(n)} := \{1\}$, and $I := J^n$. We deduce that for every $n \in \mathbb{N}$ there exist $k \in \mathbb{N}$ and elements $a_i^{(n)} \in J^{ni}$ for $i = 1, \dots, k$, such that $f^{k+1} + a_1^{(n)} f^k + \cdots + a_k^{(n)} = 0$. Therefore :

$$|f^{k+1}|_J^* \leq \max(|a_i^{(n)}|_J^* \cdot |f^{k+1-i}|_J^* \mid i = 1, \dots, k)$$

(lemma 9.1.8(ii)) whence $(|f|_J^*)^i \leq |a_i^{(n)}|_J^* \leq \rho^{ni}$ for some $i \leq k$, (lemma 9.1.8(iii)), and consequently $|f|_J^* \leq \rho^n$ for every $n \in \mathbb{N}$, whence (iii.a). □

Corollary 15.4.28. *Let $\underline{X} := (X, \mathscr{T}_X, A_X^+)$ be any quasi-affinoid scheme, and $(X^\wedge, \mathscr{T}_X^\wedge, A_{X^\wedge}^+)$ the completion of $\underline{X}$. Denote by $A_X^\wedge$ (resp. $A_X^{\wedge+}$) the separated completion of $A_X := \mathscr{O}_X(X)$ (resp. of A_X^+). Then we have :*

(i) *The kernel $\mathscr{J}$ of the natural map $\pi : A_X^\wedge \to \mathscr{O}_{X^\wedge}(X^\wedge)$ is contained in $(A_X^\wedge)^{\circ\circ}$.*
(ii) $\pi^{-1}A_{X^\wedge}^+ = A_X^{\wedge+}$.

Proof. (i): To begin with, we remark, quite generally :

Claim 15.4.29. Let A be any ring, $I \subset A$ a finitely generated ideal, and set

$$X_A := \mathrm{Spec}\,A \qquad Z := \mathrm{Spec}\,A/I \qquad U := X_A \setminus Z.$$

Then the following conditions are equivalent :

(a) U is dense in X_A.
(b) The support of the A-module I^n/I^{n+1} is Z, for every $n \in \mathbb{N}$.

Proof of the claim. Since U is constructible in X_A, condition (a) is equivalent to :

(c) $I_\mathfrak{q} = A_\mathfrak{q}$ for every minimal prime ideal $\mathfrak{q}$ of A

(proposition 8.1.47(iii)). Now, if $A = 0$ there is nothing to prove, so assume that $A \neq 0$. Suppose that (c) holds. Clearly the support of I^n/I^{n+1} lies in Z, so we consider any $\mathfrak{p} \in Z$, and we have to show that $I_\mathfrak{p}^n/I_\mathfrak{p}^{n+1} \neq 0$ for every $n \in \mathbb{N}$. However, if the latter fails for some $n \in \mathbb{N}$, Nakayama's lemma implies that $I_\mathfrak{p}^n = 0$; then $I_\mathfrak{q}^n = 0$ for every minimal prime ideal $\mathfrak{q}$ of A contained in $\mathfrak{p}$, contradicting (c).

Conversely, if (c) fails for some minimal prime ideal $\mathfrak{q}$, it follows that $I_\mathfrak{q}$ is a nilpotent ideal of $A_\mathfrak{q}$. Say that $I_\mathfrak{q}^n \neq 0$ and $I_\mathfrak{q}^{n+1} = 0$ for some $n \in \mathbb{N}$; then $\mathfrak{q}$ lies in the support of I^n/I^{n+1}, hence $\mathfrak{q} \in Z$, and therefore U cannot be dense in X_A. ◊

Set $Y := \mathrm{Spec}\,A_X$, $Y := \mathrm{Spec}\,A_X^\wedge$, $X' := X \times_Y Y'$, and let $I \subset A_X$ be any ideal such that $A_X^{\circ\circ} \subset I$ and $Y \setminus X = \mathrm{Spec}\,A_X/I$. Then $Y' \setminus X' = \mathrm{Spec}\,A_X^\wedge/I'$, where $I' := IA_X^\wedge$, and since I is open in A_X, the natural maps $I^n/I^{n+1} \to I'^n/I'^{n+1}$ are bijective for every $n \in \mathbb{N}$. Moreover, by assumption X is dense in Y; taking into account claim 15.4.29, we deduce that X' is dense in Y'. Pick any finitely generated ideal J of $A^\wedge_X$ whose radical is $A^{\wedge\circ\circ}_X$; in view of corollary 15.4.27(ii,iii), we see that

$$\bigcap_{v\in\mathrm{Spa}\,(A^\wedge_X,A^{\wedge+}_X,X')} \mathrm{Ker}\, v = \{a\in A^\wedge_X \mid |a|^*_J = 0\} \subset (A^\wedge_X)^{\circ\circ}.$$

But we have already noticed that $\mathscr{J}$ is contained in the support of every $v\in\mathrm{Spa}(A^\wedge_X, A^{\wedge+}_X, X')$ (see the proof of lemma 15.4.17(iii)), whence (i).

(ii) follows immediately from (i) and corollary 15.4.27(i) and lemma 15.4.17(iii) (details left to the reader; more directly, one can also argue as in the proof of theorem 16.5.13(ii)). □

Proposition 15.4.30. *Let $(X,\mathscr{T}_X,A^+_X)$ be any topologically local quasi-affinoid scheme, and $f\in\mathscr{O}_X(X)$ any element. The following conditions are equivalent :*

(a) $f\in\mathscr{O}_X(X)^\times$.
(b) $v(f)\neq 0$ *for every* $v\in\mathrm{Spa}(X,\mathscr{T}_X,A^+_X)$.

Proof. Clearly, it suffices to check that (b)⇒(a). Hence, suppose that (b) holds, and set

$$A_X := \mathscr{O}_X(X) \qquad Y:=\mathrm{Spec}\,A_X \qquad Y^{\circ\circ} := \mathrm{Spec}\,A_X/A^{\circ\circ}_X\cdot A_X.$$

Let $x\in X$ be any point; we need to show that the image $f(x)$ of f does not vanish in $\kappa(x)$. If $x\in Y^{\circ\circ}$, let v be the trivial valuation with support equal to x; clearly $v\in\mathrm{Spa}(X,\mathscr{T}_X,A^+_X)$, so (b) says that $v(f)\neq 0$, whence the contention, in this case.

Next, if $x\in X\setminus Y^{\circ\circ}$, we proceed as in the proof of proposition 15.4.22(iii.b) : we pick first a minimal specialization y of x in $X\setminus Y^{\circ\circ}$, then a maximal point $\mathfrak{p}$ of the non-empty closed subset $\{y\}^c\cap Y^{\circ\circ}$ of Y (where $\{y\}^c$ denotes the topological closure of $\{y\}$ in Y). The image C of $A_{X,\mathfrak{p}}$ in $\kappa(y)$ is a one-dimensional local domain, so we may find a valuation ring V of $\kappa(y)$ with value group of rank one, that dominates C (claim 15.3.27). Let $v\in\mathrm{Spv}\,A_X$ be the valuation corresponding to V; arguing as in *loc. cit.* we see that $v\in\mathrm{Spa}(X,\mathscr{T}_X,A^+_X)$, hence $v(f)\neq 0$, so $f(y)\neq 0$ and finally $f(x)\neq 0$ as well. □

15.5. **Adic spaces.** In this section we shall endow the adic spectra introduced in section 15.3 with certain natural presheaves of topological rings, and we shall show that, under suitable conditions, these presheaves are sheaves of rings or of topological rings. The first step is the following universal construction :

15.5.1. Let $\underline{A} := (A, A^+, U)$ be any quasi-affinoid ring, Λ a (small) set, $S:=(s_\lambda\mid\lambda\in\Lambda)$ a system of elements of A, and $T:=(T_\lambda\mid\lambda\in\Lambda)$ a family of subsets of A such that T_λ generates an open ideal of A, for every $\lambda\in\Lambda$. We consider the f-adic ring $A[X_\lambda\mid\lambda\in\Lambda]_T$ provided by proposition 8.3.37(ii), and its ideal J generated by the system $(1-s_\lambda X_\lambda\mid\lambda\in\Lambda)$. We set

$$A\Big(\frac{T}{S}\Big) := A[X_\bullet]_T/J$$

and we endow this ring with the quotient topology induced by $A[X_\bullet]_T$ via the natural projection. In other words, $A(\frac{T}{S})$ is an f-adic topological ring whose underlying A-algebra is naturally identified with the localization $A[s^{-1}_\lambda\mid\lambda\in\Lambda]$. From proposition 8.3.37(iii,iv) we see that – under this identification – the subset $\{t/s_\lambda\mid\lambda\in\Lambda,\ t\in T_\lambda\}$ is power bounded in $A(\frac{T}{S})$. Moreover, the localization map $h:A\to A(\frac{T}{S})$ is f-adic, and enjoys the following universal property. For every f-adic ring B and every continuous map $f:A\to B$ such that :

- $f(s_\lambda)\in B^\times$ for every $\lambda\in\Lambda$
- the subset $\{f(t)/f(s_\lambda)\mid\lambda\in\Lambda,\ t\in T_\lambda\}$ is power bounded in B

there exists a unique continuous map $g : A(\frac{T}{S}) \to B$ such that $g \circ h = f$. Furthermore, if $A_0 \subset A$ is a subring of definition, $A_0[\frac{t}{s_\lambda} \mid \lambda \in \Lambda,\ t \in T_\lambda]$ is a subring of definition of $A(\frac{T}{S})$.

Next, notice that $C := A^+[\frac{t}{s_\lambda} \mid \lambda \in \Lambda,\ t \in T_\lambda]$ is an open subring of $A(\frac{T}{S})^\circ$, and denote by C' the integral closure of C in $A(\frac{T}{S})$. Moreover, set $X := \mathrm{Spec}\, A[s_\lambda^{-1} | \lambda \in \Lambda]$, and notice that $U' := U \cap X$ contains the analytic locus of X, since h is f-adic (lemma 8.3.29(iv)). We obtain therefore a quasi-affinoid ring

$$\underline{A}\Big(\frac{T}{S}\Big) := \Big(A\Big(\frac{T}{S}\Big), C', U'\Big)$$

and the localization map yields a natural f-adic morphism of quasi-affinoid rings

$$\underline{A} \to \underline{A}\Big(\frac{T}{S}\Big). \tag{15.5.2}$$

In case $\Lambda = \{\lambda\}$ has only one element, $T_\lambda = \{f_0, \dots, f_n\}$ is a finite subset of A which generates an open ideal, and $S = \{s\}$ for some $s \in A$, we also denote this quasi-affinoid ring by :

$$\underline{A}\Big(\frac{f_0, \dots, f_n}{s}\Big).$$

15.5.3. We consider now the Yoneda embedding (see (1.2.4))

$$h : \mathsf{q.Afd.Sch}_{\mathrm{loc}} \to \mathsf{q.Afd.Sch}^\wedge_{\mathrm{loc}} \qquad \underline{X} \mapsto h_{\underline{X}}$$

(notation of remark 15.4.10(v)). Let $\underline{X}$ be any topologically local quasi-affinoid scheme, and $U \subset \mathrm{Spa}\, \underline{X}$ any open subset. We attach to U the sub-presheaf $h_U \subset h_{\underline{X}}$ given by the rule :

$$h_U(\underline{Y}) := \{\varphi \in h_{\underline{X}}(\underline{Y}) \mid \mathrm{Im}\, \mathrm{Spa}(\varphi) \subset U\} \qquad \text{for every } \underline{Y} \in \mathrm{Ob}(\mathsf{q.Afd.Sch}_{\mathrm{loc}}).$$

Definition 15.5.4. (i) In the situation of (15.5.3), we say that U is a *quasi-affinoid open subset* of $\mathrm{Spa}\, \underline{X}$, if the presheaf h_U is representable by some $\underline{Y} \in \mathrm{Ob}(\mathsf{q.Afd.Sch}_{\mathrm{loc}})$.

(ii) We say that U is an *affinoid open subset* of $\mathrm{Spa}\, \underline{X}$, if $\underline{Y}$ as in (i) is an affinoid scheme.

Theorem 15.5.5. *Every rational subset of* $\mathrm{Spa}\, \underline{X}$ *is a quasi-affinoid open subset.*

Proof. Let R be such a rational subset, and say that

$$\Gamma(\underline{X}) = (A_X, A_X^+, X) \qquad \text{and} \qquad R = R_{A_X}\Big(\frac{f_1}{f_0}, \dots, \frac{f_n}{f_0}\Big) \cap \mathrm{Spa}\, \underline{X}$$

for a sequence $(f_0, f_1, \dots, f_n)$ of elements of A_X that generates an open ideal. We consider the quasi-affinoid rings

$$\underline{A}_R := \Gamma(\underline{X})\Big(\frac{f_0, \dots, f_n}{f_0}\Big)$$

defined as in (15.5.1). Also, we let

$$i_R : \Gamma(\underline{X}) \to \underline{A}_{R,\mathrm{loc}}$$

be the composition of the natural morphism $\Gamma(\underline{X}) \to \underline{A}_R$ of (15.5.2) with the topological localization $\underline{A}_R \to \underline{A}_{R,\mathrm{loc}}$. Now, let $\underline{Y}$ be any topologically local quasi-affinoid scheme, and $\varphi \in h_R(\underline{Y})$ any element. Set $(A_Y, A_Y^+, Y) := \Gamma(\underline{Y})$, and let $\varphi^\flat : A_X \to A_Y$ be the continuous map associated with φ.

Claim 15.5.6. $\varphi^\flat(f_0) \in A_Y^\times$ and $\varphi^\flat(f_i)/\varphi^\flat(f_0) \in A_Y^+$ for every $i = 1, \dots, n$.

Proof of the claim. Indeed, for every $v \in \mathrm{Spa}\, \underline{Y}$ we have by assumption $v \circ \varphi^\flat \in R$, so that $v(\varphi^\flat(f_0)) \neq 0$ and $v(\varphi^\flat(f_i)) \leq v(\varphi^\flat(f_0))$ for $i = 1, \dots, n$. Then proposition 15.4.30 implies that $\varphi^\flat(f_0) \in A_Y^\times$, so we may write $v(\varphi^\flat(f_i)/\varphi^\flat(f_0)) \leq 1$ for every $i = 1, \dots, n$ and every $v \in \mathrm{Spa}\, \underline{Y}$. To conclude, it then suffices to invoke corollary 15.4.27(i). ◊

From claim 15.5.6, remark 8.3.9(ii) and the discussion of (15.5.1) we see that $\varphi^\flat$ factors uniquely through a continuous ring homomorphism $g : A_R \to A_Y$, and $g(f_i/f_0) \in A^+_Y$ for every $i = 1, \dots, n$. Thus, g defines a morphism of quasi-affinoid rings

$$g : \underline{A}_R \to \Gamma(\underline{Y})$$

and summing up, we easily conclude that φ factors uniquely through $\mathsf{Spec}(i_R)$ and the morphism of topologically local quasi-affinoid schemes

$$\psi := \mathsf{Spec}(g_{\mathrm{loc}}) : \underline{Y} \to \underline{R} := \mathsf{Spec}\,(\underline{A}_{R,\mathrm{loc}}).$$

Lastly, taking into account lemma 15.4.17(i) it is easily seen that $\mathrm{Spa}(i_R)$ is an injective map inducing a homeomorphism $\mathrm{Spa}\,\underline{R} \stackrel{\sim}{\to} R$, and the theorem follows. □

15.5.7. In the situation of (15.5.3), let $U \subset \mathrm{Spa}\,\underline{X}$ be a quasi-affinoid open subset, and $\underline{Y}$ any topologically local quasi-affinoid scheme that represents h_U. Then the morphism $\mathbf{1}_{\underline{Y}}$ corresponds to a well defined section $\varphi_{\underline{Y}/\underline{X}} \in h_U(\underline{Y})$, *i.e.* to a morphism $\varphi_{\underline{Y}/\underline{X}} : \underline{Y} \to \underline{X}$ of quasi-affinoid schemes with $\mathrm{Im}(\mathrm{Spa}\,\varphi_{\underline{Y}/\underline{X}}) \subset U$.

Corollary 15.5.8. *With the notation of* (15.5.7)*, the following holds :*

(i) *The map* $\mathrm{Spa}\,\varphi_{\underline{Y}/\underline{X}} : \mathrm{Spa}\,\underline{Y} \to \mathrm{Spa}\,\underline{X}$ *induces a homeomorphism* $\mathrm{Spa}\,\underline{Y} \stackrel{\sim}{\to} U$.

(ii) *Especially, every quasi-affinoid open subset is quasi-compact.*

(iii) *More precisely,* $\mathrm{Spa}\,\varphi_{\underline{Y}/\underline{X}}$ *induces homeomorphisms*

$$(\mathrm{Spa}\,\underline{Y})_{\mathrm{a}} \stackrel{\sim}{\to} U \cap \mathrm{Spa}(\underline{X})_{\mathrm{a}} \qquad (\mathrm{Spa}\,\underline{Y})_{\mathrm{na}} \stackrel{\sim}{\to} U \cap \mathrm{Spa}(\underline{X})_{\mathrm{na}}.$$

(iv) *The morphism* $\varphi_{\underline{Y}/\underline{X}}$ *is f-adic.*

Proof. (i): Let $(R_i \mid i \in I)$ be a system of rational subsets of $\mathrm{Spa}\,\underline{X}$ such that $U = \bigcup_{i \in I} R_i$, and for every $i, j \in I$ set $R_{ij} := R_i \cap R_j$ and choose topologically local quasi-affinoid schemes $\underline{Z}_i$ and $\underline{Z}_{ij}$ that represent h_{R_i} and $h_{R_{ij}}$. The inclusions $R_i \subset U$ and $R_{ij} \subset U$ are then represented by morphisms $\psi_i : \underline{Z}_i \to \underline{Y}$ and respectively $\psi_{ij} : \underline{Z}_{ij} \to \underline{Y}$ of quasi-affinoid schemes such that $\varphi_{\underline{Z}_i/\underline{X}} = \varphi_{\underline{Y}/\underline{X}} \circ \psi_i$ and $\varphi_{\underline{Z}_{ij}/\underline{X}} = \varphi_{\underline{Y}/\underline{X}} \circ \psi_{ij}$, for every $i, j \in I$. For every $i \in I$ set $U_i := \mathrm{Im}\,\mathrm{Spa}\,\psi_i \subset \mathrm{Spa}\,\underline{Y}$; it was observed in the proof of theorem 15.5.5 that $\mathrm{Spa}\,\varphi_{\underline{Z}_i/\underline{X}}$ induces a homeomorphism $\mathrm{Spa}\,\underline{Z}_i \stackrel{\sim}{\to} R_i$; it follows easily that $\mathrm{Spa}\,\psi_i$ and $\mathrm{Spa}\,\varphi_{\underline{Y}/\underline{X}}$ induce homeomorphisms $\mathrm{Spa}\,\underline{Z}_i \stackrel{\sim}{\to} U_i$ and respectively $U_i \stackrel{\sim}{\to} R_i$. It is also easily seen that $U_i \cap U_j = \mathrm{Im}\,\mathrm{Spa}\,\psi_{ij}$, so the map $\mathrm{Spa}\,\varphi_{\underline{Y}/\underline{X}}$ restricts to a homeomorphism $U' := \bigcup_{i \in I} U_i \stackrel{\sim}{\to} U$. To conclude, it suffices to check that $U' = \mathrm{Spa}\,\underline{Y}$. However, suppose that $v \in \mathrm{Spa}\,\underline{Y} \setminus U'$; we may find a rational subset R' of $\mathrm{Spa}\,\underline{Y}$ that contains v, and we may assume that $\mathrm{Spa}\,\varphi_{\underline{Y}/\underline{X}}(R') \subset R_i$ for some $i \in I$. Pick a topologically local quasi-affinoid scheme $\underline{Y}'$ that represents the subsheaf $h_{R'}$ of $h_{\underline{Y}}$, and let $\varphi' : \underline{Y}' \to \underline{Y}$ be the morphism of quasi-affinoid schemes that represents the inclusion $R' \subset \mathrm{Spa}\,\underline{Y}$. Then $\varphi_{\underline{Y}/\underline{X}} \circ \varphi' : \underline{Y}' \to \underline{X}$ lies in $h_{R_i}(\underline{Y}')$, so it corresponds to a unique morphism $\beta : \underline{Y}' \to \underline{Z}_i$ such that $\varphi_{\underline{Y}/\underline{X}} \circ \varphi' = \varphi_{\underline{Z}_i/\underline{X}} \circ \beta = \varphi_{\underline{Y}/\underline{X}} \circ \psi_i \circ \beta$. Since $\varphi_{\underline{Y}/\underline{X}}$ induces an injective morphism $h_{\underline{Y}} \to h_{\underline{X}}$ (whose image is h_U), we deduce that $\varphi' = \psi_i \circ \beta$. Especially, U_i contains the image of $\mathrm{Spa}\,\varphi'$; but we know that the latter coincides with R', a contradiction.

(ii) is an immediate consequence of (i).

(iii): By virtue of remark 15.3.13(vii), it suffices to show that $\mathrm{Spa}\,\varphi_{\underline{Y}/\underline{X}}$ maps $(\mathrm{Spa}\,\underline{Y})_{\mathrm{a}}$ into $(\mathrm{Spa}\,X)_{\mathrm{a}}$. Thus, let $v \in (\mathrm{Spa}\,\underline{Y})$, pick $i \in I$ such that $w := \mathrm{Spa}\,\varphi_{\underline{Y}/\underline{X}}(v) \in R_i$, and let $u := (\mathrm{Spa}\,\varphi_{\underline{Z}_i/\underline{X}})^{-1}(w)$. Suppose that $w \in (\mathrm{Spa}\,X)_{\mathrm{na}}$; by inspecting the proof of theorem 15.5.5, it is easily seen that $\varphi_{\underline{Z}_i/\underline{X}}$ is f-adic, so $u \in \mathrm{Spa}(\underline{Z}_i)_{\mathrm{na}}$, by corollary 15.3.17(ii). By the foregoing, we also know that $\mathrm{Spa}\,\psi_i(u) = v$, and then $v \in (\mathrm{Spa}\,\underline{Y})_{\mathrm{na}}$, again by remark 15.3.13(vii), whence the assertion.

(iv) follows immediately from (iii) and proposition 15.4.22(iii.b). □

Remark 15.5.9. (i) In the situation of (15.5.3), we can also consider the Yoneda imbeddings for the categories of topologically henselian and of complete, separated quasi-affinoid schemes

$$h' : \mathsf{q.Afd.Sch}_{\mathrm{hens}} \to \mathsf{q.Afd.Sch}^{\wedge}_{\mathrm{hens}} \qquad h'' : \mathsf{q.Afd.Sch}_{\mathrm{comp}} \to \mathsf{q.Afd.Sch}^{\wedge}_{\mathrm{comp}}$$

and if $\underline{X}$ is topologically henselian (resp. complete and separated) we set

$$h'_U(\underline{Y}') := h_U(\underline{Y}') \subset h'_{\underline{X}}(\underline{Y}') \qquad (\text{resp. } h''_U(\underline{Y}'') := h_U(\underline{Y}'') \subset h''_{\underline{X}}(\underline{Y}'')\ )$$

for every topologically henselian quasi-affinoid scheme $\underline{Y}'$ and every complete and separated quasi-affinoid scheme $\underline{Y}''$. Suppose that U is quasi-affinoid, and let $\varphi_{\underline{Y}/\underline{X}} : \underline{Y} \to \underline{X}$ be a morphism of topologically local quasi-affinoid schemes representing the sub-presheaf $h_U \subset h_{\underline{X}}$, as in (15.5.7); from remark 15.4.10(v) and lemma 15.4.17(i) we see that if $\underline{X}$ is topologically henselian, the topological henselization $\varphi^{\mathrm{h}}_{\underline{Y}/\underline{X}} : \underline{Y}^{\mathrm{h}} \to \underline{X}$ of $\varphi_{\underline{Y}/\underline{X}}$ represents h'_U. Likewise, taking into account proposition 15.4.12 and lemma 15.4.17(iii), we conclude that if $\underline{X}$ is complete and separated, the completion $\varphi^{\wedge}_{\underline{Y}/\underline{X}} : \underline{Y}^{\wedge} \to \underline{X}$ of $\varphi_{\underline{Y}/\underline{X}}$ represents h''_U.

(ii) Moreover, we may consider the Yoneda imbedding for the opposite of the category of topologically local affinoid rings :

$$h''' : \mathsf{Afd.Ring}^o_{\mathrm{loc}} \to \mathsf{Afd.Ring}^{o\wedge}_{\mathrm{loc}}$$

and if $\underline{A} := (A, A^+)$ is any topologically local affinoid ring, and $U \subset \mathrm{Spa}\,\underline{A}$ any open subset, we may form again the sub-presheaf $h'''_U :\subset h'''_{\underline{A}}$ by the rule : $h'''_U(\underline{B}) := h_U(\mathsf{Spec}\,\underline{B})$ for every topologically local affinoid ring $\underline{B}$. We may regard U as an open subset of $\mathrm{Spa}(\mathsf{Spec}\,\underline{A})$, and we say that U is a quasi-affinoid open subset of $\mathrm{Spa}\,\underline{A}$ if it is such, as an open subset of $\mathrm{Spa}\,\mathsf{Spec}\,\underline{A}$. Since Spec is fully faithful on the full subcategory $\mathsf{Afd.Ring}$, it follows that if U is quasi-affinoid, h'''_U is representable : namely, a representing affinoid ring is $\Gamma(\underline{Y})$, where $\underline{Y}$ is any topologically local quasi-affinoid scheme that represents the presheaf h_U. Lastly, we may in the same way consider variants for topologically henselian (resp. complete and separated) affinoid rings : the reader may spell out the details. (However, the method does not produce representing objects on the whole category of quasi-affinoid rings, essentially because there is – in this generality – no counterpart of proposition 15.4.30 for quasi-affinoid rings).

(iii) It follows from lemma 15.4.6 and corollary 15.5.8(iv) that the intersection of two quasi-affinoid open subsets $U, U' \subset \mathrm{Spa}\,\underline{X}$ is quasi-affinoid. Indeed, if $\underline{Y}$ and $\underline{Y}'$ are topologically local quasi-affinoid schemes that represent h_U and respectively $h_{U'}$, it is easily seen that

$$(\underline{Y} \times_{\underline{X}} \underline{Y}')_{\mathrm{loc}}$$

represents $h_U \cap h_{U'} = h_{U \cap U'}$ (see example 15.4.8).

(iv) In the same vein, if $f : \underline{X}' \to \underline{X}$ is any f-adic morphism of topologically local quasi-affinoid schemes, and $U \subset \mathrm{Spa}\,\underline{X}$ is any quasi-affinoid open subset, then $U' := (\mathrm{Spa}\,f)^{-1}U$ is a quasi-affinoid open subset of $\mathrm{Spa}\,\underline{X}'$. Indeed, if $\underline{Y}$ represents h_U, then $h_{U'}$ is represented by $(\underline{Y} \times_{\underline{X}} \underline{X}')_{\mathrm{loc}}$, where the fibre product is given as in example 15.4.8.

(v) Lastly, let U be a quasi-affinoid open subset of $\mathrm{Spa}\,\underline{X}$ such that the inclusion $h_U \subset h_{\underline{X}}$ is represented by the morphism of topologically local quasi-affinoid schemes $\varphi_{\underline{Y}/\underline{X}} : \underline{Y} \to \underline{X}$, and V a quasi-affinoid open subset of $\mathrm{Spa}\,\underline{Y}$ such that the inclusion $h_V \subset h_{\underline{Y}}$ is represented by the morphism of topologically local affinoid schemes $\varphi_{\underline{Z}/\underline{Y}} : \underline{Z} \to \underline{Y}$, and set $U' := \mathrm{Spa}\,\varphi_{\underline{Y}/\underline{X}}(V) \subset U$. Then $\varphi_{\underline{Y}/\underline{X}}$ induces an isomorphism $h_{\underline{Y}} \xrightarrow{\sim} h_U$ that identifies h_V with the sub-presheaf $h_{U'}$ of h_U. Especially, U' is a quasi-affinoid open subset of $\mathrm{Spa}\,X$, and the inclusion $h_{U'} \subset h_{\underline{X}}$ is represented by $\varphi_{\underline{Y}/\underline{X}} \circ \varphi_{\underline{Z}/\underline{Y}}$.

Lemma 15.5.10. *In the situation of remark* 15.5.9(v)*, suppose furthermore that U is a rational subset of* $\mathrm{Spa}\,\underline{X}$ *and V is a rational subset of* $\mathrm{Spa}\,\underline{Y}$*. Then V is a rational subset of* $\mathrm{Spa}\,\underline{X}$.

Proof. Say that $\Gamma(\underline{X}) = (A, A^+, X)$, and $U = R_A(\frac{f_1}{f_0}, \dots, \frac{f_n}{f_0}) \cap \mathrm{Spa}\,\underline{X}$, with $(f_0, \dots, f_n)$ a sequence of elements of A that generates an open ideal. Set $(A_U, A_U^+) := \underline{A}(\frac{f_1}{f_0}, \dots, \frac{f_n}{f_0})$, where $\underline{A} := (A, A^+)$, so that $A_U = A[f_0^{-1}]$. By inspecting the proof of theorem 15.5.5, we get an isomorphism of quasi-affinoid schemes

$$\underline{Y} \xrightarrow{\sim} \mathsf{Spec}\,(A_U, A_U^+, X \cap \mathrm{Spec}\,A_U)_{\mathrm{loc}}$$

Since X is quasi-compact, and $\mathrm{Spec}\,A_U$ is an open affine subset of $\mathrm{Spec}\,A$, we have $\mathscr{O}_X(X \cap \mathrm{Spec}\,A_U) = \mathscr{O}_X(X)[f_0^{-1}] = A_U$ ([59, Ch.I, Prop.9.2.1]). Taking into account (15.4.11), we deduce that $\Gamma(\underline{Y}) = (B, B^+, X \cap \mathrm{Spec}\,A_U)$, where $B := A_{U,\mathrm{loc}}$ and $B^+ := A^+_{U,\mathrm{loc}}$. Consequently, we have $V = R_B(\frac{g_1}{g_0}, \dots, \frac{g_m}{g_0}) \cap \mathrm{Spa}\,\underline{Y}$ for a sequence $g_\bullet := (g_0, \dots, g_m)$ of elements of B that generates an open ideal J. Since B is a localization of A, we may also find $b \in B^\times$, such that $bg_i \in A' := \mathrm{Im}(A \to B)$; after replacing $g_\bullet$ by the sequence $(bg_0, \dots, bg_n)$, we may then assume that $g_0, \dots, g_m \in A'$, and for every $i = 0, \dots, m$ we pick $h_i \in A$ whose image in B agrees with g_i. Moreover, let $A_0 \subset A$ be a ring of definition, and $I \subset A_0$ a finitely generated ideal of adic definition; according to claim 15.4.20(i), there exists $k \in \mathbb{N}$ such that $v(a) < v(h_0)$ for every $a \in I^k$ and every $v \in V$. Pick a finite system $x_1, \dots, x_r$ of generators for I^k and set $h_{i+m} := x_i$ for every $i = 1, \dots, r$; by construction, we easily see that

$$V = U \cap R \qquad \text{where } R := R_A\Big(\frac{h_1}{h_0}, \dots, \frac{h_{m+r}}{h_0}\Big)$$

and the system $(h_i \mid i = 1, \dots, m + r)$ generates an open ideal of A, so R is a rational subset of $\mathrm{Spa}\,\underline{X}$, and finally, the same holds for V. $\square$

15.5.11. Let $\underline{X} := (X, \mathscr{T}_X, A_X^+)$ be any topologically local quasi-affinoid scheme; in view of remark 15.5.9(iii) we may associate with $\underline{X}$ a site

$$(\mathscr{Q}(\underline{X}), J_{\mathscr{Q}})$$

where $\mathscr{Q}(\underline{X})$ is the category of all quasi-affinoid open subsets of $\mathrm{Spa}\,\underline{X}$; for every $U, U' \in \mathrm{Ob}(\mathscr{Q}(\underline{X}))$, the set $\mathrm{Hom}_{\mathscr{Q}(\underline{X})}(U, U')$ contains exactly one morphism if $U \subset U'$, and is empty otherwise. For every such U, the sieves covering U for the topology $J_{\mathscr{Q}}$ are precisely those generated by the families $(U_\lambda \mid \lambda \in \Lambda)$ of quasi-affinoid open subsets of $\mathrm{Spa}\,\underline{X}$ such that $\bigcup_{\lambda\in\Lambda} U_\lambda = U$. We consider nine presheaves of topological $\mathscr{O}_X(X)$-algebras on $\mathscr{Q}(\underline{X})$, related by natural morphisms of presheaves :

$$\begin{array}{ccccc}
\mathscr{O}^{\mathrm{loc}+}_{\mathrm{Spa}\,\underline{X}} & \hookrightarrow & \mathscr{O}^{\mathrm{loc}\,\circ}_{\mathrm{Spa}\,\underline{X}} & \hookrightarrow & \mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{X}} \\
\downarrow & & \downarrow & & \downarrow \\
\mathscr{O}^{\mathrm{h}+}_{\mathrm{Spa}\,\underline{X}} & \hookrightarrow & \mathscr{O}^{\mathrm{h}\,\circ}_{\mathrm{Spa}\,\underline{X}} & \hookrightarrow & \mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X}} \\
\downarrow & & \downarrow & & \downarrow \\
\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}} & \hookrightarrow & \mathscr{O}^{\wedge\circ}_{\mathrm{Spa}\,\underline{X}} & \hookrightarrow & \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}
\end{array}$$

and constructed as follows. By theorem 15.5.5, for every $U \in \mathrm{Ob}(\mathscr{Q}(\underline{X}))$ the sub-presheaf h_U of $h_{\underline{X}}$ is representable (notation of (15.5.3)); we choose a topologically local quasi-affinoid scheme $\underline{X}_U := (X_U, \mathscr{T}_U, A_U^+)$ that represents this presheaf, and we set

$$\mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{X}}(U) := \mathscr{O}_{X_U}(X_U) \qquad \mathscr{O}^{\mathrm{loc}\,\circ}_{\mathrm{Spa}\,\underline{X}}(U) := \mathscr{O}_{X_U}(X_U)^\circ \qquad \mathscr{O}^{\mathrm{loc}+}_{\mathrm{Spa}\,\underline{X}}(U) := A_U^+.$$

Any inclusion $U \subset U'$ of quasi-affinoid open subsets induces a morphism $h_U \to h_{U'}$ of presheaves, which is represented by a unique morphism $\underline{X}_U \to \underline{X}_{U'}$ of topologically local quasi-affinoid schemes (see remark 1.2.8(i)), whence well defined continuous homomorphisms

$$\mathscr{O}^{\mathrm{loc}+}_{\mathrm{Spa}\,\underline{X}}(U') \to \mathscr{O}^{\mathrm{loc}+}_{\mathrm{Spa}\,\underline{X}}(U) \qquad \mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{X}}(U') \to \mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{X}}(U)$$

of topological $\mathscr{O}_X(X)$-algebras, and clearly the rules $U \mapsto \mathscr{O}^{\mathrm{loc}+}_{\mathrm{Spa}\,\underline{X}}(U)$ and $U \mapsto \mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{X}}(U)$ yield two functors from $\mathscr{Q}(\underline{X})^o$ to the category of topologically local f-adic $\mathscr{O}_X(X)$-algebras. Likewise, in view of corollary 15.5.8(iv) and lemma 8.3.24(iii.a) we also get a continuous map $\mathscr{O}^{\mathrm{loc}\,\circ}_{\mathrm{Spa}\,\underline{X}}(U') \to \mathscr{O}^{\mathrm{loc}\,\circ}_{\mathrm{Spa}\,\underline{X}}(U)$, whence the presheaf $\mathscr{O}^{\mathrm{loc}\,\circ}_{\mathrm{Spa}\,\underline{X}}$.

Similarly, let $\underline{X}^{\mathrm{h}}_U := (X^{\mathrm{h}}_U, \mathscr{T}^{\mathrm{h}}_U, A^{\mathrm{h}+}_U)$ (resp. $\underline{X}^{\wedge}_U := (X^{\wedge}_U, \mathscr{T}^{\wedge}_U, A^{\wedge+}_U)$) be a topologically henselian (resp. complete and separated) quasi-affinoid scheme representing the sub-presheaf h'_U of $h'_{\underline{X}^{\mathrm{h}}}$ (resp. h''_U of $h''_{\underline{X}^{\wedge}}$) as in remark 15.5.9(i); we define

$$\mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X}}(U) := \mathscr{O}_{X^{\mathrm{h}}_U}(X^{\mathrm{h}}_U) \qquad \mathscr{O}^{\mathrm{h}\,\circ}_{\mathrm{Spa}\,\underline{X}}(U) := \mathscr{O}_{X^{\mathrm{h}}_U}(X^{\mathrm{h}}_U)^{\circ} \qquad \mathscr{O}^{\mathrm{h}+}_{\mathrm{Spa}\,\underline{X}}(U) := A^{\mathrm{h}+}_U$$
$$\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}(U) := \mathscr{O}_{X^{\wedge}_U}(X^{\wedge}_U) \qquad \mathscr{O}^{\wedge\circ}_{\mathrm{Spa}\,\underline{X}}(U) := \mathscr{O}_{X^{\wedge}_U}(X^{\wedge}_U)^{\circ} \qquad \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}(U) := A^{\wedge+}_U$$

and arguing as in the foregoing, it is easily seen that these rules yield well defined presheaves of topologically henselian (resp. complete and separated) f-adic $\mathscr{O}_X(X)$-algebras. All these presheaves depend on the choices of representing quasi-affinoid schemes, but for any two such sets of choices there exists a unique isomorphism of presheaves of topological $\mathscr{O}_X(X)$-algebras between the corresponding presheaves. We notice as well that the rule

$$U \mapsto \mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\underline{X}}(U)^{\circ\circ}$$

defines a sub-presheaf $\mathscr{O}^{\mathrm{loc}\,\circ\circ}_{\mathrm{Spa}\,\underline{X}} \subset \mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{X}}$ that is a presheaf of ideals in both $\mathscr{O}^{\mathrm{loc}+}_{\mathrm{Spa}\,\underline{X}}$ and $\mathscr{O}^{\mathrm{loc}\,\circ}_{\mathrm{Spa}\,\underline{X}}$. Likewise we get presheaves of topologically nilpotent sections $\mathscr{O}^{\mathrm{h}\,\circ\circ}_{\mathrm{Spa}\,\underline{X}} \subset \mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X}}$ (resp. $\mathscr{O}^{\wedge\,\circ\circ}_{\mathrm{Spa}\,\underline{X}} \subset \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}$) that are presheaves of ideals in $\mathscr{O}^{\mathrm{h}\,\circ}_{\mathrm{Spa}\,\underline{X}}$ and $\mathscr{O}^{\mathrm{h}+}_{\mathrm{Spa}\,\underline{X}}$ (resp. in $\mathscr{O}^{\wedge\circ}_{\mathrm{Spa}\,\underline{X}}$ and $\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}$).

15.5.12. With the notation of (15.5.11), let $x \in \mathrm{Spa}\,\underline{X}$ be any point; recall that x is the equivalence class of a continuous valuation $v_x : A := \mathscr{O}_X(X) \to \Gamma_x$; if $R \subset \mathrm{Spa}\,\underline{X}$ is any rational subset containing x, the valuation v_x extends uniquely to a continuous valuation $v^{\wedge}_{x,R}$ on $\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}(R)$ with value group Γ_x (claim 15.3.20(i)). Then, by restricting along the natural maps $\mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{X}}(R) \to \mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X}}(R) \to \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}(R)$ we get corresponding valuations $v^{\mathrm{h}}_{x,R}$, $v^{\mathrm{loc}}_{x,R}$, and – after taking colimits – unique valuations on the stalks of these presheaves

(15.5.13)
$$\begin{array}{ccccc} \mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{X},x} & \longrightarrow & \mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X},x} & \longrightarrow & \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x} \\ & {\scriptstyle |\cdot|^{\mathrm{loc}}_x} \searrow & \downarrow{\scriptstyle |\cdot|^{\mathrm{h}}_x} & \swarrow {\scriptstyle |\cdot|^{\wedge}_x} & \\ & & \Gamma_x. & & \end{array}$$

We denote by $\kappa(x^{\mathrm{loc}})$, $\kappa(x^{\mathrm{h}})$ and $\kappa(x^{\wedge})$ the residue fields of $|\cdot|^{\mathrm{loc}}_x$, $|\cdot|^{\mathrm{h}}_x$ and respectively $|\cdot|^{\wedge}_x$, and recall that the valuations of (15.5.13) induce natural residual valuations on these fields : see remark 9.1.4(v). There follow natural inclusion of valued fields

$$\kappa(x^{\mathrm{loc}}) \to \kappa(x^{\mathrm{h}}) \to \kappa(x^{\wedge})$$

and taking into account claim 15.3.20(ii) we see that the images of $\kappa(x^{\mathrm{loc}})$ and of $\kappa(x^{\mathrm{h}})$ in $\kappa(x^{\wedge})$ are both dense for the valuation topology of the latter field. Especially, these inclusions induce natural identifications of the completions of these fields for their respective valuation topologies (theorem 8.2.8(iii)), and we denote this common completion by

$$(\kappa(x)^{\wedge}, |\cdot|^{\wedge}_x)$$

which is a valued field with value group Γ_x, by proposition 9.1.16(iii,v).

Lemma 15.5.14. *In the situation of* (15.5.12)*, we have :*

(i) *The stalks* $\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x}$, $\mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X},x}$ *and* $\mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{X},x}$ *are local rings, and* $\kappa(x^{\mathrm{loc}})$, $\kappa(x^{\mathrm{h}})$, $\kappa(x^{\wedge})$ *are their respective residue fields.*

(ii) *The stalks* $\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X},x}$, $\mathscr{O}^{\mathrm{h}+}_{\mathrm{Spa}\,\underline{X},x}$ *and* $\mathscr{O}^{\mathrm{loc}+}_{\mathrm{Spa}\,\underline{X},x}$ *are local rings, and the induced diagrams*

$$\begin{array}{ccc} \mathscr{O}^{\mathrm{loc}+}_{\mathrm{Spa}\,\underline{X},x} & \longrightarrow & \mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{X},x} \\ \downarrow & & \downarrow{\scriptstyle \pi^{\mathrm{loc}}_x} \\ \kappa(x^{\mathrm{loc}})^+ & \longrightarrow & \kappa(x^{\mathrm{loc}}) \end{array} \qquad \begin{array}{ccc} \mathscr{O}^{\mathrm{h}+}_{\mathrm{Spa}\,\underline{X},x} & \longrightarrow & \mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X},x} \\ \downarrow & & \downarrow{\scriptstyle \pi^{\mathrm{h}}_x} \\ \kappa(x^{\mathrm{h}})^+ & \longrightarrow & \kappa(x^{\mathrm{h}}) \end{array} \qquad \begin{array}{ccc} \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X},x} & \longrightarrow & \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x} \\ \downarrow & & \downarrow{\scriptstyle \pi^{\wedge}_x} \\ \kappa(x^{\wedge})^+ & \longrightarrow & \kappa(x^{\wedge}) \end{array}$$

are cartesian (here $\kappa(x^{\mathrm{loc}})^+$ *is the valuation ring of the residual valuation on* $\kappa(x^{\mathrm{loc}})$, *and likewise for* $\kappa(x^{\mathrm{h}})^+$ *and* $\kappa(x^{\wedge})^+$*).*

(iii) *The stalk* $\mathscr{O}^{\mathrm{loc}\,\circ\circ}_{\mathrm{Spa}\,\underline{X},x}$ *(resp.* $\mathscr{O}^{\mathrm{h}\,\circ\circ}_{\mathrm{Spa}\,\underline{X},x}$, *resp.* $\mathscr{O}^{\wedge\,\circ\circ}_{\mathrm{Spa}\,\underline{X},x}$*) is the radical of the ideal* $A^{\circ\circ}\cdot\mathscr{O}^{\mathrm{loc}+}_{\mathrm{Spa}\,\underline{X},x}$ *of* $\mathscr{O}^{\mathrm{loc}+}_{\mathrm{Spa}\,\underline{X},x}$ *(resp.* $A^{\circ\circ}\cdot\mathscr{O}^{\mathrm{h}+}_{\mathrm{Spa}\,\underline{X},x}$ *of* $\mathscr{O}^{\mathrm{h}+}_{\mathrm{Spa}\,\underline{X},x}$, *resp.* $A^{\circ\circ}\cdot\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X},x}$ *of* $\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X},x}$*).*

(iv) *The pairs* $(\mathscr{O}^{\mathrm{h}+}_{\mathrm{Spa}\,\underline{X},x},\mathscr{O}^{\mathrm{h}\,\circ\circ}_{\mathrm{Spa}\,\underline{X},x})$ *and* $(\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X},x},\mathscr{O}^{\wedge\,\circ\circ}_{\mathrm{Spa}\,\underline{X},x})$ *are henselian.*

(v) *Suppose that* x *is analytic, and let*

$$\mathfrak{p}^{\mathrm{loc}}\subset\kappa(x^{\mathrm{loc}})^+ \qquad \mathfrak{p}^{\mathrm{h}}\subset\kappa(x^{\mathrm{h}})^+ \qquad \mathfrak{p}^{\wedge}\subset\kappa(x^{\wedge})^+$$

be the (unique) prime ideals of height one. Then :

(a) $\mathscr{O}^{\mathrm{loc}\,\circ\circ}_{\mathrm{Spa}\,\underline{X},x}=\pi^{\mathrm{loc}\,-1}_x(\mathfrak{p}^{\mathrm{loc}})$ $\qquad \mathscr{O}^{\mathrm{h}\,\circ\circ}_{\mathrm{Spa}\,\underline{X},x}=\pi^{\mathrm{h}\,-1}_x(\mathfrak{p}^{\mathrm{h}})$ $\qquad \mathscr{O}^{\wedge\circ\circ}_{\mathrm{Spa}\,\underline{X},x}=\pi^{\wedge\,-1}_x(\mathfrak{p}^{\wedge})$.

(b) *The pairs* $(\kappa(x^{\mathrm{h}})^+,\mathfrak{p}^{\mathrm{h}})$ *and* $(\kappa(x^{\wedge})^+,\mathfrak{p}^{\wedge})$ *are henselian.*

(c) *The local rings* $\mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X},x}$ *and* $\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x}$ *are henselian.*

(d) *The valuation rings* $\kappa(x^{\mathrm{h}})^+_{\mathfrak{p}^{\mathrm{h}}}$ *and* $\kappa(x^{\wedge})^+_{\mathfrak{p}^{\wedge}}$ *are henselian.*

(vi) *Suppose that* x *is non-analytic. Then :*

(a) $\mathscr{O}^{\mathrm{loc}\,\circ\circ}_{\mathrm{Spa}\,\underline{X},x}$ *(resp.* $\mathscr{O}^{\mathrm{h}\,\circ\circ}_{\mathrm{Spa}\,\underline{X},x}$, *resp.* $\mathscr{O}^{\wedge\,\circ\circ}_{\mathrm{Spa}\,\underline{X},x}$*) is also an ideal of* $\mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{X},x}$ *(resp. of* $\mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X},x}$, *resp. of* $\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x}$*), and it is the radical of the ideal generated by* $A^{\circ\circ}$.

(b) *The pairs* $(\mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X},x},\mathscr{O}^{\mathrm{h}\,\circ\circ}_{\mathrm{Spa}\,\underline{X},x})$ *and* $(\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x},\mathscr{O}^{\wedge\circ\circ}_{\mathrm{Spa}\,\underline{X},x})$ *are henselian.*

Proof. Let $f\in\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x}$, and pick any rational subset R in $\mathrm{Spa}\underline{X}$ with $x\in R$, and such that f extends to a section $f_R\in B:=\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}(R)$. Let $\underline{Y}^{\wedge}:=(Y^{\wedge},\mathscr{T}^{\wedge}_Y,A^{\wedge+}_Y)$ be a complete and separated quasi-affinoid scheme representing the subsheaf h''_R of $h''_{\underline{X}^{\wedge}}$, so that $B=\mathscr{O}_{Y^{\wedge}}(Y^{\wedge})$.

(i): Suppose now that $|f|^{\wedge}_x\neq 0$; then clearly $v^{\wedge}_{x,R}(f_R)\neq 0$. We set $U:=R_B\big(\frac{f_R}{f_R}\big)\cap\mathrm{Spa}\,\underline{Y}^{\wedge}$. In view of lemma 15.4.17(iii) and corollary 15.5.8(i), we may then identify U with an open subset of $\mathrm{Spa}\,X$ containing x, and we pick a rational subset $U'\subset U$ of $\mathrm{Spa}\,\underline{X}$ with $x\in U'$; by construction the image of f_R under the restriction map $\rho_{U'}:\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}(R)\to\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}(U')$ is an invertible element. This shows that $\mathrm{Ker}\,|\cdot|^{\wedge}_x$ is the unique maximal ideal of $\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x}$, and it also easily implies that the projection $\pi^{\wedge}_x:\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x}\to\kappa(x^{\wedge})$ is surjective (details left to the reader). The same argument applies to $\mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X},x}$ and $\mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{X},x}$, whence the contention.

(ii): Suppose next that $|f|^{\wedge}_x\leq 1$. Then we let $U:=R_B\big(\frac{f_R}{1}\big)\cap\mathrm{Spa}\,\underline{Y}^{\wedge}$, which again we identify naturally with an open subset of $\mathrm{Spa}\,\underline{X}$ containing x, and we pick a rational subset $U'\subset U$ of $\mathrm{Spa}\,\underline{X}$ with $x\in U'$; then $\rho_{U'}(f_R)\in\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}(U')$. This shows that $f\in\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X},x}$, whence the assertion concerning the third square diagram. The same argument applies to the other two diagrams. It follows easily that the preimage in $\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X},x}$ of the maximal ideal of $\kappa(x^{\wedge})^+$ is the unique maximal ideal of $\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X},x}$ (details left to the reader); especially, the latter is a local ring. Again, the same applies to the other two rings.

(iii): It follows easily from corollary 15.5.8(iv) that the natural map $A\to\mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{X}}(U)$ is f-adic, for every rational subset $U\subset\mathrm{Spa}\,\underline{X}$. Hence, $A^{\circ\circ}\cdot\mathscr{O}^{\mathrm{loc}+}_{\mathrm{Spa}\underline{X}}(U)$ is an open ideal of $\mathscr{O}^{\mathrm{loc}+}_{\mathrm{Spa}\underline{X}}(U)$ consisting of topologically nilpotent section, and therefore its radical equals $\mathscr{O}^{\mathrm{loc}\,\circ\circ}_{\mathrm{Spa}\underline{X}}(U)$. It suffices then to observe that the radical of $A^{\circ\circ}\cdot\mathscr{O}^{\mathrm{loc}+}_{\mathrm{Spa}\underline{X},x}$ is the colimit of the filtered system of the radicals of the ideals $(A^{\circ\circ}\cdot\mathscr{O}^{\mathrm{loc}+}_{\mathrm{Spa}\underline{X}}(U)\mid x\in U)$. The same applies to the other ideals in (iii).

(iv): By proposition 8.4.2(iii), both $(\mathscr{O}^{\mathrm{h}+}_{\mathrm{Spa}\,\underline{X}}(U),\mathscr{O}^{\mathrm{h}\,\circ\circ}_{\mathrm{Spa}\,\underline{X}}(U))$ and $(\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}(U),\mathscr{O}^{\wedge\circ\circ}_{\mathrm{Spa}\,\underline{X}}(U))$ are henselian pairs for every rational subset $U\subset\mathrm{Spa}\,\underline{X}$ containing x. The assertion follows, after taking colimits over the filtered family of such rational subsets.

(v.a): First, recall that the existence of a rank one prime ideal $\mathfrak{p}^{\mathrm{loc}}\subset\kappa(x^{\mathrm{loc}})^+$ is ensured by lemma 15.3.14(v); it follows easily that $\mathfrak{p}^{\mathrm{loc}}=\kappa(x^{\mathrm{loc}})^{\circ\circ}$, and taking into account remark 15.3.13(i) we deduce already that $\pi^{\mathrm{loc}}_x(\mathscr{O}^{\mathrm{loc}\,\circ\circ}_{\mathrm{Spa}\,\underline{X},x})\subset\mathfrak{p}^{\mathrm{loc}}$. Conversely, let $f\in\mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{X},x}\setminus\mathscr{O}^{\mathrm{loc}\,\circ\circ}_{\mathrm{Spa}\,\underline{X},x}$ be any element; denote by $\mathscr{U}$ the set of all rational subsets of $\mathrm{Spa}\,\underline{X}$ containing x, and for every $U\in\mathscr{U}$ set $U':=U\cap R_A\big(\frac{1}{f}\big)$. The assumption on f implies that U' is a non-empty constructible subset of $\mathrm{Spa}\,\underline{X}$ for every $U\in\mathscr{U}$ (corollary 15.4.27(ii)), and therefore $T:=\bigcap_{U\in\mathscr{U}}U'\neq\varnothing$ (proposition 8.1.23(ii.a)). However, T lies in the set $\mathrm{Spa}\,\underline{X}(x)$ of all generization of x in $\mathrm{Spa}\,\underline{X}$ (remark 8.1.45(i)), and must then contain the unique maximal generization of x; the latter means precisely that $\pi^{\mathrm{loc}}_x(f)\notin\mathfrak{p}^{\mathrm{loc}}$, as required.

Next, since $|\cdot|^{\mathrm{loc}}_x$ and $|\cdot|^{\wedge}_x$ have the same value group, the existence of a (unique) height one prime ideal $\mathfrak{p}^{\wedge}\subset\kappa(v^{\wedge})^+$ follows from the existence of $\mathfrak{p}^{\mathrm{loc}}$ and remark 9.1.13(vii); then, since $v^{\wedge}_{x,R}$ is continuous, we deduce likewise that $\pi^{\wedge}_x(\mathscr{O}^{\wedge\circ\circ}_{\mathrm{Spa}\,\underline{X},x})\subset\mathfrak{p}^{\wedge}$ for every rational subset $R\subset\mathrm{Spa}\,\underline{X}$. If now $f\in\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x}\setminus\mathscr{O}^{\wedge\circ\circ}_{\mathrm{Spa}\,\underline{X},x}$, pick R as in the foregoing and $\underline{Y}$ representing h''_R, so that $x\in R$, and f extends to a section $f_R\in B:=\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{Y}}(Y)$; let $\mathscr{U}$ be the set of all rational subsets of $\mathrm{Spa}\,\underline{Y}$ containing x, and for every $U\in\mathscr{U}$ set $U':=U\cap R_B\big(\frac{1}{f_R}\big)$. Due to corollary 15.5.8(i) and lemma 15.4.17(iii), the image of $T:=\bigcap_{U\in\mathscr{U}}U'$ in $\mathrm{Spa}\,\underline{X}$ lies in $\mathrm{Spa}\,\underline{X}(x)$, and is not empty, and arguing as in the foregoing we deduce again that $\pi^{\wedge}_x(f)\notin\mathfrak{p}^{\wedge}$. The same argument applies to $\mathfrak{p}^{\mathrm{h}}$.

(v.b): Let us remark more generally :

Claim 15.5.15. Let A be any ring, $J\subset I\subset A$ two ideals. Then the pair (A,I) is henselian if and only if the same holds for both $(A/J,I/J)$ and (A,J).

Proof of the claim. From [75, Rem.5.1.10(iv,v)] we see that if (A,I) is henselian, the same holds for the pairs (A,J) and $(A/J,I/J)$. Conversely, let $A\to B$ be a finite ring homomorphism; if (A,J) is henselian, the projection $B\to B/JB$ restricts to a bijection $\mathrm{Idemp}\,(B)\stackrel{\sim}{\to}\mathrm{Idemp}\,(B/JB)$ on the respective subsets of idempotent elements. Then, if also $(A/J,I/J)$ is henselian, the induced map $\mathrm{Idemp}\,(B/JB)\to\mathrm{Idemp}\,(B/IB)$ is bijective as well. Summing up, we conclude that (A,I) is henselian. ◊

In view of (iv) and claim 15.5.15, we are easily reduced to showing that the projections $\mathscr{O}^{\mathrm{h}+}_{\mathrm{Spa}\,\underline{X},x}\to\kappa(x^{\mathrm{h}})^+$ and $\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X},x}\to\kappa(x^{\wedge})^+$ are surjective. The latter follows from (ii) and from the surjectivity of π^{h}_x and $\pi^{\wedge}_x$, which has already been remarked in the proof of (i).

(v.c): Let $\mathfrak{m}^{\mathrm{h}}:=\mathrm{Ker}\,\pi^{\mathrm{h}}_x$; the proof of (i) shows that $\mathfrak{m}^{\mathrm{h}}$ is the maximal ideal of $\mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X},x}$, and (ii) implies that $\mathfrak{m}^{\mathrm{h}}$ is also an ideal in $\mathscr{O}^{\mathrm{h}+}_{\mathrm{Spa}\,\underline{X},x}$; moreover, in light of (iv) and [75, Rem.5.1.10(iv)] the pair $(\mathscr{O}^{\mathrm{h}+}_{\mathrm{Spa}\,\underline{X},x},\mathfrak{m}^{\mathrm{h}})$ is henselian. Then the assertion follows from [75, Rem.5.1.10(ii)]. The same argument applies to $\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x}$.

(v.d): It is easily seen that the localization map $\kappa(x^{\mathrm{h}})^+\to\kappa(x^{\mathrm{h}})^+_{\mathfrak{p}^{\mathrm{h}}}$ restricts to a bijection from $\mathfrak{p}^{\mathrm{h}}$ to the maximal ideal of $\kappa(x^{\mathrm{h}})^+_{\mathfrak{p}^{\mathrm{h}}}$; then the assertion follows from [75, Rem.5.1.10(ii)]. The same argument applies to $\kappa(x^{\wedge})^+_{\mathfrak{p}^{\wedge}}$.

(vi.a): By (iii) we know already that $\mathscr{O}^{\wedge\circ\circ}_{\mathrm{Spa}\,\underline{X},x}$ lies in the radical of $A^{\circ\circ}\cdot\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x}$; hence, suppose that $f^n\in A^{\circ\circ}\cdot\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x}$ for some $n\in\mathbb{N}$, and say that $f^n=\sum_{i=1}^k a_ig_i$ for some $a_1,\dots,a_k\in A^{\circ\circ}$ and $g_1,\dots,g_k\in\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x}$. Notice that since x is non-analytic, we have $\pi^{\wedge}_x(a_i)=0$ for $i=1,\dots,k$, whence $\pi^{\wedge}_x(f^n)=0$, and therefore $\pi^{\wedge}_x(f^ng_i)=0$ as well for

$i = 1, \dots, k$; then (ii) implies that $f^n g_i \in \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X},x}$, so $f^{2n} = \sum_{i=1}^k a_i \cdot (f^n g_i) \in A^{\circ\circ} \cdot \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X},x}$. The same argument applies to $\mathscr{O}^{\mathrm{loc}\,\circ\circ}_{\mathrm{Spa}\,\underline{X},x}$ and $\mathscr{O}^{\mathrm{h},\circ\circ}_{\mathrm{Spa}\,\underline{X},x}$.

(vi.b) follows directly from (vi.a), (iv) and [75, Rem.5.1.10(ii)]. □

15.5.16. Let $\underline{A} := (A, A^+, U)$ be any quasi-affinoid ring, and $J \subset A$ a finitely generated ideal such that $U = \mathrm{Spec}\,A \setminus \mathrm{Spec}\,A/J$. The *Zariski-Riemann spectrum* of $\underline{A}$ is the subset of $\mathrm{Spv}\,A$

$$\mathrm{ZR}(\underline{A}) := \mathrm{Spa}(\underline{A}) \cap \mathrm{Spv}(A, J)$$

(notation of definition 15.3.6(i)) that we endow with the topology induced by the inclusion into $\mathrm{Spv}\,A$. A *rational subset* of $\mathrm{ZR}(\underline{A})$ is a subset of the form $R \cap \mathrm{ZR}(\underline{A})$, where R is a rational subset of $\mathrm{Spv}(A, J)$ (see definition 15.3.6(ii)). Notice that neither $\mathrm{ZR}(\underline{A})$ nor the class of its rational subsets depend on the choice of J (lemma 15.3.9(i)).

Proposition 15.5.17. *With the notation of* (15.5.16)*, the following holds :*

(i) $\mathrm{ZR}(\underline{A}) = \{v \in \mathrm{Spa}(\underline{A}) \mid v$ *has no proper primary specializations in* $\mathrm{Spa}(\underline{A})\}$.

(ii) $\mathrm{ZR}(\underline{A})$ *is a pro-constructible subset of* $\mathrm{Spv}(A, J)$. *In particular, it is a spectral topological space.*

(iii) *The rational subsets of* $\mathrm{ZR}(\underline{A})$ *are constructible in* $\mathrm{ZR}(\underline{A})$*, and form a basis of the topology of* $\mathrm{ZR}(\underline{A})$ *that is closed under finite intersections.*

(iv) *The unit of adjunction* $\underline{A} \to \Gamma \circ \mathsf{Spec}\,\underline{A}$ *induces a homeomorphism*

$$\mathrm{ZR}(\Gamma \circ \mathsf{Spec}\,\underline{A}) \xrightarrow{\sim} \mathrm{ZR}(\underline{A}).$$

Especially, $\mathrm{ZR}(\underline{A})$ *depends only on the quasi-affinoid scheme* $\mathsf{Spec}\,\underline{A}$.

(v) *The homeomorphism* $\mathrm{Spa}(\underline{A}_{\mathrm{loc}}) \xrightarrow{\sim} \mathrm{Spa}(\underline{A})$ *of lemma* 15.4.17(i) *restricts to a homeomorphism :*

$$\mathrm{ZR}(\underline{A}_{\mathrm{loc}}) \xrightarrow{\sim} \mathrm{ZR}(\underline{A}).$$

Proof. (i): Recall that $\mathrm{Cont}(A)$ is closed under specializations in $\mathrm{Spv}\,A$ (remark 15.3.13(iv)); it follows easily that $\mathrm{Spa}(A, A^+)$ is closed under primary specializations. Recall as well that a proper specialization (v, w) in $\mathrm{Spv}\,A$ is J-admissible if and only if w is a primary specialization of v and the supports of v and w lie in U (see (15.3.1)); hence, if $v \in \mathrm{Spa}\,\underline{A}$, the proper specialization (v, w) is J-admissible if and only if w is a primary specialisation of v that lies in $\mathrm{Spa}\,\underline{A}$. Then the assertion follows from lemma 15.3.4(iii).

(ii): Let $A_0 \subset A$ be a subring of definition, and $I \subset A_0$ a finitely generated ideal of adic definition; recall that $\mathrm{Spa}(\underline{A})$ is a pro-constructible subset of $\mathrm{Cont}(A)$ (proposition 15.4.22(i)) and the inclusion map $\mathrm{Cont}(A) \to \mathrm{Spv}(A, IA)$ is a closed immersion (theorem 15.3.15(ii)) so $\mathrm{Spv}(\underline{A})$ is a pro-constructible subset of $\mathrm{Spv}(A, IA)$ (corollary 8.1.50(i)). Moreover, the radical of J contains IA, hence the inclusion map $\mathrm{Spv}(A, J) \to \mathrm{Spv}(A, IA)$ admits a spectral retraction (lemma 15.3.9(i))

$$r : \mathrm{Spv}(A, IA) \to \mathrm{Spv}(A, J). \qquad (15.5.18)$$

Namely, for every $v \in \mathrm{Spv}(A, IA)$, the valuation $r(v)$ is the unique J-admissible specialization of v that does not admit further proper J-admissible specializations. We claim that

$$\mathrm{ZR}(\underline{A}) = r(\mathrm{Spa}\,\underline{A}).$$

Indeed, clearly $\mathrm{ZR}(\underline{A}) = r(\mathrm{ZR}(\underline{A})) \subset r(\mathrm{Spa}\,\underline{A})$. The converse inclusion follows from the proof of (i). Then, the assertion follows from corollary 8.1.50(i).

(iii) follows immediately from (ii) and theorem 15.3.7(ii).

(iv) follows directly from (i) and lemmata 15.4.17(ii) and 9.2.25(i).

(v): Clearly the homeomorphism $\mathrm{Spa}\,\underline{A}_{\mathrm{loc}} \xrightarrow{\sim} \mathrm{Spa}\,\underline{A}$ preserves primary specializations, so the assertion follows from (i). □

Remark 15.5.19. In [157], Temkin associates with every separated morphism $f : Y \to X$ of quasi-compact and quasi-separated schemes, a spectral space that he calls the Riemann-Zariski space of f, and denotes $\mathrm{RZ}_Y(X)$, together with a continuous map $\mathrm{RZ}_Y(X) \to X$. His construction generalizes earlier work by Zariski, and is related as follows to our $\mathrm{ZR}(\underline{A})$. Let $U \to \operatorname{Spec} A^+$ be the composition of the open immersion $U \to \operatorname{Spec} A$ with the natural morphism $\operatorname{Spec} A \to \operatorname{Spec} A^+$; then we may consider the induced map $\varphi : \mathrm{RZ}_U(\operatorname{Spec} A^+) \to \operatorname{Spec} A^+$, and there is a natural homeomorphism $\varphi^{-1}(\operatorname{Spec} A^+/A^{\circ\circ}) \xrightarrow{\sim} \mathrm{ZR}(\underline{A})$.

15.5.20. Keep the notation of (15.5.16), and for some integer $n \geq -1$, let $R_\bullet := (R_i \mid i = 0, \dots, n)$ be a finite system of open subsets of $\mathrm{ZR}(\underline{A})$ such that $\mathrm{ZR}(\underline{A}) = \bigcup_{i=0}^n R_i$ (the case $n = -1$ occurs for the empty covering of the empty Zariski-Riemann spectrum); let also $A' \subset A$ be a subring, and J' an ideal of A'. Then we say that $R_\bullet$ is an (A', J')-*standard covering* of $\mathrm{ZR}(\underline{A})$ if there exists a finite system $f_\bullet := (f_0, \dots, f_n)$ of elements of A' such that :

- $R_i = R_A\big(\frac{f_0}{f_i}, \dots, \frac{f_n}{f_i}\big) \cap \mathrm{ZR}(\underline{A})$ for $i = 0, \dots, n$
- J' is contained in the radical of the ideal of A generated by the system $f_\bullet$.

Especially, each R_i is a rational subset of $\mathrm{ZR}(\underline{A})$. By construction, the retraction r of (15.5.18) restricts to a surjective continuous map

$$s : \operatorname{Spa} \underline{A} \to \mathrm{ZR}(\underline{A})$$

and if $f_\bullet$ fulfills the foregoing conditions, lemma 15.3.5(i) says that

$$s^{-1}R_i = R_A\Big(\frac{f_0}{f_i}, \dots, \frac{f_n}{f_i}\Big) \cap \operatorname{Spa} \underline{A} \qquad \text{for every } i = 0, \dots, n.$$

Especially, the system $(R_A\big(\frac{f_0}{f_i}, \dots, \frac{f_n}{f_i}\big) \cap \operatorname{Spa} \underline{A} \mid i = 0, \dots, n)$ is a covering of $\operatorname{Spa} \underline{A}$. A covering of $\operatorname{Spa} \underline{A}$ of this type shall also be called a (A', J')-*standard covering*. In case $A' = A$ and $J' = J$, we shall write simply *standard covering* for this class of coverings of $\mathrm{ZR}(\underline{A})$ and of $\operatorname{Spa} \underline{A}$. The following lemma refines [100, Lemma 2.6].

Lemma 15.5.21. *Let $j : A' \to A$ be the inclusion of a subring, and $J' \subset A'$ a finitely generated ideal with $J'A \subset J$, and such that* $\operatorname{Spec}(j)$ *restricts to an isomorphism of schemes*

$$U \xrightarrow{\sim} \operatorname{Spec}(A') \setminus \operatorname{Spec}(A'/J'). \tag{15.5.22}$$

Then every open covering of $\mathrm{ZR}(\underline{A})$ *or* $\operatorname{Spa} \underline{A}$ *is refined by an (A', J')-standard covering.*

Proof. We consider first the case where $A' = A$ and $J' = J$. Let $U_\bullet := (U_\lambda \mid \lambda \in \Lambda)$ be an open covering of $\mathrm{ZR}(\underline{A})$; we need to find a standard covering $(R_i \mid i = 0, \dots, n)$ such that, for every $i = 0, \dots, n$ there exists $\lambda \in \Lambda$ with $R_i \subset U_\lambda$. To this aim, we suppose first that A is topologically local; in light of proposition 15.5.17(i,ii) we may assume that Λ is a finite set, and each U_λ is rational, say

$$U_\lambda = R_A\Big(\frac{g_{\lambda,1}}{g_{\lambda,0}}, \dots, \frac{g_{\lambda,n_\lambda}}{g_{\lambda,0}}\Big) \cap \mathrm{ZR}(\underline{A})$$

for a finite system $g_{\lambda,\bullet} := (g_{\lambda,j} \mid j = 0, \dots, n_\lambda)$ of elements of A that generates an ideal whose radical contains J. Define S as the set of all the sequences of integers $j_\bullet := (j_\lambda \mid \lambda \in \Lambda)$ such that $0 \leq j_\lambda \leq n_\lambda$ for every $\lambda \in \Lambda$. Let also $T \subset S$ be the subset of all sequences $j_\bullet$ such that $j_\lambda = 0$ for at least one $\lambda \in \Lambda$. Set $g_{j_\bullet} := \prod_{\lambda \in \Lambda} g_{\lambda, j_\lambda}$ for every $j_\bullet \in S$. Notice that :

$$R_{k_\bullet} := R_A\Big(\frac{g_{j_\bullet}}{g_{k_\bullet}} \mid j_\bullet \in S\Big) = \bigcap_{\lambda \in \Lambda} R_A\Big(\frac{g_{\lambda,1}}{g_{\lambda,k_\lambda}}, \dots, \frac{g_{\lambda,n_\lambda}}{g_{\lambda,k_\lambda}}\Big) \qquad \text{for every } k_\bullet \in S.$$

Moreover, each $g_{\lambda,\bullet}$ defines a standard open covering of $\mathrm{ZR}(\underline{A})$. It follows easily that

$$\mathrm{ZR}(\underline{A}) = \bigcup_{k_\bullet \in T} (R_{k_\bullet} \cap \mathrm{ZR}(\underline{A})) \tag{15.5.23}$$

and furthermore, for every $k_\bullet \in T$, the subset $R_{k_\bullet} \cap \mathrm{ZR}(\underline{A})$ is contained in some U_λ.

Claim 15.5.24. $R_{k_\bullet} \cap \mathrm{ZR}(\underline{A}) = R_A\big(\frac{g_{j_\bullet}}{g_{k_\bullet}} \mid j_\bullet \in T\big) \cap \mathrm{ZR}(\underline{A})$ for every $k_\bullet \in T$.

Proof of the claim. Indeed, the inclusion $R_{k_\bullet} \subset R'_{k_\bullet} := R_A\big(\frac{g_{j_\bullet}}{g_{k_\bullet}} \mid j_\bullet \in T\big)$ is obvious. Conversely, let $v \in R'_{k_\bullet} \cap \mathrm{ZR}(A)$; we see from (15.5.23) that for every $j_\bullet \in S$ there exists $i_\bullet \in T$ such that $v(g_{j_\bullet}) \leq v(i_\bullet) \neq 0$, whence $v(g_{j_\bullet}) \leq v(k_\bullet) \neq 0$, so $v \in R_{k_\bullet}$. ◊

In light of (15.5.23) and claim 15.5.24, to conclude it now suffices to show :

Claim 15.5.25. J is contained in the radical of the ideal J' of A generated by $(g_{k_\bullet} \mid k_\bullet \in T)$.

Proof of the claim. First, we check that J' is an open ideal, using the criterion of lemma 15.3.25. Indeed, by claim 15.4.23, every continuous analytic rank one valuation of A lies in $\mathrm{Spa}\,\underline{A}$, and from (15.5.23) and claim 15.5.24 we see that for every such valuation v there exists $k_\bullet \in T$ such that $v(g_{k_\bullet}) \neq 0$, whence the assertion. By lemma 8.3.29(v), it follows that $\mathrm{Spec}A/J' \subset X^{\circ\circ}_A := \mathrm{Spec}\,A/A^{\circ\circ}A$. Hence, let $\mathfrak{p} \in X^{\circ\circ}_A \setminus \mathrm{Spec}A/J'$; it suffices to show that $J' \not\subset \mathfrak{p}$. To this aim, denote by $v_\mathfrak{p}$ the trivial valuation of A supported at $\mathfrak{p}$ (see remark 9.1.4(vii)); since $\mathfrak{p}$ is an open ideal (lemma 8.3.29(i)), the valuation $v_\mathfrak{p}$ is continuous (remark 15.3.13(vi)), and then obviously $v \in \mathrm{Spa}\,\underline{A}$. As in the foregoing, we deduce that $v_\mathfrak{p}(g_{k_\bullet}) \neq 0$ for some $k_\bullet \in T$, *i.e.* $g_{k_\bullet} \notin \mathfrak{p}$, whence the claim. ◊

• Next, let A be any f-adic ring; let us choose a subring of definition A_0 of A such that $A_0 \subset A^+$, and let $I_0 \subset A_0$ be a finitely generated ideal of definition. We apply the foregoing to the topological localization $(A, A^+, U)_{\mathrm{loc}}$: notice that proposition 15.5.17(v) naturally identifies $U_\bullet$ with an open covering of $\mathrm{ZR}(\underline{A}_{\mathrm{loc}})$. By the foregoing, there exists therefore a finite system $f_0, \dots, f_n$ of elements of $A_{\mathrm{loc}} = (1 + I_0)^{-1}A$ such that JA_{loc} lies in the radical of $\sum_{i=0}^n A_{\mathrm{loc}} f_i$, and the standard covering $(R_{A_{\mathrm{loc}}}(\frac{f_0}{f_i}, \cdots, \frac{f_n}{f_i}) \cap \mathrm{ZR}(\underline{A}_{\mathrm{loc}}))$ refines $U_\bullet$. After clearing some denominators, we may assume that $f_0, \dots, f_n \in A$, and it follows easily that there exists $s \in 1 + I_0$ such that sJ lies in the radical of $\sum_{i=0}^n Af_i$. Since J is an open ideal, we have $I_0^k \subset J$ for some $k \in \mathbb{N}$; then, after replacing k by a larger integer, we also get $sI_0^k \subset \sum_{i=0}^n Af_i$. Next, after replacing k by a still larger integer, we can assume that $sI_0^k \subset \sum_{i=0}^n A_0 f_i$. Let also $g_1, \dots, g_m$ be a finite system of generators of I_0; since $A_0 \subset A^+$, it follows that

$$\max(v(g_1)^k, \dots, v(g_m)^k) \leq \max(v(f_0), \dots, v(f_n)) \qquad \text{for every } v \in \mathrm{Spa}(A, A^+)$$

and since J is in the radical of $\sum_{i=0}^n Af_i$, we deduce :

$$\max(v(g_1)^{k+1}, \dots, v(g_m)^{k+1}) < \max(v(f_0), \dots, v(f_n)) \qquad \text{for every } v \in \mathrm{Spa}(A, A^+, U).$$

Since $s \in 1 + I_0$, it is easily seen that the radical of $\sum_{i=0} Af_i + \sum_{j=1}^m Ag_j$ contains J. Then, consider the standard covering $R'_\bullet$ of $\mathrm{ZR}(\underline{A})$ associated with the sequence $(f_\bullet, g_\bullet^{k+1})$: every element of $R'_\bullet$ of the form $R_A(\frac{f_\bullet}{f_i}, \frac{g_\bullet^{k+1}}{f_i})$ (for any $i = 0, \dots, n$) equals $R_A(\frac{f_\bullet}{f_i})$, and on the other hand $R_A(\frac{f_\bullet}{g_j^{k+1}}, \frac{g_\bullet^{k+1}}{g_j^{k+1}}) = \varnothing$ for every $j = 1, \dots, m$. Hence, $R'_\bullet$ refines $U_\bullet$.

• Lastly, consider any open covering $(U'_\lambda \mid \lambda \in \Lambda)$ of $\mathrm{Spa}\,\underline{A}$, and set $U_\lambda := U'_\lambda \cap \mathrm{ZR}(\underline{A})$ for every $\lambda \in \Lambda$; clearly $(U_\lambda \mid \lambda \in \Lambda)$ is an open covering of $\mathrm{ZR}(\underline{A})$, which can be refined by a standard covering $(R_0, \dots, R_n)$; but then the system $(s^{-1}R_0, \dots, s^{-1}R_n)$ is a standard covering of $\mathrm{Spa}\,\underline{A}$, and notice that if $R_i \subset U_\lambda$, we get

$$s^{-1}R_i \subset s^{-1}U_\lambda \subset U'_\lambda$$

where the last inclusion holds, since U'_λ is open in $\mathrm{Spa}\,\underline{A}$ and $s^{-1}U_\lambda$ is the set of all primary generizations of the elements of U_λ in $\mathrm{Spa}\,\underline{A}$. Thus, $(s^{-1}R_0, \dots, s^{-1}R_n)$ refines the covering $(U'_\lambda \mid \lambda \in \Lambda)$, as required.

• We consider next the case of a general pair (A', J'). By the foregoing, the given covering $U_\bullet$ of $\mathrm{ZR}(\underline{A})$ or $\mathrm{Spa}\,\underline{A}$ is refined by the standard covering associated with a sequence $g_0, \dots, g_n$

of elements of A. Set $I := \sum_{i=0}^n Ag_i$, and let $h_1, \dots, h_m$ be a finite system of generators of J'; under the stated assumptions, j induces an isomorphism $A'[h_k^{-1}] \xrightarrow{\sim} A[h_k^{-1}]$ for every $i = 1, \dots, m$, so there exists $N \in \mathbb{N}$ such that $f_{ki} := h_k^N g_i \in A'$ for every $k = 1, \dots, m$ and every $i = 0, \dots, n$. Let $I' \subset A'$ be the ideal generated by $f_{\bullet\bullet} := (f_{ki} \mid 1 \le k \le m, 0 \le i \le n)$; notice that $\mathrm{Spec}(A/I'A) = \mathrm{Spec}(A/I) \cup \mathrm{Spec}(A/J'A)$, and by assumption $\mathrm{Spec}(A/I) \subset \mathrm{Spec}(A/J) \subset \mathrm{Spec}(A/J'A)$. So, $\mathrm{Spec}(A/I'A) \subset \mathrm{Spec}(A/J'A)$, and notice that

$$\mathrm{Spec}(A/I'A) = (\mathrm{Spec}\, j)^{-1}(\mathrm{Spec}\, A'/I') \quad \text{and} \quad \mathrm{Spec}(A/J'A) = (\mathrm{Spec}\, j)^{-1}(\mathrm{Spec}\, A'/J').$$

In view of the isomorphism (15.5.22), it follows that $\mathrm{Spec}(A'/I') \subset \mathrm{Spec}(A'/J')$, *i.e.* the radical of I' contains J'. Moreover, by the same token we have :

$$\mathrm{Spa}\, \underline{A} = \bigcup_{j=1}^m \mathrm{Spa}(A, A^+) \cap R_A\Big(\frac{h_1^N}{h_j^N}, \dots, \frac{h_m^N}{h_j^N}\Big).$$

Taking into account remark 9.2.4(i), we conclude easily that the (A', J')-standard covering associated with the sequence $f_{\bullet\bullet}$ is the sought refinement of $U_\bullet$. □

Remark 15.5.26. The following constructions shall be exploited in the proofs of both theorem 15.5.27 and theorem 15.5.35.

(i) Let $\underline{X}$ be a topologically local quasi-affinoid scheme, set $(A, A^+, X) := \Gamma(\underline{X})$, and choose a subring of definition $A_0 \subset A$ and a finitely generated ideal $I_0 \subset A_0$ of adic definition. Consider a sequence $f_\bullet := (f_0, \dots, f_n)$ of elements of A that generates an ideal $J \subset A$ such that $X \cap \mathrm{Spec}\, A/J = \varnothing$, and let $R_\bullet := (R_0, \dots, R_n)$ be the standard covering of $\mathrm{Spa}\, \underline{X}$ associated with $f_\bullet$. For every subset $\Lambda \subset \{0, \dots, n\}$, let $A_\Lambda := A[f_i^{-1} \mid i \in \Lambda]$ and $X_\Lambda := X \cap \mathrm{Spec}\, A_\Lambda$; by inspecting the definitions we see that

$$R_\Lambda := \bigcap_{i \in \Lambda} R_i = \mathrm{Spa}\, \underline{A}_\Lambda \qquad \text{with} \qquad \underline{A}_\Lambda := (A_\Lambda, A_\Lambda^+, X_\Lambda)$$

where A_Λ^+ is the integral closure of $A^+[f_k/f_i \mid (k,i) \in \{0, \dots, n\} \times \Lambda]$ in A_Λ; moreover, $A_{0,\Lambda} := A_0[f_k/f_i \mid (k,i) \in \{0, \dots, n\} \times \Lambda]$ is a subring of definition of A_Λ, and the natural ring homomorphism $A_0 \to A_{0,\Lambda}$ is adic (here we let $R_\varnothing := \mathrm{Spa}\, \underline{X}$). Furthermore, since X is quasi-compact, we have $\mathscr{O}_X(X_\Lambda) = A_\Lambda$ ([59, Ch.I, Prop.9.2.1]), and therefore

$$\underline{A}_\Lambda = \Gamma \circ \mathsf{Spec}\, (\underline{A}_\Lambda) \qquad \text{for every } \Lambda \subset \{0, \dots, n\}.$$

(ii) Denote by $(A_{0,\Lambda}^{\mathrm{h}}, I_{0,\Lambda}^{\mathrm{h}})$ the henselization of the pair $(A_{0,\Lambda}, I_0 A_{0,\Lambda})$, and endow $A_{0,\Lambda}^{\mathrm{h}}$ with the $I_{0,\Lambda}^{\mathrm{h}}$-adic topology; we deduce a unique isomorphism of topological A-algebras :

$$\omega_\Lambda^{\mathrm{h}} : A_\Lambda^{\mathrm{h}} := A_\Lambda \otimes_{A_{0,\Lambda}} A_{0,\Lambda}^{\mathrm{h}} \xrightarrow{\sim} \mathscr{O}_{\mathrm{Spa}\, \underline{X}}^{\mathrm{h}}(R_\Lambda) \qquad \text{for every } \Lambda \subset \{0, \dots, n\}$$

where the topology on A_Λ^{h} is the unique one such that the natural map $A_{0,\Lambda}^{\mathrm{h}} \to A_\Lambda^{\mathrm{h}}$ is open (proposition 8.3.34(ii)). Likewise, let $A_\Lambda^\wedge$ be the separated completion of A_Λ; we deduce a natural continuous homomorphism of A-algebras

$$\omega_\Lambda^\wedge : A_\Lambda^\wedge \to \mathscr{O}_{\mathrm{Spa}\, \underline{X}}^\wedge(R_\Lambda) \qquad \text{for every } \Lambda \subset \{0, \dots, n\}.$$

Notice also that for every $\Lambda' \subset \Lambda$ there exist unique continuous homomorphisms of A-algebras and respectively $A_{0,\Lambda}$-algebras

$$\mu_{\Lambda',\Lambda} : A_{\Lambda'} \to A_\Lambda \qquad \mu_{0,\Lambda',\Lambda}^{\mathrm{h}} : A_{0,\Lambda'}^{\mathrm{h}} \to A_{0,\Lambda}^{\mathrm{h}}$$

and set $\mu_{\Lambda',\Lambda}^{\mathrm{h}} := \mu_{\Lambda',\Lambda} \otimes_A \mu_{0,\Lambda',\Lambda}^{\mathrm{h}}$. Let also $\mu_{\Lambda',\Lambda}^\wedge : A_{\Lambda'}^\wedge \to A_\Lambda^\wedge$ be the completion of $\mu_{\Lambda',\Lambda}$, and

$$\rho_{\Lambda',\Lambda}^{\mathrm{h}} : \mathscr{O}_{\mathrm{Spa}\, \underline{X}}^{\mathrm{h}}(R_{\Lambda'}) \to \mathscr{O}_{\mathrm{Spa}\, \underline{X}}^{\mathrm{h}}(R_\Lambda) \qquad \rho_{\Lambda',\Lambda}^\wedge : \mathscr{O}_{\mathrm{Spa}\, \underline{X}}^\wedge(R_{\Lambda'}) \to \mathscr{O}_{\mathrm{Spa}\, \underline{X}}^\wedge(R_\Lambda)$$

the restriction homomorphisms associated with the inclusion $R_\Lambda \subset R_{\Lambda'}$.

(iii) We claim that the diagrams of A-algebras:

$$\begin{array}{ccc} A^{\mathrm{h}}_{\Lambda'} & \xrightarrow{\omega^{\mathrm{h}}_{\Lambda'}} & \mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X}}(R_{\Lambda'}) \\ {\scriptstyle \mu^{\mathrm{h}}_{\Lambda',\Lambda}}\downarrow & & \downarrow{\scriptstyle \rho^{\mathrm{h}}_{\Lambda',\Lambda}} \\ A^{\mathrm{h}}_{\Lambda} & \xrightarrow{\omega^{\mathrm{h}}_{\Lambda}} & \mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X}}(R_{\Lambda}) \end{array} \qquad \begin{array}{ccc} A^{\wedge}_{\Lambda'} & \xrightarrow{\omega^{\wedge}_{\Lambda'}} & \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}(R_{\Lambda'}) \\ {\scriptstyle \mu^{\wedge}_{\Lambda',\Lambda}}\downarrow & & \downarrow{\scriptstyle \rho^{\wedge}_{\Lambda',\Lambda}} \\ A^{\wedge}_{\Lambda} & \xrightarrow{\omega^{\wedge}_{\Lambda}} & \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}(R_{\Lambda}) \end{array}$$

commute for every $\Lambda' \subset \Lambda \subset \{0, \dots, n\}$. Indeed, a simple inspection shows that $\mu^{\mathrm{h}}_{\Lambda',\Lambda}$ is continuous. On the other hand, all the arrows in the diagram are A-algebra homomorphisms, therefore also $A_{\Lambda'}$-algebra homomorphisms, and by the universal property of the topological henselization there is a unique continuous $A_{\Lambda'}$-algebra homomorphism $A^{\mathrm{h}}_{\Lambda'} \to \mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X}}(R_{\Lambda})$, whence the contention for the left diagram. For the right diagram one argues similarly, using the universal property of the separated completions.

(iv) Endow $A[Y]$ and $B := A_0[T_0, \dots, T_n]$ with the standard $\mathbb{N}$-gradings such that $\mathrm{gr}_k A[Y] = AY^k$ and $\mathrm{gr}_k B$ is the free A-module generated by the monomials $T_0^{\nu_0} \cdots T_n^{\nu_n}$ of total degree $\nu_0 + \cdots + \nu_n = k$, for every $k \in \mathbb{N}$. Set as well

$$S := \mathrm{Spec}\, A_0 \qquad \mathbb{P}^n_S := \mathrm{Proj}\, B$$

and recall that $\mathbb{P}^n_S$ admits the following finite affine open covering (see (10.6.1)). For every $i = 0, \dots, n$ we have the subring $B_i := A_0[T_0/T_i, \dots, T_n/T_i]$ of $B[1/T_i]$, and $\Omega_i := \mathrm{Spec}\, B_i$ is naturally identified with the open subscheme of $\mathbb{P}^n_S$ consisting of all homogeneous prime ideals of B that do not contain T_i; then

$$\mathbb{P}^n_S = \Omega_0 \cup \cdots \cup \Omega_n.$$

Next, according to (10.6.5), the homomorphism of $\mathbb{N}$-graded A_0-algebras

$$h : B \to A[Y] \qquad T_j \mapsto f_j Y \qquad \text{for every } j = 0, \dots, n$$

induces a morphism of A_0-schemes

$$\varphi : \mathrm{Spec}\, A \setminus \mathrm{Spec}\, A/J \to \mathbb{P}^n_S.$$

Explicitly, $\varphi^{-1}\Omega_i = \mathrm{Spec}\, A_{\{i\}}$ for every $i = 0, \dots, n$, and the restriction $\varphi^{-1}\Omega_i \to \Omega_i$ of φ corresponds to the homomorphism of A_0-algebras

$$h_i : B_i \to A_{\{i\}} \qquad T_j/T_i \mapsto f_j/f_i \qquad \text{for every } j = 0, \dots, n.$$

(v) Now, quite generally, let $\beta : \mathsf{X} \to \mathsf{Y}$ be any quasi-compact and quasi-separated morphism of schemes. Then $\beta_*\mathscr{O}_{\mathsf{X}}$ is a quasi-coherent $\mathscr{O}_{\mathsf{Y}}$-module ([59, Ch.I, Prop.9.2.1]), hence $\mathscr{I} := \mathrm{Ker}\, \beta^\sharp : \mathscr{O}_{\mathsf{Y}} \to \beta_*\mathscr{O}_{\mathsf{X}}$ is a quasi-coherent sheaf of ideals of $\mathscr{O}_{\mathsf{Y}}$, and therefore $\mathrm{Spec}\, \mathscr{O}_{\mathsf{Y}}/\mathscr{I}$ is a well defined closed subscheme of Y, called the *schematic image of* ψ. From the definition, it is clear that the construction of the schematic image is local on Y : namely, if $\mathsf{Y}' \subset \mathsf{Y}$ is any open subscheme, and $\mathsf{X}' := \beta^{-1}\mathsf{Y}'$, then the schematic image of $\beta_{|\mathsf{X}'} : \mathsf{X}' \to \mathsf{Y}'$ is the intersection of Y' with the schematic image of β.

Thus, if V is the schematic image of our φ, we get a commutative diagram of schemes

$$\begin{array}{ccc} X & \xrightarrow{\quad\psi\quad} & V \\ \downarrow & \nearrow & \downarrow{\scriptstyle \iota} \\ \mathrm{Spec}\, A \setminus \mathrm{Spec}\, A/J & \xrightarrow{\quad\varphi\quad} & \mathbb{P}^n_S \end{array}$$

whose left vertical arrow is an open immersion, and with ι a closed immersion. Lastly, set $V_\varnothing := V$ and for every subset $\Lambda \subset \{0, \dots, n\}$ let $V_\Lambda := \iota^{-1}\left(\bigcap_{i\in\Lambda} \Omega_i\right)$; then V_Λ is naturally identified with $\mathrm{Spec}\, A_{0,\Lambda}$, for every non-empty Λ.

(vi) Furthermore, let U be the analytic locus of S; recall that the morphism $\mathrm{Spec}\, A \to S$ (associated with the inclusion map $A_0 \to A$) identifies U with the analytic locus of $\mathrm{Spec}\, A$ (lemma 8.3.29(iii)), and U is an open subset of X, under this identification. Then $\mathbb{P}^n_U := \mathbb{P}^n_S \times_S U$ is an open subset of $\mathbb{P}^n_S$, and we claim that ψ restricts to an isomorphism of schemes

$$\psi_{|U} : U \xrightarrow{\sim} V \cap \mathbb{P}^n_U.$$

Indeed, $\psi_{|U}$ is a closed immersion, by [59, Ch.I, Cor.5.4.6]. On the other hand, $\psi_{|U}$ is also the schematic closure of the restriction $U \to \mathbb{P}^n_U$ of φ, whence the claim.

Theorem 15.5.27. *For any topologically local quasi-affinoid scheme $\underline{X} := (X, \mathscr{T}_X, A^+)$, the presheaves $\mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\, \underline{X}}$ and $\mathscr{O}^{\mathrm{h}+}_{\mathrm{Spa}\, \underline{X}}$ are sheaves of rings on $(\mathscr{Q}(\underline{X}), J_{\mathscr{Q}})$.*

Proof. Notice first that – by virtue of corollary 15.4.27(i) – if $\mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\, \underline{X}}$ is a sheaf, the same holds for $\mathscr{O}^{\mathrm{h}+}_{\mathrm{Spa}\, \underline{X}}$, so it suffices to check the assertion for $\mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\, \underline{X}}$. To this aim, for every $U \in \mathrm{Ob}(\mathscr{Q}(\underline{X}))$ and every $\mathscr{S} \in J_{\mathscr{Q}}(U)$, let $h_{\mathscr{S}}$ be the corresponding sub-presheaf of the presheaf h_U on $\mathscr{Q}(\underline{X})$ represented by U. According to claim 4.1.16(ii,iii), it suffices to show that the natural map

$$r_U : \mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\, \underline{X}}(U) \to \operatorname*{colim}_{\mathscr{S} \in J_{\mathscr{Q}}(U)} \mathrm{Hom}_{\mathscr{Q}(\underline{X})^\wedge}(h_{\mathscr{S}}, \mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\, \underline{X}})$$

is a bijection for every such U. However, let $\varphi_{\underline{T}/\underline{X}} : \underline{T} \to \underline{X}$ be any morphism of topologically local quasi-affinoid schemes representing the inclusion $h_U \subset h_{\underline{X}}$ (see (15.5.7)); by remark 15.5.9(v) it follows that $\varphi_{\underline{T}/\underline{X}}$ induces an equivalence of categories

$$\mathscr{Q}(\underline{T}) \xrightarrow{\sim} \mathscr{Q}(\underline{X})/U \qquad V \mapsto \mathrm{Spa}\, \varphi_{\underline{T}/\underline{X}}(V) \subset U$$

so we may replace $\underline{X}$ by $\underline{T}$, and reduce to checking that $r_{\mathrm{Spa}\, \underline{X}}$ is an isomorphism. Next, lemma 15.5.21 implies that the sieves of $\mathscr{Q}(\underline{X})$ generated by the standard coverings of $\mathrm{Spa}\, \underline{X}$ form a coinitial subset of $J_{\mathscr{Q}}(\mathrm{Spa}\, \underline{X})$. Hence, let $f_\bullet$ and $R_\bullet$ be as in remark 15.5.26(i); taking into account the discussion of (4.1.6), we are then reduced to checking that the natural map

$$\mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\, \underline{X}}(\mathrm{Spa}\, \underline{X}) \to \mathrm{Equal}\Big(\prod_{i=0}^{n} \mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\, \underline{X}}(R_i) \rightrightarrows \prod_{i,j=0}^{n} \mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\, \underline{X}}(R_{\{i,j\}})\Big)$$

is a bijection. Now, say that $(A, A^+, X) = \Gamma(\underline{X})$. Recall that the henselization morphism

$$\lambda : \underline{X}^{\mathrm{h}} := (X^{\mathrm{h}}, \mathscr{T}^{\mathrm{h}}_X, A^{\mathrm{h}+}) \to \underline{X}$$

is f-adic and induces a homeomorphism $\mathrm{Spa}\, \lambda : \mathrm{Spa}\, \underline{X}^{\mathrm{h}} \xrightarrow{\sim} \mathrm{Spa}\, \underline{X}$, as well as an isomorphism of schemes $X^{\mathrm{h}} \xrightarrow{\sim} X \times_A A^{\mathrm{h}}$; it follows easily that the system $((\mathrm{Spa}\, \lambda)^{-1} R_i \mid i = 0, \dots, n)$ is a rational covering of $\mathrm{Spa}\, \underline{X}^{\mathrm{h}}$, and moreover there is a unique isomorphism of presheaves of topological A-algebras

$$\mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\, \underline{X}^{\mathrm{h}}} \xrightarrow{\sim} (\mathrm{Spa}\, \lambda)^{-1} \mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\, \underline{X}}.$$

We may then replace $\underline{X}$ by $\underline{X}^{\mathrm{h}}$, and assume from start that $\underline{X}$ is topologically henselian.

In this situation, let $A_0 \subset A$ be a subring of definition, and $I_0 \subset A_0$ an ideal of adic definition; consider the system of quasi-affinoid rings $(\underline{A}_\Lambda \mid \Lambda \subset \{0, \dots, n\})$, their rings of definition $A_{0,\Lambda} \subset A_\Lambda$, and the systems of their topological henselizations $(A^{\mathrm{h}}_\Lambda \mid \Lambda \subset \{0, \dots, n\})$ and $(A^{\mathrm{h}}_{0,\Lambda} \mid \Lambda \subset \{0, \dots, n\})$ constructed in remark 15.5.26(i). Define also S, V, $\psi : X \to V$ and V_Λ for every subset $\Lambda \subset \{0, \dots, n\}$ as in remark 15.5.26(iv,v); set $S' := \mathrm{Spec}\, A_0/I_0$, $V'_\Lambda := V_\Lambda \times_S S'$ for every such Λ, and consider the cartesian diagram of schemes

$$\begin{array}{ccc} V' & \xrightarrow{\tau_V} & V \\ {\scriptstyle \pi'}\downarrow & & \downarrow{\scriptstyle \pi} \\ S' & \xrightarrow{\tau_S} & S \end{array}$$

where π is the restriction to V of the projection $\mathbb{P}^n_S \to S$ and $\tau_S : S' \to S$ is the closed immersion. For every scheme X, let $\mathsf{X}_{\mathrm{\acute{e}t}}$ be the étale site of X, and $\mathscr{O}_{\mathsf{X}_{\mathrm{\acute{e}t}}}$ the structure sheaf of rings on $\mathsf{X}_{\mathrm{\acute{e}t}}$. We define the sheaf on $V'_{\mathrm{\acute{e}t}}$

$$\mathscr{F} := \tau_V^* \psi_* \mathscr{O}_{X_{\mathrm{\acute{e}t}}}.$$

Claim 15.5.28. (i) For every $\Lambda \subset \{0, \dots, n\}$ there exists a commutative diagram of rings

$$\mathscr{D}_\Lambda \quad : \quad \begin{array}{ccc} A^{\mathrm{h}}_{0,\Lambda} & \xrightarrow{\omega_{0,\Lambda}} & \Gamma(V'_\Lambda, \tau_V^* \mathscr{O}_{V,\mathrm{\acute{e}t}}) \\ \downarrow & & \downarrow \\ A^{\mathrm{h}}_\Lambda & \xrightarrow{\omega_\Lambda} & \Gamma(V'_\Lambda, \mathscr{F}) \end{array}$$

whose left vertical arrow is the inclusion map, and whose right vertical arrow is deduced from $\psi^\sharp : \mathscr{O}_{V,\mathrm{\acute{e}t}} \to \psi_* \mathscr{O}_{X,\mathrm{\acute{e}t}}$. Moreover, $\omega_{0,\Lambda}$ is an isomorphism of A_0-algebras for every $\Lambda \neq \varnothing$, and ω_Λ is an isomorphism of A-algebras for every Λ.

(ii) For every $\Lambda' \subset \Lambda$, let $\rho_{\Lambda',\Lambda} : \Gamma(V'_{\Lambda'}, \mathscr{F}) \to \Gamma(V'_\Lambda, \mathscr{F})$ be the restriction homomorphism associated with the inclusion $V'_\Lambda \subset V'_{\Lambda'}$. Then we have a commutative diagram

$$\begin{array}{ccc} A^{\mathrm{h}}_{\Lambda'} & \xrightarrow{\omega_{\Lambda'}} & \Gamma(V'_{\Lambda'}, \mathscr{F}) \\ {\scriptstyle \mu^{\mathrm{h}}_{\Lambda',\Lambda}} \downarrow & & \downarrow {\scriptstyle \rho_{\Lambda',\Lambda}} \\ A^{\mathrm{h}}_\Lambda & \xrightarrow{\omega_\Lambda} & \Gamma(V'_\Lambda, \mathscr{F}). \end{array}$$

Proof of the claim. (i): We consider first the case where $\Lambda = \varnothing$, and notice that $V_\varnothing = V$, $A^{\mathrm{h}}_{0,\varnothing} = A_0$ and $A^{\mathrm{h}}_\varnothing = A$. Under the current assumptions, the pair (A_0, I_0) is henselian; by [10, Exp.XII, Th.5.1(i) and Prop.6.5(i)] we then get for every sheaf $\mathscr{G}$ on $V_{\mathrm{\acute{e}t}}$ natural isomorphisms

$$\Gamma(V, \mathscr{G}) \xrightarrow{\sim} \Gamma(S, \pi_* \mathscr{G}) \xrightarrow{\sim} \Gamma(S', \tau_S^* \pi_* \mathscr{G}) \xrightarrow{\sim} \Gamma(S', \pi'_* \tau_V^* \mathscr{G}) \xrightarrow{\sim} \Gamma(V', \tau_V^* \mathscr{G}).$$

Taking $\mathscr{G} := \psi_* \mathscr{O}_{X_{\mathrm{\acute{e}t}}}$, we then obtain the sought isomorphism $\omega_\varnothing$

$$A = \Gamma(X, \mathscr{O}_{X_{\mathrm{\acute{e}t}}}) \xrightarrow{\sim} \Gamma(V, \psi_* \mathscr{O}_{X_{\mathrm{\acute{e}t}}}) \xrightarrow{\sim} \Gamma(V', \mathscr{F}).$$

Likewise, the map $\omega_{0,\varnothing}$ is defined as the composition

$$A_0 = \Gamma(S, \mathscr{O}_S) \to \Gamma(S, \pi_* \mathscr{O}_V) \xrightarrow{\sim} \Gamma(V', \tau_V^* \mathscr{O}_V)$$

from which the commutativity of $\mathscr{D}_\varnothing$ is straightforward. Next, let $\Lambda \neq \varnothing$, so that V_Λ is an affine scheme; set $V^{\mathrm{h}}_\Lambda := \operatorname{Spec} A^{\mathrm{h}}_{0,\Lambda}$ and $X_\Lambda := X \cap \operatorname{Spec} A_\Lambda$. We let $\psi_\Lambda : X_\Lambda \to V_\Lambda$ be the restriction of ψ, and we consider the cartesian diagram of schemes

$$\begin{array}{ccccc} & & X^{\mathrm{h}}_\Lambda & \xrightarrow{\tau''_{X_\Lambda}} & X_\Lambda \\ & & {\scriptstyle \psi^{\mathrm{h}}_\Lambda} \downarrow & & \downarrow {\scriptstyle \psi_\Lambda} \\ V'_\Lambda & \xrightarrow{\tau'_{V_\Lambda}} & V^{\mathrm{h}}_\Lambda & \xrightarrow{\tau''_{V_\Lambda}} & V_\Lambda \end{array}$$

where τ'_{V_Λ} and τ''_{V_Λ} are induced by the natural projection $A^{\mathrm{h}}_{0,\Lambda} \to A^{\mathrm{h}}_{0,\Lambda}/I^{\mathrm{h}}_{0,\Lambda} \xrightarrow{\sim} A_{0,\Lambda}/I_0 A_{0,\Lambda}$, and respectively the henselization map $A_{0,\Lambda} \to A^{\mathrm{h}}_{0,\Lambda}$. Then ω_Λ is defined as the composition of isomorphisms of A-algebras

$$\begin{aligned} A^{\mathrm{h}}_\Lambda = \Gamma(X^{\mathrm{h}}_\Lambda, \mathscr{O}_{X^{\mathrm{h}}_{\Lambda,\mathrm{\acute{e}t}}}) \xrightarrow{\sim} \Gamma(V^{\mathrm{h}}_\Lambda, \psi^{\mathrm{h}}_{\Lambda*} \circ \tau''^*_{X_\Lambda} \mathscr{O}_{X_{\Lambda,\mathrm{\acute{e}t}}}) &\xrightarrow{\sim} \Gamma(V^{\mathrm{h}}_\Lambda, \tau''^*_{V_\Lambda} \circ \psi_{\Lambda*} \mathscr{O}_{X_{\Lambda,\mathrm{\acute{e}t}}}) \\ &\xrightarrow{\sim} \Gamma(V'_\Lambda, \tau'^*_{V_\Lambda} \circ \tau''^*_{V_\Lambda} \circ \psi_{\Lambda*} \mathscr{O}_{X_{\Lambda,\mathrm{\acute{e}t}}}) \\ &\xrightarrow{\sim} \Gamma(V'_\Lambda, \mathscr{F}) \end{aligned}$$

where the bijectivity of the third map is due to [10, Exp.XII, Prop.6.5(i)], and that of the second one is due to the fact that τ''_{V_Λ} is the limit of a cofiltered system of affine étale V_Λ-schemes. Likewise, $\omega_{0,\Lambda}$ is obtained as the composition

$$A^{\mathrm{h}}_{0,\Lambda} = \Gamma(V^{\mathrm{h}}_\Lambda, \mathscr{O}_{V^{\mathrm{h}}_\Lambda}) \xrightarrow{\sim} \Gamma(V'_\Lambda, \tau'^*_{V_\Lambda}\mathscr{O}_{V^{\mathrm{h}}_\Lambda}) \xrightarrow{\sim} \Gamma(V'_\Lambda, \tau^*_V\mathscr{O}_V).$$

Then the commutativity of $\mathscr{D}_\Lambda$ follows by a direct inspection.

(ii): We consider the diagram of A_0-algebras

$$\begin{array}{ccccccc} A^{\mathrm{h}}_{0,\Lambda'} & \xrightarrow{\omega_{0,\Lambda'}} & \Gamma(V'_{\Lambda'}, \tau^*_V\mathscr{O}_{V,\text{ét}}) & \longrightarrow & \Gamma(V'_{\Lambda'}, \mathscr{F}) & \longleftarrow & \Gamma(V_{\Lambda'}, \psi_*\mathscr{O}_{X,\text{ét}}) = A_{\Lambda'} \\ \downarrow{\scriptstyle \mu^{\mathrm{h}}_{0,\Lambda',\Lambda}} & & \downarrow & & \downarrow{\scriptstyle \rho_{\Lambda',\Lambda}} & & \downarrow{\scriptstyle \mu_{\Lambda',\Lambda}} \\ A^{\mathrm{h}}_{0,\Lambda} & \xrightarrow{\omega_{0,\Lambda'}} & \Gamma(V'_\Lambda, \tau^*_V\mathscr{O}_{V,\text{ét}}) & \longrightarrow & \Gamma(V'_\Lambda, \mathscr{F}) & \longleftarrow & \Gamma(V_\Lambda, \psi_*\mathscr{O}_{X,\text{ét}}) = A_\Lambda \end{array}$$

whose central square subdiagram is induced by the natural morphism $\mathscr{O}_{V,\text{ét}} \to \psi_*\mathscr{O}_{X,\text{ét}}$, and the right square subdiagram is induced by the unit of adjunction $\psi_*\mathscr{O}_{X,\text{ét}} \to \tau_{V*}\tau^*_V\psi_*\mathscr{O}_{X,\text{ét}}$ for the adjoint pair (τ^*_V, τ_{V*}), and where $\mu_{\Lambda',\Lambda}$ and $\mu^{\mathrm{h}}_{0,\Lambda',\Lambda}$ are defined as in remark 15.5.26(ii). Therefore, both these subdiagrams commute; the left square subdiagram commutes as well, due to the universal property of henselization; taking into account (i), the assertion follows (details left to the reader). ◊

Lastly, we have a natural map

$$A \xrightarrow{\alpha} \mathrm{Equal}\Big(\prod_{i=0}^{n} A^{\mathrm{h}}_{\{i\}} \underset{\beta}{\overset{\gamma}{\rightrightarrows}} \prod_{i,j=0}^{n} A^{\mathrm{h}}_{\{i,j\}}\Big)$$

induced by the maps $\mu^{\mathrm{h}}_{\varnothing,\{i\}}$, where β and γ are deduced from the maps $\mu^{\mathrm{h}}_{\{i\},\{i,j\}}$. From claim 15.5.28 we deduce that α is an isomorphism, and taking into account remark 15.5.26(iii), the theorem follows. □

Remark 15.5.29. Let $\underline{X}$ be any topologically local quasi-affinoid scheme.

(i) As explained in [59, Ch.0, §3.2.2], every sheaf on $\mathscr{Q}(\underline{X})$ admits a natural extension to a sheaf $\mathscr{F}'$ on the topological space $\mathrm{Spa}\,\underline{X}$. Namely, if $U \subset \mathrm{Spa}\,\underline{X}$ is any open subset, one sets

$$\mathscr{F}'(U) := \lim_{V\in(\mathscr{Q}(\underline{X})/U)^o} \mathscr{F}(V)$$

where $\mathscr{Q}(\underline{X})/U$ denotes the full subcategory of $\mathscr{Q}(\underline{X})$ whose objects are the quasi-affinoid open subsets of $\mathrm{Spa}\,\underline{X}$ contained in U. We shall use the notation $\mathscr{O}^{\mathrm{h}}_{\mathrm{Spa}\,\underline{X}}$ and $\mathscr{O}^{\mathrm{h}+}_{\mathrm{Spa}\,\underline{X}}$ also to refer to the sheaves on $\mathrm{Spa}\,\underline{X}$ that extend naturally the respective sheaves on $\mathscr{Q}(\underline{X})$.

(ii) Simple examples show that, in most cases, the presheaves $\mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{X}}$ and $\mathscr{O}^{\mathrm{loc}+}_{\mathrm{Spa}\,\underline{X}}$ are *not* sheaves on the site $\mathscr{Q}(\underline{X})$. On the other hand, in several situations of interest the presheaves $\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}$ and $\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}$ are sheaves of topological rings. In Huber's work [98], this sheaf property is proven under two different types of assumptions, corresponding roughly to the two main classes of non-archimedean analytic spaces that are encountered in applications : the "generic fibres" of locally noetherian formal schemes, and the rigid analytic varieties locally of finite type over a complete rank one valued field. In the literature, one finds also some attempts to unify these cases (and the few other known ones) under a single axiomatic framework; hereafter we shall adopt the approach (though, not the terminology) proposed in [71], that is based on the notions introduced in section 15.2. Later, we shall prove the sheaf property also in the case where $\mathscr{O}_X(X)$ admits a perfectoid ring of definition : this is a completely different situation, for which we shall need to develop an *ad hoc* method.

Definition 15.5.30. (i) Let A be any f-adic ring. We say that A is *f-adic analytically noetherian* (resp. *f-adic universally analytically noetherian*), if it admits an analytically noetherian (resp. universally analytically noetherian) ring of definition (see definition 15.2.1(i)).

(ii) Let $\underline{A} := (A, A^+)$ be any affinoid ring. We say that $\underline{A}$ is *analytically noetherian* (resp. *universally analytically noetherian*) if A is f-adic analytically noetherian (resp. f-adic universally analytically noetherian).

(iii) Let $\underline{A} := (A, A^+, U)$ be any quasi-affinoid ring. We say that $\underline{A}$ is *analytically noetherian* (resp. *universally analytically noetherian*) if the same holds for (A, A^+).

(iv) Let $\underline{X}$ be any quasi-affinoid scheme. We say that $\underline{X}$ is *analytically noetherian* (resp. *universally analytically noetherian*) if the same holds for $\Gamma(\underline{X})$.

15.5.31. Let A be any f-adic ring, and $n \in \mathbb{N}$ any integer. According to proposition 8.3.37(i,ii), there exists a unique f-adic topology $\mathscr{T}_n$ on $A[T_1, \dots, T_n]$ such that, if A_0 is any subring of definition of A, then $A_0[T_1, \dots, T_n]$ is a subring of definition of $A[T_1, \dots, T_n]$, and if $I \subset A_0$ is an ideal of adic definition, then $I[T_1, \dots, T_n]$ is an ideal of adic definition for $A_0[T_1, \dots, T_n]$.

Lemma 15.5.32. *With the notation of* (15.5.31)*, the following holds :*

(i) *A is f-adic analytically noetherian (resp. f-adic universally analytically noetherian) if and only if every ring of definition of A is analytically noetherian (resp. universally analytically noetherian).*

(ii) *A is f-adic universally analytically noetherian if and only if $(A[T_1, \dots, T_n], \mathscr{T}_n)$ is f-adic analytically noetherian for every $n \in \mathbb{N}$.*

(iii) *Let $B \subset A$ be any open subring, and endow B with the topology induced from A. Then A is f-adic analytically noetherian (resp. f-adic universally analytically noetherian) if and only if the same holds for B.*

(iv) *Let $f : A \to A'$ be a surjective ring homomorphism, and endow A' with the topology induced by A via f. Then, if A is f-adic analytically noetherian (resp. f-adic universally analytically noetherian), the same holds for A'.*

(v) *If $\underline{A}$ is any f-adic analytically noetherian (resp. f-adic universally analytically noetherian) quasi-affinoid ring,* $\operatorname{Spec} \underline{A}$ *is an analytically noetherian (resp. universally analytically noetherian) quasi-affinoid scheme.*

(vi) *Let $\underline{X}$ be a topologically local and universally analytically noetherian quasi-affinoid scheme, and $\underline{Y} \to \underline{X}$ a morphism of topologically local quasi-affinoid schemes that represents a rational subset of* $\operatorname{Spa} \underline{X}$*. Then $\underline{Y}$ is universally analytically noetherian.*

Proof. (i): Let $A_0, A_1 \subset A$ be two rings of definition, and let us show that A_0 is analytically noetherian if and only if the same holds for A_1. To this aim, suppose first that $A_0 \subset A_1$, and let $I \subset A_0$ be any finitely generated ideal of adic definition, so that IA_1 is an ideal of adic definition for A_1. Lemma 8.3.29(iii) says that the inclusion map $A_0 \to A_1$ identifies the analytic locus U_0 of $\operatorname{Spec} A_0$ with the analytic locus U_1 of $\operatorname{Spec} A_1$, so U_0 is a noetherian scheme if and only if the same holds for U_1. Next, suppose that A_0 is analytically noetherian; let M_1 be any A_1-module of finite type, $x_1, \dots, x_n$ any system of generators for M_1, and set $M_0 := A_0 x_1 + \cdots + A_0 x_n \subset M_1$. By proposition 8.3.18(ii), there exists $n \in \mathbb{N}$ such that $I^n A_1 \subset A_0$, whence $I^n M_1 \subset M_0$. On the other hand, by assumption there exists $r \in \mathbb{N}$ such that $\operatorname{Ann}_{M_0}(I^k) = \operatorname{Ann}_{M_0}(I^r)$ for every $k \geq r$. Thus, let $x \in \operatorname{Ann}_{M_1}(I^k A_1)$ for some $k \geq r$; we get $I^n x \in \operatorname{Ann}_{M_1}(I^k A_1) \cap M_0 = \operatorname{Ann}_{M_0}(I^k)$, so $I^{n+r} x = 0$, as asserted, in this case.

Suppose next that A_1 is analytically noetherian, and let M_0 be any A_0-module of finite type; the short exact sequence of A_0-modules $0 \to A_0 \to A_1 \to A_1/A_0 \to 0$ induces an exact sequence

$$T_1 := \operatorname{Tor}_1^{A_0}(A_1/A_0, M_0) \to M_0 \xrightarrow{\varphi} M_1 := A_1 \otimes_{A_0} M_0$$

and notice that $I^n T_1 = 0$. By assumption, there exists $r \in \mathbb{N}$ such that $\mathrm{Ann}_{M_1}(I^k A_1) = \mathrm{Ann}_{M_1}(I^r A_1)$ for every $k \geq r$. Suppose then that $x \in \mathrm{Ann}_{M_0}(I^k)$ for some $k \geq r$; it follows easily that $I^r x \subset \mathrm{Ker}\,\varphi$, whence $I^{r+n} x = 0$, as required.

Lastly, if A_0 and A_1 are arbitrary rings of definition for A, the same holds for $A_2 := A_0 \cdot A_1$ (corollary 8.3.19(i)). Suppose that A_0 is analytically noetherian; by the foregoing, it follows that the same holds for A_2, and then by the same token it holds for A_1 as well.

The assertion for the universally noetherian case is an immediate consequence.

Assertion (ii) follows directly from (i) : details left to the reader.

(iii) follows from (i) and corollary 8.3.19(ii).

(iv): First, we know that A' is f-adic, by example 8.3.27(iii), and if $A_0 \subset A$ is a ring of definition, $f(A_0)$ is a ring of definition of A'. But if A_0 is analytically noetherian (resp. universally analytically noetherian), the same holds for $f(A_0)$, by lemma 15.2.4(ii). The assertion follows.

(v): Say that $\underline{A} = (A, A^+, U)$, and let $\rho : A \to A_U := \mathscr{O}_{\mathrm{Spec}\,A}(U)$ be the restriction map. By definition, the topology $\mathscr{T}_{\rho(A)}$ on $\rho(A)$ induced by the inclusion into A_U agrees with the quotient topology induced by the surjection $A \to \rho(A)$. From (iv) we deduce that $(\rho(A), \mathscr{T}_{\rho(A)})$ is f-adic analytically noetherian (resp. f-adic universally analytically noetherian). Then, the assertion follows from (iii).

(vi) follows easily from (v) and lemma 15.2.4(ii), after inspecting the proof of theorem 15.5.5. □

Lemma 15.5.33. *Let $\underline{X} := (X, \mathscr{T}_X, A_X^+)$ be any analytically noetherian quasi-affinoid scheme. Then the natural morphism $\Gamma(\underline{X})^\wedge \to \Gamma(\underline{X}^\wedge)$ is an isomorphism (see remark* 15.4.13(ii)*).*

Proof. Let $A_X^\wedge$ be the separated completion of $A_X := \mathscr{O}_X(X)$, and set $Y := \mathrm{Spec}\,A_X^\wedge \times_{\mathrm{Spec}\,A_X} X$; in light of proposition 15.2.10(ii) and corollary 10.3.8, the natural map $A_X^\wedge \to \mathscr{O}_Y(Y)$ is an isomorphism. Then the assertion follows from remark 15.4.13(ii). □

15.5.34. For any topologically local quasi-affinoid scheme $\underline{X}$, we may consider the site

$$(\mathscr{R}(\underline{X}), J_{\mathscr{R}})$$

where $\mathscr{R}(\underline{X})$ is the full subcategory of $\mathscr{Q}(\underline{X})$ whose objects are the rational subsets of $\mathrm{Spa}\,\underline{X}$. The sieves covering a given object R of $\mathscr{R}(\underline{X})$ for the topology $J_{\mathscr{R}}$ are those generated by the families $R_\bullet := (R_\lambda \mid \lambda \in \Lambda)$ of rational subsets of $\mathrm{Spa}\,\underline{X}$ such that $\bigcup_{\lambda \in \Lambda} R_\lambda = R$. For every such $R_\bullet$, after fixing a total ordering on Λ we get an augmented alternating Čech complex $C^\bullet_{\mathrm{alt}}(R_\bullet, \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}})$, whose degree n term, for every $n \geq 0$, is a product of topological rings of the form $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(R_{\lambda_0} \cap \cdots \cap R_{\lambda_n})$, with $\lambda_0 < \cdots < \lambda_n$ ranging over all strictly increasing sequences of elements of Λ (see remark 10.2.7(i). We endow $C^n_{\mathrm{alt}}(R_\bullet, \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}})$ with the corresponding product topology, and we notice that this topology is independent of the chosen ordering for Λ, and the differentials $d^\bullet$ of the Čech complex are continuous maps. With this notation, we have:

Theorem 15.5.35. *For any topologically local and universally analytically noetherian quasi-affinoid scheme $\underline{X} := (X, \mathscr{T}_X, A_X^+)$, and every $R \in \mathrm{Ob}(\mathscr{R}(\underline{X}))$, the following holds :*

(i) *The presheaves $\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}$ and $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}$ are sheaves of topological rings on $(\mathscr{R}(\underline{X}), J_{\mathscr{R}})$.*

(ii) *For every finite covering $\mathfrak{U}$ of R consisting of rational subsets, the differentials of $C^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}})$ are strict and its cohomology has the discrete topology.*

Proof. (i): Arguing as in the proof of theorem 15.5.27, we reduce to checking the assertion for $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}$. We remark :

Claim 15.5.36. For any given $R \in \mathrm{Ob}(\mathscr{R}(\underline{X}))$, let $\varphi_{\underline{Y}/\underline{X}} : \underline{Y} \to \underline{X}$ be any morphism of quasi-affinoid schemes representing the sub-presheaf h_R of $h_{\underline{X}}$; then the morphism $\varphi_{\underline{Y}/\underline{X}}$ induces an equivalence of categories

$$\mathscr{R}(\underline{Y}) \xrightarrow{\sim} \mathscr{R}(\underline{X})/R \qquad V \mapsto \mathrm{Spa}\,\varphi_{\underline{Y}/\underline{X}}(V) \subset R.$$

Moreover, $\underline{Y}$ is still universally analytically noetherian.

Proof of the claim. These assertions follow from lemmata 15.5.10 and 15.5.32(vi). $\Diamond$

Now, say that $\Gamma(\underline{X}) = (A, A^+, X)$ and let $R_\bullet := (R_0, \dots, R_n)$ be the standard covering of $\mathrm{Spa}\,\underline{X}$ attached to a given sequence $f_\bullet := (f_0, \dots, f_n)$ of elements of A; define also the rational subset R_Λ as in remark 15.5.26(i), for every subset $\Lambda \subset \{0, \dots, n\}$. In light of claim 15.5.36 and remark 5.5.2(i), we are reduced to showing that the natural map

$$\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(\mathrm{Spa}\,\underline{X}) \to \mathrm{Equal}\Big(\prod_{i=0}^n \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(R_i) \rightrightarrows \prod_{i,j=0}^n \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(R_{\{i,j\}})\Big) \tag{15.5.37}$$

is an isomorphism of topological rings. To this aim, we pick a subring of definition $A_0 \subset A$, a finitely generated ideal $I_0 \subset A_0$ of adic definition, we set $S := \mathrm{Spec}\,A_0$, we denote by $J \subset A$ the ideal generated by $f_\bullet$, and we consider the system $(\underline{A}_\Lambda \mid \Lambda \subset \{0, \dots, n\})$ of quasi-affinoid rings, and their rings of definition $A_{0,\Lambda} \subset A_\Lambda$ constructed in remark 15.5.26(i). Let also $A^\wedge_\Lambda$ be the separated completion of A_Λ, and notice that the map

$$\omega^\wedge_\Lambda : A^\wedge_\Lambda \to \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(R_\Lambda)$$

of remark 15.5.26(ii) is an isomorphism of topological A-algebras for every $\Lambda \subset \{0, \dots, n\}$, by lemma 15.5.33. Define S, V, $\psi : X \to V$ and V_Λ for every subset $\Lambda \subset \{0, \dots, n\}$ as in remark 15.5.26(v); set also $S' := \mathrm{Spec}\,A_0/I_0$ and let $V^\wedge$ be the completion of V along $S' \times_S V$, and $\pi : V^\wedge \to V$ the induced morphism of locally ringed spaces. We define

$$\mathscr{F} := \pi^*\psi_*\mathscr{O}_X \qquad \text{and} \qquad V^\wedge_\Lambda := \pi^{-1}V_\Lambda \qquad \text{for every } \Lambda \subset \{0, \dots, n\}$$

and we regard $\mathscr{F}$ as a presheaf of topological abelian groups, as follows. The natural morphism $\mathscr{O}_V \to \psi_*\mathscr{O}_X$ induces a morphism

$$\varphi : \mathscr{O}_{V^\wedge} \to \mathscr{F}$$

and for every open subset $U \subset V^\wedge$ we endow $\mathscr{F}(U)$ with the unique group topology such that the resulting map $\varphi_U : \mathscr{O}_{V^\wedge}(U) \to \mathscr{F}(U)$ is continuous and open. It follows easily that for every inclusion $U' \subset U$ of open subsets of $V^\wedge$, the restriction map $\mathscr{F}(U) \to \mathscr{F}(U')$ is continuous.

Claim 15.5.38. (i) $\mathscr{F}(V^\wedge_\Lambda)$ is a topological ring for every $\Lambda \subset \{0, \dots, n\}$, and there exists a natural isomorphism of topological A-algebras

$$\omega_\Lambda : A^\wedge_\Lambda \xrightarrow{\sim} \mathscr{F}(V^\wedge_\Lambda).$$

(ii) For every $\Lambda' \subset \Lambda$, let $\rho_{\Lambda',\Lambda} : \mathscr{F}(V^\wedge_{\Lambda'}) \to \mathscr{F}(V^\wedge_\Lambda)$ be the restriction homomorphism associated with the inclusion $V^\wedge_\Lambda \subset V^\wedge_{\Lambda'}$. Then we have a commutative diagram

$$\begin{array}{ccc} A^\wedge_{\Lambda'} & \xrightarrow{\omega_{\Lambda'}} & \mathscr{F}(V^\wedge_{\Lambda'}) \\ {\scriptstyle \mu^\wedge_{\Lambda',\Lambda}}\downarrow & & \downarrow{\scriptstyle \rho_{\Lambda',\Lambda}} \\ A^\wedge_\Lambda & \xrightarrow{\omega_\Lambda} & \mathscr{F}(V^\wedge_\Lambda). \end{array}$$

Proof of the claim. (i): We consider first the case where $\Lambda = \varnothing$, and recall that $V_\varnothing = V$. Notice also that $\psi_*\mathscr{O}_X$ is a quasi-coherent $\mathscr{O}_V$-module, by virtue of [59, Ch.I, Cor.9.2.2]. Since V is a projective S-scheme, corollary 15.2.34(iii) and remark 15.2.38 yield a natural isomorphism

$$\omega_\varnothing : A^\wedge \xrightarrow{\sim} A^\wedge_0 \otimes_{A_0} A \xrightarrow{\sim} A^\wedge_0 \otimes_{A_0} \Gamma(V, \psi_*\mathscr{O}_X) \xrightarrow{\sim} \mathscr{F}(V^\wedge)$$

fitting into a commutative diagram

$$\begin{array}{ccc} A_0^\wedge & \longrightarrow & A^\wedge \\ \downarrow & & \downarrow{\scriptstyle \omega_\varnothing} \\ \mathscr{O}_{V^\wedge}(V^\wedge) & \xrightarrow{\varphi_{V^\wedge}} & \mathscr{F}(V^\wedge) \end{array}$$

whose left vertical arrow is the I_0-adic completion of the natural map $A_0 \to \mathscr{O}_V(V)$, and whose top horizontal arrow is the inclusion map. It follows already that $\omega_\varnothing$ is a continuous map, and it thus remains only to check that $\omega_\varnothing$ is an open map. To this aim, it suffices to check that the same holds for the left vertical arrow $A_0^\wedge \to \mathscr{O}_{V^\wedge}(V^\wedge)$. However, $\mathscr{O}_V(V)$ is an A_0-module of analytically finite type, by theorem 15.2.22, and the support of $\mathscr{O}_V(V)/A_0$ lies in the non-analytic locus of S, by virtue of remark 15.5.26(vi); by remark 15.2.2(iii) we deduce that $I_0^t \cdot \mathscr{O}_V(V) \subset A_0$ for some $t \in \mathbb{N}$, whence $I_0^t \cdot \mathscr{O}_{V^\wedge}(V^\wedge) \subset A_0^\wedge$. Since the topology of $\mathscr{O}_{V^\wedge}(V^\wedge)$ is I_0-adic (corollary 15.2.34(ii)), the assertion follows.

In case Λ is not empty, V_Λ is affine, and a direct inspection yields a natural isomorphism of topological rings $A_{0,\Lambda}^\wedge \xrightarrow{\sim} \mathscr{O}_{V^\wedge}(V_\Lambda^\wedge)$. We may then appeal to proposition 15.2.20(iii) to see that the natural map

(15.5.39) $$A_\Lambda^\wedge \xrightarrow{\sim} A_{0,\Lambda}^\wedge \otimes_{A_{0,\Lambda}} A_\Lambda \xrightarrow{\sim} A_{0,\Lambda}^\wedge \otimes_{A_{0,\Lambda}} \Gamma(V_\Lambda, \psi_*\mathscr{O}_X) \to \mathscr{F}(V_\Lambda^\wedge)$$

is also an isomorphism of rings, fitting into another commutative diagram

(15.5.40) $$\begin{array}{ccc} A_{0,\Lambda}^\wedge & \longrightarrow & A_\Lambda^\wedge \\ \downarrow & & \downarrow \\ \mathscr{O}_{V^\wedge}(V_\Lambda^\wedge) & \xrightarrow{\varphi_{V_\Lambda^\wedge}} & \mathscr{F}(V_\Lambda^\wedge) \end{array}$$

whose top horizontal arrow is again the inclusion map, so $\mathscr{F}(V_\Lambda^\wedge)$ is also a topological ring with the topology defined in the foregoing, and (15.5.39) is even an isomorphism of topological rings, if $\Lambda \neq \varnothing$.

(ii): The abelian groups appearing in the diagram are all endowed with natural $A_{\Lambda'}^\wedge$-module structures, and it is easily seen that all the arrows are both $A_{0,\Lambda'}^\wedge$-linear and $A_{\Lambda'}$-linear maps, whence the assertion. ◊

Next, consider the affine open covering $V_\bullet^\wedge := (V_{\{i\}}^\wedge \mid i = 0, \dots, n)$ of $V^\wedge$, and endow the terms of the augmented alternating Čech complex $C_{\mathrm{alt}}^\bullet(V_\bullet^\wedge, \mathscr{F})$ with the product topologies, as in (15.5.34). Combining claim 15.5.38 and remark 15.5.26(iii) we deduce an isomorphism of complexes of topological abelian groups

(15.5.41) $$C_{\mathrm{alt}}^\bullet(V_\bullet^\wedge, \mathscr{F}) \xrightarrow{\sim} C_{\mathrm{alt}}^\bullet(R_\bullet, \mathscr{O}_{\mathrm{Spa}\,\underline{X}}^\wedge).$$

Hence, to conclude it suffices to show :

Claim 15.5.42. The complex $C_{\mathrm{alt}}^\bullet(V_\bullet^\wedge, \mathscr{F})$ has strict differentials, and its cohomology has the discrete topology.

Proof of the claim. Diagram (15.5.40) implies that $\varphi_{V_\Lambda^\wedge}$ is injective for every $\Lambda \neq \varnothing$; it follows easily that the same holds for $\varphi_{V^\wedge}$. Hence the induced map of alternating Čech complexes

$$C_{\mathrm{alt}}^\bullet(V_\bullet^\wedge, \varphi) : C_{\mathrm{alt}}^\bullet(V_\bullet^\wedge, \mathscr{O}_{V^\wedge}) \to C_{\mathrm{alt}}^\bullet(V_\bullet^\wedge, \mathscr{F})$$

is injective in every degree, and by construction $C_{\mathrm{alt}}^i(V_\bullet^\wedge, \varphi)$ is an open map for every $i \in \mathbb{Z}$, so we are reduced to showing that the differentials d^i of $C_{\mathrm{alt}}^\bullet(V_\bullet^\wedge, \mathscr{O}_{V^\wedge})$ are strict and induce open maps $C_{\mathrm{alt}}^i(V_\bullet^\wedge, \mathscr{O}_{V^\wedge}) \to \mathrm{Ker}\, d^{i+1}$ for every $i \in \mathbb{Z}$. If $i < -1$, there is nothing to show. For

$i=-1$, the assertion follows from remark 5.5.2(i). In the remaining cases, the assertion comes down to the following. For every $i,t\in\mathbb{N}$ there exists $s\in\mathbb{N}$ such that

$$I_0^s\cdot C^{i+1}_{\mathrm{alt}}(V^\wedge_\bullet,\mathscr{O}_{V^\wedge})\cap\operatorname{Ker}d^{i+1}\subset I_0^t\cdot\operatorname{Im}d^i. \qquad (15.5.43)$$

For every $k\in\mathbb{N}$, denote by $d^\bullet_k$ the differentials of the Čech complex $C^\bullet_{\mathrm{alt}}(V^\wedge_\bullet,I_0^k\mathscr{O}_{V^\wedge})$; condition (15.5.43) is equivalent to

$$\operatorname{Ker}d^{i+1}_s\subset\operatorname{Im}d^i_t.$$

Taking into account theorem 15.1.37(i), we are therefore reduced to showing that for every $i,t\in\mathbb{N}$ there exists an integer $s\geq t$ such that the natural map

$$H^{i+1}(V^\wedge,I_0^s\mathscr{O}_{V^\wedge})\to H^{i+1}(V^\wedge,I_0^t\mathscr{O}_{V^\wedge})$$

vanishes. Taking into account corollaries 15.2.30(i) and 15.2.34(i), we are further reduced to showing that for every $i,t\in\mathbb{N}$ there exists $s\in\mathbb{N}$ such that $I^s\cdot H^{i+1}(V,I_0^t\mathscr{O}_V)=0$. Notice that the A_0-module $H^{i+1}(V,I_0^t\mathscr{O}_V)$ is analytically of finite type (theorem 15.2.22 and remark 15.2.38(i)); in light of remark 15.2.2(iii) it then suffices to check that the support of $H^{i+1}(V,I_0^t\mathscr{O}_V)$ lies in the non-analytic locus of S. The latter follows easily from remark 15.5.26(vi) : details left to the reader. ◊

(ii): Arguing as in the proof of (i), we reduce easily to the case where $R=\operatorname{Spa}\underline{X}$. Say that $\mathfrak{U}=(U_i\mid i\in I)$ for some set I, and pick any standard covering $\mathfrak{U}':=(U'_i\mid i\in I')$ of $\operatorname{Spa}\underline{X}$ that refines $\mathfrak{U}$; after fixing total orderings for I and I' we may consider the double complex

$$C^{\bullet\bullet}_{\mathrm{alt}}(\mathfrak{U},\mathfrak{U}'):=\operatorname{Hom}^\bullet_{\mathbb{Z}_X}(R^{\mathrm{alt}}_{\bullet\bullet}(\mathfrak{U},\mathfrak{U}'),\mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}})$$

(notation of remark 10.2.14(ii)) which vanishes in every bidegree (p,q) with either $p<-1$ or $q<-1$. For every $n\in\mathbb{N}$, define I^{n+1}_{alt} and I'^{n+1}_{alt} as in (10.2.4), and for every $\underline{t}\in I^{n+1}_{\mathrm{alt}}$ and every $\underline{t}'\in I'^{n+1}_{\mathrm{alt}}$, set $\mathfrak{U}'_{\underline{t}}:=(U'_{i'}\cap U_{\underline{t}}\mid i'\in I')$ and $\mathfrak{U}_{\underline{t}'}:=(U_i\cap U_{\underline{t}'}\mid i\in I)$. We notice that :

- The complex $C^{\bullet,-1}_{\mathrm{alt}}(\mathfrak{U},\mathfrak{U}')$ coincides with $C^\bullet_{\mathrm{alt}}(\mathfrak{U},\mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}})$.
- The complex $C^{-1,\bullet}_{\mathrm{alt}}(\mathfrak{U},\mathfrak{U}')$ coincides with $C^\bullet_{\mathrm{alt}}(\mathfrak{U}',\mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}})$.
- For every $n\in\mathbb{N}$, the complex $C^{\bullet,n}_{\mathrm{alt}}(\mathfrak{U},\mathfrak{U}')$ is the product $\prod_{\underline{t}'\in I'^{n+1}_{\mathrm{alt}}}C^\bullet_{\mathrm{alt}}(\mathfrak{U}_{\underline{t}'},\mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}})$.
- For every $n\in\mathbb{N}$, the complex $C^{n,\bullet}_{\mathrm{alt}}(\mathfrak{U},\mathfrak{U}')$ is the product $\prod_{\underline{t}\in I^{n+1}_{\mathrm{alt}}}C^\bullet_{\mathrm{alt}}(\mathfrak{U}'_{\underline{t}},\mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}})$.

Since $\mathfrak{U}'_{\underline{t}}$ is a standard covering of $U_{\underline{t}}$, the proof of (i) shows that the differentials of the complex $C^\bullet_{\mathrm{alt}}(\mathfrak{U}'_{\underline{t}},\mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}})$ induce open maps $\delta^{n,\bullet}_v$ as in (8.6.11), for every $n\in\mathbb{N}$. Likewise, the same holds for the induced maps $\delta^{-1,\bullet}_v$. Moreover, since $\mathfrak{U}'$ refines $\mathfrak{U}$, for every $n\in\mathbb{N}$ and every $\underline{t}'\in I'^{n+1}_{\mathrm{alt}}$ there exists $i\in I$ such that $U'_{\underline{t}'}\subset U_i$, in which case remark 10.2.13 yields a homotopy $h^\bullet$ from the identity automorphism of $C^\bullet_{\mathrm{alt}}(\mathfrak{U}_{\underline{t}'},\mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}})$ to the zero map, and a simple inspection shows that h^i is a continuous map, for every $i\in\mathbb{Z}$. Then, lemma 8.6.15(i) says that the differentials of $C^\bullet_{\mathrm{alt}}(\mathfrak{U}_{\underline{t}'},\mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}})$ induce open maps $\delta^{\bullet,n}_h$ as well, for every $n\in\mathbb{N}$. Lastly, we invoke corollary 8.6.12 to conclude. □

15.5.44. Let $\underline{X}:=(X,\mathscr{T}_X,A^+_X)$ be a quasi-affinoid scheme fulfilling the assumptions of theorem 15.5.35, so that $\mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}}$ is a sheaf of topological rings on the site $(\mathscr{R}(\underline{X}),J_{\mathscr{R}})$. Following [59, Ch.0, §3.2.2] (and see also remark 15.5.29(i)), we may extend (uniquely up to unique isomorphism) both $\mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}}$ and $\mathscr{O}^{\wedge+}_{\operatorname{Spa}\underline{X}}$ to sheaves of topological groups on the topological space $\operatorname{Spa}\underline{X}$, and we shall denote these extensions with the same names. Then the pair $(\operatorname{Spa}\underline{X},\mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}})$ is a topologically ringed space. Moreover, lemma 15.5.14 says that $\operatorname{Spa}\underline{X}$ is a locally ringed space, so there exists a unique morphism of locally ringed spaces

$$\sigma_{\underline{X}}:(\operatorname{Spa}\underline{X},\mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}})\to\operatorname{Spec}A \qquad (15.5.45)$$

such that the corresponding map $\mathscr{O}_{\mathrm{Spec}\,A} \to \sigma_{\underline{X}*}\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}$ yields on global sections the natural map $A \to A^{\wedge} := \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}(\mathrm{Spa}\,\underline{X})$ ([58, Ch.I, Prop.1.6.3]). By inspecting *loc.cit.* it is easily seen that $\sigma_{\underline{X}}$ is the composition

$$\mathrm{Spa}\,\underline{X} \subset \mathrm{Cont}\,A \xrightarrow{\sigma_A} \mathrm{Spec}\,A$$

where σ_A is the restriction of the support map (see remark 9.2.4(iii)). Especially, the image of $\sigma_{\underline{X}}$ lies in X, whence a well defined morphism of locally ringed spaces

$$(\mathrm{Spa}\,\underline{X}, \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}) \to (X, \mathscr{O}_X).$$

Corollary 15.5.46. *With the notation of* (15.5.44)*, the morphism $\sigma_{\underline{X}}$ induces an isomorphism*

$$A^{\wedge} \otimes_A H^i(X, \mathscr{O}_X) \xrightarrow{\sim} H^i(\mathrm{Spa}\,\underline{X}, \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}) \qquad \textit{for every } i \in \mathbb{N}.$$

Proof. Let us show first the following special case :

Claim 15.5.47. In the situation of the corollary, suppose moreover that $\underline{X}$ is affinoid. Then $H^i(\mathrm{Spa}\,\underline{X}, \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}) = 0$ for every $i > 0$.

Proof of the claim. In light of theorem 10.2.24(i) and lemma 15.5.21, it suffices to show that for every rational subset R of $\mathrm{Spa}\,\underline{X}$, and every standard covering $\mathfrak{U}$ of R, the alternating Čech complex $C^{\bullet}_{\mathrm{alt}}(\mathfrak{U}, \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}})$ is acyclic. However, notice that any such R is represented by an affinoid (topologically local) scheme; then, arguing as in the proof of theorem 15.5.35(i), we are easily reduced to the case where $R = \mathrm{Spa}\,\underline{X}$. Then, after choosing a subring of definition for A we may define the scheme V, its formal completion $V^{\wedge}$, the affine open coverings $V_{\bullet}$ and $V^{\wedge}_{\bullet}$, the projection $\pi : V^{\wedge} \to V$ and the morphism of schemes $\psi : X \to V$ as in the proof of theorem 15.5.35. In light of theorem 15.1.37(i) and of the isomorphism (15.5.41), we are then reduced to showing that $H^i(V^{\wedge}, \pi^*\psi_*\mathscr{O}_X) = 0$ for every $i > 0$. Then, corollary 15.2.34(iii) further reduces to checking that $H^i(V, \psi_*\mathscr{O}_X) = 0$ for every $i > 0$; but since X is affine, the morphism ψ is affine, so that $H^i(V, \psi_*\mathscr{O}_X) \simeq H^i(X, \mathscr{O}_X)$, whence the contention. ◊

Now, say that $X = \mathrm{Spec}\,A \setminus \mathrm{Spec}\,A/J$ for a finitely generated ideal $J \subset A$, and pick a finite system of generators $f_{\bullet} := (f_0, \dots, f_n)$ for J and a subring of definition $A_0 \subset A$. Let also $R_{\bullet}$ be the standard covering of $\mathrm{Spa}\,\underline{X}$ associated with $f_{\bullet}$, and notice that R_i is represented by an affinoid scheme, for every $i = 0, \dots, n$. Set as well $U_i := \mathrm{Spec}\,A[f_i^{-1}]$ for $i = 0, \dots, n$, and notice that $\sigma_{\underline{X}}(R_i) \subset U_i$ for $i = 0, \dots, n$, and $X = U_0 \cup \dots \cup U_n$. There follows a commutative diagram (notation of (10.2.18))

$$\begin{array}{ccc} A_0^{\wedge} \otimes_{A_0} H^i_{\mathrm{alt}}(U_{\bullet}, \mathscr{O}_X) & \xrightarrow{\alpha} & H^i_{\mathrm{alt}}(R_{\bullet}, \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}) \\ \downarrow & & \downarrow \\ A_0^{\wedge} \otimes_{A_0} H^i(X, \mathscr{O}_X) & \longrightarrow & H^i(\mathrm{Spa}\,\underline{X}, \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}) \end{array}$$

where the vertical arrows are isomorphisms, by virtue of claim 15.5.47 and corollary 10.2.21(ii). Since $A^{\wedge} = A_0^{\wedge} \otimes_{A_0} A$, it then suffices to check that α is an isomorphism. On the other hand, as in the proof of theorem 15.5.35, we may associate with the sequence $f_{\bullet}$ a morphism of schemes $\psi : X \to V$, the formal completion $V^{\wedge}$ of V with its natural projection $\pi : V^{\wedge} \to V$, and an affine covering $V_{\bullet} := (V_i \mid i = 0, \dots, n)$ of V such that $\psi^{-1}V_i = U_i$ for $i = 0, \dots, n$; we set $V_i^{\wedge} := \pi^{-1}V_i$ for $i = 0, \dots, n$, and $\mathscr{F} := \pi^*\psi_*\mathscr{O}_X$. There follows a commutative diagram

$$\begin{array}{ccc} A_0^{\wedge} \otimes_{A_0} H^i_{\mathrm{alt}}(V_{\bullet}, \psi_*\mathscr{O}_X) & \xrightarrow{\beta} & H^i_{\mathrm{alt}}(V^{\wedge}_{\bullet}, \mathscr{F}) \\ \downarrow & & \downarrow \\ A_0^{\wedge} \otimes_{A_0} H^i(V, \psi_*\mathscr{O}_X) & \longrightarrow & H^i(V^{\wedge}, \mathscr{F}) \end{array}$$

whose vertical arrows are again isomorphisms, by virtue of proposition 15.2.20(iv), and the same holds for the bottom horizontal arrow, by corollary 15.2.34(iii). To conclude, it suffices to observe that $H^i_{\mathrm{alt}}(U_\bullet, \mathscr{O}_X) = H^i_{\mathrm{alt}}(V_\bullet, \psi_*\mathscr{O}_X)$, and that the isomorphism of Čech complexes (15.5.41) identifies α with β. □

Example 15.5.48. We present two counterexamples that show how theorem 15.5.35 can fail for affinoid schemes that are not analytically noetherian. To begin with, let K be a rank one complete valued field, and fix an element $\pi \neq 0$ in the maximal ideal of K^+. For every $K^+[T]$-module J without π-torsion, let us set

$$A_J := K^+[T] \oplus J \qquad A_{J,K} := A_J \otimes_{K^+} K$$

and endow A_J with the π-adic topology and with the $K^+[T]$-algebra structure such that the inclusion map $K^+[T] \to A$ is a ring homomorphism and J is an ideal with $J^2 = 0$ (*i.e.* $(x, y)\cdot(x', y') := (xx', xy'+x'y)$ for every $(x, y), (x', y') \in A$). Clearly A is an adic topological ring, and we endow $A_{J,K}$ with the f-adic topology such that A_J is a ring of definition. Let also $A^\wedge_J$ and $A^\wedge_{J,K}$ be the completions of A_J and respectively $A_{J,K}$, and $A^{\wedge+}_{J,K}$ the integral closure of $A^\wedge_J$ in $A^\wedge_{J,K}$, and set

$$\underline{X} := \mathsf{Spec}(A^\wedge_{J,K}, A^{\wedge+}_{J,K}).$$

• Take first $J := K^+[T, T^{-1}]/K^+[T]$. We claim that in this case the presheaf $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}$ on $\mathscr{R}(\underline{X})$ is not separated. Indeed, consider the standard covering associated with the sequence (π, T); it consists of the rational subsets

$$U_0 := \{v \in \mathrm{Spa}\,\underline{X} \mid v(T) \leq v(\pi)\} \qquad \text{and} \qquad U_1 := \{v \in \mathrm{Spa}\,\underline{X} \mid v(\pi) \leq v(T)\}$$

and $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{U}_0}(U_0) = B^\wedge_0 \otimes_{K^+} K$, where $B^\wedge_0$ is the completion of $B_0 := A_J[T/\pi] \subset A_{J,K}$, where the latter is endowed with its π-adic topology. But notice that for every $k, n > 0$ the element T^{-k} of J can be written in B_0 as

$$T^{-k} = T^{-k-n} \cdot (T/\pi)^n \cdot \pi^n \in \pi^n B_0.$$

Since n is arbitrary, it follows that T^{-k} lies in the kernel of the restriction map $\rho_0 : A^\wedge_{J,K} \to \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(U_0)$, and since k is arbitrary, we get : $J \subset \mathrm{Ker}\,\rho_0$. Likewise, $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{U}_0}(U_1) = B^\wedge_1 \otimes_{K^+} K$, where $B^\wedge_1$ is the completion of $B_1 := A_J[\pi/T] \subset A_J[T^{-1}]$, where the latter is endowed with its π-adic topology. Clearly $A_J[T^{-1}] = K^+[T, T^{-1}]$, whence $J \subset \mathrm{Ker}\,(\rho_1 : A^\wedge_{J,K} \to \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(U_1))$ as well, and the claim follows.

• Next, we take J to be the $\mathbb{N}$-graded $K^+[T]$-module such that

$$\mathrm{gr}_n J := T^{-n}K^+[T]/K^+[T] \qquad \text{for every } n \in \mathbb{N}.$$

It follows that $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(U_0) = C_0 \otimes_{K^+} K$, where C_0 is the π-adic completion of $K^+[T/\pi] \oplus J'$, with J' the $\mathbb{N}$-graded $K^+[T/\pi]$-module such that

$$\mathrm{gr}_n J' := \sum_{d=0}^{n-1} K^+T^{-n}(T/\pi)^d \qquad \text{for every } n \in \mathbb{N}.$$

Especially, $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(U_0)$ contains the π-adic completion $J'^\wedge$ of J'. On the other hand, it is clear that $A_J[T^{-1}] = K[T, T^{-1}]$, so the kernel of the restriction map $\rho_{01} : \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(U_0) \to \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(U_0 \cap U_1)$ contains $J'^\wedge$. Now, consider the series

$$P := \sum_{n\in\mathbb{N}} T^{-n} \qquad \text{where } T^{-n} \in \mathrm{gr}_{2n} J' \text{ for every } n \in \mathbb{N}.$$

Then $T^{-n} = T^{-2n} \cdot (T/\pi)^n \cdot \pi^n \in \pi^n \mathrm{gr}_{2n} J'$, so the series P converges π-adically to a well defined element of $J'^\wedge$, and $\rho_{01}(P) = 0 = \rho_{10}(0)$ (where $\rho_{10} : \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(U_1) \to \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(U_0 \cap U_1)$ is the other restriction map). We shall show that the series P does not lie in the image of ρ_0, so the presheaf $\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}$ is separated but is not a sheaf. Indeed, recall that the completion $J^{\wedge}$ of J lies in the product of the completions $\mathrm{gr}_n J^{\wedge}$ of its graded summands, and likewise for $J'^{\wedge}$ (remark 8.5.2(iii)); moreover, the induced map $J^{\wedge} \to J'^{\wedge}$ is the restriction of the product of the corresponding maps $\mathrm{gr}_n J^{\wedge} \to \mathrm{gr}_n J'^{\wedge}$. It is easily seen that the latter maps are injective, so if P were in the image of ρ_0, it would be represented by the sequence $(P_n \mid n \in \mathbb{N})$ where $P_{2k+1} = 0$ and $P_{2k} = T^{-k} \in \mathrm{gr}_{2k} J^{\wedge}$ for every $k \in \mathbb{N}$. But then the series $\sum_{n\in\mathbb{N}} P_n$ must converge π-adically in $J^{\wedge}$ (proposition 8.5.3(ii)); the latter means that for every $t \in \mathbb{N}$ there exists $i \in \mathbb{N}$ such that $T^{-k} \in \pi^t \mathrm{gr}_{2k} J$ for every $k \geq i$. But T^{-k} is not divisible by π in $\mathrm{gr}_{2k} J$, for any $k \in \mathbb{N}$, a contradiction.

Remark 15.5.49. The earliest counterexample showing that in some cases the presheaf $\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}$ is not a sheaf, occurs already in [100], where it is attributed to Rost. Constructions similar to that of example 15.5.48, and several others as well, may also be found in [45] and [129], which introduce an interesting general class of "stably uniform" Tate affinoid rings $\underline{A}$ for which the authors can prove that the presheaf $\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{A}}$ is a sheaf.

15.6. **Special loci of quasi-affinoid schemes.** The results of this section will be used in chapter 16, for the study of perfectoid spaces.

Definition 15.6.1. Let $\underline{X} := (X, \mathscr{T}_X, A^+_X)$ be any quasi-affinoid scheme, $V \subset X^+ := \mathrm{Spec}\, A^+_X$ any open subset, and set $A_X := \mathscr{O}_X(X)$. Let moreover $\beta_{\underline{X}} : X \to X^+$ be the restriction of the morphism of schemes $\gamma_{\underline{X}} : \mathrm{Spec}\, A_X \to X^+$ induced by the inclusion map $A^+_X \to A_X$.

(i) We say that $\underline{X}$ *spreads over* V, if $\beta_{\underline{X}}$ restricts to an isomorphism of schemes $\beta^{-1}_{\underline{X}} V \xrightarrow{\sim} V$.

(ii) Let $\underline{Y} := (Y, \mathscr{T}_Y, A^+_Y)$ be another quasi-affinoid scheme, and $\varphi : \underline{Y} \to \underline{X}$ an f-adic morphism of quasi-affinoid schemes. Then the induced ring homomorphism $\varphi^\flat_Y : A_Y \to A_X$ restricts to an f-adic map $\varphi^{\flat+}_Y : A^+_Y \to A^+_X$, and we set

$$\varphi^+ := \mathrm{Spec}\, \varphi^{\flat+}_Y : Y^+ \to X^+.$$

We say that φ *spreads over* V, if $\underline{Y}$ spreads over $(\varphi^+)^{-1}(V)$ (in which case, we also say that $\underline{Y}$ *spreads over* V, if no ambiguity is likely to arise).

(iii) We shall also denote by $\Omega_{\underline{X}} \subset X^+$ the largest open subset such that $\underline{X}$ spreads over $\Omega_{\underline{X}}$.

Remark 15.6.2. (i) Let $\underline{X} := (X, \mathscr{T}_X, A^+_X)$ be any quasi-affinoid scheme; then $\underline{X}$ spreads over the analytic locus of $\mathrm{Spec}\, A^+_X$, by virtue of lemma 8.3.29(iii).

(ii) Keep the notation of definition 15.6.1(ii), let $\psi : \underline{Z} \to \underline{Y}$ be another morphism of quasi-affinoid schemes, and suppose that φ spreads over V and ψ spreads over $(\varphi^+)^{-1}(V)$; then clearly $\varphi \circ \psi$ spreads over V.

Lemma 15.6.3. *With the notation of definition* 15.6.1*, we have :*

(i) *Let $W \subset X$ be an open subset such that $\beta_{\underline{X}}$ restricts to an open immersion $W \to X^+$. Then $\beta_{\underline{X}}(W) \subset \Omega_{\underline{X}}$.*

(ii) *$\gamma_{\underline{X}}$ restricts to an isomorphism of schemes $\gamma^{-1}_{\underline{X}} \Omega_{\underline{X}} \xrightarrow{\sim} \Omega_{\underline{X}}$.*

Proof. (i): First, let us notice the following

Claim 15.6.4. $\mathscr{O}_{X^+}(V)$ is integrally closed in $\mathscr{O}_X(\beta^{-1}_{\underline{X}} V)$, for every open subset $V \subset X^+$.

Proof of the claim. Suppose first that $V = \mathrm{Spec}\, A^+_X[f^{-1}]$ for some $f \in A^+_X$; since $\beta_{\underline{X}*}\mathscr{O}_X$ is a quasi-coherent $\mathscr{O}_{X^+}$-module, we have $\mathscr{O}_X(\beta^{-1}_{\underline{X}} V) = A_X[f^{-1}]$, and since A^+_X is integrally closed in A_X, the assertion holds in this case. For a general open subset V, we may find an affine open covering $V = \bigcup_{i\in I} V_i$ where each V_i is of the form $\mathrm{Spec}\, A^+_X[f_i^{-1}]$ for some $f_i \in A^+_X$, and we get a commutative diagram of rings

$$\begin{array}{ccccc} \mathscr{O}_{X^+}(V) & \longrightarrow & R := \prod_{i\in I} \mathscr{O}_{X^+}(V_i) & \overset{\rho_1}{\underset{\rho_2}{\rightrightarrows}} & \prod_{i,j\in I} \mathscr{O}_{X^+}(V_i \cap V_j) \\ \downarrow & & \downarrow & & \downarrow \\ \mathscr{O}_X(\beta_{\underline{X}}^{-1}V) & \longrightarrow & R' := \prod_{i\in I} \mathscr{O}_X(\beta_{\underline{X}}^{-1}V_i) & \rightrightarrows & \prod_{i,j\in I} \mathscr{O}_X(\beta_{\underline{X}}^{-1}(V_i \cap V_j)). \end{array}$$

Now, if $h \in \mathscr{O}_X(\beta_{\underline{X}}^{-1}V)$ is integral over $\mathscr{O}_{X^+}(V)$, obviously the image h' of h in R' is integral over R; but from the foregoing case, it is easily seen that R is integrally closed in R', so $h' \in R$, and since the vertical arrows are injective maps, we deduce easily that $\rho_1(h') = \rho_2(h')$, whence $h' \in \mathscr{O}_{X^+}(V)$, and the assertion follows. ◊

Now, by assumption, $\beta_{\underline{X}}(W)$ is an open subset of X^+, and $\beta_{\underline{X}}$ restricts to a separated morphism $\beta_{\underline{X}}^{-1}\beta_{\underline{X}}(W) \to \beta_{\underline{X}}(W)$; the latter admits a section whose image is the open subset $W \subset \beta_{\underline{X}}^{-1}\beta_{\underline{X}}(W)$. Taking into account [59, Ch.I, Cor.5.4.6], we see that W is an open and closed subset of $\beta_{\underline{X}}^{-1}\beta_{\underline{X}}(W)$. There follow ring homomorphisms

$$\mathscr{O}_{X^+}(\beta_{\underline{X}}(W)) \to \mathscr{O}_X(\beta_{\underline{X}}^{-1}\beta_{\underline{X}}(W)) \xrightarrow{\rho} \mathscr{O}_X(W)$$

whose composition is an isomorphism, and the kernel of ρ is generated by an idempotent element $e \in \mathscr{O}_X(\beta_{\underline{X}}^{-1}\beta_{\underline{X}}(W))$. However, claim 15.6.4 implies that e lies in the image of $\mathscr{O}_{X^+}(\beta_{\underline{X}}(W))$, so $e = 0$, hence $W = \beta_{\underline{X}}^{-1}\beta_{\underline{X}}(W)$, and the assertion follows immediately.

Claim 15.6.5. Let $f : X \to Y$ and $g : Y \to Z$ be two morphisms of schemes, such that $h := g \circ f$ is an open immersion and the image of f is schematically dense. Then we have :

(i) f is an open immersion.
(ii) If g is separated, then $g^{-1}h(X) = f(X)$.

Proof of the claim. (i): We know from [59, Ch.I, Cor.5.3.13] that the morphism f is an immersion, and since its image is schematically dense, it must be an open immersion.

(ii): Since h is an open immersion, we may replace Z by $h(X)$ and Y by $g^{-1}h(X)$, after which we have $h = \mathbf{1}_X$, and f is a section of g. Since g is separated, [59, Ch.I, Cor.5.4.6] then tells us that f is a closed immersion in this case, and combining with (i), the claim follows. ◊

(ii): Consider now the commutative diagram of schemes

$$\begin{array}{ccc} \beta_{\underline{X}}^{-1}\Omega_{\underline{X}} & \xrightarrow{f} & \gamma_{\underline{X}}^{-1}\Omega_{\underline{X}} \\ & \searrow^{h} & \downarrow{\scriptstyle g} \\ & & \Omega_{\underline{X}} \end{array}$$

where f is the restriction of $\beta^\circ_{\underline{X}}$ and g is the restriction of $\gamma_{\underline{X}}$. Thus, h is the restriction of $\beta_{\underline{X}}$, and it is an isomorphism, by definition of $\Omega_{\underline{X}}$; moreover, clearly f has schematically dense image. By claim 15.6.5, it follows that f is a surjective open immersion, *i.e.* it is an isomorphism, and then the same holds for g as well. □

Proposition 15.6.6. *In the situation of definition* 15.6.1*, suppose that $\underline{X}$ spreads over V. Then:*

(i) *The topological localization $j_{\underline{X}} : \underline{X}_{\rm loc} \to \underline{X}$, the topological henselization $j'_{\underline{X}} : \underline{X}^{\rm h} \to \underline{X}$ and the completion $j''_{\underline{X}} : \underline{X}^\wedge \to \underline{X}$ of $\underline{X}$ spread over V.*
(ii) *Let also $f_0, \dots, f_n$ be a sequence of elements of A_X that generate an ideal I such that $(\beta_{\underline{X}}^{-1}V) \cap \operatorname{Spec} A_X/I = \varnothing$, and set $\underline{B} := \Gamma(\underline{X})(\frac{f_0,\dots,f_n}{f_0})$ (notation of* (15.5.1)*). The induced morphism $\underline{Y} := \mathsf{Spec}\,\underline{B} \to \underline{X}$ spreads over V.*

(iii) *Let $\underline{Y} \to \underline{X}$ and $\underline{Y}' \to \underline{X}$ be two f-adic morphisms of quasi-affinoid schemes that spread over V. The fibre product $\underline{Y} \times_{\underline{X}} \underline{Y}' \to \underline{X}$ spreads over V (see example* 15.4.8*).*

(iv) *Let $U \subset \beta_{\underline{X}}^{-1} V$ be a quasi-compact open subset containing the analytic subset of $\underline{X}$. The induced morphism $\varphi : U \times_X \underline{X} \to \underline{X}$ spreads over V (see example* 15.4.4*).*

Proof. (i): Say that $\underline{X}_{\mathrm{loc}} = (X', \mathscr{T}_{X'}, A^+_{X'})$, and let $j^+_{\underline{X}} : X'^+ \to X^+$ be the morphism induced by the topological localization $A^+_X \to A^+_{X'}$. By inspecting (8.4.8), and taking into account the natural identifications (15.4.11), we get a cartesian diagram of schemes :

$$\begin{array}{ccc} X' & \xrightarrow{j_{\underline{X}}} & X \\ {\scriptstyle \beta_{\underline{X}_{\mathrm{loc}}}}\downarrow & & \downarrow{\scriptstyle \beta_{\underline{X}}} \\ X'^+ & \xrightarrow{j^+_{\underline{X}}} & X^+. \end{array}$$

The assertion for $j_{\underline{X}}$ is an immediate consequence. The same argument applies to $j'_{\underline{X}}$. Next, say that $\underline{X}^\wedge = (X^\wedge, \mathscr{T}_{X^\wedge}, A^+_{X^\wedge})$, and $\Gamma(\underline{X})^\wedge = (A^\wedge_X, A^{\wedge+}_X, X')$. According to corollary 15.4.28(i), the kernel $\mathscr{J}$ of the surjective map $A^\wedge_X \to A_{X^\wedge} := \mathscr{O}_{X^\wedge}(X^\wedge)$ lies in $A^{\wedge+}_X$, and we set $Y := \mathrm{Spec}\, A^{\wedge+}_X / \mathscr{J}$; there follows a commutative diagram of schemes

$$\begin{array}{ccccc} & & X^\wedge & \longrightarrow & X \\ & {\scriptstyle \beta_{\underline{X}^\wedge}} \swarrow & \downarrow{\scriptstyle \varphi} & & \downarrow{\scriptstyle \beta_{\underline{X}}} \\ X^{\wedge+} & \xrightarrow{\nu} & Y & \longrightarrow & X^+ \end{array}$$

whose square subdiagram is cartesian. With this notation, $\varphi_* \mathscr{O}_{X^\wedge}$ is a quasi-coherent $\mathscr{O}_Y$-algebra, and $A^+_{X^\wedge} = \mathscr{A}(Y)$, where $\mathscr{A}$ is the integral closure of the image of $\mathscr{O}_Y$ in $\varphi_* \mathscr{O}_{X^\wedge}$. Let $V' \subset Y$ and $V'' \subset X^{\wedge+}$ be the preimages of V; under our assumptions, the morphism $\varphi^\flat : \mathscr{O}_Y \to \varphi_* \mathscr{O}_{X^\wedge}$ restricts to an isomorphism $\mathscr{O}_{Y|V'} \xrightarrow{\sim} (\varphi_* \mathscr{O}_{X^\wedge})_{|V'}$, so that $\mathscr{A}_{|V'} = (\varphi_* \mathscr{O}_{X^\wedge})_{|V'}$. The latter implies that the morphism $\gamma_{\underline{X}^\wedge}$ restricts to an isomorphism $\gamma^{-1}_{\underline{X}^\wedge} V'' \xrightarrow{\sim} V''$, and ν restricts to an isomorphism $V'' \xrightarrow{\sim} V'$; lastly, since the image of X in X^+ contains V, it is clear that the image of $X^\wedge$ in Y contains V', and then the image of $X^\wedge$ in $X^{\wedge+}$ contains V'', so $j''_{\underline{X}}$ spreads over V.

(ii): Set $B := A_X[f_0^{-1}]$, $B' := A^+_X[f_1/f_0, \dots, f_n/f_0] \subset B$, say that $\underline{Y} = (Y, \mathscr{T}_Y, B^+)$, and let $Y^+ := \mathrm{Spec}\, B^+$. There follows a commutative diagram of schemes

$$\begin{array}{ccccc} Y & \xrightarrow{i} & \mathrm{Spec}\, B & \xrightarrow{\rho} & \mathrm{Spec}\, B' \\ \downarrow & & \downarrow & & \downarrow \\ X & \longrightarrow & \mathrm{Spec}\, A_X & \longrightarrow & X^+ \end{array}$$

whose left square subdiagram is cartesian. Denote by $V' \subset \mathrm{Spec}\, B'$ and $V'' \subset Y^+$ the preimages of V, and let $g \in A^+_X$ be any element such that $\mathrm{Spec}\, A^+_X[g^{-1}] \subset V$; according to lemma 15.6.3(ii), the induced map $A^+_X[g^{-1}] \to A_X[g^{-1}]$ is an isomorphism. Especially, we may regard $f_0, \dots, f_n$ as elements of $C := A^+_X[g^{-1}]$, and by assumption $\sum_{i=0}^n f_i C = C$. It follows easily that f_0 is invertible in the subring $B'[g^{-1}] = C[f_1/f_0, \dots, f_n/f_0]$ of $B[g^{-1}]$, *i.e.* $B'[g^{-1}] = B[g^{-1}]$, and since g is arbitrary, it follows that ρ restricts to an isomorphism $\rho^{-1} V' \xrightarrow{\sim} V'$. Recalling now that B^+ is the integral closure of B' in $\mathscr{O}_Y(Y) = B$, we deduce that $\gamma_{\underline{Y}}$ restricts as well to an isomorphism $\gamma^{-1}_{\underline{Y}} V'' \xrightarrow{\sim} V''$. Lastly, since $\beta_{\underline{X}}(X)$ contains V, clearly the image of $\beta_{\underline{Y}}$ contains V''. The assertion follows easily (details left to the reader).

(iii): Say that $\underline{Y} = (Y, \mathscr{T}_Y, A^+_Y)$, $\underline{Y}' = (Y', \mathscr{T}_{Y'}, A^+_{Y'})$, and set $Y^+ := \mathrm{Spec}\, A^+_Y$, $Y'^+ := \mathrm{Spec}\, A^+_{Y'}$. Set also $\underline{Z} := \underline{Y} \times_{\underline{X}} \underline{Y}'$ and $(A_Z, A^+_Z, Z) := \Gamma(\underline{Z})$, so that $Z = Y \times_X Y'$. Denote

$$\varphi : Z \to Z' := Y^+ \times_{X^+} Y'^+ \qquad \text{and} \qquad \pi : Z' \to X^+$$

the induced morphisms. With this notation, $\varphi_*\mathscr{O}_Z$ is a sheaf of quasi-coherent $\mathscr{O}_{Z'}$-algebras, and $A^+_Z = \mathscr{A}(Z')$, where $\mathscr{A}$ is the integral closure of the image of $\mathscr{O}_{Z'}$ in $\varphi_*\mathscr{O}_Z$. Set $V' := \pi^{-1}V$; under the current assumptions it is clear that the associated morphism $\varphi^\flat : \mathscr{O}_{Z'} \to \varphi_*\mathscr{O}_Z$ restricts to an isomorphism $\mathscr{O}_{Z'|V'} \xrightarrow{\sim} (\varphi_*\mathscr{O}_Z)_{|V'}$, whence $\mathscr{A}_{|V'} = (\varphi_*\mathscr{O}_Z)_{|V'}$, which means that the natural morphism $\nu : Z^+ := \mathrm{Spec}\, A^+_Z \to Z'$ restricts to an isomorphism $\nu^{-1}V' \xrightarrow{\sim} V'$; lastly, since the image of φ contains V', it is clear that the image of $\beta_{\underline{Z}}$ contains $\nu^{-1}V'$, whence the assertion.

(iv): Set $\underline{U} := U \times_X \underline{X}$, and let $h : U \to X^+$ be the composition of the open immersion $U \to \beta^{-1}_{\underline{X}}V$ and the restriction $\beta^{-1}_{\underline{X}}V \to X^+$ of $\beta_{\underline{X}}$. Then $h = \varphi^+ \circ \beta_{\underline{U}}$, and clearly $\beta_{\underline{U}}$ has schematically dense image; by claim 15.6.5 we deduce that $\beta_{\underline{U}}$ is an open immersion, whence the contention. □

15.6.7. Let $\underline{X}$ and V be as in definition 15.6.1, and suppose that $\underline{X}$ is topologically local and spreads over V. We denote by

$$\mathscr{R}_V(\underline{X})$$

the site whose underlying category is the full subcategory of $\mathscr{R}(\underline{X})$ whose objects are the rational subsets R such that the sub-presheaf $h_R \subset h_{\mathrm{Spa}\,\underline{X}}$ is represented by a morphism $\underline{Y} \to \underline{X}$ of quasi-affinoid schemes that spreads over V. Notice that, in view of proposition 15.6.6(iii), if $R, R' \in \mathrm{Ob}(\mathscr{R}_V(\underline{X}))$, then also $R \cap R' \in \mathrm{Ob}(\mathscr{R}_V(\underline{X}))$. As usual, a family $(R_i \to R \mid i \in I)$ of morphisms of $\mathscr{R}_V(\underline{X})$ generates a covering sieve of $\mathscr{R}_V(\underline{X})/R$ if and only if $\bigcup_{i\in I} R_i = R$.

In light of proposition 15.6.6(iii), we see that all fibre products are representable in $\mathscr{R}_V(\underline{X})$, and the inclusion functor $\iota : \mathscr{R}_V(\underline{X}) \to \mathscr{R}(\underline{X})$ commutes with fibre products. By lemma 4.2.4, it follows that ι is continuous, *i.e* the induced functor on presheaves $\iota^\wedge : \mathscr{R}(\underline{X})^\wedge \to \mathscr{R}_V(\underline{X})^\wedge$ restricts to a functor on the respective subcategories of sheaves

$$\widetilde{\iota}_* : \mathscr{R}(\underline{X})^\sim \to \mathscr{R}_V(\underline{X})^\sim.$$

We will denote as well by $\widetilde{\iota}_*$ the corresponding functor on abelian sheaves. For every presheaf $\mathscr{F}$ on $\mathscr{R}(\underline{X})$ or $\mathscr{R}_V(\underline{X})$, let us denote as usual by $\mathscr{F}^a$ the sheaf associated to $\mathscr{F}$.

Proposition 15.6.8. *In the situation of* (15.6.7)*, let $\mathscr{G}$ be a presheaf, $\mathscr{A}$ an abelian presheaf, and $\mathscr{F}$ an abelian sheaf on $\mathscr{R}(\underline{X})$. The following holds :*

(i) *The natural morphism $(\iota^\wedge\mathscr{G})^a \to \iota^\wedge(\mathscr{G}^a)$ is an isomorphism.*

(ii) *The natural morphism $\iota_*\mathscr{F} \to R\widetilde{\iota}_*\mathscr{F}$ is an isomorphism in $\mathsf{D}(\mathbb{Z}_{\mathscr{R}_V(\underline{X})}\text{-}\mathbf{Mod})$.*

(iii) *The natural map $\check{H}^i(\mathscr{R}_V(\underline{X}), \iota^\wedge\mathscr{A}) \to \check{H}^i(\mathscr{R}(\underline{X}), \mathscr{A})$ is bijective for every $i \in \mathbb{N}$.*

Proof. (i): Define $\mathscr{F}^+$ as in the proof of theorem 4.1.13; in view of claim 4.1.16 it suffices to check that the the natural morphism $(\iota^\wedge\mathscr{G})^+ \to \iota^\wedge(\mathscr{G}^+)$ is an isomorphism. For the injectivity, let $U \in \mathrm{Ob}(\mathscr{R}_V(\underline{X}))$ be any rational subset, and $s, t \in (\iota^\wedge\mathscr{G})^+(U)$ any two sections whose images agree in $\mathscr{G}^+(U)$. Then we may find a covering family $(U_\lambda \to U \mid \lambda \in \Lambda)$ of $\mathscr{R}_V(\underline{X})/U$ such that s and t are the classes of compatible systems $(s_\lambda \mid \lambda \in \Lambda)$, $(t_\lambda \mid \lambda \in \Lambda)$ with $s_\lambda, t_\lambda \in \mathscr{G}(U_\lambda)$ for every $\lambda \in \Lambda$, and the assumption means that for every $\lambda \in \Lambda$ there exists a covering family $(U_{\lambda,i} \to U_\lambda \mid i \in I_\lambda)$ of $\mathscr{R}(\underline{X})/U_\lambda$ such that $s_{\lambda|U_{\lambda,i}} = t_{\lambda|U_{\lambda,i}}$ for every $\lambda \in \Lambda$ and every $i \in I_\lambda$. But by proposition 15.6.6(ii) and lemma 15.5.21, the covering $U_{\lambda\bullet}$ can be refined by a covering $(U'_{\lambda,i'} \to U_\lambda \mid i' \in I'_\lambda)$ of $\mathscr{R}_V(\underline{X})/U_\lambda$, for every $\lambda \in \Lambda$. Then $s_{\lambda|U'_{\lambda,i'}} = t_{\lambda|U'_{\lambda,i'}}$ for every $\lambda \in \Lambda$ and every $i' \in I'_\lambda$, so that $s = t$. Lastly, let $s \in \mathscr{G}^+(U)$ be any section; by definition we may find a covering family $(U_\lambda \to U \mid \lambda \in \Lambda)$ of $\mathscr{R}(\underline{X})/U$ such that s is represented by a compatible system $(s_\lambda \mid \lambda \in \Lambda)$ with $s_\lambda \in \mathscr{G}(U_\lambda)$ for every $\lambda \in \Lambda$. But again, the covering U_λ can be refined by a covering of $\mathscr{R}_V(\underline{X})$, and we deduce that s is the image of a section of $(\iota^\wedge\mathscr{G})^+(U)$.

(ii): The assertion means that $R^i\widetilde{\iota}_*\mathscr{F} = 0$ for every $i > 0$. However, recall that $R^i\widetilde{\iota}_*\mathscr{F}$ is the sheaf associated to the presheaf that assigns to every $U \in \mathrm{Ob}(\mathscr{R}_V(\underline{X}))$ the abelian group

$H^i(\mathscr{R}(\underline{X})/U, \mathscr{F}_{|U})$. Hence, let us fix such a rational subset U, and let $s \in H^i(\mathscr{R}(\underline{X})/U, \mathscr{F}_{|U})$ be any element; it suffices to exhibit a covering $(U_\lambda \to U \mid \lambda \in \Lambda)$ of U in $\mathscr{R}_V(\underline{X})$ such that the image of s in $H^i(\mathscr{R}(\underline{X})/U_\lambda, \mathscr{F}_{|U_\lambda})$ vanishes for every $\lambda \in \Lambda$. However, notice that there exists a covering $(U'_{\lambda'} \to U \mid \lambda' \in \Lambda')$ of U in $\mathscr{R}(\underline{X})$ such that the image of s in $H^i(\mathscr{R}(\underline{X})/U'_{\lambda'}, \mathscr{F}_{|U'_{\lambda'}})$ vanishes for every $\lambda' \in \Lambda'$ (this is clear, since these cohomology groups are computed by an injective resolution of $\mathscr{F}$, which is exact in degrees > 0). But by proposition 15.6.6(ii) and lemma 15.5.21, the covering $U'_\bullet$ can be refined by a covering $U_\bullet$ consisting of objects of $\mathscr{R}_V(\underline{X})$, and clearly such $U_\bullet$ will do.

(iii): This is an immediate consequence of the fact – already remarked in the foregoing – that every covering family of $\mathscr{R}(\underline{X})$ can be refined by a covering family of $\mathscr{R}_V(\underline{X})$: the details shall be left to the reader. ☐

15.6.9. Consider a quasi-affinoid ring $\underline{A} := (A, A^+, U)$ such that A is an adic (and f-adic) topological ring; let $A_U := \mathscr{O}_U(U)$ and $\underline{U} := (U, \mathscr{T}_U, A_U^+) := \mathsf{Spec}\,\underline{A}$, and set

$$X_A := \mathrm{Spec}\,A \qquad X_A^+ := \mathrm{Spec}\,A_U^+ \qquad X_A^\circ := \mathrm{Spec}\,A_U^\circ.$$

The induced map $A \to A_U$ is f-adic, so its image lies in A_U° (lemma 8.3.24(iii)), and we get a commutative diagram of schemes :

$$\begin{array}{ccccc} U & \xrightarrow{\ i\ } & X_A & & \\ {\scriptstyle j}\downarrow & & \uparrow{\scriptstyle j''} & & \\ \mathrm{Spec}\,A_U & \xrightarrow{\ j'\ } & X_A^\circ & \xrightarrow{\ t\ } & X_A^+. \end{array}$$

Let also $Z \subset X_A^+$ be the support of the A_U^+-module A_U°/A_U^+, and $Z' := X_A^\circ \setminus j' \circ j(U)$.

Lemma 15.6.10. *With the notation of* (15.6.9)*, the following holds :*

(i) *i, j and $j' \circ j$ are open immersions.*
(ii) *The images of j and j' are schematically dense.*
(iii) *The open subset $j' \circ j(U)$ contains the analytic locus of X_A°.*
(iv) *$X_A^+ \setminus \Omega_{\underline{U}}$ is the topological closure of $Z \cup t(Z')$.*

Proof. (ii): The assertion for j' is clear. Next, let $\mathscr{I}$ be the kernel of the induced morphism $j^\flat : \mathscr{O}_{\mathrm{Spec}\,A_U} \to j_*\mathscr{O}_U$; since U is quasi-compact, $j_*\mathscr{O}_U$ is a quasi-coherent $\mathscr{O}_{\mathrm{Spec}\,A_U}$-module, so the same holds for $\mathscr{I}$, and we are reduced to checking that $\Gamma(\mathrm{Spec}\,A_U, \mathscr{I}) = 0$, which is clear, since $j^\flat$ induces an isomorphism on global sections.

(i): For i there is nothing to prove, and the assertion for j follows from [60, Ch.II, Prop.5.1.2]. The assertion for $j' \circ j$ follows from claim 15.6.5(i).

(iii): Notice that j' maps the analytic locus of $\mathrm{Spec}\,A_U$ isomorphically onto that of X_A° (lemma 8.3.29(iii)); likewise, it is easily seen that $j'' \circ j'$ restricts to an isomorphism from the analytic locus of $\mathrm{Spec}\,A_U$ onto that of X_A. Summing up, we conclude that j'' restricts to an isomorphism from the analytic locus of X_A° onto that of X_A, whence the assertion.

(iv): Consider the commutative diagram of schemes

$$\begin{array}{ccc} \beta_{\underline{U}}^{-1}\Omega_{\underline{U}} & \xrightarrow{\ f\ } & t^{-1}\Omega_{\underline{U}} \\ & {\scriptstyle h}\searrow & \downarrow{\scriptstyle g} \\ & & \Omega_{\underline{U}} \end{array}$$

where f is the restriction of $j' \circ j$, and g is the restriction of t. Thus, h is the restriction of $\beta_{\underline{U}}$, and it is an isomorphism, by definition of $\Omega_{\underline{U}}$; moreover, clearly f has schematically dense image. By claim 15.6.5, it follows that f is a surjective open immersion, *i.e.* it is an isomorphism, and then the same holds for g as well. Now, if $x \in \Omega_{\underline{U}}$ is any point, it follows immediately that $x \notin Z$; moreover $g^{-1}(x)$ is the unique point of $t^{-1}(x)$, and this point lies in $j' \circ j(U)$. This shows that $Z \cup t(Z') \subset X^+_A \setminus \Omega_{\underline{U}}$. Conversely, suppose that $x \in X^+_A$ lies neither in $\Omega_{\underline{U}}$ nor the topological closure of Z; then there exists an open neighborhood V of x in X^+_A with $V \cap Z = \varnothing$, and it follows that t restricts to an isomorphism $t^{-1}V \xrightarrow{\sim} V$. In view of (i), the restriction $\beta^{-1}_{\underline{U}}V \to t^{-1}V$ of $j' \circ j$ is still an open immersion, so the same holds for the restriction $\beta^{-1}_{\underline{U}}V \to V$ of $\beta_{\underline{U}}$, and consequently $\beta_{\underline{U}}(U) \cap V = \beta_{\underline{U}}(\beta^{-1}_{\underline{U}}V) \subset \Omega_{\underline{U}}$, according to lemma 15.6.3(i). We conclude that $x \notin \beta_{\underline{U}}(U)$, and since $x \in t(V)$, we finally get $x \in t(Z')$, whence (iv). □

15.7. **Etale coverings of quasi-affinoid schemes.** Let Sch be the category of schemes (in the universe U). For every scheme X, let also $X_{\text{ét}}$ be the full subcategory of the category Sch/X, whose objects are the étale morphisms $Y \to X$ with Y quasi-compact and quasi-separated; notice that every morphism in $X_{\text{ét}}$ is étale. We endow $X_{\text{ét}}$ with its standard *étale topology* $J_{X,\text{ét}}$, whose covering families are all the systems $(f_i : Y_i \to Y \mid i \in I)$ of families of morphisms of X-schemes such that $\bigcup_{i\in I} f_i(Y_i) = Y$. The site $(X_{\text{ét}}, J_{X,\text{ét}})$ is called the *étale site* of X, and is also often denoted simply by $X_{\text{ét}}$, when no ambiguities are likely to arise. It is easily seen that $X_{\text{ét}}$ is a lex-site if and only if X is a quasi-compact and quasi-separated scheme (the details are left to the reader). Recall that we have a fibration $\mathsf{Cov} \to \mathsf{Sch}$ whose fibre category over every $Y \in \mathrm{Ob}(\mathsf{Sch})$ is the category of finite étale Y-schemes (see (13.1)). From the natural functor

$$X_{\text{ét}} \to \mathsf{Sch} \qquad (Y \to X) \mapsto Y$$

we deduce a fibration

$$\mathsf{Cov}_{X_{\text{ét}}} := X_{\text{ét}} \times_{\mathsf{Sch}} \mathsf{Cov} \to X_{\text{ét}}.$$

By faithfully flat descent, it is easily seen that $\mathsf{Cov}_{X_{\text{ét}}}$ is an ind-finite stack over the site $X_{\text{ét}}$.

For every $k \in \mathbb{N}$ let $[k] := \{0, \dots, n\}$, and set as well $[-1] := \varnothing$; we denote by N the full subcategory of the category $\mathbf{Set}$ with $\mathrm{Ob}(\mathsf{N}) := \{[k] \mid k \geq -1\}$. Then, let $\mathsf{N}_{X_{\text{ét}}}$ be the *constant presheaf of categories* on $X_{\text{ét}}$ with value N, *i.e.* the presheaf such that $\mathsf{N}_{X_{\text{ét}}}(Y) := \mathsf{N}$ for every $Y \in \mathrm{Ob}(X_{\text{ét}})$, and $\mathsf{N}_X(f) := \mathbf{1}_\mathsf{N}$ for every morphism f of $X_{\text{ét}}$. We get an $X_{\text{ét}}$-cartesian functor

$$\omega_X : \mathscr{F}ib(\mathsf{N}_{X_{\text{ét}}}) \to \mathsf{Cov}_{X_{\text{ét}}} \qquad (Y, [k]) \mapsto ([k] \times Y \to Y).$$

Lemma 15.7.1. *The functor ω_X is i-covering for $i = 0, 1, 2$.*

Proof. Let $f : Y \to X$ be a finite étale covering, and $x \in X$; in order to check the assertion for $i = 0$, we need to exhibit an étale morphism $g : X' \to X$ and $k \in \mathbb{N}$ from an affine scheme X' such that $x \in g(X')$, with an isomorphism of X'-schemes $X' \times_X Y \xrightarrow{\sim} [k] \times X'$. To this aim, let $\xi : \mathrm{Spec}\, \kappa \to X$ be a geometric point localized at the point x (see definition 4.9.17(i)); we argue by induction on the cardinality c of the set $f^{-1}(\xi)$ (see definition 4.9.17(iv)). If $c = 0$, we have $x \notin f(Y)$, and then there exists an affine open neighborhood X' of x in X with $X' \cap f(Y) = \varnothing$; in this case we may take for g the open inclusion $X' \to X$, and $k := 0$.

Suppose next that $c > 0$, and that the assertion is already known for all schemes X, all $x \in X$, and all finite étale coverings $f : Y \to X$ such that the cardinality of $f^{-1}(\xi)$ is $< c$, for any geometric point ξ localized at x. Notice that the diagonal morphism $\Delta_{Y/X} : Y \to Y \times_X Y$ is a finite étale morphism, hence its image is open and closed in $Y \times_X Y$. Thus, the Y-scheme $Y \times_X Y$ is isomorphic to the disjoint union of Y and a finite étale covering $h : Z \to Y$. The geometric point ξ lifts to a geometric point $\xi_Y : \mathrm{Spec}\, \kappa \to Y$, and it is then easily seen that $h^{-1}(\xi_Y) = c - 1$. By inductive assumption, we find an étale morphism $g_Y : Y' \to Y$ from an affine scheme Y', such that $g_Y(Y')$ contains the support of ξ_Y, and such that the Y'-scheme $Y' \times_Y Z$ is isomorphic to $[c-2] \times Y'$. We may then take $X' := Y'$ and $g := f \circ g_Y$.

Next, to check the assertion for $i = 1$, let $k, k' \geq -1$ be two integers, $g : [k] \times X \to [k'] \times X$ a morphism of X-schemes, and $x \in X$; it suffices to find an affine open neighborhood U of x

in X, and a map of sets $\varphi : [k] \to [k']$ such that the restriction $g_{|U} : [k] \times U \to [k'] \times U$ of g agrees with $\varphi \times U$. To this aim, it suffices to invoke [66, Ch.IV, Cor.17.4.7] : the details are left to the reader. Lastly, it is clear from the definitions that ω_X is a 2-covering functor. $\square$

15.7.2. Denote by $\mathsf{Sch}^{\mathsf{qcqs}}$ the full subcategory of Sch whose objects are the quasi-compact and quasi-separated schemes, and by $\mathsf{Sch}^{\mathsf{qcqs}}_{\text{ét}}$ the full subcategory of $\mathsf{Morph}(\mathsf{Sch}^{\mathsf{qcqs}})$ whose objects are the étale morphisms of schemes. The restriction

$$t : \mathsf{Sch}^{\mathsf{qcqs}}_{\text{ét}} \to \mathsf{Sch}^{\mathsf{qcqs}}$$

of the target functor $\mathsf{t} : \mathsf{Morph}(\mathsf{Sch}^{\mathsf{qcqs}}) \to \mathsf{Sch}^{\mathsf{qcqs}}$ is a fibration, and for every $X \in \mathrm{Ob}(\mathsf{Sch}^{\mathsf{qcqs}})$, the fibre category $t^{-1}X$ is the previously defined category $X_{\text{ét}}$, which we endow with its étale topology $J_{X,\text{ét}}$; we get therefore a well defined fibred site :

$$(\mathsf{Sch}^{\mathsf{qcqs}}_{\text{ét}}, t, J_{\bullet,\text{ét}}).$$

For every category I and every functor $F : I \to \mathsf{Sch}^{\mathsf{qcqs}}$ we let

$$F_{\text{ét}} := I \times_{(\mathsf{Sch}^{\mathsf{qcqs}},F)} (\mathsf{Sch}^{\mathsf{qcqs}}_{\text{ét}}, t, J_{\bullet,\text{ét}})$$

(notation of (4.5.11)). Thus, $F_{\text{ét}}$ is a fibred lex-site over I, whose fibre category over every $i \in \mathrm{Ob}(I)$ is naturally identified with the lex-site $(Fi)_{\text{ét}}$. Moreover, we have a natural functor :

$$F_{\text{ét}} \to \mathsf{Sch} \qquad (i, Y \to Fi) \mapsto Y$$

from which we deduce a fibration over $F_{\text{ét}}$:

$$\mathsf{Cov}_{F_{\text{ét}}} := F_{\text{ét}} \times_{\mathsf{Sch}} \mathsf{Cov} \to F_{\text{ét}}$$

whose restriction to the fibre category $(Fi)_{\text{ét}}$ is naturally identified with the fibration $\mathsf{Cov}_{(Fi)_{\text{ét}}}$, for every $i \in \mathrm{Ob}(I)$. Explicitly, the objects of $\mathsf{Cov}_{F_{\text{ét}}}$ are the data $(i, f : Y \to Fi, g : Z \to Y)$ where f is an étale morphism, g is a finite étale morphism, and $i \in \mathrm{Ob}(I)$. Let $\mathsf{N}_{F_{\text{ét}}}$ be the constant presheaf of categories on $F_{\text{ét}}$ with value N; as in (15.7), we then have a cartesian functor of $F_{\text{ét}}$-fibrations :

$$(15.7.3) \quad \mathscr{F}ib(\mathsf{N}_{F_{\text{ét}}}) \to \mathsf{Cov}_{F_{\text{ét}}} \qquad (i, f : Y \to Fi, [k]) \mapsto (i, f : Y \to Fi, [k] \times Y \to Y).$$

Clearly the restriction of (15.7.3) to each fibre category $(Fi)_{\text{ét}}$ is naturally identified with the functor ω_{Fi} of (15.7); in view of lemma 15.7.1 and proposition 5.7.1(i) we deduce that also (15.7.3) is i-covering for $i = 0, 1, 2$.

15.7.4. Let $\underline{X} := (X, \mathscr{T}_X, A^+_X)$ be a *topologically henselian* quasi-affinoid scheme; we attach to $\underline{X}$ a site $(\mathscr{Q}(\underline{X}), J_{\mathscr{Q}})$ of quasi-affinoid open subsets, as in (15.5.11). We now define as follows a fibred lex-site over the category $\mathscr{Q}(\underline{X})$. For every $U \in \mathrm{Ob}(\mathscr{Q}(\underline{X}))$ choose a topologically henselian quasi-affinoid scheme $\underline{X}^{\mathrm{h}}_U := (X^{\mathrm{h}}_U, \mathscr{T}^{\mathrm{h}}_U, A^{\mathrm{h}+}_U)$ representing the sub-presheaf h'_U of $h'_{\underline{X}}$ (notation of remark 15.5.9(i)). Every inclusion $U \subset U'$ of quasi-affinoid subsets of $\mathrm{Spa}\,\underline{X}$ induces a morphism

$$i_{UU'} : \underline{X}^{\mathrm{h}}_U \to \underline{X}^{\mathrm{h}}_{U'}$$

of quasi-affinoid schemes (cp. (15.5.11)), and for every further inclusion $U' \subset U''$ of quasi-affinoid open subsets of $\mathrm{Spa}\,\underline{X}$ we have $i_{U'U''} \circ i_{UU'} = i_{UU''}$, so we get a well defined functor

$$\underline{X}^{\mathrm{h}}_\bullet : \mathscr{Q}(\underline{X}) \to \mathsf{Sch}^{\mathsf{qcqs}}$$

whence an associated fibred site as in (15.7.2)

$$\pi_{\underline{X}} : \underline{X}^{\mathrm{h}}_{\bullet,\text{ét}} := \mathscr{Q}(\underline{X}) \times_{\mathsf{Sch}^{\mathsf{qcqs}}} (\mathsf{Sch}^{\mathsf{qcqs}}_{\text{ét}}, t, J_{\bullet,\text{ét}}) \to \mathscr{Q}(\underline{X}).$$

Notice that $\underline{X}^{\mathrm{h}}_{\bullet,\text{ét}}$ is a fibred lex-site, since $\underline{X}^{\mathrm{h}}_{U,\text{ét}}$ is quasi-compact and quasi-separated for every $U \in \mathrm{Ob}(\mathscr{Q}(\underline{X}))$. We let $(\underline{X}^{\mathrm{h}}_{\bullet,\text{ét}}, J)$ be the associated total site.

• The identity functor $\mathbf{1}_{\mathscr{Q}(\underline{X})} : \mathscr{Q}(\underline{X}) \to \mathscr{Q}(\underline{X})$ is naturally identified with the fibration $\mathscr{F}ib(\mathsf{F}_{\mathbb{1}}) \to \mathscr{Q}(\underline{X})$, where $\mathsf{F}_{\mathbb{1}} : \mathscr{Q}(\underline{X})^o \to \mathbf{Cat}$ is the constant pseudo-functor with value $\mathbb{1}$. The category $\mathbb{1}$ admits a unique topology $\mathscr{T}_{\mathbb{1}}$, and the resulting pair $(\mathbb{1}, \mathscr{T}_{\mathbb{1}})$ is obviously a lex-site, so we have the fibred lex-site

$$(\mathscr{Q}(\underline{X}), \mathbf{1}_{\mathscr{Q}(\underline{X})}, J^*_\bullet)$$

where J^*_U is the unique topology on the fibre $\mathbf{1}^{-1}_{\mathscr{Q}(\underline{X})}(U) \stackrel{\sim}{\to} \mathbb{1}$, for every $U \in \mathrm{Ob}(\mathscr{Q}(\underline{X}))$, and we let $(\mathscr{Q}(\underline{X}), J^*_{\mathscr{Q}})$ be the resulting total site.

• Denote by

$$e : \mathscr{Q}(\underline{X}) \to \underline{X}^{\mathrm{h}}_{\bullet,\text{ét}}.$$

the functor that assigns to every $U \in \mathrm{Ob}(\mathscr{Q}(\underline{X}))$ the final object X^{h}_U of the fibre category $X^{\mathrm{h}}_{U,\text{ét}}$, and to every inclusion $U \subset U'$ the morphism $i_{UU'}$. It is easily seen that e is a $\mathscr{Q}(\underline{X})$-cartesian functor. Moreover, e restricts to a morphism of sites $X^{\mathrm{h}}_{U,\text{ét}} \to (\mathbb{1}, \mathscr{T}_{\mathbb{1}})$ for every $U \in \mathrm{Ob}(\mathscr{Q}(\underline{X}))$, so e is a morphism of fibred lex-sites, and also a morphism of total sites

$$e : (\underline{X}^{\mathrm{h}}_{\bullet,\text{ét}}, J) \to (\mathscr{Q}(\underline{X}), J^*_{\mathscr{Q}}).$$

• Lastly, for every $U \in \mathrm{Ob}(\mathscr{Q}(\underline{X}))$ we have an inclusion functor $i_U : \underline{X}^{\mathrm{h}}_{U,\text{ét}} \to \underline{X}^{\mathrm{h}}_{\bullet,\text{ét}}$ which identifies $\underline{X}^{\mathrm{h}}_{U,\text{ét}}$ with the fibre category over U. This is a weak morphism of sites

$$i_U : (\underline{X}^{\mathrm{h}}_{\bullet,\text{ét}}, J) \to \underline{X}^{\mathrm{h}}_{U,\text{ét}}$$

and for $U = \mathrm{Spa}\,\underline{X}$ it is even a morphism of sites (example 4.5.8). Let now $\mathscr{E}$ be a stack on the étale site $X_{\text{ét}}$; we consider the fibration :

$$\mathscr{E}_{/\mathscr{Q}} := \mathsf{St}(e)_* \circ \mathsf{St}(i_{\mathrm{Spa}\,\underline{X}})^*\mathscr{E}.$$

Remark 15.7.5. (i) The fibres of the fibration $\mathscr{E}_{/\mathscr{Q}}$ can be described as follows. let $c_X : \mathscr{Q}(\underline{X}) \to \mathsf{Sch}^{\mathsf{qcqs}}$ be the constant functor with value X; we consider as well the fibred lex-site

$$\mathscr{Q}(\underline{X}) \times X_{\text{ét}} = \mathscr{Q}(\underline{X}) \times_{(\mathsf{Sch}^{\mathsf{qcqs}}, c_X)} (\mathsf{Sch}^{\mathsf{qcqs}}_{\text{ét}}, t, J_{\bullet,\text{ét}}) \to \mathscr{Q}(\underline{X})$$

(see (4.5.11)) whose fibre categories are all naturally identified with $X_{\text{ét}}$. Then the rule $U \mapsto (i_{U,\mathrm{Spa}\,\underline{X}} : X^{\mathrm{h}}_U \to X)$ defines a natural transformation $\underline{X}^{\mathrm{h}}_\bullet \Rightarrow c_X$ which induces, after choosing a cleavage for the fibration $\mathsf{Sch}^{\mathsf{qcqs}}_{\text{ét}}$, a morphism of fibred lex-sites over $\mathscr{Q}(\underline{X})$:

$$j_{\underline{X}} : \underline{X}^{\mathrm{h}}_{\bullet,\text{ét}} \to \mathscr{Q}(\underline{X}) \times X_{\text{ét}}$$

(see (4.5.12)) which is also a morphism on the respective total sites

$$j_{\underline{X}} : (\underline{X}^{\mathrm{h}}_{\bullet,\text{ét}}, J) \to (\mathscr{Q}(\underline{X}) \times X_{\text{ét}}, J').$$

Moreover, let $l_{\underline{X}} : X_{\text{ét}} \to \mathscr{Q}(\underline{X}) \times X_{\text{ét}}$ be the inclusion functor that identifies $X_{\text{ét}}$ with the fibre category over the final object of $\mathscr{Q}(\underline{X})$. By example 4.5.8, this functor is a morphism of sites

$$l_{\underline{X}} : (\mathscr{Q}(\underline{X}) \times X_{\text{ét}}, J') \to X_{\text{ét}}$$

and notice that $i_{\mathrm{Spa}\,\underline{X}} = j_{\underline{X}} \circ l_{\underline{X}}$. Furthermore, the projection $p_{\underline{X}} : \mathscr{Q}(\underline{X}) \times X_{\text{ét}} \to X_{\text{ét}}$ is left adjoint to $l_{\underline{X}}$, and from corollary 5.7.2(ii) it follows easily that $p_{\underline{X}}$ is a weak morphism of sites for the topology J'. Combining with proposition 5.4.29(ii,iii), we deduce a pseudo-natural equivalence of pseudo-functors :

$$\mathsf{St}(l_{\underline{X}})^* \stackrel{\sim}{\to} \mathsf{St}(p_{\underline{X}})_*.$$

Especially, we get an equivalence of stacks :

$$\mathsf{St}(i_{\mathrm{Spa}\,\underline{X}})^*\mathscr{E} \stackrel{\sim}{\to} \mathsf{St}(j_{\underline{X}})^*\mathsf{St}(p_{\underline{X}})_*(\mathscr{E}) = \mathsf{St}(j_{\underline{X}})^*(\mathscr{Q}(\underline{X}) \times \mathscr{E}).$$

In light of proposition 5.7.3, we deduce a natural equivalence of stacks on $\underline{X}^{\mathrm{h}}_{U,\mathrm{\acute{e}t}}$:

$$\mathsf{St}(i_U)_* \circ \mathsf{St}(i_{\mathrm{Spa}\,\underline{X}})^*\mathscr{E} \xrightarrow{\sim} \mathscr{E}_U := \mathsf{St}((i_{U,\mathrm{Spa}\,\underline{X}})_{\mathrm{\acute{e}t}})^*\mathscr{E} \qquad \text{for every } U \in \mathrm{Ob}(\mathscr{Q}(\underline{X})).$$

Summing up, we conclude that the fibre category over U of the fibration $\mathscr{E}_{/\mathscr{Q}}$ is naturally equivalent to the fibre category $(\mathscr{E}_U)_{\underline{X}^{\mathrm{h}}_U}$ of the fibration $\mathscr{E}_U$, over the final object $\underline{X}^{\mathrm{h}}_U$ of the site $\underline{X}^{\mathrm{h}}_{U,\mathrm{\acute{e}t}}$.

(ii) By construction, $\mathscr{E}_{/\mathscr{Q}}$ is a stack on the site $(\mathscr{Q}(\underline{X}), J^*_{\mathscr{Q}})$; but in fact we have :

Theorem 15.7.6. *If $\mathscr{E}$ is ind-finite, the fibration $\mathscr{E}_{/\mathscr{Q}}$ is a stack on the site $(\mathscr{Q}(\underline{X}), J_{\mathscr{Q}})$.*

Proof. It suffices to check that the natural functor

$$\mathscr{E}_{/\mathscr{Q}}(U) \to \underset{\mathscr{S}\in J_{\mathscr{Q}}(U)^o}{2\text{-colim}}\, \mathsf{Cart}_{\mathscr{Q}(\underline{X})}(\mathscr{S}, \mathscr{E}_{/\mathscr{Q}}) \qquad \text{for every } U \in \mathrm{Ob}(\mathscr{Q}(\underline{X}))$$

is an equivalence. Since $J_{\mathscr{Q}}(U)$ is cofiltered for the order given by inclusion of sieves, this 2-colimit is represented by the colimit of the same system of categories (example 3.3.13(iv)); then arguing as in the proof of theorem 15.5.27 we may assume that $U = \mathrm{Spa}\,\underline{X}$, and replace $J_{\mathscr{Q}}(\mathrm{Spa}\,\underline{X})$ by its coinitial subset consisting of the sieves generated by the standard coverings. Thus, let $f_\bullet := (f_0, \dots, f_n)$ and $R_\bullet$ be as in remark 15.5.26(i); for every $k \in \mathbb{N}$ let $[k] := \{0, \dots, k\}$, and set as well $[-1] := \varnothing$. We consider the category $\Sigma^+_{2,n}$ whose objects are all the maps $[j] \to [n]$ for $j = -1, 0, 1, 2$; for two such objects $[j] \xrightarrow{\varphi} [n] \xleftarrow{\varphi'} [k]$, the morphisms $\mu : \varphi \to \varphi'$ are the injective non-decreasing maps $\mu : [j] \to [k]$ such that $\varphi' \circ \mu = \varphi$. The unique map $\varphi_\varnothing : [-1] \to [n]$ is clearly the initial object of $\Sigma^+_{2,n}$. Let also $\Sigma_{2,n} \subset \Sigma^+_{2,n}$ be the full subcategory whose objects are the morphisms $[j] \to [n]$ with $j \geq 0$. Consider the functor

$$\Phi^+ : \Sigma^{+o}_{2,n} \to \mathscr{Q}(\underline{X}) \qquad : \qquad ([j] \xrightarrow{\varphi} [n]) \mapsto R_{\varphi([j])}$$

(here $R_\Lambda \subset \mathrm{Spa}\,\underline{X}$ is defined as in remark 15.5.26(i), for every subset $\Lambda \subset [n]$), and let $\Phi : \Sigma^o_{2,n} \to \mathscr{Q}(\underline{X})$ be the restriction of Φ^+. Taking into account the discussion of (3.5.18), we come down to checking that the natural functor

$$\mathscr{E}_{/\mathscr{Q}}(\mathrm{Spa}\,\underline{X}) \to \underset{\Sigma_{2,n}}{2\text{-}\lim}\, \mathscr{E}_{/\mathscr{Q}}(-) \circ \Phi^o$$

is an equivalence (notation of (3.2.4)). Following (4.5.11), we deduce two other fibred lex-sites

$$\mathscr{U}^{\mathrm{h}}_{f_\bullet} := \Sigma^{+o}_{2,n} \times_{\mathscr{Q}(\underline{X})} (\underline{X}^{\mathrm{h}}_{\bullet,\mathrm{\acute{e}t}}, J) \to \Sigma^{+o}_{2,n} \qquad \underline{\Sigma}^{+o}_{2,n} := \Sigma^{+o}_{2,n} \times_{\mathscr{Q}(\underline{X})} (\mathscr{Q}(\underline{X}), \mathbf{1}_{\mathscr{Q}(\underline{X})}, J^*_\bullet)$$

and according to (4.5.11) and (5.7) and proposition 5.4.29(ii), the projections Φ^+ and

$$\pi_{\mathscr{U}} : \mathscr{U}^{\mathrm{h}}_{f_\bullet} \to \underline{X}^{\mathrm{h}}_{\bullet,\mathrm{\acute{e}t}}$$

are cocontinuous weak morphisms of sites for the topologies of the respective total sites. Furthermore, the functor $e \circ \Phi^+ : \Sigma^{+o}_{2,n} \to X^{\mathrm{h}}_{\bullet,\mathrm{\acute{e}t}}$ factors uniquely through a $\Sigma^{+o}_{2,n}$-cartesian functor

$$e_{\mathscr{U}} : \Sigma^{+o}_{2,n} \to \mathscr{U}^{\mathrm{h}}_{f_\bullet}$$

and the projection $\pi_{\mathscr{U}}$. Just like for e, the functor $e_{\mathscr{U}}$ is a morphism of the respective total sites. Set $\mathscr{F} := \mathsf{St}(\pi_{\mathscr{U}})_* \circ \mathsf{St}(i_{\mathrm{Spa}\,\underline{X}})^*\mathscr{E}$; a direct inspection yields an equivalence of stacks

$$\mathscr{G} := \mathsf{St}(e_{\mathscr{U}})_*\mathscr{F} \xrightarrow{\sim} \mathsf{St}(\Phi^+)_*(\mathscr{E}_{/\mathscr{Q}})$$

over the total site of $\underline{\Sigma}^{+o}_{2,n}$, and we are reduced to checking that the natural functor

$$\mathscr{G}(\varphi_\varnothing) \to \underset{\Sigma_{2,n}}{2\text{-}\lim}\, \mathscr{G}(-) \tag{15.7.7}$$

is an equivalence. To this aim, we proceed as in remark 15.7.5(i) : from the constant functor $c_X : \Sigma^{+o}_{2,n} \to \mathsf{Sch}^{\mathsf{qcqs}}$ we deduce the fibred site

$$\Sigma^{+o}_{2,n} \times X_{\mathrm{\acute{e}t}} = \Sigma^{+o}_{2,n} \times_{(\mathsf{Sch}^{\mathsf{qcqs}}, c_X)} (\mathsf{Sch}^{\mathsf{qcqs}}_{\mathrm{\acute{e}t}}, t, J_{\bullet,\mathrm{\acute{e}t}}) \to \Sigma^{+o}_{2,n}$$

whose fibre categories are naturally identified with $X_{\text{ét}}$, endowed with its étale topology. Let $j_{\underline{X}} : \underline{X}^{\text{h}}_{\bullet,\text{ét}} \to \mathscr{Q}(\underline{X}) \times X_{\text{ét}}$ be as in remark 15.7.5(i); we deduce a morphism of fibred lex-sites

$$j_\Sigma := \Sigma^{+o}_{2,n} \times_{\mathscr{Q}(\underline{X})} j_{\underline{X}} : \mathscr{U}^{\text{h}}_{f_\bullet} \to \Sigma^{+o}_{2,n} \times X_{\text{ét}}$$

which as usual induces a morphism on total sites, and by the same token, the projection

$$\Sigma^{+o}_{2,n} \times_{\mathscr{Q}(\underline{X})} p_{\underline{X}} : \Sigma^{+o}_{2,n} \times X_{\text{ét}} \to X_{\text{ét}}$$

is a weak morphism of sites, for the topology of the total site, and is left adjoint to the inclusion functor

$$l_\Sigma := \Sigma^{+o}_{2,n} \times_{\mathscr{Q}(\underline{X})} l_{\underline{X}} : X_{\text{ét}} \to \Sigma^{+o}_{2,n} \times X_{\text{ét}}.$$

By proposition 5.7.3 we have then an equivalence of stacks over the total site of $\mathscr{U}^{\text{h}}_{f_\bullet}$:

$$\mathscr{F} \xrightarrow{\sim} \mathsf{St}(j_\Sigma)^*(\Sigma^{+o}_{2,n} \times \mathscr{E}).$$

Next, let $A_0 \subset A := \mathscr{O}^{\text{h}}_{\text{Spa}\,\underline{X}}(\text{Spa}\,\underline{X})$ be a subring of definition, and $I_0 \subset A_0$ an ideal of adic definition; set $S := \text{Spec}\,A_0$ and $S' := \text{Spec}\,A_0/I_0$. As in remark 15.5.26(iv,v), the sequence $f_\bullet$ induces a morphism of schemes $X \to \mathbb{P}^n_S$, whose schematic image we denote by V, and we let $\psi : X \to V$ be the resulting morphism of S-schemes; moreover, for every non-empty subset $\Lambda \subset [n]$ we have an open subset $V_\Lambda \subset V$ which is naturally identified with $\text{Spec}\,A_0[f_k/f_i \mid (k,i) \in [n] \times \Lambda]$, and we set as well $V_\varnothing := V$. Then, for every $\Lambda \subset [n]$ let V^{h}_Λ be the henselization of V_Λ along its closed subscheme $V'_\Lambda := S' \times_S V_\Lambda$; we have natural identifications

$$X^{\text{h}}_\Lambda \xrightarrow{\sim} X \times_V V^{\text{h}}_\Lambda \qquad \text{for every } \Lambda \subset [n]$$

and we denote by $\psi^{\text{h}}_\Lambda : X^{\text{h}}_\Lambda \to V^{\text{h}}_\Lambda$ the induced projection, and by $q_\Lambda : V^{\text{h}}_\Lambda \to V$ the composition of the henselization map $V^{\text{h}}_\Lambda \to V_\Lambda$ with the open immersion $V_\Lambda \to V$. We consider the functors

$$G : \Sigma^{+o}_{2,n} \to \mathsf{Sch}^{\mathsf{qcqs}} \quad : \quad ([j] \xrightarrow{\varphi} [n]) \mapsto V^{\text{h}}_{\varphi([j])}$$
$$G' : \Sigma^{+o}_{2,n} \to \mathsf{Sch}^{\mathsf{qcqs}} \quad : \quad ([j] \xrightarrow{\varphi} [n]) \mapsto V'_{\varphi([j])}$$

which to every morphism $\mu : \varphi \to \varphi'$ as in the foregoing assign the natural morphisms

$$(15.7.8) \qquad V^{\text{h}}_{\varphi'([k])} \to V^{\text{h}}_{\varphi([j])} \qquad \text{and respectively} \qquad V'_{\varphi'([k])} \to V'_{\varphi([j])}.$$

As in (15.7.2) we deduce fibred lex-sites

$$\mathscr{V}^{\text{h}}_{f_\bullet} := \Sigma^{+o}_{2,n} \times_{(\mathsf{Sch}^{\mathsf{qcqs}},G)} (\mathsf{Sch}^{\mathsf{qcqs}}_{\text{ét}}, t, J_{\bullet,\text{ét}}) \to \Sigma^{+o}_{2,n}$$
$$\mathscr{V}'_{f_\bullet} := \Sigma^{+o}_{2,n} \times_{(\mathsf{Sch}^{\mathsf{qcqs}},G')} (\mathsf{Sch}^{\mathsf{qcqs}}_{\text{ét}}, t, J_{\bullet,\text{ét}}) \to \Sigma^{+o}_{2,n}.$$

The morphisms $(\psi^{\text{h}}_\Lambda \mid \Lambda \subset [n])$, $(q_\Lambda \mid \Lambda \subset [n])$, the closed immersions $(V'_\Lambda \to V^{\text{h}}_\Lambda \mid \Lambda \subset [n])$ and $V' \to V$, and the open immersions $(V'_\Lambda \to V' \mid \Lambda \subset [n])$ define natural transformations $\underline{X}^{\text{h}}_\bullet \circ \Phi^+ \Rightarrow G$, $G \Rightarrow c_V$, $G' \Rightarrow G$, $c_{V'} \Rightarrow c_V$ and respectively $G' \Rightarrow c_{V'}$, where $c_V : \Sigma^{+o}_{2,n} \to \mathsf{Sch}$ is the constant functor with value V, and likewise for $c_{V'}$. After fixing cleavages, these natural transformations induce morphisms of fibred lex-sites

$$\mathscr{U}^{\text{h}}_{f_\bullet} \xrightarrow{\psi_{\mathscr{U}}} \mathscr{V}^{\text{h}}_{f_\bullet} \xleftarrow{\tau_{\mathscr{V}}} \mathscr{V}'_{f_\bullet} \xrightarrow{q'} \Sigma^{+o}_{2,n} \times V'_{\text{ét}} \xrightarrow{\tau_\Sigma} \Sigma^{+o}_{2,n} \times V_{\text{ét}} \xleftarrow{q} \mathscr{V}^{\text{h}}_{f_\bullet}$$

(see (4.5.12)), which are also morphisms of sites for the topologies of the respective total sites (proposition 4.5.9). Define functors $e_{\mathscr{V}} : \Sigma^{+o}_{2,n} \to \mathscr{V}^{\text{h}}_{f_\bullet}$ and $e_{\mathscr{V}'} : \Sigma^{+o}_{2,n} \to \mathscr{V}'_{f_\bullet}$ by the rules :

$$\varphi \mapsto (\varphi, V^{\text{h}}_{\varphi([j])}) \qquad \text{and respectively :} \qquad \varphi \mapsto (\varphi, V'_{\varphi[j]}) \qquad \text{for every } \varphi : [j] \to [n]$$

and which assign to every morphism $\mu : \varphi \to \psi$ as in the foregoing, the morphisms (15.7.8). Just as for e and $e_{\mathscr{U}}$, both $e_{\mathscr{V}}$ and $e_{\mathscr{V}'}$ are morphisms of the respective total sites, and we get a commutative diagram of morphisms of sites :

$$
\begin{array}{ccccc}
V'_{\text{ét}} & \xrightarrow{\tau_{\text{ét}}} & V^{\text{h}}_{\text{ét}} & \xleftarrow{\psi_{\text{ét}}} & X_{\text{ét}} \\
\uparrow{\scriptstyle l_{V'}} & & \uparrow{\scriptstyle l_V} & & \uparrow{\scriptstyle l_\Sigma} \\
\Sigma^{+o}_{2,n} \times V'_{\text{ét}} & \xrightarrow{\tau_\Sigma} & \Sigma^{+o}_{2,n} \times V_{\text{ét}} & \xleftarrow{\psi_\Sigma} & \Sigma^{+o}_{2,n} \times X_{\text{ét}} \\
\uparrow{\scriptstyle q'} & & \uparrow{\scriptstyle q} & & \uparrow{\scriptstyle j_\Sigma} \\
\mathscr{V}'_{f_\bullet} & \xrightarrow{\tau_{\mathscr{V}}} & \mathscr{V}^{\text{h}}_{f_\bullet} & \xleftarrow{\psi_{\mathscr{U}}} & \mathscr{U}^{\text{h}}_{f_\bullet} \\
\downarrow{\scriptstyle e_{\mathscr{V}'}} & & \downarrow{\scriptstyle e_{\mathscr{V}}} & & \downarrow{\scriptstyle e_{\mathscr{U}}} \\
\underline{\Sigma}^{+o}_{2,n} & = & \underline{\Sigma}^{+o}_{2,n} & = & \underline{\Sigma}^{+o}_{2,n}.
\end{array}
\tag{15.7.9}
$$

where ψ_Σ is likewise deduced from ψ. Set $\mathscr{F}' := \mathsf{St}(\psi_{\mathscr{U}})_*\mathscr{F}$. There follows an equivalence :

$$\mathscr{G} \xrightarrow{\sim} \mathsf{St}(e_{\mathscr{V}})_*\mathscr{F}'.$$

We regard the left square of the bottom row and the right square of the central row in (15.7.9) as oriented squares of sites, with orientations given by $\mathbf{1}_{e_{\mathscr{V}'}}$, respectively $\mathbf{1}_{q\circ\psi_{\mathscr{U}}}$. We remark :

Claim 15.7.10. For every ind-finite stack $\mathscr{A}$ on $\mathscr{V}^{\text{h}}_{f_\bullet}$, the base change transformation

$$\Upsilon(\mathsf{St}(\mathbf{1}_{e_{\mathscr{V}'}})^\gamma_*)_{\mathscr{A}} : \mathsf{St}(e_{\mathscr{V}})_*(\mathscr{A}) \to \mathsf{St}(e_{\mathscr{V}'})_*\mathsf{St}(\tau_{\mathscr{V}})^*(\mathscr{A})$$

is a natural equivalence (notation of (2.3.8) and (5.5.23)).

Proof of the claim. This follows by combining corollary 5.7.26 and [74, Th.1' and Cor.1]. Notice that the proof of *loc.cit.* relies on proposition 1 of the same article; for the latter, a complete proof is available in [105, Exp.XX, Prop.6.3.2]. More precisely, in the latter reference, the required results are stated only for stacks in groupoids; however, a direct inspection shows that the proofs work *verbatim* for arbitrary ind-finite stacks. ◊

Notice as well the pseudo-natural equivalences of pseudo-functors :

$$\mathsf{St}(e_{\mathscr{U}})_* \xrightarrow{\sim} \mathsf{St}(e_{\mathscr{V}})_* \circ \mathsf{St}(\psi_{\mathscr{U}})_* \qquad \mathsf{St}(\tau_{\mathscr{V}})^* \circ \mathsf{St}(q)^* \xrightarrow{\sim} \mathsf{St}(q')^* \circ \mathsf{St}(\tau_\Sigma)^*. \tag{15.7.11}$$

Claim 15.7.12. The base change transformation

$$\Upsilon(\mathsf{St}(\mathbf{1}_{q\circ\psi_{\mathscr{U}}})^\gamma_*) : \mathsf{St}(q)^* \circ \mathsf{St}(\psi_\Sigma)_* \to \mathsf{St}(\psi_{\mathscr{U}})_* \circ \mathsf{St}(j_\Sigma)^*$$

is a pseudo-natural equivalence.

Proof of the claim. For every subset $\Lambda \subset [n]$ we consider the oriented square of lex-sites :

$$
\mathscr{D}_\Lambda \quad : \quad
\begin{array}{ccc}
X^{\text{h}}_{\Lambda,\text{ét}} & \xrightarrow{j_\Lambda} & X_{\text{ét}} \\
\downarrow{\scriptstyle \psi_\Lambda} & \not\swarrow \mathbf{1}_{\psi\circ j'_\Lambda} & \downarrow{\scriptstyle \psi} \\
V^{\text{h}}_{\Lambda,\text{ét}} & \xrightarrow{q_\Lambda} & V_{\text{ét}}.
\end{array}
$$

According to corollary 5.7.26, it suffices to check that the base change transformation

$$\Upsilon(\mathsf{St}(\mathbf{1}_{\psi\circ j'_\Lambda})^\gamma_*) : \mathsf{St}(q_\Lambda)^* \circ \mathsf{St}(\psi)_* \to \mathsf{St}(\psi_\Lambda)_* \circ \mathsf{St}(j_\Lambda)^*$$

is a pseudo-natural equivalence for every such Λ. However, V^{h}_Λ is the limit of a cofiltered system of quasi-compact and quasi-separated V-schemes $(V_{\Lambda,i} \mid i \in I)$ with affine transition morphisms, and X^{h}_Λ is the limit of the induced cofiltered system $(X_{\Lambda,i} := X \times_V V_{\Lambda,i} \mid i \in$

I); hence $V^{\mathrm{h}}_{\Lambda,\text{ét}}$ and $X^{\mathrm{h}}_{\Lambda,\text{ét}}$ represent the 2-limits of the induced systems of lex-sites $V_{\bullet,\text{ét}} := (V_{i,\text{ét}} \mid i \in I)$ and $X_{\Lambda,\bullet,\text{ét}} := (X_{\Lambda,i,\text{ét}} \mid i \in I)$. We regard I as a category (see example 1.1.6(iii)), and we may assume that I admits a final object i_0 such that $V_{\Lambda,i_0} = V$; then $V_{\Lambda,\bullet,\text{ét}}$ and $X_{\Lambda,\bullet,\text{ét}}$ yield fibred lex-sites $\underline{V}_{\Lambda,\bullet,\text{ét}}$ and $\underline{X}_{\Lambda,\bullet,\text{ét}}$ over I, and the system of projections $(X_{\Lambda,i} \to V_{\Lambda,i} \mid i \in I)$ induces a morphism of fibred lex-sites $\underline{X}_{\Lambda,\bullet,\text{ét}} \to \underline{V}_{\Lambda,\bullet,\text{ét}}$. Then the assertion follows from corollary 5.7.30. ◊

Now, from proposition 5.6.34 we see that $\Sigma^{+o}_{2,n} \times \mathscr{E}$ is an ind-finite stack, and then the same holds for $\mathscr{F}$ (theorem 5.6.33), and also for $\mathscr{F}'$, again by proposition 5.6.34. Set

$$\mathscr{E}' := \mathsf{St}(\tau_{\text{ét}})^* \circ \mathsf{St}(\psi_{\text{ét}})_*(\mathscr{E}).$$

From (15.7.11) and claims 15.7.10 and 15.7.12, we deduce an equivalence of stacks :

$$\begin{aligned}\mathscr{G} &\xrightarrow{\sim} \mathsf{St}(e_{\mathscr{V}'})_* \circ \mathsf{St}(q')^* \circ \mathsf{St}(\tau_\Sigma)^* \circ \mathsf{St}(\psi_\Sigma)_*(\Sigma^{+o}_{2,n} \times \mathscr{E}) \\ &\xrightarrow{\sim} \mathsf{St}(e_{\mathscr{V}'})_* \circ \mathsf{St}(q')^* \circ \mathsf{St}(l_{V'})^*(\mathscr{E}').\end{aligned}$$

Once again, by corollary 5.7.2(ii) the projection $\Sigma^{+o}_{2,n} \times V'_{\text{ét}} \to V'_{\text{ét}}$ is a weak morphism of sites, for the topology of the total site, and is left adjoint to l_V, so we get an equivalence

$$\mathsf{St}(l_{V'})^*(\mathscr{E}') \xrightarrow{\sim} \Sigma^{+o}_{2,n} \times \mathscr{E}'$$

(proposition 5.4.29(ii,iii)). Similarly, the functor q' admits a left adjoint

$$s : \mathscr{V}'_{f_\bullet} \to \Sigma^{+o}_{2,n} \times V'_{\text{ét}} \qquad ([j] \xrightarrow{\varphi} [n], U \xrightarrow{f} V_{\varphi([j])}) \mapsto (\varphi, U \xrightarrow{f} V_{\varphi([j])} \to V')$$

and as explained in remark 5.7.34, the functor s is cocontinuous and is a weak morphism of sites, for the topologies of the total sites, whence a pseudo-natural equivalence :

$$\mathsf{St}(q')^* \xrightarrow{\sim} \mathsf{St}(s)_*.$$

Summing up, we obtain an equivalence of stacks :

$$\mathscr{G} \xrightarrow{\sim} \mathsf{St}(e_{\mathscr{V}'})_* \circ \mathsf{St}(s)_*(\Sigma^{+o}_{2,n} \times \mathscr{E}'). \tag{15.7.13}$$

Lastly, consider the functor

$$\Psi^+ : \Sigma^{+o}_{2,n} \to V'_{\text{ét}} \qquad ([j] \xrightarrow{\varphi} [n]) \mapsto V'_{\varphi([j])}$$

and let $\Psi : \Sigma^o_{2,n} \to V'_{\text{ét}}$ be the restriction of Ψ^+. By inspecting the definitions, we find that the equivalence (15.7.13) identifies the functor (15.7.7) with the similar natural functor

$$\mathscr{E}'(V') \to \underset{\Sigma_{2,n}}{2\text{-}\lim}\, \mathscr{E}'(-) \circ \Psi^o.$$

The latter is an equivalence, since $\mathscr{E}'$ is a stack on $V'_{\text{ét}}$, whence the theorem. □

15.7.14. Let $f : \underline{X}' \to \underline{X}$ be an adic morphism of topologically henselian quasi-affinoid schemes, and $(U_1, \dots, U_n)$ a finite covering of $\operatorname{Spa} \underline{X}$ consisting of quasi-affinoid open subsets; recall that $U'_i := (\operatorname{Spa} f)^{-1} U_i$ is a quasi-affinoid subset of $\operatorname{Spa} \underline{U}$, for every $i = 1, \dots, n$ (remark 15.5.9(iv)). As in (15.7.4), define the corresponding functors

$$\underline{X}^{\mathrm{h}}_\bullet : \mathscr{Q}(\underline{X}) \to \mathsf{Sch}^{\mathsf{qcqs}} \qquad \underline{X}'^{\mathrm{h}}_\bullet : \mathscr{Q}(\underline{X}') \to \mathsf{Sch}^{\mathsf{qcqs}}$$

and for every $\Lambda \subset \{1, \dots, n\}$, set $U_\Lambda := \bigcap_{i \in \Lambda} U_i$ (with $U_\varnothing := \operatorname{Spa} \underline{X}$) and $U'_\Lambda := (\operatorname{Spa} f)^{-1} U_\Lambda$. To ease notation, let X_Λ (resp. X'_Λ) be the scheme underlying the quasi-affinoid scheme $\underline{X}^{\mathrm{h}}_{U_\Lambda}$ (resp. $\underline{X}'^{\mathrm{h}}_{U'_\Lambda}$). Recall that $\underline{X}'^{\mathrm{h}}_{U'_\Lambda}$ is the topological henselization of $\underline{Z}_\Lambda := \underline{X}' \times_{\underline{X}} \underline{X}^{\mathrm{h}}_{U_\Lambda}$; the composition of the henselization morphism $\underline{X}'^{\mathrm{h}}_{U'_\Lambda} \to \underline{Z}_\Lambda$ and the projection $\underline{Z}_\Lambda \to \underline{X}^{\mathrm{h}}_{U_\Lambda}$ is then a morphism of quasi-affinoid schemes

$$f_\Lambda : \underline{X}'^{\mathrm{h}}_{U'_\Lambda} \to \underline{X}^{\mathrm{h}}_{U_\Lambda}$$

so we have a commutative diagram of schemes :

$$\begin{array}{ccc} X'_\Lambda & \xrightarrow{f_\Lambda} & X_\Lambda \\ {\scriptstyle p'_\Lambda}\downarrow & & \downarrow{\scriptstyle p_\Lambda} \\ X' & \xrightarrow{f} & X \end{array} \qquad \text{for every } \Lambda \subset \{1,\dots,n\}$$

where p_Λ and p'_Λ are the natural projections. Let also $\mathscr{E}$ be an ind-finite stack on $X_{\text{ét}}$, and set

$$\mathscr{E}' := \mathsf{St}(f_{\text{ét}})^*\mathscr{E} \qquad \mathscr{E}_\Lambda := \mathsf{St}(p_{\Lambda,\text{ét}})^*\mathscr{E} \qquad \mathscr{E}'_\Lambda := \mathsf{St}(f_{\Lambda,\text{ét}})^*\mathscr{E}_\Lambda \qquad \text{for every } \Lambda \subset \{1,\dots,n\}.$$

We consider the units of adjunction :

$$\eta : \mathscr{E} \to \mathsf{St}(f_{\text{ét}})_*\mathscr{E}' \qquad \text{and} \qquad \eta_\Lambda : \mathscr{E}_\Lambda \to \mathsf{St}(f_{\Lambda,\text{ét}})_*\mathscr{E}'_\Lambda \qquad \text{for every } \Lambda \subset \{1,\dots,n\}.$$

Lemma 15.7.15. *In the situation of* (15.7.14)*, suppose that the functor*

$$\eta_{\Lambda,X_\Lambda} : \mathscr{E}_{\Lambda,X_\Lambda} \to \mathscr{E}'_{\Lambda,X'_\Lambda}$$

is an equivalence for every non-empty $\Lambda \subset \{1,\dots,n\}$. Then $\eta_X : \mathscr{E}_X \to \mathscr{E}'_{X'}$ is an equivalence.

Proof. Define the category $\Sigma^+_{2,n}$, its full subcategory $\Sigma_{2,n}$, the fibred site $\underline{\Sigma}^+_{2,n}$ and the site $(\mathscr{Q}(\underline{X}), J^*_{\mathscr{Q}})$ as in the proof of theorem 15.7.6. We consider the functor

$$\Phi^+ : \Sigma^{+o}_{2,n} \to \mathscr{Q}(\underline{X}) \qquad : \qquad ([j] \xrightarrow{\varphi} [n]) \mapsto U_{\varphi([j])}$$

and its restriction $\Phi : \Sigma^o_{2,n} \to \mathscr{Q}(\underline{X})$. We attach likewise to the covering $(U'_1,\dots,U'_n)$ of $\operatorname{Spa}\underline{X}'$ the corresponding functors $\Phi'^+ : \Sigma^{+o}_{2,n} \to \mathscr{Q}(\underline{X}')$ and its restriction Φ' to $\Sigma^o_{2,n}$. Then, from $\Psi^+ := \underline{X}^{\mathrm{h}}_\bullet \circ \Phi^+$ and $\Psi'^+ := \underline{X}'^{\mathrm{h}}_\bullet \circ \Phi'^+$ we get fibred sites :

$$\mathscr{U} := \Sigma^{+o}_{2,n} \times_{(\mathsf{Sch},\Psi^+)} (\mathsf{Sch}^{\mathsf{qcqs}}_{\text{ét}}, t, J_{\bullet,\text{ét}}) \qquad \mathscr{U}' := \Sigma^{+o}_{2,n} \times_{(\mathsf{Sch},\Psi'^+)} (\mathsf{Sch}^{\mathsf{qcqs}}_{\text{ét}}, t, J_{\bullet,\text{ét}}).$$

Next, let $e : \Sigma^{+o}_{2,n} \to \mathscr{U}$ be the functor that assigns to every $([j] \xrightarrow{\varphi} [n]) \in \mathrm{Ob}(\Sigma^{+o}_{2,n})$ the final object $X_{\varphi([j])}$ of the site $X_{\varphi([j]),\text{ét}}$; let also $i : X_{\text{ét}} \to \mathscr{U}$ be the inclusion functor which identifies $X_{\text{ét}}$ with the fibre category of the fibration $\mathscr{U} \to \Sigma^{+o}_{2,n}$, over the final object $[-1] \in \mathrm{Ob}(\Sigma^{+o}_{2,n})$. Likewise we define the functor $e' : \Sigma^{+o}_{2,n} \to \mathscr{U}'$ and $i' : X'_{\text{ét}} \to \mathscr{U}'$.

With this notation, Φ^+ is a weak morphism of sites $(\mathscr{Q}(\underline{X}), J^*_{\mathscr{Q}}) \to \Sigma^{+o}_{2,n}$ for the topology of the total site of $\underline{\Sigma}^{+o}_{2,n}$, and likewise for Φ'^+. Also, both i and e are morphisms of sites for the topologies of the total sites, and likewise for i' and e'. Furthermore, the rule : $([j] \xrightarrow{\varphi} [n]) \mapsto f_{\varphi([j])}$ for every $\varphi \in \mathrm{Ob}(\Sigma^{+o}_{2,n})$ defines a natural transformation

$$\underline{X}'^{\mathrm{h}}_\bullet \circ \Phi^+ \Rightarrow \underline{X}^{\mathrm{h}}_\bullet \circ \Phi'^+$$

which, after choosing a cleavage for the fibration $\mathsf{Sch}^{\mathsf{qcqs}}_{\text{ét}} \to \mathsf{Sch}^{\mathsf{qcqs}}$, determines a morphism of fibred sites $\varphi : \mathscr{U}' \to \mathscr{U}$, which is again a morphism of sites for the topologies of the respective total sites. A direct inspection then yields a commutative diagram of morphisms of sites :

$$(15.7.14) \qquad \begin{array}{ccccc} \Sigma^{+o}_{2,n} & \xleftarrow{e'} & \mathscr{U}' & \xrightarrow{i_{\underline{X}'}} & X'_{\text{ét}} \\ \| & & \downarrow{\scriptstyle g} & & \downarrow{\scriptstyle f_{\text{ét}}} \\ \Sigma^{+o}_{2,n} & \xleftarrow{e} & \mathscr{U} & \xrightarrow{i_{\underline{X}}} & X_{\text{ét}}. \end{array}$$

By theorem 15.7.6, we associate with $\mathscr{E}$ a stack $\mathscr{E}_{/\mathscr{Q}}$ on $(\mathscr{Q}(\underline{X}), J_{\mathscr{Q}})$; likewise, since $\mathscr{E}'$ is also ind-finite (theorem 5.6.33), we get the stack $\mathscr{E}'_{/\mathscr{Q}}$ on $(\mathscr{Q}(\underline{X}'), J'_{\mathscr{Q}})$. Then, arguing as in the proof of theorem 15.7.6 we get equivalences of fibrations over $\Sigma^{+o}_{2,n}$:

$$\mathsf{St}(\Phi^+)_*(\mathscr{E}_{/\mathscr{Q}}) \xrightarrow{\sim} \mathscr{E}_{/\Sigma} := \mathsf{St}(e)_* \circ \mathsf{St}(i_{\underline{X}})^*\mathscr{E} \qquad \mathsf{St}(\Phi'^+)_*(\mathscr{E}'_{/\mathscr{Q}}) \xrightarrow{\sim} \mathscr{E}'_{/\Sigma} := \mathsf{St}(e')_* \circ \mathsf{St}(i_{\underline{X}'})^*\mathscr{E}'.$$

On the other hand, from diagram (15.7.14) we deduce an equivalence of stacks

$$\mathsf{St}(g)^* \circ \mathsf{St}(i_{\underline{X}})^*(\mathscr{E}) \stackrel{\sim}{\to} \mathsf{St}(i_{\underline{X}'})^*(\mathscr{E}')$$

whence, by adjunction, a morphism of stacks :

$$\mathsf{St}(i_{\underline{X}})^*(\mathscr{E}) \to \mathsf{St}(g)_* \circ \mathsf{St}(i_{\underline{X}'})^*(\mathscr{E}')$$

and after composing with $\mathsf{St}(e)_*$, we arrive at a morphism of fibrations over $\Sigma^{+o}_{2,n}$:

$$\omega : \mathscr{E}_{/\Sigma} \to \mathscr{E}'_{/\Sigma}.$$

Now, pick cleavages for $\mathscr{E}_{/\Sigma}$ and $\mathscr{E}'_{/\Sigma}$, and let c and c' be the associated pseudo-functors; then ω corresponds to a pseudo-natural transformation $\omega_\bullet : \mathsf{c} \Rightarrow \mathsf{c}'$. Arguing as in remark 15.7.5(i), we see that c_φ is equivalent to $\mathscr{E}_{\varphi([j])}$ for every $([j] \xrightarrow{\varphi} [n]) \in \mathrm{Ob}(\Sigma^{+o}_{2,n})$, and likewise for c'_φ, so we have for every such φ an essentially commutative diagram of categories :

$$\begin{array}{ccc} \mathsf{c}_\varphi & \xrightarrow{\omega_\varphi} & \mathsf{c}'_\varphi \\ \downarrow & & \downarrow \\ \mathscr{E}_{\varphi([j])} & \xrightarrow{\omega^*_\varphi} & \mathscr{E}'_{\varphi([j])} \end{array}$$

whose vertical arrows are equivalences. Lastly, since $\mathscr{E}_{/\mathscr{Q}}$ and $\mathscr{E}'_{/\mathscr{Q}}$ are stacks for the topologies $J_{\mathscr{Q}}$ and respectively $J'_{\mathscr{Q}}$, we know that the natural functors

$$\mathscr{E}_X \to \underset{\Sigma_{2,n}}{2\text{-}\lim}\,\mathsf{c} \qquad \mathscr{E}'_{X'} \to \underset{\Sigma_{2,n}}{2\text{-}\lim}\,\mathsf{c}'$$

are equivalences, hence $\omega_\varnothing : \mathscr{E}_X \to \mathscr{E}'_{X'}$ is identified, up to equivalences of categories and isomorphisms of functors, with the induced functor

$$\underset{\Sigma_{2,n}}{2\text{-}\lim}\,\omega_\bullet : \underset{\Sigma_{2,n}}{2\text{-}\lim}\,\mathsf{c} \to \underset{\Sigma_{2,n}}{2\text{-}\lim}\,\mathsf{c}'.$$

To conclude the proof, it then suffices to check that for every $\varphi : [j] \to [n]$, the functor ω^*_φ is isomorphic to the functor η_{Λ,X_Λ}, with $\Lambda := \varphi([j])$. To this aim, we notice that the right square subdiagram of (15.7.14) can be regarded as an oriented square of links, after choosing adjoints and fixing adjunctions for its four arrows; its orientation (from the bottom left corner to the upper right corner) is given by the identity $\mathbf{1}_{i_{\underline{X}}\circ g} : i_{\underline{X}} \circ g \Rightarrow f_{\text{ét}} \circ i_{\underline{X}'}$. Then, proposition 5.7.3 says that the base change transformation

$$\Upsilon(\mathsf{St}(\mathbf{1}_{i_{\underline{X}}\circ g})^\Upsilon_*) : \mathsf{St}(f_{\text{ét}})^* \circ \mathsf{St}(i_{\underline{X}})_* \to \mathsf{St}(i_{\underline{X}'})_* \circ \mathsf{St}(g)^*$$

is a pseudo-natural equivalence. The assertion then follows, after combining with proposition 2.3.14 : the details shall be left to the reader. □

15.7.16. Resume the situation of (15.7.4), and let also $\underline{X}^\wedge := (X^\wedge, \mathscr{T}^\wedge_X, A^+_{X^\wedge})$ be the completion of $\underline{X}$, and denote by $\pi_X : \underline{X}^\wedge \to \underline{X}$ the *completion morphism* of quasi-affinoid schemes (given by the counit of the adjunction of proposition 15.4.12). The morphism π_X induces a morphism of étale sites $\pi_{X,\text{ét}} : X^\wedge_{\text{ét}} \to X_{\text{ét}}$, and for every stack $\mathscr{E}$ on $X_{\text{ét}}$ we let

$$\mathscr{E}^\wedge := \mathsf{St}(\pi_{X,\text{ét}})^*(\mathscr{E}).$$

Theorem 15.7.17. *With the notation of* (15.7.16)*, if $\mathscr{E}$ is ind-finite, the unit of adjunction*

$$\mathscr{E}_X \to \mathscr{E}^\wedge_{X^\wedge} = \mathsf{St}(\pi_{X,\text{ét}})_*(\mathscr{E}^\wedge)_X$$

is an equivalence of categories.

Proof. To begin with, let $f : \underline{Y} \to \underline{X}$ be any f-adic morphism of quasi-affinoid schemes; since $\pi_X : \underline{X}^\wedge \to \underline{X}$ is also f-adic, the fibre product $\underline{Y}' := \underline{X}^\wedge \times_{\underline{X}} \underline{Y}$ is well defined (example 15.4.8), and we let $\underline{X}^\wedge \xleftarrow{p_1} \underline{Y}' \xrightarrow{p_2} \underline{Y}$ be the natural projections. The morphism $f^\wedge : \underline{Y}^\wedge \to \underline{X}^\wedge$ induced by f, and the completion morphism $\pi_Y : \underline{Y}^\wedge \to \underline{Y}$ determine a unique morphism of quasi-affinoid schemes

$$g : \underline{Y}^\wedge \to \underline{Y}' \qquad \text{such that} \qquad p_1 \circ g = f^\wedge \quad \text{and} \quad p_2 \circ g = \pi_Y.$$

Moreover, since $\underline{Y}^\wedge$ is complete, by adjunction g factors uniquely through a morphism of quasi-affinoid schemes $h : \underline{Y}^\wedge \to \underline{Y}'^\wedge$ and the completion morphism $\pi_{Y'} : \underline{Y}'^\wedge \to \underline{Y}'$.

Claim 15.7.18. In the foregoing situation, h is an isomorphism of quasi-affinoid schemes.

Proof of the claim. It suffices to show that the morphisms $p_2 \circ \pi_{Y'}$ and π_Y satisfy the same universal property. Thus, let $\underline{Z}$ be a complete quasi-affinoid schemes, and $k : \underline{Z} \to \underline{Y}$ any morphism of quasi-affinoid schemes; the composition $f \circ k : \underline{Z} \to \underline{X}$ factors uniquely through a morphism $l : \underline{Z} \to \underline{X}^\wedge$ and π_X, and there exists a unique morphism $l' : \underline{Z} \to \underline{Y}'$ such that $p_1 \circ l' = l$ and $p_2 \circ l' = k$. Again, l' factors uniquely through a morphism $l'^\wedge : \underline{Z} \to \underline{Y}'^\wedge$ and $\pi_{Y'}$. It follows easily that $l'^\wedge$ is the unique morphism such that $p_2 \circ \pi_{Y'} \circ l'^\wedge = k$, whence the contention. ◊

Claim 15.7.19. In order to prove the theorem, we may assume that $\underline{X}$ is an affinoid scheme.

Proof of the claim. Let $U_\bullet := (U_1, \dots, U_n)$ be an open covering of $\mathrm{Spa}\,\underline{X}$ consisting of finitely many affinoid open subsets. (To find such $U_\bullet$, let $A_X := \mathscr{O}_X(X)$, and $J \subset A_X$ a finitely generated ideal such that $\mathrm{Spec}\,A_X/J = \mathrm{Spec}\,A_X \setminus X$; then we may take a finite set of generators $f_\bullet := (f_1, \dots, f_n)$ of J, and let $U_\bullet$ be the standard covering associated with $f_\bullet$, as in (15.5.20).)

For every $\Lambda \subset \{1, \dots, n\}$, define the affinoid open subset $U_\Lambda \subset \mathrm{Spa}\,\underline{X}$ as in (15.7.14), and notice that $U_\Lambda^\wedge := (\mathrm{Spa}\,\pi_X)^{-1} U_\Lambda$ is an affinoid open subset of $\mathrm{Spa}\,\underline{X}^\wedge$. To ease notation, let also $\underline{X}_\Lambda := \underline{X}^{\mathrm{h}}_{U_\Lambda}$ and $\underline{X}'_\Lambda := \underline{X}^{\wedge\mathrm{h}}_{U_\Lambda^\wedge}$, for every such Λ. Let $p_\Lambda : \underline{X}_\Lambda \to \underline{X}$ be the natural projection, and $\pi_\Lambda : \underline{X}'_\Lambda \to \underline{X}_\Lambda$ the morphism of affinoid schemes deduced from π_X, as in (15.7.14), and set $\mathscr{E}_\Lambda := \mathsf{St}(p_{\Lambda,\text{ét}})^* \mathscr{E}$ and $\mathscr{E}'_\Lambda := \mathsf{St}(\pi_{\Lambda,\text{ét}})^* \mathscr{E}_\Lambda$, for every $\Lambda \subset \{1, \dots, n\}$. By lemma 15.7.15, in order to prove the theorem it suffices to show that the unit of adjunction

$$\eta_\Lambda : \mathscr{E}_{\Lambda, X_\Lambda} \to \mathscr{E}'_{\Lambda, X'_\Lambda}$$

is an equivalence for every non-empty $\Lambda \subset \{1, \dots, n\}$. To this aim, let $q_\Lambda : (\underline{X}_\Lambda)^\wedge \to \underline{X}_\Lambda$ and $q'_\Lambda : (\underline{X}'_\Lambda)^\wedge \to \underline{X}'_\Lambda$ be the completion morphisms, and denote by $(X_\Lambda)^\wedge$ (resp. $(X'_\Lambda)^\wedge$) the scheme underlying $(\underline{X}_\Lambda)^\wedge$ ($(\underline{X}'_\Lambda)^\wedge$); since $(\underline{X}'_\Lambda)^\wedge$ is also the completion of $\underline{X}^\wedge \times_{\underline{X}} \underline{X}_\Lambda$ (remark 15.4.10(vi) and corollary 8.4.15(i)), claim 15.7.18 yields an isomorphism of affinoid schemes

$$h : (\underline{X}_\Lambda)^\wedge \xrightarrow{\sim} (\underline{X}'_\Lambda)^\wedge \qquad \text{such that} \qquad \pi_\Lambda \circ q'_\Lambda \circ h = q_\Lambda. \tag{15.7.20}$$

Set $\mathscr{E}_\Lambda^\wedge := \mathsf{St}(q_{\Lambda,\text{ét}})^* \mathscr{E}_\Lambda$ and $\mathscr{E}'^\wedge_\Lambda := \mathsf{St}(q'_{\Lambda,\text{ét}})^* \mathscr{E}'_\Lambda$, and denote

$$\eta_\Lambda^\wedge : \mathscr{E}_{\Lambda, X_\Lambda} \to \mathscr{E}^\wedge_{\Lambda,(X_\Lambda)^\wedge} \qquad \text{and} \qquad \eta'^\wedge_\Lambda : \mathscr{E}'_{\Lambda, X_\Lambda} \to \mathscr{E}'^\wedge_{\Lambda,(X'_\Lambda)^\wedge}$$

the units of adjunction. Now, up to equivalences of categories and isomorphisms of functors, the composition $\eta'^\wedge_\Lambda \circ \eta_\Lambda$ is naturally identified with the counit

$$\mathscr{E}_{\Lambda, X_\Lambda} \to (\mathsf{St}((\pi_\Lambda \circ q'_\Lambda)_{\text{ét}})^* \mathscr{E}_\Lambda)_{(X'_\Lambda)^\wedge}$$

and the latter is an equivalence if and only if the same holds for $\eta^\wedge_\Lambda$, due to (15.7.20). Thus, if both $\eta^\wedge_\Lambda$ and $\eta'^\wedge_\Lambda$ are equivalences, the same will follow for η_Λ. Summing up, the theorem will follow for the quasi-affinoid scheme $\underline{X}$, once we have shown that the theorem holds for the affinoid schemes $\underline{X}_\Lambda$ and $\underline{X}'_\Lambda$, for every non-empty $\Lambda \subset \{1, \dots, n\}$, whence the claim. ◊

For every scheme Y and every finite group G, let G_Y be the group scheme $G \times Y$ over Y; recall that a (right) G-torsor on $Y_{\text{ét}}$ is the datum of a surjective étale morphism of schemes $Z \to Y$, together with a morphism $\rho : Z \times_Y G_Y \to Z$ that induces an action of the group $G_Y(T)$ of T-sections of G_Y on the set $Z(T)$ of T-sections of Z, for every Y-scheme T, and such that ρ and the projection $Z \times_Y G_Y \to Z$ induce an isomorphism

$$Z \times_Y G_Y \xrightarrow{\sim} Z \times_Y Z.$$

A morphism of G_Y-torsors $(Z, \rho) \to (Z', \rho')$ is a morphism of schemes $Z \to Z'$ compatible in the obvious way with the morphisms ρ and ρ'. Clearly the G-torsors over $Y_{\text{ét}}$ form a category :

$$\mathsf{Tors}(Y_{\text{ét}}, G).$$

According to [105, Exp.XX, Prop.6.3.2], in order to prove the theorem, it suffices to check that :

(i) for every sheaf $\mathscr{F}$ on $X_{\text{ét}}$, the natural map $H^0(X_{\text{ét}}, \mathscr{F}) \to H^0(X^\wedge_{\text{ét}}, \widetilde{\pi}^*_{X,\text{ét}}\mathscr{F})$ is bijective
(ii) For every finite group G, and every finite morphism of schemes $Y \to X$, the natural functor $\mathsf{Tors}(Y_{\text{ét}}, G) \to \mathsf{Tors}((X^\wedge \times_X Y)_{\text{ét}}, G)$ is an equivalence of categories.

Moreover, according to [10, Exp.XII, Prop.6.5(i)], condition (i) is equivalent to :

(iii) For every finite morphism of schemes $Y \to X$, the natural map $H^0(Y_{\text{ét}}, \mathbb{Z}/2\mathbb{Z}) \to H^0((X^\wedge \times_X Y)_{\text{ét}}, \mathbb{Z}/2\mathbb{Z})$ is bijective.

However, for every scheme Z, the group $H^0(Z_{\text{ét}}, \mathbb{Z}/2\mathbb{Z})$ is naturally identified with the automorphism group of the trivial $\mathbb{Z}/2\mathbb{Z}$-torsor on $Z_{\text{ét}}$, so (iii) follows from (ii), for $G := \mathbb{Z}/2\mathbb{Z}$.

Now, for every finite morphism of schemes $f : Y \to X$, let $\underline{Y} := Y \times_X \underline{X}$, and recall that the morphism of quasi-affinoid schemes $f : \underline{Y} \to \underline{X}$ is f-adic (see example 15.4.9(v)), hence $\underline{Y}' := \underline{X}^\wedge \times_{\underline{X}} \underline{Y}$ is well defined, and according to claim 15.7.18 we have an isomorphism $h : \underline{Y}^\wedge \xrightarrow{\sim} \underline{Y}'^\wedge$ of quasi-affinoid schemes. Let G be any finite group; we deduce an essentially commutative diagram :

$$\begin{array}{ccc} \mathsf{Tors}(Y_{\text{ét}}, G) & \longrightarrow & \mathsf{Tors}(Y'_{\text{ét}}, G) \\ \downarrow & & \downarrow \\ \mathsf{Tors}(Y^\wedge_{\text{ét}}, G) & \longrightarrow & \mathsf{Tors}(Y'^\wedge_{\text{ét}}, G) \end{array}$$

where $Y', Y^\wedge, Y'^\wedge$ are the schemes underlying respectively $\underline{Y}', \underline{Y}^\wedge, \underline{Y}'^\wedge$. The vertical arrows are induced by $\pi_Y : Y^\wedge \to Y$ and $\pi_{Y'} : Y'^\wedge \to Y'$, and the bottom horizontal arrow is induced by h, so it is an equivalence. Hence, condition (ii) will follow for $f : Y \to X$, if we show that the vertical arrows of the diagram are equivalences. Moreover, by comparing the respective universal properties, we easily obtain a natural isomorphism of affinoid schemes $\underline{Y}' \xrightarrow{\sim} (X^\wedge \times_X Y) \times_{X^\wedge} \underline{X}^\wedge$; since $\underline{X}^\wedge$ is topologically henselian, example 15.4.9(vi) implies that the same holds for $\underline{Y}'$. With claim 15.7.19, we are then reduced to checking that for every topologically henselian affinoid scheme $(X, \mathscr{T}_X, A^+_X)$ and every finite group G, the completion morphism induces an equivalence $\mathsf{Tors}(X_{\text{ét}}, G) \to \mathsf{Tors}(X^\wedge_{\text{ét}}, G)$.

Let $A_0 \subset A := \mathscr{O}_X(X)$ be a subring of definition; let also $(A_i \mid i \in I)$ be the filtered system of finite type A_0-subalgebras of A. For every $i \in I$, endow A_i and $A^+_i := A_i \cap A^+_X$ with the topologies $\mathscr{T}_i$ and $\mathscr{T}^+_i$ induced by the inclusions into A. Let $A^\wedge_0$ be the completion of A_0; then the completions of A_i and A^+_i are respectively $A^\wedge_i := A^\wedge_0 \otimes_{A_0} A_i$ and $A^{\wedge +}_i := A^\wedge_0 \otimes_{A_0} A^+_i$ for every $i \in I$, and the completion of A is $A^\wedge := A^\wedge_0 \otimes_{A_0} A$, so $A^\wedge$ is the colimit of the induced filtered system of $A^\wedge_0$-algebras $(A^\wedge_i \mid i \in I)$. Set as well $X_i := \operatorname{Spec} A_i$ and $X^\wedge_i := \operatorname{Spec} A^\wedge_i$, and let $\mathscr{T}^\wedge_i$ be the topology of $A^\wedge_i$, for every $i \in I$; then $\underline{X}_i := (X_i, \mathscr{T}_i, A^+_i)$ is a topologically henselian affinoid scheme (proposition 8.4.2(iii)), and its completion $\underline{X}^\wedge_i$ is $(X^\wedge_i, \mathscr{T}^\wedge_i, A^{\wedge +}_i)$.

From [65, Ch.IV, Th.8.8.2, Th.8.10.5, Th.11.2.6] it follows easily that the natural functors

$$\text{2-}\operatorname*{colim}_{i\in I} \mathsf{Tors}(X_{i,\text{ét}}, G) \to \mathsf{Tors}(X_{\text{ét}}, G) \qquad \text{2-}\operatorname*{colim}_{i\in I} \mathsf{Tors}(X^\wedge_{i,\text{ét}}, G) \to \mathsf{Tors}(X^\wedge_{\text{ét}}, G)$$

are equivalences of categories. Hence it suffices to check that for every $i \in I$ the functor

$$\mathsf{Tors}(X_{i,\text{ét}}, G) \to \mathsf{Tors}(X^\wedge_{i,\text{ét}}, G)$$

is an equivalence. We may therefore assume from start that A is an A_0-algebra of finite type, say $A = A_0[t_1, \dots, t_n]$ for a finite sequence $t_\bullet := (t_1, \dots, t_n)$ of elements of A. For every $k = 0, \dots, n$, we shall say that the sequence $t_\bullet$ is *adequate up to* k if for every $i = 1, \dots, k$, either one of the following conditions holds :

(a) $t_i \in A^+$
(b) $t_i \in A^\times$ and $1/t_i \in A^+$.

Claim 15.7.21. In order to prove the theorem, we may assume that $t_\bullet$ is adequate up to n.

Proof of the claim. Suppose that the theorem is known for every f-adic ring A generated over some topologically henselian subring of definition A_0 by a sequence of elements $(t_1, \dots, t_n)$ adequate up to n. We argue by descending induction on $k \leq n$, that the theorem then also holds for every f-adic ring generated over any such subring A_0 by a sequence $(t_1, \dots, t_n)$ that is only adequate up to k. If $k = n$, there is nothing to show; let then $k \leq n$ and $t_\bullet$ a sequence adequate up to $k - 1$, and suppose that we have already proved our assertion for all sequences adequate up to k. Let $\underline{A}$ be the affinoid ring (A, A^+); we consider the affinoid rings

$$\underline{B} := \underline{A}\left(\frac{1, t_k}{1}\right) \qquad \underline{C} := \underline{A}\left(\frac{1, t_k}{t_k}\right) \qquad \underline{D} := \underline{B} \otimes_{\underline{A}} \underline{C}$$

(notation of (15.5.1) and example 15.4.5(i)). Explicitly, we have $\underline{B} = (B, B^+)$ and $\underline{C} = (C, C^+)$, where the ring underlying the topological ring B (resp. C) is A (resp. $A[1/t_k]$) and B^+ (resp. C^+) is the integral closure in B (resp. in C) of $A^+[t_k]$ (resp. of $A^+[1/t_k]$); moreover, B (resp. C) admits the ring of definition $B_0 := A_0[t_k]$ (resp. $C_0 := A_0[1/t_k]$). Recall that the topological henselization B^{h} of B is $B_0^{\mathrm{h}} \otimes_{B_0} B$, with B_0^{h} the topological henselization of B_0. Hence the image in B^{h} of the sequence $t_\bullet$ generates the f-adic B_0^{h}-algebra B^{h}, and is adequate up to k. Likewise we see that the image of $t_\bullet$ generates the C_0^{h}-algebra C^{h}, and then the same follows for the image of $t_\bullet$ in the topological ring underlying $\underline{D}^{\mathrm{h}}$: the details are left to the reader. By inductive assumption, the theorem then holds for the affinoid schemes $\mathsf{Spec}\,\underline{B}^{\mathrm{h}}$, $\mathsf{Spec}\,\underline{C}^{\mathrm{h}}$ and $\mathsf{Spec}\,\underline{D}^{\mathrm{h}}$. But notice that $\underline{B}^{\mathrm{h}}$ and $\underline{C}^{\mathrm{h}}$ represent two affinoid open subsets U' and U'' of $\mathrm{Spa}\,\underline{X}$, and $\underline{D}^{\mathrm{h}}$ represents $U' \cap U''$; more precisely, (U', U'') is the standard covering of $\mathrm{Spa}\,\underline{A}$ associated with the sequence $(1, t_k)$ (see (15.5.20)); arguing as in the proof of claim 15.7.19, we deduce that the theorem holds for $\mathsf{Spec}\,\underline{A}$, as required. ◊

Henceforth, we assume that $t_\bullet$ is an adequate sequence up to n; let $S := \{i \leq n \mid t_i \in A^+\}$ and $T := \{1, \dots, n\} \setminus S$, and set $t'_i := t_i$ for every $i \in S$ and $t'_i := 1/t_i$ for every $i \in T$. Moreover, set $t := \prod_{i\in T} t'_i$. The subring $A'_0 := A_0[t'_1, \dots, t'_n]$ is open and bounded in A, hence it is a subring of definition of A, and after replacing A_0 by A'_0 we may assume that $A = A_0[t^{-1}]$ for an element $t \in A_0 \cap A^\times$. Let $I_0 \subset A_0$ be a finite type ideal of adic definition, and denote by B the topological ring whose underlying ring is the same as A, and whose topology is the (t, I_0)-adic topology as defined in [75, Def.5.4.10(ii)] (invoking remark 8.3.2(i), it is easily seen that the (t, I_0)-adic topology is a ring topology on A).

Since $t \in A^\times$, the ideal $t^n I_0$ is open in A for every $n \in \mathbb{N}$, therefore the identity is a continuous map $A \to B$, and its completion is a morphism of topological rings :

$$f : A^\wedge \to B^\wedge.$$

Let also $g : A \to A^\wedge$ and $h : B \to B^\wedge$ be the completion maps, $I_0^\wedge$ the topological closure of the image of I_0 in $A^\wedge$, and $\mathscr{T}$ the $(t, I_0^\wedge)$-adic topology on $A^\wedge$. We notice :

Claim 15.7.22. The map f is also a morphism $(A^\wedge, \mathscr{T}) \to B^\wedge$ of topological rings, and induces an isomorphism of topological rings :

$$f^\wedge : (A^\wedge, \mathscr{T})^\wedge \xrightarrow{\sim} B^\wedge.$$

Proof of the claim. Let $J_0^\wedge$ be the topological closure of the image of I_0 in $B^\wedge$; it is clear that f is a continuous map $(A^\wedge, \mathscr{T}) \to B^\wedge$, since $f(t^n I_0^\wedge) \subset t^n J_0^\wedge$ for every $n \in \mathbb{N}$. In order to show that $f^\wedge$ is an isomorphism, we apply the criterion of theorem 8.2.8(iii) : first, obviously the image of f is dense in $B^\wedge$, since the image of A in $B^\wedge$ is already dense. It remains to check that $\mathscr{T}$ agrees with the topology induced from $B^\wedge$ via $f^\wedge$; we show more precisely :

$$t^n I_0^\wedge = f^{-1}(t^n J_0^\wedge) \qquad \text{for every } n \in \mathbb{N}.$$

Indeed, since both $t^n I_0^\wedge$ and $f^{-1}(t^n J_0^\wedge)$ are open subgroups of $(A^\wedge, \mathscr{T})$, it suffices to check that $g^{-1}(t^n I_0^\wedge) = g^{-1}(f^{-1}(t^n J_0^\wedge))$; but $g^{-1}(t^n I_0^\wedge) = t^n g^{-1}(I_0^\wedge) = t^n I_0$, and $g^{-1}(f^{-1}(t^n J_0^\wedge)) = h^{-1}(t^n J_0^\wedge) = t^n h^{-1}(J_0^\wedge) = t^n I_0$. ◇

Since $h = f \circ g$, it suffices to check that f and h induce equivalences of categories

$$\mathsf{Tors}((\mathrm{Spec}\, A^\wedge)_{\mathrm{\acute{e}t}}, G) \xrightarrow{\sim} \mathsf{Tors}((\mathrm{Spec}\, B^\wedge)_{\mathrm{\acute{e}t}}, G) \xleftarrow{\sim} \mathsf{Tors}((\mathrm{Spec}\, A)_{\mathrm{\acute{e}t}}, G).$$

Now, the pair (A_0, I_0) is henselian by assumption, and since $A_0^\wedge$ is complete for the $I_0^\wedge$-adic topology, also the pair $(A_0^\wedge, I_0^\wedge)$ is henselian; it then follows that the pairs (A_0, tI_0) and $(A_0^\wedge, tI_0^\wedge)$ are henselian [75, Rem.5.1.10(iv)]. By [75, Prop.5.4.53] and claim 15.7.22, we deduce that f and h induce equivalences of categories of finite étale morphisms

$$\mathsf{Cov}(\mathrm{Spec}\, A^\wedge) \xrightarrow{\sim} \mathsf{Cov}(\mathrm{Spec}\, B^\wedge) \xleftarrow{\sim} \mathsf{Cov}(\mathrm{Spec}\, A) \tag{15.7.23}$$

(notation of (13.1)). Now, for any scheme Y, the G-torsors over $Y_{\mathrm{\acute{e}t}}$ are the objects $\varphi : Z \to Y$ of $\mathsf{Cov}(\mathrm{Spec}\, A^\wedge)$ endowed with a (right) G-action and such that φ is a surjective morphism. Such a morphism has an open and closed image in Y, hence it is surjective if and only if it is an epimorphism (in the category $\mathsf{Cov}(Y)$). The equivalences (15.7.23) induce formally equivalences for the corresponding categories of objects endowed with G-action (details left to the reader), and obviously respect epimorphisms, whence the contention. □

Remark 15.7.24. For every finite group G, let $\mathscr{C}_G$ be the category with $\mathrm{Ob}(\mathscr{C}_G) = \{o\}$ and such that the monoid $\mathrm{Hom}_{\mathscr{C}_G}(o, o)$ is isomorphic to G. For every scheme X, let also $\mathscr{C}_{G, X_{\mathrm{\acute{e}t}}}$ be the constant presheaf on $X_{\mathrm{\acute{e}t}}$ with value $\mathscr{C}_G$. By arguing as in the proof of lemma 15.7.1, it is easily seen that the associated stack $\mathscr{C}^a_{G, X_{\mathrm{\acute{e}t}}}$ is naturally equivalent to the stack of G-torsors on $X_{\mathrm{\acute{e}t}}$: the details shall be left to the reader.

15.7.25. For every $U \in \mathrm{Ob}(\mathscr{Q}(\underline{X}))$, choose a complete and separated quasi-affinoid scheme $\underline{X}_U^\wedge := (X_U^\wedge, \mathscr{T}_U^\wedge, A_U^{\wedge +})$ representing the sub-presheaf $h''_U \subset h''_{\underline{X}^\wedge}$ (notation of remark 15.5.9(i)). Any inclusion $U \subset U'$ of quasi-affinoid subsets of $\mathrm{Spa}\, \underline{X}$ induces a morphism $j_{UU'} : \underline{X}_U^\wedge \to \underline{X}_{U'}^\wedge$ of quasi-affinoid schemes (cp. (15.5.11)), and for any further inclusion $U' \subset U''$ we have

$$j_{U'U''} \circ j_{UU'} = j_{UU''}$$

whence a well defined functor

$$\underline{X}_\bullet^\wedge : \mathscr{Q}(\underline{X}) \to \mathsf{Sch} \qquad U \mapsto X_U^\wedge$$

and we consider the fibration over $\mathscr{Q}(\underline{X})$

$$\mathsf{Cov}_{\underline{X}}^\wedge := \mathsf{Fib}(\underline{X}_\bullet^\wedge)^*(\mathsf{Cov})$$

where the fibration $\mathsf{Cov} \to \mathsf{Sch}$ is defined as in (15.7). With this notation, we can now state :

Corollary 15.7.26. *The fibration* $\mathsf{Cov}^{\wedge}_{\underline{X}}$ *is a stack on the site* $(\mathscr{Q}(\underline{X}), J_{\mathscr{Q}})$.

Proof. We have already remarked that the stack $\mathsf{Cov}_{X_{\text{ét}}}$ is ind-finite on $X_{\text{ét}}$, hence the fibration $(\mathsf{Cov}_{X_{\text{ét}}})_{/\mathscr{Q}}$ is a stack on $(\mathscr{Q}(\underline{X}), J_{\mathscr{Q}})$, by theorem 15.7.6. But from theorem 15.7.17 we easily deduce an equivalence of fibrations $(\mathsf{Cov}_{X_{\text{ét}}})_{/\mathscr{Q}} \overset{\sim}{\to} \mathsf{Cov}^{\wedge}_{\underline{X}}$, whence the assertion. □

Remark 15.7.27. A variant of corollary 15.7.26 appears in [114, Th.2.6.9].

15.7.28. We wish to give an explicit description, up to natural equivalence of categories, of the stalks of the fibration $\mathsf{Cov}^{\wedge}_{\underline{X}}$. Hence, let $x \in \mathrm{Spa}\,\underline{X}$ be any point; recall that the stalk of $\mathsf{Cov}^{\wedge}_{\underline{X}}$ over x is the category

$$\mathsf{Cov}^{\wedge}_{\underline{X}}(x) := \underset{U\in\mathscr{Q}(\underline{X},x)^o}{2\text{-colim}}\, \mathsf{Cov}(X^{\wedge}_U)$$

where $\mathscr{Q}(\underline{X}, x)$ denotes the set of all quasi-affinoid open neighborhoods of x in $\mathrm{Spa}\,\underline{X}$, which is cofiltered by inclusion. Pick a finitely generated ideal $J \subset A_X := \mathscr{O}_X(X)$ such that $X = \mathrm{Spec}\,A_X \setminus \mathrm{Spec}\,A_X/J$, and let $f_0, \dots, f_n$ be a finite system of generators of J. Set $U_i := R_{A_X}\big(\frac{f_0,\dots,f_n}{f_i}\big) \cap \mathrm{Spa}\,\underline{X}$ for $i = 0, \dots, n$. Then we have

$$U_0 \cup \cdots \cup U_n = \mathrm{Spa}\,\underline{X}$$

and we may assume that $x \in U_0$. Notice that h''_{U_0} is represented by a quasi-affinoid scheme $\underline{X}^{\wedge}_{U_0} := (X^{\wedge}_{U_0}, \mathscr{T}^{\wedge}_{U_0}, A^{\wedge+}_{U_0})$ with $X^{\wedge}_{U_0} = \mathrm{Spec}\,\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X}}(U_0)$. Then, since $X^{\wedge}_{U_0}$ is affine, every rational subset of $\mathrm{Spa}\,\underline{X}^{\wedge}_{U_0}$ containing x is likewise represented by a quasi-affinoid scheme whose underlying scheme is affine, and the system of such rational subsets is naturally identified with a final subset of $\mathscr{Q}(\underline{X}, x)$. Taking into account lemma 13.1.6, we deduce a natural equivalence

$$\mathsf{Cov}^{\wedge}_{\underline{X}}(x) \overset{\sim}{\to} \mathsf{Cov}(\mathrm{Spec}\,\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x}).$$

• Next, if x is analytic, combining with lemma 15.5.14(i,v.c), proposition 9.1.17(iii) and [66, Ch.IV, Prop.18.5.15] we arrive at a natural equivalence

$$\mathsf{Cov}^{\wedge}_{\underline{X}}(x) \overset{\sim}{\to} \mathsf{Cov}(\mathrm{Spec}\,\kappa(x^{\wedge})) \overset{\sim}{\to} \mathsf{Cov}(\mathrm{Spec}\,\kappa(x)^{\wedge})$$

where $\kappa(x^{\wedge})$ is the residue field of the natural valuation $|\cdot|^{\wedge}_x$ on $\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x}$, and $\kappa(x)^{\wedge}$ is the completion of $\kappa(x^{\wedge})$ for its valuation topology (see (15.5.12)).

• Lastly, if x is non-analytic, lemma 15.5.14(vi.b) and [75, Th.5.5.7(iii)] yield the natural equivalence

$$\mathsf{Cov}^{\wedge}_{\underline{X}}(x) \overset{\sim}{\to} \mathsf{Cov}(\mathrm{Spec}\,\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x}/A^{\circ\circ}_X\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{X},x}).$$

16. Perfectoid rings and perfectoid spaces

In this chapter we develop a generalization of Scholze's theory of perfectoid rings and perfectoid spaces.

16.1. **Distinguished elements and transversal pairs.** Let p be a prime number, $(A, \mathscr{T})$ a complete and separated topological ring whose topology $\mathscr{T}$ is linear and coarser than the p-adic topology. Remark 9.4.12(ii) endows the topological monoid $\mathbf{E}(A)$ with a natural structure of perfect topological $\mathbb{F}_p$-algebra, such that :

- For every topologically nilpotent ideal $I \subset A$ containing pA, and which is either closed for the topology $\mathscr{T}$, or else finitely generated and closed for the p-adic topology of A, the projection $\pi_I : A \to A/I$ induces an isomorphism of topological rings
$$\mathbf{E}(\pi_I) : \mathbf{E}(A) \overset{\sim}{\to} \mathbf{E}(A/I)$$
where A/I is endowed with the quotient topology induced by $\mathscr{T}$ via π_I.

- Moreover, if $(A', \mathscr{T}')$ is any other topological ring fulfilling the above conditions, and $f : A \to A'$ is any continuous ring homomorphism, the map $\mathbf{E}(f) : \mathbf{E}(A) \to \mathbf{E}(A')$ is a morphism of topological rings.

In light of this canonical identification of $\mathbf{E}(A)$ with $\mathbf{E}(A/I)$, we shall henceforth write slightly abusively

$$\overline{u}_{A/I} : \mathbf{E}(A) \to A/I$$

for the map that would be denoted $\overline{u}_{A/I} \circ \mathbf{E}(\pi_I)$, or equivalently, $\pi_I \circ \overline{u}_A$, with the notation of section 9.4. Another basic construction of this chapter shall be the topological ring :

$$\mathbf{A}(A, \mathscr{T}) := W(\mathbf{E}(A))$$

where $W(-)$ denotes the ring of Witt vectors as in (9.3.11). From remark 9.4.9(i) and lemma 9.3.33(ii,iii) we also know that the topologies of $\mathbf{E}(A)$ and $\mathbf{A}(A, \mathscr{T})$ are linear, complete and separated. Unless we have to deal with several different topologies on A, we shall usually omit mentioning explicitly $\mathscr{T}$, and write simply $\mathbf{A}(A)$. According to proposition 9.3.44(ii), the ring $\mathbf{A}(A)$ is also complete and separated for its p-adic topology, and the same holds for A, by lemma 8.3.12; moreover we see from (9.3.41) that p is a regular element of $\mathbf{A}(A)$, and by remark 9.3.28(i) the ghost component $\boldsymbol{\omega}_0$ descends to an isomorphism of topological rings

$$\mathbf{A}(A) \otimes_{\mathbb{Z}} \mathbb{F}_p \xrightarrow{\sim} \mathbf{E}(A)$$

provided we endow $\mathbf{A}(A) \otimes_{\mathbb{Z}} \mathbb{F}_p$ with the quotient topology induced from $\mathbf{A}(A)$ via the projection $\mathbf{A}(A) \to \mathbf{A}(A) \otimes_{\mathbb{Z}} \mathbb{F}_p$. The map $\boldsymbol{\omega}_0$ also admits a continuous set-theoretic multiplicative splitting, the Teichmüller mapping of (9.3.34), which will be here denoted :

$$\tau_A : \mathbf{E}(A) \to \mathbf{A}(A).$$

Lemma 16.1.1. *With the notation of* (16.1)*, the following holds :*

(i) *There exists a unique ring homomorphism $u_A : \mathbf{A}(A) \to A$ that makes commute the diagram :*

$$\begin{array}{ccc} \mathbf{A}(A) & \xrightarrow{u_A} & A \\ {\scriptstyle \boldsymbol{\omega}_0}\downarrow & & \downarrow{\scriptstyle \pi_{pA}} \\ \mathbf{E}(A) & \xrightarrow{\overline{u}_{A/pA}} & A/pA. \end{array}$$

(ii) *The map u_A is continuous for the topology $\mathscr{T}$ and the topology of $\mathbf{A}(A, \mathscr{T}_A)$.*
(iii) $\mathbf{A}(A)^\times = u_A^{-1}(A^\times)$.
(iv) $u_A \circ \tau_A = \overline{u}_A$.

Proof. We have already remarked that A is complete and separated for its p-adic topology, and the filtration $(J_n := p^n A \mid n \in \mathbb{N})$ of A trivially fulfills the condition of lemma 9.3.4; therefore (i) follows immediately from proposition 9.3.52(iii). More precisely, (9.3.53) translates as the following explicit expression for u_A :

$$u(\underline{a}) = \sum_{n\in\mathbb{N}} p^n \cdot \overline{u}_A(a_n^{p^{-n}}) \qquad \text{for every } \underline{a} := (a_n \mid n \in \mathbb{N}) \in \mathbf{A}(A)$$

from which (ii) follows easily : details left to the reader.

(iii): The inclusion $\mathbf{A}(A)^\times \subset u_A^{-1}(A^\times)$ is obvious. For the converse, let $\alpha \in \mathbf{A}(A)$ be any element such that $u_A(\alpha) \in A^\times$; then $\boldsymbol{\omega}_0(\alpha) \in \overline{u}_A^{-1}(A^\times)$. By remark 9.4.5(iii) we deduce that $\boldsymbol{\omega}_0(\alpha) \in \mathbf{E}(A)^\times$, so it remains only to notice that $\boldsymbol{\omega}_0^{-1}(\mathbf{E}(A)^\times) = \mathbf{A}(A)^\times$, due to proposition 9.3.44(iii).

(iv) is clear from the foregoing explicit formula for u_A. □

Furthermore, $\mathbf{A}(A)$ is endowed with an automorphism $\boldsymbol{\sigma}_A : \mathbf{A}(A) \to \mathbf{A}(A)$ that lifts the Frobenius map of $\mathbf{E}(A)$, *i.e.* such that the horizontal arrows of the diagram :

(16.1.2)
$$\begin{array}{ccc} \mathbf{A}(A) & \xrightarrow{\boldsymbol{\sigma}_A} & \mathbf{A}(A) \\ {\scriptstyle \boldsymbol{\omega}_0}\downarrow\uparrow{\scriptstyle \tau_A} & & {\scriptstyle \boldsymbol{\omega}_0}\downarrow\uparrow{\scriptstyle \tau_A} \\ \mathbf{E}(A) & \xrightarrow{\Phi_{\mathbf{E}(A)}} & \mathbf{E}(A) \end{array}$$

commute with the downward arrows (proposition 9.3.22(iii)). The horizontal arrows commute also with the upward ones, due to (9.3.43).

16.1.3. Keep the notation of (16.1), and recall that τ_A induces a continuous map $\operatorname{Spec}\tau_A : \operatorname{Spec}\mathbf{A}(A) \to \operatorname{Spec}\mathbf{E}(A)$ as in proposition 9.3.66(ii); in light of lemma 16.1.1(iv) and remark 8.1.14(ii) we deduce a continuous and spectral map

$$\operatorname{Spec}\overline{u}_A := (\operatorname{Spec}\tau_A)\circ(\operatorname{Spec}u_A) : \operatorname{Spec}A \to \operatorname{Spec}\mathbf{E}(A) \qquad \mathfrak{p} \mapsto \overline{u}_A^{-1}\mathfrak{p}.$$

Moreover, due to proposition 9.3.66(iv), every morphism $\varphi : A \to A'$ of topological algebras that fulfill the conditions of (16.1) induces a commutative diagram of topological spaces :

(16.1.4)
$$\begin{array}{ccc} \operatorname{Spec}A' & \xrightarrow{\operatorname{Spec}\overline{u}_{A'}} & \operatorname{Spec}\mathbf{E}(A') \\ {\scriptstyle \operatorname{Spec}\varphi}\downarrow & & \downarrow{\scriptstyle \operatorname{Spec}\mathbf{E}(\varphi)} \\ \operatorname{Spec}A & \xrightarrow{\operatorname{Spec}\overline{u}_A} & \operatorname{Spec}\mathbf{E}(A). \end{array}$$

Lemma 16.1.5. *In the situation of* (16.1.3)*, let* $\mathfrak{p} \in \operatorname{Spec}A$ *be any prime ideal, set* $\mathfrak{q} := \operatorname{Spec}\overline{u}_A(\mathfrak{p}) \in \operatorname{Spec}\mathbf{E}(A)$*, and let* $\pi_\mathfrak{p} : A \to \kappa(\mathfrak{p})$*,* $\pi_\mathfrak{q} : \mathbf{E}(A) \to \kappa(\mathfrak{q})$ *be the projections. If* $\mathfrak{p}$ *is a closed subset in the* p*-adic topology of* A*, then* $\overline{u}_A$ *induces a morphism of multiplicative monoids*

$$\overline{u}_\mathfrak{p} : \kappa(\mathfrak{q}) \to \kappa(\mathfrak{p}) \qquad \textit{such that} \qquad \overline{u}_\mathfrak{p}\circ\pi_\mathfrak{q} = \pi_\mathfrak{p}\circ\overline{u}_A.$$

Proof. Since u_A is continuous for the p-adic topologies, $u_A^{-1}\mathfrak{p}$ is a closed subet for the p-adic topology of $\mathbf{A}(A)$, so the assertion follows immediately from proposition 9.3.66(iii). ☐

With the following definition, we single out certain elements of $\mathbf{A}(A)$ that shall play a special role in the study of perfectoid rings.

Definition 16.1.6. Let $(E, \mathscr{T})$ be any topological $\mathbb{F}_p$-algebra.

(i) An element $(a_n \mid n \in \mathbb{N}) \in W(E)$ is called *distinguished* if a_0 is topologically nilpotent in E, and $a_1 \in E^\times$.

(ii) An ideal of $W(E)$ is called *distinguished* if it is generated by a distinguished element.

Remark 16.1.7. Let E be any topological $\mathbb{F}_p$-algebra, $\underline{a} := (a_n \mid n \in \mathbb{N})$ and $\underline{b} := (b_n \mid n \in \mathbb{N})$ two elements of $W(E)$, such that $\underline{a}$ is distinguished and set $\underline{c} := \underline{a}\cdot\underline{b}$.

(i) Suppose that the topology of E is linear, complete and separated. Then $\underline{c}$ is distinguished if and only if $\underline{b}$ is invertible in $W(E)$. Indeed, say that $\underline{c} = (c_n \mid n \in \mathbb{N})$. Then remark 9.3.8 says that $c_0 = a_0b_0$, especially c_0 is topologically nilpotent. Also, $c_1 = a_0^pb_1 + a_1b_0^p$, and notice that $b_0 \in E^\times$, if and only if $\underline{b} \in W(E)^\times$ (proposition 9.3.44(iii)); on the other hand, since the topology of E is linear, $a_0^pb_1$ is topologically nilpotent (remark 8.3.9(v)). Since the topology of E is linear, complete and separated, it follows that c_1 is invertible if and only if the same holds for b_0 (details left to the reader), whence the assertion.

(ii) If E is reduced, then every distinguished ideal of $W(E)$ is a closed subset for the p-adic topology of $W(E)$ and a free $W(E)$-module of rank one (proposition 9.3.47(i,v)).

(iii) Let E be as in (i), and $I, J \subset W(E)$ any two distinguished ideals such that $I \subset J$; then (i) implies that $I = J$. By the same token, we see that every generator of I is distinguished.

Indeed, let $\underline{a}_1$ and $\underline{a}_2$ be any two generators of I; then there exists $\underline{u} := (u_n \mid n \in \mathbb{N}) \in W(E)$ such that $\underline{a}_2 = \underline{u} \cdot \underline{a}_1$. Let $N \subset E$ be the nilpotent ideal, and endow $E_{\mathrm{red}} := E/N$ with the quotient topology induced from E; it follows from (ii) that the image of $\underline{u}$ is invertible in $W(E_{\mathrm{red}})$, therefore the image of u_0 is invertible in E_{red}, so u_0 is invertible in E, and finally $\underline{u}$ is invertible in $W(E)$ (proposition 9.3.44(iii)).

Example 16.1.8. With the notation of example 9.3.78, notice that the only distinguished elements of $W(A, \mathscr{T}_T) = \mathbb{Z}_p\{T^{1/p^\infty}\}$ are of the form pu, where $u \in W(A, \mathscr{T}_T)^\times$ is an arbitrary element; especially, the only distinguished ideal of $\mathbb{Z}_p\{T^{1/p^\infty}\}$ is the principal ideal generated by p. On the other hand, the distinguished elements of $W(A^\wedge, \mathscr{T}_T^\wedge)$ are all those of the form $pu + aT^\lambda$, where a (resp. u) is an arbitrary element (resp. invertible element) of $W(A^\wedge, \mathscr{T}_T^\wedge)$, and $\lambda \in \mathbb{N}[1/p]$ is any strictly positive number.

The following result shall be applied to produce useful distinguished elements in various situations.

Lemma 16.1.9. *Let E be an $\mathbb{F}_p$-algebra, $\mathscr{I} \subset W(E)$ an ideal, $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N}) \in \mathscr{I}$, and $\beta_\bullet := (\beta_1, \dots, \beta_k)$ a finite system of elements of E. Denote by $J \subset E$ (resp. by $\mathscr{J} \subset W(E)$) the ideal generated by $\beta_\bullet$ (resp. by $\tau_E(\beta_1), \dots, \tau_E(\beta_k)$), and by $u : W(E) \to A := W(E)/\mathscr{I}$ the projection. Suppose that :*

- (a) *α_0 lies in the Jacobson radical of E and $\alpha_1 \in E^\times$.*
- (b) *The Frobenius endomorphism Φ_E of E is surjective.*

(i) *Then the following conditions are equivalent :*

- (c) *$pA \subset u(\mathscr{J})$.*
- (d) *There exists an element $\underline{\alpha}' := (\alpha'_n \mid n \in \mathbb{N}) \in \mathscr{I}$ such that $\alpha'_0 \in J$ and the image of α'_1 is invertible in E/J.*
- (e) *There exists $\underline{\alpha}' := (\alpha'_n \mid n \in \mathbb{N}) \in \mathscr{I}$ such that $\alpha'_0 \in J$ and $\alpha'_1 \in E^\times$.*

(ii) *Suppose furthermore that $\mathscr{I} = \underline{\alpha}W(E)$. Then* (c),(d) *and* (e) *are also equivalent to :*

- (f) *$\alpha_0 \in J$.*
- (g) *$pW(E) + \mathscr{J} = \underline{\alpha}W(E) + \mathscr{J}$.*

Proof. (c)⇒(d): Assumption (c) implies that there exist $\underline{\gamma}_1, \dots, \underline{\gamma}_k \in W(E)$ such that

$$\underline{\alpha}' := p + \underline{\gamma}_1 \cdot \tau_E(\beta_1) + \cdots + \underline{\gamma}_k \cdot \tau_E(\beta_k) \in \mathscr{I}$$

and we claim that (d) holds for this $\underline{\alpha}'$. Indeed, $\alpha'_0 = \sum_{i=1}^k \boldsymbol{\omega}_0(\underline{\gamma}_i) \cdot \beta_i \in J$, and clearly the image of $\underline{\alpha}'$ in $W(E/J)$ equals p, *i.e.* $\underline{\alpha}'_1 \equiv 1 \pmod J$.

(d)⇒(c): Let $\underline{\alpha}'$ be as in (d); then there exists $\lambda \in E$ such that $\lambda \cdot \alpha_1 \in 1 + J$, and assumption (b) implies that $\lambda = \gamma^p$ for some $\gamma \in E$. Recall that $\underline{\alpha}'' := \tau_E(\gamma) \cdot \underline{\alpha}' = (\gamma^{p^n} \cdot \alpha'_n \mid n \in \mathbb{N})$ (proposition 9.3.36(i)); we may then replace $\underline{\alpha}'$ by $\underline{\alpha}''$, after which we may assume that $\alpha'_1 \equiv 1 \pmod J$. Say that $\alpha'_0 = \sum_{i=1}^k c_i\beta_i$ for some $c_1, \dots, c_k \in E$, and set

$$\underline{\delta} := \underline{\alpha}' - (\tau_E(c_1) \cdot \tau_E(\beta_1) + \cdots + \tau_E(c_k) \cdot \tau_E(\beta_k)).$$

Notice that $\delta_0 = 0$, and the images of $\underline{\alpha}'$ and $\underline{\delta}$ agree in $W(E/J)$; in particular, $\delta_1 \equiv 1 \pmod J$. Invoking (b) again, we may find $\gamma \in E$ such that $\gamma^p = \delta_1$, and after replacing $\underline{\alpha}'$ by $\tau_E(\gamma^{p-1}) \cdot \underline{\alpha}'$, and c_i by $\gamma^{p-1}c_i$ for $i = 1, \dots, k$, we may further assume that $\delta_1 \equiv 1 \pmod{\Phi_E(J)}$. In this case, say that $\delta_1 = 1 + \sum_{i=1}^k d_i^p \beta_i^p$ for some $d_1, \dots, d_k \in E$; taking into account remark 9.3.8(ii) and (9.3.41) we see that

$$\underline{\delta} \equiv p + p \cdot (\tau_E(d_1) \cdot \tau_E(\beta_1) + \cdots + \tau_E(d_k) \cdot \tau_E(\beta_k)) \pmod{p^2W(E)}.$$

Summing up, we conclude that there exists $\underline{x} \in W(E)$ such that $p + p^2\underline{x} - \underline{\alpha}' \in \mathscr{J}$. Hence, $p \cdot (1 + p \cdot u(\underline{x})) \in u(\mathscr{J})$. Lastly, we have $1 + p \cdot \underline{x} \in W(E)^\times$, since p is topologically nilpotent in $W(E)$, whence (c).

Obviously, (e)⇒(d), so we suppose that (d) holds, and we show (e). Arguing as in the foregoing, we may assume that $\alpha'_1 \equiv 1 \pmod{J}$. Next, using (b) we find $\gamma \in E$ such that $\gamma^p = \alpha'_1$, and after replacing α' by $\tau_E(\gamma^{p-1}) \cdot \underline{\alpha}'$, we may even assume that $\alpha'_1 \equiv 1 \pmod{\Phi_E(J)}$.

Likewise, we may find $\delta \in E$ such that $\delta^p = \alpha_1^{-1}$, and after replacing $\underline{\alpha}$ by $\tau_E(\delta) \cdot \underline{\alpha}$ we may assume that $\alpha_1 = 1$. Now, write $\alpha'_1 = 1 - x^p$ for some $x \in J$, and set

$$\underline{\alpha}'' := \underline{\alpha}' + \tau_E(x) \cdot \underline{\alpha}.$$

In light of remark 9.3.8(ii), we easily see that $\alpha''_0 \in J$ and $\alpha''_1 - 1 \in \alpha_0 E$. Since α_0 lies in the Jacobson radical of E, it follows that $\alpha''_1 \in E^\times$, whence (e).

Lastly, suppose that $\mathscr{J} = \underline{\alpha} W(E)$. In this case, we already know that (f)⇒(e). Conversely, if (e) holds, remark 9.3.8(ii) shows that there exists $\underline{\beta} := (\beta_n \mid n \in \mathbb{N}) \in W(E)$ with

$$\alpha_0\beta_0 \in J \qquad \text{and} \qquad \alpha_0^p\beta_1 + \alpha_1\beta_0^p \in E^\times.$$

Then, since α_0 is in the Jacobson radical of E, we deduce that $\alpha_1\beta_0^p \in E^\times$, so also $\beta_0 \in E^\times$, and (f) follows. Next, if (c) holds, then $W(E)/(\mathscr{J} + \underline{\alpha}W(E)) = A/u(\mathscr{J})$ is an $\mathbb{F}_p$-algebra, *i.e.* $p \in \mathscr{J} + \underline{\alpha}W(E)$; on the other hand, (b) implies that $pW(E) = \mathrm{Ker}(\boldsymbol{\omega}_0 : W(E) \to E)$ (see (9.3.41)). Hence, $W(E)/(\mathscr{J} + \underline{\alpha}W(E)) = E/(\alpha_0 E + J) = E/J$, since we already know that (c)⇒(f); but we have as well $W(E)/(\mathscr{J} + pW(E)) = E/J$, whence (g). Conversely, if (g) holds, we see that $A/u(\mathscr{J})$ is an $\mathbb{F}_p$-algebra, whence (c). □

Remark 16.1.10. Keep the notation of lemma 16.1.9, and let $S := 1 + pW(E) + \mathscr{J}$ and $R := S^{-1}W(E)$. Suppose that for some $v \in R$ we have

$$p \in v \cdot \underline{\alpha} + \mathscr{J}R \qquad (\text{resp. } \underline{\alpha}_0 \in vp + \mathscr{J}R).$$

Then we claim that $v \in R^\times$. Indeed, it suffices to show that $v \notin \mathfrak{m}$, for every $\mathfrak{m} \in \mathrm{Max}\, R$. However, we have a natural identification : $\mathrm{Max}\, R \xrightarrow{\sim} \mathrm{Max}\, W(E)/(pW(E) + \mathscr{J}) = \mathrm{Max}\, E/J$, and since Φ_E is surjective, it follows easily that the residue field $k(\mathfrak{m})$ is perfect for every such $\mathfrak{m}$, in which case $W(k(\mathfrak{m}))$ is a discrete valuation ring of mixed characteristic $(0, p)$ (proposition 9.3.47(iii)); moreover, the projection $W(E) \to k(\mathfrak{m})$ factors through E, so we get a commutative diagram of rings :

$$\begin{array}{ccc} W(E) & \xrightarrow{W(\pi)} & W(k(\mathfrak{m})) \\ \downarrow & & \downarrow \\ E & \xrightarrow{\pi} & k(\mathfrak{m}) \end{array}$$

whose vertical arrows are the 0-th ghost components. It suffices then to check that $x := W(\pi)(v) \in W(k(\mathfrak{m}))^\times$. Now, if $p \in v \cdot \underline{\alpha} + \mathscr{J}$, we get $p = x \cdot W(\pi)(\underline{\alpha})$ in $W(k(\mathfrak{m}))$, and notice that $\pi(\alpha_0) = 0$ and $\pi(\alpha_1) \in k(\mathfrak{m})^\times$, due to assumption (a) of lemma 16.1.9; hence both p and $W(\pi)(\underline{\alpha})$ generate the maximal ideal of $W(k(\mathfrak{m}))$, whence the assertion in this case. Likewise, if $\underline{\alpha} \in vp + \mathscr{J}$, we get $W(\pi)(\underline{\alpha}) = vp$ in $W(k(\mathfrak{m}))$, and again the assertion follows.

16.1.11. Additionally, often we will be dealing with pairs $(\underline{a}, \mathscr{K})$ consisting of an ideal $\mathscr{K}$ in a given $\mathbb{F}_p$-algebra E, and an element $\underline{a} \in W(E)$ (usually $\underline{a}$ shall be a distinguished element); then we shall say that $(\underline{a}, \mathscr{K})$ is a *transversal pair* if we have

$$W(\mathscr{K}) \cap \underline{a}W(E) = \underline{a}W(\mathscr{K}).$$

This property plays a crucial role in several questions about perfectoid rings, and the following proposition collects a few example of such pairs. One more case is given by theorem 16.3.36(iv).

Proposition 16.1.12. *Let E be any perfect $\mathbb{F}_p$-algebra, and $\underline{a} := (a_n \mid n \in \mathbb{N}) \in W(E)$ any element. The following holds :*

(i) *Suppose that* $a_1 \in E^\times$, *and let* $J_1, J_2 \subset E$ *be any two ideals such that*
   (a) $J_1^{\langle 1\rangle}E = J_1$ *and* $J_2^{\langle 1\rangle}E = J_2$ *(notation of* (9.3.68)*)*
   (b) *there exist* $n, m \in \mathbb{N}$ *such that* $a_0^n J_1 \subset J_2$ *and* $a_0^m J_2 \subset J_1$.
   Then the pair $(\underline{a}, J_1)$ *is transversal if and only if the same holds for the pair* $(\underline{a}, J_2)$.

(ii) *Suppose that* $E = \sum_{n\in\mathbb{N}} a_n E$. *Then the pair* $(\underline{a}, I^{\lfloor r\rfloor}E)$ *is transversal, for every ideal* $I \subset E$ *and every* $r \in \mathbb{R}_+$ *(notation of remark* 9.3.70(i)*).*

(iii) *Let* $J \subset E$ *be any ideal such that* $J^{\langle 1\rangle}E = J$. *Then the pair* (p, J) *is transversal.*

Proof. (iii) is immediate from (9.3.45) and remark 9.3.70(iv).

(i): First, we show that the assertion holds in the special case where $n = 0$ and $m = 1$. To begin with, from lemma 9.3.27(i) and our assumption on a_1 we obtain

$$\underline{a} = \tau_E(a_0) + p\underline{u} \qquad \text{for some } \underline{u} \in W(E)^\times.$$

Notice as well that $\underline{a}$ is a regular element of $W(E)$, by virtue of proposition 9.3.47(i). Now, suppose first that the pair $(\underline{a}, J_1)$ is transversal, and let $x \in W(E)$ be any element such that $\underline{a}\cdot x \in W(J_2)$; then $\tau_E(a_0)\cdot\underline{a}\cdot x \in W(J_1)$ (proposition 9.3.36(i)), so $\tau_A(a_0)\cdot x \in W(J_1)$, by assumption. Hence $p\underline{u}\cdot x = (\underline{a} - \tau_A)\cdot x \in W(J_2)$, so $px \in W(J_2)\cap pW(E) = pW(J_2)$, where the last equality follows from (i.a) and (iii); therefore $x \in W(J_2)$, as p is regular in $W(E)$.

Likewise, suppose that $(\underline{a}, J_2)$ is a transversal pair, and let $x \in W(E)$ be any element such that $\underline{a}\cdot x \in W(J_1)$; then $\underline{a}\cdot x \in W(J_2)$, so $x \in W(J_2)$, and $\tau_E(a_0)\cdot x \in W(J_2)$ (again, by proposition 9.3.36(i)). It follows that $p\underline{u}\cdot x = (\underline{a} - \tau_E(a_0))\cdot x \in W(J_2)$, whence $px \in W(J_2)\cap pW(E) = pW(J_2)$, so $x \in W(J_2)$, as required.

Next, let (J_1, J_2) be any pair of ideals fulfilling conditions (i.a) and (i.b). Notice that we have $(a_0^i J_1)^{\langle 1\rangle}E = a_0^i J_1$ for every $i \in \mathbb{N}$ (lemma 9.3.69(iii)), and the foregoing case implies that assertion (i) holds for the pair $(a_0^i J_1, a_0^{i+1}J_1)$, for every $i \in \mathbb{N}$. It follows that assertion (i) also holds for the pair $(J_1, a_0^n J_1)$; consequently we are reduced to showing assertion (i) for the pair $(J_2, a_0^n J_1)$, and notice that $a_0^{m+n}J_2 \subset a_0^n J_1$. Thus, we may replace J_1 by $a_0^n J_1$, m by $n+m$, and assume from start that $J_1 \subset J_2$ and $a_0^m J_2 \subset J_1$. Now, we have

$$a_0\cdot(J_1 + a_0^i J_2)^{\langle 1\rangle}E = (a_0 J_1 + a_0^{i+1}J_2)^{\langle 1\rangle}E \subset (J_1 + a_0^{i+1}J_2)^{\langle 1\rangle}E \qquad \text{for every } i \in \mathbb{N}$$

so that – again by the foregoing case – we know that assertion (i) holds for the pair

$$((J_1 + a_0^i J_2)^{\langle 1\rangle}E, (J' + a_0^{i+1}J_2)^{\langle 1\rangle}E) \qquad \text{for every } i \in \mathbb{N}$$

and then it also holds for the pair $((J_1 + a_0^m J_2)^{\langle 1\rangle}E, (J_1+J_2)^{\langle 1\rangle}E)$; but $(J_1 + a_0^m J_2)^{\langle 1\rangle}E = J_1$ and $(J_1+J_2)^{\langle 1\rangle}E = J_2$, whence the contention.

(ii): Indeed, let $\underline{b} \in W(A)$ be any element, and suppose that $\underline{a}\cdot\underline{b} \in W(I^{\lfloor r\rfloor}E)$. Define $\mathscr{R}_E$ as in lemma 9.3.85; by lemma 9.3.85(iv) and proposition 9.3.82(iii), we deduce that

$$|\underline{a}|_1\cdot|\underline{b}|_1 = |\underline{a}\cdot\underline{b}|_1 \leq |I|^r \qquad \text{for every } |\cdot| \text{ in } \mathscr{R}_E.$$

But since the system $\{a_n \mid n \in \mathbb{N}\}$ generates E, it is easily seen that $|\underline{a}|_1 = 1$ for every $|\cdot|$ in $\mathscr{R}_E$. We conclude that $|\underline{b}|_1 \leq |I|^r$ for every such $|\cdot|$, and then the assertion follows, again by invoking lemma 9.3.85(iv). □

Corollary 16.1.13. *Let* E *be a perfect* $\mathbb{F}_p$*-algebra,* $b_\bullet := (b_1,\dots,b_n)$ *a finite system of elements of* E, *and* $I \subset E$ *(resp.* $\mathscr{J} \subset W(E)$*) the ideal generated by* $b_\bullet$ *(resp. by* $(\tau_E(b_1)\dots,\tau_E(b_n))$*). Let also* $\mathscr{I} := pW(E) + \mathscr{J}$, *and* $\underline{a} := (a_n \mid n \in \mathbb{N}) \in W(E)$, *and suppose that :*

(a) $E = \sum_{n\in\mathbb{N}} a_n E$.
(b) *E is complete and separated for its I-adic topology.*

We have :

(i) *$W(E)$ is complete and separated for both its $\mathscr{I}$-adic and its $\mathscr{J}$-adic topology.*

(ii) *The $\mathscr{J}$-adic topology of $W(E)$ induces the $\mathscr{J}$-adic topology on $\underline{a}W(E)$, and $\underline{a}W(E)$ is a closed ideal for the $\mathscr{J}$-adic topology of $W(E)$.*

(iii) *Suppose moreover that $a_0 \in I$ and $a_1 \in E^\times$. Then the $\mathscr{I}$-adic topology of $W(E)$ induces the $\mathscr{I}$-adic topology on $\underline{a}W(E)$.*

Proof. (i): By proposition 9.3.77(ii) and lemma 9.3.33(ii), $W(E)$ is complete and separated for its $\mathscr{I}$-adic topology, hence also for its $\mathscr{J}$-adic topology (lemma 8.3.12).

(ii): Taking into account proposition 9.3.77(i) and lemma 9.3.69(iv), we easily see that the $\mathscr{J}$-adic topology on $W(E)$ agrees with the linear topology defined by the cofiltered system of ideals $(W(I^{\lfloor q \rfloor}) \mid q \in \mathbb{Q}_+)$. Then, propositions 16.1.12(ii) and 9.3.47(i) imply that scalar multiplication by $\underline{a}$ is a $W(E)$-linear isomorphism

$$W(E) \xrightarrow{\sim} \underline{a}W(E)$$

that identifies the $\mathscr{J}$-adic topology of $\underline{a}W(E)$ with the one induced by the $\mathscr{J}$-adic topology of $W(E)$. In view of (i), we deduce that $\underline{a}W(E)$ is complete and separated for the subspace topology induced from the $\mathscr{J}$-adic topology of $W(E)$, whence the assertion.

(iii): Notice that I lies in the Jacobson radical of E, due to (b); hence, $\mathscr{I} = \underline{a}W(E) + \mathscr{J}$, by lemma 16.1.9(ii). Now, let $m \in \mathbb{N} \setminus \{0\}$; by virtue of (i) there exists $n \in \mathbb{N}$ such that for every $\underline{w} \in W(E)$ with $\underline{a} \cdot \underline{w} \in \mathscr{J}^n$ we have $\underline{w} \in \mathscr{J}^m$, and clearly we may assume that $n \geq m$. Then, let $\underline{w} \in W(E)$ be any element such that $\underline{a} \cdot \underline{w} \in \mathscr{I}^n$; thus, we have $\underline{a} \cdot \underline{w} = \sum_{i=0}^n \underline{a}^i \cdot \underline{w}_i$ where $\underline{w}_i \in \mathscr{I}^{n-i}$ for $i = 0, \dots, n$. Therefore, $\underline{a} \cdot (\underline{w} - \sum_{i=1}^n \underline{a}^{i-1} \cdot \underline{w}_i) \in \mathscr{J}^n$, so that $\underline{w} - \sum_{i=1}^n \underline{a}^{i-1} \cdot \underline{w}_i \in \mathscr{J}^m$, by the foregoing, and finally $\underline{w} \in \mathscr{I}^{m-1}$, whence the assertion. □

16.2. **P-rings.** In this section we make a preliminary study of an auxiliary class of topological rings containing the perfectoid rings that shall be introduced in section 16.3.

Definition 16.2.1. A complete and separated topological ring $(A, \mathscr{T})$ is called a *P-ring* if there exist a prime integer p and an ideal $I \subset A$ such that the following conditions hold :

(a) I is finitely generated and $\mathscr{T}$ agrees with the I-adic topology.

(b) $pA \subset I^2$ and the Frobenius endomorphism of A/I^2 is a surjection

$$\Phi_{A/I^2} : A/I^2 \to A/I^2 \qquad a \mapsto a^p.$$

Any ideal I of A fulfilling conditions (a) and (b) is called an *ideal of definition* of A. Moreover, we say that I is *special*, if the following holds :

(c) There exists a finite set of generators $a_1, \dots, a_n$ of I such that $pA \subset I^{(p)} := \sum_{i=1}^n Aa_i^p$.

It turns out that if I is a special ideal of definition of the P-ring A, the ideal $I^{(p)}$ depends only on I (and not on the choice of a system of generators for I), so this notation is not abusive. Indeed, we have more generally :

Lemma 16.2.2. *Let A be any ring, p a prime integer, and $(a_1, \dots, a_n), (b_1, \dots, b_m)$ two sequences of elements of A. Suppose that*

$$I := \sum_{i=1}^n Aa_i \subset J := \sum_{i=1}^m Ab_i \qquad \textit{and} \qquad p \in I^{(p)} := \sum_{i=1}^n Aa_i^p.$$

Then :

(i) $I^{(p)} \subset J^{(p)} := \sum_{i=1}^m Ab_i^p$.

(ii) *Especially, if $I = J$, we have $I^{(p)} = J^{(p)}$.*

Proof. It is easily seen that (i)⇒(ii), so we need only check (i). To this aim, it suffices to show that $I_\mathfrak{m}^{(p)} \subset J_\mathfrak{m}^{(p)}$ for every maximal ideal $\mathfrak{m} \subset A$, so we may replace A by $A_\mathfrak{m}$ and assume from start that A is local. Now, suppose first that $J = A$; then it is easily seen that $J^{(p)} = A$ as well, so the assertion is clear in this case. Hence, we may also assume that J is contained in the maximal ideal of A. By assumption, for every $i = 1, \dots, n$ we may write $a_i = \sum_{j=1}^m x_{ij} b_j$ for certain $x_{i1}, \dots, x_{im} \in A$; it follows easily that $a_i^p - \sum_{j=1}^m x_{ij}^p b_j^p \in pJ^p$ (details left to the reader). Summing up, we see that $I^{(p)} \subset J^{(p)} + pJ^p \subset J^{(p)} + I^{(p)} J^{(p)}$, and the assertion follows by Nakayama's lemma. □

Lemma 16.2.3. *Let A be any P-ring, and I any ideal of definition of A. We have :*

(i) *If $A \neq 0$, there exists a unique prime integer p, independent of I, such that condition* (b) *of definition* 16.2.1 *is fulfilled.*
(ii) *I is contained in the Jacobson radical of A.*
(iii) *There exists a special ideal of definition J such that $J^{(p)} = I$.*
(iv) *For p as in* (i)*, the Frobenius endomorphism $\Phi_{A/pA} : A/pA \to A/pA$ is a surjective ring homomorphism, and there exist $\pi \in A$ and $u \in A^\times$ such that $p = u\pi^p$.*
(v) *For p as in* (i)*, the ring A is p-adically complete and separated.*

Proof. (ii) is standard : if $a \in I$, then $1 - ab$ is invertible in A for every $b \in A$, since A is I-adically complete and separated (the inverse is given by the convergent series $\sum_{k \in \mathbb{N}} (ab)^n$); the claim follows.

(i): Let J be another ideal of definition of A, and $p, q \in \mathbb{Z}$ two prime integers with $p \in I^2$ and $q \in J^2$. By (ii), both p and q lie in the Jacobson radical of A; as $A \neq 0$, we get $p = q$.

(iii): Let $(f_\lambda \mid \lambda \in \Lambda)$ be a finite system of generators (indexed by the finite set Λ) for I; by assumption, we may find $g_\lambda \in A$ such that $f_\lambda - g_\lambda^p \in I^2$ for every $\lambda \in \Lambda$. From (ii) and Nakayama's lemma, we deduce that the system $(g_\lambda^p \mid \lambda \in \Lambda)$ generates I, so we can take for J the ideal generated by the system $(g_\lambda \mid \lambda \in \Lambda)$.

(iv): Let $(g_\lambda \mid \lambda \in \Lambda)$ be as in the proof of (iii). For any $a \in A$ we construct inductively a sequence $(b_n \mid n \in \mathbb{N})$ of elements of A, such that

$$a - \sum_{k=0}^{n} b_k^p \in I^{n+1} \qquad \text{and} \qquad b_n \in I^n \qquad \text{for every } n \in \mathbb{N}.$$

Indeed, for $n = 0$, since $\Phi_{A/I}$ is surjective we may find $b_0 \in A$ such that $a - b_0^p \in I$. Next, suppose that $n \geq 0$ and $b_0, \dots, b_n \in A$ are already given such that $c_n := a - \sum_{k=0}^n b_k^p \in I^{n+1}$; we may find a system $(d_{\underline{\lambda}} \mid \underline{\lambda} \in \Lambda^{n+1})$ of elements of A such that

$$c_n = \sum_{\underline{\lambda} \in \Lambda^{n+1}} g_{\underline{\lambda}}^p d_{\underline{\lambda}} \qquad \text{where} \qquad g_{\underline{\lambda}} := \prod_{i=1}^{n+1} g_{\lambda_i} \quad \text{for every } \underline{\lambda} := (\lambda_1, \dots, \lambda_{n+1}) \in \Lambda^{n+1}.$$

In turn, for each $\underline{\lambda} \in \Lambda^{n+1}$ we may write $d_{\underline{\lambda}} = e_{\underline{\lambda}}^p + e'_{\underline{\lambda}}$ for elements $e_{\underline{\lambda}} \in A$ and $e'_{\underline{\lambda}} \in I$, so that

$$c_n = c'_n + c''_n \qquad \text{where} \quad c'_n := \sum_{\underline{\lambda} \in \Lambda^{n+1}} g_{\underline{\lambda}}^p e_{\underline{\lambda}}^p \qquad c''_n := \sum_{\underline{\lambda} \in \Lambda^{n+1}} g_{\underline{\lambda}}^p e'_{\underline{\lambda}} \in I^{n+2}.$$

Thus, $b_{n+1} := \sum_{\underline{\lambda} \in \Lambda^{n+1}} g_{\underline{\lambda}} e_{\underline{\lambda}} \in I^{n+1}$, and since $p \in I^2$, a simple computation shows that $c'_n - b_{n+1}^p \in I^{n+2}$, so finally $a - \sum_{k=0}^{n+1} b_k^p \in I^{n+2}$. Notice that the series $\sum_{k \in \mathbb{N}} b_k^p$ converges to a in the I-adic topology of A, and set $b := \sum_{k \in \mathbb{N}} b_k$; it follows easily that $a - b^p \in pA$, whence the surjectivity of $\Phi_{A/pA}$. Lastly, by assumption we may write $p = \sum_{i=1}^r a_i b_i$ for finitely many elements $a_1, b_1, \dots, a_r, b_r \in I$; by the foregoing, for every $i = 1, \dots, r$ we may further find $f_i, g_i, f'_i, g'_i \in A$ such that $a_i = f_i^p + pf'_i$, $b_i = g_i^p + pg'_i$. Then $f_i^p, g_i^p \in I$, and (ii) implies that f_i and g_i lie in the Jacobson radical $\mathrm{rad}(A)$ of A, for every $i \leq r$. Set $\pi := \sum_{i=1}^r f_i g_i$; summing up, we find $p - \pi^p = pc$ for some $c \in \mathrm{rad}(A)$, so $p \cdot (1 - c) = \pi^p$, and to conclude it suffices to remark that $1 - c \in A^\times$.

(v) is a special case of lemma 8.3.12. □

Remark 16.2.4. Suppose that A is a complete and separated topological $\mathbb{F}_p$-algebra. Then it follows easily from lemma 16.2.3(iv) that A is a P-ring if and only if its Frobenius endomorphism Φ_A is surjective, and there exists a finitely generated ideal $I \subset A$ such that the topology of A agrees with the I-adic topology.

Proposition 16.2.5. *Let A be a ring, p a prime integer, $I \subset A$ a finitely generated ideal such that $pA \subset I$, and denote by $\mathscr{T}_I$ (resp. $\mathscr{T}_p$) the I-adic (resp. p-adic) topology on A. We have :*

(i) *If $(A, \mathscr{T}_I)$ is a P-ring, the same holds for $(A, \mathscr{T}_p)$.*
(ii) *If $(A, \mathscr{T}_p)$ is a P-ring, the same holds for the completion $(A^\wedge_I, \mathscr{T}^\wedge_I)$ of $(A, \mathscr{T}_I)$.*

Proof. (i) follows immediately from lemma 16.2.3(iv,v).

(ii): Let $(f_1, \dots, f_k)$ be a finite system of generators of I; by lemma 16.2.3(iv) there exists $\pi \in A$ such that $pA = \pi^p A$, and the Frobenius endomorphism $\Phi_{A/pA}$ of A/pA is surjective, so for every $i = 1, \dots, k$ we may find $g_i \in A$ such that $f_i - g_i^p \in pA$, and we let $J \subset A$ be the ideal generated by the finite system $(g_1, \dots, g_k, \pi)$. Set $N := (p-1)(k+1)+1$, and notice that $J^N \subset I \subset J^p$. Especially, $\mathscr{T}_I$ agrees with the J-adic topology on A, and moreover $p \in J^2$. Furthermore, $\mathscr{T}^\wedge_I$ agrees with the $JA^\wedge_I$-adic topology on $A^\wedge_I$ (remark 8.3.3(iv) and lemma 8.3.32(iv)), and the natural map $A/J^2 \to A^\wedge_I/J^2A^\wedge_I$ is an isomorphism (remark 8.3.3(ii,iv)); since $\Phi_{A/pA}$ is surjective by assumption, the same holds for Φ_{A/J^2}, and the assertion follows. □

16.2.6. *Henceforth we fix a prime integer p, and we shall assume that the topology of every P-ring that appears throughout the rest of this chapter, is coarser than the p-adic topology*. Let $(A, \mathscr{T})$ be any P-ring and $I \subset A$ an ideal of definition. Notice that if I is special (definition 16.2.1), the Frobenius endomorphism $\Phi_{A/I}$ of A/I factors uniquely as the composition of a morphism of topological rings

$$\overline{\Phi}_{A/I} : A/I \to A/I^{(p)}$$

and the natural projection $A/I^{(p)} \to A/I$.

Lemma 16.2.7. *In the situation of* (16.2.6)*, we have :*

(i) *The maps $u_A : \mathbf{A}(A) \to A$ and $\overline{u}_{A/pA} : \mathbf{E}(A) \to A/pA$ are open and surjective.*
(ii) $\mathrm{Ker}\, u_A$ *contains a distinguished element of* $\mathbf{A}(A)$ *(see definition* 16.1.6*).*
(iii) *If $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N})$ is any distinguished element in* $\mathrm{Ker}\, u_A$*, we have*

$$\overline{u}_A(\alpha_0) = pu \qquad \textit{for some } u \in A^\times.$$

Proof. (i): Let $I \subset A$ be any ideal of definition of A, so that the topology of A/pA agrees with the I/pA-adic topology; by lemma 16.2.3(iv) we know already that $\Phi_{A/pA}$ is surjective, and then it is easily seen that there exists $n \in \mathbb{N}$ such that $(I/pA)^n \subset \Phi_{A/pA}(I)$. Especially, $\Phi_{A/pA}$ is an open map; then, the assertion for $\overline{u}_{A/pA}$ follows from remark 9.4.9(iii). By virtue of [126, Th.8.4], we deduce the surjectivity of u_A. Next, let $(a_1, \dots, a_r)$ be a finite system of generators for I, and denote by $\overline{a}_i$ the image of a_i in A/pA, for every $i = 1, \dots, k$. Since $\overline{u}_{A/pA}$ is surjective, we may find $\overline{\alpha}_1, \dots, \overline{\alpha}_k \in \mathbf{E}(A)$ such that $\overline{u}_{A/pA}(\overline{\alpha}_i) = \overline{a}_i$ for $i = 1, \dots, k$, and we set $\alpha_i := \tau_A(\overline{\alpha}_i)$ for $i = 1, \dots, k$ (notation of (16.1)). Since I is topologically nilpotent in A, it is easily seen that $\overline{\alpha}_i$ is topologically nilpotent in $\mathbf{E}(A)$, and since τ_A is continuous, we deduce that α_i is topologically nilpotent in $\mathbf{A}(A)$, for every $i = 1, \dots, k$. Let $\mathscr{I} \subset \mathbf{A}(A)$ be the ideal generated by the system $(\alpha_1, \dots, \alpha_k)$; it follows easily that $\mathscr{I}$ is topologically nilpotent as well. On the other hand, by construction we have $a_i - u_A(\alpha_i) \in pA \subset I^2$ for every $i = 1, \dots, k$, so that $u_A(\mathscr{I}) = I$, by Nakayama's lemma. Lastly, let $\mathscr{J} \subset \mathbf{A}(A)$ be any open ideal; then $\mathscr{I}^n \subset \mathscr{J}$ for every sufficiently large $n \in \mathbb{N}$, so $I^n \subset u_A(\mathscr{J})$, and the assertion follows.

(ii): We notice the following :

Claim 16.2.8. There exist $w \in A^\times$ and $t \in \mathbf{E}(A)$ such that $p = w \cdot \overline{u}_A(t)$ in A.

Proof of the claim. By lemma 16.2.3(iv), we may write $p = v \cdot x^p$ for some $v \in A^\times$ and $x \in A$. Since $\overline{u}_{A/pA}$ is surjective, we may find $s \in \mathbf{E}(A)$ such that $x \equiv \overline{u}_A(s) \pmod{pA}$. In view of lemma 9.3.4(i) we deduce that $p \equiv v \cdot \overline{u}_A(s)^p \pmod{p^2A}$, *i.e.* $p = v \cdot \overline{u}_A(t) + p^2 b$ for $t := s^p$ and some $b \in A$; thus $p \cdot (1 - pb) = v \cdot \overline{u}_A(t)$. But since A is p-adically complete and separated (lemma 16.2.3(v)), $1 - pb \in A^\times$ (remark 8.3.10(v)), so we get the sought identity with $w := v \cdot (1 - pb)^{-1}$. ◊

Now, take w and t as in claim 16.2.8. Since u_A is surjective, we may find $\beta := (b_n \mid n \in \mathbb{N}) \in \mathbf{A}(A)$ with $u_A(\beta) = w$. By proposition 9.3.36(i) we have $\beta \cdot \tau_A(t) = (t^{p^n} b_n \mid n \in \mathbb{N})$, and (9.3.42) and remark 9.3.8(ii) show that

$$\gamma := \beta \cdot \tau_A(t) - p = (tb_0, t^p b_1, \dots) - (0, 1, \dots) = (tb_0, t^p b_1 - 1, \dots).$$

But notice that t is topologically nilpotent in $\mathbf{E}(A)$; since the topology of $\mathbf{E}(A)$ is linear, it follows that tb_0 and $t^p b_1$ are topologically nilpotent in $\mathbf{E}(A)$, and since $\mathbf{E}(A)$ is complete and separated, $1 - t^p b_1 \in \mathbf{E}(A)^\times$, so γ is distinguished, and it lies in the kernel of u_A, due to lemma 16.1.1(iv).

(iii): Indeed, from (9.3.41) and lemma 9.3.27(i) we get $\underline{\alpha} = \tau_A(\alpha_0) + p \cdot \underline{\beta}$, where $\beta := (\alpha_{n+1}^{1/p} \mid n \in \mathbb{N})$, and since $\alpha_1 \in \mathbf{E}(A)^\times$, we have $\underline{\beta} \in \mathbf{A}(A)^\times$ (proposition 9.3.44(iii)); now, $\overline{u}_A(\alpha_0) = -p \cdot u_A(\underline{\beta})$, whence the assertion, in light of lemma 16.1.1(iv). □

Proposition 16.2.9. *In the situation of* (16.2.6)*, the following conditions are equivalent :*

(a) $\mathbf{E}(A)$ *is a P-ring.*
(b) *There exists an ideal of definition I of A such that* $\mathrm{Ker}\,\Phi_{A/I}$ *is a finitely generated ideal of A/I.*
(c) *There exists a special ideal of definition J of A such that $\overline{\Phi}_{A/J}$ is an isomorphism.*

Proof. For any ideal of definition I of A, recall that $\mathbf{E}(A/I)$ is the limit of the inverse system $(A_n \mid n \in \mathbb{N})$ with $A_n := A/I$ for every $n \in \mathbb{N}$, and with transition maps $\varphi_n : A_{n+1} \to A_n$ given by the Frobenius endomorphism $\Phi_{A/I}$ of A/I. For every $n \in \mathbb{N}$ we shall denote by

$$\overline{u}_n : \mathbf{E}(A) \to A_n$$

the composition of the canonical identification $\mathbf{E}(A) \xrightarrow{\sim} \mathbf{E}(A/I)$ as in (16.1), with the natural projection $\mathbf{E}(A/I) \to A_n$. Especially $\overline{u}_0 = \overline{u}_{A/I}$; also, each $\overline{u}_n$ is surjective, since the same holds for $\Phi_{A/I}$. Set $\mathscr{J}_0 := \mathrm{Ker}\,\overline{u}_{A/I}$, and let $\Phi_{\mathbf{E}(A)}$ be the Frobenius endomorphism of $\mathbf{E}(A)$; then the family of ideals

$$\mathscr{J}_n := \Phi^n_{\mathbf{E}(A)}(\mathscr{J}_0) = \mathrm{Ker}\,\overline{u}_n \qquad \text{for every } n \in \mathbb{N}$$

is a fundamental system of open neighborhoods of 0 for the topology $\mathscr{T}_{\mathbf{E}(A)}$ of $\mathbf{E}(A)$. Especially, every element of $\mathscr{J}_0$ is topologically nilpotent, and since $\mathbf{E}(A)$ is complete and separated (remark 9.4.9(i)), we easily deduce that $\mathscr{J}_0$ is contained in the Jacobson radical of $\mathbf{E}(A)$ (cp. the proof of lemma 16.2.3(ii)).

(c)⇒(a): Let J be as in (c), and take $I := J$ in the foregoing. Pick a finite system $(a_1, \dots, a_r)$ of generators of J, and let $\pi : A \to A/J^{(p)}$ be the projection. A simple inspection of the definition yields the identity :

$$\overline{u}_{A/J^{(p)}} = \overline{\Phi}_{A/J} \circ \overline{u}_1.$$

Since $\overline{\Phi}_{A/J}$ is an isomorphism, we deduce that $\overline{u}_{A/J^{(p)}}$ is a surjection and we may find

$$\alpha_1, \dots, \alpha_r \in \mathbf{E}(A) \quad \text{with} \quad \overline{u}_{A/J^{(p)}}(\alpha_i) = \pi(a_i) \qquad \text{for every } i = 1, \dots, r.$$

Let $\mathscr{J}'_0 \subset \mathbf{E}(A)$ be the ideal generated by the system $(\alpha_1, \dots, \alpha_r)$, and set

$$\mathscr{J}'_n := \Phi^n_{\mathbf{E}(A)}(\mathscr{J}'_0) \qquad \text{for every } n \in \mathbb{N}.$$

Claim 16.2.10. $\mathscr{J}'_0 = \mathscr{J}_0$, and the $\mathscr{J}_0$-adic topology on $\mathbf{E}(A)$ agrees with $\mathscr{T}_{\mathbf{E}(A)}$.

Proof of the claim. A simple inspection shows that $\mathscr{J}'_0 \subset \mathscr{J}_0$, and consequently $\mathscr{J}'_n \subset \mathscr{J}_n$ for every $n \in \mathbb{N}$. Moreover, $\overline{u}_{A/J^{(p)}}(\mathscr{J}'_0) = J/J^{(p)}$, and therefore

$$\overline{u}_1(\mathscr{J}'_0) = \overline{\Phi}^{-1}_{A/J} \circ \overline{u}_{A/J^{(p)}}(\mathscr{J}'_0) = \overline{\Phi}^{-1}_{A/J}(J/J^{(p)}) = \operatorname{Ker}\varphi_0 = \mathscr{J}_0/\mathscr{J}_1.$$

Especially, the natural map $\mathscr{J}'_0/\mathscr{J}'_1 \to \mathscr{J}_0/\mathscr{J}_1$ is surjective, and since $\Phi_{\mathbf{E}(A)}$ is an automorphism, we deduce that the induced map $\mathscr{J}'_n/\mathscr{J}'_{n+1} \to \mathscr{J}_n/\mathscr{J}_{n+1}$ is surjective for every $n \in \mathbb{N}$. The filtration $(\mathscr{J}_n \mid n \in \mathbb{N})$ is separated on $\mathbf{E}(A)$, so the identity $\mathscr{J}_0 = \mathscr{J}'_0$ will follow from [34, Ch.III, §2, n.8, Cor.2], after we show that $\mathbf{E}(A)$ is complete for the topology $\mathscr{T}$ defined by the filtration $(\mathscr{J}'_n \mid n \in \mathbb{N})$. However, since $\mathscr{J}'_0$ is finitely generated, for every $n \in \mathbb{N}$ there exists $k(n) \in \mathbb{N}$ such that $\mathscr{J}'_{k(n)} \subset \mathscr{J}'^{k(n)}_0 \subset \mathscr{J}'_n$, so the topology $\mathscr{T}$ agrees with the $\mathscr{J}'_0$-adic topology, and $\mathscr{J}'_0$ is topologically nilpotent for the topology $\mathscr{T}_{\mathbf{E}(A)}$, since it is contained in $\mathscr{J}_0$. Then, the assertion follows from lemma 8.3.12. By the same token, we see that the $\mathscr{J}_0$-adic topology agrees with $\mathscr{T}_{\mathbf{E}(A)}$. ◊

The assertion follows immediately from claim 16.2.10 and remark 16.2.4.

(a)⇒(b): Let $I \subset A$ and $\mathscr{I} \subset \mathbf{E}(A)$ be two ideals of definition; then there exists $n \in \mathbb{N}$ such that $\mathscr{J}_n \subset \mathscr{I}$. Clearly $\mathscr{I}' := \Phi^{-n}_{\mathbf{E}(A)}(\mathscr{I})$ is still an ideal of definition, and $\mathscr{J}_0 \subset \mathscr{I}'$. After replacing $\mathscr{I}$ by $\mathscr{I}'$, we may therefore assume that $\mathscr{J}_0 \subset \mathscr{I}$. Write $\overline{u}_{A/I}(\mathscr{I}) = I'/I$ for an ideal $I' \subset A$; we have :

Claim 16.2.11. $\mathscr{I} = \operatorname{Ker}\overline{u}_{A/I'}$ and I' is an ideal of definition of A.

Proof of the claim. We have just remarked that $\operatorname{Ker}\overline{u}_{A/I} \subset \mathscr{I}$, and the stated identity is an easy consequence. Next, since both $\mathscr{I}$ and I are finitely generated, the same holds for I', and obviously $pA \subset I'^2$. Also $\mathscr{I}$ is topologically nilpotent in $\mathbf{E}(A)$, and the topology of A/I is discrete, hence I'/I is a nilpotent ideal of A/I, and it follows easily that the I-adic topology on A agrees with the I'-adic topology. ◊

Due to claim 16.2.11, we may replace I by I', and assume from start that $\mathscr{I} = \mathscr{J}_0$. We may write $\overline{u}_1(\mathscr{J}_0) = J_1/I$ for an ideal $J_1 \subset A$ containing I, and since $\mathscr{J}_0$ and I are finitely generated, the same holds for J_1. It suffices now to notice that

$$J_1/I = \operatorname{Ker}\varphi_0. \qquad (16.2.12)$$

(b)⇒(c): By assumption, there exists a finitely generated ideal $J_1 \subset A$ containing I and such that (16.2.12) holds. Furthermore, by lemma 16.2.3(iii) we may write $I = J'^{(p)}$ for some ideal of definition $J' \subset A$. Set $J := J' + J_1$. From (16.2.12) we get $J_1^{(p)} \subset I$, therefore $J^{(p)} = J'^{(p)} + J_1^{(p)} = I$. We conclude that $\Phi_{A/J}$ induces an isomorphism $A/J_1 \xrightarrow{\sim} A/I = A/J^{(p)}$; but the latter factors through $\overline{\Phi}_{A/J}$ and the projection $A/J_1 \to A/J$, so $\overline{\Phi}_{A/J}$ is an isomorphism as well (and $J = J_1$). Lastly, since $\mathscr{J}_0$ is topologically nilpotent, J_1/I is a nilpotent ideal, so the same holds for J/J', and consequently the J-adic topology agrees with the J'-adic topology; so J is an ideal of definition, whence (b). □

Let A be any P-ring; by lemma 16.2.7(ii), the kernel of u_A contains a distinguished element $\underline{a}$, and we shall see later that the case where actually $\underline{a}$ generates the ideal $\operatorname{Ker}u_A$ is the most interesting for our purposes. For the moment, let us just notice that, if the latter condition holds, the datum $(E := \mathbf{E}(A), \underline{a})$ suffices to recover A : indeed, lemma 16.2.7(i) says that in that case u_A induces an isomorphism of topological rings $W(E)/\underline{a}W(E) \xrightarrow{\sim} A$ (where $W(E)/\underline{a}W(E)$ is endowed with the quotient topology induced from $W(E)$ via the natural projection). It is then convenient to insert hereafter a preliminary study of pairs $(E, \underline{a})$ of this type.

16.2.13. Let $(E, \mathscr{T}_E)$ be a perfect topological $\mathbb{F}_p$-algebra, $\underline{a} := (a_n \mid n \in \mathbb{N}) \in W(E)$ any element, and suppose that $\mathscr{T}_E$ agrees with the a_0-adic topology. Denote by $E^\wedge$ the separated completion of E, and let also E_d (resp. $E^\wedge_d$) be the ring E (resp. $E^\wedge$) endowed with its discrete topology. To ease notation, set

$$A(E) := W(E)/\underline{a}W(E)$$

which we view as a topological ring, with the quotient topology induced from $W(E)$. Define likewise the topological rings $A(E_d)$, $A(E^\wedge)$ and $A(E^\wedge_d)$. The natural diagram of continuous ring homomorphisms

$$\begin{array}{ccc} E_d & \longrightarrow & E^\wedge_d \\ \downarrow & & \downarrow \\ E & \longrightarrow & E^\wedge \end{array}$$

induces a commutative diagram of topological rings

$$\begin{array}{ccc} A(E_d) & \longrightarrow & A(E^\wedge_d) \\ \downarrow & & \downarrow \\ A(E) & \xrightarrow{j_A} & A(E^\wedge). \end{array} \tag{16.2.14}$$

Moreover, notice that there are natural isomorphisms of topological rings

$$A(E) \otimes_{\mathbb{Z}} \mathbb{F}_p \xrightarrow{\sim} E/a_0E \qquad A(E^\wedge) \otimes_{\mathbb{Z}} \mathbb{F}_p \xrightarrow{\sim} E^\wedge/a_0E^\wedge \tag{16.2.15}$$

(where, again the sources and the targets are endowed with the quotient topologies induced from $A(E)$, E, $A(E^\wedge)$, and respectively $E^\wedge$). The composition of the first of these maps with the projection $A(E) \to A(E) \otimes_{\mathbb{Z}} \mathbb{F}_p$ is the continuous ring homomorphism

$$\pi_A : A(E) \to E/a_0E \qquad ((b_n \mid n \in \mathbb{N}) \mod \underline{a}W(E)) \mapsto (b_0 \mod a_0E)$$

and likewise we can describe the corresponding map $\pi^\wedge_A : A(E^\wedge) \to E^\wedge/a_0E^\wedge$. Lastly, denote

$$\beta : \mathbf{E}(A(E)) \to E^\wedge$$

the morphism of topological monoids obtained by composing $\mathbf{E}(\pi_A)$ with the isomorphism of topological rings $\mathbf{E}(E/a_0E) \xrightarrow{\sim} E^\wedge$ provided by corollary 9.4.14.

Proposition 16.2.16. *In the situation of* (16.2.13)*, suppose that $a_0E + a_1E = E$. Then the following holds :*

(i) *The image of $\underline{a}$ is a distinguished element of $W(E^\wedge)$.*
(ii) *All the arrows of* (16.2.14) *are isomorphisms of topological rings.*
(iii) *$A(E)$ is a P-ring, and its topology agrees with the p-adic topology.*
(iv) *β is an isomorphism of topological rings (for the topological ring structure on $A(E)$ provided by* (16.1)*), and we have a commutative diagram of topological rings*

$$\begin{array}{ccc} \mathbf{A}(A(E)) & \xrightarrow{W(\beta)} & W(E^\wedge) \\ {\scriptstyle u_{A(E)}}\downarrow & & \downarrow{\scriptstyle \pi^\wedge_W} \\ A(E) & \xrightarrow{j_A} & A(E^\wedge) \end{array}$$

where $\pi^\wedge_W$ is the natural projection.

Proof. (i): By remark 8.3.10(v), the image of a_0 lies in the Jacobson radical of $E^\wedge$, and since $a_0E + a_1E = E$, it follows easily that $a_1 \in E^\times$ (details left to the reader), whence the assertion.

(ii): Let $\mathscr{I} \subset W(E)$ (resp. $\mathscr{I}^\wedge \subset W(E^\wedge)$) be the ideal generated by the system $(p, \tau_E(a_0))$ (resp. $(p, \tau_{E^\wedge}(a_0))$); proposition 9.3.77(ii) says that the topology of $W(E)$ (resp. of $W(E^\wedge)$)

agrees with the $\mathscr{I}$-adic (resp. $\mathscr{I}^\wedge$-adic) topology, whereas the topologies of both $W(E_d)$ and $W(E_d^\wedge)$ are p-adic. Let $\overline{\mathscr{I}}$ (resp. $\overline{\mathscr{I}}^\wedge$) be the image of $\mathscr{I}$ in $A(E)$ (resp. in $A(E^\wedge)$); it follows easily that the topology of $A(E)$ (resp. of $A(E^\wedge)$) agrees with the $\overline{\mathscr{I}}$-adic (resp. $\overline{\mathscr{I}}^\wedge$-adic) topology, whereas the topologies of both $A(E_d)$ and $A(E_d^\wedge)$ are still p-adic. However, set $\underline{b} := (a_1^{1/p}, a_2^{1/p}, \dots)$, and notice that

$$\underline{a} = \tau_E(a_0) + p \cdot \underline{b} \qquad \text{in } W(E) \tag{16.2.17}$$

((9.3.41) and lemma 9.3.27(i)), which implies that $\overline{\mathscr{I}} = pA(E)$. Likewise, $\overline{\mathscr{I}}^\wedge = pA(E^\wedge)$. Summing up, this proves already that the vertical arrows of (16.2.14) are both isomorphisms.

Next, proposition 9.3.47(v) implies that $A(E)$ is complete and separated for the p-adic topology, hence also for the $\mathscr{I}$-adic topology. Recall as well that the family of ideals

$$\mathrm{Ker}\,(W(E) \to W_n(E/a_0^k E)) \qquad \text{for every } k, n \in \mathbb{N}$$

is a fundamental system of open neighborhoods of $0 \in W(E)$ for the $\mathscr{I}$-adic topology, therefore the natural map

$$A(E) \to \lim_{k,n\in\mathbb{N}} W_n(E/a_0^k E)/\underline{a}W_n(E/a_0^k E)$$

is an isomorphism of topological rings. By the same token, the same description applies to $A(E^\wedge)$, so we conclude that also the horizontal arrows of (16.2.14) are isomorphisms.

(iii): We know already that the topology of $A(E)$ is complete and separated, and agrees with the p-adic topology. On the other hand, notice that $\underline{b}$ is invertible in $W(E^\wedge)$, by (i) and proposition 9.3.44(iii); since the images of $\tau_{E^\wedge}(a_0)$ and $-p \cdot \underline{b}$ agree in $A(E^\wedge)$, we deduce that the p-adic filtration agrees with the $\tau_E(a_0)$-adic filtration on $A(E^\wedge)$, and therefore also on $A(E)$, since we already know that j_A is an isomorphism. Set $J := \tau_E(a_0^{1/p}) \cdot A(E)$; it follows that the topology of $A(E)$ agrees with the J-adic topology, and moreover $p \in J^p \subset J^2$. Lastly, the Frobenius endomorphism is surjective on $A(E)/J^2$, due to the isomorphism (16.2.15), whence the assertion.

(iv): From (iii) and the discussion of (16.1) we see that β is an isomorphism of topological rings; also, under the identifications (16.2.15), the morphism $j_A \otimes_{\mathbb{Z}} \mathbb{F}_p$ corresponds to the natural map $\iota : E/a_0E \xrightarrow{\sim} E^\wedge/a_0E^\wedge$. Therefore we have

$$\pi_A^\wedge \circ j_A \circ u_{A(E)} = \iota \circ \pi_A \circ u_{A(E)} = \iota \circ \pi_A \circ \overline{u}_{A(E)} \circ \boldsymbol{\omega}_0$$

where $\boldsymbol{\omega}_0 : \mathbf{A}(A(E)) \to \mathbf{E}(A(E))$ is the 0-th ghost component map. Then, since $A(E^\wedge)$ is complete and separated for the p-adic topology, proposition 9.3.52(iii) reduces to checking

Claim 16.2.18. $\pi_A^\wedge \circ \pi_W^\wedge \circ W(\beta) = \iota \circ \pi_A \circ \overline{u}_{A(E)} \circ \boldsymbol{\omega}_0$.

Proof of the claim. Notice the identities :

$$\beta \circ \boldsymbol{\omega}_0 = \boldsymbol{\omega}_0^\wedge \circ W(\beta) \qquad \pi_A^\wedge \circ \pi_W^\wedge = \pi_{E^\wedge} \circ \boldsymbol{\omega}_0^\wedge$$

(where $\boldsymbol{\omega}_0^\wedge : W(E^\wedge) \to E^\wedge$ is the 0-th ghost component map, and $\pi_{E^\wedge} : E^\wedge \to E^\wedge/a_0E^\wedge$ is the projection) in light of which, it suffices to show that

$$\pi_{E^\wedge} \circ \beta = \iota \circ \pi_A \circ \overline{u}_{A(E)}.$$

The latter follows by a simple inspection of the definition of β : details left to the reader. $\square$

16.2.19. For any prime p, consider the following categories :

- The category $\mathscr{E}$ whose objects are all the pairs $(E, \mathscr{I})$ where E is both a perfect topological $\mathbb{F}_p$-algebra and a P-ring, and $\mathscr{I} \subset W(E)$ is a distinguished ideal. The morphisms $(E, \mathscr{I}) \to (E', \mathscr{I}')$ are the continuous ring homomorphisms $f : E \to E'$ such that $W(f)(\mathscr{I}) \subset \mathscr{I}'$.

- The category $\mathscr{A}$ of all P-rings A such that $\mathrm{Ker}\, u_A$ is a distinguished ideal of $W(A)$. The morphisms in $\mathscr{A}$ are all the continuous ring homomorphisms.
- The full subcategory $\mathscr{E}_p$ of $\mathscr{E}$ whose objects are all the pairs $(E, \mathscr{I})$ such that the topology of E agrees with the $\boldsymbol{\omega}_0(\mathscr{I})$-adic topology, and the full subcategory $\mathscr{A}_p$ of $\mathscr{A}$ consisting of those objects A whose topology agrees with the p-adic topology.

Then proposition 16.2.16(iii,iv) yields an equivalence of categories

$$(16.2.20) \qquad \mathscr{E}_p \xrightarrow{\sim} \mathscr{A}_p \quad : \quad (E, \mathscr{I}) \mapsto A(E, \mathscr{I}) := W(E)/\mathscr{I}$$

with quasi-inverse given by the rule : $A \mapsto (\mathbf{E}(A), \mathrm{Ker}\, u_A)$. In the following, we aim to extend this equivalence to the whole of $\mathscr{E}$. The first step is :

Proposition 16.2.21. *With the notation of* (16.2.19)*, let* $(E, \mathscr{I})$ *be any object of* $\mathscr{E}$*. Then :*

(i) $A(E, \mathscr{I})$ *is a P-ring.*

(ii) *Especially,* $\mathscr{I}$ *is closed in the topology* $\mathscr{T}_{W(E)}$.

Proof. Clearly, it suffices to check (i). To this aim, let $(a_n \mid n \in \mathbb{N}) \in \mathscr{I}$ be any distinguished element, $I \subset E$ be any ideal of definition, $(x_0, \dots, x_r)$ a finite system of generators for I, denote by $\mathscr{J} \subset W(E)$ the ideal generated by the system $(\tau_E(x_0), \dots, \tau_E(x_r))$, and set $\mathscr{J}' := \mathscr{J} + pW(E)$. By proposition 9.3.77(ii), we know that the topology of $A(E)$ agrees with the $\mathscr{J}'$-adic topology. Now, by assumption a_0 is topologically nilpotent, hence $a_0^k \in I$ for every sufficiently large $k \in \mathbb{N}$; since the Frobenius endomorphism Φ_E is an automorphism of the topological ring E, we may then replace I by $\Phi_E^{-t} I$ for some suitably large $t \in \mathbb{N}$, after which we may assume that $a_0 \in I^{(p)}$, and recall that $I^{(p)}$ is generated by $(x_0^p, \dots, x_r^p)$. Then, lemma 16.1.9(ii) implies that

$$(16.2.22) \qquad p \in \mathscr{J}^2 A(E).$$

and therefore $\mathscr{J}' A(E) = \mathscr{J} A(E)$; especially, the topology of $A(E)$ agrees with the $\mathscr{J}$-adic topology. By corollary 16.1.13(i,ii), $\mathscr{I}$ is a closed subset for the $\mathscr{J}$-adic topology on $W(E)$, and the $\mathscr{J}$-adic topology of $W(E)$ is complete and separated, so the same holds for the $\mathscr{J}$-adic topology of $A(E)$. Moreover, the Frobenius endomorphism of $A(E)/\mathscr{J} A(E)$ is surjective, by virtue of (16.2.15); taking into account (16.2.22), the proposition follows. □

To define a quasi-inverse for our extension of (16.2.20), we shall also need the following:

Proposition 16.2.23. *Let* A *be any P-ring. We have :*

(i) *If* $\mathrm{Ker}\, u_A$ *is the topological closure of a finitely generated ideal,* $\mathbf{E}(A)$ *is a P-ring.*

(ii) *The following conditions are equivalent :*

  (a) $\mathrm{Ker}\, u_A$ *is generated by any distinguished element contained in it.*

  (b) $\mathrm{Ker}\, u_A$ *is a principal ideal.*

  (c) $\mathrm{Ker}\, u_A$ *is the topological closure of a principal ideal.*

Proof. (i): For any topological space X, and any subset $S \subset X$, denote by S^c the topological closure of S in X. By assumption, there exists a finitely generated ideal $\mathscr{I} \subset \mathbf{A}(A)$ such that $\mathscr{I}^c = \mathrm{Ker}\, u_A$. Let now $\boldsymbol{\omega}_0 : \mathbf{A}(A) \to \mathbf{E}(A)$ be the 0-th ghost component; we notice :

Claim 16.2.24. (i) $\boldsymbol{\omega}_0(\mathrm{Ker}\, u_A) = \mathrm{Ker}\, (\overline{u}_{A/pA} : \mathbf{E}(A) \to A/pA)$.

(ii) $(\mathrm{Ker}\, \overline{u}_{A/pA})^c = \mathrm{Ker}\, \overline{u}_{A/(pA)^c}$.

Proof of the claim. (i): Say that $x \in \mathrm{Ker}\, \overline{u}_{A/pA}$, and pick any $y \in \mathbf{A}(A)$ such that $\boldsymbol{\omega}_0(y) = x$; then $u_A(y) = pa$ for some $a \in A$. We pick $z \in \mathbf{A}(A)$ such that $u_A(z) = a$; then $y - pz \in \mathrm{Ker}\, u_A$ and $\boldsymbol{\omega}_0(y - pz) = x$, whence the contention.

(ii): The ideal $K := (\mathrm{Ker}\, \overline{u}_{A/pA})^c$ contains $\mathrm{Ker}\, \overline{u}_{A/pA}$, therefore

$$K = \overline{u}_{A/pA}^{-1}(\overline{u}_{A/pA}(K))$$

so $\overline{u}_{A/pA}(K)$ is a closed ideal of A/pA, by lemma 16.2.7(i), hence $(pA)^c/pA \subset \overline{u}_{A/pA}(K)$ and consequently $K = \overline{u}_{A/pA}^{-1}((pA)^c/pA)$. On the other hand, $\overline{u}_{A/(pA)^c}$ is the composition of $\overline{u}_{A/pA}$ with the projection $A/pA \to A/(pA)^c$, whence the claim. ◊

Claims 8.3.25 and 16.2.24(i) imply that $\boldsymbol{\omega}_0(\mathscr{I})^c = (\mathrm{Ker}\,\overline{u}_{A/pA})^c$. From claim 16.2.24(ii) we deduce that $\mathrm{Ker}\,\overline{u}_{A/(pA)^c}$ is the topological closure in $\mathbf{E}(A)$ of a finitely generated ideal. Next, let $I \subset A$ be any ideal of definition, and $\mathscr{J} \subset \mathbf{E}(A)$ any finitely generated ideal such that $\overline{u}_{A/(pA)^c}(\mathscr{J}) = I/(pA)^c$; it follows easily that $\mathscr{J} + \mathrm{Ker}\,\overline{u}_{A/(pA)^c} = \mathrm{Ker}\,\overline{u}_{A/I}$ (details left to the reader), and then also $\mathrm{Ker}\,\overline{u}_{A/I}$ is the topological closure of a finitely generated ideal of $\mathbf{E}(A)$. Lastly, we have a commutative diagram of continuous and surjective ring homomorphisms

$$\begin{array}{ccc} \mathbf{E}(A) & \xrightarrow{\overline{u}_{A/I}} & A/I \\ {\scriptstyle v}\downarrow & & \| \\ A/I & \xrightarrow{\Phi_{A/I}} & A/I \end{array} \qquad \text{where } v := \overline{u}_{A/I} \circ \Phi^{-1}_{\mathbf{E}(A)}$$

whence $v(\mathrm{Ker}\,\overline{u}_{A/I}) = \mathrm{Ker}\,\Phi_{A/I}$. Since the topology of A/I is discrete, claim 8.3.25 implies that $\mathrm{Ker}\,\Phi_{A/I}$ is a finitely generated ideal, so the assertion follows from proposition 16.2.9.

(ii): Clearly (a)⇒(b), and since $\mathrm{Ker}\,u_A$ is a closed subset of $W(A)$, we have as well (b)⇒(c). Thus, it remains only to check that (c)⇒(a). To this aim, let again $I \subset A$ be any ideal of definition, denote by $J \subset A$ the radical of I, and fix any element $\underline{b} := (b_n \mid n \in \mathbb{N}) \in \mathbf{A}(A)$ such that $\mathrm{Ker}\,u_A$ is the topological closure of $\underline{b}\mathbf{A}(A)$ in $\mathbf{A}(A)$. We notice that A/J is a perfect $\mathbb{F}_p$-algebra, and its quotient topology induced by the projection $\pi : A \to A/J$ is discrete. We have a commutative diagram of continuous and surjective ring homomorphisms :

$$\begin{array}{ccc} \mathbf{A}(A) & \xrightarrow{u_A} & A \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle \pi} \\ W(A/J) & \xrightarrow{\boldsymbol{\omega}_0} & A/J \end{array}$$

whose bottom horizontal arrow is the 0-th ghost map (see (9.3.2)), and with $f := W(\varphi)$, where $\varphi : \mathbf{E}(A) \to A/J$ is the composition of $\overline{u}_{A/pA} : \mathbf{E}(A) \to A/pA$ with the natural projection $A/pA \to A/J$ (details left to the reader).

Claim 16.2.25. $f(\mathrm{Ker}\,u_A) = pW(A/J)$.

Proof of the claim. It is clear that $f(\mathrm{Ker}\,u_A) \subset pW(A/J)$, so we need only show the converse inclusion. Now, according to lemma 16.2.7(ii), we may find a distinguished element $\underline{a} := (a_n \mid n \in \mathbb{N})$ in $\mathrm{Ker}\,u_A$. Since a_0 is topologically nilpotent in $\mathbf{E}(A)$, the element $\overline{u}_{A/pA}(a_0)$ is topologically nilpotent in A/pA, and therefore its image vanishes in A/J; in other words, $a_0 \in \mathrm{Ker}\,\varphi$. However, $\underline{a} = \tau_A(a_0) + p \cdot \underline{u}$, for some $\underline{u} \in \mathbf{A}(A)^\times$, so that

$$f(\underline{a}) = f \circ \tau_A(a_0) + p \cdot f(\underline{u}) = \tau_{A/J} \circ \varphi(a_0) + p \cdot f(\underline{u}) = p \cdot f(\underline{u})$$

(see (9.3.35)) whence the claim. ◊

In light of claims 8.3.25 and 16.2.25 and example 9.3.48(i) we deduce that $f(\underline{b}) \cdot W(A/J)$ is a dense subset of $pW(A/J)$, for the p-adic topology on $W(A/J)$; especially, we have

$$pW(A/J) = p^2W(A/J) + f(\underline{b}) \cdot W(A/J).$$

Then, since p lies in the Jacobson radical of $W(A/J)$, Nakayama's lemma shows that $f(\underline{b}) \cdot W(A/J) = pW(A/J)$, which in turn implies that $\varphi(b_0) = 0$ and $\varphi(b_1)$ is invertible in A/J.

Claim 16.2.26. $\underline{b}$ is a distinguished element of $\mathbf{A}(A)$.

Proof of the claim. First, since J is contained in the Jacobson radical of A (remark 8.3.10(v)) and $\varphi(b_1) \in (A/J)^\times$, we deduce that $\overline{u}_A(b_1) \in A^\times$, and therefore $b_1 \in \mathbf{E}(A)^\times$, by remark 9.4.5(iii). Likewise, we have $\overline{u}_A(b_0) \in JA$, which easily implies that b_0 is topologically nilpotent in $\mathbf{E}(A)$ (details left to the reader). ◊

Now, from (i) and assumption (ii.c) we see that $\mathbf{E}(A)$ is a P-ring; from claim 16.2.26 and proposition 16.2.21(ii) it then follows that $\underline{b}\mathbf{A}(A)$ is a closed ideal of $\mathbf{A}(A)$, and therefore it must coincide with $\mathrm{Ker}\, u_A$. Lastly, let $\underline{a}$ be any other distinguished element of $\mathbf{A}(A)$ contained in $\mathrm{Ker}\, u_A$; taking into account remark 16.1.7(i) and again claim 16.2.26, we conclude that $\underline{a}\mathbf{A}(A) = \underline{b}\mathbf{A}(A)$, whence (ii.a). ☐

16.3. **Perfectoid rings.** We are now ready to introduce our generalizations of Scholze's perfectoid rings that will intervene in the proof of the log regular version of almost purity.

Definition 16.3.1. Let A be any P-ring. We say that A is *perfectoid* if it fulfills any of the three equivalent conditions of proposition 16.2.23(ii).

Example 16.3.2. (i) Let $(A, \mathscr{T})$ be any topological $\mathbb{F}_p$-algebra. Then A is perfectoid if and only if it is perfect, $\mathscr{T}$ is complete and separated, and there exists a finitely generated ideal $I \subset A$ such that $\mathscr{T}$ agrees with the I-adic topology. Indeed, under these assumptions, A is a P-ring (remark 16.2.4), and the map $\overline{u}_A : \mathbf{E}(A) \to A$ is an isomorphism of topological rings that identifies u_A with the 0-th ghost map $\boldsymbol{\omega}_0 : W(A) \to A$, whose kernel is the principal ideal $pW(A)$, by (9.3.45), so A is perfectoid. Conversely, clearly $p \in \mathrm{Ker}\, u_A$, and p is obviously a distinguished element of $\mathbf{A}(A)$, so if A is a perfectoid $\mathbb{F}_p$-algebra we must have $\mathrm{Ker}\, u_A = pW(A)$; moreover, u_A is an open ring homomorphism (lemma 16.2.7(i)), so it induces an isomorphism $\mathbf{E}(A) \xrightarrow{\sim} A$ of topological rings, especially $(A, \mathscr{T})$ is a perfect topological $\mathbb{F}_p$-algebra, as claimed.

(ii) Let E be any perfectoid $\mathbb{F}_p$-algebra, and $\underline{a} := (a_n \mid n \in \mathbb{N})$ any distinguished element of $W(E)$. Then $A(E) := W(E)/\underline{a}W(E)$ is perfectoid for the quotient topology induced by $W(E)$. Indeed, $A(E)$ is a P-ring, by proposition 16.2.21(i); next, lemma 8.3.12 implies that E is complete and separated for the a_0-adic topology, and therefore proposition 16.2.16(ii,iv) applies, and shows that $\mathrm{Ker}\, u_{A(E)}$ is a principal ideal, whence the contention. Moreover, in this case the perfectoid ring E can be recovered from $A(E)$: indeed, we have a natural isomorphism of topological rings

$$\mathbf{E}(A(E)) \xrightarrow{\sim} E$$

obtained as follows. First, since the 0-th ghost component $W(E) \to E$ is an open and surjective map, the same holds for the projection $\alpha : A(E) \to A(E)/pA(E) \xrightarrow{\sim} E/a_0E$, where E/a_0E is endowed with the quotient topology induced by E. Then, α induces an isomorphism $\mathbf{E}(\alpha) : \mathbf{E}(A(E)) \xrightarrow{\sim} \mathbf{E}(E/a_0E)$ of topological rings, by (16.1). But since a_0 is topologically nilpotent, the projection $\beta : \mathbf{E}(E) \to \mathbf{E}(E/a_0E)$ is an isomorphism of topological rings as well (theorem 9.4.10), and the same holds for the map $\overline{u}_E : \mathbf{E}(E) \to E$, since E is perfect. Thus, the sought isomorphism is the composition $\overline{u}_E \circ \beta^{-1} \circ \mathbf{E}(\alpha)$.

Let us also point out the following complement to proposition 16.2.9 :

Corollary 16.3.3. *Let A be any perfectoid ring. Then $\overline{\Phi}_{A/J}$ is an isomorphism for every special ideal of definition J of A.*

Proof. Set $E := \mathbf{E}(A)$; we may assume that there exists a distinguished element $\underline{a} := (a_n \mid n \in \mathbb{N}) \in W(E)$ such that A is the ring $A(E)$ as defined in (16.2.13), and $u_A : W(E) \to A(E)$ is the projection. Moreover, we may find a finite system $\underline{x}_\bullet := (\underline{x}_0, \dots, \underline{x}_r)$ of elements of $W(E)$, such that J is the image in $A(E)$ of the ideal generated by $\underline{x}_\bullet$. We may write

(16.3.4) $$\underline{x}_i = \tau_{\mathbf{E}}(t_i) + p \cdot \underline{y}_i \qquad \text{where } t_i \in E \text{ and } \underline{y}_i \in W(E) \text{ for every } i = 0, \dots, r.$$

In view of lemma 9.3.4(i), we deduce that

$$\underline{x}_i^p \equiv \tau_E(t_i)^p \pmod{p^2 W(E)} \qquad \text{for } i = 0, \dots, r. \tag{16.3.5}$$

Let $\mathscr{J} \subset W(E)$ be the ideal generated by $\tau_E(t_0), \dots, \tau_E(t_r)$; we notice :

Claim 16.3.6. $p \in \mathscr{J}^{(p)} A(E)$ and $\mathscr{J} A(E) = J$.

Proof of the claim. It follows easily from (16.3.5) that there exists $\underline{z} \in W(E)$ with

$$p \cdot u_A(1 + p \cdot \underline{z}) \in \mathscr{J}^{(p)} A(E)$$

(recall that $\mathscr{J}^{(p)}$ is the ideal generated by $\tau_E(t_0)^p, \dots, \tau_E(t_r)^p$: see definition 16.2.1). However, p is topologically nilpotent in $W(E)$, therefore $1+p\cdot\underline{z} \in W(E)^\times$, so $p \in \mathscr{J}^{(p)} A(E)$. The other assertion follows directly from the first one and (16.3.4) : details left to the reader. $\Diamond$

Let $I \subset E$ be the ideal generated by $t_0, \dots, t_r$, and set $E_0 := E/a_0 E$; taking into account lemma 16.1.9(ii) and claim 16.3.6, we deduce that $a_0 \in I^{(p)}$. Also, it is clear that the natural isomorphism (16.2.15) maps the image of J (resp. of $J^{(p)}$) onto IE_0 (resp. $I^{(p)} E_0$). But it also follows that $E_0/IE_0 = E/I$ and $E_0/I^{(p)}E_0 = E/I^{(p)}$; lastly, since E is perfect, the Frobenius endomorphism Φ_E maps I onto $I^{(p)}$, whence the contention. $\square$

Remark 16.3.7. (i) We may now say that the category $\mathscr{A}$ of (16.2.19) is the *category of perfectoid rings*, and we shall denote it henceforth by

$$\mathsf{Perf}.$$

More generally, if A is any perfectoid ring, we shall write

$$A\text{-}\mathsf{Perf}$$

for the category A/Perf of *perfectoid A-algebras*, whose objects are the continuous ring homomorphisms $A \to B$ with B perfectoid. The objects of the category $\mathscr{E}$ of (16.2.19) are the pairs $(E, \mathscr{I})$ consisting of a perfectoid $\mathbb{F}_p$-algebra and a distinguished ideal of $W(E)$. Taking into account example 16.3.2, we see that (16.2.19) generalizes *verbatim* to an equivalence

$$\mathscr{E} \xrightarrow{\sim} \mathsf{Perf} \quad : \quad (E, \mathscr{I}) \mapsto A(E, \mathscr{I}) := W(E)/\mathscr{I}$$

with a natural quasi-inverse given by the functor $\mathbf{E}$, which restricts to equivalences

$$\mathbf{E} : A\text{-}\mathsf{Perf} \xrightarrow{\sim} \mathbf{E}(A)\text{-}\mathsf{Perf} \qquad \text{for every perfectoid ring } A.$$

Hereafter, we shall study the stability of the class of perfectoid rings under some standard operations. The following observations (iii) and (iv) show stability under completion with respect to the J-adic topology corresponding to an ideal $J \subset A$ of finite type with $pA \subset J$.

(ii) Let A be any perfectoid ring, set $\mathbf{E} := \mathbf{E}(A)$, and let $\alpha_\bullet := (\alpha_n \mid n \in \mathbb{N})$ be any distinguished element in $\operatorname{Ker} u_A$. Notice that $\overline{u}_{A/pA} : \mathbf{E} \to A/pA$ induces an isomorphism of topological rings :

$$\omega : \mathbf{E}/\alpha_0 \mathbf{E} \xrightarrow{\sim} A/pA$$

for the quotient topologies induced by the projections $A \to A/pA$ and $\mathbf{E} \to \mathbf{E}/\alpha_0$. Indeed, $\overline{u}_{A/pA}$ is open and surjective (lemma 16.2.7(i)), and $\alpha_\bullet$ generates $\operatorname{Ker} u_A$, so α_0 generates the kernel of $u_{A/pA}$, by virtue of lemma 16.1.1(i), whence the contention.

(iii) The isomorphism ω of (ii) induces a natural bijection :

$$\{\text{ideals } \mathscr{J} \subset \mathbf{E} \mid \alpha_0 \mathbf{E} \subset \mathscr{J}\} \leftrightarrow \{\text{ideals } J \subset A \mid pA \subset J\}.$$

Namely, $\mathscr{J} \subset \mathbf{E}$ and $J \subset A$ correspond under this bijection, if and only if $\omega(\mathscr{J}/\alpha\mathbf{E}) = J/pA$. Then, clearly J is finitely generated if and only if the same holds for $\mathscr{J}$. Let $\mathscr{T}_J$ (resp. $\mathscr{T}_{\mathscr{J}}$) denote the J-adic (resp. $\mathscr{J}$-adic) topology on A (resp. on $\mathbf{E}$); taking into account remark 9.4.9(ii), we deduce that if J is finitely generated, then the topology of $\mathbf{E}(A, \mathscr{T}_J)$ agrees with $\mathscr{T}_{\mathscr{J}}$. Combining with example 16.3.2(i), lemma 8.3.32(iv), example 9.3.48(ii) and remark 9.4.9(v), we conclude that the completion $\mathbf{E}(A,\mathscr{T}_J)^\wedge$ of $\mathbf{E}(A,\mathscr{T}_J)$ is perfectoid.

(iv) In the situation of (iii), suppose that J and $\mathscr{J}$ are finitely generated; notice that, since $\alpha_0 \in \mathscr{J}$, the image of $\alpha_\bullet$ is distinguished in $W(\mathbf{E}(A,\mathscr{T}_J)^\wedge)$, and let $\mathscr{I} := \alpha_\bullet W(\mathbf{E}(A,\mathscr{T}_J)^\wedge)$. We claim that there is a natural isomorphism of topological rings

$$W(\mathbf{E}(A,\mathscr{T}_J)^\wedge)/\mathscr{I} \xrightarrow{\sim} (A_J,\mathscr{T}_J)^\wedge$$

for the quotient topology on $W(\mathbf{E}(A,\mathscr{T}_J)^\wedge)/\mathscr{I}$ induced by $W(\mathbf{E}(A,\mathscr{T}_J)^\wedge)$. Especially, this shows that $(A_J,\mathscr{T}_J)^\wedge$ is perfectoid. For the proof, fix a finite system $(\beta_1,\dots,\beta_k)$ of generators of $\mathscr{J}$, and let $\mathscr{J}_W \subset W(\mathbf{E})$ be the ideal generated by the system $(p,\tau_{\mathbf{E}}(\beta_1),\dots,\tau_{\mathbf{E}}(\beta_k))$; by proposition 9.3.77(ii), the topology $\mathscr{T}_W$ of $W(\mathbf{E},\mathscr{T}_{\mathscr{J}})$ agrees with the $\mathscr{J}_W$-adic topology. By construction we have $u_A(\mathscr{J}_W)/pA = J/pA$, and consequently $u_A(\mathscr{J}_W) = J$, so the quotient topology induced by $\mathscr{T}_W$ on A via u_A agrees with $\mathscr{T}_J$. Lastly, in view of (iii) and proposition 16.2.21(ii) we know that $\mathscr{I}$ is a closed ideal of $W(\mathbf{E}(A,\mathscr{T}_J)^\wedge)$. Taking into account proposition 8.2.13(v) and lemma 9.3.33(iv), the assertion follows.

We can summarize these observations in the following :

Proposition 16.3.8. *Let A be a ring, p a prime integer, $I \subset A$ a finitely generated ideal such that $pA \subset I$, and denote by $\mathscr{T}_I$ (resp. $\mathscr{T}_p$) the I-adic (resp. p-adic) topology on A. We have :*

(i) *If $(A,\mathscr{T}_I)$ is perfectoid, the same holds for $(A,\mathscr{T}_p)$.*
(ii) *If $(A,\mathscr{T}_p)$ is perfectoid, the same holds for the completion $(A_I,\mathscr{T}_I)^\wedge$ of $(A,\mathscr{T}_I)$.*

Proof. (i) follows immediately from proposition 16.2.5(i).

(ii): It suffices to apply remark 16.3.7(iv) to the ideal $I \subset A$ and the corresponding ideal $\mathscr{J} := \overline{u}^{-1}_{A/pA}(I/pA)$ of $\mathbf{E}(A)$. □

The next observation establishes the stability of Perf under completed tensor products :

Proposition 16.3.9. *Let A_0 be a perfectoid ring and A_1, A_2 two perfectoid A_0-algebras. Then:*

(i) *The topological ring $A_3 := A_1 \widehat{\otimes}_{A_0} A_2$ is perfectoid.*
(ii) *There exists a natural isomorphism $\mathbf{E}(A_3) \xrightarrow{\sim} \mathbf{E}(A_1)\widehat{\otimes}_{\mathbf{E}(A_0)}\mathbf{E}(A_2)$ in* Perf.
(iii) *Especially, all finite coproducts are representable in the category* Perf.

Proof. (i): Set $\mathbf{E}_i := \mathbf{E}(A_i)$ for $i = 0,1,2$, and pick a distinguished element $\underline{\alpha} \in W(\mathbf{E}_0)$ that generates the kernel of u_{A_0}; then the image of $\underline{\alpha}$ in $W(\mathbf{E}_i)$ is still distinguished, and we know that $\underline{\alpha}W(\mathbf{E}_i)$ is the kernel of u_{A_i} also for $i = 1,2$. Moreover, it is clear from remark 9.3.56(iii) that the $\mathbb{F}_p$-algebra $\mathbf{E}_3 := \mathbf{E}_1 \widehat{\otimes}_{\mathbf{E}_0} \mathbf{E}_2$ is perfectoid, and then the same holds for the topological ring $A(\mathbf{E}_3) := W(\mathbf{E}_3)/\underline{\alpha}W(\mathbf{E}_3)$, by virtue of example 16.3.2(ii). Lastly, the isomorphism (9.3.58) induces an isomorphism of topological rings

$$A(\mathbf{E}_3) \xrightarrow{\sim} A_1 \widehat{\otimes}_{A_0} A_2$$

whence the assertion.

(ii): Example 16.3.2(ii) also identifies naturally $\mathbf{E}_3$ with $\mathbf{E}(A(\mathbf{E}_3))$, whence the contention.

(iii) is clear, since complete tensor products represent these coproducts, by (8.3.7). □

16.3.10. For any ring A and any ideal $I \subset A$, let $\mathscr{T}_I$ be the I-adic topology on A, and denote $(A_I^\wedge,\mathscr{T}_I^\wedge)$ the separated completion of $(A,\mathscr{T}_I)$. Notice that if $I' \subset A$ is another ideal with $I' \subset I$, the identity map of A yields a continuous map $(A,\mathscr{T}_{I'}) \to (A,\mathscr{T}_I)$, whose completion is a natural continuous ring homomorphism

$$(A_{I'}^\wedge,\mathscr{T}_{I'}^\wedge) \to (A_I^\wedge,\mathscr{T}_I^\wedge). \qquad (16.3.11)$$

Now, suppose that $I, J \subset A$ are any two ideals; we deduce a commutative diagram

(16.3.12)
$$\begin{array}{ccc} (A^\wedge_{I\cap J}, \mathscr{T}^\wedge_{I\cap J}) & \xrightarrow{\varphi_I} & (A^\wedge_I, \mathscr{T}^\wedge_I) \\ {\scriptstyle\varphi_J}\downarrow & & \downarrow{\scriptstyle\beta_I} \\ (A^\wedge_J, \mathscr{T}^\wedge_J) & \xrightarrow{\beta_J} & (A^\wedge_{I+J}, \mathscr{T}^\wedge_{I+J}) \end{array}$$

whose arrows are the continuous ring homomorphisms (16.3.11). Moreover, for every $k \in \mathbb{N}$ let $A^\wedge_{I,k} := A^\wedge_I / J^k A^\wedge_I$, and endow $A^\wedge_{I,k}$ with the quotient topology $\mathscr{T}_{I,k}$ induced by $\mathscr{T}^\wedge_I$ via the natural projection $A^\wedge_I \to A^\wedge_{I,k}$. We set

(16.3.13)
$$(A^\wedge_{I,J}, \mathscr{T}^\wedge_{I,J}) := \lim_{k\in\mathbb{N}} (A^\wedge_{I,k}, \mathscr{T}_{I,k}).$$

For every $k \in \mathbb{N}$, let $\mathscr{T}_{d,k}$ be the discrete topology on $A/(I + J)^k$; the system of continuous projections $((A^\wedge_I, \mathscr{T}^\wedge_I) \to (A/(I + J)^k, \mathscr{T}_d) \mid k \in \mathbb{N})$ factors uniquely through a system of continuous ring homomorphisms $((A^\wedge_{I,k}, \mathscr{T}_{I,k}) \to (A/(I + J)^k, \mathscr{T}_d) \mid k \in \mathbb{N})$, whose limit is a natural continuous ring homomorphism

(16.3.14)
$$(A^\wedge_{I,J}, \mathscr{T}^\wedge_{I,J}) \to (A^\wedge_{I+J}, \mathscr{T}^\wedge_{I+J}).$$

Lemma 16.3.15. *In the situation of* (16.3.10)*, we have :*

(i) (16.3.14) *is an open and surjective map.*

(ii) *Suppose that A is either a noetherian ring or a perfect $\mathbb{F}_p$-algebra, and that both I and J are finitely generated. Then :*

  (a) (16.3.12) *is a cartesian diagram of topological rings and a cocartesian diagram of topological A-modules.*

  (b) (16.3.14) *is an isomorphism of topological rings.*

Proof. For every $n \in \mathbb{N}$, we have a natural diagram of rings

(16.3.16)
$$\begin{array}{ccc} A/(I^n \cap J^n) & \longrightarrow & A/I^n \\ \downarrow & & \downarrow \\ A/J^n & \longrightarrow & A/(I^n + J^n) \end{array}$$

whence a complex of A-modules

$$\Sigma_n \qquad : \qquad 0 \to A/(I^n \cap J^n) \to A/I^n \oplus A/J^n \to A/(I^n + J^n) \to 0$$

and it is easily seen that Σ_n is exact for every $n \in \mathbb{N}$. Therefore, (16.3.16) is a cartesian diagram of discrete topological rings (details left to the reader); let $\mathscr{T}'_{d,n}$ be the discrete topology on $A/(I^n \cap J^n)$ for every $n \in \mathbb{N}$, and set

$$(A', \mathscr{T}') := \lim_{n\in\mathbb{N}} (A/(I^n \cap J^n), \mathscr{T}'_{d,n}).$$

Notice as well that $(I + J)^{2n-1} \subset I^n + J^n \subset (I + J)^n$ for every $n \in \mathbb{N}$, so the $(I + J)$-adic topology on A agrees with the linear topology defined by the descending system of ideals $(I^n + J^n \mid n \in \mathbb{N})$. In light of example 1.5.15(ii), we deduce that the limit of the system of these diagrams is a cartesian diagram of topological rings

(16.3.17)
$$\begin{array}{ccc} (A', \mathscr{T}') & \xrightarrow{\varphi'_I} & (A^\wedge_I, \mathscr{T}^\wedge_I) \\ {\scriptstyle\varphi'_J}\downarrow & & \downarrow{\scriptstyle\beta'_I} \\ (A^\wedge_J, \mathscr{T}^\wedge_J) & \xrightarrow{\beta'_J} & (A^\wedge_{I+J}, \mathscr{T}^\wedge_{I+J}). \end{array}$$

Moreover, since the inverse system $(A/(I^n \cap J^n) \mid n \in \mathbb{N})$ has surjective transition maps, the limit of the system of exact sequences $(\Sigma_n \mid n \in \mathbb{N})$ is still exact (see [163, Lemma 3.5.3]), and therefore (16.3.17) is also a cocartesian diagram of A-modules. Furthermore, by proposition 8.2.13(i,v) we have an induced morphism of exact complexes

$$\begin{array}{ccccccccccc}
\Sigma'_n & & 0 & \longrightarrow & (I^n \cap J^n)^\wedge & \longrightarrow & I^{n\wedge} \oplus J^{n\wedge} & \longrightarrow & (I^n + J^n)^\wedge & \longrightarrow & 0 \\
{\scriptstyle\sigma_n}\downarrow & & & & \downarrow & & \downarrow & & \downarrow & & \\
\Sigma & & 0 & \longrightarrow & A' & \longrightarrow & A^\wedge_I \oplus A^\wedge_J & \xrightarrow{\beta'_{I,J}} & A^\wedge_{I+J} & \longrightarrow & 0
\end{array}$$

where :

- $(I^n \cap J^n)^\wedge$ is the topological closure of $I^n \cap J^n$ in $(A', \mathscr{T}')$, and likewise for $I^{n\wedge} \oplus J^{n\wedge}$ and $(I^n + J^n)^\wedge$.
- $\mathrm{Coker}\, \sigma_n$ is naturally isomorphic to Σ_n, for every $n \in \mathbb{N}$.
- $\beta'_{I,J}$ is the sum of β'_I and β'_J.

Especially, $\beta'_{I,J}$ is a continuous, open and surjective map, for the product topology $\mathscr{T}^\wedge_I \times \mathscr{T}^\wedge_J$ on $A^\wedge_I \oplus A^\wedge_J$, and it follows easily that (16.3.17) is a cocartesian diagram of topological A-modules.

(i): The system of natural maps $(A^\wedge_I \to A^\wedge_{I,k} \leftarrow A/J^k \mid k \in \mathbb{N})$ yields ring homomorphisms

$$A^\wedge_I \xrightarrow{\psi_I} (A^\wedge_I)^\wedge_J \xleftarrow{\psi_J} A^\wedge_J.$$

There follows a map of abelian groups $\gamma : A^\wedge_I \oplus A^\wedge_J \to (A^\wedge_I)^\wedge_J$ which is continuous for the topology $\mathscr{T}^\wedge_I \times \mathscr{T}^\wedge_J$ and a simple inspection shows that (16.3.14) $\circ\, \gamma$ equals $\beta'_{I,J}$. Now, let $K \subset (A^\wedge_I)^\wedge_J$ be any open ideal; then $K' := \gamma^{-1}K$ is an open subgroup of $A^\wedge_I \oplus A^\wedge_J$ and therefore $\beta'_{I,J}K'$ is an open subgroup of $A^\wedge_{I+J}$ contained in the image K'' of K under (16.3.14), so K'' is open as well, whence (i).

(ii.a): The system of projections $(A/(I \cap J)^n \to A/(I^n \cap J^n) \mid n \in \mathbb{N})$ yields a natural continuous ring homomorphism

$$\nu : (A^\wedge_{I\cap J}, \mathscr{T}^\wedge_{I\cap J}) \to (A', \mathscr{T}')$$

and a simple inspection shows that $\varphi'_I \circ \nu = \varphi_I$ and $\varphi'_J \circ \nu = \varphi_J$. To conclude the proof of (ii.a), it then suffices to check :

Claim 16.3.18. Under the assumptions of (ii), the map ν is an isomorphism of topological rings.

Proof of the claim. Since $(IJ)^{2n} \subset (I \cap J)^{2n} \subset (IJ)^n$ for every $n \in \mathbb{N}$, the $(I \cap J)$-adic and IJ-adic topologies coincide on A. On the other hand, in case A is noetherian, the Artin-Rees lemma ([126, Th.8.5]) implies that for every $n \in \mathbb{N}$ there exists $m \in \mathbb{N}$ such that $I^m \cap J^n \subset I^n J^n \subset (I \cap J)^n$, from which the claim follows easily.

Thus, suppose A is perfect and both I and J are finitely generated, so the same holds for IJ, and therefore lemma 9.3.69(iv) says that the IJ-adic topology on A agrees with the linear topology defined by the cofiltered system of ideals $((IJ)^{\langle n\rangle}A \mid n \in \mathbb{N})$. Likewise, the linear topology on A defined by the cofiltered system of ideals $(I^n \cap J^n \mid n \in \mathbb{N})$ agrees with the one defined by the cofiltered system of ideals $(I^{\langle n\rangle}A \cap J^{\langle n\rangle}A \mid n \in \mathbb{N})$. So, it suffices to prove that

$$I^{\langle pn\rangle}A \cap J^{\langle pn\rangle}A \subset (IJ)^{\langle n\rangle}A \qquad \text{for every } n \in \mathbb{N}.$$

However, if $x \in I^{\langle pn\rangle}A \cap J^{\langle pn\rangle}A$, we may write $x = x^{1/p} \cdot x^{(p-1)/p} \in I^{\langle n\rangle}J^{\langle (p-1)n/p\rangle}A \subset (IJ)^{\langle n\rangle}A$ whence the contention. ◊

(ii.b): For every $h, k \in \mathbb{N}$, let $A_{h,k} := A/(I^h + J^k)$, and endow $A_{h,k}$ with the discrete topology $\mathscr{T}_{h,k}$; moreover, set

$$(C_k, \mathscr{T}_{C,k}) := \lim_{h\in\mathbb{N}} (A_{h,k}, \mathscr{T}_{h,k}) \qquad \text{for every } k \in \mathbb{N}$$

(where the transition maps $A_{h+1,k} \to A_{h,k}$ are the natural projections). Since I and J are both finitely generated, for every $h, k \in \mathbb{N}$ there exists $n \in \mathbb{N}$ such that $(I+J)^n \subset I^h + J^k$, so the natural map

$$(16.3.19) \qquad (A^\wedge_{I+J}, \mathscr{T}^\wedge_{I+J}) \to \lim_{h,k\in\mathbb{N}} (A_{h,k}, \mathscr{T}_{h,k}) \xrightarrow{\sim} \lim_{k\in\mathbb{N}} (C_k, \mathscr{T}_{C,k})$$

is an isomorphism of topological rings (see example 1.5.15(ii)). On the other hand, the projection $A \to A/J^k$ extends uniquely to a continuous map $\varphi_k : (A^\wedge_I, \mathscr{T}^\wedge_I) \to (C_k, \mathscr{T}_{C,k})$, and the latter factors uniquely through a continuous ring homomorphism

$$\overline{\varphi}_k : (A^\wedge_{I,k}, \mathscr{T}_{I,k}) \to (C_k, \mathscr{T}_{C,k}) \qquad \text{for every} \in \mathbb{N}.$$

With this notation, a simple inspection shows that (16.3.13) and (16.3.19) identify (16.3.14) with the limit of the system of maps $(\overline{\varphi}_k \mid k \in \mathbb{N})$. However, proposition 8.2.13(i,v) says that φ_k is surjective and its kernel is the topological closure $(J^k A^\wedge_I)^c$ of $J^k A^\wedge_I$ in $(A^\wedge_I, \mathscr{T}^\wedge_I)$, for every $k \in \mathbb{N}$. Thus, in order to show the lemma, it suffices to check that the linear topology on $A^\wedge_I$ defined by the system of ideals $((J^k A^\wedge_I)^c \mid k \in \mathbb{N})$ agrees with the $JA^\wedge_I$-adic topology. In case A is noetherian, this is clear, since in that case $J^k A^\wedge_I$ is already closed in $A^\wedge_I$ ([126, Th.8.11]). For the case where A is perfect, we remark :

Claim 16.3.20. Let $(B, \mathscr{T}_B)$ be a perfect, complete and separated topological $\mathbb{F}_p$-algebra, $I, J \subset B$ two ideals of finite type, such that $\mathscr{T}_B$ agrees with the I-adic topology. For every $\lambda \in \mathbb{N}[1/p]$ let $J^{\langle\lambda\rangle} B^c$ be the topological closure of $J^{\langle\lambda\rangle} B$ in B (notation of (9.3.68)). Then

$$J^{\langle\lambda\rangle} B^c \subset \bigcap_{n\in\mathbb{N}} (J + I^n)^{\langle\lambda\rangle} B \subset J^{\langle\lambda'\rangle} B \qquad \text{for every } \lambda' < \lambda.$$

Proof of the claim. We show first that $J^{\langle\lambda\rangle c} B \subset J^{\langle\lambda'\rangle} B$. Indeed, pick a finite system of generators $(b_1, \dots, b_k)$ (resp. $(b_{k+1}, \dots, b_s)$) for J (resp. for I), and let $x \in J^{\langle\lambda\rangle} B^c$ be any element; we can write

$$x = \sum_{n\in\mathbb{N}} x_n \qquad \text{with} \qquad x_n \in J^{\langle\lambda\rangle} B \cap I^{\langle n\rangle} B \qquad \text{for every } n \in \mathbb{N}.$$

Choose a strictly positive $\varepsilon \in \mathbb{N}[1/p]$ such that $\lambda'' := (1-\varepsilon)\cdot\lambda > \lambda'$, and notice that

$$x_n = x_n^{1-\varepsilon} \cdot x_n^{\varepsilon} \in J^{\langle\lambda''\rangle} \cdot I^{\langle n\varepsilon\rangle} B \qquad \text{for every } n \in \mathbb{N}.$$

By definition, for every $n \in \mathbb{N}$ there exist :

- a finite set $S_n \subset \mathbb{N}[1/p]^{\oplus k}$ with $\mu_1 + \cdots + \mu_k = \lambda''$ for every $\mu := (\mu_1, \dots, \mu_k) \in S_n$
- a system $(a_\mu \mid \mu \in S_n)$ of elements of B such that

$$x_n^{1-\varepsilon} = \sum_{\mu\in S_n} a_\mu b^\mu \qquad \text{where } b^\mu := b_1^{\mu_1} \cdots b_k^{\mu_k} \text{ for every } \mu \in S_n.$$

Now, choose $N \in \mathbb{N}$ such that $\lambda'' - \lambda' \geq kp^{-N}$ and define $\overline{\mu}$ and μ^* as in the proof of proposition 9.3.77, so that $\overline{\mu} \in S := \{\nu \in p^{-N}\mathbb{N}^{\oplus k} \mid \lambda'' \geq \nu_1 + \cdots + \nu_k > \lambda'\}$ for every $n \in \mathbb{N}$ and every $\mu \in S_n$. It follows that

$$x = \sum_{\nu\in S} b^\nu c_\nu \qquad \text{where} \qquad c_\nu := \sum_{n\in\mathbb{N}} x_n^\varepsilon \cdot \sum_{\substack{\mu\in S_n \\ \overline{\mu}=\nu}} a_\mu b^{\mu^*}.$$

Clearly $b^\nu \in J^{\langle\lambda'\rangle} B$, and by lemma 9.3.69(iv) the series c_ν converges in the I-adic topology of B for every $\nu \in S$; also it is easily seen that S is a finite set, whence the contention.

Next, for any $n \in \mathbb{N}$, the ideal $(J + I^n)^{\langle\lambda\rangle} B$ is generated by all monomials of the form

$$b^\mu := b_1^{\mu_1} \cdots b_s^{\mu_s} \qquad \text{such that} \qquad \lambda_1 + n^{-1} \cdot \lambda_2 = \lambda \quad \text{where} \quad \lambda_1 := \sum_{i=1}^{k} \mu_i \quad \lambda_2 := \sum_{i=k+1}^{s} \mu_i$$

and where $\mu := (\mu_1, \dots, \mu_s)$ is any sequence of elements of $\mathbb{N}[1/p]$. Fix also $\lambda'' \in \mathbb{N}[1/p]$ with $\lambda' < \lambda'' < \lambda$. Now, for any such μ, we have either $\lambda_1 \geq \lambda''$, in which case $b^\mu \in J^{\langle\lambda''\rangle}B$, or else $\lambda_2 > n \cdot (\lambda - \lambda'')$. We conclude that

$$\bigcap_{n\in\mathbb{N}} (J + I^n)^{\langle\lambda\rangle}B \subset \bigcap_{n\in\mathbb{N}} (J^{\langle\lambda''\rangle}B + I^{\langle n\cdot(\lambda-\lambda'')\rangle}B) = J^{\langle\lambda''\rangle}B^c$$

where the last identity follows from lemma 9.3.69(iv). But we know already that $J^{\langle\lambda''\rangle}B^c \subset J^{\langle\lambda'\rangle}B$, whence the claim. ◊

To conclude, it suffices now to apply claim 16.3.20 with $B := A_I^\wedge$ and invoke lemma 9.3.69(iv) (details left to the reader). □

Theorem 16.3.21. *In the situation of* (16.3.10)*, let $\mathscr{T}_p$ be the p-adic topology of A, and suppose:*

(a) $(A, \mathscr{T}_p)$ *is perfectoid.*
(b) $p^N \in I \cap J$ *for every sufficiently large* $N \in \mathbb{N}$.
(c) I *and* J *are finitely generated ideals of* A.

Then we have :

(i) (16.3.12) *is a cartesian diagram of rings and a cocartesian diagram of A-modules.*
(ii) (16.3.14) *is an isomorphism of topological rings.*

Proof. (i): Let $\pi \in A$ be as in lemma 16.2.3(iv); quite generally, if $K \subset A$ is any finitely generated ideal containing p^N (for some $N \in \mathbb{N}$), then it is easily seen that the K-adic topology on A agrees with the $(K + \pi A)$-adic topology. In view of our assumptions (b) and (c) we may therefore replace I and J by $I + \pi A$ and respectively $J + \pi A$, and assume from start that $\pi \in I \cap J$. Fix a finite system $(\bar{b}_1, \dots, \bar{b}_n)$ (resp. $(\bar{b}_{n+1}, \dots, \bar{b}_m)$) of generators of the ideal I/pA (resp. of J/pA) of A/pA, and let also $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N})$ be a distinguished element of $\mathbf{A} := \mathbf{A}(A, \mathscr{T}_p)$ that generates $\operatorname{Ker} u_A$. Pick elements $\beta_1, \dots, \beta_m \in \mathbf{E} := \mathbf{E}(A)$ such that $\overline{u}_{A/pA}(\beta_i) = \bar{b}_i$ for $i = 1, \dots, m$, denote by $\mathscr{I}_\mathbf{E}$ (resp. $\mathscr{J}_\mathbf{E}$) the ideal of $\mathbf{E}$ generated by the system $(\alpha_0, \beta_1, \dots, \beta_n)$ (resp. $(\alpha_0, \beta_{n+1}, \dots, \beta_m)$), and let $(\mathbf{E}^\wedge_\mathscr{I}, \mathscr{T}^\wedge_\mathscr{I})$ (resp. $(\mathbf{E}^\wedge_\mathscr{J}, \mathscr{T}^\wedge_\mathscr{J})$, resp. $(\mathbf{E}^\wedge_{\mathscr{I}\cap\mathscr{J}}, \mathscr{T}^\wedge_{\mathscr{I}\cap\mathscr{J}})$, resp. $(\mathbf{E}^\wedge_{\mathscr{I}+\mathscr{J}}, \mathscr{T}^\wedge_{\mathscr{I}+\mathscr{J}})$) be the $\mathscr{I}_\mathbf{E}$-adic (resp. $\mathscr{J}_\mathbf{E}$-adic, resp. $(\mathscr{I} \cap \mathscr{J})$-adic, resp. $(\mathscr{I} + \mathscr{J})$-adic) completion of $\mathbf{E}$. By lemma 16.3.15(ii), we get a cartesian diagram of topological rings

$$\mathscr{E} \quad : \quad \begin{array}{ccc} (\mathbf{E}^\wedge_{\mathscr{I}\cap\mathscr{J}}, \mathscr{T}^\wedge_{\mathscr{I}\cap\mathscr{J}}) & \longrightarrow & (\mathbf{E}^\wedge_\mathscr{I}, \mathscr{T}^\wedge_\mathscr{I}) \\ \downarrow & & \downarrow \\ (\mathbf{E}^\wedge_\mathscr{J}, \mathscr{T}^\wedge_\mathscr{J}) & \longrightarrow & (\mathbf{E}^\wedge_{\mathscr{I}+\mathscr{J}}, \mathscr{T}^\wedge_{\mathscr{I}+\mathscr{J}}) \end{array}$$

which is also cocartesian as a diagram of topological abelian groups.

Claim 16.3.22. $W(\mathscr{E})$ is still a cartesian diagram of topological rings, and a cocartesian diagram of $\mathbf{A}$-modules.

Proof of the claim. The cartesian property follows from remark 9.3.28(ii). To prove the cocartesian property, it suffices to show that the map of abelian groups deduced from $W(\mathscr{E})$

$$\tau : W(\mathbf{E}^\wedge_\mathscr{I}) \oplus W(\mathbf{E}^\wedge_\mathscr{J}) \to W(\mathbf{E}^\wedge_{\mathscr{I}+\mathscr{J}})$$

is surjective. Endow both target and source of τ with their p-adic filtrations, so that τ becomes a map of filtered abelian groups, and for every $k \in \mathbb{N}$, denote by $\operatorname{gr}^k\tau$ the map induced by τ on the respective k-graded subquotients. Since both target and source of τ are p-adically complete and separated (proposition 9.3.44(iii)), it then suffices to check that $\operatorname{gr}^k\tau$ is surjective for every $k \in \mathbb{N}$ ([34, Ch.III, §2, n.8, Cor.2]). Since multiplication by p is an injective endomorphism for both target and source of τ, we are then further reduced to the case where $k = 0$, in which case

$\mathrm{gr}^0\tau$ is naturally identified with the map $\mathbf{E}^\wedge_{\mathscr{I}} \oplus \mathbf{E}^\wedge_{\mathscr{J}} \to \mathbf{E}^\wedge_{\mathscr{I}+\mathscr{J}}$ deduced from $\mathscr{E}$. But the latter map is indeed surjective, since $\mathscr{E}$ is cocartesian. $\Diamond$

Now, remark 16.3.7(iii) says that the topology of $\mathbf{E}(A, \mathscr{T}_I)$ agrees with the $\mathscr{I}_\mathbf{E}$-adic topology, so the completion $\mathbf{E}^\wedge_I$ of $\mathbf{E}(A, \mathscr{T}_I)$ is isomorphic to $(\mathbf{E}^\wedge_{\mathscr{I}}, \mathscr{T}^\wedge_{\mathscr{I}})$. Likewise, the completion $\mathbf{E}^\wedge_J$ of $\mathbf{E}(A, \mathscr{T}_J)$ is isomorphic to $(\mathbf{E}^\wedge_{\mathscr{J}}, \mathscr{T}^\wedge_{\mathscr{J}})$, and the completion $\mathbf{E}^\wedge_{I+J}$ of $\mathbf{E}(A, \mathscr{T}_{I+J})$ is isomorphic to $(\mathbf{E}^\wedge_{\mathscr{I}+\mathscr{J}}, \mathscr{T}^\wedge_{\mathscr{I}+\mathscr{J}})$.

Next, set $\mathscr{K} := \mathscr{I}\mathscr{J} + \alpha_0\mathbf{E} \subset \mathbf{E}$; since $\mathscr{I}$ and $\mathscr{J}$ are finitely generated and they both contain α_0, it is easily seen that the $(\mathscr{I}\cap\mathscr{J})$-adic topology on $\mathbf{E}$ agrees with the $\mathscr{K}$-adic topology. Likewise, topology $\mathscr{T}_{I\cap J}$ on A agrees with the (IJ)-adic topology. Moreover, $\mathscr{K}$ is a finitely generated ideal, by construction $p \in IJ$, and $\overline{u}_{A/pA}(\mathscr{K}) = (IJ)/pA$, hence remark 16.3.7(iii) also tells us that $(\mathbf{E}^\wedge_{\mathscr{I}\cap\mathscr{J}}, \mathscr{T}^\wedge_{\mathscr{I}\cap\mathscr{J}})$ is isomorphic to the completion $\mathbf{E}^\wedge_{I\cap J}$ of $\mathbf{E}(A, \mathscr{T}_{I\cap J})$.

Notice now that, since the image of A is dense in $A^\wedge_{I\cap J}$, the map φ_I in (16.3.12) is the unique continuous homomorphism of topological A-algebras from $A^\wedge_{I\cap J}$ to $A^\wedge_I$, and the other maps in (16.3.12) enjoy corresponding uniqueness properties. Combining with remark 16.3.7(iv), we conclude that $W(\mathscr{E}) \otimes_\mathbf{A} A$ is naturally identified with (16.3.12), and the image of $\underline{\alpha}$ is still distinguished in each of the Witt rings appearing in $W(\mathscr{E})$. Due to of claim 16.3.22, we already see that (16.3.12) is a cocartesian diagram of A-modules; moreover, it will follow that it is a cartesian diagram of rings, once we know that

$$\mathrm{Tor}_1^\mathbf{A}(W(\mathbf{E}^\wedge_{\mathscr{I}+\mathscr{J}}), A) = 0. \qquad (16.3.23)$$

However $A = \mathbf{A}/\underline{\alpha}\mathbf{A}$, and $\underline{\alpha}$ is a regular element of $W(\mathbf{E}^\wedge_{\mathscr{I}+\mathscr{J}})$ (remark 16.1.7(ii)), so (16.3.23) holds by a standard calculation.

(ii): We know already that (16.3.14) is open and surjective (lemma 16.3.15(i)), so it suffices to show that this map is a ring isomorphism. However, in light of remark 16.3.7(iv) we have a diagram of continuous maps

$$\mathscr{D} \quad : \quad \begin{array}{ccccc} (A^\wedge_I)^\wedge_J & \longrightarrow & A(\mathbf{E}^\wedge_{\mathscr{I}}, \alpha_0\mathbf{E}^\wedge_{\mathscr{I}})^\wedge_J & \longrightarrow & A((\mathbf{E}^\wedge_{\mathscr{I}})^\wedge_{\mathscr{J}}, \alpha_0(\mathbf{E}^\wedge_{\mathscr{I}})^\wedge_{\mathscr{J}}) \\ \downarrow & & & & \downarrow \\ A^\wedge_{I+J} & & \longrightarrow & & A(\mathbf{E}^\wedge_{\mathscr{I}+\mathscr{J}}, \alpha_0\mathbf{E}^\wedge_{\mathscr{I}+\mathscr{J}}) \end{array}$$

whose left vertical arrow equals (16.3.14), and whose remaining arrows are ring isomorphisms. Thus, it suffices to check that $\mathscr{D}$ commutes, *i.e.* that the two continuous ring homomorphisms $f, g : (A^\wedge_I)^\wedge_J \to A(\mathbf{E}^\wedge_{\mathscr{I}+\mathscr{J}}, \alpha_0\mathbf{E}^\wedge_{\mathscr{I}+\mathscr{J}})$ deduced from $\mathscr{D}$ coincide. However, let $i : A \to (A^\wedge_I)^\wedge_J$ denote the completion map; a simple inspection shows that $f \circ i = g \circ i$, and since the topology of $A(\mathbf{E}^\wedge_{\mathscr{I}+\mathscr{J}}, \alpha_0\mathbf{E}^\wedge_{\mathscr{I}+\mathscr{J}})$ is separated and i has dense image, the assertion follows. $\square$

16.3.24. Let A, $\overline{D}$, $\overline{A}$ be three perfectoid rings, and set $\mathbf{E} := \mathbf{E}(A)$, $\overline{\mathbf{E}} := \mathbf{E}(\overline{D})$. Suppose that $\overline{A}$ is a discrete topological $\mathbb{F}_p$-algebra, so that $\mathbf{E}(\overline{A}) = \overline{A}$ (see also corollary 16.3.63(iii)), let $\overline{\varphi}_A : \overline{D} \to \overline{A}$ and $\pi_A : A \to \overline{A}$ be two continuous ring homomorphisms, and suppose as well that π_A is surjective. Define the topological rings D_A and $D_\mathbf{E}$ as the fibre products in the resulting cartesian diagrams of topological rings

$$\begin{array}{ccc} D_A & \xrightarrow{\varphi_A} & A \\ \downarrow & & \downarrow{\scriptstyle \pi_A} \\ \overline{D} & \xrightarrow{\overline{\varphi}_A} & \overline{A} \end{array} \qquad \begin{array}{ccc} D_\mathbf{E} & \xrightarrow{\varphi_\mathbf{E}} & \mathbf{E} \\ \downarrow & & \downarrow{\scriptstyle \pi_\mathbf{E}} \\ \overline{\mathbf{E}} & \xrightarrow{\overline{\varphi}_\mathbf{E}} & \overline{A}. \end{array}$$

where $\pi_\mathbf{E} := \mathbf{E}(\pi_A)$ and $\overline{\varphi}_\mathbf{E} := \mathbf{E}(\overline{\varphi}_A)$.

Proposition 16.3.25. *In the situation of* (16.3.24)*, the rings D_A and $D_{\mathbf{E}}$ are perfectoid, and there exists a natural isomorphism of topological rings*

$$\omega : \mathbf{E}(D_A) \stackrel{\sim}{\to} D_{\mathbf{E}} \qquad \textit{such that} \qquad \varphi_{\mathbf{E}} \circ \omega = \mathbf{E}(\varphi_A).$$

Proof. To begin with, we notice that D_A (resp. $D_{\mathbf{E}}$) is complete and separated, since $\overline{A}$ is separated and both $\overline{D}$ and A (resp. $\overline{\mathbf{E}}$ and $\mathbf{E}$) are complete and separated. Let $(\alpha_n \mid n \in \mathbb{N})$ (resp. $(\alpha'_n \mid n \in \mathbb{N})$) be a distinguished element in $\mathrm{Ker}\, u_A$ (resp. in $\mathrm{Ker}\, u_{\overline{D}}$), and pick a finitely generated ideal of adic definition $J_{\mathbf{E}} \subset \mathrm{Ker}\, \pi_{\mathbf{E}}$ (resp. $J_{\overline{\mathbf{E}}} \subset \mathrm{Ker}\, \overline{\varphi}_{\mathbf{E}}$) for $\mathbf{E}$ (resp. for $\overline{\mathbf{E}}$).

Claim 16.3.26. We may assume that $\alpha_0^{1/p^2}\mathbf{E} \subset J_{\mathbf{E}}$ and $\alpha_0'^{1/p^2}\overline{\mathbf{E}} \subset J_{\overline{\mathbf{E}}}$.

Proof of the claim. For the first stated inclusion, notice that $\alpha_0^{1/p^n} \in \mathrm{Ker}\, \pi_{\mathbf{E}}$ for every $n \in \mathbb{N}$, so $J_{\mathbf{E}} + \alpha_0^{1/p^n}\mathbf{E}$ is still an ideal of adic definition of $\mathbf{E}$ contained in $\mathrm{Ker}\, \pi_{\mathbf{E}}$, for every such n. The same argument applies to $J_{\overline{\mathbf{E}}}$. ◊

By virtue of claim 16.3.26 we may find a system of generators $\beta_\bullet := (\beta_1, \dots, \beta_k)$ for $J_{\mathbf{E}}$ with $\beta_1 = \alpha_0^{1/p^2}$, and we set $b_i := \overline{u}_A(\beta_i)$ for $i = 1, \dots, k$. It follows that $b_\bullet := (b_1, \dots, b_k)$ is a system of generators for an ideal J_A of adic definition of A. Likewise, pick a system of generators $\beta'_\bullet := (\beta'_1, \dots, \beta'_h)$ for $J_{\overline{\mathbf{E}}}$ with $\beta'_1 = \alpha_0'^{1/p^2}$, and set $b'_i := \overline{u}_{\overline{D}}(\beta'_1)$ for $i = 1, \dots, h$. Then $b'_\bullet := (b'_1, \dots, b'_h)$ is a system of generators for an ideal $J_{\overline{D}}$ of adic definition of $\overline{D}$. Notice that $J_A \times J_{\overline{D}} \subset D_A$ (resp. $J_{\mathbf{E}} \times J_{\overline{\mathbf{E}}} \subset D_{\mathbf{E}}$), and the topology of D_A (resp. of $D_{\mathbf{E}}$) is the linear topology defined by the system of ideals $(J_A^n \times J_{\overline{D}}^n \mid n \in \mathbb{N})$ (resp. $(J_{\mathbf{E}}^n \times J_{\overline{\mathbf{E}}}^n \mid n \in \mathbb{N})$). Denote by $K_{\mathbf{E}} \subset D_{\mathbf{E}}$ the ideal generated by $(\beta_\bullet \times \{0\}, \{0\} \times \beta'_\bullet)$; it is easily seen that

$$J_{\mathbf{E}}^{n+1} \times J_{\overline{\mathbf{E}}}^{n+1} \subset K_{\mathbf{E}}^n \subset J_{\mathbf{E}}^n \times J_{\overline{\mathbf{E}}}^n \qquad \text{for every } n \in \mathbb{N}$$

so the topology of $D_{\mathbf{E}}$ agrees with its $K_{\mathbf{E}}$-adic topology, and therefore $D_{\mathbf{E}}$ is a perfectoid $\mathbb{F}_p$-algebra. Likewise, let $K_A \subset D_A$ be the ideal generated by $(b_\bullet \times \{0\}, \{0\} \times b'_\bullet)$; by the same token, we have

$$J_A^{n+1} \times J_{\overline{D}}^{n+1} \subset K_A^n \subset J_A^n \times J_{\overline{D}}^n \qquad \text{for every } n \in \mathbb{N}$$

so the topology of D_A agrees with the K_A-adic topology. Moreover, by construction we have $pA \subset J_A^{p^2}$ and $p\overline{D} \subset J_{\overline{\mathbf{E}}}^{p^2}$ (lemma 16.2.7(iii)); since $p^2 - 1 \geq 2$, we deduce that $pD_A \subset K_A^2$, and we see already that D_A is a P-ring. Next, by remark 9.3.28(ii), we deduce a short exact sequence of $W(D_A)$-modules

$$\mathscr{W} \quad : \quad 0 \to W(D_A) \to W(A) \oplus W(\overline{D}) \to W(\overline{A}) \to 0.$$

On the other hand, by lemma 16.2.7(ii) we may find a distinguished element $\underline{\alpha}'' := (\alpha''_n \mid n \in \mathbb{N})$ in $\mathrm{Ker}\, u_{D_A}$ and to ease notation we set $D'_A := W(D_A)/\underline{\alpha}''W(D_A)$; since the image of $\underline{\alpha}''$ is still distinguished in $W(\overline{A})$, remark 16.1.7(ii) implies that $\mathrm{Tor}_1^{W(D_A)}(D'_A, W(\overline{A})) = 0$, so the sequence

$$\mathscr{W} \otimes_{W(D_A)} D'_A \quad : \quad 0 \to D'_A \to A \oplus \overline{D} \to \overline{A} \to 0$$

is still exact, and consequently u_{D_A} induces a ring isomorphism $D'_A \to D_A$, *i.e.* D_A is perfectoid. Lastly, notice that $u_A \otimes_{\mathbb{Z}} \mathbb{F}_p$ and $u_{\overline{D}}$ induce isomorphisms of topological $\mathbb{F}_p$-algebras

$$D_A/pD_A \stackrel{\sim}{\to} \overline{D}/p\overline{D} \times_{\overline{A}} A/pA \stackrel{\sim}{\to} \overline{D}/\alpha''_0\overline{D} \times_{\overline{\mathbf{E}}} \mathbf{E}/\alpha''_0\mathbf{E} \stackrel{\sim}{\to} D_{\mathbf{E}}/\alpha''_0 D_{\mathbf{E}}.$$

Combining with theorem 9.4.10 we deduce an isomorphism

$$\mathbf{E}(D_A) \stackrel{\sim}{\to} \mathbf{E}(D_A/pD_A) \stackrel{\sim}{\to} \mathbf{E}(D_{\mathbf{E}}/\alpha''_0 D_{\mathbf{E}}) \stackrel{\sim}{\to} D_{\mathbf{E}}$$

which fulfills the stated condition, by a simple inspection. □

Definition 16.3.27. Let A be a perfectoid ring and $\mathscr{J} \subset \mathscr{K} \subset \mathbf{E} := \mathbf{E}(A)$ any two ideals. Let also $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N}) \in \mathrm{Ker}\, u_A$ be any distinguished element and $\beta \in \mathbf{E}$ any element.

(i) We say that the inclusion of $\mathscr{J}$ in $\mathscr{K}$ is *β-taut* if we have
$$\beta \cdot \Phi_{\mathbf{E}}^{-1}(\mathscr{K}^p) \subset \mathscr{J}.$$

(ii) We say that $\mathscr{J}$ is *β-taut* if the identity map of $\mathscr{J}$ is a β-taut inclusion.

(iii) We say that $\mathscr{J}$ is *strictly β-taut* if it is β^λ-taut for some $\lambda \in \mathbb{Z}[1/p]$ with $0 \leq \lambda < 1$.

(iv) $\mathscr{J}$ is *taut* (resp. *strictly taut*) if it is α_0-taut (resp. strictly α_0-taut), and the inclusion $\mathscr{J} \subset \mathscr{K}$ is *taut* (resp. *strictly taut*), if it is α_0-taut (resp. strictly α_0-taut).

(v) We denote by $\{\mathscr{J}\} \subset A$ the topological closure of the ideal generated by the system $(\overline{u}_A(x) \mid x \in \mathscr{J})$ (notation of (9.3.34)).

Remark 16.3.28. With the notation of definition 16.3.27, the following holds.

(i) It follows easily from remark 16.1.7(i) that the definition of taut and strictly taut ideals does not depend on the choice of $\underline{\alpha}$.

(ii) By inspecting the definition of angular powers (see (9.3.68)), it is easily seen that $\mathscr{J}$ is 1-taut if and only if $\mathscr{J} = \mathscr{J}^{\langle 1 \rangle}\mathbf{E}$.

(iii) It follows from (ii) and lemma 9.3.69(ii.c) that for every ideal $\mathscr{J}$ of $\mathbf{E}$ and every $\lambda \in \mathbb{N}[1/p]$, the ideal $\mathscr{J}^{\langle\lambda\rangle}\mathbf{E}$ is strictly taut. Moreover, say that $\alpha_0 \in \mathscr{J}^{\langle\varepsilon\rangle}\mathbf{E}$ for some $\varepsilon \in \mathbb{N}[1/p]$; then the inclusion $\mathscr{J}^{\langle\lambda+\varepsilon\rangle}\mathbf{E} \subset \mathscr{J}^{\langle\lambda\rangle}\mathbf{E}$ is taut for every $\lambda \in \mathbb{N}[1/p]$, by lemma 9.3.69(ii.b).

(iv) If $\mathscr{J}_1, \mathscr{J}_2 \subset \mathbf{E}$ are two β-taut (resp. strictly β-taut, resp. taut, resp. strictly taut) ideals, then the same holds for $\mathscr{J}_1 \cap \mathscr{J}_2$. Indeed, suppose that both ideals are β-taut; then we have :
$$\begin{aligned}\beta \cdot \Phi_{\mathbf{E}}^{-1}((\mathscr{J}_1 \cap \mathscr{J}_2)^p) &\subset \beta \cdot \Phi_{\mathbf{E}}^{-1}(\mathscr{J}_1^p \cap \mathscr{J}_2^p) \\ &= \beta \cdot (\Phi_{\mathbf{E}}^{-1}(\mathscr{J}_1^p) \cap \Phi_{\mathbf{E}}^{-1}(\mathscr{J}_2^p)) \\ &\subset (\beta \cdot \Phi_{\mathbf{E}}^{-1}(\mathscr{J}_1^p)) \cap (\beta \cdot \Phi_{\mathbf{E}}^{-1}(\mathscr{J}_2^p)) \\ &\subset \mathscr{J}_1 \cap \mathscr{J}_2\end{aligned}$$
whence the claim. In the same vein, if $\mathscr{J}_1 \subset \mathscr{J}_2$ is a β-taut inclusion, and $\mathscr{K}$ is any β-taut ideal of $\mathbf{E}$, then the inclusion $\mathscr{K} \cap \mathscr{J}_1 \subset \mathscr{K} \cap \mathscr{J}_2$ is β-taut as well (details left to the reader); the same holds if β-taut is replaced by strictly β-taut, taut or strictly taut.

(v) If $\mathscr{J}$ is β-taut, then the same holds for the topological closure $\mathscr{J}^c$ of $\mathscr{J}$ in $\mathbf{E}$. Likewise, if $\mathscr{J} \subset \mathscr{K}$ is a β-taut inclusion, then the same holds for the inclusion $\mathscr{J}^c \subset \mathscr{K}^c$ of the respective topological closures; moreover, both $\mathscr{J}$ and $\mathscr{K}$ are β-taut. Then clearly the same assertions hold with β-taut replaced by strictly β-taut, taut, or strictly taut (details left to the reader). In the same vein, notice that
$$\{\mathscr{J}^c\} = \{\mathscr{J}\} \qquad \text{for every ideal } \mathscr{J} \subset \mathbf{E}.$$

(vi) Let $\mathscr{J}_1, \mathscr{J}_2, \mathscr{J}_3 \subset \mathbf{E}$ be three ideals, $n, m \in \mathbb{N}$ any two integers, and suppose that
$$\beta_1 \cdot \Phi_{\mathbf{E}}^{-n}(\mathscr{J}_1^{p^n}) \subset \mathscr{J}_2 \quad \text{and} \quad \beta_2 \cdot \Phi_{\mathbf{E}}^{-m}(\mathscr{J}_2^{p^m}) \subset \mathscr{J}_3 \qquad \text{for some } \beta_1, \beta_2 \in \mathbf{E}.$$
Then it is easily seen that $\beta_1\beta_2 \cdot \Phi_{\mathbf{E}}^{-n-m}(\mathscr{J}_1^{p^{n+m}}) \subset \mathscr{J}_3$. Especially, if $\mathscr{J}$ is β-taut, we have
$$\beta^n \cdot \Phi_{\mathbf{E}}^{-n}(\mathscr{J}^{p^n}) \subset \mathscr{J} \qquad \text{for every } n \in \mathbb{N}. \tag{16.3.29}$$

(vii) For $i = 1, 2$, let $\beta_i \in \mathbf{E}$ be any element, and $\mathscr{J}_i$ a β_i-taut ideal; then it is easily seen that $\mathscr{J}_1\mathscr{J}_2$ is $\beta_1\beta_2$-taut. More generally, if $\mathscr{J} \subset \mathscr{K}$ is a β_1-taut inclusion of ideals of $\mathbf{E}$, and $\mathscr{J}' \subset \mathbf{E}$ is any other β_2-taut ideal, then the inclusion $\mathscr{J}\mathscr{J}' \subset \mathscr{K}\mathscr{J}'$ is $\beta_1\beta_2$-taut.

(viii) Suppose that $\mathscr{J}$ is an open ideal of $\mathbf{E}$. Then the system $(\overline{u}_A(x) \mid x \in \mathscr{J})$ generates an open ideal J of A, and therefore $\{\mathscr{J}\} = J$ is open as well in A. Indeed, let $I \subset A$ be any ideal of definition, pick a finite system $(\overline{a}_1, \dots, \overline{a}_k)$ of generators of I/pA, let $\alpha_1, \dots, \alpha_k$ be elements of $\mathbf{E}$ such that $\overline{u}_{A/pA}(\alpha_i) = \overline{a}_i$ for $i = 1, \dots, k$, and denote by $\mathscr{I} \subset \mathbf{E}$ the ideal generated by the system $(\alpha_1, \dots, \alpha_k)$. Arguing as in the proof of lemma 16.2.7(i), we see that the system

$(\overline{u}_A(\alpha_i) \mid i = 1, \dots, k)$ generates I, and $\mathscr{I}^n \subset \mathscr{J}$ for every sufficiently large $n \in \mathbb{N}$, so that $I^n \subset J$ for every such n, whence the assertion.

16.3.30. Keep the notation of definition 16.3.27, and let $\mathscr{J} \subset \mathscr{K}$ be a taut inclusion of ideals of $\mathbf{E}$. Notice that $\alpha_0 \mathscr{K} \subset \mathscr{J}$, so $\mathscr{K}/\mathscr{J}$ is an $\mathbf{E}/\alpha_0\mathbf{E}$-module, and then it can be viewed as an A/pA-module, via the isomorphism ω of remark 16.3.7(ii). Likewise, from lemma 16.2.7(iii) we easily deduce that $p\{\mathscr{K}\} \subset \{\mathscr{J}\}$, so $\{\mathscr{K}\}/\{\mathscr{J}\}$ is an A/pA-module as well.

Theorem 16.3.31. *Let A be any perfectoid ring, and set $\mathbf{E} := \mathbf{E}(A)$. The following holds :*

(i) *Every taut inclusion $\mathscr{J}_1 \subset \mathscr{J}_2$ of ideals of $\mathbf{E}$ induces an A/pA-linear map*

$$\overline{\tau} : \mathscr{J}_2/\mathscr{J}_1 \to \{\mathscr{J}_2\}/\{\mathscr{J}_1\} \quad : \quad (x \mod \mathscr{J}_1) \mapsto (\overline{u}_A(x) \mod \{\mathscr{J}_1\}).$$

(ii) *If both $\mathscr{J}_1$ and $\mathscr{J}_2$ are closed in the topology of $\mathbf{E}$, the map $\overline{\tau}$ of* (i) *is an isomorphism.*

Proof. Let $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N}) \in \operatorname{Ker} u_A$ be any distinguished element.

(i): Let $x, y \in \mathscr{J}_2$ be any two elements, and set $\delta := \tau_A(x + y) - \tau_A(x) - \tau_A(y)$. In light of lemma 16.1.1(iv), we have to check that $u_A(\delta)$ lies in $\{\mathscr{J}_1\}$. However, proposition 9.3.62 expresses δ as a series of the form $\sum_{n\in\mathbb{N}} p^n b_n$, where each b_n is in turn a finite sum of terms of the form $c_{n,\sigma}\tau_A(\beta_{n,\sigma})$ (for σ ranging over a certain finite set Σ_n), and with $\beta_{n,\sigma} \in \Phi_{\mathbf{E}}^{-n}(\mathscr{J}_2^{p^n})$ and $c_{n,\sigma} \in \mathbb{Z}_p$ for every $n \in \mathbb{N}$ and every $\sigma \in \Sigma_n$. Thus, we come down to checking that $p^n \cdot \overline{u}_A(\beta_{n,\sigma}) \in \{\mathscr{J}_1\}$ for every $n \in \mathbb{N}$ and $\sigma \in \Sigma_n$. In light of lemma 16.2.7(iii), this holds if and only if $\overline{u}_A(\alpha_0^n \cdot \beta_{n,\sigma}) \in \{\mathscr{J}_1\}$, which in turns will follow, once we know that $\alpha_0^n \cdot \beta_{n,\sigma} \in \mathscr{J}_1$. But the latter is clear from remark 16.3.28(vi) (with $\beta := \alpha_0$: details left to the reader).

Lastly, for any $x \in \mathscr{J}_2$ and $\beta \in \mathbf{E}$ we have $\tau_A(\beta x) = \tau_A(\beta) \cdot \tau_A(x)$, and the isomorphism ω of remark 16.3.7(ii) maps the class of β in $\mathbf{E}/\alpha_0\mathbf{E}$ to the class of $\overline{u}_A(\beta)$ in A/pA; this shows that $\overline{\tau}(\overline{a} \cdot x) = \overline{a} \cdot \overline{\tau}(x)$ for every $\overline{a} \in A/pA$ and every $x \in \mathscr{J}_2/\mathscr{J}_1$, whence (i).

Next, choose a strictly positive $\varepsilon \in \mathbb{N}[1/p]$ such that $\alpha_0 \in \mathscr{J}^{\langle\varepsilon\rangle}\mathbf{E}$, and for every $r \in \mathbb{R}_+$ define the ideal $\mathscr{J}^{\lfloor r\rfloor}\mathbf{E}$ as in remark 9.3.70(i); we point out the following special case of (ii) :

Claim 16.3.32. Let $\mathscr{J}$ be any ideal of definition of $\mathbf{E}$, and $r, r' \in \mathbb{R}_+$ two real numbers such that $\varepsilon \geq r' - r \geq 0$. Then (ii) holds for the taut inclusion $\mathscr{J}^{\lfloor r'\rfloor}\mathbf{E} \subset \mathscr{J}^{\lfloor r\rfloor}\mathbf{E}$.

Proof of the claim. Let us set $W\lfloor s\rfloor := W(\mathscr{J}^{\lfloor s\rfloor}\mathbf{E})$ for every $s \in \mathbb{N}[1/p]$ (notation of remark 9.3.28(iv)); from (9.3.73) we see that τ_A induces a natural isomorphism

$$\mathscr{J}^{\lfloor r\rfloor}\mathbf{E}/\mathscr{J}^{\lfloor r'\rfloor}\mathbf{E} \xrightarrow{\sim} W\lfloor r\rfloor/(pW\lfloor r\rfloor + W\lfloor r'\rfloor)$$

and we are reduced to showing that the restriction of u_A to $W\lfloor r\rfloor$ induces an isomorphism

$$W\lfloor r\rfloor/(pW\lfloor r\rfloor + W\lfloor r'\rfloor) \xrightarrow{\sim} \{\mathscr{J}^{\lfloor r\rfloor}\mathbf{E}\}/\{\mathscr{J}^{\lfloor r'\rfloor}\mathbf{E}\}. \qquad (16.3.33)$$

However, remark 16.3.28(viii) already implies that (16.3.33) is surjective, and its kernel is the image of $W\lfloor r\rfloor \cap \underline{\alpha}W(E)$. In light of proposition 16.1.12(ii) we then come down to showing :

$$\underline{\alpha}W\lfloor r\rfloor \subset pW\lfloor r\rfloor + W\lfloor r'\rfloor.$$

But due to our choice of ε we get $\alpha_0\mathscr{J}^{\lfloor r\rfloor}\mathbf{E} \subset \mathscr{J}^{\lfloor r'\rfloor}\mathbf{E}$, so the latter inclusion follows again from (9.3.73). ◊

Claim 16.3.34. Let B be any ring, $f : M \to M'$ and $g : M' \to M''$ two continuous maps of topological B-modules, and suppose that

(a) the topologies of M and M'' are discrete and that of M' is separated
(b) f has dense image and $g \circ f$ is injective.

Then f is an isomorphism of topological B-modules.

Proof of the claim. By assumption, the topological closure of $f(M)$ in M' equals M'; by claim 8.3.25 it follows that the topological closure of $g \circ f(M)$ in M'' equals the topological closure of $g(M')$. But since the topology of M'' is discrete, this just means that $g \circ f(M) = g(M')$. We may therefore replace M'' by $g(M')$, and assume from start that g is surjective and $g \circ f$ is an isomorphism. Then we may even assume that $M'' = M$ and $g \circ f = \mathbf{1}_M$. Let us endow $\mathrm{Im}\, f$ and $\mathrm{Ker}\, g$ with the topologies induced from the inclusion into M'; then the addition law of M' restricts to a continuous and bijective B-linear map

$$h : \mathrm{Im}\, f \oplus \mathrm{Ker}\, g \to M'$$

(where the direct sum is endowed with the product topology). However, the inverse of h is the map given by the rule : $m' \mapsto (f \circ g(m'), m' - f \circ g(m'))$ for every $m' \in M'$. Clearly, this map is also continuous, so h is an isomorphism of topological B-modules. Now, since M' is separated, the same must hold for $\mathrm{Ker}\, g$; especially, $L := h(\mathrm{Im}\, f \oplus 0)$ is a closed subset of M'. On the other hand, $\mathrm{Im}\, f = L$; since f has dense image, we must then have $L = M'$, *i.e.* $\mathrm{Ker}\, g = 0$, whence the claim. ♢

We may now complete the proof of (ii): fix an ideal of definition $\mathscr{J}$ of $\mathbf{E}$ with $\alpha_0 \in \mathscr{J}$, and for every ideal $\mathscr{K} \subset \mathbf{E}$ set

$$\mathrm{Fil}^n \mathscr{K} := \mathscr{K} \cap \mathscr{J}^{\lfloor n \rfloor}\mathbf{E} \qquad \mathrm{Fil}^n\{\mathscr{K}\} := \{\mathrm{Fil}^n \mathscr{K}\} \qquad \text{for every } n \in \mathbb{N}.$$

If $\mathscr{K}' \subset \mathscr{K}$ is any inclusion of ideals of $\mathbf{E}$, the image of $\mathrm{Fil}^\bullet \mathscr{K}$ in $\mathscr{K}/\mathscr{K}'$ defines a filtration $\mathrm{Fil}^\bullet(\mathscr{K}/\mathscr{K}')$ of $\mathscr{K}/\mathscr{K}'$, and likewise we get a filtration $\mathrm{Fil}^\bullet(\{\mathscr{K}\}/\{\mathscr{K}'\})$ on $\{\mathscr{K}\}/\{\mathscr{K}'\}$. Notice that the inclusion $\mathrm{Fil}^{n+1}\mathscr{K} \subset \mathrm{Fil}^n \mathscr{K}$ is taut for every $n \in \mathbb{N}$ and every taut ideal $\mathscr{K}$, and denote by $\mathrm{gr}^\bullet \mathscr{K}$ (resp. $\mathrm{gr}^\bullet\{\mathscr{K}\}$) the graded A/pA-module associated to the filtration $\mathrm{Fil}^\bullet \mathscr{K}$ (resp. to $\mathrm{Fil}^\bullet\{\mathscr{K}\}$). Likewise we define $\mathrm{gr}^\bullet(\mathscr{K}/\mathscr{K}')$ and $\mathrm{gr}^\bullet(\{\mathscr{K}\}/\{\mathscr{K}'\})$ for an inclusion of ideals $\mathscr{K}' \subset \mathscr{K}$. We remark :

Claim 16.3.35. If $\mathscr{K}$ is taut, the map $\overline{\tau}$ of (i) induces an isomorphism

$$\mathrm{gr}^n \mathscr{K} \xrightarrow{\sim} \mathrm{gr}^n\{\mathscr{K}\} \qquad \text{for every } n \in \mathbb{N}.$$

Proof of the claim. Let us endow any ideal of $\mathbf{E}$ (resp. of A) with the topology induced from the inclusion into $\mathbf{E}$ (resp. into A), and for any inclusion $\mathscr{I} \subset \mathscr{I}'$ (resp. $I \subset I'$) of ideals of $\mathbf{E}$ (resp. of A), let us endow $\mathscr{I}'/\mathscr{I}$ (resp. I'/I) with the corresponding quotient topology. Notice that the inclusions $\mathrm{Fil}^{n+1}\mathscr{K} \subset \mathrm{Fil}^n \mathscr{K}$ and $\mathrm{Fil}^{n+1}\{\mathscr{K}\} \subset \mathrm{Fil}^n\{\mathscr{K}\}$ are both taut (remark 16.3.28(iv)); from (i) we deduce a commutative diagram of A/pA-modules :

$$\begin{array}{ccc} \mathrm{gr}^n \mathscr{K} & \longrightarrow & \mathrm{gr}^n\{\mathscr{K}\} \\ \big\downarrow & & \big\downarrow \\ \mathrm{gr}^n \mathbf{E} & \longrightarrow & \mathrm{gr}^n A \end{array}$$

whose left vertical arrow is injective, and whose bottom horizontal arrow is already known to be an isomorphism, by claim 16.3.32. Moreover, all these maps are continuous, for the topologies that we have just defined on these modules, and furthermore, the top horizontal arrow has dense image. Also, since $\mathscr{J}$ is open, the same holds for $\mathscr{J}^{\lfloor r' \rfloor}\mathbf{E}$, and therefore the two modules on the bottom row have both the discrete topology. Likewise, $\mathscr{K} \cap \mathscr{J}^{\lfloor r' \rfloor}\mathbf{E}$ is open in $\mathscr{K} \cap \mathscr{J}^{\lfloor r' \rfloor}\mathbf{E}$, so also the source of the map on the top row is a discrete A/pA-module. Lastly, since $\{\mathscr{K} \cap \mathscr{J}^{\lfloor r' \rfloor}\mathbf{E}\}$ is a closed ideal, the target of the same map is a separated A/pA-module. Thus, all the conditions of claim 16.3.34 are fulfilled, and it follows that the top horizontal arrow is an isomorphism. ♢

There follows, for every $n \in \mathbb{N}$ a commutative diagram with exact rows

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{gr}^n \mathscr{J}_1 & \longrightarrow & \mathrm{gr}^n \mathscr{J}_2 & \longrightarrow & \mathrm{gr}^n(\mathscr{J}_2/\mathscr{J}_1) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \mathrm{gr}^n\{\mathscr{J}_1\} & \longrightarrow & \mathrm{gr}^n\{\mathscr{J}_2\} & \longrightarrow & \mathrm{gr}^n(\{\mathscr{J}_2\}/\{\mathscr{J}_1\}) & \longrightarrow & 0 \end{array}$$

and claim 16.3.35 shows that the leftmost and central vertical arrows are both isomorphisms, so the same holds for the rightmost vertical arrow. Now, notice that the filtration $\mathrm{Fil}^\bullet(\mathscr{J}_2/\mathscr{J}_1)$ defines a separated and complete topology on $\mathscr{J}_2/\mathscr{J}_1$, since $\mathscr{J}_2$ and $\mathscr{J}_1$ are both closed ideals in $\mathbf{E}$. The same holds for the topology on $\{\mathscr{J}_2\}/\{\mathscr{J}_1\}$ determined by the filtration $\mathrm{Fil}^\bullet(\{\mathscr{J}_2\}/\{\mathscr{J}_1\})$, since $\{\mathscr{J}_2\}$ and $\{\mathscr{J}_1\}$ are closed ideals in A. Then (ii) follows directly from [34, Ch.III, §2, n.8, Cor.3]. □

Theorem 16.3.36. *Let A be any perfectoid ring, $\mathscr{K}$ a taut ideal of $\mathbf{E} := \mathbf{E}(A)$, and $W(\mathscr{K})^c$ the topological closure of $W(\mathscr{K})$ in $\mathbf{A}(A)$ (notation of remark* 9.3.28(iv)*). We have :*

(i) $\{\mathscr{K}\} = u_A(W(\mathscr{K})^c)$.

(ii) *$\mathscr{K}$ is an open ideal if and only if the same holds for $\{\mathscr{K}\}$.*

(iii) *If $\mathscr{K}' \subset \mathscr{K}$ is another taut ideal, and both $\mathscr{K}$ and $\mathscr{K}'$ are closed, then $\mathscr{K} = \mathscr{K}'$ if and only if $\{\mathscr{K}\} = \{\mathscr{K}'\}$.*

(iv) *Suppose that $\mathscr{K}$ is 1-taut and closed, and let $\underline{\alpha}$ be any distinguished element of* $\mathrm{Ker}\, u_A$. *Then the pair $(\underline{\alpha}, \mathscr{K})$ is transversal (see* (16.1.11)*).*

Proof. Pick any distinguished element $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N})$ of $\mathrm{Ker}\, u_A$.

(i): First we prove that $u_A(W(\mathscr{K})^c) \subset \{\mathscr{K}\}$. Indeed, let $\underline{a} := (a_n \mid n \in \mathbb{N}) \in W(\mathscr{K})$ be any element; taking into account (9.3.46), we are easily reduced to showing that

$$u_A(p^n \cdot \tau_A(a_n^{p^{-n}})) \in \{\mathscr{K}\} \qquad \text{for every } n \in \mathbb{N}.$$

In light of lemmata 16.2.7(iii) and 16.1.1(iv), it then suffices to check that $\overline{u}_A(\alpha_0^n \cdot a_n^{p^{-n}}) \in \{\mathscr{K}\}$, and the latter is clear from (16.3.29) (applied with $\beta := \alpha_0$). Next, fix an ideal of definition $\mathscr{J}$ of $\mathbf{E}$ containing α_0, and define the filtrations $\mathrm{Fil}^\bullet\mathscr{K}$ on $\mathscr{K}$ and $\mathrm{Fil}^\bullet\{\mathscr{K}\}$ on $\{\mathscr{K}\}$ as in the proof of theorem 16.3.31(ii); by (9.3.29) and remark 16.3.28(v) we may assume that $\mathscr{K}$ is a closed ideal of $\mathbf{E}$, in which case theorem 16.3.31(ii) shows that the map $\overline{u}_A$ induces an isomorphism $\mathrm{gr}^\bullet\mathscr{K} \xrightarrow{\sim} \mathrm{gr}^\bullet\{\mathscr{K}\}$ on the respective associated graded A/pA-modules. Now, let $x \in \{\mathscr{K}\}$ be any element; it follows easily that we may write

$$x = u_A\Big(\sum_{n\in\mathbb{N}} \tau_A(\beta_n)\Big) \qquad \text{where } \beta_n \in \mathrm{Fil}^n\mathscr{K} \text{ for every } n \in \mathbb{N}$$

and the series converges in the topology of $\mathbf{A}(A)$. But clearly $\tau_A(\beta_n) \in W(\mathscr{K})$ for every $n \in \mathbb{N}$, whence the sought converse inclusion.

(ii): In light or remark 16.3.28(viii) we may assume that $\{\mathscr{K}\}$ is open, and we need to show that the same holds for $\mathscr{K}$; then, by lemma 8.3.21(ii.b), we may also assume that $\mathscr{K}$ is a closed ideal. The inclusion of $\mathscr{K}$ into $\mathbf{E}$ is a map of filtered $\mathbf{E}$-modules $\mathrm{Fil}^\bullet\mathscr{K} \to \mathrm{Fil}^\bullet\mathbf{E}$, and likewise we get a map of filtered A-modules $\mathrm{Fil}^\bullet\{\mathscr{K}\} \to \mathrm{Fil}^\bullet A$. The assumption on $\{\mathscr{K}\}$ implies that there exists $n \in \mathbb{N}$ such that the map of associated graded modules $\mathrm{gr}^k\{\mathscr{K}\} \to \mathrm{gr}^k A$ is an isomorphism for every $k \geq n$. Then theorem 16.3.31(ii) implies that the same holds for the corresponding map $\mathrm{gr}^k\mathscr{K} \to \mathrm{gr}^k\mathbf{E}$. However, both $\mathscr{K}$ and $\mathbf{E}$ are complete and separated for their filtrations, so $\mathrm{Fil}^n\mathscr{K} = \mathrm{Fil}^n\mathbf{E} = \mathscr{J}^{\langle n\rangle}$ ([34, Ch.III, §2, n.8, Cor.3]), *i.e.* $\mathscr{K}$ is open.

(iii) is similar : we may assume that $\{\mathscr{K}\} = \{\mathscr{K}'\}$, and we consider the induced map of filtered $\mathbf{E}$-modules $\mathrm{Fil}^\bullet\mathscr{K}' \to \mathrm{Fil}^\bullet\mathscr{K}$. Arguing as in the proof of (ii), we see that the latter induces an isomorphism on the associated graded $\mathbf{E}$-modules, so $\mathscr{K} = \mathscr{K}'$, again by [34, Ch.III, §2, n.8, Cor.3].

(iv): Denote by $(\alpha_0\mathscr{K})^c$ the topological closure of $\underline{\alpha}\mathscr{K}$ in $\mathbf{E}$. We shall show first that

Claim 16.3.37. $W(\mathscr{K}) \cap \mathrm{Ker}\, u_A = W((\alpha_0\mathscr{K})^c) \cap \mathrm{Ker}\, u_A + \underline{\alpha}W(\mathscr{K})$.

Proof of the claim. Indeed, let $\underline{\omega} := (\omega_n \mid n \in \mathbb{N}) \in W(\mathscr{K}) \cap \mathrm{Ker}\, u_A$ be any element; due to remarks 9.3.70(iv) and 16.3.28(ii), we may write

$$\underline{\omega} = \tau_A(\omega_0) + p \cdot \underline{\omega}' \qquad \text{for some } \underline{\omega}' \in W(\mathscr{K})$$

whence $0 = u_A(\underline{\omega}) = \overline{u}_A(\omega_0) + p \cdot u_A(\underline{\omega}')$, and especially, the image of $\overline{u}_A(\omega_0)$ vanishes in $\{\mathscr{K}\}/\{(\alpha_0\mathscr{K})^c\}$ (lemma 16.2.7(iii)). In view of theorem 16.3.31(ii), we deduce that $\omega_0 \in (\alpha_0\mathscr{K})^c$. Write also $\underline{\alpha} = \tau_A(\alpha_0) + p\underline{u}$ for some $\underline{u} \in \mathbf{A}(A)^\times$; we obtain

$$\underline{\omega} = \tau_A(\omega_0) + (\underline{u}^{-1}\underline{\alpha} - \tau_A(\alpha_0)) \cdot \underline{\omega}')$$

and it suffices to notice that $\underline{u}^{-1}\underline{\alpha} \cdot \underline{\omega}' \in \underline{\alpha}W(\mathscr{K}) \subset W(\mathscr{K}) \cap \mathrm{Ker}\, u_A$, and consequently $\tau_A(\omega_0) - \tau_A(\alpha_0) \cdot \underline{\omega}' \in W((\alpha_0\mathscr{K})^c) \cap \mathrm{Ker}\, u_A$. ◊

Notice next that if $\mathscr{K}$ is 1-taut, then the same holds for $\alpha_0\mathscr{K}$, and then also for $(\alpha_0\mathscr{K})^c$ (remark 16.3.28(v)). Thus, we may apply claim 16.3.37 to $(\alpha_0^n\mathscr{K})^c$, and get

$$W((\alpha_0^n\mathscr{K})^c) \cap \mathrm{Ker}\, u_A = W((\alpha_0^{n+1}\mathscr{K})^c) \cap \mathrm{Ker}\, u_A + \underline{\alpha}W((\alpha_0^n\mathscr{K})^c) \qquad \text{for every } n \in \mathbb{N}.$$

Now, let $x_0 \in W(\mathscr{K}) \cap \underline{\alpha}W(\mathbf{E})$ be any element; we may then find inductively identities

$$x_n = \underline{\alpha} \cdot y_n + x_{n+1} \qquad \text{with } x_{n+1} \in W((\alpha^{n+1}\mathscr{K})^c) \cap \mathrm{Ker}\, u_A \text{ and } y_n \in W((\alpha_0^n\mathscr{K})^c)$$

for every $n \in \mathbb{N}$. Therefore :

$$x_0 = \underline{\alpha} \cdot (y_0 + y_1 + \cdots + y_n) + x_{n+1} \qquad \text{for every } n \in \mathbb{N}.$$

Lastly, since $\mathscr{K}$ is 1-taut, the ideal $W(\mathscr{K})$ is closed in the topology of $W(\mathbf{E})$ (see remark 9.3.28(iv)), and since α_0 is topologically nilpotent, for every open ideal I of $W(\mathbf{E})$ there exists $n \in \mathbb{N}$ such that $W((\alpha_0^n\mathscr{K})^c) \subset I$. Consequently, the series $\sum_{n\in\mathbb{N}} y_n$ converges to an element $y \in W(\mathscr{K})$, and $\lim_{n\to+\infty} x_n = 0$, so finally $x = \underline{\alpha} \cdot y$, which concludes the proof. □

Corollary 16.3.38. *Let A be any perfectoid ring, $\mathscr{K} \subset \mathbf{E} := \mathbf{E}(A)$ an ideal such that $\Phi_\mathbf{E}(\mathscr{K}) = \mathscr{K}$, and endow $A/\{\mathscr{K}\}$ (resp. $\mathbf{E}/\mathscr{K}^c$) with the quotient topology induced via the projection $\pi_A : A \to A/\{\mathscr{K}\}$ (resp. $\pi_\mathbf{E} : \mathbf{E} \to \mathbf{E}/\mathscr{K}^c$). Then $A/\{\mathscr{K}\}$ is perfectoid, and there exists a natural isomorphism of topological rings*

$$\omega : \mathbf{E}(A/\{\mathscr{K}\}) \xrightarrow{\sim} \mathbf{E}/\mathscr{K}^c \qquad \textit{such that} \qquad \omega \circ \mathbf{E}(\pi_A) = \pi_\mathbf{E}.$$

Proof. The topological $\mathbb{F}_p$-algebra $\mathbf{E}/\mathscr{K}^c$ is complete and separated, and clearly $\Phi_\mathbf{E}(\mathscr{K}^c) = \mathscr{K}^c$, so $\mathbf{E}/\mathscr{K}^c$ is perfectoid, and we have

$$W(\mathscr{K}^c) = \mathrm{Ker}\,(W(\pi_\mathbf{E}) : W(\mathbf{E}) \to W(\mathbf{E}/\mathscr{K}^c)).$$

It follows that the kernel of the induced projection $\pi'_A : A \to A \otimes_{W(\mathbf{E})} W(\mathbf{E}/\mathscr{K}^c)$ is naturally identified with $u_A(W(\mathscr{K}^c))$. Moreover, since $W(\mathbf{E}/\mathscr{K}^c)$ is separated (lemma 9.3.33(ii)), $W(\mathscr{K}^c)$ is a closed subset of $W(\mathbf{E})$, and taking into account theorem 16.3.36(i) we deduce that $\mathrm{Ker}\,\pi'_A = \{\mathscr{K}\}$, so we get a cocartesian diagram

$$\mathscr{D} \quad : \quad \begin{array}{ccc} W(\mathbf{E}) & \xrightarrow{W(\pi_\mathbf{E})} & W(\mathbf{E}/\mathscr{K}) \\ {\scriptstyle u_A}\downarrow & & \downarrow{\scriptstyle u'} \\ A & \xrightarrow{\pi_A} & A/\{\mathscr{K}\} \end{array}$$

and notice that both u_A and π_A are open and surjective (lemma 16.2.7(i)), so the same holds for u', and therefore $A/\{\mathscr{K}\}$ is perfectoid (proposition 16.2.21(i)). Let also $\pi : A \to A/pA$ be the proejction; taking into account remark 9.4.5(ii), there follows a commutative diagram

$$\mathbf{E}(\mathscr{D} \otimes_{\mathbb{Z}} \mathbb{F}_p) \qquad : \qquad \begin{array}{ccc} \mathbf{E} & \xrightarrow{\pi_{\mathbf{E}}} & \mathbf{E}/\mathscr{K} \\ {\scriptstyle \mathbf{E}(\pi)}\downarrow & & \downarrow{\scriptstyle \mathbf{E}(u')} \\ \mathbf{E}(A/pA) & \xrightarrow{\mathbf{E}(\pi_A \otimes_{\mathbb{Z}} \mathbb{F}_p)} & \mathbf{E}(A/(\{\mathscr{K}\} + pA)) \end{array}$$

whose vertical arrows are both isomorphisms. The assertion follows easily. □

Remark 16.3.39. (i) In the situation of corollary 16.3.38, let $(\alpha_n \mid n \in \mathbb{N})$ be any distinguished element of $\mathrm{Ker}\, u_A$, and suppose that $\mathscr{K} \subset \mathrm{Ann}_{\mathbf{E}}(\alpha_0)$. Then the inclusion $0 \subset \mathscr{K}^c$ is taut, and therefore theorem 16.3.31(ii) yields a natural $W(\mathbf{E})$-linear identification

$$\mathscr{K}^c \xrightarrow{\sim} \{\mathscr{K}\} \qquad \beta \mapsto \overline{u}_A(\beta).$$

Especially, $\{\mathscr{K}\} \subset \mathrm{Ann}_A(p)$.

(ii) Let $\mathscr{I}, \mathscr{K} \subset \mathbf{E}$ be two ideals such the topology of $\mathbf{E}$ agrees with the $\mathscr{I}$-adic topology, and suppose that

$$\mathscr{K}\mathscr{I} = 0 \qquad \text{and} \qquad \Phi_{\mathbf{E}}(\mathscr{K}) = \mathscr{K}.$$

Notice that $\mathscr{K} = \mathscr{K}^{\langle 1 \rangle}$, and $\alpha_0^n \in \mathscr{I}$ for some $n \in \mathbb{N}$, from which it follows easily that $\mathscr{K} \subset \mathrm{Ann}_{\mathbf{E}}(\alpha_0)$. Moreover, $\mathscr{K} \cap \mathscr{I} = 0$; indeed, if $x \in \mathscr{K} \cap \mathscr{I}$, then $x^2 = 0$, hence $x = 0$. Thus, $\mathscr{K} + \mathscr{I}^n = \mathscr{K} \oplus \mathscr{I}^n$ for every $n \in \mathbb{N}$, and therefore

$$\bigcap_{n \in \mathbb{N}} (\mathscr{K} + \mathscr{I}^n) = \mathscr{K} \oplus \bigcap_{n \in \mathbb{N}} \mathscr{I}^n = \mathscr{K}$$

i.e. $\mathscr{K}$ is closed in the topology of $\mathbf{E}$, so corollary 16.3.38 says that $\mathbf{E}/\mathscr{K}$ and $A/\{\mathscr{K}\}$ are perfectoid for their quotient topologies, and there exists an isomorphism of topological rings

$$\omega : \mathbf{E}(A/\{\mathscr{K}\}) \xrightarrow{\sim} \mathbf{E}/\mathscr{K} \qquad \text{such that} \qquad \omega \circ \mathbf{E}(\pi_A) = \pi_{\mathbf{E}}$$

where $\pi_A : A \to A/\{\mathscr{K}\}$ and $\pi_{\mathbf{E}} : \mathbf{E} \to \mathbf{E}/\mathscr{K}$ are the projections.

Corollary 16.3.40. *Let A be any perfectoid ring, and $a_\bullet := (a_1, \dots, a_k)$ a finite system of elements of $\mathbf{E} := \mathbf{E}(A)$. Denote by $J \subset \mathbf{E}$ (resp. $\mathscr{J} \subset W(\mathbf{E})$) the ideal generated by $a_\bullet$ (resp. by $\tau_{\mathbf{E}}(a_1), \dots, \tau_{\mathbf{E}}(a_k)$), and define the ideal $[a_\bullet]^{\langle \lambda \rangle} \subset W(\mathbf{E})$ as in remark* 9.3.70(iii)*, for every $\lambda \in \mathbb{N}[1/p]$. We regard A as a $W(\mathbf{E})$-algebra, via the map u_A. Then we have :*

(i) $[a_\bullet]^{\langle \lambda \rangle} A \subset \{J^{\langle \lambda \rangle}\mathbf{E}\} \subset [a_\bullet]^{\langle \lambda' \rangle} A$ *for every $\lambda' < \lambda$ in $\mathbb{N}[1/p]$.*

(ii) *The following conditions are equivalent :*

(a) *J is open in $\mathbf{E}$*

(b) *$\mathscr{J} A$ is open in A*

(c) *$[a_\bullet]^{\langle \lambda \rangle} A$ is open in A for every $\lambda \in \mathbb{N}[1/p]$*

(d) *There exists a strictly positive $\lambda \in \mathbb{N}[1/p]$ such that $[a_\bullet]^{\langle \lambda \rangle} A$ is open in A*

and if these conditions hold, then $[a_\bullet]^{\langle \lambda \rangle} A = \{J^{\langle \lambda \rangle}\mathbf{E}\}$ for every $\lambda \in \mathbb{N}[1/p]$.

(iii) *If I is any ideal of definition of $\mathbf{E}$, the following holds :*

(a) *$\{I^{\langle \lambda \rangle}\mathbf{E}\}$ is a topologically nilpotent open ideal of A for every $\lambda > 0$ in $\mathbb{N}[1/p]$.*

(b) *$\bigcap_{n \in \mathbb{N}} \{J^{\langle \lambda \rangle}\mathbf{E} + I^{\langle n \rangle}\mathbf{E}\} \subset \{J^{\langle \lambda' \rangle}\mathbf{E}\}$ for every $\lambda' < \lambda$ in $\mathbb{N}[1/p]$.*

Proof. (i): The first inclusion is clear. For the second, notice that $\{J^{\langle \lambda \rangle}\mathbf{E}\} = W(J^{\langle \lambda \rangle})^c \cdot A$ by theorem 16.3.36(i) and remark 16.3.28(iii,v). On the other hand, pick any $\lambda'' \in \mathbb{N}[1/p]$ such that $\lambda' < \lambda'' < \lambda$; we have $W(J^{\langle \lambda \rangle})^c = \prod_{n \in \mathbb{N}} (J^{\langle p^n \lambda \rangle}\mathbf{E})^c$ (see remark 9.3.28(iv) and lemma 9.3.69(ii.a)), and moreover $(J^{\langle p^n \lambda \rangle}\mathbf{E})^c \subset J^{\langle p^n \lambda'' \rangle}\mathbf{E}$ for every $n \in \mathbb{N}$ (claim 16.3.20), hence

$$W(J^{\langle \lambda \rangle})^c \subset W(J^{\langle \lambda'' \rangle}) \subset [a_\bullet]^{\langle \lambda' \rangle}$$

where the last inclusion follows from proposition 9.3.77(i).

(ii): Taking into account lemma 9.3.69(ii.a,iv), it is easily seen that (ii.b)⇔(ii.c)⇔(ii.d). Combining with (i), we conclude that (ii.b) holds if and only if $\{J^{\langle 1\rangle}\mathbf{E}\}$ is open in A. However, from theorem 16.3.36(ii) and remark 16.3.28(iii) we see as well that $\{J^{\langle 1\rangle}\mathbf{E}\}$ is open in A if and only if $J^{\langle 1\rangle}\mathbf{E}$ is open in $\mathbf{E}$. Lastly, $J^{\langle 1\rangle}\mathbf{E}$ is open in $\mathbf{E}$ if and only if the same holds for J, due to lemma 9.3.69(ii.a,iv). Thus (ii.a)⇔(ii.b). Next, we remark :

Claim 16.3.41. For every $\lambda \in \mathbb{N}[1/p]$ and every $n \in \mathbb{N}$, the ideal generated by the system $(\overline{u}_A(x) \mid x \in J^{\langle\lambda\rangle}\mathbf{E})$ is contained in $p^nA + [a_\bullet]^{\langle\lambda\rangle}A$.

Proof of the claim. The claim follows easily from proposition 9.3.62 and lemma 16.1.1(iv) (details left to the reader). ◊

Now, if $\mathscr{J}A$ is open in A, the same holds for $[a_\bullet]^{\langle\lambda\rangle}A$, for every $\lambda \in \mathbb{N}[1/p]$, in which case the latter contains p^n for some sufficiently large $n \in \mathbb{N}$; taking into account claim 16.3.41, we get the second assertion of (ii).

(iii.a): It follows easily from (ii) that $\{I^{\langle\lambda\rangle}\}$ is open, and combining lemma 9.3.69(ii.a,iv) with (i), it is easily seen that $\{I^{\langle\lambda\rangle}\mathbf{E}\}$ is topologically nilpotent : details left to the reader.

(iii.b): Fix $N \in \mathbb{N}$ such that $\lambda' < (1 - p^{-N})\lambda$, let $x \in J^{\langle\lambda\rangle}\mathbf{E}$, $y \in I^{\langle n\rangle}$ be any two elements, and $\alpha \in \mathbb{N}[1/p]$ any rational number ≤ 1; notice that $z_\alpha := \tau_A(x^{1-\alpha} \cdot y^\alpha)$ lies in $\{I^{\langle n/p^N\rangle}\mathbf{E}\}$ if $\alpha \geq p^{-N}$, and lies in $\{J^{\langle\lambda'\rangle}\mathbf{E}\}$ otherwise. However, proposition 9.3.62 says that $\tau_A(x + y)$ can be written as a p-adically convergent series whose terms are of the form $u_\alpha \cdot z_\alpha$ for certain $u_\alpha \in W(\mathbf{E})$; since (ii) implies that $\{I^{\langle n/p^N\rangle}\mathbf{E}\}$ is an open ideal in A, we deduce

$$\bigcap_{n\in\mathbb{N}}\{J^{\langle\lambda\rangle}\mathbf{E} + I^{\langle n\rangle}\mathbf{E}\} \subset \bigcap_{n\in\mathbb{N}}(\{J^{\langle\lambda'\rangle}\mathbf{E}\} + \{I^{\langle n/p^N\rangle}\mathbf{E}\}) = \{J^{\langle\lambda'\rangle}\mathbf{E}\}$$

where the last equality holds because $\{J^{\langle\lambda'\rangle}\mathbf{E}\}$ is a closed ideal, taking into account (iii.a). □

Theorem 16.3.42. *Let $f : A \to A'$ be a continuous ring homomorphism of perfectoid rings; set $C := \operatorname{Im} f$ and $D := \operatorname{Im} \mathbf{E}(f)$. The following holds :*

(i) *f is surjective (resp. bijective, resp. adic, resp. open, resp. open and injective) if and only if the same holds for $\mathbf{E}(f)$.*

(ii) *C is open in A' if and only if D is open in $\mathbf{E}(A')$.*

(iii) *Suppose that C is open in A', then we have :*

(a) *$A'^{\circ\circ} \subset C$.*

(b) *C is perfectoid both for the quotient topology induced by the projection $A \to C$, and for the subspace topology induced by the inclusion map $C \to A'$.*

Proof. Set $\mathbf{E} := \mathbf{E}(A)$ and $\mathbf{E}' := \mathbf{E}(A')$. Also, denote by $\mathscr{T}_D$ and $\mathscr{T}'_D$ (resp. $\mathscr{T}_C$ and $\mathscr{T}'_C$) the topologies on D (resp. on C) induced respectively by the projection $\mathbf{E} \to D$ and the open inclusion $D \to \mathbf{E}'$ (resp. induced by the projection $A \to C$ and the open inclusion $C \to A'$).

Let $\alpha_\bullet := (\alpha_n \mid n \in \mathbb{N})$ be a distinguished element in the kernel of $u_A : W(\mathbf{E}) \to A$, and recall that the image of $\alpha_\bullet$ in $W(\mathbf{E}')$ is a distinguished element in the kernel of $u_{A'}$. We denote by $\mathrm{Fil}^\bullet A$ and $\mathrm{Fil}^\bullet A'$ the p-adic filtrations on A and respectively A'; likewise, let $\mathrm{Fil}^\bullet\mathbf{E}$ and $\mathrm{Fil}^\bullet\mathbf{E}'$ be the α_0-adic filtrations on $\mathbf{E}$ and respectively $\mathbf{E}'$. Moreover, we let $A^\bullet$ be the complex concentrated in degrees 0 and 1, with $A^0 := A$, $A^1 := A'$, and $d^0 := f$. Likewise, we define the complex $\mathbf{E}^\bullet := (\mathbf{E} \xrightarrow{\mathbf{E}(f)} \mathbf{E}')$ in degrees 0 and 1. With the foregoing filtrations, $A^\bullet$ and $\mathbf{E}^\bullet$ are filtered complexes of $\mathbb{Z}$-modules, and we wish to consider the associated spectral sequences, as described in (7.2.12). Explicitly, we have $Z(A^\bullet)^{pq}_r = 0$ whenever $p + q \neq 0, 1$, and :

$$\begin{aligned} Z(A^\bullet)^{p,-p}_r &:= \{a \in \mathrm{Fil}^p A \mid f(a) \in \mathrm{Fil}^{p+r} A'\} \\ Z(A^\bullet)^{p,-p+1}_r &:= \mathrm{Fil}^p A' \end{aligned} \qquad \text{for every } p \in \mathbb{Z} \text{ and } r \in \mathbb{N}$$

and correspondingly for $Z(\mathbf{E}^\bullet)^{pq}_r$. Since $\overline{u}_A(\mathrm{Fil}^p\mathbf{E}) \subset \mathrm{Fil}^pA$ for every $p \in \mathbb{Z}$, and likewise for $\overline{u}_{A'}$, it is then clear that $\overline{u}_A$ and $\overline{u}_{A'}$ restrict to well defined maps

$$\overline{u}^{pq}_r : Z(\mathbf{E}^\bullet)^{pq}_r \to Z(A^\bullet)^{pq}_r \qquad \text{for every } p, q \in \mathbb{Z} \text{ and } r \in \mathbb{N}.$$

Moreover, we have $B(A^\bullet)^{pq}_r = 0$ whenever $p + q \neq 0, 1$, and :

$$\left.\begin{aligned} B(A^\bullet)^{p,-p}_r &:= \mathrm{Fil}^{p+1}A \cap Z(A^\bullet)^{p,-p}_r \\ B(A^\bullet)^{p,-p+1}_r &:= (\mathrm{Fil}^{p+1}A' + f(\mathrm{Fil}^{p-r+1}A)) \cap \mathrm{Fil}^pA' \end{aligned}\right. \qquad \text{for every } p \in \mathbb{Z} \text{ and } r \in \mathbb{N}$$

and correspondingly for $B(\mathbf{E}^\bullet)^{pq}_r$.

Claim 16.3.43. $\overline{u}^{a,b}_r(B(\mathbf{E}^\bullet)^{a,b}_r) \subset B(A^\bullet)^{a,b}_r$ for every $a, b \in \mathbb{Z}$ and $r \in \mathbb{N}$.

Proof of the claim. The assertion is trivial for $a + b \neq 0, 1$. If $b = -a$, the assertion follows directly from our explicit descriptions of $B(\mathbf{E}^\bullet)^{a,-a}_r$ and $B(A^\bullet)^{a,-a}_r$. Next, notice that $B(\mathbf{E}^\bullet)^{a,-a+1}_0 = \mathrm{Fil}^{a+1}\mathbf{E}'$, and likewise for $B(A^\bullet)^{a,-a+1}_0$; the assertion follows then when $r = 0$ and $b = -a + 1$. For the case where $r > 0$ and $b = -a + 1$, lemma 7.2.13 shows that

$$B(\mathbf{E}^\bullet)^{a,-a+1}_r = \mathrm{Fil}^{a+1}\mathbf{E}' + f(Z(\mathbf{E}^\bullet)^{a-r+1,-a+r-1}_{r-1})$$

and likewise for $B(A^\bullet)^{a,-a+1}_r$. Hence, let $x \in \mathrm{Fil}^{p+1}\mathbf{E}'$ and $y \in Z(\mathbf{E}^\bullet)^{a-r+1,-a+r-1}_{r-1}$ and set $z := x + \mathbf{E}(f)(y)$; we need to check that $\overline{u}_{A'}(z) \in \mathrm{Fil}^{a+1}A' + f(Z(A^\bullet)^{a-r+1,-a+r-1}_{r-1})$. However, proposition 9.3.62 says that $\overline{u}_{A'}(z) = \overline{u}_{A'}(x) + \overline{u}_{A'} \circ \mathbf{E}(f)(y) + w$, where w is the limit of a p-adically convergent series whose terms are $\mathbb{Z}_p$-linear combinations of products of the form $p^n \cdot \overline{u}_{A'}(x^{\sigma_0} \cdot \mathbf{E}(f)(y)^{\sigma_1})$, with $n \in \mathbb{N} \setminus \{0\}$, $\sigma_0, \sigma_1 \in \mathbb{Q}_+$, and $\sigma_0 + \sigma_1 = 1$. Now :

$$\overline{u}_{A'} \circ \mathbf{E}(f)(y) = f(\overline{u}_A(y)) \in f(Z(A^\bullet)^{a-r+1,-a+r-1}_{r-1}) \qquad \text{and} \qquad \overline{u}_{A'}(x) \in \mathrm{Fil}^{a+1}A'.$$

Moreover, since $f(\overline{u}_A(y)) \in \mathrm{Fil}^aA'$, we see that p^m divides $\overline{u}_{A'}(x^{\sigma_0} \cdot \mathbf{E}(f)(y)^{\sigma_1}) = \overline{u}_{A'}(x)^{\sigma_0} \cdot f(\overline{u}_A(y))^{\sigma_1}$ in A', for every integer $m \leq \sigma_0 \cdot (a + 1) + \sigma_1 \cdot a = a + \sigma_0$. Thus, $w \in \mathrm{Fil}^{a+1}A'$, whence the contention. ◊

Next, notice that $E(A^\bullet)^{p,-p}_0 = \mathrm{gr}^pA$ and $E(A^\bullet)^{p,-p+1}_0 = \mathrm{gr}^pA'$ for every $p \in \mathbb{Z}$, and likewise for $E(\mathbf{E}^\bullet)^{pq}_0$, whenever $p + q = 0, 1$. Especially, $E(A^\bullet)^{a,b}_r$ is a $\mathbb{Z}/p\mathbb{Z}$-module for every $a, b \in \mathbb{Z}$ and $r \in \mathbb{N}$. Invoking proposition 9.3.62 again, we deduce that the composition

$$Z(\mathbf{E}^\bullet)^{pq}_r \xrightarrow{\overline{u}^{pq}_r} Z(A^\bullet)^{pq}_r \to E(A^\bullet)^{pq}_r$$

is an additive map, and combining with claim 16.3.43, it follows that the latter factors through a well defined group homomorphism

$$v^{pq}_r : E(\mathbf{E}^\bullet)^{pq}_r \to E(A^\bullet)^{pq}_r \qquad \text{for every } p, q \in \mathbb{Z} \text{ and } r \in \mathbb{N}.$$

Lastly, a simple inspection shows that the system of maps $v^{\bullet\bullet}_\bullet$ yields a morphism of spectral sequences $E(\mathbf{E}^\bullet)^{\bullet\bullet}_\bullet \to E(A^\bullet)^{\bullet\bullet}_\bullet$. Since v^{pq}_0 is an isomorphism for every $p, q \in \mathbb{Z}$, it follows that $v^{\bullet\bullet}_\bullet$ is an isomorphism of spectral sequences.

Let us endow $\mathrm{Coker}\, f$ with the filtration induced by $\mathrm{Fil}^\bullet A'$: namely

$$\mathrm{Fil}^p(\mathrm{Coker}\, f) := \mathrm{Im}(\mathrm{Fil}^pA' \to \mathrm{Coker}\, f) \qquad \text{for every } p \in \mathbb{Z}.$$

Likewise, we define a filtration $\mathrm{Fil}^\bullet\mathrm{Coker}\,\mathbf{E}(f)$ on $\mathrm{Coker}\,\mathbf{E}(f)$. Let moreover $\mathscr{T}_{A',p}$ be the p-adic topology on A', and $\mathscr{T}_{\mathbf{E}',\alpha_0}$ the α_0-adic topology on $\mathbf{E}'$.

Claim 16.3.44. C is open in $(A', \mathscr{T}_{A',p})$ (resp. D is open in $(\mathbf{E}', \mathscr{T}_{\mathbf{E}',\alpha_0})$) if and only if there exists $i \in \mathbb{N}$ such that $\mathrm{gr}^i\mathrm{Coker}\, f = 0$ (resp. such that $\mathrm{gr}^i\mathrm{Coker}\,\mathbf{E}(f) = 0$).

Proof of the claim. Clearly, if C is open in $(A', \mathscr{T}_{A',p})$, then we find $i \in \mathbb{N}$ with $\mathrm{gr}^i\mathrm{Coker}\, f = 0$. Conversely, if the latter condition holds, set $M := \mathrm{Fil}^i A' + C \subset A'$; we deduce that $M = pM + C$, whence $M = C$, by [126, Th.8.4] and lemma 16.2.3(v); *i.e.* $\mathrm{Fil}^i A' \subset C$, so C is open in $(A', \mathscr{T}_{A',p})$. Since $\mathbf{E}$ and $\mathbf{E}'$ are complete and separated for their α_0-adic topologies (see (16.2.19)), the same argument shows the assertion for D. ◊

According to (7.2.17), the spectral sequences $E(A^\bullet)^{\bullet\bullet}_{\bullet}$ and $E(\mathbf{E}^\bullet)^{\bullet\bullet}_{\bullet}$ admit natural abutments, and by inspecting the constructions, we deduce natural isomorphisms :

$$E(A^\bullet)^{a,1-a}_\infty \xrightarrow{\sim} \mathrm{gr}^a\mathrm{Coker}\, f \qquad E(\mathbf{E}^\bullet)^{a,1-a}_\infty \xrightarrow{\sim} \mathrm{gr}^a\mathrm{Coker}\,\mathbf{E}(f) \qquad \text{for every } a \in \mathbb{Z}.$$

Moreover, by proposition 7.2.18 they converge in degree 1. Since these spectral sequences are isomorphic, combining with claim 16.3.44 we conclude that C is open in $(A', \mathscr{T}_{A',p})$ if and only if D is open in $(\mathbf{E}', \mathscr{T}_{\mathbf{E}',\alpha_0})$.

(ii): By the foregoing, in order to prove the assertion we may assume that C is open in $(A', \mathscr{T}_{A',p})$ and D is open in $(\mathbf{E}', \mathscr{T}_{\alpha_0,\mathbf{E}'})$. Hence, $\alpha_0^n\mathbf{E}' \subset D$ for some $n \in \mathbb{N}$, and since D and $\mathbf{E}'$ are perfect rings, it follows easily that $\alpha_0\mathbf{E}' \subset D$, *i.e.* $\mathrm{gr}^1\mathrm{Coker}\,\mathbf{E}(f) = 0$. By the foregoing, we deduce that $\mathrm{gr}^1\mathrm{Coker}\, f = 0$ as well, *i.e.* $pA' \subset C$. Endow $\mathbf{E}'/\alpha_0\mathbf{E}'$ and A'/pA' with the quotient topologies $\mathscr{T}_{\mathbf{E}'/\alpha_0\mathbf{E}'}$ and $\mathscr{T}_{A'/pA'}$ induced by $\mathbf{E}'$ and A', and recall that $\overline{u}_{A'/pA'}$ induces an isomorphism of topological rings

$$\omega : (\mathbf{E}'/\alpha_0\mathbf{E}', \mathscr{T}_{\mathbf{E}'/\alpha_0\mathbf{E}'}) \xrightarrow{\sim} (A'/pA', \mathscr{T}_{A'/pA'})$$

(remark 16.3.7(ii)); clearly $\omega(C/pA') = D/\alpha_0\mathbf{E}'$, and especially C/pA' is open in A'/pA' if and only if $D/\alpha_0\mathbf{E}'$ is open in $\mathbf{E}'/\alpha_0\mathbf{E}'$. The contention follows immediately.

(iii.a): In view of (ii), the subring D is open in $\mathbf{E}'$; since D is perfect, it follows easily that $\mathbf{E}'^{\circ\circ} \subset D$. Endow $D/\alpha_0\mathbf{E}'$ (resp. C/pA') with the topology $\mathscr{T}'_{D/\alpha_0\mathbf{E}'}$ (resp. $\mathscr{T}'_{C/pA'}$) induced by $\mathscr{T}'_D$ via the projection $D \to D/\alpha_0\mathbf{E}'$ (resp. by $\mathscr{T}'_C$ via the projection $C \to C/pA'$). Then we have $(D, \mathscr{T}'_D)^{\circ\circ} = \mathbf{E}'^{\circ\circ}$, and notice that

$$(D/\alpha_0\mathbf{E}', \mathscr{T}'_{D/\alpha_0\mathbf{E}'})^{\circ\circ} = (D, \mathscr{T}'_D)^{\circ\circ}/\alpha_0\mathbf{E}' \qquad \text{and} \qquad (C/pA', \mathscr{T}'_{C/pA'})^{\circ\circ} = (C, \mathscr{T}'_C)^{\circ\circ}/pA'.$$

Moreover, according to lemma 8.2.3(i), the topology $\mathscr{T}'_{D/\alpha_0\mathbf{E}'}$ agrees with the topology induced by $\mathscr{T}_{\mathbf{E}'/\alpha_0\mathbf{E}'}$ via the inclusion map $D/\alpha_0\mathbf{E}' \to \mathbf{E}'/\alpha_0\mathbf{E}'$, and likewise for $\mathscr{T}'_{C/pA'}$; it follows that the foregoing isomorphism ω restricts to an isomorphism of topological rings

$$(C/pA', \mathscr{T}'_{C/pA'}) \xrightarrow{\sim} (D/\alpha_0\mathbf{E}', \mathscr{T}'_{D/\alpha_0\mathbf{E}'}).$$

Since $(D/\alpha_0\mathbf{E}', \mathscr{T}'_{D/\alpha_0\mathbf{E}'})^{\circ\circ} = \mathbf{E}'^{\circ\circ}/\alpha_0\mathbf{E}' = (\mathbf{E}'/\alpha_0, \mathscr{T}_{\mathbf{E}'/\alpha_0})^{\circ\circ}$, we get $(C/pA', \mathscr{T}'_{C/pA'})^{\circ\circ} = (A'/pA', \mathscr{T}_{A'/pA'})^{\circ\circ} = A'^{\circ\circ}/pA'$, and finally $A'^{\circ\circ} = (C, \mathscr{T}'_C)^{\circ\circ}$.

(i): If f is bijective, then clearly the same holds for $\mathbf{E}(f)$; conversely, if $\mathbf{E}(f)$ is bijective, then the same holds for

$$W(\mathbf{E})/\alpha_\bullet W(\mathbf{E}) \otimes_{W(\mathbf{E})} W(\mathbf{E}(f)) : W(\mathbf{E})/\alpha_\bullet W(\mathbf{E}) \to W(\mathbf{E}')/\alpha_\bullet W(\mathbf{E}').$$

But the image of $\alpha_\bullet$ is still distinguished in $W(\mathbf{E}')$, and lies in $\mathrm{Ker}\, u_{A'}$, hence the latter map is naturally identified with f; especially, f is bijective.

- If either f or $\mathbf{E}(f)$ is surjective, then $pA' \subset C$ and $\alpha_0\mathbf{E}' \subset D$ by the proof of (ii), and moreover the isomorphism $\mathbf{E}'/\alpha_0\mathbf{E}' \xrightarrow{\sim} A'/pA'$ induced by $\overline{u}_{A/pA}$ restricts to an isomorphism $D/\alpha_0\mathbf{E}' \xrightarrow{\sim} C/pA'$. Then clearly $C = A'$ if and only if $D = \mathbf{E}'$.
- Next, let $\mathscr{J} \subset \mathbf{E}$ be any ideal of definition, $(\beta_1, \dots, \beta_k)$ a finite system of generators for $\mathscr{J}$, and $J \subset A$ the ideal generated by $(\overline{u}_A(\beta_1), \dots, \overline{u}_A(\beta_k))$. By corollary 16.3.40(ii), the ideal JA' is open in A' if and only if $\mathscr{J}\mathbf{E}'$ is open in $\mathbf{E}'$. Moreover, $\mathscr{J}\mathbf{E}'$ (resp. JA') is topologically nilpotent in $\mathbf{E}'$ (resp. in A'), since the same holds for $\mathscr{J}$ (resp. for J); thus, $\mathscr{J}\mathbf{E}'$ is an ideal of adic definition for $\mathbf{E}'$ if and only if JA' is an ideal of adic definition for A', *i.e.* f is adic if and only if $\mathbf{E}(f)$ is adic.

• If either f of $\mathbf{E}(f)$ is open, we know already that C is open in A' and D is open in $\mathbf{E}'$, by (ii). Also, by the foregoing we know already that f is adic if and only if the same holds for $\mathbf{E}(f)$; combining with proposition 8.3.18(v), we conclude that f is open if and only if the same holds for $\mathbf{E}(f)$.

• Lastly, if either f or $\mathbf{E}(f)$ is open and injective, by the foregoing we know already that both f and $\mathbf{E}(f)$ are open, and then $A'^{\circ\circ} \subset C$ and $\mathbf{E}'^{\circ\circ} \subset D$, by (iii.a). Endow $\overline{A}' := A'/A'^{\circ\circ}$, $\overline{\mathbf{E}}' := \mathbf{E}'/\mathbf{E}'^{\circ\circ}$, $\overline{C} := C/A'^{\circ\circ}$ and $\overline{D} := D/\mathbf{E}'^{\circ\circ}$ with their discrete topologies; then the foregoing isomorphism ω induces a ring isomorphism $\overline{\mathbf{E}}' \xrightarrow{\sim} \overline{A}'$, restricting to a ring isomorphism $\overline{D} \xrightarrow{\sim} \overline{C}$. Moreover, we get natural isomorphisms of topological rings :

$$(C, \mathscr{T}'_C) \xrightarrow{\sim} \overline{C} \times_{\overline{A}'} A' \qquad \text{and} \qquad (D, \mathscr{T}'_D) \xrightarrow{\sim} \overline{D} \times_{\overline{\mathbf{E}}'} \mathbf{E}'.$$

Taking into account proposition 16.3.25, it follows that the projection $A \to (C, \mathscr{T}'_C)$ is an isomorphism of topological rings if and only if the same holds for the projection $\mathbf{E} \to (D, \mathscr{T}'_D)$; *i.e.* f is open and injective if and only if the same holds for $\mathbf{E}(f)$.

(iii.b): The map $\mathbf{E}(f)$ is a composition of continuous ring homomorphisms :

$$\mathbf{E} \xrightarrow{g_1} (D, \mathscr{T}_D) \xrightarrow{g_2} (D, \mathscr{T}'_D) \xrightarrow{g_3} \mathbf{E}'$$

where g_1 is open and surjective, g_2 is bijective, and g_3 is an open injective map. Since $\operatorname{Ker} g_1 = \operatorname{Ker} \mathbf{E}(f)$ is a closed ideal of $\mathbf{E}$, we see that $(D, \mathscr{T}_D)$ is a perfect, separated and complete topological ring (proposition 8.2.13(v)) whose topology is I-adic, for an ideal $I \subset D$ of finite type, *i.e.* $(D, \mathscr{T}_D)$ is perfectoid, and the same holds for $(D, \mathscr{T}'_D)$, by virtue of corollaries 8.3.20(i) and 8.3.19(iii). Since the category of perfectoid A-algebras is equivalent to that perfectoid $\mathbf{E}$-algebras (remark 16.3.7(i)) we deduce a corresponding factorization of f :

$$A \xrightarrow{f_1} C_1 \xrightarrow{f_2} C_2 \xrightarrow{f_3} A'$$

where C_1 and C_2 are perfectoid A-algebras with isomorphisms of perfectoid $\mathbf{E}$-algebras

$$\mathbf{E}(C_1) \xrightarrow{\sim} (D, \mathscr{T}_D) \qquad \text{and} \qquad \mathbf{E}(C_2) \xrightarrow{\sim} (D, \mathscr{T}'_D).$$

Moreover, f_1 is open and surjective, f_2 is bijective, and f_3 is open and injective, by (i). But then C_1 is isomorphic to $(C, \mathscr{T}_C)$ and C_2 is isomorphic to $(C, \mathscr{T}'_C)$, whence the contention. □

16.3.45. Let $A_\bullet := (A_\lambda \mid \lambda \in \Lambda)$ be a filtered system of perfectoid rings, with adic transition maps, and for every $\lambda \in \Lambda$ set $\mathbf{E}_\lambda := \mathbf{E}(A_\lambda)$. By virtue of theorem 16.3.42(i), the transition maps of the induced system $\mathbf{E}_\bullet := (\mathbf{E}_\lambda \mid \lambda \in \Lambda)$ are also adic. Endow the colimit A of $A_\bullet$ (resp. $\mathbf{E}$ of $\mathbf{E}_\bullet$) of the unique adic topology $\mathscr{T}_A$ (resp. $\mathscr{T}_\mathbf{E}$) such that the universal co-cone $(\tau_{A,\lambda} : A_\lambda \to A \mid \lambda \in \Lambda)$ (resp. $(\tau_{\mathbf{E},\lambda} : \mathbf{E}_\lambda \to \mathbf{E} \mid \lambda \in \Lambda)$) consists of adic maps. We have :

Corollary 16.3.46. *In the situation of* (16.3.45)*, the separated completion $A^\wedge$ of $(A, \mathscr{T}_A)$ (resp. $\mathbf{E}^\wedge$ of $(\mathbf{E}, \mathscr{T}_\mathbf{E})$) is perfectoid, and there exists a unique isomorphism of topological rings*

$$\omega : \mathbf{E}(A^\wedge) \xrightarrow{\sim} \mathbf{E}^\wedge \qquad \textit{such that} \qquad \omega \circ \mathbf{E}(\tau^\wedge_{A,\lambda}) = \tau^\wedge_{\mathbf{E},\lambda} \qquad \textit{for every } \lambda \in \Lambda.$$

Proof. We may assume that Λ admits an initial element λ_0, and let $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N})$ be a distinguished element in $\operatorname{Ker}(u_{A_{\lambda_0}})$. It suffices to show that there exists a unique isomorphism of topological rings

$$\omega' : A^\wedge \xrightarrow{\sim} A_{\lambda_0} \otimes_{W(\mathbf{E}_{\lambda_0})} W(\mathbf{E}^\wedge) \quad \text{such that} \quad \omega' \circ \tau^\wedge_{A,\lambda} = A_{\lambda_0} \otimes_{W(\mathbf{E}_{\lambda_0})} W(\tau^\wedge_{\mathbf{E},\lambda}) \text{ for every } \lambda \in \Lambda$$

(under the natural identification $A_\lambda \xrightarrow{\sim} A_0 \otimes_{W(\mathbf{E}_{\lambda_0})} W(\mathbf{E}_\lambda)$). Let $\beta_1, \dots, \beta_k$ be a finite sequence of elements of $\mathbf{E}_{\lambda_0}$ that generates an ideal of adic definition. Let $\mathscr{W}$ be the colimit of the induced system $(W(\mathbf{E}_\lambda) \mid \lambda \in \Lambda)$; denote by $\mathscr{I}_0 \subset W(A_{\lambda_0})$ the ideal generated by the sequence

$(p, \tau_{A_{\lambda_0}}(\beta_1), \dots, \tau_{A_{\lambda_0}}(\beta_k))$, so that the topology of $W(A_{\lambda_0})$ is $\mathscr{I}_0$-adic (proposition 9.3.77(ii)). Let also $\mathscr{W}^\wedge$ be the separated completion of $\mathscr{W}$; by corollary 9.3.79, the natural map

$$\mathscr{W}^\wedge \to W(\mathbf{E}^\wedge)$$

is an isomorphism of topological rings. On the other hand, we have a short exact sequence :

$$0 \to \underline{\alpha}\mathscr{W} \to \mathscr{W} \xrightarrow{u} A \to 0$$

and the topology of A is induced by $\mathscr{W}$ via u. By proposition 8.2.13(iii), it follows that the kernel of the induced map $u^\wedge : \mathscr{W}^\wedge \to A^\wedge$ is the topological closure of the image of $\underline{\alpha}\mathscr{W}$; the latter is also the topological closure of $\underline{\alpha}\mathscr{W}^\wedge$, and moreover it is easily seen that $A^\wedge$ is a P-ring. Hence, $\mathrm{Ker}\, u^\wedge = \underline{\alpha}\mathscr{W}^\wedge$ (proposition 16.2.23(ii)), whence the corollary. □

In the situation of theorem 16.3.36, let $\mathscr{K}$ and $\mathscr{K}'$ be any two closed and taut ideals of $\mathbf{E}$; we would like to show that $\mathscr{K} = \mathscr{K}'$ if and only if $\{\mathscr{K}\} = \{\mathscr{K}'\}$, and taking into account theorem 16.3.36(iii), it would suffice to prove that $\{\mathscr{K} \cap \mathscr{K}'\} = \{\mathscr{K}\} \cap \{\mathscr{K}'\}$. We do not know whether the latter identity always holds, but we have at least the following :

Theorem 16.3.47. *Let A be any perfectoid ring, $\mathscr{K}$ and $\mathscr{K}'$ two taut and closed ideals of $\mathbf{E} := \mathbf{E}(A)$, and $(\alpha_n \mid n \in \mathbb{N})$ any distinguished element of* $\mathrm{Ker}\, u_A$. *Suppose that either one of the following conditions holds :*

(a) $\alpha_0 \in \mathscr{K}'$
(b) *$\mathscr{K}'$ is strictly taut and $\alpha_0^n \subset \mathscr{K}'$ for some sufficiently large $n \in \mathbb{N}$.*

Then $\{\mathscr{K} \cap \mathscr{K}'\} = \{\mathscr{K}\} \cap \{\mathscr{K}'\}$.

Proof. Suppose that (a) holds; in this case, both inclusions $\mathscr{K}' \subset \mathbf{E}$ and $\mathscr{K}' \cap \mathscr{K} \subset \mathscr{K}$ are taut, by remark 16.3.28(iv). There follows a commutative diagram of A/pA-modules

$$\begin{array}{ccc} \mathscr{K}/(\mathscr{K}' \cap \mathscr{K}) & \longrightarrow & \{\mathscr{K}\}/\{\mathscr{K}' \cap \mathscr{K}\} \\ \downarrow & & \downarrow \\ \mathbf{E}/\mathscr{K}' & \longrightarrow & A/\{\mathscr{K}'\} \end{array}$$

both of whose horizontal arrows are isomorphisms, by theorem 16.3.31(ii), and whose left vertical arrow is clearly injective. Then the right vertical arrow is injective as well, whence the contention, in this case.

In case (b) holds, pick $\varepsilon \in \mathbb{N}[1/p]$ with $0 < \varepsilon < 1$ and such that $\mathscr{K}'$ is $\alpha_0^{1-\varepsilon}$-taut. We set

$$\mathscr{I}_n := \{x \in \mathbf{E} \mid \alpha_0^{n\varepsilon} x \in \mathscr{I}\} \qquad \text{for every } n \in \mathbb{N} \text{ and every ideal } \mathscr{I} \subset \mathbf{E}.$$

Claim 16.3.48. With the foregoing notation we have :

(i) $\mathscr{K}'_n$ is a closed ideal of $\mathbf{E}$, for every $n \in \mathbb{N}$.
(ii) The inclusion $\mathscr{K}'_n \subset \mathscr{K}'_{n+1}$ is taut for every $n \in \mathbb{N}$.
(iii) $\mathscr{K}'_0 = \mathscr{K}'$ and $\mathscr{K}'_r = \mathbf{E}$ for every sufficiently large $r \in \mathbb{N}$.

Proof of the claim. Since $\mathscr{K}'$ is closed, it is easily seen that (i) holds. Say that $\alpha_0^n \in \mathscr{K}'$; then clearly $\mathscr{K}'_k = \mathbf{E}$ for every integer $k \geq \varepsilon^{-1}n$. Next, directly from the definition we see that, for any two ideals $\mathscr{I}, \mathscr{J} \subset \mathbf{E}$ and any $n \in \mathbb{N}$ we have

$$\mathscr{J} \cdot \mathscr{I}_n \subset (\mathscr{J}\mathscr{I})_n \qquad \alpha_0^\varepsilon \cdot \mathscr{I}_{n+1} \subset \mathscr{I}_n \qquad (\mathscr{I}_n)^p \subset (\mathscr{I}^p)_{np} \qquad (\Phi_{\mathbf{E}}^{-1}\mathscr{I})_n = \Phi_{\mathbf{E}}^{-1}(\mathscr{I}_{np}).$$

Therefore :

$$\begin{aligned}\alpha_0 \cdot \Phi_{\mathbf{E}}^{-1}(\mathscr{K}'_{n+1})^p &\subset \alpha_0 \cdot \Phi_{\mathbf{E}}^{-1}((\mathscr{K}'^p)_{(n+1)p}) \\ &= \alpha_0 \cdot (\Phi_{\mathbf{E}}^{-1}\mathscr{K}'^p)_{n+1} \\ &\subset \alpha_0^{1-\varepsilon} \cdot (\Phi_{\mathbf{E}}^{-1}\mathscr{K}'^p)_n \\ &\subset (\alpha_0^{1-\varepsilon} \cdot \Phi_{\mathbf{E}}^{-1}\mathscr{K}'^p)_n \\ &\subset \mathscr{K}'_n\end{aligned}$$

as required. ◊

By claim 16.3.48 we have $\mathscr{K}'_r = \mathbf{E}$ for some $r \in \mathbb{N}$, and for every $n \in \mathbb{N}$ we get a commutative diagram of A/pA-modules

$$\begin{array}{ccc}\{\mathscr{K} \cap \mathscr{K}'_{n+1}\}/\{\mathscr{K} \cap \mathscr{K}'_n\} & \longrightarrow & \{\mathscr{K}'_{n+1}\}/\{\mathscr{K}'_n\} \\ \downarrow & & \downarrow \\ (\mathscr{K} \cap \mathscr{K}'_{n+1})/(\mathscr{K} \cap \mathscr{K}'_n) & \longrightarrow & \mathscr{K}'_{n+1}/\mathscr{K}'_n\end{array}$$

whose vertical arrows are isomorphisms, by theorem 16.3.31(ii), and whose bottom horizontal arrow is injective. Then the top horizontal arrow is injective as well, so that

$$\{\mathscr{K} \cap \mathscr{K}'_{n+1}\} \cap \{\mathscr{K}'_n\} \subset \{\mathscr{K} \cap \mathscr{K}'_n\} \qquad \text{for every } n \in \mathbb{N}.$$

We may now prove that $\{\mathscr{K}\} \cap \{\mathscr{K}'_n\} = \{\mathscr{K} \cap \mathscr{K}'_n\}$, by descending induction on n. Indeed, the assertion is obvious in case $n \geq r$. Suppose that the identity has already been shown for some $n > 0$; then we get

$$\{\mathscr{K}\} \cap \{\mathscr{K}'_{n-1}\} = \{\mathscr{K}\} \cap \{\mathscr{K}'_n\} \cap \{\mathscr{K}'_{n-1}\} = \{\mathscr{K} \cap \mathscr{K}'_n\} \cap \{\mathscr{K}'_{n-1}\} \subset \{\mathscr{K} \cap \mathscr{K}'_{n-1}\}$$

and the converse inclusion is obvious, so the sought identity holds for $n-1$. Letting $n = 0$, we get the assertion. □

In the same vein, let us also point out :

Lemma 16.3.49. *In the situation of theorem* 16.3.47*, let* $\lambda_1, \lambda_2 \in \mathbb{N}[1/p]$ *be two rationals such that* $\lambda_1 + \lambda_2 \leq 1$*, and* $\mathscr{J}_1, \mathscr{J}_2 \subset \mathbf{E}$ *two ideals such that* $\mathscr{J}_i$ *is* $\alpha_0^{\lambda_i}$*-taut for* $i = 1, 2$*. Then*

$$(\{\mathscr{J}_1\}\{\mathscr{J}_2\})^c = \{\mathscr{J}_1\mathscr{J}_2\}.$$

Proof. The inclusion $\{\mathscr{J}_1\}\{\mathscr{J}_2\} \subset \{\mathscr{J}_1\mathscr{J}_2\}$ is obvious from the definitions, so it suffices to check that for every $x \in \mathscr{J}_1\mathscr{J}_2$ we have $\overline{u}_A(x) \in (\{\mathscr{J}_1\}\{\mathscr{J}_2\})^c$. However, every such x can be written as a finite sum $\sum_{i=1}^n y_i z_i$, with $y_1, \dots, y_n \in \mathscr{J}_1$ and $z_1, \dots, z_n \in \mathscr{J}_2$; by proposition 9.3.62 we know that $\overline{u}_A(x)$ is the limit of a p-adically convergent series of the form $\sum_{j\in\mathbb{N}} w_j$, where in turn each w_j is a finite $\mathbb{Z}_p$-linear combination of terms of the form

$$w_j^{\underline{\mu}} := p^j \cdot \overline{u}_A((y_1z_1)^{\mu_1} \cdots (y_nz_n)^{\mu_n}) \quad \text{for certain } \mu_1, \dots, \mu_n \in p^{-j}\mathbb{N} \text{ such that } \sum_{i=1}^n \mu_i = 1.$$

Thus, we are reduced to checking that any such term lies in $\{\mathscr{J}_1\}\{\mathscr{J}_2\}$. Now, set $y^{\underline{\mu}} := y_1^{\mu_1} \cdots y_n^{\mu_n}$, and define likewise $z^{\underline{\mu}}$, for every $\underline{\mu} := (\mu_1, \dots, \mu_n) \in p^{-j}\mathbb{N}$; under our assumptions we have $p = \overline{u}_A(\alpha_0^{\lambda_1+\lambda_2}) \cdot a$ for some $a \in A$ (lemma 16.2.7(iii)), hence

$$w_j^{\underline{\mu}} = a^j \cdot \overline{u}_A(\alpha_0^{j\lambda_1} \cdot y^{\underline{\mu}}) \cdot \overline{u}_A(\alpha_0^{j\lambda_2} \cdot z^{\underline{\mu}})$$

and notice that $\alpha_0^{j\lambda_1} \cdot y^{\underline{\mu}} \in \alpha_0^{j\lambda_1} \cdot \Phi_{\mathbf{E}}^{-j}(\mathscr{J}_1^{p^j}) \subset \mathscr{J}_1$ by (16.3.29). Likewise, $\alpha_0^{j\lambda_2} \cdot z^{\underline{\mu}} \in \mathscr{J}_2$, and the assertion follows. □

Corollary 16.3.50. *Let A be a perfectoid ring, $\mathscr{K}, \mathscr{K}' \subset \mathbf{E}(A)$ two taut and closed ideals, and suppose that either $\mathscr{K}$ or $\mathscr{K}'$ fulfills conditions* (a) *and* (b) *of theorem* 16.3.47*. Then we have $\mathscr{K} \subset \mathscr{K}'$ if and only if $\{\mathscr{K}\} \subset \{\mathscr{K}'\}$.*

Proof. As already announced, this follows straightforwardly from remark 16.3.28(iv) and theorems 16.3.47 and 16.3.36(iii). □

Corollary 16.3.51. *In the situation of corollary* 16.3.40*, let $a'_\bullet := (a'_1, \dots, a'_t)$ be another finite system of elements of $\mathbf{E}$, and $J' \subset \mathbf{E}$ the ideal generated by $a'_\bullet$. Define the ideal $[a'_\bullet]^{\langle\beta\rangle} \subset W(\mathbf{E})$ as in remark* 9.3.70(iii)*, for every $\beta \in \mathbb{N}[1/p]$. Moreover, let $\lambda, \mu \in \mathbb{N}[1/p]$ be any two rational numbers. We have :*

(i) *The following conditions are equivalent :*
   (a) $J^{\langle\lambda\rangle}\mathbf{E} \subset J'^{\lfloor\mu\rfloor}\mathbf{E}$.
   (b) $[a_\bullet]^{\langle\lambda\rangle}A \subset [a'_\bullet]^{\langle\mu-\varepsilon\rangle}A$ *for every $\varepsilon \in \mathbb{N}[1/p]$ with $0 < \varepsilon \leq \mu$.*

(ii) *Suppose that either J or J' is open. Then the following conditions are equivalent :*
   (a) $J^{\langle\lambda\rangle}\mathbf{E} \subset J'^{\langle\mu\rangle}\mathbf{E}$.
   (b) $[a_\bullet]^{\langle\lambda\rangle}A \subset [a'_\bullet]^{\langle\mu\rangle}A$.

(iii) *For every $l, m \in \mathbb{N}[1/p]$ such that $l\mu + m\lambda < \lambda\mu$ we have*

$$[a_\bullet]^{\langle\lambda\rangle}A \cap [a'_\bullet]^{\langle\mu\rangle}A \subset [a_\bullet]^{\langle l\rangle} \cdot [a'_\bullet]^{\langle m\rangle}A.$$

Proof. (i): Suppose that (i.a) holds; we deduce :

$$[a_\bullet]^{\langle\lambda\rangle}A \subset \{J^{\langle\lambda\rangle}\mathbf{E}\} \subset \{J'^{\langle\mu-\varepsilon/p\rangle}\mathbf{E}\} \subset [a'_\bullet]^{\langle\mu-\varepsilon\rangle}A \qquad \text{for every } \varepsilon \text{ as in (i.b)}$$

where the first and last inclusions follow from corollary 16.3.40(i).

Conversely, suppose that (i.b) holds; fix a finite system $b_\bullet := (b_1, \dots, b_r)$ of generators for an ideal of definition I of the perfectoid ring $\mathbf{E}$, and for every $n \in \mathbb{N}$, let $b^n_\bullet$ be the finite system consisting of the products of the form $b_{j(1)} \cdots b_{j(n)}$, where j ranges over all the mappings $\{1, \dots, n\} \to \{1, \dots, r\}$. For every $n \in \mathbb{N}$, we may then form the system $(a'_\bullet, b^n_\bullet)$ which is the union of the systems $a'_\bullet$ and $b^n_\bullet$, and for every $\lambda \in \mathbb{N}[1/p]$ consider the ideal $[a'_\bullet, b^n_\bullet]^{\langle\lambda\rangle} \subset W(\mathbf{E})$ attached as in remark 9.3.70(iii) to the system $(a'_\bullet, b^n_\bullet)$. With this notation, corollary 16.3.40(ii) yields :

$$[a_\bullet]^{\langle\lambda\rangle}A \subset [a'_\bullet, b^n_\bullet]^{\langle\mu-\varepsilon/p\rangle}A = \{(J' + I^n)^{\langle\mu-\varepsilon/p\rangle}\mathbf{E}\} \qquad \text{for every } n \in \mathbb{N} \text{ and } \varepsilon \text{ as in (i.a).}$$

However, since the topology of A is coarser than the p-adic topology, claim 16.3.41 implies that $[a_\bullet]^{\langle\lambda\rangle}A$ is a dense subset of $\{J^{\langle\lambda\rangle}\mathbf{E}\}$; but $\{(J' + I^n)^{\langle\mu-\varepsilon/p\rangle}\mathbf{E}\}$ is a closed ideal, so

$$\{J^{\langle\lambda\rangle}\mathbf{E}\} \subset \{(J' + I^n)^{\langle\mu-\varepsilon/p\rangle}\mathbf{E}\} \qquad \text{for every } n \in \mathbb{N} \text{ and } \varepsilon \text{ as in (i.a).} \tag{16.3.52}$$

Now, the topological closure $J^{\langle\lambda\rangle}\mathbf{E}^c$ of $J^{\langle\lambda\rangle}\mathbf{E}$ is (strictly) taut, and $\{J^{\langle\lambda\rangle}\mathbf{E}\} = \{J^{\langle\lambda\rangle}\mathbf{E}^c\}$ (remark 16.3.28(v)); moreover, $(J' + I^n)^{\langle\mu-\varepsilon/p\rangle}\mathbf{E}$ is an open ideal of $W(\mathbf{E})$, hence, from corollary 16.3.50 and (16.3.52) we derive

$$J^{\langle\lambda\rangle}\mathbf{E}^c \subset (J' + I^n)^{\langle\mu-\varepsilon/p\rangle}\mathbf{E} \qquad \text{for every } n \in \mathbb{N} \text{ and } \varepsilon \text{ as in (i.a)}$$

and combining with claim 16.3.20 we conclude that $J^{\langle\lambda\rangle}\mathbf{E} \subset J'^{\langle\mu-\varepsilon\rangle}\mathbf{E}$ for every ε as in (i.a).

(ii): From lemma 9.3.69(ii.a,iv) it follows easily that J is open if and only if the same holds for $J^{\langle\lambda\rangle}\mathbf{E}$, and likewise, J' is open if and only if the same holds for $J'^{\langle\mu\rangle}\mathbf{E}$. Hence, suppose that J is open; if condition (ii.a) holds, then it follows that J' is open as well, and if (ii.b) holds, we use corollary 16.3.40(ii) to deduce first that $[a_\bullet]^{\langle\lambda\rangle}A$ is open, so the same holds for $[a'_\bullet]^{\langle\mu\rangle}A$, and then also for J', again by corollary 16.3.40(ii). In conclusion, for the proof of (ii) we may assume that J' is open. Now, suppose that (ii.a) holds; then we get

$$[a_\bullet]^{\langle\lambda\rangle}A \subset \{J^{\langle\lambda\rangle}\mathbf{E}\} \subset \{J'^{\langle\mu\rangle}\mathbf{E}\} = [a'_\bullet]^{\langle\mu\rangle}A$$

where the first inclusion follows from corollary 16.3.40(i), and the last identity follows from corollary 16.3.40(ii). Conversely, suppose that (ii.b) holds; since the topology of A is coarser that the p-adic topology, claim 16.3.41 implies that $[a_\bullet]^{\langle\lambda\rangle}A$ is a dense subset of $\{J^{\langle\lambda\rangle}\mathbf{E}\}$, and since $\{J'^{\langle\mu\rangle}\mathbf{E}\}$ is a closed ideal, corollary 16.3.40(ii) yields $\{J^{\langle\lambda\rangle}\mathbf{E}\} \subset \{J'^{\langle\mu\rangle}\mathbf{E}\}$. Then, arguing as in the proof of (i), we easily deduce that (ii.a) holds.

(iii): We may assume that $\lambda, \mu > 0$, since otherwise there is nothing to prove. Define $b^n_\bullet$ as in the foregoing, for every $n \in \mathbb{N}$; combining corollary 16.3.40(i) and theorem 16.3.47, we get

$$[a_\bullet, b^n_\bullet]^{\langle\lambda\rangle}A \cap [a'_\bullet, b^n_\bullet]^{\langle\mu\rangle}A = \{(J+I^n)^{\langle\lambda\rangle}\mathbf{E}\} \cap \{(J'+I^n)^{\langle\mu\rangle}\mathbf{E}\} = \{(J+I^n)^{\langle\lambda\rangle}\mathbf{E} \cap (J'+I^n)^{\langle\mu\rangle}\mathbf{E}\}$$

for every $n \in \mathbb{N}$. Now, pick $\alpha \in \mathbb{N}[1/p]$ such that $l/\lambda < 1-\alpha$ and $m/\mu < \alpha$ and set $l' := (1-\alpha)\lambda$, $m' := \alpha\mu$. If $x \in (J+I^n)^{\langle\lambda\rangle}\mathbf{E} \cap (J'+I^n)^{\langle\mu\rangle}\mathbf{E}$, we may write

$$x = x^\alpha \cdot x^{1-\alpha} \in (J+I^n)^{\langle l'\rangle} \cdot (J'+I^n)^{\langle m'\rangle}\mathbf{E}.$$

Next, to ease notation, for any finite sequence $\nu_\bullet := (\nu_1, \dots, \nu_m)$ of elements of $\mathbb{N}[1/p]$ and any sequence $(x_1, \dots, x_m)$ of elements of $\mathbf{E}$, set

$$x^{\nu_\bullet}_\bullet := x_1^{\nu_1} \cdots x_m^{\nu_m} \qquad \text{and} \qquad |\nu_\bullet| := \nu_1 + \cdots + \nu_m.$$

We remark that the ideal $(J+I^n)^{\langle l'\rangle} \cdot (J'+I^n)^{\langle m'\rangle}\mathbf{E}$ is generated by all products

$$a^{\nu_\bullet}_\bullet \cdot a'^{\nu'_\bullet}_\bullet \cdot b^{\beta_\bullet}_\bullet \cdot b^{\beta'_\bullet}_\bullet \qquad \text{where} \qquad |\nu_\bullet| + n^{-1} \cdot |\beta_\bullet| = l' \qquad |\nu'_\bullet| + n^{-1} \cdot |\beta'_\bullet| = m'.$$

Fix $l'', m'' \in \mathbb{N}[1/p]$ such that $l < l'' < l'$ and $m < m'' < m'$, and set $\varepsilon := (l'-l'') + (m'-m'')$; it is easily seen that each of the above products lies either in $J^{\langle l''\rangle} \cdot J'^{\langle m''\rangle}\mathbf{E}$ or else in $I^{\langle n\varepsilon\rangle}\mathbf{E}$. Moreover, we can write $l'' = p^{-N}f$, $m'' := p^{-N}g$ for suitable $f, g, N \in \mathbb{N}$, and summing up, we conclude that, for every $\delta < p^{-N}$, the ideal $[a_\bullet]^{\langle\lambda\rangle}A \cap [a'_\bullet]^{\langle\mu\rangle}A$ is contained in :

$$\bigcap_{n\in\mathbb{N}} \{J^{\langle l''\rangle} \cdot J'^{\langle m''\rangle}\mathbf{E} + I^{\langle n\varepsilon\rangle}\mathbf{E}\} = \bigcap_{n\in\mathbb{N}} \{(J^f J'^g)^{\langle 1/p^N\rangle}\mathbf{E} + I^{\langle n\varepsilon\rangle}\mathbf{E}\} \subset \{(J^f J'^g)^{\langle\delta\rangle}\mathbf{E}\}$$

where the first equality follows from lemma 9.3.69(ii.a,iii) the last inclusion follows from corollary 16.3.40(iii.b). Let us then choose $\delta, \delta' \in \mathbb{N}[1/p]$ with $p^{-N} > \delta > \delta'$ and δ' close enough to p^{-N}, so that $\delta' \cdot f > l$ and $\delta' \cdot g > m$; using corollary 16.3.40(i) we get

$$\{(J^f J'^g)^{\langle\delta\rangle}\mathbf{E}\} \subset [a^f_\bullet a'^g_\bullet]^{\langle\delta'\rangle}A \subset [a_\bullet]^{\langle l\rangle} \cdot [a'_\bullet]^{\langle m\rangle}A$$

whence the contention. □

As an application, we can complement as follows theorem 16.3.21(i) :

Proposition 16.3.53. *In the situation of theorem* 16.3.21*, we have :*

(i) (16.3.12) *is a cartesian diagram of topological rings.*
(ii) *All the topological rings appearing in* (16.3.12) *are perfectoid.*

Proof. We know already that (16.3.17) is a cartesian diagram of topological rings. Moreover, it is easily seen that the I-adic topology on A agrees with the $(I+pA)$-adic topology, and likewise for the J-adic and $(I+J)$-adic topologies, so all the topological rings appearing in (16.3.17) except possibly for $(A', \mathscr{T}')$ are perfectoid (proposition 16.3.8(ii)). By the same token, the IJ-adic topology on A agrees with the $(IJ+pA)$-adic topology, so the proposition will follow, once we have shown the following

Claim 16.3.54. The IJ-adic topology on A agrees with the linear topology $\mathscr{T}$ defined by the cofiltered system of ideals $(I^n \cap J^n \mid n \in \mathbb{N})$.

Proof of the claim. Set $I' := I + pA$ and $J' := J + pA$, and notice that $I^{k+N} \subset I'^{N+k} \subset I^{k+1}$ for every $k \in \mathbb{N}$, and likewise for J. Therefore, $\mathscr{T}$ agrees with the topology defined by the cofiltered system of ideals $(I'^n \cap J'^n \mid n \in \mathbb{N})$, and the IJ-adic topology on A agrees with the $I'J'$-adic topology. Thus, we can replace I, J by I', J', and assume from start that

$p \in I \cap J$. Now, let $(\alpha_n \mid n \in \mathbb{N})$ be any distinguished element in $\mathrm{Ker}\, u_A$. Fix finite systems $\beta_\bullet := (\beta_1, \dots, \beta_k)$ and $\beta'_\bullet := (\beta'_1, \dots, \beta'_r)$ of elements of $\mathbf{E}(A)$ such that $\overline{u}_{A/pA}(\beta_\bullet)$ (resp. $\overline{u}_{A/pA}(\beta'_\bullet)$) is a system of generators for I/pA (resp. for J/pA). In light of lemma 16.2.7(iii), it follows that the sequence $(\overline{u}_A(\alpha_0), \overline{u}_A(\beta_1), \dots, \overline{u}_A(\beta_k))$ is a system of generators for I, and $(\overline{u}_A(\alpha_0), \overline{u}_A(\beta'_1), \dots, \overline{u}_A(\beta'_r))$ is a system of generators for J. On the other hand, lemma 9.3.69(iv) implies that the I-adic (resp. J-adic) topology on A agrees with the linear topology defined by the cofiltered system of ideals $([\alpha_0, \beta_\bullet]^{\langle\lambda\rangle} A \mid \lambda \in \mathbb{N}[1/p])$ (resp. $([\alpha_0, \beta'_\bullet]^{\langle\lambda\rangle} A \mid \lambda \in \mathbb{N}[1/p])$). Then, the claim follows from corollary 16.3.51(iii). □

16.3.55. Let A be a ring, and $a_\bullet := (a_1, \dots, a_k)$ a finite system of elements of A; denote by I the ideal generated by $a_\bullet$, and suppose that

$$p \in I^t \qquad \text{where } t := k(p-1)+1. \tag{16.3.56}$$

Set $J := I^{(p)}$, the ideal generated by the system $(a_1^p, \dots, a_k^p)$, and notice that

$$I^t \subset J. \tag{16.3.57}$$

Therefore J is well defined independently of the choice of $a_\bullet$ (lemma 16.2.2). Denote by $\mathrm{gr}^\bullet_I A$ (resp. $\mathrm{gr}^\bullet_J A$) the graded ring associated with the I-adic (resp. J-adic) filtration on A. Notice that both these two rings are $\mathbb{F}_p$-algebras.

Remark 16.3.58. Let A be any P-ring, I any ideal of definition of A, and $(a_1, \dots, a_k)$ a system of generators of I. By virtue of lemma 16.2.3(iii) and its proof, we may find a sequence of ideals $(I_n \mid n \in \mathbb{N})$ such that

- $I^{(p)}_{n+1} = I_n$ for every $n \in \mathbb{N}$
- I_n admits a system of generators consisting of k elements of A.

Then I_n is still an ideal of definition of A for every $n \in \mathbb{N}$, and $p \in I_n^t$ for every sufficiently large $n \in \mathbb{N}$, where t is defined as in (16.3.55). We may thus regard the following result as a refinement of corollary 16.3.3.

Proposition 16.3.59. *In the situation of* (16.3.55)*, the following holds :*

(i) *The Frobenius endomorphism of* $\mathrm{gr}^\bullet_I A$ *factors through a graded ring homomorphism*

$$\Phi_I : \mathrm{gr}^\bullet_I A \to \mathrm{gr}^\bullet_J A \qquad (x \mod I^{n+1}) \mapsto (x^p \mod J^{n+1}) \qquad \textit{for every } n \in \mathbb{N} \textit{ and } x \in I^n.$$

(ii) *Suppose that* A *is perfectoid for its* p*-adic topology. Then* Φ_I *is an isomorphism.*

Proof. (i): To begin with, we remark :

Claim 16.3.60. For every $n \in \mathbb{N}$ and every $x, y \in I^n$, we have $(x+y)^p - x^p - y^p \in J^{n+1}$.

Proof of the claim. The difference in the claim is a sum of terms that lie in pI^{pn}. Taking into account (16.3.56), we see that $pI^{pn} \subset I^{t+pn}$, so it remains only to check that

$$I^{t+pn} \subset J^{n+1}.$$

We argue by induction on n, and notice that the case where $n = 0$ is (16.3.57). Hence, suppose that $r > 0$, and that the sought inclusion has already been checked for $n := r-1$. The ideal I^{t+pr} is generated by all elements of the type $b := \prod_{j=1}^{t+pr} a_{\varphi(j)}$, where φ is any mapping $\{1, \dots, t+pr\} \to \{1, \dots, k\}$. Since $r \geq 0$, it is easily seen that there exists at least one index $i \in \{1, \dots, k\}$ such that $\varphi^{-1}(i)$ has cardinality $\geq p$. For such index i, we have $b = a_i^p \cdot c$, where $c \in I^{t+pn}$, and the inductive assumption says that $c \in J^{n+1}$, whence $b \in J^{r+1}$, as required. ◊

Let us now check that if $x \in I^n$, then $x^p \in J^n$. Indeed, the assertion is clear if x is a monomial $\prod_{j=1}^n a_{\varphi(j)}$ for some mapping $\varphi : \{1, \dots, n\} \to \{1, \dots, k\}$. However, we may write $x = x_1 + \cdots + x_r$ for some $r \in \mathbb{N}$ and a sequence $x_1, \dots, x_r$ of such monomials. Lastly, claim 16.3.60 and an easy induction on r shows that $x^p - \sum_{j=1}^r x_j^p \in J^{n+1}$, whence the contention.

Thus, the map Φ_I is well defined, and claim 16.3.60 also shows that $\Phi_I(x+y) = \Phi_I(x)+\Phi_I(y)$ for every $n \in \mathbb{N}$ and every $x, y \in \mathrm{gr}^n_I A$. For any such x and y it is also clear that $\Phi_I(xy) = \Phi_I(x) \cdot \Phi_I(y)$, so Φ_I is a ring homomorphism.

(ii): Set $\mathbf{E} := \mathbf{E}(A)$, and let $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N})$ be a distinguished element in $\mathrm{Ker}\, u_A$; arguing as in the proof of lemma 16.2.7(i), we may assume that for every $i = 1, \dots, k$ we have $a_i = \overline{u}_A(\beta_i)$ for some $\beta_i \in \mathbf{E}$. Denote by $\mathscr{I} \subset \mathbf{E}$ the ideal generated by $(\beta_1, \dots, \beta_k)$, and set $\mathscr{J} := \mathscr{I}^{(p)}$, the ideal generated by $(\beta_1^p, \dots, \beta_k^p)$; from (16.3.56) and lemma 16.1.9(ii) we get

$$\alpha_0 \in \mathscr{I}^t \subset \mathscr{J}. \tag{16.3.61}$$

Let $\mathrm{gr}^\bullet_{\mathscr{I}}$ and $\mathrm{gr}^\bullet_{\mathscr{J}}$ be the graded rings associated with the $\mathscr{I}$-adic and $\mathscr{J}$-adic filtrations on $\mathbf{E}$.

Claim 16.3.62. (i) For every $n \in \mathbb{N}$ we have :

(a) The inclusion $\mathscr{I}^{n+1} \subset \mathscr{I}^n$ is $\alpha_0^{1/p}$-taut and the inclusion $\mathscr{J}^{n+1} \subset \mathscr{J}^n$ is taut.

(b) $\{\mathscr{I}^n\} = I^n$ and $\{\mathscr{J}^n\} = J^n$.

(ii) The map $\overline{u}_A : \mathbf{E}(A) \to A$ induces graded ring isomorphisms

$$\mathrm{gr}^\bullet_{\mathscr{I}} \xrightarrow{\sim} \mathrm{gr}^\bullet_I \qquad \mathrm{gr}^\bullet_{\mathscr{J}} \xrightarrow{\sim} \mathrm{gr}^\bullet_J.$$

Proof of the claim. (i.a): Clearly $\mathscr{J} = \Phi_{\mathbf{E}}(\mathscr{I})$, therefore it suffices to prove the assertion for $\mathscr{J}$; however $\alpha_0 \cdot \Phi_{\mathbf{E}}^{-1}(\mathscr{J}^{np}) = \alpha_0 \mathscr{I}^{np} \subset \mathscr{I}^{t+np}$ by (16.3.61), and arguing as in the proof of claim 16.3.60, we see that $\mathscr{I}^{t+np} \subset \mathscr{J}^{n+1}$, whence the claim.

(i.b): We consider first the assertion for $\mathscr{I}^n$. By construction, it is clear that $a_i \in \{\mathscr{I}\}$ for every $i = 1, \dots, k$, hence $I^n \subset \{\mathscr{I}^n\}$. On the other hand, since A is endowed with its p-adic topology, $\mathbf{E}$ carries the α_0-adic topology (see (16.2.19)), therefore $\mathscr{I}^n$ is open in $\mathbf{E}$, and consequently $\{\mathscr{I}^n\}$ is the ideal generated by the system $(\overline{u}_A(x) \mid x \in \mathscr{I}^n)$ (remark 16.3.28(viii)). Thus, we come down to checking that $\overline{u}_A(x) \in I^n$ for every $x \in \mathscr{I}^n$. This is clear in case x is a monomial of the form $\prod_{j=1}^n \beta_{\varphi(j)}$ for some mapping $\varphi : \{1, \dots, n\} \to \{1, \dots, k\}$. In general, x shall be a finite sum $x_1 + \cdots + x_s$, where $x_1, \dots, x_s$ are monomials of this type. According to proposition 9.3.62, $\tau_A(x)$ can then be expressed as a p-adically convergent series $\sum_{r \in \mathbb{N}} p^r \cdot y_r$, where each y_r is in turn a finite sum of terms of the form $w \cdot \tau_A(z)$, for certain $w \in \mathbb{Z}_p$ and $z \in \Phi_{\mathbf{E}}^{-r}(\mathscr{I}^n)^{p^r}$. In view of (i;A) and remark 16.3.28(vi), we have

$$\alpha_0^{r/p} \cdot \Phi_{\mathbf{E}}^{-r}(\mathscr{I}^n)^{p^r} \subset \mathscr{I}^{n+r} \qquad \text{for every } r, n \in \mathbb{N}.$$

Pick $\pi \in A$ as in lemma 16.2.3(iv); recalling lemma 16.2.7(iii), we deduce that

$$p^r \cdot \overline{u}_A(z) \in \pi^{(p-1)r} \cdot \{\mathscr{I}^{n+r}\} \qquad \text{for every } r \in \mathbb{N} \text{ and every } z \in \Phi_{\mathbf{E}}^{-r}(\mathscr{I}^n)^{p^r}.$$

Since $\{\mathscr{I}^{n+r}\}$ is closed in the p-adic topology of A for every $n, r \in \mathbb{N}$, it follows that $\{\mathscr{I}^n\} \subset I^n + \pi^{(p-1)r}\{\mathscr{I}^{n+r}\}$ for every $r \in \mathbb{N}$. But clearly $\pi^{(p-1)r} \in I^n$ for every large enough $r \in \mathbb{N}$, so $\{\mathscr{I}^n\} \subset I^n$, as required.

To deal with $\mathscr{J}^n$, we repeat the foregoing argument, to get : $\{\mathscr{J}^n\} \subset J^n + \{\mathscr{J}^{n+r}\}$ for every $r \in \mathbb{N}$. However, clearly $\mathscr{J}^{n+r} \subset \mathscr{I}^{n+r}$; taking into account the previous case, we conclude that $\{\mathscr{J}^n\} \subset J^n + I^s$ for every $s \in \mathbb{N}$. But we may find $s \in \mathbb{N}$ large enough, so that $I^s \subset J^n$, so at last $\{\mathscr{J}^n\} \subset J^n$, whence the claim.

(ii) follows immediately from (i) and theorem 16.3.31(ii). ◊

Claim 16.3.62(ii) yields a commutative diagram of graded rings

$$\begin{array}{ccc} \mathrm{gr}^\bullet_{\mathscr{I}} & \longrightarrow & \mathrm{gr}^\bullet_I A \\ \downarrow & & \downarrow{\scriptstyle \Phi_I} \\ \mathrm{gr}^\bullet_{\mathscr{J}} & \longrightarrow & \mathrm{gr}^n_J A \end{array}$$

whose horizontal arrows are isomorphisms, and whose left vertical arrow is induced by $\Phi_{\mathbf{E}}$. Now, since $\mathbf{E}$ is perfect, the left vertical arrow is an isomorphism, so the same holds for the right vertical arrow, as stated. □

Corollary 16.3.63. *Let A be a perfectoid ring, and $\beta \in \mathbf{E}(A)$ any element.*

(i) *A is a reduced ring.*
(ii) *If $\beta \neq 0$, then $\overline{u}_A(\beta) \neq 0$.*
(iii) *If the topology of A is discrete, then A is an $\mathbb{F}_p$-algebra.*

Proof. (i): Suppose that A contains a nilpotent element $x \neq 0$, and let $n > 1$ be the smallest integer such that $x^n = 0$; set $y := x^{n-1}$, so that $y \neq 0$ and $y^p = 0$. By remark 16.3.58 we can find an ideal of definition I of A fulfilling condition (16.3.56); we set $J := I^{(p)}$ and let $\Phi_I : \mathrm{gr}^\bullet_I A \xrightarrow{\sim} \mathrm{gr}^\bullet_J A$ be the isomorphism of proposition 16.3.59(ii). Let also $r \in \mathbb{N}$ be the largest integer such that $y \in I^r$, and denote by $\overline{y} \in \mathrm{gr}^r_I A$ the class of y, so that $\overline{y} \neq 0$; but clearly $\Phi_I(\overline{y}) = 0$, a contradiction.

(ii) and (iii) are immediate consequences of (i). □

Theorem 16.3.64. *In the situation of* (16.3.55)*, let $\mathscr{T}_I$ be the I-adic topology on A, and suppose that $(A, \mathscr{T}_I)$ is a P-ring. Define also the graded ring homomorphism Φ_I as in proposition* 16.3.59(i)*. Then the following conditions are equivalent :*

(a) *$(A, \mathscr{T}_I)$ is perfectoid.*
(b) *The map Φ_I is an isomorphism.*

Proof. Suppose that (a) holds, and let $\mathscr{T}_p$ be the p-adic topology on A; then $(A, \mathscr{T}_p)$ is perfectoid, by proposition 16.3.8(i), in which case proposition 16.3.59(ii) says that (b) holds.

Next, suppose that (b) holds; then proposition 16.2.9 and example 16.3.2(i) say that $\mathbf{E} := \mathbf{E}(A)$ is a perfectoid ring. Moreover, $\overline{u}_{A/pA}$ is surjective (lemma 16.2.7(i)), so for every $i = 1, \dots, k$ we may find $\beta_i \in \mathbf{E}$ such that $\overline{u}_{A/pA}(\beta_i)$ equals the image of a_i in A/pA. Denote by $\mathscr{J} \subset \mathbf{E}$ the ideal generated by the system $(\beta_1, \dots, \beta_k)$; from claim 16.2.10 we see that $\mathscr{J}$ is an ideal of definition of $\mathbf{E}$, and $\overline{u}_{A/pA}$ induces a ring isomorphism

$$\mathbf{E}/\mathscr{J} \xrightarrow{\sim} A/I. \qquad (16.3.65)$$

Denote by $\mathscr{J}_W \subset W(\mathbf{E})$ the ideal generated by $(\tau_{\mathbf{E}}(\beta_1), \dots, \tau_{\mathbf{E}}(\beta_k))$; by construction we have $u_A(\tau_{\mathbf{E}}(\beta_i)) - a_i \in pA$ for every $i = 1, \dots, k$, and notice that $p \in I^t \subset I^2$, so $\mathscr{J}_W A + I^2 = I$ and Nakayama's lemma yields

$$\mathscr{J}_W A = I. \qquad (16.3.66)$$

Furthermore, recall that $\mathscr{I} := \mathrm{Ker}\, u_A$ contains a distinguished element $\underline{\alpha}$ of $W(\mathbf{E})$ (lemma 16.2.7(ii)); on the other hand, (16.3.66) and (16.3.56) imply that $p \in \mathscr{J}^t_W A$, in which case we may apply lemma 16.1.9(i) to get an element $\underline{\alpha}' := (\alpha'_n \mid n \in \mathbb{N}) \in \mathscr{I}$ such that $\alpha'_0 \in \mathscr{J}^t$ and $\alpha'_1 \in \mathbf{E}^\times$. Especially, $\underline{\alpha}'$ is a distinguished element of $W(\mathbf{E})$, and so the ring

$$B := W(\mathbf{E})/\underline{\alpha}' W(\mathbf{E})$$

is perfectoid, for the quotient topology arising from the natural projection $W(\mathbf{E}) \to B$ (example 16.3.2(ii)). By construction, u_A factors through a surjective and continuous ring homomorphism

$$v : B \to A.$$

Moreover, set $I_B := \mathscr{J}_W B \subset B$, and notice that on the one hand, $u_B \circ \tau_{\mathbf{E}}(\alpha'_0) = pt$ for some $t \in B^\times$ (lemma 16.2.7(iii)), and on the other hand we have $u_B \circ \tau_{\mathbf{E}}(\alpha'_0) \in I^t_B$, so

$$p \in I^t_B. \qquad (16.3.67)$$

Combining with proposition 9.3.77(ii), we deduce that I_B is an ideal of definition of B, and taking into account (16.3.66), we also get

$$v(I_B) = I. \tag{16.3.68}$$

Set $J_B := I_B^{(p)}$; from (16.3.67), (16.3.68) and propositions 16.3.59(ii) and 16.3.8(i) we then get a commutative diagram of graded ring homomorphisms

$$\begin{array}{ccc} \mathrm{gr}^\bullet_{I_B} B & \longrightarrow & \mathrm{gr}^\bullet_I A \\ \downarrow & & \downarrow \\ \mathrm{gr}^\bullet_{J_B} B & \longrightarrow & \mathrm{gr}^\bullet_J A \end{array} \tag{16.3.69}$$

both of whose vertical arrows are isomorphisms, and whose horizontal arrows are induced by v. Since B is complete and separated for its I_B-adic topology, and A is complete and separated for its I-adic topology, the theorem will follow from :

Claim 16.3.70. The map v induces a ring isomorphism $v_n : B/I_B^{p^n} \xrightarrow{\sim} A/I^{p^n}$ for every $n \in \mathbb{N}$.

Proof of the claim. We argue by induction on n. For $n = 0$, notice that the projection $W(\mathbf{E}) \to B/I_B$ factors through $\mathbf{E}$, and by construction, the kernel of the resulting surjection is $\mathscr{J}$. Then the assertion follows from (16.3.65). Next, suppose that $n \geq 0$, and that v_n is an isomorphism. In this case, v induces isomorphisms $\mathrm{gr}^r_{I_B} B \xrightarrow{\sim} \mathrm{gr}^r_I A$ for every $r < p^n$. Due to (16.3.69), we then deduce that v also induces isomorphisms $\mathrm{gr}^r_{J_B} B \xrightarrow{\sim} \mathrm{gr}^r_J A$ for every $r < p^n$, from which it follows easily that v induces an isomorphism $B/J_B^{p^n} \xrightarrow{\sim} A/J^{p^n}$. However, clearly $J \subset I^p$ and $J_B \subset I_B^p$, hence $J_B^{p^n} \subset I_B^{p^{n+1}}$ and $J^{p^n} \subset I^{p^{n+1}}$, so finally v_{n+1} is an isomorphism. □

As a corollary of theorem 16.3.64 we obtain the following criterion :

Corollary 16.3.71. *Let A be a ring, $t \in \mathbb{N}$ any integer, $\beta := (b_n \mid n \in \mathbb{N})$ an element of $\mathbf{E}(A)$; suppose that A is complete and separated for its b_0-adic topology $\mathscr{T}_0$, and $p = ab_0$ for some $a \in A$. Let also $J := \bigcup_{n\in\mathbb{N}} b_n A$. Consider the following conditions :*

(a) *A/J is a perfect $\mathbb{F}_p$-algebra.*
(b) *The p-th power map of $A/b_t^2 A$ induces a bijection $b_{t+1}A/b_{t+1}^2 A \xrightarrow{\sim} b_t A/b_t^2 A$.*
(c) $\mathrm{Ann}_A(b_0) = \mathrm{Ann}_A(b_n)$ *for every $n \in \mathbb{N}$.*
(d) *The Frobenius endomorphism Φ_{A/b_iA} of A/b_iA induces an isomorphism*

$$\overline{\Phi}_{A/b_iA} : A/b_{i+1}A \xrightarrow{\sim} A/b_iA \qquad \textit{for every } i \in \mathbb{N}.$$

(e) *$(A, \mathscr{T}_0)$ is a perfectoid ring.*

Then (e) *is equivalent to the conjunction of* (a),(b) *and* (c)*, and also to the conjunction of* (c) *and* (d)*. Moreover, if* (e) *holds, then $A/\mathrm{Ann}_A(b_0)$ is perfectoid for the b_0-adic topology, and the map $\overline{u}_A : \mathbf{E}(A) \to A$ induces an isomorphism of $\mathbf{E}(A)$-modules :*

$$\mathrm{Ann}_{\mathbf{E}(A)}(\beta) \xrightarrow{\sim} \mathrm{Ann}_A(b_0). \tag{16.3.72}$$

Proof. Suppose first that (a),(b),(c) hold. For every $i, j > 0$, consider the commutative diagram

$$\begin{array}{ccc} b_i^{j-1}A/b_i^jA & \xrightarrow{f_{i,j}} & b_i^jA/b_i^{j+1}A \\ \downarrow{\scriptstyle \varphi_{i,j-1}} & & \downarrow{\scriptstyle \varphi_{i,j}} \\ b_{i-1}^{j-1}A/b_{i-1}^jA & \xrightarrow{f_{i-1,j}} & b_{i-1}^jA/b_{i-1}^{j+1}A \end{array}$$

where $\varphi_{i,j}$ is induced by the p-th power map of $A/b_{i-1}^{j+1}A$ for every $i, j \in \mathbb{N}$ with $i > 0$, and $f_{i,j}$ is induced by scalar multiplication by b_i, for every $i, j \in \mathbb{N}$ with $j > 0$. We notice :

Claim 16.3.73. (i) $f_{i,j}$ is an isomorphism for every $i, j \in \mathbb{N}$ with $j > 1$.

(ii) $\varphi_{i,1}$ is an isomorphism for every $i > t$.

Proof of the claim. (i): The surjectivity of $f_{i,j}$ is clear. For the injectivity, suppose that $x = b_i^{j-1}y$ and $b_i x = b_i^{j+1}z$ for some $y, z \in A$. It follows that $b_i^j y = b_i^{j+2}z$, so $b_i^j(y - b_i^2 z) = 0$, and therefore also $b_i(y - b_i^2 z) = 0$, by (c). Since $j > 1$, we deduce that $x = b_i^j z$, whence the assertion.

(ii): We argue by induction on i. The case $i = t+1$ is (b). Suppose then that $i > t$ and that the surjectivity of $\varphi_{i,1}$ is already known. This means that for every $x \in A$ there exist $y, z \in A$ such that $b_{i-1}x = b_{i-1}y^p + b_{i-1}^2 z$, *i.e.* that $b_{i-1}(x - y^p - b_{i-1}z) = 0$. By assumption (c), we deduce that $b_i(x - y^p - b_{i-1}z) = 0$. Set $z' := b_i^{p-1}z$; then $b_i(x - y^p - b_i z') = 0$, *i.e.* $b_i x = b_i y_p + b_i^2 z'$, whence the surjectivity of $\varphi_{i+1,1}$.

The injectivity of $\varphi_{i,1}$ means the following. For every $x \in A$ such that $b_{i-1}x^p \in b_{i-1}^2 A$ we have $b_i x \in b_i^2 A$. Now, let $a \in A$, and suppose that $b_i a^p \in b_i^2 A$; then $b_{i-1}(b_i^{p-1}a^p) = b_i^{2p-1}a^p \in b_{i-1}^2 A$, so that $b_{i+1}^{2p-1}a = b_i b_{i+1}^{p-1} a \in b_i^2 A$. Say that $b_{i+1}^{2p-1}a = b_i^2 y$; then

$$b_{i+2}^{2p^2-p-1}(b_{i+2}a - b_{i+2}^{p+1}y) = 0.$$

By assumption (c), it follows that $b_{i+2}^{p-1}(b_{i+2}a - b_{i+2}^{p+1}y) = 0$ as well, and therefore $b_{i+1}a \in b_{i+1}^2 A$, hence $\varphi_{i+1,1}$ is injective. ◊

From claim 16.3.73 it follows immediately that $\varphi_{i,j}$ is an isomorphism for every $i > t$ and every $j > 0$. Notice now that $(A, \mathscr{T}_0)$ is a P-ring, and $I := b_i A$ is an ideal of definition of A, for every $i > 0$, due to assumptions (a) and (b); moreover, any such I fulfills the conditions of (16.3.55). In light of theorem 16.3.64, it then suffices to show that $\overline{\Phi}_{A/b_iA}$ is bijective for every $i \geq t$. To this aim, from the snake lemma and assumption (a), we are easily reduced to checking that $\Phi_{A/b_{i-1}A}$ induces a bijection $J/b_iA \xrightarrow{\sim} J/b_{i-1}A$ for every $i > t$. Then, since J is the union of its subideals b_kA (for all $k \in \mathbb{N}$), we are further reduced to checking that $\Phi_{A/b_{i-1}A}$ induces a bijection $b_kA/b_iA \xrightarrow{\sim} b_{k-1}A/b_{i-1}A$ for every $k \geq i$. By considering the filtration

$$0 \subset b_{i+1}A/b_iA \subset b_{i+2}A/b_i \subset \cdots \subset b_kA/b_iA$$

an easy induction then reduces to the case where $k = i+1$. Lastly, a similar induction argument, using the filtration $0 \subset b_{i+1}^{p-1}/b_i \subset b_{i+1}^{p-2}/b_i \subset \cdots \subset b_{i+1}/b_i$ further reduces the assertion to the surjectivity of $\varphi_{i,j}$ for every $j = 1, \ldots, p-1$, which is already known, by the foregoing.

Conversely, if (e) holds, then we get both (b) and (d), by virtue of proposition 16.3.59; then, notice that the direct limit of the system of maps $(\overline{\Phi}_{A/b_iA} \mid i \geq t)$ is the Frobenius endomorphism of A/J, whence (a). Next, let $x \in A$ with $b_0 x = 0$; it follows that $(b_n x)^{p^n} = 0$ for every $n \in \mathbb{N}$, and since A is reduced (corollary 16.3.63(i)), we get $b_n x = 0$, whence (c).

Lastly, suppose that (c) and (d) hold; then we get a commutative diagram whose horizontal arrows are restrictions of Φ_{A/b_0A}, and are therefore bijections :

$$\begin{array}{ccc} b_{t+1}^2A/b_1A & \xrightarrow{\sim} & b_t^2A/b_0A \\ {\scriptstyle j_{t+1}}\downarrow & & \downarrow{\scriptstyle j_t} \\ b_{t+1}A/b_1A & \xrightarrow{\sim} & b_tA/b_0A \end{array}$$

and whose vertical arrows are the natural injections; hence, we get an induced isomorphism $\mathrm{Coker}\, j_{t+1} \xrightarrow{\sim} \mathrm{Coker}\, j_t$, whence (b). It has already been remarked that (d) implies (a), so the proof of the stated equivalences is complete.

Next, suppose that A is perfectoid, so all conditions (a),...,(e) hold, and let us notice that

$$\mathrm{Ann}_A(b_0) \cap b_n A = 0 \qquad \text{for every } n \in \mathbb{N}. \tag{16.3.74}$$

Indeed, if $x \in A$ and we have $b_0 \cdot (b_n x) = 0$, then $b_n x = 0$ by (c). This means that $\mathscr{T}_0$ induces the discrete topology on $\mathrm{Ann}_A(b_0)$, so $\overline{A} := A/\mathrm{Ann}_A(b_0)$ is complete and separated for its b_0-adic topology. Consider now the commutative diagram :

$$\begin{array}{ccc} A/b_{t+1}A & \xrightarrow{\overline{\Phi}_{A/b_iA}} & A/b_tA \\ {\scriptstyle f_{1,t+1}}\downarrow & & \downarrow{\scriptstyle f_{1,t}} \\ b_{t+1}A/b_{t+1}^2A & \longrightarrow & b_tA/b_t^2A \end{array}$$

whose left (resp. right) vertical arrow is induced by multiplication by b_{t+1} (resp. by b_t), and whose top (resp. bottom) horizontal arrow is induced by the Frobenius endomorphism of A/b_tA (resp. of A/b_t^2A). Due to (b),(d) and (16.3.74), we see that $\overline{\Phi}_{A/b_tA}$ restricts to a bijection

$$\mathrm{Ann}_A(b_{t+1}) = \mathrm{Ker}\, f_{1,t+1} \xrightarrow{\sim} \mathrm{Ker}\, f_{1,t} = \mathrm{Ann}_A(b_t)$$

and combining with (c) we deduce that the Frobenius endomorphism of A/b_iA restricts to a bijection $\mathrm{Ann}_A(b_0) \xrightarrow{\sim} \mathrm{Ann}_A(b_0)$ for every $i \in \mathbb{N}$. Then, using (d) we conclude that the Frobenius endomorphism of $\overline{A}/b_i\overline{A}$ induces an isomorphism $\overline{\Phi}_{\overline{A}/b_i\overline{A}} : \overline{A}/b_{i+1}\overline{A} \xrightarrow{\sim} \overline{A}/b_i\overline{A}$ for every $i \in \mathbb{N}$. Lastly, it is easily seen that $\mathrm{Ann}_{\overline{A}}(b_i) = 0$ for every $i \in \mathbb{N}$. Summing up, we have shown that the ring $\overline{A}$ fulfills conditions (c) and (d), so it is perfectoid for its b_0-adic topology, by the foregoing. Now, by virtue of (16.3.74), we may naturally identify $\mathrm{Ann}_A(b)$ with its image in A/b_0A, and likewise one easily sees that $\mathrm{Ann}_{\mathbf{E}(A)}(\beta) \cap \beta\mathbf{E}(A) = 0$, hence we may identify $\mathrm{Ann}_{\mathbf{E}(A)}(\beta)$ with its image in $\mathbf{E}(A)/\beta\mathbf{E}(A)$. By claim 16.3.62(ii), we have a commutative diagram of A_0/b_0A-modules

$$\begin{array}{ccc} \mathbf{E}(A)/\beta\mathbf{E}(A) & \longrightarrow & \beta\mathbf{E}(A)/\beta^2\mathbf{E}(A) \\ \downarrow & & \downarrow \\ A/b_0A & \longrightarrow & b_0A_0/b_0^2A_0 \end{array}$$

whose top (resp. bottom) horizontal arrow is induced by multiplication by β (resp. by b_0), and whose vertical arrows are induced by $\overline{u}_A$. To conclude, it suffices to remark that the kernel of the top (resp. bottom) horizontal arrow is $\mathrm{Ann}_{\mathbf{E}(A)}(\beta)$ (resp. $\mathrm{Ann}_A(b_0)$). ☐

Let us point out the following variant of corollary 16.3.71 :

Corollary 16.3.75. *Let A be ring, $b \in A$ an element such that $p \in b^pA$, and such that the b-adic topology $\mathscr{T}$ of A is complete and separated. Then $(A, \mathscr{T})$ is perfectoid if and only if the following two conditions hold :*

(a) *The Frobenius endomorphism Φ_{A/b^pA} of A/b^pA induces a bijection $A/bA \xrightarrow{\sim} A/b^pA$.*
(b) $\mathrm{Ann}_A(b^p) = \mathrm{Ann}_A(b^{p-1})$.

Proof. If A is perfectoid, then $\overline{u}_{A/pA} : \mathbf{E}(A) \to A/pA$ is surjective (lemma 16.2.7(i)), so there exists $(b_n \mid n \in \mathbb{N}) \in \mathbf{E}(A)$ such that $b_0 - b \in pA_0$, and it follows easily that $b_0/b \in A_0^\times$. Thus, we may replace b by b_0, in which case the assumptions of corollary 16.3.71 are fulfilled, and we deduce that both (a) and (b) hold.

Conversely, if (a) holds, then A is a P-ring, and if also (b) holds, arguing as in the foregoing we may again assume that $b = b_0$ for some $(b_n \mid n \in \mathbb{N}) \in \mathbf{E}(A)$; then we have, more generally:

Claim 16.3.76. If (a) holds and there exists $t \in \mathbb{N}$ such that $\mathrm{Ann}_A(b^p) = \mathrm{Ann}_A(b^p/b_t)$, then A is perfectoid.

Proof of the claim. In light of theorem 16.3.64, it suffices to show that the Frobenius endomorphism of A/b_tA induces bijections

$$\Phi_i : \mathrm{gr}_i^{(t+1)} := b_{t+1}^i A/b_{t+1}^{i+1}A \stackrel{\sim}{\to} \mathrm{gr}_i^{(t)} := b_t^i A/b_t^{i+1}A \qquad \text{for every } i \in \mathbb{N}.$$

However, (a) easily implies that Φ_i is an isomorphism for every $i = 0, \dots, p^{t+1} - 1$. We then argue by induction on $i \geq p^{t+1} - 1$. Thus suppose that Φ_i is an isomorphism for such i; we consider the commutative diagram

$$\begin{array}{ccc} \mathrm{gr}_i^{(t+1)} & \xrightarrow{\Phi_i} & \mathrm{gr}_i^{(t)} \\ {\scriptstyle \overline{b}_{t+1}}\downarrow & & \downarrow{\scriptstyle \overline{b}_t} \\ \mathrm{gr}_{i+1}^{(t+1)} & \xrightarrow{\Phi_{i+1}} & \mathrm{gr}_{i+1}^{(t)} \end{array}$$

whose vertical arrows are induced by scalar multiplication by b_{t+1} and respectively b_t. Clearly both vertical arrows are surjections; thus, we are reduced to checking that $\overline{b}_t$ is injective. Hence, say that for some $a \in A$, the class of $b_t^i a$ in $\mathrm{gr}_i^{(t)}$ lies in the kernel of $\overline{b}_t$; this means that there exists $c \in A$ with $b_t^{i+1}a = b_t^{i+2}c$, so that $b_t^{i+1}(a - b_tc) = 0$, and since $i + 1 \geq p^{t+1}$, our assumption easily implies that $b_t^i(a - b_tc) = 0$ as well. So, the class of $b_t^i a$ vanishes in $\mathrm{gr}_i^{(t)}$, as required. □

Proposition 16.3.8 shows that the completion of a perfectoid ring for the topology defined by a p-adically open and finitely generated ideal, is again perfectoid for the p-adic topology. We now wish to prove that the same still holds for a general finitely generated ideal.

16.3.77. Namely, let A be a perfectoid ring, $I \subset A$ (resp. $\mathscr{I} \subset \mathbf{E} := \mathbf{E}(A)$) a finitely generated ideal such that the topology of A (resp. of $\mathbf{E}$) agrees with the I-adic topology $\mathscr{T}_I$ (resp. with the $\mathscr{I}$-adic topology $\mathscr{T}_\mathscr{I}$). Let also $\beta_\bullet := (\beta_1, \dots, \beta_n)$ be any finite system of elements of $\mathbf{E}$ and $\mathscr{J} \subset \mathbf{E}$ (resp. $J \subset A$) the ideal generated by $\beta_\bullet$ (resp. by $\overline{u}_A(\beta_1), \dots, \overline{u}_A(\beta_n)$). Denote by $\mathscr{T}_J$ (resp. $\mathscr{T}_\mathscr{J}$) the J-adic on A (resp. the $\mathscr{J}$-adic topology on $\mathbf{E}$), and let

$$(A_J^\wedge, \mathscr{T}_J^\wedge) \qquad \text{and} \qquad (\mathbf{E}_\mathscr{J}^\wedge, \mathscr{T}_\mathscr{J}^\wedge)$$

respectively the completion of $(A, \mathscr{T}_J)$ and of $(\mathbf{E}, \mathscr{T}_\mathscr{J})$. Lastly, let $\mathscr{T}_I^\wedge$ (resp. $\mathscr{T}_\mathscr{I}^\wedge$) be the $IA_J^\wedge$-adic topology on $A_J^\wedge$ (resp. the $\mathscr{I}\mathbf{E}_\mathscr{J}^\wedge$-adic topology on $\mathbf{E}_\mathscr{J}^\wedge$).

Theorem 16.3.78. *In the situation of* (16.3.77)*, the following holds :*

(i) $(A_J^\wedge, \mathscr{T}_I^\wedge)$ *is perfectoid.*

(ii) *There is a natural isomorphism of topological rings* $\mathbf{E}(A_J^\wedge, \mathscr{T}_I^\wedge) \stackrel{\sim}{\to} (\mathbf{E}_\mathscr{J}^\wedge, \mathscr{T}_\mathscr{I}^\wedge)$.

Proof. Let $J_\mathbf{A} \subset \mathbf{A} := W(\mathbf{E})$ be the ideal generated by $\tau_\mathbf{E}(\beta_1), \dots, \tau_\mathbf{E}(\beta_n)$, set $J'_\mathbf{A} := J_\mathbf{A} + p\mathbf{A}$ and denote by $\mathbf{A}_J^\wedge$ (resp. $\mathbf{A}_{J'}^\wedge$) the $J_\mathbf{A}$-adic (resp. $J'_\mathbf{A}$-adic) completion of $\mathbf{A}$. Moreover, pick any finite system of generators $(\gamma_1, \dots, \gamma_k)$ for $\mathscr{I}$, let $I_\mathbf{A} \subset \mathbf{A}$ be the ideal generated by the system $(p, \tau_\mathbf{E}(\gamma_1), \dots, \tau_\mathbf{E}(\gamma_k))$, and denote by $\mathscr{T}_{I,\mathbf{A}}^\wedge$ indifferently the $I_\mathbf{A}$-adic topologies on $\mathbf{A}_{J'}^\wedge$ and on $\mathbf{A}_J^\wedge$, and by $\mathscr{T}_{J',\mathbf{A}}^\wedge$ the $J'_\mathbf{A}$-adic topology on $\mathbf{A}_{J'}^\wedge$. With this notation, we have natural isomorphisms of topological $\mathbf{A}$-algebras

$$W(\mathbf{E}_\mathscr{J}^\wedge, \mathscr{T}_\mathscr{J}^\wedge) \stackrel{\sim}{\to} (\mathbf{A}_{J'}^\wedge, \mathscr{T}_{J',\mathbf{A}}^\wedge) \qquad \text{and} \qquad W(\mathbf{E}_\mathscr{J}^\wedge, \mathscr{T}_\mathscr{I}^\wedge) \stackrel{\sim}{\to} (\mathbf{A}_{J'}^\wedge, \mathscr{T}_{I,\mathbf{A}}^\wedge) \tag{16.3.79}$$

(proposition 9.3.77(ii) and lemma 9.3.33(iv)). On the other hand, since the $J_\mathbf{A}$-adic topology is finer than the $J'_\mathbf{A}$-adic topology, the completion map $\mathbf{A} \to \mathbf{A}_{J'}^\wedge$ factors through a unique map of $\mathbf{A}$-algebras

$$\mathbf{A}_J^\wedge \to \mathbf{A}_{J'}^\wedge. \tag{16.3.80}$$

Claim 16.3.81. The map (16.3.80) is a ring isomorphism.

Proof of the claim. Quite generally, consider any abelian group M, endowed with two topologies $\mathscr{T}$ and $\mathscr{T}'$ defined by cofiltered systems of subgroups $(M_\lambda \mid \lambda \in \Lambda)$ and respectively $(M'_\mu \mid \mu \in \Lambda')$. Endow each quotient $Q_\lambda := M/M_\lambda$ with the quotient topology $\mathscr{T}'_\lambda$ induced by $\mathscr{T}'$ via the projection map $M \to Q_\lambda$, and suppose moreover that $\mathscr{T}$ is finer than $\mathscr{T}'$ and $(Q_\lambda, \mathscr{T}'_\lambda)$ is separated and complete for every $\lambda \in \Lambda$. Then it follows that the natural map

$$(M, \mathscr{T})^\wedge \to (M, \mathscr{T}')^\wedge$$

(that extends the completion map $M \to (M, \mathscr{T}')^\wedge$), is an isomorphism of abelian groups. Indeed, clearly the family $(M_\lambda + M'_\mu \mid \lambda \in \Lambda, \mu \in \Lambda')$ is still a fundamental system of open neighborhoods of zero in M for the topology $\mathscr{T}'$, so we have natural isomorphisms

$$(M, \mathscr{T}')^\wedge \xrightarrow{\sim} \lim_{(\lambda,\mu)\in\Lambda\times\Lambda'} M/(M_\lambda + M'_\mu) \xrightarrow{\sim} \lim_{\lambda\in\Lambda} \lim_{\mu\in\Lambda'} M/(M_\lambda + M'_\mu) \xrightarrow{\sim} \lim_{\lambda\in\Lambda} (Q_\lambda, \mathscr{T}')^\wedge$$

(where the second isomorphism follows from example 1.5.15(ii)) but $(Q_\lambda, \mathscr{T}')^\wedge = Q_\lambda$ under the current assumptions, whence the assertion.

Recall now that the family $(W(\mathscr{J}^{\langle\lambda\rangle}) \mid \lambda \in \mathbb{N}[1/p])$ is a fundamental system of open neighborhoods of zero in for the $J_{\mathbf{A}}$-adic topology on $\mathbf{A}$ (proposition 9.3.77(i) and lemma 9.3.69(iv)). In view of the foregoing, the claim will then follow, once we have shown that the quotients $\mathbf{A}/W(\mathscr{J}^{\langle\lambda\rangle})$ are complete and separated for the $J'_{\mathbf{A}}$-adic topology. Moreover, it is clear that $J'_{\mathbf{A}}$-adic topology on $\mathbf{A}/W(\mathscr{J}^{\langle\lambda\rangle})$ agrees with the p-adic topology, so – taking into account proposition 9.3.44(ii) – we come down to checking that $W(\mathscr{J}^{\langle\lambda\rangle})$ is a closed ideal for the p-adic topology $\mathscr{T}_{p,\mathbf{A}}$ on $\mathbf{A}$. But notice that if $\mathscr{T}_d$ denotes the discrete topology on $\mathbf{E}$, then $W(\mathbf{E}, \mathscr{T}_d) = (\mathbf{A}, \mathscr{T}_{p,\mathbf{A}})$, so the assertion is a special case of remark 9.3.28(iv). ◊

Claim 16.3.82. $(\mathbf{E}^\wedge_{\mathscr{J}}, \mathscr{T}^\wedge_{\mathscr{J}})$ is perfectoid.

Proof of the claim. Since $\mathbf{E}$ is a perfect topological ring, the same holds for $(\mathbf{E}, \mathscr{T}_{\mathscr{J}})$, hence also for $(\mathbf{E}^\wedge_{\mathscr{J}}, \mathscr{T}^\wedge_{\mathscr{J}})$ (remark 9.4.9(v) and example 9.3.48(ii)), and by the same token, $(\mathbf{E}^\wedge_{\mathscr{J}}, \mathscr{T}^\wedge_{\mathscr{J}})$ is a perfect topological $\mathbb{F}_p$-algebra. By example 16.3.2(i), it then remains only to check that the topology $\mathscr{T}^\wedge_{\mathscr{J}}$ is complete and separated. However, since $\mathbf{E}$ is complete and separated for the $\mathscr{I}$-adic topology, $\mathbf{E}^\wedge_{\mathscr{J}}$ is complete and separated for the $(\mathscr{I} + \mathscr{J})$-adic topology (lemma 16.3.15(ii.b)) and then the assertion follows from lemma 8.3.12. ◊

Let $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N}) \in \mathrm{Ker}\, u_A$ be any distinguished element; clearly $\underline{\alpha}$ is still distinguished in $W(\mathbf{E}^\wedge_{\mathscr{J}}, \mathscr{T}^\wedge_{\mathscr{J}})$, hence $W(\mathbf{E}^\wedge_{\mathscr{J}}, \mathscr{T}^\wedge_{\mathscr{J}}) \otimes_{\mathbf{A}} A$ is perfectoid (example 16.3.2(ii)). From (16.3.79) and claim 16.3.81 we deduce that both (i) and (ii) will follow, once we have shown

Claim 16.3.83. There is a natural isomorphism of topological rings :

$$(\mathbf{A}^\wedge_J, \mathscr{T}^\wedge_{I,\mathbf{A}}) \otimes_{\mathbf{A}} A \xrightarrow{\sim} (A^\wedge_J, \mathscr{T}^\wedge_I).$$

Proof of the claim. By construction, the $J_{\mathbf{A}}$-adic topology induces the J-adic topology on A, via the projection $u_A : \mathbf{A} \to A$. Therefore, u_A extends to a surjective map

$$u^\wedge_A : \mathbf{A}^\wedge_J \to A^\wedge_J$$

whose kernel is the topological closure of $\underline{\alpha}\mathbf{A}$ in the $J_{\mathbf{A}}$-adic topology of $\mathbf{A}^\wedge_J$ (proposition 8.2.13(i,v) and lemma 8.3.32(iv)). On the other hand, by proposition 9.3.77(ii) and lemma 16.2.7(i), the $I_{\mathbf{A}}$-adic topology on $\mathbf{A}$ induces the I-adic topology on A via u_A, so the topology $\mathscr{T}^\wedge_{I,\mathbf{A}}$ induces the topology $\mathscr{T}^\wedge_I$ on $A^\wedge_J$, via $u^\wedge_A$. Thus, we are reduced to checking that $\underline{\alpha}\mathbf{A}^\wedge_J$ is a closed ideal in the $J_{\mathbf{A}}$-adic topology of $\mathbf{A}^\wedge_J$. By claim 16.3.81, it then further suffices to show that $\underline{\alpha}\mathbf{A}^\wedge_{J'}$ is closed for the topology $\mathscr{T}^\wedge_{J',\mathbf{A}}$. But in light of (16.3.79), the latter assertion follows from corollary 16.1.13(ii). □

As an application we get the following generalization of theorem 16.3.21(ii) :

Corollary 16.3.84. *Let $(A, \mathscr{T})$ be a perfectoid ring, $\beta_\bullet := (\beta_1, \dots, \beta_k)$ and $\gamma_\bullet := (\gamma_1, \dots, \gamma_l)$ two finite sequences of elements of $\mathbf{E} := \mathbf{E}(A)$, and denote by I (resp. J) the ideal of A generated by the system $(\overline{u}_A(\beta_1), \dots, \overline{u}_A(\beta_k))$ (resp. by $\overline{u}_A(\gamma_1), \dots, \overline{u}_A(\gamma_l)$). Then the resulting map* (16.3.14) *is an isomorphism.*

Proof. Let A' be the I-adic completion of A, and for every $k \in \mathbb{N}$, denote by $(J^k)^c$ the topological closure of the ideal J^kA' relative to the IA'-adic topology; arguing as in the proof of lemma 16.3.15(ii.b), we are easily reduced to showing that the JA'-adic topology on A' agrees with the linear topology defined by the system of ideals $((J^k)^c \mid k \in \mathbb{N})$. However, let K be an ideal of definition of A, and and endow A' with its KA'-adic topology $\mathscr{T}'$; by theorem 16.3.78, the topological ring $(A', \mathscr{T}')$ is also perfectoid. Moreover, for every $i \leq l$, denote by $\gamma'_i \in \mathbf{E}' := \mathbf{E}(A')$ the image of γ_i under the homomorphism $\mathbf{E} \to \mathbf{E}'$ induced by the completion map $A \to A'$; then clearly JA' is the ideal generated by the system $(\overline{u}_{A'}(\gamma'_1), \dots, \overline{u}_{A'}(\gamma'_l))$. Hence, we may replace A by A', after which we may assume that A is complete and separated for its I-adic topology. To conclude, it then suffices to show :

Claim 16.3.85. In the situation of the corollary, suppose moreover that A is complete and separated for the I-adic topology. Then the J-adic topology of A agrees with the linear topology induced by the system of ideals $((J^k)^c \mid k \in \mathbb{N})$.

Proof of the claim. From lemma 9.3.69(iv) we know already that the J-adic topology on A agrees with the linear topology defined by the system of ideals $([\gamma_\bullet]^{\langle\lambda\rangle}A \mid \lambda \in \mathbb{N}[1/p])$ so it suffices to check that

$$([\gamma_\bullet]^{\langle\lambda\rangle}A)^c \subset [\gamma_\bullet]^{\langle\lambda'\rangle}A \qquad \text{for every } \lambda, \lambda' \text{ in } \mathbb{N}[1/p] \text{ with } \lambda' < \lambda.$$

Now, any element of $([\gamma_\bullet]^{\langle\lambda\rangle}A)^c$ can be written as an I-adically convergent series $\sum_{n\in\mathbb{N}} x_n$, where $x_n \in [\gamma_\bullet]^{\langle\lambda\rangle}A \cap [\beta_\bullet]^{\langle n\rangle}A$ for every $n \in \mathbb{N}$ (again by lemma 9.3.69(iv)). Fix $\lambda'', \varepsilon \in \mathbb{N}[1/p]$ with $\lambda' < \lambda'' < \lambda$, and $0 < \varepsilon < 1 - \lambda''/\lambda$; by corollary 16.3.51(iii) we get

$$x_n \in [\gamma_\bullet]^{\langle\lambda''\rangle} \cdot [\beta_\bullet]^{\langle n\varepsilon\rangle}A \qquad \text{for every } n \in \mathbb{N}.$$

Now we argue as in the proof of claim 16.3.20 : by definition, for every $n \in \mathbb{N}$ there exist

- a finite set $S_n \subset \mathbb{N}[1/p]^{\oplus l}$ with $\mu_1 + \cdots + \mu_l = \lambda''$ for every $\mu := (\mu_1, \dots, \mu_l) \in S_n$
- a system $(a_\mu \mid \mu \in S_n)$ of elements of $[\beta_\bullet]^{\langle n\varepsilon\rangle}A$ such that

$$x_n = \sum_{\mu\in S_n} a_\mu \cdot \overline{u}_A(\gamma_\bullet^\mu) \qquad \text{where } \gamma_\bullet^\mu := \gamma_1^{\mu_1} \cdots \gamma_l^{\mu_l} \text{ for every } \mu \in S_n.$$

Choose $N \in \mathbb{N}$ such that $\lambda'' - \lambda' > lp^{-N}$, and define $\overline{\mu}$ and μ^* as in the proof of proposition 9.3.77, so that $\overline{\mu} \in S := \{\nu \in p^{-N}\mathbb{N}^{\oplus l} \mid \lambda'' \geq \nu_1 + \cdots + \nu_l > \lambda'\}$ for every $n \in \mathbb{N}$ and every $\mu \in S_n$. It follows that

$$x = \sum_{\nu\in S} c_\nu \cdot \overline{u}_A(\gamma_\bullet^\nu) \qquad \text{where} \qquad c_\nu := \sum_{n\in\mathbb{N}} \sum_{\substack{\mu\in S_n \\ \overline{\mu}=\nu}} a_\mu \cdot \overline{u}_A(\gamma_\bullet^{\mu^*}).$$

Clearly $\overline{u}_A(\gamma_\bullet^\nu) \in [\gamma_\bullet]^{\langle\lambda'\rangle}A$, and by lemma 9.3.69(iv) the series c_ν converges in the I-adic topology of A for every $\nu \in S$; also it is easily seen that S is a finite set, whence the contention. □

16.4. **Homological theory of perfectoid rings.** This section gathers some results on the homological properties of perfectoid rings. The first result is a simplification of the criterion of theorem 16.3.64, valid in the case where a regular sequence generates a special ideal of definition of the P-ring A.

Theorem 16.4.1. *Let A be a P-ring, and $(a_1, \dots, a_k)$ a regular sequence of elements of A that generates a special ideal of definition I of A. Then the following conditions are equivalent :*

(a) *The Frobenius endomorphism of A/pA induces an isomorphism $A/I \xrightarrow{\sim} A/I^{(p)}$.*
(b) *A is perfectoid.*

Proof. We know already that (b)⇒(a), by corollary 16.3.3. Suppose that (a) holds. Then $\mathbf{E} := \mathbf{E}(A)$ is perfectoid (proposition 16.2.9 and example 16.3.2(i)). Arguing as in the proof of theorem 16.3.64, we may then find elements $\beta_1, \dots, \beta_k$ in $\mathbf{E}$, which generate an ideal of definition $\mathscr{J}$ of $\mathbf{E}$, and such that $\overline{u}_{A/pA}(\beta_i)$ equals the image of a_i in A/pA, for $i = 1, \dots, k$; moreover, $\overline{u}_{A/pA}$ induces an isomorphism (16.3.65).

Next, since $p \in I^{(p)}$, we may find – again as in the proof of theorem 16.3.64 – a distinguished element $\underline{\alpha}' \in \mathrm{Ker}\, u_A$ such that $\alpha'_0 \in \Phi_{\mathbf{E}}(\mathscr{J})$. We let $B := W(\mathbf{E})/\underline{\alpha}'W(\mathbf{E})$, and we notice, as in *loc. cit.* that B is perfectoid for the quotient topology inherited from $W(\mathbf{E})$, and u_A factors through a surjective ring homomorphism $v : B \to A$. We define the ideal $I_B \subset B$ as in the proof of theorem 16.3.64, so (16.3.68) holds as well in the current situation, and arguing as in *loc. cit.* we also see that $p \in I_B^{(p)}$. Set $B_0 := B/I_B$ and $A_0 := A/I$; there follows a commutative diagram

$$\begin{array}{ccc} \mathrm{Sym}^\bullet_{B_0}(I_B/I_B^2) & \longrightarrow & \mathrm{gr}^\bullet_{I_B} B \\ \downarrow & & \downarrow \\ \mathrm{Sym}^\bullet_{A_0}(I/I^2) & \longrightarrow & \mathrm{gr}^\bullet_I A \end{array} \qquad (16.4.2)$$

where $\mathrm{gr}^\bullet_I A$ is the graded ring associated to the I-adic filtration on A, and likewise for $\mathrm{gr}^\bullet_{I_B} B$. The top horizontal arrow of this diagram is surjective, and by assumption, the bottom horizontal arrow is an isomorphism. Furthermore, we notice :

Claim 16.4.3. The maps $\overline{u}_{A/pA}$, $\overline{u}_{B/pB}$ and v induce ring isomorphisms

$$\mathbf{E}/\mathscr{J}^2 \xrightarrow{\sim} B/I_B^2 \xrightarrow{\sim} A/I^2.$$

Proof of the claim. We have a commutative diagram

$$\begin{array}{ccc} \mathbf{E}/\mathscr{J} & \longrightarrow & A/I \\ {\scriptstyle \overline{\Phi}_{\mathbf{E}/\mathscr{J}}} \downarrow & & \downarrow {\scriptstyle \overline{\Phi}_{A/I}} \\ \mathbf{E}/\mathscr{J}^{(p)} & \longrightarrow & A/I^{(p)} \end{array}$$

whose horizontal arrows are induced by $\overline{u}_{A/pA}$. Now, the vertical arrows are isomorphisms, and we have already remarked that the top horizontal arrow is also an isomorphism. Thus, the same holds for the bottom horizontal arrow; since $\overline{u}_{A/pA}(\mathscr{J}^2) = I^2/pA$, we deduce already that $\overline{u}_{A/pA}$ induces an isomorphism $\mathbf{E}/\mathscr{J}^2 \xrightarrow{\sim} A/I^2$. Similarly, since B is perfectoid, $\overline{u}_{B/pB}$ induces an isomorphism $\mathbf{E}/\alpha'_0\mathbf{E} \xrightarrow{\sim} B/pB$; however, $\alpha'_0 \in \mathscr{J}^2$, $p \in I_B^2$, and $\overline{u}_{B/pB}(\mathscr{J}^2) = I_B^2/pB$, so $\overline{u}_{B/pB}$ induces an isomorphism $\mathbf{E}/\mathscr{J}^2 \xrightarrow{\sim} B/I_B^2$. By construction, it is then clear that v induces an isomorphism $B/I_B^2 \xrightarrow{\sim} A/I^2$. ◊

From claim 16.4.3 we see that v induces an isomorphism $B_0 \xrightarrow{\sim} A_0$, and we get as well isomorphisms of $\mathbf{E}$-modules

$$\mathscr{J}/\mathscr{J}^2 \xrightarrow{\sim} I_B/I_B^2 \xrightarrow{\sim} I/I^2.$$

Thus, the left vertical arrow of (16.4.2) is an isomorphism; therefore the same holds for the top horizontal arrow, and hence also for the right vertical arrow. Since B is complete and separated for its I_B-adic topology, and A is complete and separated for its I-adic topology, we conclude that v is an isomorphism of topological rings, whence (b). □

16.4.4. For every $n, r \in \mathbb{N}$, set (see also example 4.8.55(iii))

$$P_r := \mathbb{N}[1/p]^{\oplus r} \qquad R_{r,n} := \mathbb{Z}[P_r] = \mathbb{Z}[T_1^{1/p^\infty}, \dots, T_r^{1/p^\infty}]$$

so, actually $R_{r,n}$ is independent of n, but we also consider the ring homomorphism

$$v_{r,n} : R_{r,n} \to R_{r,0} \qquad T_i^a \mapsto T_i^{a/p^n} \qquad \text{for every } a \in \mathbb{N}[1/p] \text{ and } i = 1, \dots, r$$

for every $r, n \in \mathbb{N}$. Let also $T_\bullet P_r \subset P_r$ be the ideal generated by $\mathbb{N}^{\oplus r}$, and set

$$I_{r,n} := (T_\bullet P_r) \cdot R_{r,n} \qquad I_{r,n}^{\lceil s \rceil} := (T_\bullet P_r)^{\lceil s \rceil} \cdot R_{r,n} \qquad \text{for every } s \in \mathbb{R}_+$$

(notation of remark 9.3.70(i)). Thus $I_{r,n}^{\lceil s \rceil}$ is an ideal of $R_{r,n}$, for every $s \in \mathbb{R}_+$ and every $r, n \in \mathbb{N}$. Next, let A be any ring, $u_0 : R_{r,0} \to A$ any ring homomorphism, and for every $n \in \mathbb{N}$ set $u_n := u_0 \circ v_{r,n} : R_{r,n} \to A$, denote by $\mathbf{f}^{(n)}$ the sequence $(u_n(T_1), \dots, u_n(T_r))$ of elements of A; for $n = 0$, we shall also write just $\mathbf{f}$ instead of $\mathbf{f}^{(0)}$ and denote by $J \subset A$ the ideal generated by $\mathbf{f}$. We may then state :

Lemma 16.4.5. *In the situation of* (16.4.4)*, suppose furthermore that*

$$\mathrm{Tor}_i^{R_{r,0}}(R_{r,0}/I_{r,0}^{\lceil s \rceil}, A) = 0 \qquad \textit{for every } i > 0 \textit{ and every } s \in \mathbb{R}_+.$$

Then the following holds :

(i) *The ring A satisfies condition* $(\mathrm{a})_{\mathbf{f}^{(n)}}^{\mathrm{un}}$ *of* (7.8.21) *with step $\leq r$, for every $n \in \mathbb{N}$.*
(ii) $\mathrm{Ann}_A(J^k) = \mathrm{Ann}_A(I_{r,0}^{\lceil 0 \rceil} \cdot A)$ *for every $k > 0$.*
(iii) $\mathrm{Ann}_A(J) \cap I_{r,0}^{\lceil 0 \rceil} \cdot A = 0$.

Proof. (i): In case $r = 0$, there is nothing to prove, so we assume henceforth that $r > 0$. For every $n \in \mathbb{N}$, endow A with the $R_{r,n}$-module structure induced by u_n.

Claim 16.4.6. $\mathrm{Tor}_i^{R_{r,n}}(R_{r,n}/I_{r,n}^{\lceil s \rceil}, A) = 0$ for every $i > 0$ and every $s \in \mathbb{R}_+$.

Proof of the claim. The base change $v_{r,n} : R_{r,n} \to R_{r,0}$ yields a spectral sequence

$$E_{ij}^2 := \mathrm{Tor}_i^{R_{r,0}}(\mathrm{Tor}_j^{R_{r,n}}(R_{r,n}/I_{r,n}^{\lceil s \rceil}, R_{r,0}), A) \Rightarrow \mathrm{Tor}_i^{R_{r,n}}(R_{r,n}/I_{r,n}^{\lceil s \rceil}, A).$$

But since $v_{r,n}$ is an isomorphism and $v_{r,n}(I_{r,n}^{\lceil s \rceil}) = I_{r,0}^{\lceil s/p^n \rceil}$, we see that $E_{ij}^2 = 0$ for every $j > 0$, and $E_{i0}^2 = \mathrm{Tor}_i^{R_{r,0}}(R_{r,0}/I_{r,0}^{\lceil s/p^n \rceil}, A)$. Thus, $E_{i0}^2 = 0$ for $i > 0$, whence the claim. $\diamondsuit$

In view of claim 16.4.6, we may replace u_0 by u_n, and reduce to checking condition $(\mathrm{a})_{\mathbf{f}}^{\mathrm{un}}$ for A. To this aim, define A_r, I_r and the ring homomorphism $\beta_{\mathbf{f}} : A_r \to A$ as in (7.8.21); endow also $R_{r,0}$ with the A_r-module structure induced by the inclusion map $A_r \to R_{r,0}$, and consider the change of rings spectral sequence

$$E(n)_{pq}^2 := \mathrm{Tor}_p^{R_{r,0}}(\mathrm{Tor}_q^{A_r}(A_r/I_r^n, R_{r,0}), A) \Rightarrow \mathrm{Tor}_{p+q}^{A_r}(A_r/I_r^n, A) \qquad \text{for every } n \in \mathbb{N}.$$

It is easily seen that $R_{r,0}$ is a free A_r-module, hence $E(n)_{pq}^2 = 0$ whenever $q > 0$, and $E(n)_{p0}^2 = R_{r,0}/I_{r,0}^n$. There follows a natural isomorphism

$$\mathrm{Tor}_p^{R_{r,0}}(R_{r,0}/I_{r,0}^n, A) \xrightarrow{\sim} \mathrm{Tor}_p^{A_r}(A_r/I_r^n, A) \qquad \text{for every } p, n \in \mathbb{N}.$$

Now, recall that $I_{r,0}^{n+r} \subset I_{r,0}^{\lceil n+r-1 \rceil} \subset I_{r,0}^n$ for every $n \in \mathbb{N}$ (lemma 9.3.69(iv)); then our assumption implies immediately that the inverse system $(\mathrm{Tor}_p^{A_r}(A_r/I_r^n, A) \mid n \in \mathbb{N})$ is uniformly essentially zero, with step $\leq r$.

(iii): We have just seen that condition $(\mathrm{a})_{\mathbf{f}^{(n)}}^{\mathrm{un}}$ holds for every n, with step bounded by r. For every $n \in \mathbb{N}$, let $J_n \subset A$ be the ideal generated by $\mathbf{f}^{(n)}$; according to remark 7.8.34(ii), it follows that there exists a sequence of integers $(d(i) \mid i \in \mathbb{N})$ such that inverse system

$(H_{i+1}(\mathbf{f}^{(n)}, J_n^k) \mid k \in \mathbb{N})$ is uniformly essentially zero, with step bounded by $d(i)$, for every $i, n \in \mathbb{N}$. Especially, for $d := d(r)$ we get

$$\mathrm{Ann}_A(J_n) \cap J_n^d = 0 \qquad \text{for every } n \in \mathbb{N}.$$

By a simple induction argument, we deduce that $\mathrm{Ann}_A(J_n^{k+1}) \cap J_n^d = 0$ for every $n, k \in \mathbb{N}$. But clearly, for every $n \in \mathbb{N}$ there exists $k \in \mathbb{N}$ such that $J_n^{k+1} \subset J$, whence

$$\mathrm{Ann}_A(J) \cap J_n^d = 0 \qquad \text{for every } n \in \mathbb{N}$$

which yields easily the contention.

(ii) is an easy consequence of (iii). □

Proposition 16.4.7. *Let $f : A \to B$ be any homomorphism of perfect $\mathbb{F}_p$-algebras, $I \subset A$ any ideal. Then the natural morphism*

$$A/I^{\lceil s \rceil}A \overset{\mathbf{L}}{\otimes}_A B \to A/I^{\lceil s \rceil}A \otimes_A B[0]$$

is an isomorphism in $\mathsf{D}(A\text{-}\mathbf{Mod})$, for every $s \in \mathbb{R}_+$ (notation of remark 9.3.70(i)).

Proof. We reduce easily to the case where I is finitely generated, and $f = \mathbf{E}^*(f_0)$ for a map $f_0 : A_0 \to B_0$ of $\mathbb{F}_p$-algebras of finite type (where A_0 and B_0 are endowed with their discrete topologies : notation of (9.4.7)). Then we may also assume that $I = I_0 A$ for some finitely generated ideal $I_0 \subset A_0$, and it suffices to show :

Claim 16.4.8. In the foregoing situation, for every $\lambda, \lambda' \in \mathbb{N}[1/p]$ with $\lambda' < \lambda$, the inclusion $I^{\langle\lambda\rangle}A \subset I^{\langle\lambda'\rangle}A$ induces the zero map

$$\mathrm{Tor}_i^A(A/I^{\langle\lambda\rangle}A, B) \to \mathrm{Tor}_i^A(A/I^{\langle\lambda'\rangle}A, B) \qquad \text{for every } i > 0.$$

Proof of the claim. Under the current assumptions, A is the colimit of the system of $\mathbb{F}_p$-algebras $(A_n \mid n \in \mathbb{N})$ such that $A_n := A_0$ for every $n \in \mathbb{N}$, with transition maps $\varphi_n : A_n \to A_{n+1}$ given by the Frobenius map Φ_{A_0}, and likewise for B. Moreover, say that $\lambda = ap^k$ and $\lambda' = bp^k$ for some $a, b, k \in \mathbb{N}$, and for every $n \in \mathbb{N}$ define ideals of A_n by the rules :

$$I_n := \begin{cases} 0 & \text{for } n < k \\ I_0^{ap^{n-k}} & \text{for } n \geq k \end{cases} \qquad \text{and} \qquad I'_n := \begin{cases} 0 & \text{for } n < k \\ I_0^{bp^{n-k}} & \text{for } n \geq k. \end{cases}$$

Then it is easily seen that $\varphi_n(I_n) \subset I_{n+1}$, and likewise for I'_n, for every $n \in \mathbb{N}$. Furthermore, the colimit of the system $(I_n \mid n \in \mathbb{N})$ (resp. $(I'_n \mid n \in \mathbb{N})$) is $I^{\langle\lambda\rangle}A$ (resp. $I^{\langle\lambda'\rangle}A$). By claim 7.11.37(i), we are therefore reduced to showing that the map induced by the inclusion $I_n \subset I'_n$

$$\mathrm{Tor}_i^{A_0}(A_0/I_n, B_0) \to \mathrm{Tor}_i^{A_0}(A_0/I'_n, B_0)$$

vanishes, for every sufficiently large $n \in \mathbb{N}$. Since $a > b$, the latter assertion follows from claim 7.9.18(ii) (applied with $M := A$ and $N := B$). □

16.4.9. We are going now to apply the general setup of (16.4.4) to the case where A is a perfectoid ring, and

$$\mathbf{f} := (\overline{u}_A(\beta_1), \dots, \overline{u}_A(\beta_r))$$

for a given sequence $\beta_\bullet := (\beta_1, \dots, \beta_r)$ of elements of $\mathbf{E} := \mathbf{E}(A)$. To ease notation, we shall simply write P instead of P_r and R instead of $R_{r,0}$. Also, we shall write $I, I^{\lceil s \rceil} \subset R$ instead of $I_{r,0}$, and respectively $I_{r,0}^{\lceil s \rceil}$, for every $s \in \mathbb{R}_+$. Likewise, we shall write u instead of u_0; hence $u : R \to A$ is the unique ring homomorphism such that $u(T_i) = \overline{u}_A(\beta_i)$ for $i = 1, \dots, r$.

Proposition 16.4.10. (i) *With the notation of* (16.4.9)*, the natural morphism*

$$R/I^{\lceil s\rceil} \overset{\mathbf{L}}{\otimes}_R A \to A/I^{\lceil s\rceil}A[0]$$

is an isomorphism in $\mathsf{D}(R\text{-}\mathbf{Mod})$*, for every* $s \in \mathbb{R}_+$*.*

(ii) *In particular, A satisfies condition* $(\mathrm{a})^{\mathrm{un}}_{\mathbf{f}^{(n)}}$ *of* (7.8.21) *with step* $\leq r$*, for every* $n \in \mathbb{N}$*.*

Proof. In view of lemma 16.4.5(i), it suffices to check (i). Notice that $R_0 := R \otimes_{\mathbb{Z}} \mathbb{F}_p$ is a perfect $\mathbb{F}_p$-algebra, and $I^{\lceil s\rceil}R_0 = I_0^{\lceil s\rceil}R_0$, where $I_0 \subset R_0$ is the ideal generated by $(T_1, \dots, T_r)$. In light of proposition 16.4.7, we deduce

$$\text{(16.4.11)} \qquad \mathrm{Tor}_i^{R_0}(R_0/I^{\lceil s\rceil}R_0, \mathbf{E}) = 0 \qquad \text{for every } s \in \mathbb{R}_+ \text{ and every } i > 0.$$

On the other hand, we have a standard 2-spectral sequence

$$E^2_{pq} := \mathrm{Tor}_p^{R_0}(\mathrm{Tor}_q^R(R/I^{\lceil s\rceil}, R_0), \mathbf{E}) \Rightarrow \mathrm{Tor}^R_{p+q}(R/I^{\lceil s\rceil}, \mathbf{E})$$

([163, Th.5.6.6]). However, by construction $I^{\lceil s\rceil}$ is a direct summand of the free $\mathbb{Z}$-module R, so $R/I^{\lceil s\rceil}$ is also a free $\mathbb{Z}$-module, and then a standard calculation shows that $E^2_{pq} = 0$ whenever $q > 0$. From (16.4.11) we see as well that $E^2_{p0} = 0$ for every $p > 0$, so we conclude

$$\mathrm{Tor}_i^R(R/I^{\lceil s\rceil}, \mathbf{E}) = 0 \qquad \text{for every } s \in \mathbb{R}_+ \text{ and every } i > 0.$$

Next, an easy induction argument using the short exact sequences of $W(\mathbf{E})$-modules

$$0 \to \mathbf{E} \simeq p^n W_{n+1}(\mathbf{E}) \to W_{n+1}(\mathbf{E}) \to W_n(\mathbf{E}) \to 0 \qquad \text{for every } n \in \mathbb{N}$$

shows more generally that

$$\text{(16.4.12)} \qquad \mathrm{Tor}_i^R(R/I^{\lceil s\rceil}, W_n(\mathbf{E})) = 0 \qquad \text{for every } s \in \mathbb{R}_+, \text{ every } i > 0 \text{ and every } n \in \mathbb{N}.$$

For every $n \in \mathbb{N}$, set $J_n := \boldsymbol{p}_P^{-n}(T_\bullet P)$, where $\boldsymbol{p}_P$ denotes the p-Frobenius automorphism of P (see definition 4.8.40(ii)), and consider the projection

$$\pi_n^{(a,b)} : R/J_n^a R \to R/J_n^b R \qquad \text{for every } a, b, n \in \mathbb{N} \text{ with } a \geq b.$$

Claim 16.4.13. With the foregoing notation, we have :

(i) $\mathrm{Tor}_i^R(\pi_n^{(a,b)}, W_m(\mathbf{E})) = 0$ for every $a, b, i, m, n \in \mathbb{N}$ with $a - b \geq r$ and $i > 0$.

(ii) For every $a, n \in \mathbb{N}$ there exists a complex of free R-modules of finite type $L^\bullet_{a,n}$ with a quasi-isomorphism $L^\bullet_{a,n} \to R/J_n^a[0]$ of complexes of R-modules.

(iii) $\mathrm{Tor}_i^R(\pi_n^{(a,b)}, W(\mathbf{E})) = 0$ for every $a, b, i, n \in \mathbb{N}$ with $a - b \geq 2r$ and $i > 0$.

Proof of the claim. If $r = 0$ there is nothing to prove, so we may assume that $r > 0$.

(i): Notice that J_n is generated by a system of r elements of P, for every $n \in \mathbb{N}$; in view of lemma 9.3.69(ii.c,iv), we deduce

$$J_n^a \subset J_n^{\langle a\rangle} \subset (T_\bullet P)^{\lceil (b+r-1)p^{-n}\rceil} \subset J_n^{\langle b+r-1\rangle} \subset J_n^b$$

so the assertion follows from (16.4.12).

(ii): The ideal J_nR is generated by the system $(T_1^{1/p^n}, \dots, T_r^{1/p^n})$ of elements of the subring $S_n := \mathbb{Z}[T_1^{1/p^n}, \dots, T_r^{1/p^n}]$; since S_n is noetherian, we may find a complex $L'^\bullet_{a,n}$ of free S_n-modules of finite type, with a quasi-isomorphism $L'^\bullet_{a,n} \to S_n/J_n^a S_n[0]$, and since the inclusion map $S_n \to R$ is flat, the complex $L^\bullet_{a,n} := L'^\bullet_{a,n} \otimes_{S_n} R$ will do.

(iii): For given $a, n \in \mathbb{N}$, let $L^\bullet_{a,n}$ be as in (ii); it is easily seen that the natural map

$$\lim_{m\in\mathbb{N}} L^\bullet_{a,n} \otimes_R W_m(\mathbf{E}) \to L^\bullet_{a,n} \otimes_R W(\mathbf{E})$$

is an isomorphism in $\mathsf{C}(R\text{-}\mathbf{Mod})$. To ease notation, set $\mathscr{T}^a_{i,n,m} := \mathrm{Tor}^R_i(R/J^a_nR, W_m(\mathbf{E}))$ for every $i, m, n \in \mathbb{N}$; in light of [163, Th.3.5.8] we deduce natural short exact sequences

$$0 \to R^1 \lim_{m\in\mathbb{N}} \mathscr{T}^a_{i-1,n,m} \to \mathrm{Tor}^R_i(R/J^a_nR, W(\mathbf{E})) \to \lim_{m\in\mathbb{N}} \mathscr{T}^a_{i,n,m} \to 0$$

for every $i, a, n \in \mathbb{N}$. Then the assertion follows from (i). $\diamondsuit$

Now, for any $s \in \mathbb{R}_+$, let S_s be the set of all pairs $(a, n) \in \mathbb{N} \times \mathbb{N}$ such that $ap^{-n} > s$; we define a partial ordering on S_s by the rule : $(a, n) \geq (b, m)$ if and only if $n \geq m$ and $ap^m \leq bp^n$. With this notation, notice that $J^b_m \subset J^a_n$ whenever $(a, n) \geq (b, m)$, and $I^{\lceil s\rceil}$ is the union of its filtered system of subideals $(J^a_nR \mid (a, n) \in S_s)$. Taking into account claim 16.4.13(iii) we deduce that

$$\text{(16.4.14)} \qquad \mathrm{Tor}^R_i(R/I^{\lceil s\rceil}, W(\mathbf{E})) = 0 \qquad \text{for every } s \in \mathbb{R}_+ \text{ and every } i > 0.$$

Next, from remark 16.1.7(ii) we get a short exact sequence of R-modules

$$0 \to W(\mathbf{E}) \xrightarrow{\underline{\alpha}} W(\mathbf{E}) \to A \to 0$$

where $\underline{\alpha}$ is any distinguished element in $\mathrm{Ker}\, u_A$. Then, by the induced long exact Tor-sequence, (16.4.14) implies already that $\mathrm{Tor}^R_i(R/I^{\lceil s\rceil}, A)$ vanishes for every $i > 1$. By the same token, we also see that $\mathrm{Tor}^R_1(R/I^{\lceil s\rceil}, A)$ is isomorphic to the kernel of scalar multiplication by $\underline{\alpha}$ on the R-module $W(\mathbf{E})/I^{\lceil s\rceil}W(\mathbf{E})$; to conclude the proof, it then suffices to remark :

Claim 16.4.15. $\underline{\alpha}W(\mathbf{E}) \cap I^{\lceil s\rceil}W(\mathbf{E}) = \underline{\alpha}I^{\lceil s\rceil}W(\mathbf{E})$.

Proof of the claim. Denote by $\mathscr{I} \subset \mathbf{E}$ the ideal generated by $\beta_\bullet$; from proposition 9.3.77(i) we easily deduce that $I^{\lceil s\rceil}W(\mathbf{E}) = \bigcup_{s'>s} W(\mathscr{I}^{\lfloor s'\rfloor})$, and in view of proposition 16.1.12(ii) we get

$$\underline{\alpha}W(\mathbf{E}) \cap I^{\lceil s\rceil}W(\mathbf{E}) = \bigcup_{s'>s}(\underline{\alpha}W(\mathbf{E}) \cap W(\mathscr{I}^{\lfloor s'\rfloor})) = \bigcup_{s'>s} \underline{\alpha}W(\mathscr{I}^{\lfloor s'\rfloor}) = \underline{\alpha}I^{\lceil s\rceil}W(\mathbf{E})$$

as stated. $\square$

Corollary 16.4.16. *In the situation of* (16.4.9)*, set $J := IA$, and denote by $A^\wedge_J$ the J-adic completion of A. Let also $C_\bullet$ be any bounded above complex of flat A-modules such that for every $i \in \mathbb{Z}$ there exists $c(i) \in \mathbb{N}$ with $J^{c(i)} \cdot H_iC_\bullet = 0$. Then the natural morphism*

$$C_\bullet \to A^\wedge_J \otimes_A C_\bullet$$

is an isomorphism in $\mathsf{D}(A\text{-}\mathbf{Mod})$.

Proof. It is an immediate consequence of proposition 16.4.10(ii) and corollary 8.6.34. $\square$

Proposition 16.4.17. *In the situation of* (16.4.9)*, suppose that the sequence $\beta_\bullet$ generates an open ideal of* $\mathbf{E}$*. Then the following conditions are equivalent :*

(a) *The sequence $\beta_\bullet$ is completely secant in* $\mathbf{E}$*.*
(b) *The sequence $b_\bullet := (\overline{u}_A(\beta_1), \dots, \overline{u}_A(\beta_r))$ is completely secant in A.*

Proof. Set as usual $J := IA$, and let $A^\wedge_J$ be the J-adic completion of A. In view of corollary 16.4.16, we see that the sequence $b_\bullet$ is completely secant in A if and only if its image is completely secant in $A^\wedge_J$. Moreover, if $\mathscr{J} \subset \mathbf{E}$ denotes the ideal generated by $\beta_\bullet$, we have a natural ring isomorphism $\mathbf{E}(A^\wedge_J) \xrightarrow{\sim} \mathbf{E}^\wedge_{\mathscr{J}}$ (theorem 16.3.78(ii)), and by the same token the sequence $\beta_\bullet$ is completely secant in the perfectoid ring $\mathbf{E}$ if and only if the same holds for its image in $\mathbf{E}^\wedge_{\mathscr{J}}$. Thus, we may replace A by $A^\wedge_J$, and assume from start that A is J-adically complete and separated. Next, let $(\alpha_n \mid n \in \mathbb{N})$ be any distinguished element in $\mathrm{Ker}\, u_A$; since $\mathscr{J}$ is open, we have $\alpha_0^n \in \mathscr{J}$ for some integer $n \in \mathbb{N}$, and then we may find $k \in \mathbb{N}$ such that α_0 is contained in the ideal generated by the sequence $\beta'_\bullet := (\beta_1^{1/p^k}, \dots, \beta_r^{1/p^k})$. In light of corollary 7.8.8, we may then replace $\beta_\bullet$ with $\beta'_\bullet$, and assume that $\alpha_0 \in \mathscr{J}$. Notice now that $\{\mathscr{J}^n\} = J^n$ for every

$\in \mathbb{N}$ (remark 16.3.28(viii)), and the inclusion $\mathscr{J}^{n+1} \subset \mathscr{J}^n$ is taut for every $n \in \mathbb{N}$, so theorem 16.3.31(ii) yields a natural isomorphism

$$\overline{\tau} : \bigoplus_{n \in \mathbb{N}} \mathscr{J}^n / \mathscr{J}^{n+1} \xrightarrow{\sim} \bigoplus_{n \in \mathbb{N}} J^n / J^{n+1}.$$

Moreover, a simple inspection shows that $\overline{\tau}$ is an isomorphism of A/pA-algebras; it follows immediately that the sequence $\beta_\bullet$ is $\mathbf{E}$-quasi-regular if and only if the sequence $b_\bullet$ is A-quasi-regular (see remark 7.10.44(i)). To conclude, it suffices now to invoke proposition 7.10.47. $\square$

Proposition 16.4.18. *Let $f : A \to A'$ be any continuous map of perfectoid rings, I (resp. $\mathscr{I}$) a finite type ideal of definition of A (resp. of $\mathbf{E}(A)$), and denote by $\mathscr{T}_I$ (resp. $\mathscr{T}_\mathscr{I}$) the IA'-adic topology of A' (resp. the $\mathscr{I}\mathbf{E}(A')$-adic topology of $\mathbf{E}(A')$). Then $f : A \to (A', \mathscr{T}_I)$ is adically flat if and only if the same holds for $\mathbf{E}(f) : \mathbf{E}(A) \to (\mathbf{E}(A'), \mathscr{T}_\mathscr{I})$ (see definition* 8.3.23(iii)*).*

Proof. Set $\mathbf{E} := \mathbf{E}(A)$, $\mathbf{E}' := \mathbf{E}(A')$, and let $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N})$ be a distinguished element of $\mathrm{Ker}(u_A)$; by lemma 8.3.12 and proposition 16.3.8, the topological ring $(A', \mathscr{T}_I)$ is perfectoid, so we may assume that f is adic, in which case the same holds for $\mathbf{E}(f) : \mathbf{E} \to \mathbf{E}'$, by theorem 16.3.42(i). Let also $\beta_\bullet := (\beta_1, \dots, \beta_n)$ be a sequence of elements of $\mathbf{E}$ that generates $\mathscr{I}$; we may assume that $\alpha_0 \in \mathscr{I}$, and by corollary 16.3.40(i,ii) we may also assume that I is generated by $\mathbf{f} := (\overline{u}_A(\beta_1), \dots, \overline{u}_A(\beta_k))$. Set moreover $\gamma_\bullet := (p, \tau_A(\beta_1), \dots, \tau_A(\beta_k))$ and $\delta_\bullet := (\underline{\alpha}, \tau_A(\beta_1), \dots, \tau_A(\beta_k))$ (notation of (16.1)), and denote by ∂_γ (resp. ∂_δ) the $W(\mathbf{E})$-linear form $W(\mathbf{E})^{\oplus k+1} \to W(\mathbf{E})$ such that $\partial_\gamma(w_0, \dots, w_k) := pw_0 + \sum_{i=1}^k \tau_A(\beta_i)w_i$ (resp. $\partial_\gamma(w_0, \dots, w_k) := \underline{\alpha}w_0 + \sum_{i=1}^k \tau_A(\beta_i)w_i$) for every $(w_0, \dots, w_k) \in W(\mathbf{E})^{\oplus k+1}$. Let $\mathscr{J} \subset W(\mathbf{E})$ be the ideal generated by the sequence $\gamma_\bullet$, and set $S := 1 + \mathscr{J}$; according to remark 16.1.10, there exists a $S^{-1}W(\mathbf{E})$-linear automorphism f of $S^{-1}W(\mathbf{E})^{\oplus k+1}$ with $S^{-1}\partial_\delta = S^{-1}\partial_\gamma \circ f$; the latter induces an isomorphism of differential graded $S^{-1}W(\mathbf{E})$-algebras :

$$\mathbf{K}_\bullet(\gamma_\bullet) \xrightarrow{\sim} \mathbf{K}_\bullet(\delta_\bullet) \tag{16.4.19}$$

(notation of (7.8)). Recall furthermore that p and $\underline{\alpha}$ are regular elements of $W(\mathbf{E})$ (proposition 9.3.47(i)); there follow natural identifications in $\mathsf{D}(W(\mathbf{E}))$:

$$\mathbf{K}_\bullet(p) \xrightarrow{\sim} W(\mathbf{E})/pW(\mathbf{E})[0] \xrightarrow{\sim} E[0] \qquad \mathbf{K}_\bullet(\underline{\alpha}) \xrightarrow{\sim} W(\mathbf{E})/\underline{\alpha}W(\mathbf{E})[0] \xrightarrow{\sim} A[0]$$

whence $W(\mathbf{E})$-linear isomorphisms :

$$H_i(\gamma_\bullet, W(\mathbf{E})) \xrightarrow{\sim} H_i(\mathbf{f}, A) \qquad H_i(\delta_\bullet, W(\mathbf{E})) \xrightarrow{\sim} H_i(\beta_\bullet, \mathbf{E}) \qquad \text{for every } i \in \mathbb{N}.$$

Notice that $H_i(\gamma_\bullet, W(\mathbf{E}))$ is a $W(\mathbf{E})/\mathscr{J}$-module for every $i \in \mathbb{N}$ (lemma 7.8.2(i)), hence the localization map $H_i(\gamma_\bullet, W(\mathbf{E})) \to H_i(\gamma_\bullet, S^{-1}W(\mathbf{E}))$ is an isomorphism, and likewise for $H_i(\delta_\bullet, W(\mathbf{E}))$, since $\delta_\bullet$ generates $\mathscr{J}$ (lemma 16.1.9(ii)). Combining with (16.4.19), we then deduce a commutative diagram :

$$\begin{array}{ccc} H_i(\gamma_\bullet, W(\mathbf{E})) & \xrightarrow{\sim} & H_i(\delta_\bullet, W(\mathbf{E})) \\ \downarrow & & \downarrow \\ H_i(\mathbf{f}, A) & \xrightarrow{\omega_{i,\mathbf{f}}} & H_i(\beta_\bullet, \mathbf{E}) \end{array} \qquad \text{for every } i \in \mathbb{N}$$

all whose arrows are isomorphisms of $W(\mathbf{E})$-modules. Next, denote by $\beta'_\bullet$ (resp. $\mathbf{f}'$) the image of the sequence $\beta_\bullet$ in $\mathbf{E}'$ (resp. of the sequence $\mathbf{f}$ in A'); we get likewise an isomorphism of $W(\mathbf{E}')$-modules $\omega_{i,\mathbf{f}'} : H_i(\mathbf{f}', A') \xrightarrow{\sim} H_i(\beta'_\bullet, \mathbf{E}')$ for every $i \in \mathbb{N}$. Lastly, since $\alpha_0 \in \mathscr{I}$, the map $\overline{u}_{A'} : \mathbf{E}' \to A'$ induces an isomorphism of $W(\mathbf{E}')$-algebras $\mathbf{E}'/\mathscr{I}\mathbf{E}' \xrightarrow{\sim} A'/IA'$, and notice that

$H_i(\mathbf{f}', A')$ (resp. $H_i(\beta'_\bullet, \mathbf{E}')$) is an A'/IA'-module (resp. an $\mathbf{E}'/\mathscr{I}\mathbf{E}'$-module) for every $i \in \mathbb{N}$. By inspecting the constructions, we then obtain a commutative diagram of $W(\mathbf{E}')$-modules :

$$\begin{array}{ccc} A'/IA' \otimes_A H_i(\mathbf{f}, A) & \xrightarrow{A'/IA' \otimes_A \omega_{i,\mathbf{f}}} & \mathbf{E}'/\mathscr{I}\mathbf{E}' \otimes_{\mathbf{E}} H_i(\beta_\bullet, \mathbf{E}) \\ \downarrow & & \downarrow \\ H_i(\mathbf{f}', A') & \xrightarrow{\omega_{i,\mathbf{f}'}} & H_i(\beta'_\bullet, \mathbf{E}'). \end{array}$$

The proposition now follows, by combining with proposition 14.2.49(i,iii). □

Remark 16.4.20. (i) In the situation of proposition 16.4.18, we also have that $f : A \to (A', \mathscr{T}_I)$ is adically faithfully flat if and only if the same holds for $\mathbf{E}(f) : \mathbf{E}(A) \to (\mathbf{E}(A'), \mathscr{T}_{\mathscr{I}})$. Indeed, notice that the closed immersion $\mathrm{Spec}\, A/I \to \mathrm{Spec}\, A/I^n$ is a homeomorphism for every $n \in \mathbb{N}$, and likewise for the map $\mathrm{Spec}\, \mathbf{E}(A)/\mathscr{I} \to \mathrm{Spec}\, \mathbf{E}(A)/\mathscr{I}^n$. However, f is adically faithfully flat if and only if it is adically flat and the induced map $h_n : \mathrm{Spec}\, A'/I^nA' \to \mathrm{Spec}\, A'/I^n$ is surjective for every $n \in \mathbb{N}$, and the latter condition then holds if and only if h_1 is surjective. Likewise, $\mathbf{E}(f)$ is adically faithfully flat if and only if it is adically flat and the induced map k_1 : $\mathrm{Spec}\, \mathbf{E}(A')/\mathscr{I}\mathbf{E}(A') \to \mathrm{Spec}\, \mathbf{E}(A)/\mathscr{I}$ is surjective. Thus, we come down to checking that h_1 is surjective if and only the same holds for k_1, but this is clear, because arguing as in the proof of proposition 16.4.18 we may assume that $\overline{u}_A$ and $\overline{u}_{A'}$ induce isomorphisms $\mathbf{E}(A)/\mathscr{I} \xrightarrow{\sim} A/I$ and $\mathbf{E}(A')/\mathscr{I}\mathbf{E}(A') \xrightarrow{\sim} A'/IA'$, and these isomorphisms identify h_1 with k_1.

(ii) For every perfectoid ring A, let A-$\mathsf{Perf}_{\mathrm{ad.fl}}$ be the full subcategory of A-Perf whose objects are the adic and adically flat maps $A \to B$ of perfectoid rings. Proposition 16.4.18 shows that the functor $\mathbf{E}$ of remark 16.3.7(i) restricts to an equivalence of categories

$$A\text{-}\mathsf{Perf}_{\mathrm{ad.fl}} \xrightarrow{\sim} \mathbf{E}(A)\text{-}\mathsf{Perf}_{\mathrm{ad.fl}}.$$

(iii) Let $\mathscr{I} \subset \mathbf{E}(A)$ be an ideal of adic definition, set $\mathbf{E}_0 := \mathbf{E}(A)/\mathscr{I}$, and denote by $\mathscr{A}(\mathbf{E}_0)$ the category whose objects are all the flat ring homomorphisms $f : \mathbf{E}_0 \to C$ such that the following commutative diagram is cocartesian :

(16.4.21)
$$\begin{array}{ccc} \mathbf{E}_0 & \xrightarrow{f} & C \\ {\scriptstyle\Phi_{\mathbf{E}_0}}\downarrow & & \downarrow{\scriptstyle\Phi_C} \\ \mathbf{E}_0 & \xrightarrow{f} & C \end{array}$$

where the vertical arrows are the Frobenius endomorphisms. Now, let $g : \mathbf{E}(A) \to E$ be any object of $\mathbf{E}(A)$-$\mathsf{Perf}_{\mathrm{ad.fl}}$; we get a commutative diagram :

$$\begin{array}{ccccc} \mathbf{E}_0 & \xrightarrow{\overline{\Phi}_{\mathbf{E}(A)}} & \mathbf{E}(A)/\mathscr{I}^p & \longrightarrow & \mathbf{E}_0 \\ \downarrow & & \downarrow & & \downarrow \\ E/\mathscr{I}E & \xrightarrow{\overline{\Phi}_E} & E/\mathscr{I}^pE & \longrightarrow & E/\mathscr{I}E \end{array}$$

where $\overline{\Phi}_{\mathbf{E}(A)}$ (resp. $\overline{\Phi}_E$) is induced by the Frobenius endomorphism of $\mathbf{E}(A)$ (resp. of E). Since $\mathbf{E}(A)$ and E are perfect $\mathbb{F}_p$-algebras, we easily see that both square subdiagrams of this diagram are cocartesian, whence an object $\mathbf{E}_0 \otimes_{\mathbf{E}(A)} g : \mathbf{E}_0 \to E/\mathscr{I}E$ of $\mathscr{A}(\mathbf{E}_0)$. We have thus a well defined functor :

(16.4.22)
$$\mathbf{E}(A)\text{-}\mathsf{Perf}_{\mathrm{ad.fl}} \to \mathscr{A}(\mathbf{E}_0).$$

Proposition 16.4.23. *The functor* (16.4.22) *is an equivalence of categories.*

Proof. We construct an explicit quasi-inverse as follows. Let $f : \mathbf{E}_0 \to C$ be any object of $\mathscr{A}(\mathbf{E}_0)$, and set $\mathbf{E}_n := \mathbf{E}(A)/\mathscr{I}^{n+1}$ for every $n \in \mathbb{N}$; we exhibit inductively a compatible system of flat ring homomorphisms $(f_n : \mathbf{E}_n \to C_n \mid n \in \mathbb{N})$ with isomorphisms

$$\varphi_n : C_n/\mathscr{I}^n C_n \xrightarrow{\sim} C_{n-1} \quad \text{such that} \quad \varphi_n \circ (\mathbf{E}_{n-1} \otimes_{\mathbf{E}_n} f_n) = f_{n-1} \quad \text{for every } n > 0$$

and such that the following commutative diagram is cocartesian :

$$\mathscr{D}_n \quad : \quad \begin{array}{ccc} \mathbf{E}_n & \xrightarrow{f_n} & C_n \\ {\scriptstyle \Phi_{\mathbf{E}_n}}\downarrow & & \downarrow{\scriptstyle \Phi_{C_n}} \\ \mathbf{E}_n & \xrightarrow{f_n} & C_n. \end{array}$$

Indeed, set $C_0 := C$, and $f_0 := f$. Suppose next that $n \in \mathbb{N}$, and that f_n and φ_n have already been given; according to [75, Lemma 6.5.13(i)], we have $\mathbb{L}_{C_n/\mathbf{E}_n} = 0$ in $\mathsf{D}(C\text{-}\mathbf{Mod})$, so the existence of a flat ring homomorphism $f_{n+1} : \mathbf{E}_{n+1} \to C_{n+1}$ with the sought isomorphism φ_{n+1} is ensured by [75, Cor.3.2.11(i)]. Diagram $\mathscr{D}_{n+1}$ induces a map of $\mathbf{E}_{n+1}$-algebras ψ_{n+1} : $\mathbf{E}_{n+1,\Phi} \otimes_{\mathbf{E}_{n+1}} C_{n+1} \to C_{n+1}$, where $\mathbf{E}_{n+1,\Phi}$ denotes the ring $\mathbf{E}_{n+1}$, regarded as a $\mathbf{E}_{n+1}$-algebra via the map $\Phi_{\mathbf{E}_{n+1}}$. Since (16.4.21) is cocartesian, $\mathbf{E}_1 \otimes_{\mathbf{E}_{n+1}} \psi_{n+1}$ is an isomorphism, hence the same for $\mathscr{I}^k/\mathscr{I}^{k+1} \otimes_{\mathbf{E}_{n+1}} \psi_{n+1}$, for every $k = 0, \dots, n+1$; but since both C_{n+1} and $D_{n+1} := \mathbf{E}_{n+1,\Phi} \otimes_{\mathbf{E}_{n+1}} C_{n+1}$ are flat $\mathbf{E}_{n+1}$-algebras, the latter map is naturally identified with the map $\mathscr{I}^k D_{n+1}/\mathscr{I}^{k+1} D_{n+1} \to \mathscr{I}^k C_{n+1}/\mathscr{I}^{k+1} C_{n+1}$ induced by ψ_{n+1} ([126, Th.22.3]). It follows easily that ψ_{n+1} is an isomorphism, *i.e.* $\mathscr{D}_{n+1}$ is cocartesian, as required, and this completes the construction of C_n. Let $E := \lim_{n\in\mathbb{N}} C_n$; according to [59, Ch.0, Prop.7.2.7] (and its proof), E is complete and separated for its $\mathscr{I}$-adic topology, and the natural map $E/\mathscr{I}^{n+1}E \to C_n$ is an isomorphism for every $n \in \mathbb{N}$. Moreover, the limit of the system $(f_n \mid n \in \mathbb{N})$ yields an adic ring homomorphism $g : \mathbf{E} \to E$. Lastly, for every $n \in \mathbb{N}$ we consider the commutative diagram

$$\begin{array}{ccccc} \mathbf{E}_n & \xrightarrow{\pi_{\mathbf{E},n}} & \mathbf{E}/\Phi_{\mathbf{E}}^{-1}(\mathscr{I}^{n+1}) & \xrightarrow{\overline{\Phi}_{\mathbf{E}_n}} & \mathbf{E}_n \\ {\scriptstyle f_n}\downarrow & & \downarrow & & \downarrow{\scriptstyle f_n} \\ C_n & \xrightarrow{\pi_{E,n}} & E/\Phi_{\mathbf{E}}^{-1}(\mathscr{I}^{n+1})E & \xrightarrow{\overline{\Phi}_{C_n}} & C_n \end{array}$$

where $\pi_{\mathbf{E},n}$ and $\pi_{E,n}$ are the natural projections, and $\overline{\Phi}_{\mathbf{E}_n}$ (resp. $\overline{\Phi}_{C_n}$) is induced by the Frobenius endomorphism of $\mathbf{E}_n$ (resp. of C_n), so that the composition of the top (resp. bottom) horizontal arrows is $\Phi_{\mathbf{E}_n}$ (resp. Φ_{C_n}). Since $\mathscr{D}_n$ is cocartesian, and since $\pi_{\mathbf{E},n}$ is surjective, it is easily seen that the right square subdiagram is cocartesian; but $\overline{\Phi}_{\mathbf{E}_n}$ is an isomorphism, so the same holds for $\overline{\Phi}_{C_n}$. On the other hand, $(\Phi_{\mathbf{E}}^{-1}(\mathscr{I}^{n+1})E \mid n \in \mathbb{N})$ is a fundamental system of open ideals of E; therefore, the limit of the system of maps $(\overline{\Phi}_{C_n} \mid n \in \mathbb{N})$ is an automorphism of E; clearly the latter is the Frobenius automorphism, so E is a perfectoid $\mathbb{F}_p$-algebra.

In order to check the functoriality of the rule : $(f : \mathbf{E}_0 \to C) \mapsto (g : \mathbf{E}(A) \to E)$, consider any other system $(f'_n : \mathbf{E}_n \to C'_n \mid n \in \mathbb{N})$ of ring homomorphisms, with isomorphisms

$$\varphi'_n : C'_n/\mathscr{I}^n C'_n \xrightarrow{\sim} C'_{n-1} \quad \text{such that} \quad \varphi'_n \circ (\mathbf{E}_{n-1} \otimes_{\mathbf{E}_n} f'_n) = f'_{n-1} \quad \text{for every } n > 0$$

and let $h_0 : C = C_0 \to C'_0$ be a given map of $\mathbf{E}_0$-algebras. We construct inductively a system $h_\bullet := (h_n : C_n \to C'_n \mid n \in \mathbb{N})$ where h_n is a map of $\mathbf{E}_n$-algebras, and $\varphi'_{n+1} \circ (\mathbf{E}_n \otimes_{\mathbf{E}_{n+1}} h_{n+1}) = h_n \circ \varphi_{n+1}$ for every $n \in \mathbb{N}$. The map h_0 is already given. Suppose now that $n \in \mathbb{N}$, and that h_n has already been exhibited. Notice, since f_{n+1} is flat, the projection $C_{n+1} \to C_n$ induces $\mathbf{E}_n$-linear isomorphisms

$$\mathscr{I}\mathbf{E}_{n+1} \otimes_{\mathbf{E}_{n+1}} C_n \xrightarrow{\sim} \mathscr{I}\mathbf{E}_{n+1} \otimes_{\mathbf{E}_{n+1}} C_{n+1} \xrightarrow{\sim} \mathscr{I} C_{n+1}$$

whence a $\mathbf{E}_n$-linear map

$$l_{n+1} : \mathscr{I}C_{n+1} \stackrel{\sim}{\to} \mathscr{I}\mathbf{E}_{n+1} \otimes_{\mathbf{E}_{n+1}} C_n \to \mathscr{I}\mathbf{E}_{n+1} \otimes_{\mathbf{E}_{n+1}} C'_n \stackrel{\sim}{\to} \mathscr{I}\mathbf{E}_{n+1} \otimes_{\mathbf{E}_{n+1}} C'_{n+1} \to \mathscr{I}C'_{n+1}.$$

Then, since $\mathbb{L}_{C_n/\mathbf{E}_n} = 0$, by [75, Prop.3.2.16] there exists a unique ring homomorphism $h_{n+1} : C_{n+1} \to C'_{n+1}$ that makes commute the diagram :

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathscr{I}C_{n+1} & \longrightarrow & C_{n+1} & \longrightarrow & C_n & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle l_{n+1}} & & \downarrow{\scriptstyle h_{n+1}} & & \downarrow{\scriptstyle h_n} & & \\ 0 & \longrightarrow & \mathscr{I}C'_{n+1} & \longrightarrow & C'_{n+1} & \longrightarrow & C'_n & \longrightarrow & 0 \end{array}$$

and this completes the construction of the system $h_\bullet$. The sought functoriality follows immediately. Furthermore, for any object $g' : \mathbf{E}(A) \to E'$ of $\mathbf{E}(A)\text{-}\mathsf{Perf}_{\mathrm{ad.fl}}$, set $C_0 := E'/\mathscr{I}E'$, and let $(\mathbf{E}_n \to C_n \mid n \in \mathbb{N})$ be the system of ring homomorphisms associated to $\mathbf{E}_0 \otimes_{\mathbf{E}(A)} g'$ by the foregoing inductive procedure; by the above, we obtain a compatible system of maps $(h'_n : C_n \to E'/\mathscr{I}^{n+1}E' \mid n \in \mathbb{N})$, and h'_0 is an isomorphism. By a simple induction, we deduce that h'_n is an isomorphism for every $n \in \mathbb{N}$, whence an isomorphism of $\mathbf{E}(A)$-algebras $\lim_{n\in\mathbb{N}} C_n \stackrel{\sim}{\to} E'$; this shows that our functor is indeed a quasi-inverse for (16.4.22). $\square$

16.4.24. Let A be a perfectoid ring, set $\mathbf{E} := \mathbf{E}(A)$, and denote by $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N})$ any distinguished element of $\mathrm{Ker}\, u_A$. Set $I_1 := \mathrm{Ann}_{\mathbf{E}}(\alpha_0)$, let $I_2 \subset \mathbf{E}$ be the radical of the ideal $\alpha_0\mathbf{E}$, and $I_3 := I_1 + I_2$; let also $\mathbf{E}_i := \mathbf{E}/I_i$ for $i = 1, 2, 3$. We claim that the resulting diagram of ring homomorphisms

$$\mathscr{E} \quad : \quad \begin{array}{ccc} \mathbf{E} & \longrightarrow & \mathbf{E}_1 \\ \downarrow & & \downarrow \\ \mathbf{E}_2 & \longrightarrow & \mathbf{E}_3 \end{array}$$

is cartesian. Indeed, it is clear the induced map $\mathbf{E} \to \mathbf{E}_1 \times_{\mathbf{E}_3} \mathbf{E}_2$ is surjective; for the injectivity, suppose that $x \in I_1 \cap I_2$; then $x^n \in \alpha_0 A$ for some $n \in \mathbb{N}$, and $\alpha_0 x = 0$, so that $x^{n+1} = 0$, and therefore $x = 0$, since $\mathbf{E}$ is perfect. Notice also that the $\alpha_0\mathbf{E}$-adic topology agrees with the discrete topology on $\mathbf{E}_2$ and $\mathbf{E}_3$, and by arguing as in remark 16.3.39(ii) we see that I_1 is a closed ideal for the α_0-adic topology of $\mathbf{E}$. Moreover, since $\mathbf{E}$ is perfect, it is easily seen that I_1 is a radical ideal; then it follows that the same holds for I_3, since we have already observed that the latter equals $I_1 \oplus I_2$. Summing up, we deduce that $\mathbf{E}_i$, endowed with its α_0-adic topology, is a perfectoid ring for $i = 1, 2, 3$. Consequently, the same holds for the rings

$$A_i := A \otimes_{\mathbb{W}(\mathbf{E})} W(\mathbf{E}_i) \qquad i = 1, 2, 3$$

and $\mathbf{E}(A_i) = \mathbf{E}_i$, provided we endow each A_i with its p-adic topology (proposition 16.2.21(i)). Furthermore, arguing as in the proof of claim 16.3.22 we easily see that the resulting diagram of ring homomorphisms :

$$A(\mathscr{E}) \quad : \quad \begin{array}{ccc} A & \longrightarrow & A_1 \\ \downarrow & & \downarrow \\ A_2 & \longrightarrow & A_3 \end{array}$$

is still cartesian. Set as well

$$X_{\mathbf{E}} := \mathrm{Spec}\, \mathbf{E} \quad X_A := \mathrm{Spec}\, A \quad \text{and} \quad X_{\mathbf{E}_k} := \mathrm{Spec}\, \mathbf{E}_k \quad X_{A_k} := \mathrm{Spec}\, A_k \quad \text{for } k = 1, 2, 3$$

and denote the resulting closed immersions by

$$i_{\mathbf{E}_k} : X_{\mathbf{E}_k} \to X_{\mathbf{E}} \qquad i_{A_k} : X_{A_k} \to X_A \qquad \text{for } k = 1, 2, 3.$$

According to (16.1.3), we get moreover a continuous and spectral map

$$\varphi := (\mathrm{Spec}\, \overline{u}_A) : X_A \to X_{\mathbf{E}}$$

Remark 16.4.25. In the situation of (16.4.24), we notice that :

(i) The image of α_0 is regular on $\mathbf{E}_1$, hence the induced isomorphism $\mathbf{E} \xrightarrow{\sim} \mathbf{E}_1 \times_{\mathbf{E}_3} \mathbf{E}_2$ identifies I_1 with $0 \times_{\mathbf{E}_3} \mathbf{E}_2$, *i.e.* with $\mathrm{Ker}\,(\mathbf{E}_2 \to \mathbf{E}_3)$.

(ii) Therefore, the image of $\overline{u}_A(\alpha_0)$ is regular in A_1 (proposition 16.4.17), and consequently, also p is regular in A_1.

(iii) For $i = 2, 3$, the image of $\underline{\alpha}$ in $W(\mathbf{E}_i)$ equals pu, for some $u \in W(\mathbf{E}_i)^\times$, so u_{A_2} and u_{A_3} induce isomorphisms of topological rings

$$\mathbf{E}_2 \xrightarrow{\sim} A_2 \qquad \mathbf{E}_3 \xrightarrow{\sim} A_3$$

that identify the projection $\mathbf{E}_2 \to \mathbf{E}_1$ in $\mathscr{E}$ with the map $A_2 \to A_3$ in $A(\mathscr{E})$.

(iv) Consequently, the isomorphism $A \xrightarrow{\sim} A_1 \times_{A_3} A_2$ induced by $A(\mathscr{E})$ identifies $\mathrm{Ann}_A(p)$ with $0 \times_{A_3} A_2$, *i.e.* with $\mathrm{Ker}\,(A_2 \to A_3)$, and summing up, we get a natural $W(\mathbf{E})$-linear identification

$$\mathrm{Ann}_{\mathbf{E}}(\alpha_0) \xrightarrow{\sim} \mathrm{Ann}_A(p) \qquad : \qquad \beta \mapsto \overline{u}_A(\beta).$$

(v) Let I be an ideal of adic definition of A, and $J \subset A$ another ideal such that $IJ = 0$. Since A is reduced (corollary 16.3.63(i)), we deduce that $I^n \cap J = 0$ for every $n \in \mathbb{N}$, whence $J + I^n = J \oplus I^n$ for every such n. It follows that

$$\bigcap_{n\in\mathbb{N}} (J + I^n) = \bigcap_{n\in\mathbb{N}} (J \oplus I^n) = J \oplus \bigcap_{n\in\mathbb{N}} I^n = J$$

which means that J is closed in the topology of A.

Proposition 16.4.26. *With the notation of* (16.4.24)*, the following holds :*

(i) *The map φ is surjective.*

(ii) *For every quasi-coherent $\mathscr{O}_{X_A}$-module $\mathscr{F}$ and every integer $i > 0$ we have*

$$R^i\varphi_*\mathscr{F} = 0.$$

Proof. (i): Consider any $\mathfrak{q} \in X_{\mathbf{E}}$, set

$$J := \sum_{x\in\mathfrak{q}} \overline{u}_A(x) \cdot A \qquad S := \{\overline{u}_A(x) \mid x \in \mathbf{E} \setminus \mathfrak{q}\}$$

and notice that S is a multiplicative subset of A. Let $\mathfrak{p} \in X_A$ be any prime ideal; it is easily seen that $\varphi(\mathfrak{p}) = \mathfrak{q}$ if and only if $S \cap \mathfrak{p} = \varnothing$ and $J \subset \mathfrak{p}$. Thus, we come down to showing that $JA_S \neq A_S$. Suppose this fails; then there exist $y \in \mathbf{E} \setminus \mathfrak{q}$ and sequences $x_\bullet := (x_1, \dots, x_k)$, $a_\bullet := (a_1, \dots, a_k)$ of elements of $\mathfrak{q}$ and respectively A, such that

$$\overline{u}_A(y) = \sum_{i=1}^k \overline{u}_A(x_i) \cdot a_i.$$

Especially, $[y]^{\langle 1\rangle}A \subset [x_\bullet]^{\langle 1\rangle}A$. Set $\mathscr{J} := \sum_{i=1}^k \mathbf{E}x_i \subset \mathbf{E}$; by corollary 16.3.51(i) we deduce

$$y \in \mathscr{J}^{\langle 1-1/p\rangle}\mathbf{E} \subset \mathfrak{q}$$

a contradiction.

(ii): Let $f \in \mathbf{E}$ any element, and set $[f] := \overline{u}_A(f)$; in light of (9.3.67) we get

$$\varphi^{-1}(\mathrm{Spec}\, E_f) = \mathrm{Spec}\, A_{[f]}. \tag{16.4.27}$$

Now, recall that $R^i\varphi_*\mathscr{F}$ is naturally isomorphic to the sheaf associated to the presheaf

$$U \mapsto H^i(\varphi^{-1}U, \mathscr{F}) \qquad \text{for every open subset } U \subset X_{\mathbf{E}}.$$

Then the assertion follows immediately from (16.4.27). □

16.4.28. In the situation of (16.4.24), let $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N})$ be any distinguished element of $\mathrm{Ker}\, u_A$; notice the commutative diagram of topological spaces

$$\begin{array}{ccc} X_A^0 := \mathrm{Spec}\, A/pA & \xrightarrow{\varphi_0} & X_{\mathbf{E}}^0 := \mathrm{Spec}\, \mathbf{E}/\alpha_0\mathbf{E} \\ \downarrow{\scriptstyle \iota_A} & & \downarrow{\scriptstyle \iota_{\mathbf{E}}} \\ X_A & \xrightarrow{\varphi} & X_{\mathbf{E}} \end{array}$$

whose vertical arrows are the inclusion maps, and with $\varphi_0 := \mathrm{Spec}\, \omega$, where $\omega : \mathbf{E}/\alpha_0\mathbf{E} \xrightarrow{\sim} A/pA$ is the ring isomorphism deduced from $u_A \otimes_{\mathbb{Z}} \mathbb{F}_p$ as in remark 16.3.7(ii). Denote also

$$\mathscr{O}^{\mathrm{t}}_{X_{\mathbf{E}}} \subset \mathscr{O}^{\mathrm{t}}_{X_{\mathbf{E}}} \qquad \text{and} \qquad \mathscr{O}^{\mathrm{t}}_{X_A} \subset \mathscr{O}^{\mathrm{t}}_{X_A}$$

respectively the subsheaf of α_0-torsion sections and the subsheaf of p-torsion sections. Notice that $\mathscr{O}^{\mathrm{t}}_{X_{\mathbf{E}}}$ is independent of the choice of $\underline{\alpha}$ (remark 16.1.7(i)); more precisely, corollary 16.3.63(i) implies that

$$\mathscr{O}^{\mathrm{t}}_{X_{\mathbf{E}}} = \underline{\Gamma}_{X^0_{\mathbf{E}}} \mathscr{O}_{X_{\mathbf{E}}} = \mathrm{Ker}\,(\mathscr{O}_{X_{\mathbf{E}}} \to i_{\mathbf{E}_1 *}\mathscr{O}_{X_{\mathbf{E}_1}})$$
$$\mathscr{O}^{\mathrm{t}}_{X_A} = \underline{\Gamma}_{X^0_A} \mathscr{O}_{X_A} = \mathrm{Ker}\,(\mathscr{O}_{X_A} \to i_{A_1 *}\mathscr{O}_{X_{A_1}}).$$

Lemma 16.4.29. *In the situation of* (16.4.28)*, the following holds :*

(i) *The corresponding isomorphism of sheaves* $\varphi_0^\flat : \mathscr{O}_{X^0_{\mathbf{E}}} \xrightarrow{\sim} \varphi_{0*}\mathscr{O}_{X^0_A}$ *lifts to a map of sheaves of monoids*
$$\varphi^\flat : \mathscr{O}_{X_{\mathbf{E}}} \to \varphi_*\mathscr{O}_{X_A}.$$

(ii) $\varphi^\flat$ *restricts to an isomorphism of sheaves of abelian groups*
$$\mathscr{O}^{\mathrm{t}}_{X_{\mathbf{E}}} \xrightarrow{\sim} \varphi_*\mathscr{O}^{\mathrm{t}}_{X_A}.$$

(iii) *For every open subset* $U \subset X_{\mathbf{E}}$ *we have*
$$\varphi^\flat_U(x+y) = \varphi^\flat_U(x) + \varphi^\flat_U(y) \qquad \text{for every } x \in \mathscr{O}^{\mathrm{t}}_{X_{\mathbf{E}}}(U) \text{ and } y \in \mathscr{O}_{X_{\mathbf{E}}}(U).$$

(iv) *For every closed subset* $W_A \subset X^0_A$*, the* $\mathscr{O}_{X_A}$*-module* $\underline{\Gamma}_{W_A}\mathscr{O}_{X_A}$ *is quasi-coherent.*

Proof. (i): For every $f \in \mathbf{E}$, set $D(f) := \mathrm{Spec}\, \mathbf{E}_f$ and $[f] := \overline{u}_A(f)$, and let

$$\varphi^\flat_f := (\overline{u}_A)_f : \mathbf{E}_f \to A_{[f]}$$

(notation of (4.8.33)). Now, let $g \in \mathbf{E}$ be any other element, and suppose that $D(g) \subset D(f)$; there follows a commutative diagram

$$\begin{array}{ccccc} \mathbf{E} & \longrightarrow & \mathbf{E}_f & \longrightarrow & \mathbf{E}_g \\ \downarrow{\scriptstyle \overline{u}_A} & & \downarrow{\scriptstyle \varphi^\flat_f} & & \downarrow{\scriptstyle \varphi^\flat_g} \\ A & \longrightarrow & A_{[f]} & \longrightarrow & A_{[g]} \end{array}$$

whose horizontal arrows are the localization maps. Since all localizations are epimorphisms in the category of monoids, we deduce that the diagram commutes for every such f, g. Especially, $\varphi^\flat_f$ depends only on $D(f)$ (and not on f). Then the rule $D(f) \mapsto \varphi^\flat_f$ extends to a morphism of sheaves of monoids on $X_{\mathbf{E}}$ (see [59, Ch.0, §3.2.3]), and by construction the resulting diagram

$$\begin{array}{ccc} \mathscr{O}_{X_{\mathbf{E}}} & \xrightarrow{\varphi^\flat} & \varphi_*\mathscr{O}_{X_A} \\ \downarrow & & \downarrow \\ \iota_{\mathbf{E}*}\mathscr{O}_{X^0_{\mathbf{E}}} & \xrightarrow{\iota_{\mathbf{E}*}(\varphi^\flat_0)} & \iota_{\mathbf{E}*}\varphi_{0*}\mathscr{O}_{X^0_A} \end{array}$$

commutes.

(iii): It suffices to check the stated identity for U of the form $\mathrm{Spec}\,\mathbf{E}_f$, where $f \in \mathbf{E}$ is any element. Then, in light of (16.4.30), we easily reduce to the case where $x, y \in \mathrm{Im}\,(\mathbf{E} \to \mathbf{E}_f)$. Then, we are further reduced to checking that $\overline{u}_A(x+y) = \overline{u}_A(x) + \overline{u}_A(y)$ for every $x, y \in \mathbf{E}$ such that $\alpha_0 \cdot x = 0$. The latter follows easily from proposition 9.3.62 and lemma 16.2.7(iii) : details left to the reader.

(ii): Lemma 16.2.7(iii) easily implies that $\varphi^\flat$ send $\mathscr{O}_{X_\mathbf{E}}$ into $\varphi_*\mathscr{O}_{X_A}$. In light of (iii), it then suffices to check that the map $\varphi^\flat_f$ restricts to an isomorphism $\mathrm{Ann}_{\mathbf{E}_f}(\alpha_0) \xrightarrow{\sim} \mathrm{Ann}_{A_{[f]}}(p)$ for every $f \in \mathbf{E}$. However

$$\mathrm{Ann}_{\mathbf{E}_f}(\alpha_0) = \mathrm{Ann}_{\mathbf{E}}(\alpha_0)_f \qquad \text{and} \qquad \mathrm{Ann}_{A_{[f]}}(p) = \mathrm{Ann}_A(p)_{[f]} \tag{16.4.30}$$

so the assertion follows from remark 16.4.25(iv).

(iv): Set $W_\mathbf{E} := \varphi_0(W_A)$; from (ii) we see that $\varphi^\flat$ induces an isomorphism

$$\underline{\Gamma}_{W_A}\mathscr{O}_{X_A} = \underline{\Gamma}_{W_A} \circ \underline{\Gamma}_{X^0_A}\mathscr{O}_{X_A} \xrightarrow{\sim} \underline{\Gamma}_{W_A}(\iota_{A*}\varphi_0^{-1}\iota_\mathbf{E}^{-1}\underline{\Gamma}_{X^0_\mathbf{E}}\mathscr{O}_{X_\mathbf{E}}) = \iota_{A*}\varphi_0^{-1}\iota_\mathbf{E}^{-1}\underline{\Gamma}_{W_\mathbf{E}}\mathscr{O}_{X_\mathbf{E}}$$

of $\mathscr{O}_{X_A}$-modules (lemma 10.4.13(v)). Since the functor ι_{A*} sends quasi-coherent $\mathscr{O}_{X^0_A}$-modules to quasi-coherent $\mathscr{O}_{X_A}$-modules ([59, Ch.I, Cor.9.2.2]), we are then reduced to checking that $\iota_\mathbf{E}^{-1}\underline{\Gamma}_{W_\mathbf{E}}\mathscr{O}_{X_\mathbf{E}}$ is a quasi-coherent $\mathscr{O}_{X^0_\mathbf{E}}$-module. However, it was already remarked in (16.4.28) that $\underline{\Gamma}_{W_\mathbf{E}}\mathscr{O}_{X_\mathbf{E}} = \underline{\Gamma}_{W_\mathbf{E}}\mathscr{O}^{\mathrm{t}}_{X_\mathbf{E}}$ is an $\iota_{\mathbf{E}*}\mathscr{O}_{X^0_\mathbf{E}}$-module, so we are further reduced to checking that $\underline{\Gamma}_{W_\mathbf{E}}\mathscr{O}^{\mathrm{t}}_{X_\mathbf{E}}$ is a quasi-coherent $\mathscr{O}_{X_\mathbf{E}}$-module.

Thus, let $f \in \mathbf{E}$ be any element, and $s \in \underline{\Gamma}_{W_\mathbf{E}}\mathscr{O}^{\mathrm{t}}_{X_\mathbf{E}}(D(f))$ any section; pick also a subset $S \subset \mathbf{E}$ such that $U_\mathbf{E} := X_\mathbf{E} \setminus W_\mathbf{E} = \bigcup_{g \in S} D(g)$. By assumption, $s_{|D(fg)} = 0$ for every $g \in S$, and there exist $n \in \mathbb{N}$ and $t \in \mathbf{E}$ such that $s = f^{-n}t$; it follows that for every $g \in S$ there exists an integer $m_g \in \mathbb{N}$ such that $(fg)^{m_g}t = 0$ in $\mathbf{E}$. Since $\mathbf{E}$ is perfect, we deduce that $fgt = 0$ for every such g, hence $(ft)_{|U_\mathbf{E}} = 0$, so finally $s \in (\Gamma_{W_\mathbf{E}}\mathscr{O}^{\mathrm{t}}_{X_\mathbf{E}})_f$, whence the contention. □

Remark 16.4.31. (i) Keep the notation of lemma 16.4.29. Notice that the rule $A \mapsto (\varphi, \varphi^\flat)$ is functorial in A. Namely, if $g : A' \to A''$ is any continuous ring homomorphism of perfectoid rings, and $(\varphi', \varphi'^\flat)$ $(\varphi'', \varphi''^\flat)$ the pairs attached to A' and respectively A'' as in lemma 16.4.29, then we have commutative diagrams of topological spaces and of sheaves of monoids :

$$\begin{array}{ccc} X_{A''} & \xrightarrow{\varphi''} & X_{\mathbf{E}''} \\ {\scriptstyle \psi_A}\downarrow & & \downarrow{\scriptstyle \psi_\mathbf{E}} \\ X_{A'} & \xrightarrow{\varphi'} & X_{\mathbf{E}'} \end{array} \qquad \begin{array}{ccc} \mathscr{O}_{X_{\mathbf{E}'}} & \xrightarrow{\psi^\flat_E} & \psi_{\mathbf{E}*}\mathscr{O}_{X_{\mathbf{E}''}} \\ {\scriptstyle \varphi'^\flat}\downarrow & & \downarrow{\scriptstyle \psi_{\mathbf{E}*}\varphi''^\flat} \\ \varphi'_*\mathscr{O}_{X_{A'}} & \xrightarrow{\varphi'_*\psi^\flat_A} & \psi_{\mathbf{E}*}\varphi''_*\mathscr{O}_{X_{A''}} = \varphi'_*\psi_{A*}\mathscr{O}_{X_{A''}} \end{array}$$

where $X_{A'} := \mathrm{Spec}\,A'$, $X_{\mathbf{E}'} := \mathrm{Spec}\,\mathbf{E}(A')$ and similarly for $X_{A''}$ and $X_{\mathbf{E}''}$, and $\psi_A := \mathrm{Spec}\,g$, $\psi_\mathbf{E} := \mathrm{Spec}\,\mathbf{E}(g)$. The verification shall be left to the reader.

(ii) The short exact sequence of $\mathscr{O}_{X_\mathbf{E}}$-modules

$$\mathscr{E} \quad : \quad 0 \to \mathscr{O}^{\mathrm{t}}_{X_\mathbf{E}} \to \mathscr{O}_{X_\mathbf{E}} \to i_{\mathbf{E}_1*}\mathscr{O}_{X_{\mathbf{E}_1}} \to 0$$

induces a commutative ladder for every open subset $\Omega \subset X_\mathbf{E}$:

$$\begin{array}{ccccccccc} 0 & \to & H^0(\Omega, \mathscr{O}^{\mathrm{t}}_{X_\mathbf{E}}) & \to & H^0(\Omega, \mathscr{O}_{X_\mathbf{E}}) & \to & H^0(\Omega, i_{\mathbf{E}_1*}\mathscr{O}_{X_{\mathbf{E}_1}}) & \to & H^1(\Omega, \mathscr{O}^{\mathrm{t}}_{X_\mathbf{E}}) \\ & & {\scriptstyle \beta^{\mathrm{t}}}\downarrow & & \downarrow{\scriptstyle \beta} & & \downarrow{\scriptstyle \beta_1} & & \downarrow{\scriptstyle \gamma} \\ 0 & \to & H^0(\varphi^{-1}\Omega, \mathscr{O}^{\mathrm{t}}_{X_A}) & \to & H^0(\varphi^{-1}\Omega, \mathscr{O}_{X_A}) & \to & H^0(\varphi^{-1}\Omega, i_{A_1*}\mathscr{O}_{X_{A_1}}) & \to & H^1(\varphi^{-1}\Omega, \mathscr{O}^{\mathrm{t}}_{X_A}) \end{array}$$

whose rows are the initial terms of the long exact cohomology sequence attached to $\mathscr{E}$, and where β is induced by $\varphi^\flat$. The map β_1 is induced by $i_{\mathbf{E}_1*}\varphi_1^\flat$, where $\varphi_1^\flat : \mathscr{O}_{X_{\mathbf{E}_1}} \to \varphi_1^*\mathscr{O}_{X_{A_1}}$ is the morphism associated with the perfectoid ring A_1 and the induced continuous map $\varphi_1 : X_{\mathbf{E}_1} \to X_{A_1}$ as in lemma 16.4.29(i). Lastly, β^{t} and γ are deduced from the restriction $\mathscr{O}^{\mathrm{t}}_{X_\mathbf{E}} \to \varphi_*\mathscr{O}^{\mathrm{t}}_{X_A}$

of $\varphi^\flat$, which is an isomorphism of abelian sheaves (lemma 16.4.29(ii,iii)); furthermore, these subsheaves are supported on the closed subsets $X^0_{\mathbf{E}}$ and respectively X^0_A, and φ restricts to a homeomorphism $\varphi_0 : X^0_{\mathbf{E}} \xrightarrow{\sim} X^0_A$, so β^{t} and γ are isomorphisms of abelian groups. The commutativity of the left square subdiagram is clear, and that of the central one follows from (i). To show the commutativity of the right square subdiagram, pick any $\overline{s} \in H^0(\Omega, i_{\mathbf{E}1*}\mathscr{O}_{X_{\mathbf{E}}})$, and find a covering $\Omega = \bigcup_{i\in I} \Omega_i$ consisting of open subsets, such that $\overline{s}_{|\Omega_i}$ is the image of some $s_i \in H^0(\Omega_i, \mathscr{O}_{X_{\mathbf{E}}})$, for every $i \in I$. Set $\Omega_{ij} := \Omega_i \cap \Omega_j$ for every $i, j \in I$, and let $s_{ij} := s_{i|\Omega_{ij}} - s_{j|\Omega_{ij}}$, and notice that $s_{ij} \in H^0(\Omega_{ij}, \mathscr{O}^{\mathrm{t}}_{X_{\mathbf{E}}})$ for every such i, j. Then the image of $\overline{s}$ in $H^1(\Omega, \mathscr{O}^{\mathrm{t}}_{X_{\mathbf{E}}})$ is the class of the Čech cocycle $(s_{ij} \mid i, j \in I)$, and the latter maps to the class of the cocycle $(\varphi^\flat_{\Omega_{ij}}(s_{ij}) \mid i, j \in I)$ in $H^1(\varphi^{-1}\Omega, \mathscr{O}^{\mathrm{t}}_{X_A})$. On the other hand, set $\overline{t} := \beta(\overline{s})$; for every $i \in I$, the restriction of $\overline{t}$ to $\varphi^{-1}\Omega_i$ is the image of $\varphi^\flat_{\Omega_i}(s_i) \in H^0(\Omega_i, \mathscr{O}_{X_A})$, hence the image of $\overline{t}$ in $H^1(\varphi^{-1}\Omega, \mathscr{O}^{\mathrm{t}}_{X_A})$ is the class of the cocycle $(t_{ij} \mid i \in I)$ with $t_{ij} := t_{i|\varphi^{-1}\Omega_{ij}} - t_{j|\varphi^{-1}\Omega_{ij}}$ for every $i, j \in I$. Lemma 16.4.29(iii) implies that $t_{ij} = \varphi^\flat_{\Omega_{ij}}(s_{ij})$ for every $i, j \in I$, whence the assertion.

The following result shows that if A is a perfectoid ring, proposition 8.3.30 holds even in case the open subset U of $\operatorname{Spec} A$ is not quasi-compact.

Lemma 16.4.32. *Let A be a perfectoid ring, and $U \subset X_A := \operatorname{Spec} A$ an open subset containing the analytic locus of X_A. We have :*

- (i) *There exists a unique topology $\mathscr{T}_U$ on $A_U := \mathscr{O}_{X_A}(U)$ such that $(A_U, \mathscr{T}_U)$ is f-adic and the restriction map $\rho_U : A \to A_U$ is open.*
- (ii) *$(A_U, \mathscr{T}_U)$ is complete and separated.*
- (iii) *Let $f : A \to B$ be any morphism of f-adic topological rings, such that the image of $\operatorname{Spec} f$ lies in U. Then the resulting map $f_U : (A_U, \mathscr{T}_U) \to B$ is continuous.*

Proof. (i): We pick a system of elements $(\beta_1, \dots, \beta_r)$ of $\mathbf{E}(A)$ such that the system $(f_i := \overline{u}_A(\beta_i) \mid i = 1, \dots, r)$ generates an ideal I of adic definition of A. Like in the proof of proposition 8.3.30(i), there exists a unique topology $\mathscr{T}_U$ on A_U such that $(A_U, \mathscr{T}_U)$ is a topological group for its additive group structure, and we need to check the following. For every $a \in A_U$ and every $n \in \mathbb{N}$ there exists $k \in \mathbb{N}$ such that

$$a \cdot \rho_U(I^k) \subset \rho_U(I^n).$$

Now, for $i = 1, \dots, r$, let $a_i \in \operatorname{Spec} A_{f_i}$ be the image of a under the restriction map $\rho_i : A_U \to A_{f_i}$; we may find $m \in \mathbb{N}$ and $b_1, \dots, b_r \in A$ such that $a_i = f_i^{-m} b_i$, hence $f_i^m a - b_i \in \operatorname{Ker} \rho_i$ for $i = 1, \dots, r$. Pick a family $(g_\lambda \mid \lambda \in \Lambda)$ of elements of A such that $U = \bigcup_{\lambda\in\Lambda} V_\lambda$, where $V_\lambda := \operatorname{Spec} A_{g_\lambda}$ for every $\lambda \in \Lambda$. Notice that $(f_i^m a - b_i)_{|V_\lambda}$ lies in the kernel of the restriction map $\mathscr{O}_U(V_\lambda) \to \mathscr{O}_U(V_\lambda \cap \operatorname{Spec} A_{f_i})$, for every $i = 1, \dots, r$ and every $\lambda \in \Lambda$. Thus, for every such λ and i there exist $t_\lambda, s_\lambda \in \mathbb{N}$ and $c_{i,\lambda} \in A$ such that

$$g_\lambda^{s_\lambda} \cdot (f_i^m a - b_i)_{|V_\lambda} = \rho_\lambda(c_{i,\lambda}) \qquad \text{and} \qquad f_i^{t_\lambda} c_{i,\lambda} = 0 \qquad \text{in } A$$

where $\rho_\lambda : A \to A_{g_\lambda}$ is the localization map. From corollary 16.3.63(i) we then deduce that $f_i c_{i,\lambda} = 0$, so

$$(f_i^{m+1} a - f_i b_i)_{|V_\lambda} = 0 \qquad \text{for every } \lambda \in \Lambda \text{ and every } i = 1, \dots, r$$

i.e. $f_i^{m+1} a = \rho_U(f_i b_i)$ for every $i = 1, \dots, r$. From this, we may argue as in the proof of proposition 8.3.30(i), to derive the assertion.

(ii): It suffices to show that $\operatorname{Ker} \rho_U$ is a closed ideal of A. However, clearly $I \cdot \operatorname{Ker} \rho_U = 0$, so the assertion follows from remark 16.4.25(v).

(iii) is proven as proposition 8.3.30(iii). □

We wish next to show that the formula for the Teichmüller representative of a sum obtained in proposition 9.3.62, is still valid in f-adic rings of the type considered in lemma 16.4.32.

16.4.33. Indeed, resume the situation of (16.4.28), and let $U \subset X_{\mathbf{E}}$ be an open subset containing $X_{\mathbf{E}} \setminus \operatorname{Spec} \mathbf{E}/\mathbf{E}^{\circ\circ}$; from (16.4.27) we easily see that $X_A \setminus \operatorname{Spec} A/A^{\circ\circ} \subset \varphi^{-1}U$, so

$$\mathbf{E}_U := \mathscr{O}_{X_{\mathbf{E}}}(U) \qquad \text{and} \qquad A_U := \mathscr{O}_{X_A}(\varphi^{-1}U)$$

admit the f-adic topologies $\mathscr{T}_U$ and respectively $\mathscr{T}_{\varphi^{-1}U}$ furnished by lemma 16.4.32.

Proposition 16.4.34. *With the notation of* (16.4.33)*, the following holds :*

(i) *The map* $\varphi^\flat_U : (\mathbf{E}_U, \mathscr{T}_U) \to (A_U, \mathscr{T}_{\varphi^{-1}U})$ *of lemma* 16.4.29(i) *is continuous.*

(ii) *For every* $\underline{x} := (x_0, \dots, x_k) \in \mathbf{E}_U^{k+1}$ *we have the identity*

$$\varphi^\flat_U(x_0 + \cdots + x_k) = \sum_{n\in\mathbb{N}} p^n \cdot \sum_{\sigma\in\Sigma^{(k)}_n} c_\sigma \cdot \varphi^\flat_U(\underline{x}^\sigma)$$

where $\Sigma^{(k)}_n$ *is defined as in* (9.3.61) *for every* $n \in \mathbb{N}$*, and* $c_\sigma \in \mathbb{Z}_p$ *is provided by proposition* 9.3.62*, for every* $\sigma \in \bigcup_{n\in\mathbb{N}} \Sigma^{(k)}_n$*; the convergence of the series is relative to the topology* $\mathscr{T}_{\varphi^{-1}U}$*.*

Proof. (Recall that $\underline{x}^\sigma := x_0^{\sigma_0} \cdots x_k^{\sigma_k}$ for every $\sigma := (\sigma_0, \dots, \sigma_k) \in \mathbb{N}[1/p]^{k+1}$).

(ii): Let $(\alpha_n \mid n \in \mathbb{N})$ be any distinguished element in $\operatorname{Ker} u_A$; since α_0 is topologically nilpotent in $\mathbf{E}$, its image is topologically nilpotent in $\mathbf{E}_U$, hence there exists $c \in \mathbb{N}$ such that $\alpha_0^c \cdot x_i \in \operatorname{Im}(\mathbf{E} \to \mathbf{E}_U)$ for $i = 0, \dots, k$. In light of lemma 16.2.7(iii), we deduce that

$$y_n(\underline{x}) := \sum_{\sigma\in\Sigma^{(k)}_n} p^n \cdot c_\sigma \cdot \varphi^\flat_U(x^\sigma) \in p^{n-c} \cdot \operatorname{Im}(A \to A_U) \qquad \text{for every integer } n \geq c.$$

Taking into account lemma 16.4.32(ii), it follows that the series $\sum_{n\in\mathbb{N}} y_n(\underline{x})$ converges for the topology $\mathscr{T}_{\varphi^{-1}U}$ to a well determined element $y \in A_U$, and it remains only to check that $y = \varphi^\flat_U(x_0 + \cdots + x_k)$. To this aim, pick a family $(g_\lambda \mid \lambda \in \Lambda)$ of elements of $\mathbf{E}$, such that $U = \bigcup_{\lambda\in\Lambda} V_\lambda$, where $V_\lambda := \operatorname{Spec} \mathbf{E}_{g_\lambda}$ for every $\lambda \in \Lambda$. Then, for every such λ we may find $n_\lambda \in \mathbb{N}$ such that $(g_\lambda^{n_\lambda} \cdot x_i)_{|V_\lambda} \in \operatorname{Im}(\mathbf{E} \to \mathbf{E}_{g_\lambda})$ for $i = 0, \dots, k$, and it suffices to check that $([g_\lambda^{n_\lambda}] \cdot \varphi^\flat_U(x_0 + \cdots + x_k))_{|\varphi^{-1}V_\lambda} = ([g_\lambda^{n_\lambda}] \cdot y)_{|\varphi^{-1}V_\lambda}$, where $[g_\lambda^{n_\lambda}] := \overline{u}_A(g_\lambda^{n_\lambda})$ for every such λ. However, we have

$$[g_\lambda^{n_\lambda}] \cdot \varphi^\flat_U(x_0 + \cdots + x_k) = \varphi^\flat_U(g_\lambda^{n_\lambda} \cdot x_0 + \cdots + g_\lambda^{n_\lambda} \cdot x_k) \qquad \text{and} \qquad [g_\lambda^{n_\lambda}] \cdot y = \sum_{n\in\mathbb{N}} y_n(g_\lambda^{n_\lambda} \cdot \underline{x})$$

where $g_\lambda^{n_\lambda} \cdot \underline{x} := (g_\lambda^{n_\lambda} \cdot x_0, \dots, g_\lambda^{n_\lambda} \cdot x_k)$. Hence, we may replace $\underline{x}$ by $g_\lambda^{n_\lambda} \cdot \underline{x}$, after which we may assume that $x_i \in \operatorname{Im}(\rho_U : \mathbf{E} \to \mathbf{E}_U)$ for $i = 0, \dots, k$. In this case, say that $x_i = \rho_U(z_i)$ for $i = 0, \dots, k$ and for certain $z_0, \dots, z_k \in \mathbf{E}$; we have

$$\varphi^\flat_U(x_0 + \cdots + x_k) = \rho_{\varphi^{-1}U} \circ \varphi^\flat_{X_{\mathbf{E}}}(z_0 + \cdots + z_k) = \rho_{\varphi^{-1}U} \circ \overline{u}_A(z_0 + \cdots + z_k)$$

where $\rho_{\varphi^{-1}U} : A \to A_U$ is the corresponding restriction map; on the other hand, since $\rho_{\varphi^{-1}U}$ is continuous for the topology $\mathscr{T}_{\varphi^{-1}U}$, we have as well

$$\begin{aligned} y &= \sum_{n\in\mathbb{N}} p^n \cdot \sum_{\sigma\in\Sigma^{(k)}_n} c_\sigma \cdot \rho_{\varphi^{-1}U} \circ \varphi^\flat_{X_{\mathbf{E}}}(\underline{z}^\sigma) = \rho_{\varphi^{-1}U}\Big(\sum_{n\in\mathbb{N}} p^n \cdot \sum_{\sigma\in\Sigma^{(k)}_n} c_\sigma \cdot \varphi^\flat_{X_{\mathbf{E}}}(\underline{z}^\sigma)\Big) \\ &= \rho_{\varphi^{-1}U}\Big(\sum_{n\in\mathbb{N}} p^n \cdot \sum_{\sigma\in\Sigma^{(k)}_n} c_\sigma \cdot \overline{u}_A(\underline{z}^\sigma)\Big) = \rho_{\varphi^{-1}U} \circ u_A\Big(\sum_{n\in\mathbb{N}} p^n \cdot \sum_{\sigma\in\Sigma^{(k)}_n} c_\sigma \cdot \tau_A(\underline{z}^\sigma)\Big) \end{aligned}$$

so the sought identity follows from proposition 9.3.62.

(i): Fix $x_0 \in \mathbf{E}_U$; the proof of (ii) shows that for every $k \in \mathbb{N}$ there exists $n \in \mathbb{N}$ such that $y_r(x_0 + x) \in p^k \cdot \operatorname{Im}(A \to A_U)$ for every $r \geq n$ and every $x \in \operatorname{Im}(\mathbf{E} \to \mathbf{E}_U)$. On the other hand, clearly the mappings y_i are continuous for every $i \in \mathbb{N}$, relative to the topologies $\mathscr{T}_U$ and $\mathscr{T}_{\varphi^{-1}U}$. The assertion follows immediately. □

16.4.35. Keep the notation of (16.4.28), let $U_{\mathbf{E}} \subset X_{\mathbf{E}}$ be any open subset, and set $U_A := \varphi^{-1}U_{\mathbf{E}}$, $Z_{\mathbf{E}} := X_{\mathbf{E}} \setminus U_{\mathbf{E}}$, $Z_A := X_A \setminus U_A$. Denote by $j_{\mathbf{E}} : U_{\mathbf{E}} \to X_{\mathbf{E}}$ and $j_A : U_A \to X_A$ the open immersions; the map $\varphi^\flat$ of lemma 16.4.29(i) induces a morphism of sheaves of monoids

$$\psi : j_{\mathbf{E}*}\mathscr{O}_{U_{\mathbf{E}}} \xrightarrow{j_{\mathbf{E}*}j^*_{\mathbf{E}}(\varphi^\flat)} j_{\mathbf{E}*}j^*_{\mathbf{E}}\varphi_*\mathscr{O}_{X_A} \xrightarrow{\sim} \varphi_*j_{A*}\mathscr{O}_{U_A}.$$

Moreover, let

$$\overline{\mathscr{O}}_{X_{\mathbf{E}}} := \mathrm{Im}\,(\mathscr{O}_{X_{\mathbf{E}}} \to j_{\mathbf{E}*}\mathscr{O}_{U_{\mathbf{E}}}) \qquad \overline{\mathscr{O}}_{X_A} := \mathrm{Im}\,(\mathscr{O}_{X_A} \to j_{A*}\mathscr{O}_{U_A}).$$

Denote by $\pi_{\mathbf{E}} : j_{\mathbf{E}*}\mathscr{O}_{U_{\mathbf{E}}} \to R^1\underline{\Gamma}_{Z_{\mathbf{E}}}\mathscr{O}_{X_{\mathbf{E}}}$ and $\pi_A : j_{A*}\mathscr{O}_{U_A} \to R^1\underline{\Gamma}_{Z_A}\mathscr{O}_{X_A}$ the projections, set $q := \overline{u}_A(\alpha_0)$, and for every $c \in \mathbb{N}[1/p]$ define

$$\alpha_0^{-c}\mathscr{O}_{X_{\mathbf{E}}} := \mathrm{Ker}\,\alpha_0^c \cdot \pi_{\mathbf{E}} \qquad p^{-c}\mathscr{O}_{X_A} := \mathrm{Ker}\,q^c \cdot \pi_A$$
$$\mathscr{Q}^c_{U_{\mathbf{E}}} := \pi_{\mathbf{E}}(\alpha_0^{-c}\mathscr{O}_{X_{\mathbf{E}}}) \qquad \mathscr{Q}^c_{U_A} := \pi_A(p^{-c}\mathscr{O}_{X_A}).$$

Also, set

$$\mathscr{R}^c := \mathrm{Coker}\,(\varphi_*\overline{\mathscr{O}}_{X_A} \to \varphi_*(p^{-c}\mathscr{O}_{X_A})) \qquad \text{and let} \qquad \lambda : \mathscr{R}^c \to \varphi_*\mathscr{Q}^c_{U_A}$$

be the natural morphism of $\mathscr{O}_{X_A}$-modules; lemma 16.2.7(iii) easily implies that ψ restricts to a morphism of sheaves of sets

$$\psi^c : \alpha_0^{-c}\mathscr{O}_{X_{\mathbf{E}}} \to \varphi_*(p^{-c}\mathscr{O}_{X_A}) \qquad \text{for every } c \in \mathbb{N}[1/p].$$

Proposition 16.4.36. *With the notation of* (16.4.35)*, suppose moreover that :*

(a) $\mathrm{Spec}\,\mathbf{E}[\alpha_0^{-1}] \subset U_{\mathbf{E}}$.
(b) $U_{\mathbf{E}}$ *is quasi-compact.*
(c) $c \leq p/(p-1)$.

Then we have :

(i) *The map ψ^c descends to a morphism of sheaves of sets*

$$\overline{\psi}^c : \mathscr{Q}^c_{U_{\mathbf{E}}} \to \mathscr{R}^c \xrightarrow{\lambda} \varphi_*\mathscr{Q}^c_{U_A}.$$

(ii) *There exist unique morphisms of sheaves of sets*

$$\overline{\boldsymbol{p}}^c_{\mathbf{E}} : \mathscr{Q}^{c/p}_{U_{\mathbf{E}}} \to \mathscr{Q}^c_{U_{\mathbf{E}}} \qquad \textit{and} \qquad \overline{\boldsymbol{p}}^c_A : \mathscr{Q}^{c/p}_{U_A} \to \mathscr{Q}^c_{U_A}$$

fitting into commutative diagrams

$$\begin{array}{ccc} \alpha_0^{-c/p}\mathscr{O}_{X_{\mathbf{E}}} & \longrightarrow & \alpha_0^{-c}\mathscr{O}_{X_{\mathbf{E}}} \\ \downarrow & & \downarrow \\ \mathscr{Q}^{c/p}_{U_{\mathbf{E}}} & \xrightarrow{\overline{\boldsymbol{p}}^c_{\mathbf{E}}} & \mathscr{Q}^c_{U_{\mathbf{E}}} \end{array} \qquad \begin{array}{ccc} p^{-c/p}\mathscr{O}_{X_A} & \longrightarrow & p^{-c}\mathscr{O}_{X_A} \\ \downarrow & & \downarrow \\ \mathscr{Q}^{c/p}_{U_A} & \xrightarrow{\overline{\boldsymbol{p}}^c_A} & \mathscr{Q}^c_{U_A} \end{array}$$

whose vertical arrows are the projections, and whose top horizontal arrows are the restrictions of the p-Frobenius endomorphisms of the sheaves of monoids $j_{\mathbf{E}*}\mathscr{O}_{U_{\mathbf{E}}}$ and respectively $j_{A*}\mathscr{O}_{U_A}$ (with composition law given by multiplication).

(iii) *Moreover, we have a commutative diagram of sheaves of sets :*

$$\begin{array}{ccc} \mathscr{Q}^{c/p}_{U_{\mathbf{E}}} & \xrightarrow{\overline{\boldsymbol{p}}^c_{\mathbf{E}}} & \mathscr{Q}^c_{U_{\mathbf{E}}} \\ {\scriptstyle \overline{\psi}^{c/p}}\downarrow & & \downarrow{\scriptstyle \overline{\psi}^c} \\ \varphi_*\mathscr{Q}^{c/p}_{U_A} & \xrightarrow{\varphi_*(\overline{\boldsymbol{p}}^c_A)} & \varphi_*\mathscr{Q}^c_{U_A}. \end{array}$$

(iv) *If $c \leq 1$, the map $\overline{\psi}^c$ is an isomorphism of sheaves of abelian groups.*

Proof. (i): Let $f \in \mathbf{E}$ be any element, and set $V := \mathrm{Spec}\,\mathbf{E}_f$; we easily come down to showing

Claim 16.4.37. If $c \leq p/(p-1)$, we have

$$\psi^c_V(x+y) - \psi^c_V(x) \in \overline{\mathscr{O}}_{X_A}(\varphi^{-1}V) \qquad \text{for every } x \in \alpha_0^{-c}\mathscr{O}_{X_\mathbf{E}}(V) \text{ and } y \in \overline{\mathscr{O}}_{X_\mathbf{E}}(V).$$

Proof of the claim. Since $U_\mathbf{E}$ is quasi-compact, $j_{\mathbf{E}*}\mathscr{O}_{X_\mathbf{E}}$ is a quasi-coherent $\mathscr{O}_{X_\mathbf{E}}$-module ([59, Ch.I, Cor.9.2.2]), hence the same holds for $\alpha_0^{-c}\mathscr{O}_{X_\mathbf{E}}$, and consequently

$$\alpha_0^{-c}\mathscr{O}_{X_\mathbf{E}}(V) = \alpha_0^{-c}\mathscr{O}_{X_\mathbf{E}}(X_\mathbf{E})_f.$$

We may therefore find $n \in \mathbb{N}$ such that $f^n x$ (resp. $f^n y$) is the restriction to V of a global section $x' \in \alpha_0^{-c}\mathscr{O}_{X_\mathbf{E}}(X_\mathbf{E})$ (resp. of an element $y' \in \mathbf{E}$), and it suffices to show that

$$\psi^c_{X_\mathbf{E}}(x'+y') - \psi^c_{X_\mathbf{E}}(x') \in \mathrm{Im}\,(A \to j_{A*}\mathscr{O}_{U_A}(X_A) = \mathscr{O}_{X_A}(U_A)).$$

Hence, we may replace V by $X_\mathbf{E}$, and assume from start that

$$x \in \mathscr{O}_{X_\mathbf{E}}(U_\mathbf{E}) \qquad \text{and} \qquad \alpha_0^c \cdot x, y \in \mathrm{Im}\,(\mathbf{E} \to \mathscr{O}_{X_\mathbf{E}}(U_\mathbf{E}))$$

and we have to show that $\varphi^\flat_{U_\mathbf{E}}(x+y) - \varphi^\flat_{U_\mathbf{E}}(x) \in \mathrm{Im}\,(A \to \mathscr{O}_{X_A}(U_A))$. Notice that the assertion is independent of the topology $\mathscr{T}$ of A such that $(A, \mathscr{T})$ is perfectoid; by virtue of proposition 16.3.8(i) we may then assume that $\mathscr{T}$ is the p-adic topology on A, and therefore the topology of $\mathbf{E}$ agrees with the α_0-adic topology. In this case, assumption (a), proposition 16.4.34(ii) and lemma 16.2.7(iii) imply that $\varphi^\flat_{U_\mathbf{E}}(x+y) - \varphi^\flat_{U_\mathbf{E}}(x) - \varphi^\flat_{U_\mathbf{E}}(y)$ is a p-adically convergent series $\sum_{n>0} z_n$, where z_n is a $\mathbb{Z}_p$-linear combination of terms of the form $\varphi^\flat_{U_\mathbf{E}}(\alpha_0^n \cdot x^\sigma \cdot y^{1-\sigma})$, with $1-\sigma, \sigma \in p^{-n}\mathbb{N} \setminus p^{1-n}\mathbb{N}$, for every $n \in \mathbb{N}$. Hence, it suffices to check that $n \geq p \cdot \sigma/(p-1)$ for every such σ and every integer $n > 0$. We leave the easy verification to the reader. ◊

(ii): The uniqueness of $\overline{\boldsymbol{p}}^c_{U_A}$ is clear. For the existence, let V be as in the foregoing; we come down to showing that

$$(x+y)^p - x^p \in \overline{\mathscr{O}}_{X_A}(V) \qquad \text{for every } x \in p^{-c/p}\mathscr{O}_{X_A}(V) \text{ and every } y \in \overline{\mathscr{O}}_{X_A}(V).$$

However, $(x+y)^p - x^p = y^p + \sum_{i=1}^{p-1} \binom{p}{i} \cdot x^i y^{p-i}$, and $px^i \in \overline{\mathscr{O}}_{X_A}(V)$ for every $i = 1, \dots, p-1$, since $c \leq p/(p-1)$, whence the contention. Assertion (iii) shall be left to the reader.

(iv): Let V be as in the foregoing; in order to prove that $\overline{\psi}^c$ is a morphism of abelian sheaves when $c \leq 1$, we come down to showing that

$$\psi^1_V(x+y) - \psi^1_V(x) - \psi^1_V(y) \in \overline{\mathscr{O}}_{X_A}(\varphi^{-1}V) \qquad \text{for every } x, y \in \alpha_0^{-1}\mathscr{O}_{X_\mathbf{E}}(V)$$

and arguing as in the proof of claim 16.4.37, we reduce to the case where $V = X_\mathbf{E}$ and x, y are sections of $\mathscr{O}_{X_\mathbf{E}}(U_\mathbf{E})$ such that $\alpha_0 x, \alpha_0 y \in \mathrm{Im}\,(\mathbf{E} \to \mathscr{O}_{X_\mathbf{E}}(U_\mathbf{E}))$. Then, it suffices to check that

$$\varphi^\flat_{U_\mathbf{E}}(\alpha_0^n \cdot y^\sigma \cdot x^{1-\sigma}) \in \mathrm{Im}(A \to \mathscr{O}_{X_A}(U_A)) \qquad \text{whenever } n > 0 \text{ and } 1-\sigma, \sigma \in \mathbb{N}[1/p]$$

which is clear. Next notice that, by remark 16.4.31, the pair $(\varphi, \varphi^\flat)$ restricts to isomorphisms of schemes

$$(\varphi_2, \varphi_2^\flat) : X_{A_2} \xrightarrow{\sim} X_{\mathbf{E}_2} \qquad (\varphi_3, \varphi_3^\flat) : X_{A_3} \xrightarrow{\sim} X_{\mathbf{E}_3} \qquad \text{such that} \qquad \varphi_2(Z_A) = Z_\mathbf{E}.$$

Claim 16.4.38. Assertion (iv) holds for $U_\mathbf{E} = \mathrm{Spec}\,\mathbf{E}[\alpha_0^{-1}]$.

Proof of the claim. We have commutative diagrams

$$\begin{array}{ccc} U_{\mathbf{E}_1} := \mathrm{Spec}\,\mathbf{E}_1[\alpha_0^{-1}] & \longrightarrow & U_\mathbf{E} \\ {\scriptstyle j_{\mathbf{E}_1}}\downarrow & & \downarrow{\scriptstyle j_\mathbf{E}} \\ X_{\mathbf{E}_1} & \xrightarrow{i_{\mathbf{E}_1}} & X_\mathbf{E} \end{array} \qquad \begin{array}{ccc} U_{A_1} := \mathrm{Spec}\,A_1[p^{-1}] & \longrightarrow & U_A \\ {\scriptstyle j_{A_1}}\downarrow & & \downarrow{\scriptstyle j_A} \\ X_{A_1} & \xrightarrow{i_{A_1}} & X_A \end{array}$$

whose top horizontal arrows are isomorphisms of schemes, whence commutative diagrams of abelian sheaves

$$\begin{array}{ccc} \overline{\mathscr{O}}_{X_{\mathbf{E}}} & \xrightarrow{\sim} & i_{\mathbf{E}_1*}\mathscr{O}_{X_{\mathbf{E}_1}} \\ \downarrow & & \downarrow \\ j_{\mathbf{E}*}\mathscr{O}_{U_{\mathbf{E}}} & \xrightarrow{\sim} & i_{\mathbf{E}_1*}\circ j_{\mathbf{E}_1*}\mathscr{O}_{U_{\mathbf{E}_1}} \end{array} \qquad \begin{array}{ccc} \overline{\mathscr{O}}_{X_A} & \xrightarrow{\sim} & i_{A_1*}\mathscr{O}_{X_{A_1}} \\ \downarrow & & \downarrow \\ j_{A*}\mathscr{O}_{U_A} & \xrightarrow{\sim} & i_{A_1*}\circ j_{A_1*}\mathscr{O}_{U_{A_1}} \end{array}$$

whose left (resp. right) vertical arrows are the inclusion maps (resp. are induced by the inclusion maps $\mathscr{O}_{X_{\mathbf{E}_1}} \to j_{\mathbf{E}_1*}\mathscr{O}_{U_{\mathbf{E}_1}}$ and $\mathscr{O}_{X_{A_1}} \to j_{A_1*}\mathscr{O}_{U_{A_1}}$). Moreover, denote by $\varphi_1 : X_{A_1} \to X_{\mathbf{E}_1}$ the continuous map associated with A_1, as in (16.4.24), and by

$$\psi_1 : j_{\mathbf{E}_1*}\mathscr{O}_{U_{\mathbf{E}_1}} \to \varphi_{1*}j_{A_1*}\mathscr{O}_{U_{A_1}} \qquad (\text{resp. } \overline{\psi}{}^c_1 : \mathscr{Q}^c_{U_{\mathbf{E}_1}} \to \varphi_{1*}\mathscr{Q}^c_{U_{A_1}})$$

the corresponding morphism of sheaves of monoids as in (16.4.35) (resp. morphism of sheaves of sets, as in (i)); then $i_{\mathbf{E}_1}\circ\varphi_1 = \varphi\circ i_{A_1}$ (remark 16.4.31), and the foregoing isomorphisms identify ψ with $i_{\mathbf{E}_1*}\psi_1$. So finally, $\overline{\psi}{}^c$ is identified with $i_{\mathbf{E}_1*}\overline{\psi}{}^c_1$ for every $c \leq p/(p-1)$, and we may replace from start A by A_1, after which, we may assume that α_0 (resp. p) is regular in $\mathbf{E}$ (resp. in A). In this case, for every $c \leq 1$ we have a commutative diagram of sheaves :

$$\begin{array}{ccc} \mathscr{Q}^c_{U_{\mathbf{E}}} & \xrightarrow{\overline{\psi}{}^c_1} & \varphi_*\mathscr{Q}^c_{U_A} \\ \downarrow & & \downarrow \\ \mathscr{O}_{X_{\mathbf{E}}}/\alpha_0^c\mathscr{O}_{X_{\mathbf{E}}} & \longrightarrow & \varphi_*(\mathscr{O}_{X_A}/p^c\mathscr{O}_{X_A}) \end{array}$$

whose left (resp. right) vertical arrow is the isomorphism induced by scalar multiplication by α_0^c (resp. by q^c) and whose bottom horizontal arrow is the isomorphism induced by $\varphi_0^\flat$ (notation of (16.4.28)). The claim follows. ◊

Claim 16.4.39. We may assume that the natural maps $\mathscr{O}_{X_{\mathbf{E}}} \to \overline{\mathscr{O}}_{X_{\mathbf{E}}}$ and $\mathscr{O}_{X_A} \to \overline{\mathscr{O}}_{X_A}$ are isomorphisms.

Proof of the claim. Assumption (a) implies that $Z_{\mathbf{E}} \subset X_{\mathbf{E}_2}$ and $Z_A \subset X_{A_2}$, therefore

$$\mathscr{J}_{\mathbf{E}} := \mathrm{Ker}\,(\mathscr{O}_{X_{\mathbf{E}}} \to \overline{\mathscr{O}}_{X_{\mathbf{E}}}) = \underline{\Gamma}_{Z_{\mathbf{E}}}\mathscr{O}^{\mathrm{t}}_{X_{\mathbf{E}}} \qquad \mathscr{J}_A := \mathrm{Ker}\,(\mathscr{O}_{X_A} \to \overline{\mathscr{O}}_{X_A}) = \underline{\Gamma}_{Z_A}\mathscr{O}^{\mathrm{t}}_{X_A}$$

(notation of (16.4.28)), and lemma 16.4.29(ii,iii) implies that $\varphi^\flat$ restricts to an isomorphism of abelian sheaves

$$\mathscr{J}_{\mathbf{E}} \xrightarrow{\sim} \varphi_*\mathscr{J}_A. \tag{16.4.40}$$

Notice that $J := \Gamma(X_{\mathbf{E}}, \mathscr{J}_{\mathbf{E}})$ is an ideal of both $\mathbf{E}$ and $\mathbf{E}_2$, and moreover $\Phi_{\mathbf{E}}(J) = J$. Indeed, J consists of all $x \in \mathbf{E}$ whose images vanish in $\mathbf{E}_f$, for every $f \in \mathbf{E}$ such that $\mathrm{Spec}\,\mathbf{E}_f \subset U_{\mathbf{E}}$; since $\mathbf{E}_f$ is still a perfect $\mathbb{F}_p$-algebra, it follows easily that $x \in J$ if and only if $x^p \in J$, whence the assertion. Thus, both $\overline{\mathbf{E}} := \mathbf{E}/J$ and $\overline{\mathbf{E}}_2 := \mathbf{E}_2/J$ are still perfect $\mathbb{F}_p$-algebras, and are even perfectoid, with the quotient topologies induced by the projections $\mathbf{E} \to \overline{\mathbf{E}}$ and $\mathbf{E}_2 \to \overline{\mathbf{E}}_2$. Moreover, it is easily seen that the diagram $\mathscr{E}$ of (16.4.24) induces a natural identification

$$\overline{\mathbf{E}} \xrightarrow{\sim} \mathbf{E}_1 \times_{\mathbf{E}_3} \overline{\mathbf{E}}_2.$$

Let $h_{\mathbf{E}} : X_{\overline{\mathbf{E}}} := \mathrm{Spec}\,\overline{\mathbf{E}} \to X_{\mathbf{E}}$ be the closed immersion, $j_{\overline{\mathbf{E}}} : U_{\overline{\mathbf{E}}} := U_{\mathbf{E}} \cap X_{\overline{\mathbf{E}}} \to X_{\overline{\mathbf{E}}}$ the open immersion, and consider the corresponding quasi-coherent $\mathscr{O}_{X_{\overline{\mathbf{E}}}}$-module $\mathscr{Q}^c_{U_{\overline{\mathbf{E}}}}$ as in (16.4.35). Since $U_{\mathbf{E}}$ is quasi-compact, $\mathscr{J}_{\mathbf{E}}$ is a quasi-coherent $\mathscr{O}_{X_{\mathbf{E}}}$-module (see (10.4.16)), so

$\mathscr{J}_{\mathbf{E}} = \mathrm{Ker}\,(\mathscr{O}_{X_{\mathbf{E}}} \to h_{\mathbf{E}*}\mathscr{O}_{X_{\overline{\mathbf{E}}}})$; it follows that the induced map $\mathscr{O}_{X_{\overline{\mathbf{E}}}} \to j_{\overline{\mathbf{E}}*}\mathscr{O}_{U_{\overline{\mathbf{E}}}}$ is a monomorphism, and $h_{\mathbf{E}}$ restricts to an isomorphism of open subschemes $U_{\overline{\mathbf{E}}} \xrightarrow{\sim} U_{\mathbf{E}}$, so the resulting map $j_{\mathbf{E}*}\mathscr{O}_{U_{\mathbf{E}}} \to h_{\mathbf{E}*}j_{\overline{\mathbf{E}}*}\mathscr{O}_{U_{\overline{\mathbf{E}}}}$ is an isomorphism, and we get a natural identification

$$\omega_{\mathbf{E}} : \mathscr{Q}^c_{U_{\mathbf{E}}} \xrightarrow{\sim} h_{\mathbf{E}*}\mathscr{Q}^c_{U_{\overline{\mathbf{E}}}}.$$

Next, consider the cartesian diagram $A(\mathscr{E})$ of (16.4.24), and recall that the bottom horizontal arrow $A_2 \to A_3$ of $A(\mathscr{E})$ is naturally isomorphic to the bottom horizontal arrow $\mathbf{E}_2 \to \mathbf{E}_3$ of $\mathscr{E}$ (remark 16.4.24(iii)). There follows a commutative diagram

$$\begin{array}{ccccc} A & \longrightarrow & \overline{A} & \xrightarrow{\overline{\pi}_1} & A_1 \\ \downarrow & & \downarrow{\scriptstyle \overline{\pi}_2} & & \downarrow \\ \mathbf{E}_2 & \longrightarrow & \overline{\mathbf{E}}_2 & \longrightarrow & \mathbf{E}_3 \end{array}$$

whose two square subdiagrams are cartesian. Especially, J is naturally identified with the kernel of the projection $A \to \overline{A}$; moreover, we have an isomorphism of topological rings

$$\mathbf{E}(\overline{A}) \xrightarrow{\sim} \overline{\mathbf{E}}$$

that identifies $\mathbf{E}(\overline{\pi}_1)$ and $\mathbf{E}(\overline{\pi}_2)$ with the projections $\overline{\mathbf{E}} \to \mathbf{E}_1$ and $\overline{\mathbf{E}} \to \overline{\mathbf{E}}_2$, and furthermore, $\overline{A}$ is perfectoid (proposition 16.3.25). Let also

$$h_A : X_{\overline{A}} := \mathrm{Spec}\,\overline{A} \to X_A \qquad \text{and} \qquad j_{\overline{A}} : U_{\overline{A}} := U_A \cap X_{\overline{A}} \to X_{\overline{A}}$$

be respectively the closed and the open immersion, and consider the corresponding quasi-coherent $\mathscr{O}_{X_{\overline{A}}}$-module $\mathscr{Q}^c_{U_{\overline{A}}}$ defined as in (16.4.35); in light of (16.4.40), we see that $\mathscr{J}_A = \mathrm{Ker}\,(\mathscr{O}_{X_A} \to h_{A*}\mathscr{O}_{X_{\overline{A}}})$, and h_A restricts to an isomorphism of open subschemes $U_{\overline{A}} \xrightarrow{\sim} U_A$, so the resulting map $j_{A*}\mathscr{O}_{U_A} \to h_{A*}j_{\overline{A}*}\mathscr{O}_{U_{\overline{A}}}$ is an isomorphism, and we get a natural identification

$$\omega_A : \mathscr{Q}^c_{U_A} \xrightarrow{\sim} h_{A*}\mathscr{Q}^c_{U_{\overline{A}}}.$$

Lastly, let $\overline{\varphi} : X_{\overline{A}} \to X_{\overline{\mathbf{E}}}$ be the continuous map provided by (16.4.24), and $\overline{\psi}^c_{\overline{A}} : \mathscr{Q}^c_{U_{\overline{\mathbf{E}}}} \to \overline{\varphi}_*\mathscr{Q}^c_{U_{\overline{A}}}$ the morphism of abelian sheaves attached to $\overline{A}$ and $U_{\overline{\mathbf{E}}}$ as in (i); a direct inspection yields a commutative diagram

$$\begin{array}{ccc} \mathscr{Q}^c_{U_{\mathbf{E}}} & \xrightarrow{\overline{\psi}^c} & \varphi_*\mathscr{Q}^c_{U_A} \\ {\scriptstyle \omega_{\mathbf{E}}}\downarrow & & \downarrow{\scriptstyle \varphi_*\omega_A} \\ h_{\mathbf{E}*}\mathscr{Q}^c_{U_{\overline{\mathbf{E}}}} & \xrightarrow{h_{\mathbf{E}*}\overline{\psi}^c_{\overline{A}}} & h_{\mathbf{E}*}\overline{\varphi}_*\mathscr{Q}^c_{U_{\overline{A}}} = \varphi_* h_{A*}\mathscr{Q}^c_{U_{\overline{A}}} \end{array}$$

whence the claim. ◇

Henceforth we assume that $\mathscr{O}_{X_{\mathbf{E}}} = \overline{\mathscr{O}}_{X_{\mathbf{E}}}$ an $\mathscr{O}_{X_A} = \overline{\mathscr{O}}_{X_A}$. Set $U'_{\mathbf{E}} := \mathrm{Spec}\,\mathbf{E}[\alpha_0^{-1}]$, so that $U'_A := \varphi^{-1}U'_{\mathbf{E}}$ is the open subset $\mathrm{Spec}\,A[p^{-1}]$ of X_A, and let $j'_{\mathbf{E}} : U'_{\mathbf{E}} \to X_{\mathbf{E}}$ and $j'_A : U'_A \to X_A$ be the open immersions. Set also $Z'_{\mathbf{E}} := X_{\mathbf{E}} \setminus U'_{\mathbf{E}}$ and $Z'_A := X_A \setminus U'_A$. Notice that

$$i_{\mathbf{E}_1*}\mathscr{O}_{X_{\mathbf{E}_1}} = \mathrm{Im}(\mathscr{O}_{X_{\mathbf{E}}} \to j'_{\mathbf{E}*}\mathscr{O}_{U'_{\mathbf{E}}}) \qquad \text{and} \qquad i_{A_1*}\mathscr{O}_{X_{A_1}} = \mathrm{Im}(\mathscr{O}_{X_A} \to j'_{A*}\mathscr{O}_{U'_A})$$

and denote by $\overline{\psi}'^c : \mathscr{Q}^c_{U'_{\mathbf{E}}} \to \mathscr{Q}^c_{U'_A}$ the map of abelian sheaves associated as in (i) with A and $U'_{\mathbf{E}}$. Since $U'_{\mathbf{E}} \subset U_{\mathbf{E}}$, the natural maps $j_{\mathbf{E}*}\mathscr{O}_{U_{\mathbf{E}}} \to j'_{\mathbf{E}*}\mathscr{O}_{U'_{\mathbf{E}}}$ and $j_{A*}\mathscr{O}_{U_A} \to j'_{A*}\mathscr{O}_{U'_A}$ induce morphisms $\rho_{\mathbf{E}} : R^1\underline{\Gamma}_{Z_{\mathbf{E}}}\mathscr{O}_{X_{\mathbf{E}}} \to R^1\underline{\Gamma}_{Z'_{\mathbf{E}}}\mathscr{O}_{X_{\mathbf{E}}}$ and $\rho_A : R^1\underline{\Gamma}_{Z_A}\mathscr{O}_{X_A} \to R^1\underline{\Gamma}_{Z'_A}\mathscr{O}_{X_A}$, and notice that the image of $\rho_{\mathbf{E}}$ (resp. of ρ_A) lies in $\underline{\Gamma}_{Z_{\mathbf{E}}} R^1\underline{\Gamma}_{Z'_{\mathbf{E}}}\mathscr{O}_{X_{\mathbf{E}}}$ (resp. in $\underline{\Gamma}_{Z_A} R^1\underline{\Gamma}_{Z'_A}\mathscr{O}_{X_A}$); there follows a commutative diagram

$$\begin{array}{ccc} \mathscr{Q}^c_{U_{\mathbf{E}}} & \xrightarrow{\quad\overline{\psi}^c\quad} & \varphi_*\mathscr{Q}^c_{U_A} \\ {\scriptstyle \rho^c_{\mathbf{E}}}\downarrow & & \downarrow{\scriptstyle \varphi_*(\rho^c_A)} \\ \underline{\Gamma}_{Z_{\mathbf{E}}}\mathscr{Q}^c_{U'_{\mathbf{E}}} & \xrightarrow{\underline{\Gamma}_{Z_{\mathbf{E}}}\overline{\psi}'^c} & \underline{\Gamma}_{Z_{\mathbf{E}}}\varphi_*\mathscr{Q}^c_{U'_A} = \varphi_*\underline{\Gamma}_{Z_A}\mathscr{Q}^c_{U'_A} \end{array}$$

where $\rho^c_{\mathbf{E}}$ (resp. ρ^c_A) is the restriction of $\rho_{\mathbf{E}}$ (resp. of ρ_A). From the snake lemma, we obtain natural identifications

$$\mathrm{Ker}\,\rho^c_{\mathbf{E}} \xrightarrow{\sim} \mathrm{Ker}\,(\alpha_0^{-c}\mathscr{O}_{X_{\mathbf{E}}} \to j'_{\mathbf{E}*}\mathscr{O}_{U'_{\mathbf{E}}})/\mathrm{Ker}\,(\mathscr{O}_{X_{\mathbf{E}}} \to i_{\mathbf{E}_1*}\mathscr{O}_{X_{\mathbf{E}_1}}) = (\underline{\Gamma}_{X_{\mathbf{E}_2}}\alpha_0^{-c}\mathscr{O}_{X_{\mathbf{E}}})/\mathscr{O}^{\mathrm{t}}_{X_{\mathbf{E}}}$$

$$\mathrm{Ker}\,\rho^c_A \xrightarrow{\sim} \mathrm{Ker}\,(p^{-c}\mathscr{O}_{X_A} \to j'_{A*}\mathscr{O}_{U'_A})/\mathrm{Ker}\,(\mathscr{O}_{X_A} \to i_{A_1*}\mathscr{O}_{X_{A_1}}) = (\underline{\Gamma}_{X_{A_2}}p^{-c}\mathscr{O}_{X_A})/\mathscr{O}^{\mathrm{t}}_{X_A}$$

(notation of (16.4.28)).

Claim 16.4.41. The map $\overline{\psi}^c$ restricts to an isomorphism of abelian sheaves

$$\mathrm{Ker}\,\rho^c_{\mathbf{E}} \xrightarrow{\sim} \mathrm{Ker}\,\varphi_*(\rho^c_A).$$

Proof of the claim. Notice that

$$\underline{\Gamma}_{X_{\mathbf{E}_2}}\alpha_0^{-c}\mathscr{O}_{X_{\mathbf{E}}} = j_{\mathbf{E}*}j^*_{\mathbf{E}}\mathscr{O}^{\mathrm{t}}_{X_{\mathbf{E}}} \qquad \text{and} \qquad \underline{\Gamma}_{X_{A_2}}p^{-c}\mathscr{O}_{X_A} = j_{A*}j^*_A\mathscr{O}^{\mathrm{t}}_{X_A}.$$

In view of lemma 16.4.29(ii), we deduce that $\varphi^\flat$ induces an isomorphism of abelian sheaves

$$\mathrm{Ker}\,\rho^c_{\mathbf{E}} \xrightarrow{\sim} \mathscr{R}' := \varphi_*(\underline{\Gamma}_{X_{\mathbf{E}_2}}\alpha_0^{-c}\mathscr{O}_{X_{\mathbf{E}}})/\varphi_*(\mathscr{O}^{\mathrm{t}}_{X_A}).$$

Now, proposition 16.4.26(ii) implies that φ_* is an exact functor on the category of quasi-coherent $\mathscr{O}_{X_A}$-modules, and since both U_A and U'_A are quasi-compact (see (16.1.3)), the $\mathscr{O}_{X_A}$-modules $j_{A*}j^*_A\mathscr{O}^{\mathrm{t}}_{X_A}$ and $\mathscr{O}^{\mathrm{t}}_{X_A}$ are quasi-coherent ([59, Ch.I, Cor.9.2.2]) so λ restricts to an isomorphism $\mathscr{R}' \xrightarrow{\sim} \varphi_*\mathrm{Ker}\,\rho^c_A = \mathrm{Ker}\,\varphi_*(\rho^c_A)$, whence the claim. ◊

Now, claim 16.4.38 implies that $\underline{\Gamma}_{Z_{\mathbf{E}}}\overline{\psi}'^c$ is an isomorphism, and in light of claim 16.4.41 we see that $\overline{\psi}^c$ is a monomorphism, so we are reduced to showing that $\underline{\Gamma}_{Z_{\mathbf{E}}}\overline{\psi}'^c$ induces an epimorphism $\mathrm{Im}\,\rho^c_{\mathbf{E}} \to \mathrm{Im}\,\varphi_*(\rho^c_A)$. To this aim, let $x \in X_{\mathbf{E}}$ be any point, and $s_x \in \mathrm{Im}\,(\varphi_*\rho^c_A)_x = \varphi_*(\mathrm{Im}\,\rho^c_A)_x$ any element; by proposition 16.4.26(ii), the functor φ_* is exact on quasi-coherent $\mathscr{O}_{X_A}$-modules, so both maps

$$\varphi_*(p^{-c}\mathscr{O}_{X_A})_x \to \varphi_*(\mathscr{Q}^c_{U_A})_x \to \varphi_*(\mathrm{Im}\,\rho^c_A)_x$$

are surjective, hence we may find an open neighborhood $\Omega \subset X_{\mathbf{E}}$ of x such that s_x lifts to a section $s \in \mathscr{O}_{X_A}(U_A \cap \varphi^{-1}\Omega)$ and $q^c \cdot s$ extends to a section of $\mathscr{O}_{X_A}(\varphi^{-1}\Omega)$ (where q is as in (16.4.35)). Denote by $t_x \in (\underline{\Gamma}_{Z_{\mathbf{E}}}\mathscr{Q}^c_{U'_{\mathbf{E}}})_x$ the preimage of s_x. Notice that

$$\underline{\Gamma}_{Z_{\mathbf{E}}}R^1\underline{\Gamma}_{Z'_{\mathbf{E}}}\mathscr{O}_{X_{\mathbf{E}}} = (j_{\mathbf{E}*}j^*_{\mathbf{E}}(i_{\mathbf{E}_1*}\mathscr{O}_{X_{\mathbf{E}_1}}))/i_{\mathbf{E}_1*}\mathscr{O}_{X_{\mathbf{E}_1}}$$

so we may replace Ω by a smaller open neighborhood of x, and assume that t_x is the image of a section $\overline{t} \in i_{\mathbf{E}_1*}\mathscr{O}_{X_{\mathbf{E}_1}}(U_{\mathbf{E}} \cap \Omega)$. Denote by $\overline{s} \in i_{A_1*}\mathscr{O}_{X_{A_1}}(U_A \cap \varphi^{-1}\Omega)$ the image of s, and set

$$\overline{u} := i_{\mathbf{E}_1*}\varphi^\flat_1(\overline{t}) - \overline{s} \in j_{A*}j^*_A i_{A_1*}\mathscr{O}_{X_{A_1}}(\varphi^{-1}\Omega).$$

By construction, the image of $\overline{u}_x$ vanishes in $(\varphi_*R^1\underline{\Gamma}_{Z'_A}\mathscr{O}_{X_A})_x$, thus $\overline{u}_x \in \varphi_*(i_{A_1*}\mathscr{O}_{X_{A_1}})_x$. By proposition 16.4.26(ii), the natural map $\varphi_*(\mathscr{O}_{X_A})_x \to \varphi_*(i_{A_1*}\mathscr{O}_{X_{A_1}})_x$ is surjective, so we may replace Ω by a smaller open neighborhood of x, and assume that $\overline{u}$ is the image of a local section $u \in \mathscr{O}_{X_A}(\varphi^{-1}\Omega)$. However, s and $s' := s + u_{|U_A \cap \varphi^{-1}\Omega}$ have the same image in $\varphi_*(\mathscr{Q}^c_{U_A})_x$, so we may replace s by s', and assume that $i_{\mathbf{E}_1*}\varphi^\flat_1(\overline{t}) = \overline{s}$. In this situation, remark 16.4.31(ii) implies that $\overline{t}$ lifts to a section $t \in \mathscr{O}_{X_{\mathbf{E}}}(U_{\mathbf{E}} \cap \Omega)$ such that $\varphi^\flat(t) = s$, and we denote by $v \in R^1\underline{\Gamma}_{Z_\mathbf{E}}\mathscr{O}_{X_\mathbf{E}}(\Omega)$ the image of t. Clearly, the image of v in $(\underline{\Gamma}_{Z_\mathbf{E}}R^1\underline{\Gamma}_{Z'_\mathbf{E}}\mathscr{O}_{X_\mathbf{E}})_x$ agrees with t_x, hence it remains only to check that $v_x \in \mathscr{Q}^c_{U_\mathbf{E},x}$. But notice that $\alpha_0^c \cdot t_x = 0$, so $\alpha_0^c \cdot v_x \in (j_{\mathbf{E}*}j^*_\mathbf{E}\mathscr{O}^\mathrm{t}_{X_\mathbf{E}})_x$. Pick any $\varepsilon \in \mathbb{N}[1/p]$ such that $0 < \varepsilon \leq \min(p/(p-1)-c, 1)$; by virtue of corollary 16.3.63(i), it follows that $\alpha_0^{c+\varepsilon} \cdot v_x = 0$, *i.e.* $\alpha_0^c \cdot v_x \in \mathscr{Q}^\varepsilon_{U_\mathbf{E},x}$. Lastly, from (i) we get

$$\overline{\psi}^\varepsilon(\alpha_0^c v_x) = q^c \cdot \overline{\psi}^{c+\varepsilon}(v_x)$$

and $\overline{\psi}^{c+\varepsilon}(v_x)$ is the image of s in $\varphi_*(\mathscr{Q}^{c+\varepsilon}_{U_A})_x$. By construction, the image of $q^c \cdot s$ vanishes in $\varphi_*(\mathscr{Q}^{c+\varepsilon}_{U_A})_x$, and therefore $\alpha_0^c \cdot v_x = 0$, since we have already remarked that $\overline{\psi}^\varepsilon$ is a monomorphism. The assertion follows. □

16.5. **Perfectoid quasi-affinoid rings.** We wish now to merge the theory of perfectoid rings with that of affinoid rings of section 15.3. First, let us make the following :

Definition 16.5.1. (i) We say that a quasi-affinoid ring (A, A^+, U) is *perfectoid* if A is a perfectoid ring.

(ii) We say that a quasi-affinoid scheme $\underline{X}$ is *perfectoid*, if there exists a perfectoid quasi-affinoid ring $\underline{A}$ and an isomorphism $\underline{X} \xrightarrow{\sim} \mathsf{Spec}\,\underline{A}$.

(iii) We denote by

$$\mathsf{q.Afd.Ring}_\mathrm{perf} \qquad \text{and} \qquad \mathsf{q.Afd.Sch}_\mathrm{perf}$$

the subcategories of q.Afd.Ring and respectively q.Afd.Sch whose objects are the perfectoid quasi-affinoid rings (resp. schemes), and whose morphisms are the f-adic morphisms of quasi-affinoid rings (resp. schemes).

16.5.2. Clearly we have a well defined functor

$$\mathsf{q.Afd.Ring}_\mathrm{perf} \to \mathsf{q.Afd.Sch}^o_\mathrm{perf} \qquad \underline{A} \mapsto \mathsf{Spec}\,\underline{A}$$

and we will construct a right adjoint. To this aim, we need a few preliminaries : we consider any perfectoid quasi-affinoid ring $\underline{A} := (A, A^+, U_A)$ and set $X_A := \mathrm{Spec}\,A$, $Z_A := X_A \setminus U_A$. Let also $\mathbf{E} := \mathbf{E}(A)$, define the continuous map $\varphi : X_A \to X_\mathbf{E} := \mathrm{Spec}\,\mathbf{E}$ as in (16.4.24), and set $Z_\mathbf{E} := \varphi(Z_A)$ and $U_\mathbf{E} := X_\mathbf{E} \setminus Z_\mathbf{E}$. Then it is easily seen that $U_\mathbf{E}$ contains the analytic locus of $X_\mathbf{E}$, so *any choice of ring of integral elements* $\mathbf{E}^+ \subset \mathbf{E}$ will give another perfectoid quasi-affinoid ring $\underline{\mathbf{E}} := (\mathbf{E}, \mathbf{E}^+, U_\mathbf{E})$, as well as the attached perfectoid quasi-affinoid schemes

$$(U_A, \mathscr{T}_{U_A}, A^+_U) := \mathsf{Spec}\,\underline{A} \qquad (U_\mathbf{E}, \mathscr{T}_{U_\mathbf{E}}, \mathbf{E}^+_U) := \mathsf{Spec}\,\underline{\mathbf{E}}.$$

More precisely, let $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N})$ be any distinguished element in $\mathrm{Ker}\,u_A$; since φ maps $\mathrm{Spec}\,A/pA$ bijectively onto $\mathrm{Spec}\,\mathbf{E}/\alpha_0\mathbf{E}$, and maps $\mathrm{Spec}\,A[p^{-1}]$ onto $\mathrm{Spec}\,\mathbf{E}[\alpha_0^{-1}]$, it is easily seen that $U_\mathbf{E}$ is the unique open subset of $X_\mathbf{E}$ containing the analytic locus, and such that

$$\varphi^{-1}(U_\mathbf{E}) = U_A. \tag{16.5.3}$$

Recall that, according to lemma 16.4.32, the topologies $\mathscr{T}_{U_A}$ on $A_U := \mathscr{O}_{X_A}(U_A)$ and $\mathscr{T}_{U_\mathbf{E}}$ on $\mathbf{E}_U := \mathscr{O}_{X_\mathbf{E}}(U_\mathbf{E})$ are f-adic, complete and separated, and the restriction maps $A \to A_U$ and $\mathbf{E} \to \mathbf{E}_U$ are open. Especially the image $\overline{A}$ of A (resp. $\overline{\mathbf{E}}$ of $\mathbf{E}$) is open in A_U (resp. in $\mathbf{E}_U$), and we endow this subring with the quotient topology induced by the projection $\pi_A : A \to \overline{A}$ (resp. $\pi_\mathbf{E} : \mathbf{E} \to \overline{\mathbf{E}}$). Moreover, we have a continuous map of (multiplicative) monoids

$$\varphi^\flat_U : \mathbf{E}_U \to A_U$$

(proposition 16.4.34(i)). Let also

$$j^\circ_\mathbf{E} : \overline{\mathbf{E}} \to \mathbf{E}^\circ_U \qquad \text{and} \qquad j^\circ_A : \overline{A} \to A^\circ_U$$

be the inclusion maps, and we endow A°_U (resp. $\mathbf{E}^\circ_U$) with the topology induced by the inclusion into A_U (resp. into $\mathbf{E}_U$), so that j°_A and $j^\circ_\mathbf{E}$ are open maps.

Proposition 16.5.4. *In the situation of* (16.5.2)*, we have :*

(i) *For every $x \in A_U$, the following conditions are equivalent :*
   (a) *x is power bounded in A_U.*
   (b) *The subset $\{x^{p^n} \mid n \in \mathbb{N}\}$ is bounded in A_U.*
   (c) *The image of x in $R^1\Gamma_{Z_A}\mathscr{O}_{X_A}$ is annihilated by $A^{\circ\circ}$.*
   (d) *$x \cdot A_U^{\circ\circ} \subset A_U^{\circ\circ}$.*
   (e) *$v(x) \leq 1$ for every analytic rank one valuation $v \in \mathrm{Spa}\,\underline{A}$.*

(ii) *$\overline{A}$ and $\overline{\mathbf{E}}$ are perfectoid rings, and there exists a unique isomorphism*

$$\overline{\omega} : \overline{\mathbf{E}} \xrightarrow{\sim} \mathbf{E}(\overline{A}) \qquad \textit{such that} \qquad \overline{\omega} \circ \pi_{\mathbf{E}} = \mathbf{E}(\pi_A).$$

(iii) *The maps π_A and $\pi_{\mathbf{E}}$ restrict to bijections $\mathbf{E}^{\circ\circ} \xrightarrow{\sim} \mathbf{E}_U^{\circ\circ}$ and $A^{\circ\circ} \xrightarrow{\sim} A_U^{\circ\circ}$.*

(iv) *The map $\varphi_U^\flat$ restricts to a continuous map of topological monoids*

$$\varphi_U^{\flat\circ} : \mathbf{E}_U^\circ \to A_U^\circ$$

which induces an isomorphism of perfect $\mathbb{F}_p$-algebras

$$\overline{\varphi}_U^{\flat\circ} : \mathbf{E}_U^\circ/\mathbf{E}_U^{\circ\circ} \xrightarrow{\sim} A_U^\circ/A_U^{\circ\circ}.$$

Proof. We consider first the following special case :

Claim 16.5.5. In the situation of (16.5.2), let $\beta \in \mathbf{E}$ be any regular element such that $\alpha_0 \in \beta\mathbf{E}$, set $b := \overline{u}_A(\beta) \in A$, and suppose moreover that bA is an ideal of adic definition for A, and U_A is the analytic locus of X_A. Then conditions (i.a)–(i.d) are equivalent in this case, and

$$A^{\circ\circ} = A_U^{\circ\circ} = \bigcup_{\lambda \in \mathbb{N}[1/p]\setminus\{0\}} b^\lambda A \qquad \text{with } b^\lambda := \overline{u}_A(\beta^\lambda) \text{ for every } \lambda \in \mathbb{N}[1/p].$$

Proof of the claim. First, notice that under the assumptions of the claim, $p \in bA$ (lemma 16.2.7(iii)) and b^λ is a regular element of A for every $\lambda \in \mathbb{N}[1/p]$ (proposition 16.4.17). Especially, the localization map $A \to A[b^{-1}]$ is injective, and $U_A = \mathrm{Spec}\,A[b^{-1}]$, so that $A_U = A[b^{-1}]$, $R^1\Gamma_{Z_A}\mathscr{O}_{X_A} = A[b^{-1}]/A$, and condition (i.c) implies :

(i.f) $b^\lambda x \in A$ for every $\lambda \in \mathbb{N}[1/p] \setminus \{0\}$.

We show first the equivalence of (i.a), (i.b) and (i.f). Indeed, obviously (i.f)⇒(i.a)⇒(i.b), so we may assume that (i.b) holds, and we set

$$\rho := \inf\{\gamma \in \mathbb{N}[1/p] \mid b^\gamma x^{p^n} \in A \text{ for every } n \in \mathbb{N}\}.$$

Notice that (i.b) implies that $\rho < +\infty$. We claim that $\rho = 0$. Indeed suppose, by way of contradiction, that $\rho > 0$ and pick any $\gamma \in \mathbb{N}[1/p]$ such that $\rho > \gamma > \max(\rho/p, \rho - 1/p)$. Then $b^{1/p}b^\gamma x^{p^n} \in A$, and hence $b^\gamma x^{p^n} \in b^{-1/p}A$ for every $n \in \mathbb{N}$; on the other hand, we also see that $b^{p\gamma}x^{p^n} \in A$ for every $n \in \mathbb{N}$. Now, by corollary 16.3.3, the Frobenius endomorphism of A/pA induces an isomorphism $A/b^{1/p}A \to A/bA$; since b is regular, there follows a bijective map

$$b^{-1/p}A/A \xrightarrow{\sim} b^{-1}A/A \qquad (x \mod A) \mapsto (x^p \mod A).$$

We deduce that $b^\gamma x^{p^n} \in A$ for every $n \in \mathbb{N}$, *i.e.* $\gamma \leq \rho$, which is absurd. This shows that (i.f) holds, whence the assertion. Next, say that $x \in A[b^{-1}]^{\circ\circ}$; since bA is open in $A[b^{-1}]$, we must have $x^{p^n} \in bA$ for some $n \in \mathbb{N}$, so if set $y := b^{-1/p^n}x$, we get $y^{p^n} \in A$, and therefore the subset $\{y^{p^n} \mid n \in \mathbb{N}\}$ is bounded in A_U. Pick any integer $r > n$; by the foregoing, it follows that $b^{1/p^r}y \in A$, and finally $x \in b^{1/p^n - 1/p^r}A$. This also implies the equivalence of (i.c),(i.d) and (i.f), so the proof of the claim is complete. ◊

For the general case, pick a finite system $\beta_\bullet := (\beta_0, \dots, \beta_k)$ of elements of $\mathbf{E}$ with $\beta_0 = \alpha_0$, and such that $\beta_\bullet$ generates an ideal $\mathscr{I}$ of adic definition for $\mathbf{E}$. Then the ideal $I \subset A$ generated by $(\overline{u}_A(\beta_0), \dots, \overline{u}_A(\beta_k))$ is of adic definition for A (see remark 16.3.7(iii)). We notice :

Claim 16.5.6. The ideal $A^{\circ\circ}$ is generated by $(\overline{u}_A(\beta_i^\lambda) \mid i = 0, \dots, k, \ \lambda \in \mathbb{N}[1/p] \setminus \{0\})$.

Proof of the claim. Clearly $\overline{u}_A(\beta_i^\lambda) \in A^{\circ\circ}$ for every $i = 0, \dots, k$ and every strictly positive $\lambda \in \mathbb{N}[1/p]$. Conversely, let $c \in A^{\circ\circ}$ be any element; then $c^{p^n} \in I$ for every sufficiently large $n \in \mathbb{N}$. By remark 16.3.7(iii) we may find $\gamma \in \mathbf{E}$ such that $\overline{u}_A(\gamma) - c \in pA$, and the image of γ^{p^n} in $\mathbf{E}/\alpha_0\mathbf{E}$ lies in $\mathscr{I}/\alpha_0\mathbf{E}$, so $\gamma^{p^n} \in \mathscr{I}$, hence $\gamma \in \mathscr{I}^{\langle 1/p^n\rangle}\mathbf{E}$, and therefore $c \in \mathscr{I}^{\langle 1/p^n\rangle}A + pA = \mathscr{I}^{\langle 1/p^n\rangle}A$ (notation of remark 9.3.70(i)), whence the claim. ◊

(i.c)⇒(i.a): By assumption, $\overline{u}_A(\beta_i^\lambda) \cdot x$ lies in $\overline{A}$, for every $i = 0, \dots, k$ and every strictly positive $\lambda \in \mathbb{N}[1/p]$; let $n > 0$ be any integer, and pick $t \in \mathbb{N}$ such that $p^t \geq n$; then $\overline{u}_A(\beta_i^{n/p^t}) \cdot x^n = (\overline{u}_A(\beta^{1/p^t}) \cdot x)^n$ lies as well in $\overline{A}$, and we conclude that $\overline{u}_A(\beta_i) \cdot x^n \in \overline{A}$ for every $n \in \mathbb{N}$, whence the assertion.

Obviously, (i.a)⇒(i.b). To show that (i.b)⇒(i.c), let $\mathscr{T}_{A,p}$ be the p-adic topology on A, and $\mathscr{T}_{U,p}$ the unique f-adic topology on A_U such that the restriction map $(A, \mathscr{T}_{A,p}) \to (A_U, \mathscr{T}_{U,p})$ is open (lemma 16.4.32(i)). Suppose first that the topology of A agrees with $\mathscr{T}_{A,p}$, and let

$$A_1 := A/\mathrm{Ann}_A(p) \qquad Z' := \mathrm{Spec}\, A/pA \qquad U' := X_A \setminus Z'.$$

Denote as well by $x_{|U'} \in \mathscr{O}_{X_A}(U') = A[1/p]$ the image of x. We recall that p is regular in A_1 (remark 16.4.25(ii)), and we endow A_1 with its p-adic topology $\mathscr{T}_{A_1,p}$, and $A[1/p]$ with the unique f-adic topology $\mathscr{T}_{U',p}$ such that the inclusion map $(A_1, \mathscr{T}_{A_1,p}) \to (A[1/p], \mathscr{T}_{U',p})$ is open, so that the subset $\{x_{|U'}^{p^n} \mid n \in \mathbb{N}\}$ is bounded in $A[1/p]$. Set $q := \overline{u}_A(\alpha_0)$; by claim 16.5.5 and lemma 16.2.7(iii), it then follows that $q^\lambda \cdot x_{|U'}$ lies in A_1 for every $\lambda \in \mathbb{N}[1/p] \setminus \{0\}$. Denote also by $\overline{x} \in R^1\Gamma_Z\mathscr{O}_{X_A}$ the image of x; we deduce that the image of $q^\lambda \cdot \overline{x}$ vanishes in $R^1\Gamma_{Z'}\mathscr{O}_{X_A}$, for every such λ. To conclude in this case, it suffices to remark :

Claim 16.5.7. The kernel of the natural map $R^1\Gamma_{Z_A}\mathscr{O}_{X_A} \to R^1\Gamma_{Z'}\mathscr{O}_{X_A}$ is annihilated by q^λ for every $\lambda \in \mathbb{N}[1/p] \setminus \{0\}$.

Proof of the claim. By the snake lemma, this kernel is a quotient of $\Gamma_{Z'}j_{A*}\mathscr{O}_{U_A}$, where $j_A : U_A \to X_A$ is the open immersion. However, $\Gamma_{Z'}j_*\mathscr{O}_{U_A} = H^0(U_A, \underline{\Gamma}_{Z'}\mathscr{O}_{X_A})$. Since $\underline{\Gamma}_{Z'}\mathscr{O}_{X_A}$ is a quasi-coherent $\mathscr{O}_{X_A}$-module (lemma 10.4.17(i)), we are reduced to checking that $\mathrm{Ann}_A(p)$ is annihilated by q^λ for every $\lambda \in \mathbb{N}[1/p] \setminus \{0\}$. The latter holds by corollary 16.3.63(i). ◊

Next, let A be any perfectoid ring; let $j_{\mathbf{E}} : U_{\mathbf{E}} \to X_{\mathbf{E}}$ be the open immersion, and for every $c \in \mathbb{N}[1/p]$ consider the $\mathscr{O}_{X_{\mathbf{E}}}$-module $\mathscr{Q}^c_{U_{\mathbf{E}}}$ and the $\mathscr{O}_{X_A}$-module $\mathscr{Q}^c_{U_A}$ as in (16.4.35). We set

$$\mathscr{Q}^0_{U_{\mathbf{E}}} := \bigcap_{c>0} \mathscr{Q}^c_{U_{\mathbf{E}}} \qquad \text{and} \qquad \mathscr{Q}^0_{U_A} := \bigcap_{c>0} \mathscr{Q}^c_{U_A}.$$

Condition (i.b) implies that the set $\{x^{p^n} \mid n \in \mathbb{N}\}$ is bounded also for the topology $\mathscr{T}_{U,p}$ of A_U, and since $(A, \mathscr{T}_{A,p})$ is perfectoid (proposition 16.3.8(i)), the foregoing case shows that $\overline{x}$ lies in $\mathscr{Q}^0_{U_A}(X_A)$. By proposition 16.4.36(iv), the map $\varphi^\flat$ of lemma 16.4.29(i) induces an isomorphism

$$\overline{\psi}^0 : \mathscr{Q}^0_{U_{\mathbf{E}}} \xrightarrow{\sim} \varphi_*\mathscr{Q}^0_{U_A}$$

of abelian sheaves, fitting into a commutative diagram

$$\text{(16.5.8)} \qquad \begin{array}{ccc} \mathscr{Q}^0_{U_{\mathbf{E}}} & \xrightarrow{\overline{\psi}^0} & \varphi_*\mathscr{Q}^0_{U_A} \\ {\scriptstyle \overline{\boldsymbol{p}}_{\mathbf{E}}}\downarrow & & \downarrow{\scriptstyle \varphi_*(\overline{\boldsymbol{p}}_A)} \\ \mathscr{Q}^0_{U_{\mathbf{E}}} & \xrightarrow{\overline{\psi}^0} & \varphi_*\mathscr{Q}^0_{U_A} \end{array}$$

where $\overline{\boldsymbol{p}}_{\mathbf{E}}$ (resp. $\overline{\boldsymbol{p}}_A$) is induced by the p-Frobenius endomorphism of the sheaf of monoids $j_{\mathbf{E}*}\mathscr{O}_{U_{\mathbf{E}}}$ (resp. $j_{A*}\mathscr{O}_{U_A}$). With this notation, condition (i.b) says that for some $n \in \mathbb{N}$ we have

$$\text{(16.5.9)} \qquad \overline{u}_A(\beta_i^n) \cdot \overline{\boldsymbol{p}}_A^r(\overline{x}) = 0 \qquad \text{for every } i = 0, \dots, k \text{ and every } r \in \mathbb{N}.$$

Let $\overline{\gamma} \in \mathscr{Q}^0_{U_{\mathbf{E}}}(X_{\mathbf{E}})$ be the preimage of $\overline{x}$; then $\beta_i^\lambda \cdot \overline{\gamma}$ is the preimage of the class of $\overline{u}_A(\beta_i^\lambda) \cdot x$ in $\mathscr{Q}^0_{U_A}(X_A)$, for every $i = 0, \dots, k$ and every $\lambda \in \mathbb{N}[1/p]$. By virtue of claim 16.5.6, we are then reduced to checking that $\beta_i^\lambda \cdot \overline{\gamma} = 0$ for every such i and λ, and (16.5.9) yields already

$$\beta_i^n \cdot \overline{\boldsymbol{p}}^r_{\mathbf{E}}(\overline{\gamma}) = 0 \qquad \text{for every } i = 0, \dots, k \text{ and every } r \in \mathbb{N}.$$

Now, we may write $\lambda = t \cdot p^{-r}$ for some integers $t \geq n$ and $r \in \mathbb{N}$; we deduce

$$\overline{\boldsymbol{p}}^r_{\mathbf{E}}(\beta_i^\lambda \cdot \overline{\gamma}) = \beta_i^t \cdot \overline{\boldsymbol{p}}^r_{\mathbf{E}}(\overline{\gamma}_{\mathbf{E}}) = 0.$$

Lastly, since $\mathbf{E}$ is perfect, it is easily seen that $\overline{\boldsymbol{p}}_{\mathbf{E}}$ is an isomorphism, whence the assertion.

(ii): This was already remarked in the proof of claim 16.4.39. Let us add the following :

Claim 16.5.10. The map $\pi_{\mathbf{E}}$ and π_A restrict to bijections $\mathbf{E}^{\circ\circ} \xrightarrow{\sim} \overline{\mathbf{E}}^{\circ\circ}$ and $A^{\circ\circ} \xrightarrow{\sim} \overline{A}^{\circ\circ}$.

Proof of the claim. First, notice that the image of $\beta_\bullet$ in $\overline{\mathbf{E}}$ generates an ideal of adic definition for $\overline{\mathbf{E}}$; in view of (ii) and claim 16.5.6, we deduce immediately that $\overline{A}^{\circ\circ} = \pi_A(A^{\circ\circ})$ and $\overline{\mathbf{E}}^{\circ\circ} = \pi_{\mathbf{E}}(\mathbf{E}^{\circ\circ})$. Next, if I is any ideal of adic definition for A, clearly we have $I \cdot \mathrm{Ker}\,\pi_A = 0$, whence $I \cap \mathrm{Ker}\,\pi_A = 0$, since A is reduced (corollary 16.3.63); but $A^{\circ\circ}$ is the union of all ideals of adic definition for A, so we conclude that $A^{\circ\circ} \cap \mathrm{Ker}\,\pi_A = 0$. Likewise, we see that $\mathbf{E}^{\circ\circ} \cap \mathrm{Ker}\,\pi_{\mathbf{E}} = 0$, whence the claim. ◊

(iii): Let $x \in A_U^{\circ\circ}$ be any element; denote by $\overline{x} \in R^1\Gamma_{Z_A}\mathscr{O}_{X_A}$ the image of x; from (i) we see that $\overline{x} \in Q_A := \mathscr{Q}^0_{U_A}(X_A)$, and since $\overline{A}$ is open in A_U, there exists $n \in \mathbb{N}$ such that $x^{p^n} \in \overline{A}$, therefore $\overline{\boldsymbol{p}}^n_A(\overline{x}) = 0$. On the other hand, we have already remarked that the maps $\overline{\psi}^0$ and $\overline{\boldsymbol{p}}_{\mathbf{E}}$ appearing in (16.5.8) are isomorphisms, so the same holds for $\overline{\boldsymbol{p}}_A$, and consequently $\overline{x} = 0$, *i.e.* $x \in \overline{A}$; then the assertion follows from claim 16.5.10. Next, from claim 16.5.6 it is easily seen that the isomorphism $\mathbf{E}/\alpha_0\mathbf{E} \xrightarrow{\sim} A/pA$ of remark 16.3.7(ii) restricts to a natural identification

$$\mathbf{E}^{\circ\circ}/\alpha_0\mathbf{E} \xrightarrow{\sim} A^{\circ\circ}/pA \tag{16.5.11}$$

therefore $Z_{\mathbf{E}} \subset X_{\mathbf{E}} \setminus \mathrm{Spec}\,\mathbf{E}/\mathbf{E}^{\circ\circ}$, so the foregoing applies as well to the perfectoid ring $\mathbf{E}$ and its closed subset $Z_{\mathbf{E}}$, and the proof of (iii) is thus complete.

Now, taking into account (iii), we easily see that (i.d)⇒(i.c). Conversely, if (i.c) holds, we get $x \cdot A^{\circ\circ} \cdot A^{\circ\circ} \subset A_U^{\circ\circ}$, but claim 16.5.6 implies that $A^{\circ\circ} \cdot A^{\circ\circ} = A^{\circ\circ}$, whence (i.d). Lastly, from remark 15.4.15(iv) it is clear that (i.a)⇒(i.e). Conversely, suppose (i.e) holds; then we have as well $v(xa) < 1$ for every $a \in A_U^{\circ\circ}$ and every rank one analytic valuation $v \in \mathrm{Spa}\,\underline{A}$. Taking into account lemma 15.3.14(v), it follows that $v(xa) < 1$ for every $a \in A_U^{\circ\circ}$ and every $v \in (\mathrm{Spa}\,\underline{A})_{\mathrm{a}}$. On the other hand, we have $v(xa) = 0$ for every $v \in (\mathrm{Spa}\,\underline{A})_{\mathrm{na}}$, and we conclude that $xa \in A_U^{\circ\circ}$, by corollary 15.4.27(ii). This shows that (i.e)⇒(i.d), and completes the proof of (i).

(iv): Set also $Q_{\mathbf{E}} := \mathscr{Q}^0_{U_{\mathbf{E}}}(X_{\mathbf{E}})$; in light of (16.5.11), it is easily seen that the isomorphism $\overline{\psi}^0$ restricts to a natural identification

$$\mathrm{Ann}_{Q_{\mathbf{E}}}(\mathbf{E}^{\circ\circ}) \xrightarrow{\sim} \mathrm{Ann}_{Q_A}(A^{\circ\circ})$$

and taking into account (i) we deduce that $\varphi_U^\flat(\mathbf{E}_U^\circ) \subset A_U^\circ$, so the sought map $\varphi_U^{\flat\circ}$ is well defined, and it is continuous, by proposition 16.4.34(i); combining with (iii), we also see that $\varphi_U^{\flat\circ}$ induces bijections

$$\mathbf{E}_U^\circ/\overline{\mathbf{E}} \xrightarrow{\sim} A_U^\circ/\overline{A} \qquad \overline{\mathbf{E}}/\mathbf{E}_U^{\circ\circ} \xrightarrow{\sim} \overline{A}/A_U^{\circ\circ}.$$

On the other hand, we remark :

Claim 16.5.12. (i) For every $x, y \in \mathbf{E}_U^\circ$ we have $\varphi_U^\flat(x+y) - \varphi_U^\flat(x) - \varphi_U^\flat(y) \in A_U^{\circ\circ}$.

(ii) $\varphi_U^{\flat\circ}(\mathbf{E}_U^{\circ\circ}) \subset A_U^{\circ\circ}$.

Proof of the claim. (i): By proposition 16.4.34(ii), the difference in the claim can be written as a p-adically convergent series $\sum_{n\in\mathbb{N}\setminus\{0\}} p^n \cdot c_n$, where each summand c_n is a finite $\mathbb{Z}_p$-linear combination of terms of the form $\varphi^\flat_U(x^\lambda y^{1-\lambda})$, where $\lambda, 1-\lambda \in \mathbb{N}[1/p]$. It is easily seen that $x^\lambda y^{1-\lambda} \in \mathbf{E}^\circ_U$ for every such λ, and obviously $p \in A^{\circ\circ}_U$, whence the contention.

(ii) is obvious, since $\varphi^{\flat\circ}_U$ is a continuous morphism of multiplicative monoids. ◊

From claim 16.5.12 it follows that $\varphi^{\flat\circ}_U$ descends to a map $\overline{\varphi}^{\flat\circ}_U : \mathbf{E}^\circ_U/\mathbf{E}^{\circ\circ}_U \to A^\circ_U/A^{\circ\circ}_U$ of abelian groups, which must then be bijective, by the foregoing. By remark 8.3.10(iv), both the source and target of $\overline{\varphi}^{\flat\circ}_U$ are endowed with natural quotient ring structures, and it is easily seen that $\mathbf{E}^\circ_U/\mathbf{E}^{\circ\circ}_U$ is a perfect $\mathbb{F}_p$-algebra (details left to the reader); to conclude the proof it then suffices to notice that, by construction, $\overline{\varphi}^{\flat\circ}_U$ is also a morphism of multiplicative monoids. □

Theorem 16.5.13. *In the situation of* (16.5.2)*, the following holds :*

(i) $\mathbf{E}^\circ_U$ *and* A°_U *are both perfectoid, and there exists an isomorphism of topological rings*
$$\omega^\circ : \mathbf{E}^\circ_U \xrightarrow{\sim} \mathbf{E}(A^\circ_U) \qquad \textit{such that} \qquad \omega^\circ \circ j^\circ_{\mathbf{E}} = \mathbf{E}(j^\circ_A).$$

(ii) *The rule* $D \mapsto \mathbf{E}(D)$ *establishes a bijection from the set* $\mathscr{S}_A$ *of open integrally closed subrings of* A°_U *to the set* $\mathscr{S}_{\mathbf{E}}$ *of open integrally closed subrings of* $\mathbf{E}^\circ_U$*.*

(iii) *Moreover, every open integrally closed subring of* A°_U *is perfectoid (for the topology induced by* A°_U*).*

Proof. (i): First, notice that $\mathbf{E}^{\circ\circ}_U$ (resp. $\mathbf{A}^{\circ\circ}_U$) is a bounded open ideal of $\mathbf{E}^\circ_U$ (resp. of A°_U), by virtue of proposition 16.5.4(iii); it follows that $\mathbf{E}^\circ_U$ and A°_U are bounded, so their topologies are both adic and f-adic (corollary 8.3.19(iii)). Moreover, since $\mathbf{E}_U$ and A_U are complete and separated (lemma 16.4.32(ii)), the same holds for $\mathbf{E}^\circ_U$ and A°_U. Furthermore, since $\mathbf{E}_U$ is a perfect $\mathbb{F}_p$-algebra, proposition 16.5.4(i) easily implies that the same holds for $\mathbf{E}^\circ_U$, so the latter is perfectoid (example 16.3.2(i)). Next, let $I \subset A$ be any ideal of definition; proposition 16.5.4(iii) implies that $I_U := IA^\circ_U \subset A^{\circ\circ}$, so I_U is a finitely generated ideal of adic definition for A°_U (corollary 8.3.19(iii)), and clearly $p \in I^2_U$. Furthermore, $I_U \subset \overline{A}$ (by claim 16.5.10), and the Frobenius endomorphism Φ_{A_U/I_U} of A_U/I_U induces surjective endomorphisms of both $\overline{A}/I_U$ and $A_U/\overline{A}$ (proposition 16.5.4(iv)); thus, Φ_{A_U/I_U} is surjective, which shows that A_U is a P-ring. Next, endow A°_U/pA°_U with the quotient topology induced by the projection $\pi_U : A^\circ_U \to A^\circ_U/pA^\circ_U$, and let $\varphi^{\flat\circ}_U : \mathbf{E}^\circ_U \to A^\circ_U$ and $\overline{\omega} : \overline{\mathbf{E}} \xrightarrow{\sim} \mathbf{E}(\overline{A})$ be respectively the continuous morphism of topological monoids and the isomorphism of topological rings provided by proposition 16.5.4(iii,iv); in light of proposition 16.4.34(ii) it is easily seen that $\pi_U \circ \varphi^{\flat\circ}_U : \mathbf{E}^\circ_U \to A^\circ_U/pA^\circ_U$ is a continuous ring homomorphism fitting into a commutative diagram

$$\begin{array}{ccc} \overline{\mathbf{E}} & \xrightarrow{\overline{u}_{\overline{A}/p\overline{A}} \circ \overline{\omega}} & \overline{A}/p\overline{A} \\ {\scriptstyle j^\circ_{\mathbf{E}}}\downarrow & & \downarrow{\scriptstyle j^\circ_A \otimes_{\mathbb{Z}} \mathbb{F}_p} \\ \mathbf{E}^\circ_U & \xrightarrow{\pi_U \circ \varphi^{\flat\circ}_U} & A^\circ_U/pA^\circ_U. \end{array}$$

By proposition 9.3.52(iii), there follows a continuous ring homomorphism $v_U : W(\mathbf{E}^\circ_U) \to A^\circ_U$ fitting into a commutative diagram

$$\begin{array}{ccc} W(\overline{\mathbf{E}}) & \xrightarrow{u_{\overline{A}} \circ W(\overline{\omega})} & \overline{A} \\ {\scriptstyle W(j^\circ_{\mathbf{E}})}\downarrow & & \downarrow{\scriptstyle j^\circ_A} \\ W(\mathbf{E}^\circ_U) & \xrightarrow{v_U} & A^\circ_U. \end{array}$$

Since both $u_{\overline{A}}$ and j°_A are open, the same holds for v_U, and since $\overline{A}$ is perfectoid (proposition 16.5.4(iii)), the kernel of $u_{\overline{A}} \circ W(\overline{\omega})$ is a distinguished ideal, so it remains only to check

Claim 16.5.14. v_U induces a ring isomorphism

$$\overline{v}_U : W(\mathbf{E}_U^\circ) \otimes_{W(\overline{\mathbf{E}})} \overline{A} \xrightarrow{\sim} A_U^\circ.$$

Proof of the claim. Let $\Phi_{\mathbf{E}_U^\circ}$ be the Frobenius endomorphism of $\mathbf{E}_U^\circ$, and notice that

$$\Phi_{\mathbf{E}_U^\circ}(\mathbf{E}_U^{\circ\circ}) = \mathbf{E}_U^{\circ\circ}.$$

Moreover, $W(\mathbf{E}_U^{\circ\circ})$ is a closed ideal of both $W(\overline{\mathbf{E}})$ and $W(\mathbf{E}_U^\circ)$ (remark 9.3.28(iv)); there follows a commutative ladder with exact rows :

$$\mathscr{L} \quad : \quad \begin{array}{ccccccccc} 0 & \longrightarrow & W(\mathbf{E}_U^{\circ\circ}) & \longrightarrow & W(\overline{\mathbf{E}}) & \longrightarrow & W(\overline{\mathbf{E}}/\mathbf{E}_U^{\circ\circ}) & \longrightarrow & 0 \\ & & \| & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & W(\mathbf{E}_U^{\circ\circ}) & \longrightarrow & W(\mathbf{E}_U^\circ) & \longrightarrow & W(\mathbf{E}_U^\circ/\mathbf{E}_U^{\circ\circ}) & \longrightarrow & 0. \end{array}$$

Let $\underline{\alpha}$ be any distinguished element of $\mathrm{Ker}\, u_A$; since the image of $\underline{\alpha}$ is a regular element in both $W(\mathbf{E}_U^\circ/\mathbf{E}_U^{\circ\circ})$ and $W(\overline{\mathbf{E}}/\mathbf{E}_U^{\circ\circ})$, we have

$$\mathrm{Tor}_1^{W(\mathbf{E})}(W(\mathbf{E}_U^\circ/\mathbf{E}_U^{\circ\circ}), A) = 0 \qquad \mathrm{Tor}_1^{W(\mathbf{E})}(W(\overline{\mathbf{E}}/\mathbf{E}_U^{\circ\circ}), A) = 0$$

so the rows of the ladder $\mathscr{L} \otimes_{W(\overline{\mathbf{E}})} \overline{A}$ are still exact. Furthermore, since the topologies of $\overline{\mathbf{E}}/\mathbf{E}_U^{\circ\circ}$ and $\mathbf{E}_U^\circ/\mathbf{E}_U^{\circ\circ}$ are discrete, the isomorphism $\overline{\varphi}_U^{\flat\circ}$ of proposition 16.5.4(iv) induces identifications

$$W(\overline{\mathbf{E}}/\mathbf{E}_U^{\circ\circ}) \otimes_{W(\overline{\mathbf{E}})} \overline{A} \xrightarrow{\sim} \overline{A}/A_U^{\circ\circ} \qquad W(\mathbf{E}_U^\circ/\mathbf{E}_U^{\circ\circ}) \otimes_{W(\overline{\mathbf{E}})} \overline{A} \xrightarrow{\sim} A_U^\circ/A_U^{\circ\circ}.$$

Summing up, we obtain the commutative diagram with exact rows :

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A_U^{\circ\circ} & \longrightarrow & \overline{A} & \longrightarrow & \overline{A}/A_U^{\circ\circ} & \longrightarrow & 0 \\ & & \| & & \downarrow{\scriptstyle w} & & \downarrow & & \\ 0 & \longrightarrow & A_U^{\circ\circ} & \longrightarrow & W(\mathbf{E}_U^\circ) \otimes_{W(\overline{\mathbf{E}})} \overline{A} & \longrightarrow & A_U^\circ/A_U^{\circ\circ} & \longrightarrow & 0 \\ & & \| & & \downarrow{\scriptstyle \overline{v}_U} & & \| & & \\ 0 & \longrightarrow & A_U^{\circ\circ} & \longrightarrow & A_U^\circ & \longrightarrow & A_U^\circ/A_U^{\circ\circ} & \longrightarrow & 0 \end{array}$$

and to conclude, it suffices to check that $\overline{v}_U \circ w = j_A^\circ$. To this aim, it suffices to show that $\overline{v}_U \circ w \circ u_{\overline{A}} = j_A^\circ \circ u_{\overline{A}} : W(\mathbf{E}(\overline{A})) \to A_U^\circ$. However, by construction we have

$$\overline{v}_U \circ w \circ u_{\overline{A}} = v_U \circ W(j_{\mathbf{E}}^\circ \circ \overline{\omega}^{-1}) \qquad \text{and} \qquad j_A^\circ \circ u_{\overline{A}} \circ W(\overline{\omega}) = v_U \circ W(j_{\mathbf{E}}^\circ)$$

whence the claim. ◊

(ii): Let $D \subset A_U^\circ$ be any open integrally closed subring; it is easily seen that $A_U^{\circ\circ} \subset D$, so $A_U^{\circ\circ}$ is an ideal of D (remark 8.3.10(iv)) and we set $\overline{D} := D/A_U^{\circ\circ} \subset C_A := A_U^\circ/A_U^{\circ\circ}$.

Claim 16.5.15. With the foregoing notation, the rule : $D \mapsto \overline{D}$ establishes a bijection from the set of open integrally closed subrings of A_U° to the set of integrally closed subrings of C_A.

Proof of the claim. Let us check that $\overline{D}$ is integrally closed in C_A. Indeed, let $\overline{x} \in C_A$, and $P(T) \in D[T]$ a monic polynomial such that $P(\overline{x}) = 0$ in C_A; if $x \in A_U^\circ$ is any representative for the class $\overline{x}$, we get $P(x) \in A_U^{\circ\circ}$. Set $Q(T) := P(T) - P(x)$; then $Q(T) \in D[T]$ and $Q(x) = 0$, so $x \in D$, and therefore $\overline{x} \in \overline{D}$, which shows the contention. Conversely, if $\overline{D} \subset C_A$ is any integrally closed subring, let us show that the preimage $D \subset A_U^\circ$ of $\overline{D}$ is integrally closed in A_U°. Indeed, say that $x \in A_U^\circ$ is integral over D; then the class $\overline{x} \in C_A$ of x is integral over $\overline{D}$, hence $\overline{x} \in \overline{D}$, and the claim follows. ◊

Claim 16.5.15 also implies that if $D \subset \mathbf{E}_U^\circ$ is any open and integrally closed subring, then $\mathbf{E}_U^{\circ\circ} \subset D$, and the rule $D \mapsto D/\mathbf{E}_U^{\circ\circ}$ establishes a bijection between the set of all open integrally closed subrings of $\mathbf{E}_U^\circ$ and the set of all integrally closed subrings of $C_\mathbf{E} := \mathbf{E}_U^\circ/\mathbf{E}_U^{\circ\circ}$. However, proposition 16.5.4(iv) yields a natural ring isomorphism $\overline{\varphi}_U^{\flat\circ} : C_A \xrightarrow{\sim} C_\mathbf{E}$, whence a bijection $\mathscr{S}_A \xrightarrow{\sim} \mathscr{S}_\mathbf{E}$, and it remains to check that this bijection is realized by the rule $D \mapsto \mathbf{E}(D)$. To this aim, notice that every integrally closed subring of C_A is a perfect $\mathbb{F}_p$-algebra; then the assertion follows easily from proposition 16.3.25, which also gives (iii). □

16.5.16. In the situation of (16.5.2), pick a finitely generated ideal $J_\mathbf{E} \subset \mathbf{E}$ with $\alpha_0 \in J_\mathbf{E}$ and $Z_\mathbf{E} = \operatorname{Spec} \mathbf{E}/J_\mathbf{E}$. From (16.5.3), it follows easily that $Z_A = \operatorname{Spec} A/J_\mathbf{E}^{\langle 1\rangle} A$ (notation of remark 9.3.70(i)). Also, we easily see that $J_\mathbf{E}^{\lceil 0\rceil}$ is the radical of $J_\mathbf{E}$; on the other hand, $\overline{u}_A$ induces an isomorphism $\mathbf{E}/J_\mathbf{E}^{\lceil 0\rceil} \xrightarrow{\sim} A/J_\mathbf{E}^{\lceil 0\rceil} A$, so $A/J_\mathbf{E}^{\lceil 0\rceil} A$ is reduced, *i.e.* $J_\mathbf{E}^{\lceil 0\rceil} A$ is the radical of $J_\mathbf{E}^{\langle 1\rangle} A$.

Corollary 16.5.17. *With the notation of* (16.5.16)*, suppose moreover that* $A = A^+$*. Then :*

$$J_\mathbf{E}^{\lceil 0\rceil} A_U^+ = J_\mathbf{E}^{\lceil 0\rceil}\overline{A}.$$

Proof. Notice that it suffices to show that $J_\mathbf{E}^{\lceil 0\rceil} A_U^+ \subset \overline{A}$. Indeed, suppose that the latter holds; since we have as well $(J_\mathbf{E}^{\lceil 0\rceil})^2 = J_\mathbf{E}^{\lceil 0\rceil}$, we deduce that $J_\mathbf{E}^{\lceil 0\rceil} A_U^+ \subset J_\mathbf{E}^{\lceil 0\rceil}\overline{A}$, and the converse inclusion is obvious. Notice that $\mathbf{E}_U^+$ is the integral closure of $\overline{\mathbf{E}}$ in $\mathbf{E}_U$, so that theorem 16.8.2(ii) implies that the assertion holds for $\mathbf{E}_U^+$, *i.e.*

$$J_\mathbf{E}^{\lceil 0\rceil} \mathbf{E}_U^+ \subset \overline{\mathbf{E}}. \tag{16.5.18}$$

Next, recall that proposition 16.5.4(iv) yields a ring isomorphism $\overline{\varphi}_U^{\flat\circ} : \mathbf{E}_U^\circ/\mathbf{E}^{\circ\circ} \xrightarrow{\sim} A_U^\circ/A_U^{\circ\circ}$ restricting to an isomorphism $\overline{\mathbf{E}}/\mathbf{E}_U^{\circ\circ} \xrightarrow{\sim} \overline{A}/A_U^{\circ\circ}$. Moreover, claim 16.5.15 shows that the subring $\mathbf{E}_U^+/\mathbf{E}_U^{\circ\circ}$ is the integral closure of $\overline{\mathbf{E}}/\mathbf{E}_U^{\circ\circ}$ in $\mathbf{E}_U^\circ/\mathbf{E}^{\circ\circ}$ and likewise, $A_U^+/A_U^{\circ\circ}$ is the integral closure of $\overline{A}/A_U^{\circ\circ}$ in $A_U/A_U^{\circ\circ}$. Hence, $A_U^+/A_U^{\circ\circ} = \overline{\varphi}_U^{\flat\circ}(\mathbf{E}_U^+/\mathbf{E}_U^{\circ\circ})$, and taking into account (16.5.18), the assertion follows easily. □

16.5.19. Keep the notation of (16.5.2). By virtue of lemma 15.6.10(i,iii) we may identify naturally U_A with an open subset of $X_A^\circ := \operatorname{Spec} A_U^\circ$, and we have a well defined quasi-affinoid ring $\underline{A}_U^\circ := (A_U^\circ, A_U^+, U_A)$, which is perfectoid, by theorem 16.5.13(i). Set

$$(U_A, \mathscr{T}_{U_A}^\circ, A_U^+) := \mathsf{Spec}\, \underline{A}_U^\circ.$$

since, by definition, the continuous maps $A \to A_U^\circ \to A_U$ are both f-adic, we see that the topology $\mathscr{T}_{U_A}^\circ$ agrees with $\mathscr{T}_{U_A}$; *i.e.* we have a natural identification

$$\mathsf{Spec}\, \underline{A}_U^\circ \xrightarrow{\sim} \mathsf{Spec}\, \underline{A}.$$

Lastly, it is clear that $\underline{A}_U^\circ$ depends only on $\mathsf{Spec}\, \underline{A}$, and we claim that the rule $\mathsf{Spec}\, \underline{A} \mapsto \underline{A}_U^\circ$ extends to a well defined functor

$$\Gamma^\circ : \mathsf{q.Afd.Sch}_{\mathrm{perf}} \to \mathsf{q.Afd.Ring}^o_{\mathrm{perf}}$$

with a natural isomorphism $\varepsilon_{\underline{X}} : \mathsf{Spec} \circ \Gamma^\circ(\underline{X}) \xrightarrow{\sim} \underline{X}$ for every object $\underline{X}$ of $\mathsf{q.Afd.Sch}_{\mathrm{perf}}$. Indeed, if $\underline{X} := (X, \mathscr{T}_X, A_X^+)$ and $\underline{Y} := (Y, \mathscr{T}_Y, A_Y^+)$ are any two perfectoid quasi-affinoid schemes, and $\psi : \underline{X} \to \underline{Y}$ any f-adic morphism of quasi-affinoid schemes, then the corresponding map $\psi^\flat : \mathscr{O}_Y(Y) \to \mathscr{O}_X(X)$ induces a morphism $\psi^{\flat\circ} : (\mathscr{O}_Y(Y)^\circ, A_Y^+) \to (\mathscr{O}_X(X)^\circ, A_X^+)$ of affinoid rings (lemma 8.3.24(iii.a)), which is obviously also f-adic, and the resulting diagram

$$\begin{array}{ccc}
\operatorname{Spec} \mathscr{O}_X(X) & \xrightarrow{\operatorname{Spec}\psi^\flat} & \operatorname{Spec} \mathscr{O}_Y(Y) \\
{\scriptstyle j_X}\downarrow & & \downarrow{\scriptstyle j_Y} \\
\operatorname{Spec} \mathscr{O}_X(X)^\circ & \xrightarrow{\operatorname{Spec}\psi^{\flat\circ}} & \operatorname{Spec} \mathscr{O}_Y(Y)^\circ
\end{array}$$

shows that $\mathrm{Spec}\,\psi^{\flat\circ}$ restricts to a morphism $j_X(X) \to j_Y(Y)$, whence a well defined morphism of perfectoid quasi-affinoid rings :

$$\Gamma^\circ(\psi) : \Gamma^\circ(\underline{Y}) \to \Gamma^\circ(\underline{X}).$$

Moreover, if $\underline{A} := (A, A^+, U)$ is any perfectoid quasi-affinoid ring, the natural map $A \to \mathscr{O}_U(U)^\circ$ induces a morphism of quasi-affinoid rings $\eta_{\underline{A}} : \underline{A} \to \Gamma^\circ \circ \mathsf{Spec}(\underline{A})$ which is f-adic, and therefore it is a morphism of perfectoid quasi-affinoid rings. Lastly, it is easily seen that the pair $(\varepsilon_\bullet, \eta_\bullet)$ fulfills the triangular conditions of (1.1.13), so Γ° is right adjoint to Spec.

16.5.20. We also want to upgrade the functor $\mathbf{E}$ to well defined functors

$$\mathbf{E} : \mathsf{q.Afd.Ring}_{\mathrm{perf}} \to \mathsf{q.Afd.Ring}_{\mathrm{perf}} \qquad \mathbf{E} : \mathsf{q.Afd.Sch}_{\mathrm{perf}} \to \mathsf{q.Afd.Sch}_{\mathrm{perf}}.$$

Namely, let $\underline{A} := (A, A^+, U)$ be any perfectoid quasi-affinoid ring, and set $\mathbf{E} := \mathbf{E}(A)$; by applying theorem 16.5.13(ii) to the perfectoid quasi-affinoid ring $(A, A^+, \mathrm{Spec}\,A)$, we see that $\mathbf{E}^+ := \mathbf{E}(A^+)$ is a subring of integral elements of $\mathbf{E}$, so we get a perfectoid quasi-affinoid ring

$$\mathbf{E}(\underline{A}) := (\mathbf{E}, \mathbf{E}^+, \mathbf{E}(U))$$

where $\mathbf{E}(U) \subset \mathrm{Spec}\,\mathbf{E}$ is defined as in (16.5.2) : namely, it is the unique open subset of $\mathrm{Spec}\,\mathbf{E}$ containing the analytic locus and such that $\varphi^{-1}\mathbf{E}(U) = U$, where $\varphi : \mathrm{Spec}\,A \to \mathrm{Spec}\,\mathbf{E}$ is the continuous map given by (16.4.24). Moreover, if $\underline{\alpha}$ is any distinguished element in $\mathrm{Ker}\,u_A$, endow $A_0 := A/pA$ and $\mathbf{E}_0 := \mathbf{E}/\alpha_0\mathbf{E}$ with the ring topologies induced by A and respectively $\mathbf{E}$; from remark 16.3.7(ii) we see as well that the map $u_A : A \to \mathbf{E}$ induces a natural isomorphism of quasi-affinoid rings (notation of example 15.4.7(i)) :

$$A_0 \otimes_A \underline{A} \xrightarrow{\sim} \mathbf{E}_0 \otimes_{\mathbf{E}} \mathbf{E}(\underline{A}). \tag{16.5.21}$$

Furthermore, for every morphism $f : \underline{A} \to \underline{B} := (B, B^+, V)$ of perfectoid quasi-affinoid rings, it follows easily from (16.1.4) that the morphism of schemes $\mathrm{Spec}\,\mathbf{E}(f) : \mathrm{Spec}\,\mathbf{E}(B) \to \mathrm{Spec}\,\mathbf{E}$ maps $\mathbf{E}(V)$ into $\mathbf{E}(U)$. Moreover, the ring homomorphism $\mathbf{E}(f) : \mathbf{E} \to \mathbf{E}(B)$ is adic (theorem 16.3.42(i)), whence a well defined morphism of perfectoid quasi-affinoid rings

$$\mathbf{E}(f) : \mathbf{E}(\underline{A}) \to \mathbf{E}(\underline{B}).$$

Let also $\underline{B}\text{-}\mathsf{q.Afd.Ring}_{\mathrm{perf}} := \underline{B}/\mathsf{q.Afd.Ring}_{\mathrm{perf}}$ for every perfectoid quasi-affinoid ring $\underline{B}$; just as in remark 16.3.7(i), this new functor $\mathbf{E}$ restricts to an equivalence

$$\underline{A}\text{-}\mathsf{q.Afd.Ring}_{\mathrm{perf}} \xrightarrow{\sim} \mathbf{E}(\underline{A})\text{-}\mathsf{q.Afd.Ring}_{\mathrm{perf}}$$

which admits a natural quasi-inverse functor

$$\mathbf{A} : \mathbf{E}(\underline{A})\text{-}\mathsf{q.Afd.Ring}_{\mathrm{perf}} \xrightarrow{\sim} \underline{A}\text{-}\mathsf{q.Afd.Ring}_{\mathrm{perf}} \qquad (E, E^+, V) \mapsto (\mathbf{A}(E), \mathbf{A}(E^+), \mathbf{A}(V))$$

with $\mathbf{A}(E) := W(E) \otimes_{W(A)} A$ and correspondingly for $\mathbf{A}(E^+)$, and where $\mathbf{A}(V) := \varphi^{-1}V$. Likewise, for every perfectoid quasi-affinoid scheme $\underline{U}$ we define

$$\mathbf{E}(\underline{U}) := \mathsf{Spec} \circ \mathbf{E} \circ \Gamma^\circ(\underline{U}) \qquad \text{and} \qquad \underline{U}\text{-}\mathsf{q.Afd.Sch}_{\mathrm{perf}} := \mathsf{q.Afd.Sch}_{\mathrm{perf}}/\underline{U}.$$

Then, the resulting functor $\mathbf{E}$ on quasi-affinoid schemes restricts to an equivalence

$$\underline{U}\text{-}\mathsf{q.Afd.Sch}_{\mathrm{perf}} \xrightarrow{\sim} \mathbf{E}(\underline{U})\text{-}\mathsf{q.Afd.Sch}_{\mathrm{perf}}$$

with quasi-inverse given by the rule : $\underline{V} \mapsto \mathsf{Spec} \circ \mathbf{A} \circ \Gamma^\circ(\underline{V})$ (details left to the reader). Lastly, say that $\underline{U} = \Gamma^\circ(\underline{A})$, and set $\underline{U}_0 := \mathsf{Spec}\,(A_0 \otimes_A \underline{A})$ and $\mathbf{E}(\underline{U})_0 := \mathsf{Spec}\,(\mathbf{E}_0 \otimes_{\mathbf{E}} \underline{\mathbf{E}})$; then we deduce from (16.5.21) a natural isomorphism of quasi-affinoid schemes

$$\underline{U}_0 \times_{\underline{U}} \underline{V} \xrightarrow{\sim} \mathbf{E}(\underline{U})_0 \times_{\mathbf{E}(\underline{U})} \mathbf{E}(\underline{V}) \qquad \text{for every } \underline{V} \in \mathrm{Ob}(\underline{U}\text{-}\mathsf{q.Afd.Sch}_{\mathrm{perf}}). \tag{16.5.22}$$

(see example 15.4.8).

16.5.23. Next, we wish to extend the results of section 16.4 to the perfectoid quasi-affinoid case. Consider any perfectoid quasi-affinoid ring $\underline{A} := (A, A^+, U_A)$, and let $(\mathbf{E}, \mathbf{E}^+, U_{\mathbf{E}}) := \mathbf{E}(\underline{A})$ (notation of (16.5.20)). Let also $\overline{A}$ and $\overline{\mathbf{E}}$ be the images of the restriction maps $A \to A_U := \mathscr{O}_{U_A}(U_A)$ and respectively $\mathbf{E} \to \mathbf{E}_U := \mathscr{O}_{U_{\mathbf{E}}}(U_{\mathbf{E}})$. We endow $\overline{A}$ and $\overline{\mathbf{E}}$ with the quotient topologies induced by the projections $A \to \overline{A}$ and respectively $\mathbf{E} \to \overline{\mathbf{E}}$. Pick any finitely generated ideal of definition I of $\mathbf{E}$; we get a descending filtration on $\mathbf{E}_U$ and A_U by the rules :

$$\mathrm{Fil}^s\mathbf{E}_U := I^{\langle s\rangle}\overline{\mathbf{E}} \qquad \mathrm{Fil}^s A_U := I^{\langle s\rangle}\overline{A}$$

$$\mathrm{Fil}^{-s}\mathbf{E}_U := \{x \in \mathbf{E}_U \mid I^{\langle s\rangle}x \subset \overline{\mathbf{E}}\} \qquad \mathrm{Fil}^{-s}A_U := \{x \in A_U \mid I^{\langle s\rangle}x \subset \overline{A}\}$$

for every $s \in \mathbb{N}[1/p]$. As in example 9.1.9(i) we associate with I an *angular order function*

$$\nu : \mathbf{E}_U \to \mathbb{R} \cup \{+\infty\} \qquad x \mapsto \sup\{s \in \mathbb{Z}[1/p] \mid x \in \mathrm{Fil}^s\mathbf{E}_U\}.$$

Notice that, since the topology of $\mathbf{E}_U$ is separated, we have $\nu(x) = +\infty$ if and only if $x = 0$. Then, we fix $\rho \in]0, 1[$, and set

$$|x|_I := \rho^{\nu(x)} \qquad \text{for every } x \in \mathbf{E}_U$$

(with the convention that $\rho^{+\infty} := 0$).

Lemma 16.5.24. *With the notation of* (16.5.23)*, we have :*

(i) *The mapping* $|\cdot|_I$ *is the asymptotic Samuel function on* $\mathbf{E}_U$ *associated with* I *(see example* 9.1.9(i)*). Especially, it is a real-valued power-multiplicative norm on* $\mathbf{E}_U$.

(ii) $\varphi^\flat_U(\mathrm{Fil}^s\mathbf{E}_U) \subset \mathrm{Fil}^s A_U$ *for every* $s \in \mathbb{Z}[1/p]$ *(notation of proposition* 16.4.34(i)*).*

Proof. (i): Let $|\cdot|^*_I$ be the asymptotic Samuel function attached to I (and the real number ρ), let $x \in \mathbf{E}_U$ be any element, and $s \in \mathbb{Z}[1/p]$ any rational number; consider the following conditions:

(a) $|x|_I \leq \rho^s$.
(b) For every $t < s$ in $\mathbb{Z}[1/p]$ we have $x \in \mathrm{Fil}^t\mathbf{E}_U$.
(c) For every $t < s$ in $\mathbb{Z}[1/p]$ we may find $n \in \mathbb{N}$ such that $p^n t \in \mathbb{Z}$ and $x^{p^n} \in I^{p^n t}$, where the integral power $I^{p^n t}$ is defined as in example 9.1.9(i).
(d) $|x|^*_I \leq \rho^s$.

It is easily seen that each of these conditions is equivalent to the following one, whence the assertion.

(ii): Suppose first that $s \geq 0$; in this case, by definition we have $\varphi^\flat_U(I^{\langle s\rangle}) \subset \mathrm{Fil}^s A_U$. On the other hand, proposition 16.4.34(ii) implies that $\varphi^\flat_U(\mathrm{Fil}^s\mathbf{E}_U)$ lies in the topological closure of the $\overline{A}$-submodule of A_U generated by $\varphi^\flat_U(I^{\langle s\rangle})$, and since $\mathrm{Fil}^s A_U$ is an open $\overline{A}$-submodule of A_U, the assertion follows.

Lastly, suppose that $s < 0$, and let $x \in \mathrm{Fil}^s\mathbf{E}_U$ be any element; the condition means that $I^{\langle s\rangle}x \subset \overline{\mathbf{E}}$, whence $\varphi^\flat_U(x) \cdot \varphi^\flat_U(I^{\langle s\rangle}) \subset \overline{A}$, and finally $\varphi^\flat_U(x) \in \mathrm{Fil}^s A_U$, as stated. □

16.5.25. The norm $|\cdot|_I$ in turns induces a mapping

$$|\cdot|_1 : W(\mathbf{E}_U) \to \mathbb{R}_+ \cup \{+\infty\} \qquad (a_n \mid n \in \mathbb{N}) \mapsto \sup_{n\in\mathbb{N}} |a_n|_I^{p^{-n}}$$

as in (9.3.80), such that the subset

$$W(\mathbf{E}_U, 1) := \{\underline{a} \in W(\mathbf{E}_U) \mid |\underline{a}|_1 \in \mathbb{R}_+\}$$

is a subring of $W(\mathbf{E}_U)$, and the restriction of $|\cdot|_1$ is a real-valued norm on $W(\mathbf{E}_U, 1)$ (proposition 9.3.82(ii)). We endow $W(\mathbf{E}_U, 1)$ with the topology defined by the norm $|\cdot|_1$. Then clearly $W(\mathbf{E}_U, 1)$ is a separated topological ring, and it is independent of the choice of I (see example 9.1.9(iv)). Furthermore, for every $s \in \mathbb{Z}[1/p]$ we set

$$W\langle s\rangle := \{(x_n \mid n \in \mathbb{N}) \in W(\mathbf{E}_U) \mid x_n \in \mathrm{Fil}^{p^n s}\mathbf{E}_U \text{ for every } n \in \mathbb{N}\} \subset W(\mathbf{E}_U, 1).$$

Recall that the f-adic topologies of $\mathbf{E}_U$ and A_U agree with the $\mathbb{Z}$-linear topologies defined by $\mathrm{Fil}^\bullet\mathbf{E}_U$ and respectively $\mathrm{Fil}^\bullet A_U$ (lemma 9.3.69(iv) and corollary 16.3.40(ii)). Moreover, $\mathrm{Fil}^s A_U$ and $\mathrm{Fil}^s\mathbf{E}_U$ are bounded subsets of A_U and respectively $\mathbf{E}_U$, for every $s \in \mathbb{Z}[1/p]$. It follows easily that for every $\underline{a} := (a_n \mid n \in \mathbb{N}) \in W(\mathbf{E}_U, 1)$, the series

$$\sum_{n\in\mathbb{N}} p^n \cdot \varphi^\flat_U(a_n^{1/p^n})$$

converges to a unique element $u_U(\underline{a})$ of A_U. Moreover, just as in definition 16.3.27(v), for any $\overline{\mathbf{E}}$-submodule $\mathscr{K}$ of $\mathbf{E}_U$ we denote by $\{\mathscr{K}\}$ the topological closure in A_U of the $\overline{A}$-submodule generated by $(\varphi^\flat_U(x) \mid x \in \mathscr{K})$. We also define filtrations on $\mathscr{K}$ and $\{\mathscr{K}\}$ by the rules :

$$\mathrm{Fil}^s\mathscr{K} := \mathscr{K} \cap \mathrm{Fil}^s\mathbf{E}_U \qquad \text{and} \qquad \mathrm{Fil}^s\{\mathscr{K}\} := \{\mathrm{Fil}^s\mathscr{K}\} \qquad \text{for every } s \in \mathbb{Z}[1/p].$$

Proposition 16.5.26. *With the notation of* (16.5.25)*, we have :*

(i) *The resulting mapping* $u_U : W(\mathbf{E}_U, 1) \to A_U$ *is a morphism of topological rings.*
(ii) $u_U(W\langle s\rangle) = \{\mathrm{Fil}^s\mathbf{E}_U\} \subset \mathrm{Fil}^s A_U$ *for every* $s \in \mathbb{Z}[1/p]$.
(iii) $pW(\mathbf{E}_U) \cap W\langle s\rangle = pW\langle s\rangle$ *for every* $s \in \mathbb{Z}[1/p]$.
(iv) *The topological ring* $W(\mathbf{E}_U, 1)$ *is complete and separated.*

Proof. (i): The continuity of u_U follows from the continuity of $\varphi^\flat_U$ (proposition 16.4.34(i)) and a simple inspection of the definition. Next, we remark :

Claim 16.5.27. For every $a \in \mathbf{E}_U$ and every $\underline{x} \in W(\mathbf{E}_U, 1)$ we have

$$\tau_{\mathbf{E}_U}(a) \cdot \underline{x} \in W(\mathbf{E}_U, 1) \qquad \text{and} \qquad u_U(\tau_{\mathbf{E}_U}(a) \cdot \underline{x}) = \varphi^\flat_U(a) \cdot u_U(\underline{x}).$$

Proof of the claim. Say that $\underline{x} = (x_n \mid n \in \mathbb{N})$; by proposition 9.3.36(i) we have $\tau_{\mathbf{E}_U}(a) \cdot \underline{x} = (a^{p^n}x_n \mid n \in \mathbb{N})$, whence the first assertion. By the same token, since $\varphi^\flat_U$ is a continuous morphism of multiplicative monoids, we may compute

$$u_U(\tau_{\mathbf{E}_U}(a) \cdot \underline{x}) = \sum_{n\in\mathbb{N}} p^n \cdot \varphi^\flat_U(ax_n^{1/p^n}) = \varphi^\flat_U(a) \cdot \sum_{n\in\mathbb{N}} p^n \cdot \varphi^\flat_U(x_n^{1/p^n}) = \varphi^\flat_U(a) \cdot u_U(\underline{x})$$

as stated. ◊

To conclude, we have to check that

$$u_U(\underline{x} + \underline{y}) = u_U(\underline{x}) + u_U(\underline{y}) \qquad \text{and} \qquad u_U(\underline{x} \cdot \underline{y}) = u_U(\underline{x}) \cdot u_U(\underline{y})$$

for every $\underline{x} := (x_n \mid n \in \mathbb{N}), \underline{y} := (y_n \mid n \in \mathbb{N}) \in W(\mathbf{E}_U, 1)$. However, pick $s \in \mathbb{Z}[1/p]$ such that $\underline{x}, \underline{y} \in W\langle s\rangle$, and notice that u_U restricts to a map $W\langle s\rangle \to \mathrm{Fil}^s A_U$; set $\underline{x}^{(k)} := \sum_{n=0}^k p^n \cdot \tau_{\mathbf{E}_U}(x_n)$ and define likewise $\underline{y}^{(k)}$ for every $k \in \mathbb{N}$. The sequences $(\underline{x}^{(k)} \mid n \in \mathbb{N})$ and $(\underline{y}^{(k)} \mid n \in \mathbb{N})$ lie in $W\langle s\rangle$ and converge p-adically to $\underline{x}$ and respectively $\underline{y}$; moreover, the p-adic topology is separated on $\mathrm{Fil}^s A_U$, so it suffices to check the sought identities with $\underline{x}$ and $\underline{y}$ replaced by $\underline{x}^{(k)}$ and $\underline{y}^{(k)}$, for every $k \in \mathbb{N}$. We may thus assume that there exists $k \in \mathbb{N}$ such that $x_n = y_n = 0$ for every $n > k$. Then, we argue as in the proof of proposition 16.4.34(ii) : we pick a family $(g_\lambda \mid \lambda \in \Lambda)$ of elements of $\mathbf{E}$ such that $U_\mathbf{E} = \bigcup_{\lambda\in\Lambda} \mathrm{Spec}\,\mathbf{E}[g_\lambda^{-1}]$, and we set

$$h_\lambda := \overline{u}_A(g_\lambda) \in A \qquad \text{and} \qquad t_\lambda := \tau_\mathbf{E}(g_\lambda) \in W(\mathbf{E}) \qquad \text{for every } \lambda \in \Lambda$$

so that $U_A = \bigcup_{\lambda\in\Lambda} \mathrm{Spec}\,A[h_\lambda^{-1}]$, and it suffices to check that the sought identities hold in $A[h_\lambda^{-1}] = \overline{A}[h_\lambda^{-1}]$, for every $\lambda \in \Lambda$. Now, for every $\lambda \in \Lambda$ we may find $n_\lambda \in \mathbb{N}$ such that $g_\lambda^{p^i n_\lambda} \cdot x_i, g_\lambda^{p^i n_\lambda} \cdot y_i \in \overline{\mathbf{E}}$ for every $i = 0, \dots, k$, and therefore

$$\underline{x}_\lambda := t_\lambda^{n_\lambda} \cdot \underline{x},\ \underline{y}_\lambda := t_\lambda^{n_\lambda} \cdot \underline{y} \in W(\overline{\mathbf{E}})$$

(proposition 9.3.36(i)). Lastly, we consider the commutative diagram

$$\begin{array}{ccccc} W(\overline{\mathbf{E}}) & \xrightarrow{u_{\overline{A}}} & \overline{A} & \longrightarrow & \overline{A}[h_\lambda^{-1}] \\ \downarrow & & \downarrow & & \| \\ W(\mathbf{E}_U, 1) & \xrightarrow{u_U} & A_U & \longrightarrow & A[h_\lambda^{-1}] \end{array}$$

whose two vertical arrows are the natural inclusions, and whose unmarked horizontal arrows are the localization maps; taking into account claim 16.5.27, we may compute for every $\lambda \in \Lambda$:

$$\begin{aligned} \varphi_U^\flat(t_\lambda^{n_\lambda}) \cdot u_U(\underline{x} + \underline{y}) &= u_U(\underline{x}_\lambda + \underline{y}_\lambda) \\ &= u_{\overline{A}}(\underline{x}_\lambda + \underline{y}_\lambda) \\ &= u_{\overline{A}}(\underline{x}_\lambda) + u_{\overline{A}}(\underline{y}_\lambda) \\ &= u_U(\underline{x}_\lambda) + u_U(\underline{y}_\lambda) \\ &= \varphi_U^\flat(t_\lambda^{n_\lambda}) \cdot (u_U(\underline{x}) + u_U(\underline{y})) \end{aligned}$$

as required. Likewise one shows the other sought identity.

(ii): Notice first that if $s \geq 0$, then $W\langle s\rangle$ is the ideal $W(I^{\langle s\rangle}\overline{\mathbf{E}})$ of $W(\overline{\mathbf{E}})$ (notation of remark 9.3.28(iv)); since $I^{\langle s\rangle}\overline{\mathbf{E}}$ is a taut and open ideal of $\overline{\mathbf{E}}$, the ideal $W(I^{\langle s\rangle}\overline{\mathbf{E}})$ is closed in $W(\overline{\mathbf{E}})$, and from theorem 16.3.36(i) it follows that

$$u_U(W\langle s\rangle) = u_{\overline{A}}(W(I^{\langle s\rangle}\overline{\mathbf{E}})) = \{\mathrm{Fil}^s\mathbf{E}_U\}$$

as required. Especially $u_U(W\langle s\rangle)$ is an open $\overline{A}$-submodule of A_U for every $s \geq 0$; but then obviously the same holds also more generally for every $s \in \mathbb{Z}[1/p]$. Next, for a general $s \in \mathbb{Z}[1/p]$ notice that every element of $W\langle s\rangle$ can be written as a p-adically convergent series $\sum_{n\in\mathbb{N}} p^n \cdot \tau_{\mathbf{E}_U}(x_n)$, for a unique sequence $(x_n \mid n \in \mathbb{N})$ of elements of $\mathrm{Fil}^s\mathbf{E}_U$; to any such element, the map u_U assigns the p-adically convergent series $\sum_{n\in\mathbb{N}} p^n \cdot \varphi_U^\flat(x_n)$, which clearly lies in $\{\mathrm{Fil}^s\mathbf{E}_U\}$, from which we see that $u_U(W\langle s\rangle)$ is dense in $\{\mathrm{Fil}^s\mathbf{E}_U\}$. However, we have just seen that $u_U(W\langle s\rangle)$ is a closed subset of A_U for every such s, whence the assertion.

(iii): The intersection $pW(\mathbf{E}_U) \cap W\langle s\rangle$ consists of all elements $\underline{x} := (x_n \mid n \in \mathbb{N})$ such that $x_0 = 0$ and $x_n \in \mathrm{Fil}^{sp^n}\mathbf{E}_U$ for every $n \geq 1$. For such $\underline{x}$, we have $y_n := x_{n+1}^{1/p} \in \mathrm{Fil}^{sp^n}\mathbf{E}_U$ for every $n \in \mathbb{N}$, whence $\underline{y} := (y_n \mid n \in \mathbb{N}) \in W\langle s\rangle$ and $p \cdot \underline{y} = \underline{x}$, whence the contention.

(iv): Since $W(\overline{\mathbf{E}})$ is an open subring of $W(\mathbf{E}_U, 1)$, it suffices to show that $W(\overline{\mathbf{E}})$ is complete and separated for the topology $\mathscr{T}$ induced by the norm $|\cdot|_1$. To this aim, let $x_1, \dots, x_n$ be any finite system of generators of $I\overline{\mathbf{E}}$, and denote by $\mathscr{I} \subset W(\overline{\mathbf{E}})$ the ideal generated by $\tau_{\overline{\mathbf{E}}}(x_1), \dots, \tau_{\overline{\mathbf{E}}}(x_n)$. Taking into account proposition 9.3.77(i) and lemma 9.3.69(iv), it is easily seen that $\mathscr{T}$ agrees with the $\mathscr{I}$-adic topology on $W(\overline{\mathbf{E}})$. However, let also $\mathscr{T}_{\overline{\mathbf{E}}}$ be the $I\overline{\mathbf{E}}$-adic topology on $\overline{\mathbf{E}}$ and $\mathscr{T}_{W(\overline{\mathbf{E}})}$ the topology of $W(\overline{\mathbf{E}}, \mathscr{T}_E)$ (as in definition 9.3.14); then $\mathscr{T}_{W(\overline{\mathbf{E}})}$ agrees with the $(pW(\overline{\mathbf{E}}) + \mathscr{I})$-adic topology (proposition 9.3.77(ii)). On the other hand, since $\mathscr{T}_{\overline{\mathbf{E}}}$ is complete and separated, the same holds for $\mathscr{T}_{W(\overline{\mathbf{E}})}$ (lemma 9.3.33(ii)). To conclude, we may now appeal to lemma 8.3.12. □

16.5.28. In the situation of (16.5.23), let $\mathscr{K}, \mathscr{J} \subset \mathbf{E}_U$ be any two $\overline{\mathbf{E}}$-submodules; we let $\mathscr{K}\mathscr{J} \subset \mathbf{E}_U$ be the $\overline{\mathbf{E}}$-submodule generated by the system $(xy \mid x \in \mathscr{K}, y \in \mathscr{J})$. Especially, we have well defined $\overline{\mathbf{E}}$-submodules $\mathscr{K}^n$ of $\mathbf{E}_U$, defined inductively by the rule : $\mathscr{K}^0 := \overline{\mathbf{E}}$ and $\mathscr{K}^{n+1} := \mathscr{K}^n\mathscr{K}$ for every $n \in \mathbb{N}$. Next, suppose that $\mathscr{J} \subset \mathscr{K}$, and let $\beta \in \mathbf{E}$ be any element; as in definition 16.3.27, we shall say that the inclusion of $\mathscr{J}$ in $\mathscr{K}$ is *β-taut* if

$$\beta \cdot \Phi_{\mathbf{E}_U}^{-1}(\mathscr{K}^p) \subset \mathscr{J}$$

where $\Phi_{\mathbf{E}_U}$ is the Frobenius automorphism of $\mathbf{E}_U$. For $\beta = \alpha_0$ (where $(\alpha_n \mid n \in \mathbb{N})$ is a fixed distinguished element in $\mathrm{Ker}\, u_A$), we just say that the inclusion is *taut*. Likewise, we say that $\mathscr{K}$ is *β-taut* (resp. *taut*) if the identity map of $\mathscr{K}$ is a β-taut (resp. taut) inclusion. Just as in (16.3.30), for any taut inclusion $\mathscr{J} \subset \mathscr{K}$, the quotients $\mathscr{K}/\mathscr{J}$ and $\{\mathscr{K}\}/\{\mathscr{J}\}$ are both $\overline{A}/p\overline{A}$-modules. Also, just as in remark 16.3.28(v), if the inclusion $\mathscr{J} \subset \mathscr{K}$ is taut, then both $\mathscr{J}$ and $\mathscr{K}$ are taut. With this terminology, we have the following extension of theorem 16.3.31:

Lemma 16.5.29. *In the situation of* (16.5.25)*, the following holds :*

(i) *Every taut inclusion $\mathscr{K}_1 \subset \mathscr{K}_2$ of $\overline{\mathbf{E}}$-submodules of $\mathbf{E}_U$ induces an $\overline{A}/p\overline{A}$-linear map*

$$\mathscr{K}_2/\mathscr{K}_1 \to \{\mathscr{K}_2\}/\{\mathscr{K}_1\} \quad : \quad (x \mod \mathscr{K}_1) \mapsto (\varphi^\flat_U(x) \mod \mathscr{K}_1).$$

(ii) *If $\mathscr{K}_1$ and $\mathscr{K}_2$ are topologically closed in $\mathbf{E}_U$, the map of* (i) *is an isomorphism.*

(iii) *For every taut $\overline{\mathbf{E}}$-submodule $\mathscr{K}$ of $\mathbf{E}_U$ and every $t \in \mathbb{Z}[1/p]$ we have*

$$\{\mathscr{K}\} \cap \{\mathrm{Fil}^t \mathbf{E}_U\} = \mathrm{Fil}^t\{\mathscr{K}\}.$$

Proof. (i): The proof is the same as that of theorem 16.3.31(i) : the only difference is that instead of using proposition 9.3.62 one must appeal to the more general proposition 16.4.34(ii).

Next, we prove the following special case of (ii) :

Claim 16.5.30. Pick any strictly positive $\varepsilon \in \mathbb{N}[1/p]$ such that $\alpha_0 \in I^{\langle\varepsilon\rangle}\mathbf{E}$. Then we have :

(i) For every $s, t \in \mathbb{Z}[1/p]$ such that $t - \varepsilon \leq s \leq t$, the inclusion $\mathrm{Fil}^t\mathbf{E}_U \subset \mathrm{Fil}^s\mathbf{E}_U$ is taut, and the map of (i) is an isomorphism

$$\tau_{s,t} : \mathrm{Fil}^s\mathbf{E}_U/\mathrm{Fil}^t\mathbf{E}_U \xrightarrow{\sim} \{\mathrm{Fil}^s\mathbf{E}_U\}/\{\mathrm{Fil}^t\mathbf{E}_U\}.$$

(ii) Moreover, the inclusion $\{\mathrm{Fil}^s\mathbf{E}_U\} \subset \mathrm{Fil}^s A_U$ induces an injection

$$\mu_{s,t} : \{\mathrm{Fil}^s\mathbf{E}_U\}/\{\mathrm{Fil}^t\mathbf{E}_U\} \to \mathrm{Fil}^s A_U/\mathrm{Fil}^t A_U.$$

Proof of the claim. (i): First notice that, since $\overline{A}$ is perfectoid and $\mathbf{E}(\overline{A}) = \overline{\mathbf{E}}$, the assertion in case $s \geq 0$ is a special case of theorem 16.3.31(ii). Thus, we assume henceforth that $s < 0$. Next, suppose that $t > 0$; in this case, we know already that $\tau_{0,t}$ is an isomorphism, and therefore the 5-lemma implies that $\tau_{s,t}$ is an isomorphism if and only if the same holds for $\tau_{s,0}$ (details left to the reader). Hence, we may further assume that $t \leq 0$ as well. Then, notice that the map $\tau_{s,t}$ has dense image, for the quotient topology on the target; however, $\{\mathrm{Fil}^t\mathbf{E}_U\}$ is an open $\mathbf{E}_U$-submodule of $\{\mathrm{Fil}^t\mathbf{E}_U\}$, so this quotient topology is discrete, and thus $\tau_{s,t}$ is surjective. To conclude, it then suffices to check that $\mu_{s,t} \circ \tau_{s,t}$ is injective. Hence, let $x \in \mathrm{Fil}^s\mathbf{E}_U$ be any element, and suppose that $\varphi^\flat_U(x) \in \mathrm{Fil}^t A_U$; we need to show that $x \in \mathrm{Fil}^t\mathbf{E}_U$, *i.e.* that for every $b \in I^{\langle -t\rangle}$ we have $z := bx \in \overline{\mathbf{E}}$. However, for such z we have

$$\varphi^\flat_U(z) = \varphi^\flat_U(b) \cdot \varphi^\flat_U(x) \in I^{\langle -t\rangle} \cdot \mathrm{Fil}^t A_U \subset \overline{A}.$$

Notice that $z \in \mathrm{Fil}^{s-t}\mathbf{E}_U$, and let $\overline{z} \in \mathrm{Fil}^{s-t}\mathbf{E}_U/\mathrm{Fil}^0\mathbf{E}_U = \mathrm{Fil}^{s-t}\mathbf{E}_U/\overline{\mathbf{E}}$ be the class of z. Since $s - t \geq -\varepsilon$, and since $\alpha_0 \in I^{\langle\varepsilon\rangle}\mathbf{E}$, we see that $\mathrm{Fil}^{s-t}\mathbf{E}_U/\overline{\mathbf{E}} \subset \mathrm{Ann}_{\mathbf{E}_U/\overline{\mathbf{E}}}(\alpha_0)$; on the other hand, proposition 16.4.36(iv) implies that $\varphi^\flat_U$ induces an isomorphism

$$\mathrm{Ann}_{\mathbf{E}_U/\overline{\mathbf{E}}}(\alpha_0) \xrightarrow{\sim} \mathrm{Ann}_{A_U/\overline{A}}(p)$$

whence the contention. Assertion (ii) is an immediate consequence. ◊

(iii): Let $\varepsilon, s, t \in \mathbb{Z}[1/p]$ be as in claim 16.5.30(i), and notice that the composition

$$M := \frac{\mathrm{Fil}^s\mathscr{K}}{\mathrm{Fil}^t\mathscr{K}} \xrightarrow{\beta} M' := \frac{\mathrm{Fil}^s\{\mathscr{K}\}}{\mathrm{Fil}^t\{\mathscr{K}\}} \xrightarrow{\gamma} \frac{\{\mathscr{K}\} \cap \{\mathrm{Fil}^s\mathbf{E}_U\}}{\{\mathscr{K}\} \cap \{\mathrm{Fil}^t\mathbf{E}_U\}} \to M'' := \frac{\{\mathrm{Fil}^s\mathbf{E}_U\}}{\{\mathrm{Fil}^t\mathbf{E}_U\}}$$

factors through an injective map $M \to \mathrm{Fil}^s\mathbf{E}_U/\mathrm{Fil}^t\mathbf{E}_U$ and the isomorphism $\tau_{s,t}$. Hence, β is injective; moreover, β has dense image, and the quotient topologies on M and M'' are discrete, so β is an isomorphism, by claim 16.3.34. We deduce that γ is injective.

Claim 16.5.31. Assertion (iii) holds if there exists $s \in \mathbb{Z}[1/p]$ such that $\mathscr{K} \subset \mathrm{Fil}^s\mathbf{E}_U$.

Proof of the claim. Notice that $\mathscr{K} \cap \mathrm{Fil}^r\mathbf{E}_U$ is still taut for every $r \in \mathbb{Z}[1/p]$. Now, if $t < s$ there is nothing to prove. In case $t \geq s$, let $n \in \mathbb{N}$ be the unique integer such that $t - n\varepsilon - s \in [0, \varepsilon[$; arguing by induction on n, we are easily reduced to the case where $n = 0$, *i.e.* we may assume that $t - \varepsilon < s \leq t$. In this case, clearly γ is an isomorphism, and the sought identity follows immediately. ◊

Now, for a general $\mathscr{K}$, clearly $\{\mathscr{K}\}$ is the topological closure of $\bigcup_{s\in\mathbb{Z}[1/p]}\{\mathscr{K} \cap \mathrm{Fil}^s\mathbf{E}_U\}$ in A_U, and since $\{\mathrm{Fil}^t\mathbf{E}_U\}$ is open in A_U, we deduce that $\{\mathscr{K}\} \cap \{\mathrm{Fil}^t\mathbf{E}_U\}$ is the topological closure of $\bigcup_{s\in\mathbb{Z}[1/p]}(\{\mathscr{K} \cap \mathrm{Fil}^s\mathbf{E}_U\} \cap \{\mathrm{Fil}^t\mathbf{E}_U\})$. But for every $s \leq t$, we have $\{\mathscr{K} \cap \mathrm{Fil}^s\mathbf{E}_U\} \cap \{\mathrm{Fil}^t\mathbf{E}_U\} = \{\mathscr{K} \cap \mathrm{Fil}^t\mathbf{E}_U\}$, by virtue of claim 16.5.31, whence (iii).

We may now complete the proof of (ii) arguing as in the proof of theorem 16.3.31(ii) : namely, we may assume that $\alpha_0 \in I$, and for every $\overline{\mathbf{E}}$-submodule $\mathscr{K}$ of $\mathbf{E}_U$ we set

$$\mathrm{gr}^n\mathscr{K} := \mathrm{Fil}^n\mathscr{K}/\mathrm{Fil}^{n+1}\mathscr{K} \qquad \mathrm{gr}^n\{\mathscr{K}\} := \mathrm{Fil}^n\{\mathscr{K}\}/\mathrm{Fil}^{n+1}\{\mathscr{K}\} \qquad \text{for every } n \in \mathbb{Z}.$$

Moreover, for every $n \in \mathbb{Z}$ we let $\mathrm{Fil}^n(\mathscr{K}_2/\mathscr{K}_1)$ (resp. $\mathrm{Fil}^n(\{\mathscr{K}_2\}/\{\mathscr{K}_1\})$) be the image of $\mathrm{Fil}^n\mathscr{K}_2$ in $\mathscr{K}_2/\mathscr{K}_1$ (resp. of $\mathrm{Fil}^b\{\mathscr{K}_2\}$ in $\{\mathscr{K}_2\}/\{\mathscr{K}_1\}$) and we denote again by $\mathrm{gr}^\bullet(\mathscr{K}_2/\mathscr{K}_1)$ and $\mathrm{gr}^\bullet(\{\mathscr{K}_2\}/\{\mathscr{K}_1\})$ the respective associated graded modules. There follows for every $n \in \mathbb{Z}$ a commutative diagram with exact rows

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \mathrm{gr}^n\mathscr{K}_1 & \longrightarrow & \mathrm{gr}^n\mathscr{K}_2 & \longrightarrow & \mathrm{gr}^n(\mathscr{K}_2/\mathscr{K}_1) & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & \mathrm{gr}^n\{\mathscr{K}_1\} & \longrightarrow & \mathrm{gr}^n\{\mathscr{K}_2\} & \longrightarrow & \mathrm{gr}^n(\{\mathscr{K}_2\}/\{\mathscr{K}_1\}) & \longrightarrow & 0
\end{array}$$

and since both $\mathscr{K}_1$ and $\mathscr{K}_2$ are taut, we know already from the proof of (iii) that the leftmost and central vertical arrows are isomorphisms, hence the same holds for the rightmost vertical arrow. Now, notice that the filtration $\mathrm{Fil}^\bullet(\mathscr{K}_2/\mathscr{K}_1)$ defines a separated and complete topology on $\mathscr{K}_2/\mathscr{K}_1$, since $\mathscr{K}_2$ and $\mathscr{K}_1$ are both closed $\overline{\mathbf{E}}$-submodules of $\mathbf{E}$. The same holds for the topology on $\{\mathscr{K}_2\}/\{\mathscr{K}_1\}$ determined by the filtration $\mathrm{Fil}^\bullet(\{\mathscr{K}_2\}/\{\mathscr{K}_1\})$, since $\{\mathscr{K}_2\}$ and $\{\mathscr{K}_1\}$ are closed $\overline{A}$-submodules in A. Then (ii) follows directly from [34, Ch.III, §2, n.8, Cor.3]. □

Theorem 16.5.32. *In the situation of* (16.5.25)*, we have :*

(i) *The continuous ring homomorphism u_U is surjective and open.*
(ii) $\mathrm{Ker}\, u_U = \underline{\alpha}W(\mathbf{E}_U, 1)$.

Proof. (ii): Clearly $\underline{\alpha} \in \mathrm{Ker} u_U$; thus, it suffices to check that u_U induces an isomorphism

$$\overline{u}_s : W\langle s\rangle/\underline{\alpha}W\langle s\rangle \xrightarrow{\sim} \{\mathrm{Fil}^s\mathbf{E}_U\} \qquad \text{for every } s \in \mathbb{Z}[1/p]$$

and by virtue of proposition 16.5.26(ii) we know already that $\overline{u}_s$ is surjective for every such s. Now, if $s \geq 0$, we have $W\langle s\rangle = W(I^{\langle s\rangle}\overline{\mathbf{E}}) \subset \mathbb{W}(\overline{\mathbf{E}})$, and the assertion follows from theorem 16.3.36(iv). For the general case, we may assume that $\alpha_0 \in I$, and then an easy induction argument then reduces to checking :

Claim 16.5.33. Suppose that $\alpha_0 \in I$. Then, if $\overline{u}_{s+1}$ is injective, the same holds for $\overline{u}_s$.

Proof of the claim. We consider the commutative diagram

(16.5.34)
$$\begin{array}{ccc}
W\langle s+1\rangle/\underline{\alpha}W\langle s+1\rangle & \xrightarrow{\ j\ } & W\langle s\rangle/\underline{\alpha}W\langle s\rangle \\
{\scriptstyle \overline{u}_{s+1}}\downarrow & & \downarrow{\scriptstyle \overline{u}_s} \\
\{\mathrm{Fil}^{s+1}\mathbf{E}_U\} & \xrightarrow{\ i\ } & \{\mathrm{Fil}^s\mathbf{E}_U\}
\end{array}$$

where i is the inclusion map, and j is induced by the inclusion $W\langle s+1\rangle \subset W\langle s\rangle$. Since $\overline{u}_{s+1}$ is injective by assumption, the same holds for j. Next, let us write $\alpha = \tau_{\mathbf{E}}(\alpha_0) + p \cdot \underline{u}$ for some invertible element $\underline{u}$ of $W(\mathbf{E})$; from proposition 9.3.36(ii) and our assumption on α_0, we deduce that $\tau_{\mathbf{E}}(\alpha_0) \cdot W\langle s\rangle \subset W\langle s+1\rangle$, hence the cokernel of j is annihilated by p. Taking into account proposition 16.5.26(iii), it follows that $\mathrm{Coker}\, j$ is naturally identified with the cokernel of the natural map $j' : (\mathrm{Fil}^{s+1}\mathbf{E}_U)/\alpha_0(\mathrm{Fil}^{s+1}\mathbf{E}_U) \to (\mathrm{Fil}^s\mathbf{E}_U)/\alpha_0(\mathrm{Fil}^s\mathbf{E}_U)$. But by the same token we see that $\alpha_0(\mathrm{Fil}^s\mathbf{E}_U) \subset \mathrm{Fil}^{s+1}\mathbf{E}_U$, so $\mathrm{Coker}\, j' = \mathrm{Fil}^s\mathbf{E}_U/\mathrm{Fil}^{s+1}\mathbf{E}_U$. Moreover, a simple inspection of the definitions shows that the map $\mathrm{Coker}\, j' \to \mathrm{Coker}\, i$ resulting from (16.5.34) is the same as the isomorphism $\tau_{s,s+1}$ of claim 16.5.30(i). Then the assertion follows from the 5-lemma. $\diamondsuit$

(i): By proposition 16.5.26(ii) we know already that u_U is an open map. Next, we remark :

Claim 16.5.35. To prove that u_U is surjective, we may assume that the topology of $\mathbf{E}$ is α_0-adic.

Proof of the claim. Notice that the image R of u_U contains $u_U(W(\overline{\mathbf{E}})) = u_{\overline{A}}(W(\overline{\mathbf{E}})) = \overline{A}$ (lemma 16.2.7(i)). Especially, R is an open subring of A_U; by the same token, R contains the $\overline{A}$-subalgebra R' of A_U generated by $\varphi_U^\flat(\mathbf{E}_U)$, and proposition 16.5.26(ii) implies that R' is dense in R. However, R' is also open in A_U, so $R = R'$. Furthermore, a simple inspection shows that the definition of $\varphi_U^\flat$ depends only on the ring A and the open subset U (and is independent of the topology of A or of $\mathbf{E}$). This shows that the image of u_U is independent of the topology of $\mathbf{E}_U$. Lastly, let $\mathscr{T}_{\alpha_0}$ be the α_0-adic topology of $\mathbf{E}$; it follows easily from example 16.3.2(i) and lemma 8.3.12 that the topological ring $(\mathbf{E}, \mathscr{T}_{\alpha_0})$ is perfectoid, and $U_{\mathbf{E}}$ contains the analytic locus of $\mathrm{Spec}\,\mathbf{E}$, relative to the topology $\mathscr{T}_{\alpha_0}$, whence the claim. $\diamondsuit$

Henceforth, we assume that the topology of $\mathbf{E}_U$ is α_0-adic. Set $J_1 := \mathrm{Ann}_{\overline{\mathbf{E}}}(\alpha_0)$, let $J_2 \subset \overline{\mathbf{E}}$ be the radical of the ideal $\alpha_0\overline{\mathbf{E}}$, and $J_3 := J_1 + J_2$; let $\overline{X}_{\mathbf{E}} := \mathrm{Spec}\,\overline{\mathbf{E}}$, $\overline{X}_A := \mathrm{Spec}\,\overline{A}$, and for $i = 1,2,3$ set $\overline{\mathbf{E}}_i := \overline{\mathbf{E}}/J_i$, $\overline{A}_i := W(\overline{\mathbf{E}}_i) \otimes_{W(\overline{A})} \overline{A}$, $\overline{X}_{\mathbf{E},i} := \mathrm{Spec}\,\overline{\mathbf{E}}_i$ and $\overline{X}_{A,i} := \mathrm{Spec}\,\overline{A}_i$. Lastly, let $j_{\mathbf{E},i} : \overline{X}_{\mathbf{E},i} \to \overline{X}_{\mathbf{E}}$ and $j_{A,i} : \overline{X}_{A,i} \to \overline{X}_A$ be the induced closed immersions and set $\mathbf{E}_{U,i} := j_{\mathbf{E},i*}\mathscr{O}_{\overline{X}_{\mathbf{E},i}}(U_{\mathbf{E}})$, $A_{U,i} := j_{A,i*}\mathscr{O}_{\overline{X}_{A,i}}(U_A)$ for $i = 1,2,3$. According to (16.4.24) we have cartesian diagrams of quasi-coherent $\mathscr{O}_{\overline{X}_{\mathbf{E}}}$-modules

$$\begin{array}{ccc} \mathscr{O}_{\overline{X}_{\mathbf{E}}} & \longrightarrow & j_{E,1*}\mathscr{O}_{\overline{X}_{\mathbf{E},1}} \\ \downarrow & & \downarrow \\ j_{\mathbf{E},2*}\mathscr{O}_{\overline{X}_{\mathbf{E},2}} & \longrightarrow & j_{\mathbf{E},3*}\mathscr{O}_{\overline{X}_{\mathbf{E},3}} \end{array} \qquad \begin{array}{ccc} \mathscr{O}_{\overline{X}_A} & \longrightarrow & j_{A,1*}\mathscr{O}_{\overline{X}_{A,1}} \\ \downarrow & & \downarrow \\ j_{A,2*}\mathscr{O}_{\overline{X}_{A,2}} & \longrightarrow & j_{A,3*}\mathscr{O}_{\overline{X}_{A,3}} \end{array}$$

whence cartesian diagrams of ring homomorphisms

$$(16.5.36) \qquad \begin{array}{ccc} \mathbf{E}_U & \longrightarrow & \mathbf{E}_{U,1} \\ \downarrow & & \downarrow \\ \mathbf{E}_{U,2} & \longrightarrow & \mathbf{E}_{U,3} \end{array} \qquad \begin{array}{ccc} A_U & \longrightarrow & A_{U,1} \\ \downarrow & & \downarrow \\ A_{U,2} & \longrightarrow & A_{U,3}. \end{array}$$

We endow each $\mathbf{E}_{U,i}$ with its α_0-adic topology $\mathscr{T}_i$; then $\mathscr{T}_i$ is the discrete topology for $i = 2,3$, and the topological ring $(\mathbf{E}_{U,i}, \mathscr{T}_i)$ is perfectoid for $i = 1,2,3$ (see (16.4.24)). We also define the power-multiplicative norms $|\cdot|_{I,i} : \mathbf{E}_{U,i} \to \mathbb{R}_+$ associated with the ideal $I\mathbf{E}_{U,i}$ as in (16.5.23), and we get consequently the normed topological rings $W(\mathbf{E}_{U,i}, 1)$ as in (16.5.25).

Claim 16.5.37. The induced diagrams of rings

$$\mathscr{W}(\mathbf{E}) \ : \ \begin{array}{ccc} W(\mathbf{E}_U) & \longrightarrow & W(\mathbf{E}_{U,1}) \\ \downarrow & & \downarrow \\ W(\mathbf{E}_{U,2}) & \longrightarrow & W(\mathbf{E}_{U,3}) \end{array} \qquad \mathscr{W}(\mathbf{E},1) \ : \ \begin{array}{ccc} W(\mathbf{E}_U,1) & \longrightarrow & W(\mathbf{E}_{U,1},1) \\ \downarrow & & \downarrow \\ W(\mathbf{E}_{U,2},1) & \longrightarrow & W(\mathbf{E}_{U,3},1) \end{array}$$

are cartesian.

Proof of the claim. The assertion is clear for the left diagram. Next, set

$$\mathbf{E}_U^+ := \{x \in \mathbf{E}_U \mid |x|_I \leq 1\}$$

and define likewise the subring $\mathbf{E}_{U,i}^+ \subset \mathbf{E}_{U,i}$ for $i = 1, 2$. For every $x \in \mathbf{E}_U$ and $i = 1, 2$, denote by $x^{(i)} \in \mathbf{E}_{U,i}$ the image of x; since we already know that diagram $\mathscr{W}(\mathbf{E})$ is cartesian, the assertion for $\mathscr{W}(\mathbf{E}, 1)$ comes down to checking that if $x \in \mathbf{E}_U$ and $|x^{(i)}|_{I,i} \leq \rho^{-s}$ for $i = 1, 2$ and some $s \in \mathbb{N}[1/p]$, then $|x|_I \leq \rho^{-s}$. The latter is equivalent in turn to the following. Suppose that for every strictly positive $\varepsilon \in \mathbb{N}[1/p]$ and every $b \in I^{\langle s+\varepsilon\rangle}$ we have $b^{(i)}x^{(i)} \in \overline{\mathbf{E}}_i$; then $z := bx \in \mathbf{E}_U^+$. Now, for such x and b pick $y_i \in \overline{\mathbf{E}}$ with $y_i^{(i)} = b^{(i)}x^{(i)}$ for $i = 1, 2$; then $(z - y_1)(z - y_2) \in J_1 \cap J_2 = 0$, and especially, z is integral over $\overline{\mathbf{E}}$. But $\overline{\mathbf{E}} \subset \mathbf{E}_U^+$, and $\mathbf{E}_U^+$ is integrally closed in $\mathbf{E}_U$ (remark 9.1.4(vi)), whence the claim. ◊

Claim 16.5.38. The diagram of rings $\mathscr{W}(\mathbf{E}, 1) \otimes_{W(\mathbf{E})} A$ is cartesian.

Proof of the claim. Consider the complex in $\mathsf{C}^{[0,1]}(W(\mathbf{E})\text{-}\mathbf{Mod})$

$$K^\bullet \quad : \quad 0 \to W(\mathbf{E}_{U,1}, 1) \oplus W(\mathbf{E}_{U,2}, 1) \to W(\mathbf{E}_{U,3}, 1) \to 0$$

whose differential is deduced from $\mathscr{W}(\mathbf{E}, 1)$, so that $H^0K^\bullet = W(\mathbf{E}_U, 1)$. Taking into account proposition 9.3.47(i), we have a short exact sequence

$$0 \to K^\bullet \xrightarrow{\underline{\alpha}\cdot\mathbf{1}_{K^\bullet}} K^\bullet \to K^\bullet/\underline{\alpha}K^\bullet \to 0$$

and by the same token, scalar multiplication is injective on $H^0K^\bullet$, so we get a long exact cohomology sequence

$$0 \to H^0(K^\bullet)/\underline{\alpha} \cdot H^0(K^\bullet) \xrightarrow{f_{\underline{\alpha}}} H^0(K^\bullet/\underline{\alpha}K^\bullet) \to H^1K^\bullet \xrightarrow{\underline{\alpha}} H^1K^\bullet$$

and the claim comes down to checking that $f_{\underline{\alpha}}$ is an isomorphism, or equivalently, that scalar multiplication by $\underline{\alpha}$ is injective on $H^1K^\bullet$. However, notice that $H^1K^\bullet$ is a quotient of the $W(\mathbf{E})$-module $W(\mathbf{E}_{U,3}, 1)$, and the latter is annihilated by $\tau_{\mathbf{E}}(\alpha_0)$. Since $\underline{\alpha} = \tau_{\mathbf{E}}(\alpha_0) + p\underline{u}$ for an invertible element $\underline{u}$ of $W(\mathbf{E})$, we are reduced to checking that scalar multiplication by p is injective on $H^1K^\bullet$, *i.e.* we may assume that $\underline{\alpha} = p$, and then it suffices to show that f_p is an isomorphism. However, it follows easily from proposition 16.5.26(iii) that

$$pW(\mathbf{E}_{U,i}) \cap W(\mathbf{E}_{U,i}, 1) = pW(\mathbf{E}_{U,i}, 1) \qquad \text{for } i = 1, 2, 3 \tag{16.5.39}$$

and likewise for $W(\mathbf{E}_U, 1)$. Therefore, $H^0(K^\bullet)/p \cdot H^0(K^\bullet) = \mathbf{E}_U$, and $K^\bullet/pK^\bullet$ is the complex

$$0 \to \mathbf{E}_{U,1} \oplus \mathbf{E}_{U,2} \to \mathbf{E}_{U,2} \to 0$$

deduced from the cartesian diagram (16.5.36). The claim follows. ◊

From claim 16.5.38 we deduce a commutative diagram of rings

$$\begin{array}{ccccccc}
A_U & & \longrightarrow & & & & A_{U,i} \\
& \nwarrow^{u_U} & & & & \nearrow^{u_{U,1}} & \\
\Big\downarrow & & W(\mathbf{E}_U, 1) \otimes_{W(\mathbf{E})} A & \longrightarrow & W(\mathbf{E}_{U,1}, 1) \otimes_{W(\mathbf{E})} A & & \Big\downarrow \\
& & \Big\downarrow & & \Big\downarrow & & \\
& & W(\mathbf{E}_{U,2}, 1) \otimes_{W(\mathbf{E})} A & \longrightarrow & W(\mathbf{E}_{U,3}, 1) \otimes_{W(\mathbf{E})} A & & \\
& \swarrow_{u_{U,2}} & & & & \searrow_{u_{U,3}} & \\
A_{U,2} & & \longrightarrow & & & & A_{U,3}
\end{array}$$

whose two square subdiagrams are both cartesian. Recall that the topologies of $\mathbf{E}_{U,2}$ and $\mathbf{E}_{U,3}$ are discrete; taking into account theorem 16.5.13(i) it follows that $\mathbf{E}_{U,i} = \mathbf{E}^{\circ}_{U,i} = A^{\circ}_{U,i} = A_{U,i}$ and $W(\mathbf{E}_{U,i}, 1) = W(\mathbf{E}_{U,i})$ for $i = 2, 3$, which easily implies that $u_{U,2}$ and $u_{U,3}$ are isomorphisms. Thus, to conclude the proof it suffices to show that $u_{U,1}$ is an isomorphism. Hence, we may replace $\mathbf{E}$ by $\overline{\mathbf{E}}_1$ and assume from start that α_0 is a regular element of $\mathbf{E}$ and the topology of $\mathbf{E}$ is α_0-adic. Let R be the image of u_U; under the current assumptions, p is a regular element of A (remark 16.4.25(ii)), and therefore

$$A \subset R \subset A_U \subset A[1/p]$$

whence $R[1/p] = A[1/p]$. Moreover, we notice :

Claim 16.5.40. The inclusion $R \subset A$ induces an injective map $R/pR \to A_U/pA_U$.

Proof of the claim. From (ii) and (16.5.39) we get a natural identification

$$R/pR \xrightarrow{\sim} W(\mathbf{E}_U, 1)/(\underline{\alpha}W(\mathbf{E}_U, 1) + pW(\mathbf{E}_U, 1)) \xrightarrow{\sim} \mathbf{E}_U/\alpha_0\mathbf{E}_U \qquad (16.5.41)$$

and from the short exact sequence of $\mathscr{O}_{U_{\mathbf{E}}}$-modules

$$0 \to \mathscr{O}_{U_{\mathbf{E}}} \xrightarrow{\alpha_0 \cdot} \mathscr{O}_{U_{\mathbf{E}}} \to \mathscr{O}_{U_{\mathbf{E}}}/\alpha_0\mathscr{O}_{U_{\mathbf{E}}} \to 0$$

we see that the natural map

$$\mathbf{E}_U/\alpha_0\mathbf{E}_U \to \mathbf{E}^0_U := H^0(U_{\mathbf{E}} \cap \mathrm{Spec}\,\mathbf{E}/\alpha_0\mathbf{E}, \mathscr{O}_{U_{\mathbf{E}}}/\alpha_0\mathscr{O}_{U_{\mathbf{E}}})$$

is injective. Likewise, we see that the same holds for the natural map

$$A_U/pA_U \to A^0_U := H^0(U_A \cap \mathrm{Spec}\,A/pA, \mathscr{O}_{U_A}/p\mathscr{O}_{U_A}).$$

On the other hand, recall that the ring homomorphism $u_A : W(\mathbf{E}) \to A$ induces an isomorphism of schemes $\varphi_0 : \mathrm{Spec}\,A/pA \xrightarrow{\sim} \mathrm{Spec}\,\mathbf{E}/\alpha_0\mathbf{E}$ (see (16.4.28)), whence a ring isomorphism $\varphi^\flat_{0,U} : \mathbf{E}^0_U \xrightarrow{\sim} A^0_U$ and a simple inspection of the definitions shows that the resulting diagram

$$\begin{array}{ccc} \mathbf{E}_U/\alpha_0\mathbf{E}_U & \xrightarrow{u_U \otimes_{W(\mathbf{E})} A/pA} & A_U/pA_U \\ \downarrow & & \downarrow \\ \mathbf{E}^0_U & \xrightarrow{\varphi^\flat_{0,U}} & A^0_U \end{array}$$

commutes. But it is easily seen that the isomorphism (16.5.41) identifies $u_U \otimes_{W(\mathbf{E})} A/pA$ with the map $R/pR \to A_U/pA_U$ induced by the inclusion $R \subset A$, whence the claim. ◊

Now, let $a \in A_U$ be any element, and pick $n \in \mathbb{N}$ such that $p^n a \in A$; then there exists $\underline{x} \in W(\mathbf{E})$ such that $u_U(\underline{x}) = u_A(\underline{x}) = p^n a$. To conclude, we shall show, by induction on $i = 0, \dots, n$ that $p^{n-i}a \in R$. Indeed, we have just shown that $p^n a \in R$. Suppose that $i \geq 0$ and $p^{n-i}a \in R$; if $i = n$, we are done, and if $i < n$, the image of $p^{n-i}a$ vanishes in A_U/pA_U, hence also in R/pR, *i.e.* there exists $b \in R$ with $pb = p^{n-i}a$; since p is regular in R, it follows that $b = p^{n-i-1}a$, as required. □

Corollary 16.5.42. *In the situation of* (16.5.25)*, we have :*

(i) $\{\mathrm{Fil}^s\mathbf{E}_U\} = \mathrm{Fil}^s A_U$ *for every* $s \in \mathbb{Z}[1/p]$.

(ii) *The map* $\varphi^\flat_U$ *induces a ring isomorphism* $\mathbf{E}_U/\alpha_0\mathbf{E}_U \xrightarrow{\sim} A_U/pA_U$.

Proof. (i): Let us first remark that

$$\{\mathrm{Fil}^{s-n}\mathbf{E}_U\} \cap \mathrm{Fil}^s A_U = \{\mathrm{Fil}^s\mathbf{E}_U\} \qquad \text{for every } n \in \mathbb{N} \text{ and every } s \in \mathbb{Z}[1/p].$$

Indeed, the case where $n = 1$ follows immediately from claim 16.5.30(ii), and then the general case follows by a simple induction on $n \in \mathbb{N}$: details left to the reader. But theorem 16.5.32(i) shows that $A_U = \bigcup_{n\in\mathbb{N}}\{\mathrm{Fil}^{s-n}\mathbf{E}_U\}$, whence the assertion.

(ii) follows directly from theorem 16.5.32(i) and (16.5.41). □

As an application, we point out the following criterion :

Corollary 16.5.43. *Let A be any perfectoid ring, $U_{\mathbf{E}} \subset V_{\mathbf{E}} \subset X_{\mathbf{E}} := \mathrm{Spec}\,\mathbf{E}(A)$ two constructible open subsets that contain the analytic locus. Set also $U_A := \varphi^{-1}U_{\mathbf{E}}$ and $V_A := \varphi^{-1}V_{\mathbf{E}}$, where $\varphi : X_A := \mathrm{Spec}\,A \to X_{\mathbf{E}}$ is the continuous map of* (16.4.24). *Then we have :*

(i) *$U_{\mathbf{E}}$ is an affine scheme if and only if the same holds for U_A.*
(ii) *More generally, the inclusion map $U_{\mathbf{E}} \to V_{\mathbf{E}}$ is an affine morphism of schemes if and only if the same holds for the inclusion map $U_A \to V_A$.*

Proof. (i): Set $\mathbf{E}_U := \mathscr{O}_{X_{\mathbf{E}}}(U_{\mathbf{E}})$ and $A_U := \mathscr{O}_{X_A}(U_A)$; by lemma 15.6.10(i), we get commutative diagrams of schemes

$$\begin{array}{ccc} U_{\mathbf{E}} & \xrightarrow{j_{\mathbf{E}}} & \mathrm{Spec}\,\mathbf{E}_U \\ & {\scriptstyle i_{\mathbf{E}}}\searrow & \downarrow{\scriptstyle j'_{\mathbf{E}}} \\ & & X_{\mathbf{E}} \end{array} \qquad \begin{array}{ccc} U_A & \xrightarrow{j_A} & \mathrm{Spec}\,A_U \\ & {\scriptstyle i_A}\searrow & \downarrow{\scriptstyle j'_A} \\ & & X_A \end{array}$$

where $i_{\mathbf{E}}$, i_A, $j_{\mathbf{E}}$ and j_A are open immersions. We have to show that $j_{\mathbf{E}}$ is an isomorphism if and only if the same holds for j_A. To this aim, set $Z_{\mathbf{E}} := X_{\mathbf{E}} \setminus U_{\mathbf{E}}$ and $Z_A := X_A \setminus U_A$; equivalently, we have to check that $j'^{-1}_{\mathbf{E}} Z_{\mathbf{E}} = \varnothing$ if and only if $j'^{-1}_A Z_A = \varnothing$. Now, since $U_{\mathbf{E}}$ contains the analytic locus of $X_{\mathbf{E}}$, we may assume that $Z_{\mathbf{E}} \subset X^0_{\mathbf{E}} := \mathrm{Spec}\,\mathbf{E}/\alpha_0\mathbf{E}$, where $(\alpha_n \mid n \in \mathbb{N})$ is any fixed distinguished element of $\mathrm{Ker}\,u_A$, and likewise $Z_A \subset X^0_A := \mathrm{Spec}\,A/pA$. On the other hand, by corollary 16.5.42(ii) we have a commutative diagram of schemes

$$\begin{array}{ccc} \mathrm{Spec}\,A_U/pA_U & \longrightarrow & \mathrm{Spec}\,\mathbf{E}_U/\alpha_O\mathbf{E}_U \\ \downarrow & & \downarrow \\ X^0_A & \xrightarrow{\varphi_0} & X^0_{\mathbf{E}} \end{array}$$

whose horizontal arrows are isomorphisms induced by φ and by the map $\varphi^\flat_U : \mathbf{E}_U \to A_U$ of proposition 16.4.34(i), and whose vertical arrows are the restrictions of $j'_{\mathbf{E}}$ and j'_A. Lastly, by construction we have $\varphi_0^{-1} Z_{\mathbf{E}} = Z_A$, whence the contention.

(ii) is analogous : the open immersion $U_{\mathbf{E}} \to V_{\mathbf{E}}$ is affine if and only if for every affine open subset $W \subset V_{\mathbf{E}}$, the intersection $W \cap U_{\mathbf{E}}$ is still affine. The latter condition means that

$$\mathrm{Spec}\,\mathscr{O}_{X_{\mathbf{E}}}(W \cap U_{\mathbf{E}}) \times_W Z_{\mathbf{E}} = \varnothing \qquad \text{for every such } W$$

which in turns is equivalent to the condition :

$$j'^{-1}_{\mathbf{E}}(Z_{\mathbf{E}} \cap V_{\mathbf{E}}) = \varnothing. \tag{16.5.44}$$

Likewise, we easily see that the inclusion $U_A \subset V_A$ is affine if and only if $j'^{-1}_A(Z_A \cap V_A) = \varnothing$, and since $Z_{\mathbf{E}} \subset X^0_{\mathbf{E}}$, this latter condition is equivalent to (16.5.44) : details left to the reader. □

Lemma 16.5.45. *In the situation of* (16.5.23)*, let $\mathscr{K}$ be any $\overline{\mathbf{E}}$-submodule of $\mathbf{E}_U$, and set :*

$$W(\mathscr{K}) := \{(x_n \mid n \in \mathbb{N}) \mid x_n \in \mathscr{K}^{p^n} \text{ for every } n \in \mathbb{N}\} \qquad W(\mathscr{K}, 1) := W(\mathscr{K}) \cap W(\mathbf{E}_U, 1).$$

(notation of (16.5.28)*). Denote also by $(\mathscr{K}^n)^c$ the topological closure of $\mathscr{K}^n$ in $\mathbf{E}_U$, for every $n \in \mathbb{N}$, and by $W(\mathscr{K}, 1)^c$ the topological closure of $W(\mathscr{K}, 1)$ in $W(\mathbf{E}_U, 1)$. We have :*

(i) *$W(\mathscr{K})$ and $W(\mathscr{K}, 1)$ are $W(\overline{\mathbf{E}})$-submodules of respectively $W(\mathbf{E}_U)$ and $W(\mathbf{E}_U, 1)$.*
(ii) *$W(\mathscr{K}, 1)^c = M := \{(x_n \mid n \in \mathbb{N}) \in W(\mathbf{E}_U, 1) \mid x_n \in (\mathscr{K}^{p^n})^c \text{ for every } n \in \mathbb{N}\}$.*
(iii) *If $\mathscr{K}$ is taut, $u_U(W(\mathscr{K}, 1)^c) = \{\mathscr{K}\}$.*
(iv) *If $\mathscr{K}$ is 1-taut and topologically closed in $\mathbf{E}_U$, then u_U induces an isomorphism*

$$W(\mathscr{K}, 1)/\underline{\alpha}W(\mathscr{K}, 1) \xrightarrow{\sim} \{\mathscr{K}\}.$$

Proof. (i): This is analogous to remark 9.3.28 : details left to the reader.

(ii): Let $\underline{x} := (x_n \mid n \in \mathbb{N}) \in M$ be any element, and fix any $\varepsilon \in \mathbb{R}_{>0}$. We shall exhibit inductively a sequence $\underline{y} := (y_n \mid n \in \mathbb{N})$ of elements of $\mathbf{E}_U$ such that

$$|\underline{y}|_1 \leq \varepsilon \qquad \text{and} \qquad \underline{x} + \underline{y} \in W(\mathscr{K}, 1).$$

Indeed, let $n \in \mathbb{N}$, and suppose that we have already exhibited $y_i \in (\mathscr{K}^{p^i})^c$ for $i = 0, \dots, n-1$ such that $\underline{y}^{(n)} := \sum_{i=0}^{n-1} p^i \cdot \tau_{\mathbf{E}_U}(y_i)$ has norm $< \varepsilon$ and such that if we set $(z_i^{(n)} \mid i \in \mathbb{N}) := \underline{x} + \underline{y}^{(n)}$, we have $z_i^{(n)} \in \mathscr{K}^{p^i}$ for every $i = 0, \dots, n-1$. It follows easily that $z_i^{(n)} \in (\mathscr{K}^{p^i})^c$ for every $i \in \mathbb{N}$. We may then pick $y_n \in (\mathscr{K}^{p^n})^c$ such that $|y_n|_I < \varepsilon^{p^n}$ and $z_n^{(n)} + y_n \in \mathscr{K}^{p^n}$. Set $\underline{y}^{(n+1)} := \underline{y}^{(n)} + p^n \cdot \tau_{\mathbf{E}_U}(y_n)$ and $(z_i^{(n+1)} \mid i \in \mathbb{N}) := \underline{x} + \underline{y}^{(n+1)}$. In light of lemma 9.3.27(i) and claim 9.3.31 it is easily seen that $z_i^{(n+1)} = z_i^{(n)}$ for every $i = 0, \dots, n-1$, and $z_n^{(n+1)} = z_n^{(n)} + y_n$. Then, it is clear that the element $\underline{y} := \sum_{n\in\mathbb{N}} p^n \cdot \tau_{\mathbf{E}_U}(y_n)$ will do.

This shows that $M \subset W(\mathscr{K}, 1)^c$. The converse inclusion is obvious, since $\prod_{n\in\mathbb{N}}(\mathscr{K}^{p^n})^c$ is a closed subset of $W(\mathbf{E}_U)$ that contains $W(\mathscr{K}, 1)$ and the topology of $W(\mathbf{E}_U, 1)$ is finer than the one induced by $W(\mathbf{E}_U)$.

(iii): Recall that $\varphi_U^\flat(\alpha_0) = \overline{u}_{\overline{A}}(\alpha_0) = pv$ for an element $v \in \overline{A}^\times$. Then, since $\mathscr{K}$ is taut, we see that $p^n \cdot \varphi_U^\flat(x^{1/p^n}) = v^{-n}\varphi_U^\flat(\alpha_0^n x^{1/p^n}) \in \{\mathscr{K}\}$ for every $x \in \mathscr{K}^{p^n}$. It follows easily that $u_U(\underline{x}) \in \{\mathscr{K}\}$ for every $\underline{x} \in W(\mathscr{K})$, and thus $u_U(W(\mathscr{K}, 1)^c) \subset \{\mathscr{K}\}$.

For the converse inclusion, pick a strictly positive $\varepsilon \in \mathbb{N}[1/p]$ such that $\alpha_0 \in I^{\langle\varepsilon\rangle}$; it was observed in the proof of lemma 16.5.29(iii) that $\varphi_U^\flat$ induces an $\overline{A}/p\overline{A}$-linear isomorphism

$$(\mathrm{Fil}^s\mathscr{K})/(\mathrm{Fil}^{s+\varepsilon}\mathscr{K}) \xrightarrow{\sim} (\mathrm{Fil}^s\{\mathscr{K}\})/(\mathrm{Fil}^{s+\varepsilon}\{\mathscr{K}\}) \qquad \text{for every } s \in \mathbb{Z}[1/p]$$

and moreover $\mathrm{Fil}^s\{\mathscr{K}\} = \{\mathscr{K}\} \cap \{\mathrm{Fil}^s\mathbf{E}_U\} = \{\mathscr{K}\} \cap \mathrm{Fil}^s A_U$ for every $s \in A_U$ (lemma 16.5.29(iii) and corollary 16.5.42), hence the filtration $\mathrm{Fil}^\bullet\{\mathscr{K}\}$ is exhaustive and separated on $\{\mathscr{K}\}$. Thus, say that $x \in \mathrm{Fil}^s\{\mathscr{K}\}$ for some $s \in \mathbb{Z}[1/p]$; it follows easily that we may find a sequence $(y_n \mid n \in \mathbb{N})$ of elements of $\mathbf{E}_U$ such that $y_n \in \mathrm{Fil}^{s+n\varepsilon}\mathscr{K}$ for every $n \in \mathbb{N}$, and the series $\sum_{n\in\mathbb{N}} \varphi_U^\flat(y_n)$ converges to x in the topology of A_U. Clearly $\tau_{\mathbf{E}_U}(y_n) \in W(\mathscr{K})$ and $|\tau_{\mathbf{E}_U}(y_n)|_1 \leq \rho^{s+n\varepsilon}$ for every $n \in \mathbb{N}$, so the series $\sum_{n\in\mathbb{N}} \tau_{\mathbf{E}_U}(y_n)$ converges in $W(\mathbf{E}_U, 1)$ to an element $\underline{z} \in W(\mathscr{K})^c$, and finally $u_U(\underline{z}) = \sum_{n\in\mathbb{N}} u_U \circ \tau_{\mathbf{E}_U}(y_n) = x$.

(iv): The assumptions on $\mathscr{K}$ imply that $\mathscr{K}^{p^n}$ is topologically closed in $\mathbf{E}_U$, for every $n \in \mathbb{N}$; combining with (ii) and (iii), it follows already that the induced map $W(\mathscr{K}, 1)/\underline{\alpha}W(\mathscr{K}, 1) \to \{\mathscr{K}\}$ is surjective. Next, say that $\alpha_0 \in I^{\langle\varepsilon\rangle}$ for some element $\varepsilon > 0$ of $\mathbb{Z}[1/p]$; notice that $\mathrm{Fil}^s\mathscr{K}$ is still 1-taut and topologically closed in $\mathbf{E}_U$ for every $s \in \mathbb{Z}[1/p]$; taking into account lemma 16.5.29(iii), we may therefore reduce to the case where $\mathscr{K} \subset \mathrm{Fil}^{-n\varepsilon}\mathbf{E}_U$ for some $n \in \mathbb{N}$. We argue by induction on n : indeed, the assertion for $n = 0$ is already known, by theorem 16.3.36(iv). Thus, suppose that $n > 0$, and that the assertion is already known for $\mathscr{K} \cap \mathrm{Fil}^{(1-n)\varepsilon}\mathbf{E}_U$; let $\underline{x} := (x_n \mid n \in \mathbb{N}) \in W(\mathscr{K}, 1)$ be an element in the kernel of u_U. This means that $\sum_{n\in\mathbb{N}} p^i \cdot \varphi_U^\flat(x_n^{1/p^n}) = 0$ in A_U, and we need to check that $\underline{x} \in \underline{\alpha}W(\mathscr{K}, 1)$. Now, since $\mathscr{K}$ is 1-taut, we have $\underline{z} := (x_{n+1}^{1/p} \mid n \in \mathbb{N}) \in W(\mathscr{K}, 1)$ as well, so that

$$\varphi_U^\flat(x_0) = -\sum_{n\in\mathbb{N}} p^{n+1} \cdot \varphi_U^\flat(x_{n+1}^{1/p^{n+1}}) \in \mathrm{Fil}^{(1-n)\varepsilon}A_U.$$

In view of claim 16.5.30(ii), we deduce that $x_0 \in \mathrm{Fil}^{(1-n)\varepsilon}\mathscr{K}$. Moreover, $\underline{x} = \tau_{\mathbf{E}_U}(x_0) + p \cdot \underline{z}$, and recall that $\underline{\alpha} = \tau_{\mathbf{E}}(\alpha_0) + p \cdot \underline{u}$ for an invertible element $\underline{u} \in W(\mathbf{E})$; we conclude that $\underline{x}$ is the sum of

$$\tau_{\mathbf{E}_U}(x_0) - \underline{u}^{-1} \cdot \tau_{\mathbf{E}}(\alpha_0) \cdot \underline{z} \in W(\mathrm{Fil}^{(1-n)\varepsilon}\mathscr{K}, 1) \qquad \text{and} \qquad \underline{u}^{-1} \cdot \underline{\alpha} \cdot \underline{z} \in \underline{\alpha}W(\mathscr{K}, 1).$$

Especially, $\tau_{\mathbf{E}_U}(x_0) - \underline{u}^{-1} \cdot \tau_{\mathbf{E}}(\alpha_0) \cdot \underline{z}$ lies as well in the kernel of u_U; by inductive assumption it is therefore an element of $\underline{\alpha}W(\mathrm{Fil}^{(1-n)\varepsilon}\mathscr{K}, 1)$, and the proof is concluded. □

Proposition 16.5.46. *Let A be any complete and separated topological ring, whose topology is linear and coarser than the p-adic topology, and $v \in \mathrm{Cont}(A)$ any valuation. We have :*

(i) *The mapping $v \circ \overline{u}_A$ is a continuous valuation of the topological ring $\mathbf{E} := \mathbf{E}(A)$ (see remark* 9.4.12(ii)*).*

(ii) *The rule : $v \mapsto v \circ \overline{u}_A$ defines continuous maps*

$$\mathrm{Cont}(\overline{u}_A) : \mathrm{Cont}(A) \to \mathrm{Cont}(\mathbf{E}) \qquad \mathrm{Cont}^+(\overline{u}_A) : \mathrm{Cont}^+(A) \to \mathrm{Cont}^+(\mathbf{E}).$$

(iii) *The diagrams of continuous maps*

$$\begin{array}{ccc} \mathrm{Cont}(A) & \xrightarrow{\mathrm{Cont}(\overline{u}_A)} & \mathrm{Cont}(\mathbf{E}) \\ \downarrow & & \downarrow \\ \mathrm{Spec}\,A & \xrightarrow{\mathrm{Spec}\,\overline{u}_A} & \mathrm{Spec}\,\mathbf{E} \end{array} \qquad \begin{array}{ccc} \mathrm{Cont}^+(A) & \xrightarrow{\mathrm{Cont}^+(\overline{u}_A)} & \mathrm{Cont}^+(\mathbf{E}) \\ \downarrow & & \downarrow \\ \mathrm{Spec}\,A & \xrightarrow{\mathrm{Spec}\,\overline{u}_A} & \mathrm{Spec}\,\mathbf{E} \end{array}$$

commute, where $\mathrm{Spec}\,\overline{u}_A$ is defined as in (16.1) *and the vertical arrows in the left (resp. right) diagram are the restrictions of the support maps σ_A and $\sigma_{\mathbf{E}}$ (resp. of the center maps σ_A^+ and $\sigma_{\mathbf{E}}^+$) : see remark* 9.2.4(iii,v)*.*

(iv) *If $v' \in \mathrm{Cont}(A)$ is a primary (resp. secondary) specialization of v, then $\mathrm{Cont}(\overline{u}_A)(v')$ is a primary (resp. secondary) specialization of $\mathrm{Cont}(\overline{u}_A)(v)$.*

(v) *The map $\mathrm{Cont}(\overline{u}_A)$ restricts to a surjection from the set of secondary specializations of v onto the set of secondary specializations of $\mathrm{Cont}(\overline{u}_A)(v)$.*

(vi) *If A is a P-ring, $\mathrm{Cont}(\overline{u}_A)$ also restricts to a surjection from the set of secondary generizations of v onto the set of secondary generizations of $\mathrm{Cont}(\overline{u}_A)(v)$.*

Proof. (i): Since both v and $\overline{u}_A$ are continuous morphisms of pointed monoids, the same holds for $v \circ \overline{u}_A$. Thus, it remains only to check that

$$v(\overline{u}_A(a_\bullet + b_\bullet)) \leq \max(v(a_0), v(b_0)) \qquad \text{for every } a_\bullet, b_\bullet \in \mathbf{E}.$$

However, recall that

$$\overline{u}_A(a_\bullet + b_\bullet) = \lim_{n \to +\infty} (a_n + b_n)^{p^n}$$

(remark 9.4.12(ii)). Since the pointed monoid $\Gamma_{v\circ}$ is separated for its topology $\mathscr{T}_{\Gamma_v}$ (notation of definition 15.3.12(i)), it follows that $v(\overline{u}_A(a_\bullet + b_\bullet))$ is the unique limit point of the sequence $(v(a_n + b_n)^{p^n} \mid n \in \mathbb{N})$. However :

$$v(a_n + b_n)^{p^n} \leq \max(v(a_n)^{p^n}, v(b_n)^{p^n}) = \max(v(a_0), v(b_0))$$

whence the assertion.

(ii): Let $a_\bullet, b_\bullet \in \mathbf{E}$ be any two elements, and set $U := \{v \in \mathrm{Cont}(\mathbf{E}) \mid v(a_\bullet) \leq v(b_\bullet) \neq 0\}$; directly from the definition we find :

$$\mathrm{Cont}(\overline{u}_A)^{-1}U = \{w \in \mathrm{Cont}(A) \mid w(a_0) \leq w(b_0) \neq 0\}$$

whence the assertion.

(iii) and (iv) are immediate from the definitions.

(v): Set $w := \mathrm{Cont}(\overline{u}_A)(v)$ and notice that $\mathfrak{p} := \sigma_A(v)$ is a closed subset in the p-adic topology of A; we remark the following :

Claim 16.5.47. Denote by $\overline{v}$ (resp. $\overline{w}$) the residual valuation of v (resp. of w). Then we have :

(i) The map $\overline{u}_{\mathfrak{p}} : \kappa(w) \to \kappa(v)$ of lemma 16.1.5 restricts to a local morphism of multiplicative monoids $\overline{u}_v^+ : (\kappa(w), \overline{w})^+ \to (\kappa(v), \overline{v})^+$.

(ii) Let also $\overline{\kappa}(v)$ (resp. $\overline{\kappa}(w)$) be the residue field of $\kappa(v)^+$ (resp. of $\kappa(w)^+$). There exists a unique ring homomorphism $\overline{\varphi}_v : \overline{\kappa}(w) \to \overline{\kappa}(v)$ fitting into a commutative diagram

$$\begin{array}{ccc} \kappa(w)^+ & \xrightarrow{\overline{u}_v^+} & \kappa(v)^+ \\ \downarrow & & \downarrow \\ \overline{\kappa}(w) & \xrightarrow{\overline{\varphi}_v} & \overline{\kappa}(v) \end{array}$$

whose vertical arrows are the projections.

Proof of the claim. (i): Indeed, a simple inspection of the definitions yields a commutative diagram of monoids

$$\begin{array}{ccc} \kappa(w) & \xrightarrow{\overline{u}_{\mathfrak{p}}} & \kappa(v) \\ & {\scriptstyle \overline{w}}\searrow \quad \swarrow{\scriptstyle \overline{v}} & \\ & \Gamma_v & \end{array}$$

whence the assertion : details left to the reader.

(ii): Let $\overline{\pi}_v : \kappa(v)^+ \to \overline{\kappa}(v)$ be the projection; since $\overline{u}_v^+$ is local, we are easily reduced to checking that the composition $\psi := \overline{\pi}_v \circ \overline{u}_v^+$ is a ring homomorphism. However, ψ is obviously a morphism of multiplicative monoids, so it suffices to show that

$$\overline{v}(\overline{u}_v^+(x_1 + x_2) - \overline{u}_v^+(x_1) - \overline{u}_v^+(x_2)) < 1 \qquad \text{for every } x_1, x_2 \in \kappa(w)^+.$$

However, let $\pi_w : \mathbf{E} \to \kappa(w)$ and $\pi_v : A \to \kappa(v)$ be the projections; we may write

$$x_1 = \pi_w(\beta_1)/\pi_w(\gamma) \qquad \text{and} \qquad x_2 = \pi_w(\beta_2)/\pi_w(\gamma) \qquad \text{for some } \beta_1, \beta_2, \gamma \in \mathbf{E}$$

with $w(\beta_1), w(\beta_2) \leq w(\gamma) \neq 0$. Set $x_3 := x_1 + x_2$ and $\beta_3 := \beta_1 + \beta_2$; then

$$\overline{u}_v^+(x_i) = \pi_v \circ \overline{u}_A(\beta_i)/\pi_v \circ \overline{u}_A(\gamma) \qquad \text{for } i = 1, 2, 3.$$

Let $y := \overline{u}_A(\beta_3) - \overline{u}_A(\beta_1) - \overline{u}_A(\beta_2)$; we are then reduced to checking that $v(y) < v(\overline{u}_A(\gamma))$. However, proposition 9.3.62 says that $y = \sum_{n \in \mathbb{N}} p^{n+1} z_n$ where each z_n is a finite $\mathbb{Z}_p$-linear combination of terms of the form $\overline{u}_A(\beta_1^\lambda \beta_2^{1-\lambda})$ with $\lambda, 1 - \lambda \in \mathbb{N}[1/p]$. Clearly $w(\beta_1^\lambda \beta_2^{1-\lambda}) \leq w(\gamma)$ for every such λ, so that

$$v(p^{n+1} z_n) \leq v(p)^{n+1} \cdot v(\overline{u}_A(\gamma)) \qquad \text{for every } n \in \mathbb{N}.$$

Since v is a continuous valuation and $v(p)$ is final in Γ_v, the contention follows easily : details left to the reader. ◊

Now we argue as in the proof of lemma 9.2.25(iii). Namely, let w' be a secondary specialization of w; then $\kappa(w') = \kappa(w)$, and $\kappa(w')^+ \subset \kappa(w)^+$. The image W of $\kappa(w')^+$ in $\overline{\kappa}(w)$ is a valuation ring, and by corollary 9.1.25 there exists a valuation ring V of $\overline{\kappa}(v)$ that dominates $\overline{\varphi}_v(W)$. The preimage of V in $\kappa(v)^+$ is a valuation ring of $\kappa(v)$, and the corresponding valuation v' is a secondary specialization of v. Lastly, v' is continuous, by remark 15.3.13(iv), and by construction we have $\mathrm{Cont}(\overline{u}_A)(v') = w'$.

(vi): Clearly $\overline{u}_A$ induces an injective morphism of ordered groups $i : \Gamma_w \to \Gamma_v$, and $\mathrm{Spec}\, i$ is surjective, by remark 9.1.2(v). Now, let w' be a secondary generization of $w := \mathrm{Cont}(\overline{u}_A)(v)$, so that $w' = w_\Delta$ for a convex subgroup $\Delta \subset \Gamma_w$, and we may write $\Delta = i^{-1}\Delta'$ for some convex subgroup $\Delta' \subset \Gamma_v$. If $\Delta' \neq \Gamma_{v'}$, the projection $\Gamma_{v\circ} \to (\Gamma_v/\Delta')_\circ$ is continuous (remark 15.3.13(iii)), so $v' := v_{\Delta'}$ is a secondary specialization of v in $\mathrm{Cont}(A)$ with $\mathrm{Cont}(\overline{u}_A)(v') = w'$. Hence, we may assume that w' is a trivial valuation. It follows easily that $\mathbf{E}^{\circ\circ} \subset \mathrm{Ker}\, w'$. On the other hand, we may find finitely many elements $\beta_1, \dots, \beta_k \in \mathbf{E}^{\circ\circ}$ such that the system $\overline{u}_A(\beta_1), \dots, \overline{u}_A(\beta_k)$ generates an open ideal of A (see the proof of lemma 16.2.7(i)). Summing up, we see that v' is an analytic valuation of A, especially $v' \in \mathrm{Cont}(A)$, and the proof is concluded. $\square$

Remark 16.5.48. Keep the notation of proposition 16.5.46; for every $v \in \mathrm{Cont}(A)$ we have the commutative diagram of topological monoids

$$\begin{array}{ccc} \mathbf{E} & \xrightarrow{\overline{u}_A} & A \\ {\scriptstyle \mathbf{E}(v)}\downarrow & & \downarrow{\scriptstyle v} \\ \mathbf{E}(\Gamma_{v\circ}) & \xrightarrow{\overline{u}_{\Gamma_{v\circ}}} & \Gamma_{v\circ} \end{array}$$

(where $\Gamma_{v\circ}$ is endowed with its natural topology $\mathscr{T}_{\Gamma_v}$ as in definition 15.3.12(i)) and under the natural identification $\mathbf{E}(\Gamma_{v\circ}) \xrightarrow{\sim} \mathbf{E}(\Gamma_v)_\circ$, the map $\overline{u}_{\Gamma_{v\circ}}$ corresponds to $(\overline{u}_{\Gamma_v})_\circ$. Then $\mathbf{E}(\Gamma_v)$ inherits from Γ_v a unique ordering such that $\overline{u}_{\Gamma_v}$ is an injective morphism of ordered abelian groups. Moreover, since the p-Frobenius endomorphism of Γ_v is injective, it is easily seen that the topology of $\mathbf{E}(\Gamma_{v\circ}, \mathscr{T}_{\Gamma_v})$ is the same as the topology $\mathscr{T}_{\mathbf{E}(\Gamma_v)}$ provided by definition 15.3.12(i) (details left to the reader). In view of proposition 16.5.46(i), it follows that $\mathbf{E}(v)$ is a continuous valuation on $\mathbf{E}(v)$, and we have

$$\mathrm{Cont}(\overline{u}_A)(v) = \mathbf{E}(v) \qquad \text{in } \mathrm{Cont}(\mathbf{E}).$$

Proposition 16.5.49. *Let A be any perfectoid ring. We have :*

(i) *A is a valuation ring if and only if the same holds for $\mathbf{E} := \mathbf{E}(A)$.*

(ii) *Suppose that A is a valuation ring, and let*

$$v_A : A \to \Gamma_{A\circ} := (\mathrm{Frac}\, A)/A^\times \qquad \text{and} \qquad v_{\mathbf{E}} : \mathbf{E} \to \Gamma_{\mathbf{E}\circ} := (\mathrm{Frac}\, \mathbf{E})/\mathbf{E}^\times$$

be the valuations of A and $\mathbf{E}$ (see remark 9.1.13(iv)). Then :

(a) *$v_A \in \mathrm{Cont}(A)$ and $v_{\mathbf{E}} \in \mathrm{Cont}(\mathbf{E})$.*

(b) *The map $\overline{u}_A$ induces an isomorphism of ordered abelian groups :*

$$\gamma_A : \Gamma_{\mathbf{E}} \xrightarrow{\sim} \Gamma_A$$

fitting into a commutative diagram

$$\begin{array}{ccc} \mathbf{E} & \xrightarrow{\overline{u}_A} & A \\ {\scriptstyle v_{\mathbf{E}}}\downarrow & & \downarrow{\scriptstyle v_A} \\ \Gamma_{\mathbf{E}\circ} & \xrightarrow{\gamma_{A\circ}} & \Gamma_{A\circ}. \end{array}$$

(c) *More precisely, if $(\alpha_n \mid n \in \mathbb{N})$ is any distinguished element of $\mathrm{Ker}\, u_A$, the map $\overline{u}_A$ induces a group isomorphism*

$$\mathrm{Frac}(\mathbf{E})^\times/(1 + \alpha_0 \mathbf{E}) \xrightarrow{\sim} \mathrm{Frac}(A)^\times/(1 + pA).$$

(iii) *Let V be a valuation ring, and $\mathscr{T}_V$ a linear, complete, separated and f-adic topology on V that is coarser than the p-adic topology. Suppose that :*

(a) *The value group of V is p-divisible.*

(b) *The Frobenius endomorphism of V/pV is surjective.*

Then $(V, \mathscr{T}_V)$ is a perfectoid ring.

Proof. (i): We remark :

Claim 16.5.50. If $\mathbf{E}$ is a valuation ring, then for every $a \in A$ there exist $t \in A^\times$ and $e \in \mathbf{E}$ such that $a = t \cdot \overline{u}_A(e)$.

Proof of the claim. Fix any distinguished element $(\alpha_n \mid n \in \mathbb{N})$ of $\mathrm{Ker}\, u_A$, and recall that $p = w \cdot \overline{u}_A(\alpha_0)$ for some $w \in A^\times$ (lemma 16.2.7(iii)). Since the p-adic topology is separated on A, there exists $n \in \mathbb{N}$ such that $a \in p^n A \setminus p^{n+1}A$, so that $a = p^n b$ for some $b \in A \setminus pA$. Then there exists $\beta \in \mathbf{E}$ such that $b - \overline{u}_A(\beta) = pz$ for some $z \in A$ (lemma 16.2.7(i)), and notice that $\beta \notin \alpha_0\mathbf{E}$, since otherwise we would have $\overline{u}_A(\beta) \in pA$, whence $b \in pA$, a contradiction. Thus, $\alpha_0 = \beta \cdot \gamma$ for some element γ of the maximal ideal of $\mathbf{E}$, and we may write

$$x = p^n b = p^n \cdot (\overline{u}_A(\beta) + pz) = w^n \cdot \overline{u}_A(\alpha_0^n \beta) \cdot (1 + \overline{u}_A(\gamma) \cdot wz).$$

We need to check that $u := 1 + \overline{u}_A(\gamma) \cdot wz$ is invertible in A; to this aim, since p lies in the Jacobson radical of A, it suffices to show that the image of u is invertible in A/pA, and we are further reduced to checking that the image $\overline{\gamma}$ of $\overline{u}_A(\gamma)$ lies in the Jacobson radical of A/pA. However, u_A induces a ring isomorphism $\omega : \mathbf{E}/\alpha_0\mathbf{E} \xrightarrow{\sim} A/pA$ (remark 16.3.7(ii)), and $\omega^{-1}(\overline{\gamma})$ is the class of γ, whence the contention. ◊

Now, suppose that $\mathbf{E}$ is a valuation ring; directly from claim 16.5.50 and corollary 16.3.63(ii) we deduce that A is a domain. Then, let $a_1, a_2 \in A$ be any two elements, and write $a_i = t_i \cdot \overline{u}_A(e_i)$ with $t_i \in A^\times$ and $e_i \in \mathbf{E}$ for $i = 1, 2$; we may assume that $e_1 \in e_2\mathbf{E}$, whence $a_1 \in a_2 A$, which easily implies that A is a valuation ring.

Conversely, suppose that A is a valuation ring; if the field of fractions K of A has characteristic 0, we know already from lemma 9.4.16 that $\mathbf{E}$ is a valuation ring. If the characteristic of K equals p, the ring $\mathbf{E}$ is isomorphic to A, whence the assertion.

(ii.a): In light of proposition 9.1.16(i,ii) we see that either the topology $\mathscr{T}_A$ of A is discrete, or else it agrees with the valuation topology of A. In either case, it is clear that $v_A \in \mathrm{Cont}(A)$. The same applies to $\mathbf{E}$, since the latter is perfectoid as well.

(ii.b): From claim 16.5.50 we immediately see that γ_A is surjective, and the injectivity follows from remark 16.5.48.

(ii.c): By (ii.b) and the snake lemma, we are reduced to showing that $\overline{u}_A$ induces a group isomorphism

$$\mathbf{E}^\times/(1 + \alpha_0\mathbf{E}) \xrightarrow{\sim} A^\times/(1 + pA).$$

However, $\overline{u}_A$ induces a ring isomorphism $\mathbf{E}/\alpha_0\mathbf{E} \xrightarrow{\sim} A/pA$ (remark 16.3.7(ii)), whence a group isomorphism $(\mathbf{E}/\alpha_0\mathbf{E})^\times \xrightarrow{\sim} (A/pA)^\times$, and it remains only to observe that the natural maps

$$\mathbf{E}^\times/(1 + \alpha_0\mathbf{E}) \to (\mathbf{E}/\alpha_0\mathbf{E})^\times \qquad A^\times/(1 + pA) \to (A/pA)^\times$$

are isomorphisms, since $\alpha_0\mathbf{E}$ (resp. pA) lies in the Jacobson radical of $\mathbf{E}$ (resp. of A).

(iii): In light of proposition 9.1.16(i), we see that $\mathscr{T}_V$ is either the discrete topology or the valuation topology on V. If $\mathscr{T}_V$ is discrete and coarser than the p-adic topology, then V must be an $\mathbb{F}_p$-algebra, so in this case the assertion is a special case of example 16.3.2(i). If $\mathscr{T}_V$ is the valuation topology, let us endow $K := \mathrm{Frac}\, V$ with its valuation topology $\mathscr{T}_K$; then $(K, \mathscr{T}_K)$ is a Tate ring, by proposition 9.1.16(ii), hence V admits an ideal of adic definition of the form $I := aV$, for a non-zero topologically nilpotent element $a \in V$ (corollary 8.3.20(ii)). Since the value group of V is p-divisible, and p is topologically nilpotent in V, we may assume that $p \in I^p$, in which case, assumption (iii.b) implies that the Frobenius endomorphism of V/pV induces an isomorphism $V/I \xrightarrow{\sim} V/I^p$. By the same token, we easily see that $(V, \mathscr{T}_V)$ is a P-ring, so the assertion follows from theorem 16.4.1. □

Remark 16.5.51. Let A, A' be two perfectoid valuation rings with valuations $v : A \to \Gamma_{A^\circ}$, $v' : A' \to \Gamma_{A'^\circ}$, and $f : A \to A'$ a continuous ring homomorphism; according to proposition 16.5.49(i), both $\mathbf{E} := \mathbf{E}(A)$ and $\mathbf{E}' := \mathbf{E}(A')$ are valuation rings, and we denote by $v_\mathbf{E} : \mathbf{E} \to \Gamma_{\mathbf{E}^\circ}$, $v_{\mathbf{E}'} : \mathbf{E}' \to \Gamma_{\mathbf{E}'^\circ}$ their respective valuations. Then it follows easily from proposition 16.5.49(ii.c) that f is injective if and only if the same holds for $\mathbf{E}(f) : \mathbf{E} \to \mathbf{E}'$. Moreover, if

f is injective there exist unique group homomorphisms $\varphi_{\mathbf{E}} : \Gamma_{\mathbf{E}} \to \Gamma_{\mathbf{E}'}$, $\varphi_A : \Gamma_A \to \Gamma_{A'}$ fitting into a commutative diagram :

$$\Gamma_{\mathbf{E}^\circ} \xrightarrow{\varphi_{\mathbf{E}^\circ}} \Gamma_{\mathbf{E}'^\circ}$$

$$\begin{array}{ccccccc} \Gamma_{\mathbf{E}^\circ} & \xleftarrow{v_{\mathbf{E}}} & \mathbf{E} & \xrightarrow{\mathbf{E}(f)} & \mathbf{E}' & \xrightarrow{v_{\mathbf{E}'}} & \Gamma_{\mathbf{E}'^\circ} \\ \downarrow{\scriptstyle \gamma_{A^\circ}} & & \downarrow{\scriptstyle \overline{u}_A} & & \downarrow{\scriptstyle \overline{u}_{A'}} & & \downarrow{\scriptstyle \gamma_{A'^\circ}} \\ \Gamma_{A^\circ} & \xleftarrow{v_A} & A & \xrightarrow{f} & A' & \xrightarrow{v_{A'}} & \Gamma_{A'^\circ} \end{array}$$

$$\Gamma_{A^\circ} \xrightarrow{\varphi_{A^\circ}} \Gamma_{A'^\circ}$$

where γ_A and $\gamma_{A'}$ are the group isomorphisms provided by proposition 16.5.49(ii.b) : details left to the reader.

Theorem 16.5.52. *Let A be any perfectoid ring, and set $\mathbf{E} := \mathbf{E}(A)$. We have :*

(i) *The induced map* $\mathrm{Cont}(\overline{u}_A)$ *of proposition* 16.5.46(ii) *is a homeomorphism.*

(ii) *For every rational subset R of* $\mathrm{Cont}(\mathbf{E})$*, the preimage* $\mathrm{Cont}(\overline{u}_A)^{-1}R$ *is a rational subset of* $\mathrm{Cont}(A)$ *(see* (15.3.16)*).*

(iii) $\mathrm{Cont}(\overline{u}_A)$ *restricts to bijections*

$$\mathrm{Cont}(A)_{\mathrm{a}} \xrightarrow{\sim} \mathrm{Cont}(\mathbf{E})_{\mathrm{a}} \qquad \textit{and} \qquad \mathrm{Cont}(A)_{\mathrm{na}} \xrightarrow{\sim} \mathrm{Cont}(\mathbf{E})_{\mathrm{na}}.$$

(iv) *Let $w \in \mathrm{Cont}(A)$ be any valuation, and set $v := \mathrm{Cont}(\overline{u}_A)(w)$. Then $\overline{u}_A$ induces group isomorphisms*

$$\gamma_w : \Gamma_v \xrightarrow{\sim} \Gamma_w \qquad \textit{and} \qquad c\Gamma_v \xrightarrow{\sim} c\Gamma_w.$$

Proof. (ii): If A is perfectoid, both $\mathrm{Cont}(A)$ and $\mathrm{Cont}(\mathbf{E})$ are spectral spaces, and their rational subsets form a basis of constructible open subsets. Thus, let $(e_i \mid i = 0, \dots, n)$ be any finite system of elements of $\mathbf{E}$ that generate an open ideal, and set $R := R_{\mathbf{E}}(\frac{e_1}{e_0}, \dots, \frac{e_n}{e_0}) \cap \mathrm{Cont}(\mathbf{E})$. Let also $a_i := \overline{u}_A(e_i)$ for every $i = 0, \dots, n$. Then

$$\mathrm{Cont}(\overline{u}_A)^{-1}R = R_A\Big(\frac{a_1}{a_0}, \dots, \frac{a_n}{a_0}\Big) \cap \mathrm{Cont}(A).$$

However, the system $(a_i \mid i = 0, \dots, n)$ generates an open ideal of A (corollary 16.3.40(ii)), whence the assertion.

(iii): Let $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N})$ be any distinguished element of $\mathrm{Ker}\, u_A$; since α_0 is topologically nilpotent, it lies in every open prime ideal of $\mathbf{E}(A/pA)$. Likewise, pA is contained in every open prime ideal of A, and due to lemmata 16.2.7(i,iii) and 16.1.1(iv), the map $\overline{u}_A$ induces an isomorphism

$$\omega : \mathbf{E}/\alpha_0\mathbf{E} \xrightarrow{\sim} A/pA$$

of topological rings, so that $\mathrm{Cont}(\overline{u}_A)$ agrees with $\mathrm{Cont}(\omega)$ on the closed subset $\mathrm{Cont}(\mathbf{E}/\alpha_0\mathbf{E})$ of $\mathrm{Cont}(\mathbf{E})$, and induces a homeomorphism

$$\mathrm{Cont}(\mathbf{E}/\alpha_0\mathbf{E}) \xrightarrow{\sim} \mathrm{Cont}(A/pA).$$

It is also clear that $\mathrm{Cont}(\omega)$ maps $\mathrm{Cont}(\mathbf{E}/\alpha_0\mathbf{E})_{\mathrm{na}} = \mathrm{Cont}(\mathbf{E})_{\mathrm{na}}$ homeomorphically onto $\mathrm{Cont}(A/pA)_{\mathrm{na}} = \mathrm{Cont}(A)_{\mathrm{na}}$, so we need only to check that the restriction

$$C(A) := \mathrm{Cont}(A) \cap R_A\Big(\frac{p}{p}\Big) \to C(\mathbf{E}) := \mathrm{Cont}(\mathbf{E}) \cap R_{\mathbf{E}}\Big(\frac{\alpha_0}{\alpha_0}\Big)$$

of $\mathrm{Cont}(\overline{u}_A)$ is a bijection. Set $C^+(A) := C(A) \cap \mathrm{Spv}^+ A$ and $C^+(\mathbf{E}) := C(\mathbf{E}) \cap \mathrm{Spv}^+\mathbf{E}$. Clearly $\mathrm{Cont}(\overline{u}_A)$ restricts to a mapping $C^+(A) \to C^+(\mathbf{E})$, and we shall first exhibit an inverse mapping

$$\sigma : C^+(\mathbf{E}) \to C^+(A)$$

for $\mathrm{Cont}(\overline{u}_A)_{|C^+(A)}$. To this aim, let $v \in C^+(\mathbf{E})$ be any valuation; then v factors through a ring homomorphism $\pi : \mathbf{E} \to V := \kappa(v)^+$ and the residual valuation $\overline{v} : V \to \Gamma_{v\circ}$ of v. Since $\mathbf{E}$ is a perfect $\mathbb{F}_p$-algebra, the field $\kappa(v)$ is perfect, hence V is a perfect $\mathbb{F}_p$-algebra as well : indeed, it is clear that $x^p \in V$ if and only if $x \in V$, for every $x \in \kappa(v)$. Let us endow V with its valuation topology $\mathscr{T}_V$, so that $\overline{v}$ is continuous for the topology $\mathscr{T}_V$ (remark 15.3.13(i)).

Claim 16.5.53. The completion $(V^\wedge, \mathscr{T}_V^\wedge)$ of $(V, \mathscr{T}_V)$ is a perfectoid valuation ring.

Proof of the claim. We know that $V^\wedge$ is a valuation ring, by proposition 9.1.16(iii), and its topology $\mathscr{T}_V^\wedge$ is adic with a principal ideal of adic definition, since the same holds for $\mathscr{T}_V$ (lemma 15.3.14(ii)). Moreover, it is easily seen that the Frobenius endomorphism Φ_V of V is a homeomorphism for the topology $\mathscr{T}_V$, hence it induces a homeomorphism $\Phi_V^\wedge$ on $V^\wedge$; but clearly $\Phi_V^\wedge$ is just the Frobenius endomorphism of $V^\wedge$, so the latter is a perfect topological $\mathbb{F}_p$-algebra, and the assertion follows (see example 16.3.2(i)). ◊

Let $\pi^\wedge : \mathbf{E} \to V^\wedge$ be the composition of π with the completion map $V \to V^\wedge$; since $\pi^\wedge$ is a continuous map of perfectoid $\mathbb{F}_p$-algebras (remark 15.3.13(i)), the image of $\underline{\alpha}$ under the map $W(\pi^\wedge)$ is still distinguished in $W(V^\wedge)$, so claim 16.5.53 and proposition 16.5.49(i,ii) say that

$$A_V := W(V^\wedge) \otimes_{W(\mathbf{E})} A$$

is a perfectoid valuation ring whose valuation v_{A_V}, is continuous, and the map $\overline{u}_{A_V}$ induces an isomorphism of ordered abelian groups from the value group of $V^\wedge$ onto that of A_V

$$\gamma_{V^\wedge} : \Gamma_{V^\wedge} \xrightarrow{\sim} \Gamma_{A_V} \qquad \text{such that} \qquad v_{A_V} \circ \overline{u}_{A_V} = \gamma_{V^\wedge\circ} \circ \overline{v}^\wedge$$

where $\overline{v}^\wedge$ is the valuation of $V^\wedge$. Moreover, we get a continuous map of perfectoid rings

$$\varphi := W(\pi^\wedge) \otimes_{W(\mathbf{E})} A : A \to A_V$$

and $w := v_{A_V} \circ \varphi$ is a continuous valuation of A such that

$$\mathrm{Cont}(\overline{u}_A)(w) = w \circ \overline{u}_A = v_{A_V} \circ \overline{u}_{V^\wedge} \circ \pi^\wedge = \gamma_{V^\wedge\circ} \circ \overline{v}^\wedge \circ \pi^\wedge = \gamma_{V^\wedge\circ} \circ v.$$

Since $v(\alpha_0) \neq 0$, we have $w(p) \neq 0$ as well, so we obtain the sought map σ, by setting $\sigma(v) := w$, and we already see that σ is a right inverse for $\mathrm{Cont}(\overline{u}_A)_{|C^+(A)}$. We notice that since $v(\mathbf{E}) \cap \Gamma_v$ generates the group Γ_v, the subset $w \circ \overline{u}_A(\mathbf{E}) \cap \Gamma_{A_V}$ generates the group Γ_{A_V}, so that $\overline{u}_A$ induces an isomorphism

$$\Gamma_v \xrightarrow{\sim} \Gamma_{\sigma(v)} \qquad \text{for every } v \in C^+(\mathbf{E}). \tag{16.5.54}$$

Next, we check that σ is a left inverse as well. To this aim, let $v' \in C^+(A)$ be any valuation; then v' factors through a ring homomorphism $\pi' : A \to V' := \kappa(v')^+$ and the residual valuation $\overline{v}' : V' \to \Gamma_{v'\circ}$. By lemma 15.3.14(ii), the map π' is continuous for the valuation topology $\mathscr{T}_{V'}$ of V', and $\mathscr{T}_{V'}$ is adic with a principal ideal of adic definition. Since $pV' \neq 0$ and p is topologically nilpotent in A, the ideal pV' is open and topologically nilpotent in V', so $\mathscr{T}_{V'}$ agrees with the p-adic topology on V'. Let $(V'^\wedge, \mathscr{T}_{V'}^\wedge)$ be the completion of $(V', \mathscr{T}_{V'})$; then $V'^\wedge$ is a valuation ring whose valuation $\overline{v}'^\wedge : V'^\wedge \to \Gamma_{v'\circ}$ extends $\overline{v}'$ (proposition 9.1.16(iii,v)), and we let $\pi'^\wedge : A \to V'^\wedge$ be the composition of π' with the completion map $V' \to V'^\wedge$. Then $V'_{\mathbf{E}} := \mathbf{E}(V'^\wedge)$ is a valuation ring whose valuation is

$$\overline{v}'_{\mathbf{E}} := \overline{v}'^\wedge \circ \overline{u}_{V'^\wedge} : V'_{\mathbf{E}} \to \Gamma_{v'\circ}$$

(lemma 9.4.16) and $\mathbf{E}(\pi'^{\wedge}) : \mathbf{E} \to V'_{\mathbf{E}}$ is a continuous ring homomorphism. Since $\pi'^{\wedge} \circ \overline{u}_A = \overline{u}_{V'^{\wedge}} \circ \mathbf{E}(\pi'^{\wedge})$, we deduce that

$$v'_{\mathbf{E}} := \overline{v}'_{\mathbf{E}} \circ \mathbf{E}(\pi'^{\wedge}) = \mathrm{Cont}(\overline{u}_A)(v') \qquad \text{in } \mathrm{Cont}(\mathbf{E}). \tag{16.5.55}$$

Claim 16.5.56. (i) The topology of $V'_{\mathbf{E}}$ agrees with the valuation topology $\mathscr{T}_{V'_{\mathbf{E}}}$.

(ii) $(V'_{\mathbf{E}}, \mathscr{T}_{V'_{\mathbf{E}}})$ is a perfectoid ring.

Proof of the claim. (i): Since the quotient topology induced by $\mathscr{T}_{V'}$ on V'/pV' is discrete, the topology of $V'_{\mathbf{E}}$ is linear, complete and separated (remark 9.4.9(i)), so it suffices to check that this topology is not discrete (proposition 9.1.16(i)). To this aim, since α_0 is topologically nilpotent in $\mathbf{E}$, it suffices to check that $\nu := \mathbf{E}(\pi'^{\wedge})(\alpha_0) \neq 0$. However :

$$\overline{u}_{V'^{\wedge}}(\nu) = \pi'^{\wedge} \circ \overline{u}_A(\alpha_0) = \pi'^{\wedge}(pu) \qquad \text{for some } u \in A^{\times}$$

(lemma 16.2.7(iii)), and since $v'(p) \neq 0$, we must have $\pi'^{\wedge}(p) \neq 0$, whence the claim.

(ii): We have just seen that ν is a non-zero topologically nilpotent element of $V'_{\mathbf{E}}$, so $\mathscr{T}_{V'_{\mathbf{E}}}$ agrees with the ν-adic topology on $V'_{\mathbf{E}}$; then the assertion follows from example 16.3.2(i). ◊

Arguing as in the foregoing we see that the image of $\underline{\alpha}$ in $W(V'_{\mathbf{E}})$ is still distinguished, so

$$A_{V'} := W(V'_{\mathbf{E}}) \otimes_{W(\mathbf{E})} A$$

is a perfectoid valuation ring whose value group is naturally identified with the value group $\Gamma_{v'_{\mathbf{E}}}$ of $v'_{\mathbf{E}}$ (proposition 16.5.49(i,ii.b) and claim 16.5.56(ii)); by the same token, we get a natural isomorphism

$$\beta : \mathbf{E}(A_{V'}) \xrightarrow{\sim} V'_{\mathbf{E}} \qquad \text{such that} \qquad \pi_{V'_{\mathbf{E}}} \circ W(\beta) = u_{A_{V'}}$$

where $\pi_{V'_{\mathbf{E}}} : W(V'_{\mathbf{E}}) \to A_{V'}$ is the projection (proposition 16.2.16(iv)). Moreover, in light of the commutative diagram

$$\begin{array}{ccc} W(\mathbf{E}) & \xrightarrow{u_A} & A \\ {\scriptstyle W(\mathbf{E}(\pi'^{\wedge}))}\downarrow & & \downarrow{\scriptstyle \pi'^{\wedge}} \\ W(V'_{\mathbf{E}}) & \xrightarrow{u_{V'^{\wedge}}} & V'^{\wedge} \end{array}$$

we get a unique homomorphism of A-algebras

$$\psi : A_{V'} \to V'^{\wedge} \qquad \text{such that} \qquad u_{V'^{\wedge}} = \psi \circ \pi_{V'_{\mathbf{E}}}.$$

There follows a diagram :

$$\begin{array}{ccccc} & & \overset{\psi}{\frown} & & \\ A_{V'} & \xleftarrow{\overline{u}_{A_{V'}} \circ \beta^{-1}} & V'_{\mathbf{E}} & \xrightarrow{\overline{u}_{V'^{\wedge}}} & V'^{\wedge} \\ {\scriptstyle v'_A}\downarrow & & \downarrow{\scriptstyle \overline{v}'_{\mathbf{E}}} & & \downarrow{\scriptstyle \overline{v}'^{\wedge}} \\ \Gamma_{v'^{\circ}_{\mathbf{E}}} & = & \Gamma_{v'^{\circ}_{\mathbf{E}}} & \xrightarrow{j} & \Gamma_{v'^{\circ}} \end{array}$$

whose two square subdiagrams commute, where v'_A is the valuation of $A_{V'}$ and j the inclusion map of $\Gamma_{v'^{\circ}_{\mathbf{E}}}$ into $\Gamma_{v'^{\circ}}$. Let also $\varphi' : A \to A_{V'}$ be the structure map of the A-algebra $A_{V'}$.

Claim 16.5.57. (i) The top subdiagram commutes as well.

(ii) The external subdiagram also commutes, *i.e.* $\overline{v}'^{\wedge} \circ \psi = j \circ v'_A$.

(iii) The topology of $A_{V'}$ agrees with its valuation topology.

(iv) ψ is an isomorphism of topological rings and $\Gamma_{v'_{\mathbf{E}}} = \Gamma_{v'}$.

Proof of the claim. (i): Indeed, taking into account lemma 16.1.1(iv) we may compute :

$$\begin{aligned}\psi\circ\overline{u}_{A_{V'}} &= \psi\circ u_{A_{V'}}\circ\tau_{\mathbf{E}(A_{V'})}\\ &= \psi\circ\pi_{V'_{\mathbf{E}}}\circ W(\beta)\circ\tau_{\mathbf{E}(A_{V'})}\\ &= u_{V'}\circ W(\beta)\circ\tau_{\mathbf{E}(A_{V'})}\\ &= u_{V'}\circ\tau_{V'_{\mathbf{E}}}\circ\beta\\ &= \overline{u}_{V'}\circ\beta.\end{aligned}$$

(ii): Let $x\in A_{V'}$ be any element; since the left square subdiagram commutes, we may find $y\in V'_{\mathbf{E}}$ such that $\overline{u}_{A_{V'}}\circ\beta^{-1}(y)\cdot u = x$ for some $u\in A^{\times}_{V'}$, and therefore $\psi(x)=\overline{u}_{V'^{\wedge}}(y)\cdot\psi(u)$. Obviously, $\psi(u)$ is invertible in $V'^{\wedge}$, so that $\overline{v}'^{\wedge}\circ\psi(x)=\overline{v}'^{\wedge}\circ\overline{u}_{V'^{\wedge}}(y)=j\circ\overline{v}'_{\mathbf{E}}(y)=j\circ v'_A(x)$, as stated.

(iii): In light of proposition 9.1.16(i), it suffices to check that the topology of $A_{V'}$ is not discrete. However, notice that by construction φ' is a continuous map; thus, if the topology of $A_{V'}$ were discrete, $\mathrm{Ker}\,\varphi'$ would be an open ideal, and then the same would hold for $\mathrm{Ker}\,\pi'^{\wedge}$. But this is absurd, since v' is analytic.

(iv): As an immediate consequence of (ii), we already see that ψ is injective. Then it is clear that φ' factors uniquely through π' and an injective map $V'\to A_{V'}$ whose composition with ψ equals the completion map. Thus, the image of ψ is a dense subring of $V'^{\wedge}$; combining with (ii), we deduce already the stated equality of value groups. Then by (iii) the topology of $A_{V'}$ agrees with the topology induced by $V'^{\wedge}$ via ψ. Since $A_{V'}$ is complete and separated, theorem 8.2.8(iii) implies that ψ is an isomorphism. ♢

From claim 16.5.57(ii) we get the following equalities in $\mathrm{Cont}(A)$:

$$\begin{aligned}\sigma\circ\mathrm{Cont}(\overline{u}_A)(v') &= \sigma(\overline{v}'^{\wedge}\circ\overline{u}_{V'^{\wedge}}\circ\mathbf{E}(\pi'^{\wedge}_{\mathbf{E}}))\\ &= \sigma(\overline{v}'_{\mathbf{E}}\circ\mathbf{E}(\pi'^{\wedge}))\\ &= v'_A\circ\varphi'\\ &= \overline{v}'^{\wedge}\circ\psi\circ\varphi'\\ &= \overline{v}'^{\wedge}\circ\pi'^{\wedge}\\ &= v'\end{aligned}$$

as required. Let $\kappa(v'_{\mathbf{E}})^{\wedge+}$ be the completion of $\kappa(v'_{\mathbf{E}})^+$ for its valuation topology, $\pi'_{\mathbf{E}}:\mathbf{E}\to\kappa(v'_{\mathbf{E}})^+$ the natural ring homomorphism (whose composition with the valuation $\kappa(v'_{\mathbf{E}})^+\to\Gamma_{v'^{\circ}}$ yields $v'_{\mathbf{E}}$), and $\pi'^{\wedge}_{\mathbf{E}}:\mathbf{E}\to\kappa(v'_{\mathbf{E}})^{\wedge+}$ the completion of $\pi'_{\mathbf{E}}$; we notice as well :

Claim 16.5.58. There exists a ring isomorphism

$$\omega^{\wedge}_{\mathbf{E}}:\kappa(v'_{\mathbf{E}})^{\wedge+}\xrightarrow{\sim}V'_{\mathbf{E}}\qquad\text{such that}\qquad\omega^{\wedge}_{\mathbf{E}}\circ\pi'^{\wedge}_{\mathbf{E}}=\mathbf{E}(\pi'^{\wedge}).$$

Proof of the claim. The map $\mathbf{E}(\pi'^{\wedge})$ factors through $\pi'_{\mathbf{E}}$ and a unique injective ring homomorphism $\omega_{\mathbf{E}}:\kappa(v'_{\mathbf{E}})^+\to V'_{\mathbf{E}}$ such that $\overline{v}'_{\mathbf{E}}\circ\omega_{\mathbf{E}}:\kappa(v'_{\mathbf{E}})^+\to\Gamma_{v'^{\circ}}$ is the residual valuation. Thus, the valuation topology of $\kappa(v'_{\mathbf{E}})^+$ agrees with the topology induced from $V'_{\mathbf{E}}$ via $\omega_{\mathbf{E}}$, so the latter extends to a continuous ring homomorphism $\omega^{\wedge}_{\mathbf{E}}:\kappa(v'_{\mathbf{E}})^{\wedge+}\to V'_{\mathbf{E}}$ such that $\overline{v}'_{\mathbf{E}}\circ\omega^{\wedge}_{\mathbf{E}}$ is the valuation of $\kappa(v'_{\mathbf{E}})^{\wedge+}$. The map $\omega^{\wedge}_{\mathbf{E}}$ is injective (proposition 8.2.13(i)), and clearly $\omega^{\wedge}_{\mathbf{E}}\circ\pi'^{\wedge}_{\mathbf{E}}=\mathbf{E}(\pi'^{\wedge})$, so it remains only to check that $\omega^{\wedge}_{\mathbf{E}}$ is bijective. To this aim, set $V'':=W(\kappa(v'_{\mathbf{E}})^{\wedge+})\otimes_{W(\mathbf{E})}A$; by the foregoing we know already that V'' is a perfectoid valuation ring with value group $\Gamma_{v'}$, and it suffices to show that

$$\omega^{\wedge}_A:=W(\omega^{\wedge}_{\mathbf{E}})\otimes_{W(\mathbf{E})}A:V''\to A_{V'}$$

is an isomorphism. However, set $\pi'^{\wedge}_A := W(\pi'^{\wedge}_{\mathbf{E}}) \otimes_{W(\mathbf{E})} A$; by remark 16.5.51, we know already that $\omega^{\wedge}_A$ is injective, and moreover we have a commutative diagram

$$\begin{array}{ccccc} A & \xrightarrow{\pi'^{\wedge}_A} & V'' & \xrightarrow{v''} & \Gamma_{v'^{\circ}} \\ & \searrow^{\varphi'} & \downarrow{\scriptstyle \omega^{\wedge}_A} & & \| \\ & & A_{V'} & \xrightarrow{v'_A} & \Gamma_{v'^{\circ}} \end{array}$$

where v'' is the valuation of V''. It follows that the valuation topology of V'' is induced by the valuation topology of $A_{V'}$ via $\omega^{\wedge}_A$. Furthermore, we deduce that $v'' \circ \pi'^{\wedge}_A = v'_A \circ \varphi' = v'$, so $\pi'^{\wedge}_A$ factors through $\pi' : A \to V'$ and an injective map $V' \to V''$ whose composition with $\omega^{\wedge}_A$ has dense image, by virtue of claim 16.5.57(iv). Since V'' is complete, it follows that $\omega^{\wedge}_A$ is surjective, whence the claim. $\Diamond$

Next, let A^+ be the smallest subring of integral elements of A (remark 15.4.2(iv)); by theorem 16.5.13(ii,iii), the ring A^+ is perfectoid, and $\mathbf{E}(A^+)$ is naturally identified with the smallest ring $\mathbf{E}^+$ of integral elements of $\mathbf{E}$. Moreover, we get a commutative diagram

$$\begin{array}{ccc} \mathrm{Cont}(A) & \xrightarrow{\mathrm{Cont}(\overline{u}_A)} & \mathrm{Cont}(\mathbf{E}) \\ {\scriptstyle \mathrm{Cont}(j_A)}\downarrow & & \downarrow{\scriptstyle \mathrm{Cont}(j_{\mathbf{E}})} \\ \mathrm{Cont}(A^+) & \xrightarrow{\mathrm{Cont}(\overline{u}_{A^+})} & \mathrm{Cont}(\mathbf{E}^+) \end{array}$$

where $j_A : A^+ \to A$ and $j_{\mathbf{E}} : \mathbf{E}^+ \to \mathbf{E}$ are the inclusion maps. Since A^+ is the integral closure in A of the $\mathbb{Z}$-subalgebra generated by $A^{\circ\circ}$, it is easily seen that $\mathrm{Cont}(A^+) = \mathrm{Cont}^+(A^+)$, and likewise for $\mathrm{Cont}(\mathbf{E}^+)$. Therefore, $C(A^+) = C^+(A^+)$ and $C(\mathbf{E}^+) = C^+(\mathbf{E}^+)$, and the foregoing shows that $\mathrm{Cont}(\overline{u}_{A^+})$ restricts to a bijection

$$C(\mathbf{E}^+) \xrightarrow{\sim} C(A^+).$$

Lastly, proposition 15.3.18(ii) says that $\mathrm{Cont}(j_A)$ restricts to a bijection from the analytic valuations of A to those of A^+, and likewise for $\mathrm{Cont}(j_{\mathbf{E}})$, whence (iii).

(iv): Let $\pi_A : A \to A/pA$ and $\pi_{\mathbf{E}} : \mathbf{E} \to \mathbf{E}/\alpha_0\mathbf{E}$ be the projections; if $w(p) = 0$, then $w = \mathrm{Cont}(\pi_A)(w')$ for a unique $w' \in \mathrm{Cont}(A/pA)$, and $v = \mathrm{Cont}(\pi_{\mathbf{E}})(v')$, where $v' := \mathrm{Cont}(\omega)(w')$. Since π_A and $\pi_{\mathbf{E}}$ are surjective, obviously $\Gamma_w = \Gamma_{w'}$ and $\Gamma_v = \Gamma_{v'}$, and likewise for the characteristic subgroups; since ω is a ring isomorphism, it induces a group isomorphism $\Gamma_{v'} \xrightarrow{\sim} \Gamma_{w'}$ that identifies the respective characteristic subgroups, whence the assertion, in this case. Next, suppose that $w \in C(A)$, and set $w' := \mathrm{Cont}(j_A)(w)$, $v' := \mathrm{Cont}(\overline{u}_{A^+})(w')$; then $w' \in C^+(A^+)$, and from (iii) and (16.5.54) we see that $\overline{u}_{A^+}$ induces an isomorphism $\gamma_{w'} : \Gamma_{w'} \xrightarrow{\sim} \Gamma_{v'}$. Moreover, we have a commutative diagram of groups

$$\begin{array}{ccc} \Gamma_{w'} & \xrightarrow{\gamma_{w'}} & \Gamma_{v'} \\ {\scriptstyle i_w}\downarrow & & \downarrow{\scriptstyle i_v} \\ \Gamma_w & \xrightarrow{\gamma_w} & \Gamma_v \end{array}$$

where i_w and i_v are the injective maps induced by j_A and $j_{\mathbf{E}}$. In order to prove that γ_w is an isomorphism, it suffices therefore to check that i_w and i_v are surjective. To this aim, it suffices to show that $S_{A^+} := w(A^+) \cap \Gamma_w$ generates Γ_w and $S_{\mathbf{E}^+} := v(A^+) \cap \Gamma_v$ generates Γ_v. However, notice that $pA \subset A^+$ and $\alpha_0\mathbf{E} \subset \mathbf{E}^+$; since $w(p) \neq 0$ and $v(\alpha_0) \neq 0$, it follows easily that S_{A^+} and $S_A := w(A) \cap \Gamma_w$ generate the same subgroup of Γ_w, and likewise for $S_{\mathbf{E}^+}$. To conclude, it suffices to remark that S_A generates Γ_w, and likewise for Γ_v.

Next, obviously γ_w restricts to an injective group homomorphism $c\Gamma_v \to c\Gamma_w$. To show that this map is surjective, consider any $a \in A$ such that $w(a) > 1$; since $\overline{u}_{A/pA}$ is surjective (lemma

16.2.7(i)), we may write $a = \overline{u}_A(\beta) + pb$ for some $\beta \in \mathbf{E}$ and $b \in A$, and since $pb \in A^{\circ\circ}$, we have $w(pb) < 1$, so that $w(a) = v(\beta)$, whence the contention.

(i): We argue as in the proof of proposition 15.3.19 : by (ii) and (iii) we know already that $\mathrm{Cont}(\overline{u}_A)$ is a spectral and bijective map of spectral spaces, so it suffices to check that $\mathrm{Cont}(\overline{u}_A)$ is a closed map, and by proposition 8.1.47(i) and corollary 8.1.50(i) we are further reduced to showing that $\mathrm{Cont}(\overline{u}_A)$ is specializing. Hence, let $w \in \mathrm{Cont}(A)$ be any valuation, and $v' \in \mathrm{Cont}(A)$ any specialization of $v := \mathrm{Cont}(\overline{u}_A)(w)$; we may find a valuation v'' of $\mathbf{E}$ that is both a secondary specialization of v and a primary generization of v', and $v'' \in \mathrm{Cont}(\mathbf{E})$, by remark 15.3.13(iv). By proposition 16.5.46(v), there exists a secondary specialization w'' of w such that $\mathrm{Cont}(\overline{u}_A)(w'') = v''$. By (iv) we know that w'' and v'' have the same value groups and characteristic subgroups, so we may find a primary specialization w' of w such that $\mathrm{Cont}(\overline{u}_A)(w') = v'$, whence the assertion. □

16.5.59. Let $\underline{X}$ be any perfectoid quasi-affinoid scheme, and with the notation of (16.5.19) and (16.5.20), let us set

$$\underline{A} := (A^\circ_X, A^+_X, X) := \Gamma^\circ(\underline{X}) \qquad \text{and} \qquad \underline{\mathbf{E}} := (\mathbf{E}^\circ_X, \mathbf{E}^+_X, X_{\mathbf{E}}) := \mathbf{E}(\underline{A}).$$

Especially, $\mathbf{E}^\circ_X = \mathbf{E}(A^\circ_X)$ and $\mathbf{E}^+_X = \mathbf{E}(A^+_X)$; it is then clear that $\mathrm{Cont}(\overline{u}_{A^\circ_X})$ maps the subset $\mathrm{Spa}\,(A^\circ_X, A^+_X)$ into $\mathrm{Spa}\,(\mathbf{E}^\circ_X, \mathbf{E}^+_X)$. Conversely, let $v : A^\circ_X \to \Gamma_v$ be any continuous valuation such that $v \circ \overline{u}_{A^\circ_X} \in \mathrm{Spa}\,(\mathbf{E}^\circ_X, \mathbf{E}^+_X)$, and $\underline{\alpha}$ any distinguished element of $\mathrm{Ker}\, u_{A^\circ_X}$; for every $a \in A^+_X$ there exists $b \in A^+_X$ and $e \in \mathbf{E}^+_X$ such that $a = \overline{u}_{A^\circ_X}(e) + \alpha_0 b$, and since $\alpha_0 b \in A^{\circ\circ}_X$, we deduce that $v(a) \leq 1$, so $v \in \mathrm{Spa}\,(A^\circ_X, A^+_X)$. Combining with proposition 16.5.46(iii), we deduce that $\mathrm{Cont}(\overline{u}_{A^\circ_X})$ restricts to a homeomorphism

$$\mathrm{Spa}\,(\overline{u}_{\underline{A}}) : \mathrm{Spa}\,\underline{A} \xrightarrow{\sim} \mathrm{Spa}\,\underline{\mathbf{E}}$$

and taking into account the natural identifications $\mathrm{Spa}\,\underline{A} \xrightarrow{\sim} \mathrm{Spa}\,\underline{X}$ and $\mathrm{Spa}\,\underline{\mathbf{E}} \xrightarrow{\sim} \mathrm{Spa}\,\mathbf{E}(\underline{X})$, we get as well an induced homeomorphism

$$\mathrm{Spa}(\overline{u}_{\underline{X}}) : \mathrm{Spa}\,\underline{X} \xrightarrow{\sim} \mathrm{Spa}\,\mathbf{E}(\underline{X}).$$

Moreover, it is easily seen that every morphism $f : \underline{Y} \to \underline{X}$ of perfectoid quasi-affinoid schemes yields a commutative diagram

$$\begin{array}{ccc} \mathrm{Spa}\,\underline{Y} & \xrightarrow{\mathrm{Spa}(\overline{u}_{\underline{Y}})} & \mathrm{Spa}\,\mathbf{E}(\underline{Y}) \\ {\scriptstyle \mathrm{Spa}\,f}\downarrow & & \downarrow{\scriptstyle \mathrm{Spa}\,\mathbf{E}(f)} \\ \mathrm{Spa}\,\underline{X} & \xrightarrow{\mathrm{Spa}(\overline{u}_{\underline{X}})} & \mathrm{Spa}\,\mathbf{E}(\underline{X}). \end{array} \tag{16.5.60}$$

Corollary 16.5.61. *In the situation of* (16.5.59)*, let $x \in \mathrm{Spa}\,\underline{X}$ be any element and set $y := \mathrm{Spa}\,(\overline{u}_{\underline{X}})(x)$. Denote also by $\pi^{\wedge+}_x : A^+_X \to \kappa(x)^{\wedge+}$ and $\pi^{\wedge+}_y : \mathbf{E}^+_X \to \kappa(y)^{\wedge+}$ the natural maps (notation of* (15.5.12)*), and endow $\kappa(x)^{\wedge+}$ and $\kappa(y)^{\wedge+}$ with the unique ring topologies $\mathscr{T}^\wedge_x$ and $\mathscr{T}^\wedge_y$ such that $\pi^{\wedge+}_x$ and $\pi^{\wedge+}_y$ are adic ring homomorphisms. We have :*

(i) *The topological rings $(\kappa(x)^{\wedge+}, \mathscr{T}^\wedge_x)$ and $(\kappa(y)^{\wedge+}, \mathscr{T}^\wedge_y)$ are perfectoid valuation rings.*
(ii) *There exists a unique isomorphism of topological rings :*

$$\omega^{\wedge+} : \mathbf{E}(\kappa(x)^{\wedge+}) \xrightarrow{\sim} \kappa(y)^{\wedge+} \qquad \textit{such that} \qquad \omega^{\wedge+} \circ \mathbf{E}(\pi^{\wedge+}_x) = \pi^{\wedge+}_y.$$

Proof. Suppose first that $p \in \mathrm{Ker}\,\pi^+_x$; in this case x corresponds to a continuous ring homomorphism $\overline{\pi}_x : A^\circ_X/pA^\circ_X \to \kappa(x)$ and y corresponds to the continuous ring homomorphism $\overline{\pi}_y := \overline{\pi}_x \circ \varphi : \mathbf{E}^\circ_X/\alpha_0\mathbf{E}^\circ_X \to \kappa(x)$, where α_0 is as in (16.5.59) and $\varphi : \mathbf{E}^\circ_X/\alpha_0\mathbf{E}^\circ_X \xrightarrow{\sim} A^\circ_X/pA^\circ_X$

is the isomorphism of topological rings induced by $\overline{u}_{A^\circ_X}$. There follows a unique isomorphism of valued fields $\omega : \kappa(y) \xrightarrow{\sim} \kappa(x)$ fitting into the commutative diagram

$$\begin{array}{ccc} \mathbf{E}^\circ_X/\alpha_0\mathbf{E}^\circ_X & \xrightarrow{\ \varphi\ } & A^\circ_X/pA^\circ_X \\ {\scriptstyle\overline{\pi}_y}\downarrow & & \downarrow{\scriptstyle\overline{\pi}_x} \\ \kappa(y) & \xrightarrow{\ \ \omega\ \ } & \kappa(x). \end{array}$$

Let us now endow $\kappa(x)^+$ and $\kappa(y)^+$ with the unique ring topologies such that the natural maps $\pi^+_x : A^+_X \to \kappa(x)^+$ and $\pi^+_y : \mathbf{E}^+_X \to \kappa(y)^+$ are adic; then clearly ω restricts to an isomorphism $\omega^+ : \kappa(y)^+ \xrightarrow{\sim} \kappa(x)^+$ of topological rings, and assertion (ii) follows straightforwardly in this case. Moreover, since $\mathbf{E}$ is a perfect $\mathbb{F}_p$-algebra, the same holds for its quotient $\mathbf{E}/\mathrm{Ker}\,\pi_y$, and then also for $\kappa(y) = \mathrm{Frac}\,(\mathbf{E}/\mathrm{Ker}\,\pi_y)$, and for $\kappa(y)^\wedge$ as well (example 9.3.48(ii)). By remark 9.4.9(v), it follows easily that $\kappa(y)^{\wedge+}$ is a perfect adic and f-adic topological ring (details left to the reader), and hence it is perfectoid (example 16.3.2(i)); the same then holds for $\kappa(x)^{\wedge+}$.

Next, if $\pi^+_x(p) \neq 0$, the point x is analytic, and the same then holds for y. In this case, it is easily seen that the topologies $\mathscr{T}^\wedge_x$ and $\mathscr{T}^\wedge_y$ are separated and not discrete, so they coincide with the respective valuation topologies (proposition 9.1.16(i)). Recall that the inclusion map $i : A^+_X \to A^\circ_X$ induces a homeomorphism $\mathrm{Cont}(i)_\mathrm{a} : \mathrm{Cont}(A^\circ_X)_\mathrm{a} \xrightarrow{\sim} \mathrm{Cont}(A^+_X)_\mathrm{a}$ and likewise for $\mathrm{Cont}(\mathbf{E}^\circ_X)$ (proposition 15.3.18(ii)); moreover, if $x' := \mathrm{Cont}(i)(x)$, we have a unique isomorphism of valued fields $\kappa(x') \xrightarrow{\sim} \kappa(x)$ fitting into the commutative diagram

$$\begin{array}{ccccc} A^+_X & & \xrightarrow{\qquad i \qquad} & & A^\circ_X \\ {\scriptstyle\pi^+_{x'}}\downarrow & & & & \downarrow{\scriptstyle\pi^\circ_x} \\ \kappa(x')^+ & \hookrightarrow & \kappa(x') & \xrightarrow{\ \sim\ } & \kappa(x) \end{array}$$

where π°_x and $\pi^+_{x'}$ are the natural maps, and likewise for y and its image $y' \in \mathrm{Cont}(\mathbf{E}^+_X)$. Hence we may regard x and y as elements of $\mathrm{Cont}(A^+_X)$ and respectively $\mathrm{Cont}(\mathbf{E}^+_X)$, and in this case assertions (i) and (ii) follow from claims 16.5.57(iv) and 16.5.58. ☐

16.6. **Graded perfectoid rings.** This section is mainly dedicated to the construction and investigation of certain *angular Rees algebras* that shall be useful in the study of blowing up morphisms of perfectoid formal schemes.

Proposition 16.6.1. *Let $(\Gamma, +, 0)$ be a monoid, $(A, \underline{B})$ a Γ-graded structure on the topological ring $(A, \mathscr{T})$, and $i_0 : \mathrm{gr}_0 B \to A$ the inclusion map. Suppose that A is a P-ring. Then we have :*

(i) *If the p-Frobenius endomorphism $\boldsymbol{p}_\Gamma$ of Γ is injective, there exists a finitely generated graded ideal J of B such that JA is an ideal of definition of A.*
(ii) *Suppose that i_0 is c-adic and $\boldsymbol{p}_\Gamma$ is injective. Then $\mathrm{gr}_0 B$ is a P-ring, and if A is perfectoid, the same holds for $\mathrm{gr}_0 B$.*
(iii) *If A is a perfectoid ring, $\mathrm{Ker}\, u_A$ is generated by a distinguished element in $\mathbf{A}(\mathrm{gr}_0 B)$.*

Proof. (i): By lemma 16.2.3(iv), we may write $p = b^p u$ for some $u \in A^\times$ and $b \in A$, and by the same token, $u = x^p + py$ for some $x, y \in A$, so that $p = a^p + p^2 w$, with $a := bx$ and $w := u^{-1} y$. Let now $(a_\gamma \mid \gamma \in \Gamma)$ be the sequence attached to a, as in remark 8.5.2(iii), and c (resp. d) the limit of the Cauchy net $(c_S \mid S \subset \Gamma)$ (resp. $(d_S \mid S \subset \Gamma)$) provided by lemma 8.5.6(i), where S ranges over the finite subsets of Γ, and $a^p_S = c_S + p \cdot d_S$ for every such S (with a_S defined as in remark 8.5.2(iii)). In light of proposition 8.5.3(ii), we deduce that $a^p = c + pd$, whence $p = c + pd + p^2 w$. Moreover, since the p-Frobenius map of Γ is injective, we have

$\pi'_{p\gamma}(c_S) = a^p_\gamma$ for every $S \subset \Gamma$ and every $\gamma \in S$; therefore $\pi'_{p\gamma}(c) = a^p_\gamma$ for every $\gamma \in \Gamma$, and especially, $\pi'_0(c) = a^p_0$. Consequently

$$p = a^p_0 + p \cdot d_0 + p^2 w_0$$

where $(d_\gamma \mid \gamma \in \Gamma)$ and $(w_\gamma \mid \gamma \in \Gamma)$ are the sequences attached to d and respectively w. Next, notice that a is topologically nilpotent in A, hence a_γ is topologically nilpotent in B, for every $\gamma \in \Gamma$ (lemma 8.5.6(ii)), and then the same holds for d_0. Thus $v := 1 - d_0 - pw_0$ is invertible in A, with inverse given by the convergent series $\sum_{n\in\mathbb{N}}(d_0 + pw_0)^n$, and since $\mathrm{gr}_0 B$ is closed in A, we conclude that $v \in (\mathrm{gr}_0 B)^\times$. Summing up, we arrive at the identity

$$pv = a^p_0 \qquad \text{with } v \in (\mathrm{gr}_0 B)^\times \text{ and } a_0 \in \mathrm{gr}_0 B.$$

Lastly, by proposition 8.5.11(i.a) we know already that A admits an ideal of adic definition of the form $J'A$, for some graded ideal $J' \subset B$, and we set $J := J' + a_0 B$; then it is easily seen that JA is an ideal of definition for the P-ring A.

(ii): We remark :

Claim 16.6.2. In the situation of the proposition, suppose that $\boldsymbol{p}_\Gamma$ is injective. Then we have :

(i) The Frobenius endomorphism of B/pB restricts to surjective maps

$$\mathrm{gr}_\gamma B \otimes_\mathbb{Z} \mathbb{F}_p \to \mathrm{gr}_{p\gamma} B \otimes_\mathbb{Z} \mathbb{F}_p \qquad \text{for every } \gamma \in \Gamma.$$

(ii) $\mathrm{gr}_\gamma B = 0$ for every $\gamma \in \Gamma \setminus \mathbf{E}(\Gamma)$.

Proof of the claim. (i): Say that $b \in \mathrm{gr}_\gamma B$; by lemma 16.2.3(iv) there exists $x \in A$ such that $x^p - b \in pA$. Let $(x_\gamma \mid \gamma \in \Gamma)$ be the system attached to x as in remark 8.5.2(iii); it was remarked in the proof of (i) that the system $(x^p_\gamma \mid \gamma \in \mathbb{N})$ is a Cauchy net in B, and if $y \in A$ denotes the limit of this net, then $x^p - y \in pA$, so that $y - b \in pA$ as well. Consequently,

$$b = \pi'_\gamma(b) \equiv \pi'_\gamma(y) = x^p_{p^{-1}\gamma} \pmod{p \cdot \mathrm{gr}_\gamma B}$$

if $\gamma \in p\Gamma$, and otherwise $b \in p \cdot \mathrm{gr}_\gamma B$. Assertion (i) follows already. Next, using part (i) of the claim it is easily seen that, if $\gamma \in \Gamma \setminus \mathbf{E}(\Gamma)$, we have $\mathrm{gr}_\gamma B \otimes_\mathbb{Z} \mathbb{F}_p = 0$, whence (ii), since the p-adic topology is separated on B. ◊

Claim 16.6.2 says especially that the Frobenius endomorphism of $\mathrm{gr}_0 B \otimes_\mathbb{Z} \mathbb{F}_p$ is surjective. On the other hand, we already know by proposition 8.5.11(iii) that the topology of $\mathrm{gr}_0 B$ is adic with a finitely generated ideal of adic definition I. Moreover, the proof of (i) shows that there exists $a_0 \in \mathrm{gr}_0 B$ such that $p = a^p_0 u$ for some $u \in (\mathrm{gr}_0 B)^\times$; then, it is easily seen that $\mathrm{gr}_0 B$ is a P-ring with ideal of definition $I + a_0 \cdot \mathrm{gr}_0 B$.

Lastly, suppose that A is perfectoid, and to ease notation set $B_0 := \mathrm{gr}_0 B$. By the foregoing, we know already that B_0 is a P-ring, and then i_0 is adic, by lemma 8.3.24(i.c). Pick any ideal of definition I_0 of B_0, and say that I_0 is generated by k elements, for some $k \in \mathbb{N}$; by remark 16.3.58, we can assume that $p \in I_0^{k(p-1)+1}$, and therefore $I := I_0 A$ is an open ideal of A that fulfills the same condition. Set $J_0 := I_0^{(p)}$ and $J := I^{(p)} = J_0 A$; it follows that the Frobenius endomorphism of A/pA induces an isomorphism $\Phi_I : \mathrm{gr}^\bullet_I A \to \mathrm{gr}_J A$ (propositions 16.3.8(i) and 16.3.59(ii)).

Claim 16.6.3. The natural maps

$$\mathrm{gr}^n_I B := I^n_0 B / I^{n+1}_0 B \to \mathrm{gr}^n_I A \qquad \mathrm{gr}^n_J B := J^n_0 B / J^{n+1}_0 B \to \mathrm{gr}^n_J A$$

are bijective for every $n \in \mathbb{N}$.

Proof of the claim. By claim 8.3.26 we have $(I^n B)^c = I^n A$, so that $I^n = I^n B + I^{n+1}$, whence the surjectivity of the first map. For the injectivity, we need to show that $I^{n+1}_0 B = I^n_0 B \cap I^{n+1}$. Hence, let $x \in I^n_0 B \cap I^{n+1}$; then $x = \sum_{i=1}^r x_r a_r$ for some $r \in \mathbb{N}$ and certain $x_i \in I^{n+1}_0$ and

$a_i \in A$ ($i = 1, \dots, r$). Say that $x \in \mathrm{gr}_S B := \bigoplus_{\gamma \in S} \mathrm{gr}_\gamma B$ for some finite subset $S \subset \Gamma$, and let $\pi'_S : A \to \mathrm{gr}_S B$ be the induced projection (the sum of the canonical γ-projections as in remark 8.5.2(iii), for γ ranging over the subset S). Then $x = \pi'_S(x) = \sum_{i=0}^r x_i \cdot \pi'_S(a)$, whence the contention. The same argument applies to the second map. $\diamondsuit$

From claim 16.6.3 we conclude that the map $\Phi_I : \mathrm{gr}^\bullet_I B \to \mathrm{gr}^\bullet_J B$ is also an isomorphism. But then, since $\boldsymbol{p}_\Gamma$ is injective, clearly the direct summand $\mathrm{gr}_0 \Phi_I := \Phi_{I_0} : \mathrm{gr}^\bullet_{I_0} B_0 \to \mathrm{gr}^\bullet_{J_0} B_0$ is still an isomorphism, and therefore B_0 is perfectoid, by theorem 16.3.64.

(iii): By proposition 16.3.8(i), we may assume that $\mathscr{T}$ is the p-adic topology of A. Let $j_A : A \to B'$ be as in remark 8.5.2(iii); clearly $p^n B' \cap B_0 = p^n B_0$ and $p^n A \subset j_A^{-1}(p^n B')$, so $B_0 \cap p^n A = p^n B_0$ for every $n \in \mathbb{N}$, and therefore the topology of B_0 agrees with its p-adic topology. It follows that i_0 is an adic map, and therefore B_0 is even perfectoid, by (ii); then any distinguished element of $\mathrm{Ker}\, u_{B_0}$ generates $\mathrm{Ker}\, u_A$, by proposition 16.2.23(ii). $\square$

16.6.4. Let $(\Gamma, 0, +)$ be a p-perfect monoid, $(A, \underline{B})$ a perfectoid ring with Γ-graded structure, and set $(\mathbf{E}, \underline{B}_{\mathbf{E}}) := \mathbf{E}(A, \underline{B})$. Let also $\beta_1, \dots, \beta_r$ (resp. $\gamma_1, \dots, \gamma_r$) be a finite system of elements of $\mathbf{E}$ (resp. of Γ), such that $\beta_i \in \mathrm{gr}_{\gamma_i} \underline{B}_{\mathbf{E}}$ for every $i = 1, \dots, r$. Set $\mathbf{f} := (\overline{u}_A(\beta_1), \dots, \overline{u}_A(\beta_r))$ and define the ring $R_{r,0}$ and its ideals $I_{r,0}^{\lceil s \rceil}$ for every $s \in \mathbb{R}_+$, as in (16.4.4); we endow $\underline{B}$ with the $R_{r,0}$-module structure induced by the unique ring homomorphism $u : R_{r,0} \to \underline{B}$ such that $u(T_i^{1/p^n}) := \overline{u}_A(\beta_i^{1/p^n})$ for every $i = 1, \dots, r$ and every $n \in \mathbb{N}$.

Proposition 16.6.5. *In the situation of* (16.6.4)*, suppose moreover that the translation map* $\Gamma \to \Gamma \ : \ \gamma \mapsto \gamma + \gamma_i$ *is injective for every* $i = 1, \dots, r$. *Then we have :*

(i) $\mathrm{Tor}_i^{R_{r,0}}(R_{r,0}/I_{r,0}^{\lceil s \rceil}, \underline{B}) = 0$ *for every* $i > 0$ *and every* $s \in \mathbb{R}_+$.

(ii) *The ring* $\underline{B}$ *satisfies condition* $(\mathrm{a})^{\mathrm{un}}_{\mathbf{f}}$ *of* (7.8.21).

Proof. (i): Denote by $\Gamma_0 \subset \Gamma$ the submonoid generated by $(\gamma_1/p^n, \dots, \gamma_r/p^n \mid n \in \mathbb{N})$, and let $\underline{B}_0 := \Gamma_0 \times_\Gamma \underline{B}$. Recall that $R_{r,0} := \mathbb{Z}[P_r]$, where $P_r := \mathbb{N}[1/p]^{\oplus r}$, and let $\varphi : P_r \to \Gamma_0$ be the unique morphism of monoids such that $\varphi(e_i) := \gamma_i$ for $i = 1, \dots, r$, where $(e_1, \dots, e_r)$ is the standard minimal system of generators of $\mathbb{N}^{\oplus r}$. With this notation, $R_{r,0}$ is a P_r-graded $\mathbb{Z}$-algebra, and we set $\underline{S} := (R_{r,0})_{/\Gamma_0}$ (see definition 7.6.1(v)). Then clearly u induces a morphism of Γ_0-graded $\mathbb{Z}$-algebras $\underline{S} \to \underline{B}_0$, and $\underline{B}$ can be regarded naturally as a Γ-graded $\underline{S}_{/\Gamma}$-module. We remark, quite generally :

Claim 16.6.6. Let $(\Delta, 0, +)$ be a monoid, $\Delta_0 \subset \Delta$ a submonoid such that the translation maps $\Delta \to \Delta : \delta \mapsto \delta + \delta_0$ are injective for every $\delta_0 \in \Delta_0$. Let also $\underline{S} = (S, \mathrm{gr}_\bullet S)$ be a Δ_0-graded $\mathbb{Z}$-algebra, N a Δ_0-graded $\underline{S}$-module, and M a Δ-graded $\underline{S}_{/\Delta}$-module. Then we have :

(i) The product $M' := \prod_{\delta \in \Delta} \mathrm{gr}_\delta M$ carries a natural S-module structure such that the natural map $M \to M'$ is S-linear.

(ii) The induced map $\tau_i : \mathrm{Tor}_i^S(N, M) \to \mathrm{Tor}_i^S(N, M')$ is injective, for every $i \in \mathbb{N}$.

Proof of the claim. (i): We define a $\mathbb{Z}$-bilinear map

$$\mu_{\delta_0} : \mathrm{gr}_{\delta_0} S \times M' \to M' \qquad \text{for every } \delta_0 \in \Delta_0$$

by the rule : $(s, (m_\delta \mid \delta \in \Delta)) \mapsto (m'_\delta \mid \delta \in \Delta)$, where $m'_\delta := s \cdot m_\gamma$ if there exists a (necessarily unique) $\gamma \in \Delta$ with $\gamma + \delta_0 = \delta$, and otherwise $m'_\delta := 0$. The sum of the maps μ_{δ_0} yields a well defined $\mathbb{Z}$-bilinear map

$$\mu : S \times M' \to M'$$

and it is easily seen that μ defines an S-module structure on M' with the sought property.

(ii): In view of remark 7.6.18(i), we may find a resolution $L_\bullet \to N$ by free S-modules such that L_i is a Δ_0-graded $\underline{S}$-module, and the differential $d_{i+1} : L_{i+1} \to L_i$ is a morphism of Δ_0-graded $\underline{S}$-modules, for every $i \in \mathbb{N}$. Then, for every $i \in \mathbb{N}$ the tensor product $P_i := L_i \otimes_S M$

carries a natural structure of Δ-graded $\underline{S}_{/\Delta}$-module : namely

$$\mathrm{gr}_\delta P_i := \mathrm{Im}\Big(\bigoplus_{(\delta_0,\gamma)\in D(\delta)} \mathrm{gr}_{\delta_0} L_i \otimes_{\mathbb{Z}} \mathrm{gr}_\gamma M \to P_i\Big) \qquad \text{for every } \delta \in \Delta$$

where $D(\delta)$ is the set of all pairs $(\delta_0, \gamma) \in \Delta_0 \times \Delta$ such that $\gamma + \delta_0 = \delta$. With this definition, it is then easily seen that the differential $d^P_{i+1} := d_{i+1} \otimes_S \mathbf{1}_M$ of $P_\bullet$ is a morphism of Δ-graded $\underline{S}_{/\Delta}$-modules, whence an induced Δ-graded $\underline{S}_{/\Delta}$-module structure on $\mathrm{Tor}^S_i(N, M)$, for every $i \in \mathbb{N}$. Moreover, we get a $\mathbb{Z}$-bilinear map

$$\psi : L_i \times M' \to P'_i := \prod_{\delta\in\Delta} \mathrm{gr}_\delta P_i \qquad \text{for every } i \in \mathbb{N}$$

namely, the unique one whose restriction $\mathrm{gr}_{\delta_0} L_i \times M' \to P'_i$ for every $\delta_0 \in \Delta_0$ is given by the rule : $(l, (m_\delta \mid \delta \in \Delta)) \mapsto (l \otimes m'_\delta \mid \delta \in \Delta)$, where $m'_\delta := m_\gamma$ if $\gamma + \delta_0 = \delta$, and $m'_\delta := 0$ if there is no such γ. Then it is easily seen that ψ is even S-bilinear, so it induces an S-linear map

$$L_i \otimes_S M' \to P'_i \qquad \text{for every } i \in \mathbb{N}.$$

Furthermore, the resulting diagram of S-linear maps

$$\begin{array}{ccc} L_{i+1} \otimes_S M' & \longrightarrow & P'_{i+1} \\ {\scriptstyle d_{i+1}\otimes_S \mathbf{1}_{M^\wedge}} \downarrow & & \downarrow {\scriptstyle \prod_{\delta\in\Delta} \mathrm{gr}_\delta d^P_{i+1}} \\ L_i \otimes_S M' & \longrightarrow & P'_i \end{array}$$

commutes for every $i \in \mathbb{N}$, and we deduce an S-linear map

$$\mathrm{Tor}^S_i(N, M') \to \prod_{\delta\in\Delta} \mathrm{gr}_\delta \mathrm{Tor}^S_i(N, M) \qquad \text{for every } i \in \mathbb{N}$$

whose composition with τ_i is the natural injection. The claim follows. ◊

Now, set $B' := \prod_{\gamma\in\Gamma} \mathrm{gr}_\gamma B$, endow B' with the linear topology defined as in remark 8.5.2(ii), and recall that the inclusion map $j : B \to B'$ factors through the inclusion map $B \to A$ and a continuous map $j_A : A \to B'$ (remark 8.5.2(iii)). Endow B' with the S-module structure provided by claim 16.6.6(i); a direct inspection of the proof of *loc.cit.* shows that scalar multiplication by any homogeneous element s of S defines a continuous endomorphism of B', and on the other hand we have $j(s \cdot b) = s \cdot j(b)$ for every such s and every $b \in B$; since j is also a continuous map, we deduce that the same identity holds more generally for every $b \in A$, *i.e.* j_A is an S-linear map. Lastly, notice that the ideal $I^{[s]}_{r,0}$ of $\underline{S}$ is Γ_0-graded, so $R_{r,0}/I^{[s]}_{r,0}$ is a Γ_0-graded $\underline{S}$-module for every $s \in \mathbb{R}_+$. By claim 16.6.6, it follows that the composition of the two natural maps

$$\mathrm{Tor}^{R_{r,0}}_i(R_{r,0}/I^{\lceil s\rceil}_{r,0}, \underline{B}) \to \mathrm{Tor}^{R_{r,0}}_i(R_{r,0}/I^{\lceil s\rceil}_{r,0}, A) \to \mathrm{Tor}^{R_{r,0}}_i(R_{r,0}/I^{\lceil s\rceil}_{r,0}, B')$$

is injective for every $i \in \mathbb{N}$; on the other hand, the middle term vanishes for $i > 0$, due to proposition 16.4.10(i), whence the contention.

(ii) follows from (i) and lemma 16.4.5(i). □

16.6.7. We consider now a perfectoid quasi-affinoid ring (A, A^+, U_A), and let $(\mathbf{E}, \mathbf{E}^+, U_{\mathbf{E}}) := \mathbf{E}(A, A^+, U_A)$ (see (16.5.20)). Set as well $X_A := \mathrm{Spec}\, A$, $X_{\mathbf{E}} := \mathrm{Spec}\, \mathbf{E}$, and define as usual the f-adic rings $A_U := \mathscr{O}_{X_A}(U_A)$ and $\mathbf{E}_U := \mathscr{O}_{X_{\mathbf{E}}}(U_{\mathbf{E}})$, so that the restriction maps $A \to A_U$ and $\mathbf{E} \to \mathbf{E}_U$ are open, hence the image $\overline{A}$ of A (resp. $\overline{\mathbf{E}}$ of $\mathbf{E}$) is open in A_U (resp. in $\mathbf{E}_U$), and we endow it with the topology induced by the projection $A \to \overline{A}$ (resp. $\mathbf{E} \to \overline{\mathbf{E}}$). Suppose we are given a family $(\mathscr{K}_\gamma \mid \gamma \in \Gamma)$ consisting of topologically closed 1-taut bounded $\overline{\mathbf{E}}$-submodules of $\mathbf{E}_U$, indexed by a p-perfect monoid $(\Gamma, +, 0)$, and such that (notation of (16.5.28)) :

(a) $1 \in \mathscr{K}_0$
(b) $\mathscr{K}_{p\gamma} = \mathscr{K}_\gamma^p$ for every $\gamma \in \Gamma$
(c) $\mathscr{K}_\gamma \cdot \mathscr{K}_\mu \subset \mathscr{K}_{\gamma+\mu}$ for every $\gamma, \mu \in \Gamma$

(notice that, in terms of the descending filtration $\mathrm{Fil}^\bullet \mathbf{E}_U$ defined in (16.5.23), a subset of $\mathbf{E}_U$ is bounded if and only if it lies in $\mathrm{Fil}^s \mathbf{E}_U$, for some $s \in \mathbb{Z}[1/p]$). Set

$$\mathscr{E} := \bigoplus_{\gamma\in\Gamma} \mathscr{K}_\gamma \qquad \mathscr{A} := \bigoplus_{\gamma\in\Gamma} \{\mathscr{K}_\gamma\}.$$

It is easily seen that the multiplication of $\mathbf{E}_U$ (resp. of A_U) induces a Γ-graded $\overline{\mathbf{E}}$-algebra structure (resp. $\overline{A}$-algebra structure) on $\mathscr{E}$ (resp. on $\mathscr{A}$). Choose ideals of definition J for A and $\mathscr{J}$ for $\mathbf{E}$, and endow $\mathscr{E}$ (resp. $\mathscr{A}$) with its $\mathscr{J}$-adic (resp. J-adic) topology. Let also $\mathscr{E}^\wedge$ (resp. $\mathscr{A}^\wedge$) be the separated completion of $\mathscr{E}$ (resp. of $\mathscr{A}$).

Lemma 16.6.8. *The pairs*

$$(\mathscr{E}^\wedge, \mathscr{E}) \qquad \textit{and} \qquad (\mathscr{A}^\wedge, \mathscr{A})$$

are topological rings with Γ*-graded structures.*

Proof. Indeed, the assertion comes down to checking that $\mathscr{K}_\gamma$ (resp. $\{\mathscr{K}_\gamma\}$) is a closed subset of $\mathscr{E}^\wedge$ (resp. of $\mathscr{A}^\wedge$) for every $\gamma \in \Gamma$, and notice that the topological closure of $\mathscr{K}_\gamma$ in $\mathscr{E}^\wedge$ (resp. of $\{\mathscr{K}_\gamma\}$ in $\mathscr{A}^\wedge$) is the $\mathscr{J}$-adic (resp. J-adic) completion of $\mathscr{K}_\gamma$ (resp. of $\{\mathscr{K}_\gamma\}$). Now, by assumption $\mathscr{K}_\gamma$ is bounded in $\mathbf{E}_U$, so $\{\mathscr{K}_\gamma\}$ is bounded in A_U, for every $\gamma \in \Gamma$; it follows that the topology $\mathscr{T}_\gamma$ on $\mathscr{K}_\gamma$ (resp. on $\{\mathscr{K}_\gamma\}$) induced by the inclusion into $\mathbf{E}_U$ (resp. into A_U) is coarser than the $\mathscr{J}$-adic (resp. J-adic) topology; on the other hand, $\mathscr{T}_\delta$ is complete and separated, since the same holds for the topology of $\mathbf{E}_U$ (resp. of A_U). Then lemma 8.3.12 implies that $\mathscr{K}_\gamma$ (resp. $\{\mathscr{K}_\gamma\}$) is complete and separated for its $\mathscr{J}$-adic (resp. J-adic) topology, whence the contention. □

Proposition 16.6.9. *With the notation of* (16.6.7)*, the following holds :*

(i) *The rings* $\mathscr{E}^\wedge$*, and* $\mathscr{A}^\wedge$ *are perfectoid.*
(ii) *There is a natural isomorphism of topological rings with* Γ*-graded structures*

$$\mathbf{E}(\mathscr{A}^\wedge, \mathscr{A}) \xrightarrow{\sim} (\mathscr{E}^\wedge, \mathscr{E}).$$

Proof. Taking into account remark 9.4.9(v) and example 9.3.48(ii), it is easily seen that $\mathscr{E}^\wedge$ is a perfect topological $\mathbf{E}$-algebra, hence it is perfectoid (see example 16.3.2(i)). Set

$$(\mathscr{W}^\wedge, \mathscr{W}) := W(\mathscr{E}^\wedge, \mathscr{E}) \qquad (\overline{\mathscr{W}}^\wedge, \overline{\mathscr{W}}) := (\mathscr{W}^\wedge, \mathscr{W}) \otimes_{W(\mathbf{E})} A.$$

To prove both assertions, it will therefore suffice to exhibit isomorphisms

$$(\overline{\mathscr{W}}^\wedge, \overline{\mathscr{W}}) \xrightarrow{\sim} (\mathscr{A}^\wedge, \mathscr{A}) \tag{16.6.10}$$

of topological A-algebras with Γ-graded structures. We shall first exhibit a continuous map

$$u_\mathscr{A} : (\mathscr{W}^\wedge, \mathscr{W}) \to (\mathscr{A}^\wedge, \mathscr{A}).$$

To this aim, define $W(\mathscr{K}_\gamma)$ as in lemma 16.5.45, and notice that condition (b) of (16.6.7) yields:

$$\mathrm{gr}_\gamma \mathscr{W} = W(\mathscr{K}_\gamma) \qquad \text{for every } \gamma \in \Gamma$$

and the multiplication law of $\mathscr{W}$ is the unique bilinear map $\mathscr{W} \times \mathscr{W} \to \mathscr{W}$ whose restriction

$$W(\mathscr{K}_\gamma) \times W(\mathscr{K}_\mu) \to W(\mathscr{K}_{\delta+\gamma})$$

is induced by the multiplication law of $W(\mathbf{E}_U)$, for every $\gamma, \mu \in \Gamma$. Also, since $\mathscr{K}_\gamma$ is closed and 1-taut, lemma 16.5.45(iv) says that u_U restricts to a well defined surjective map

$$\mathrm{gr}_\gamma u_\mathscr{A} : W(\mathscr{K}_\gamma) \to \mathrm{gr}_\gamma \mathscr{A} \qquad \text{for every } \gamma \in \Gamma$$

whose kernel is $\underline{\alpha}W(\mathscr{K}_\gamma)$, for any distinguished element $\underline{\alpha}$ of $\mathrm{Ker}\, u_A$. Summing up, we conclude that the direct sum of the system of maps $(\mathrm{gr}_\gamma u_{\mathscr{A}} \mid \gamma \in \Gamma)$ is a well defined surjective ring homomorphism $\mathrm{gr}_\bullet u_{\mathscr{A}}$ that makes commute the diagram

$$\begin{array}{ccc} W(\mathbf{E}) & \xrightarrow{u_A} & A \\ \downarrow & & \downarrow \\ \mathscr{W} & \xrightarrow{\mathrm{gr}_\bullet u_{\mathscr{A}}} & \mathscr{A} \end{array} \tag{16.6.11}$$

and with kernel equal to $\underline{\alpha}\mathscr{W}$. Moreover, it follows easily from propositions 9.3.77(ii) and 8.5.11(i.b) that the left vertical map of (16.6.11) is an adic ring homomorphism, and the same obviously holds for the right vertical map. Since u_A is an open map, we deduce that $\mathrm{gr}_\bullet u_{\mathscr{A}}$ is continuous and open as well; especially, it extends to a well defined continuous surjective ring homomorphism $u_{\mathscr{A}}$ as sought, whose kernel is the topological closure of $\underline{\alpha}\mathscr{W}$ in $\mathscr{W}^\wedge$ (proposition 8.2.13). However, recall that $\underline{\alpha}\mathscr{W}^\wedge$ is a closed ideal of $\mathscr{W}^\wedge$ (proposition 16.2.21(ii)), and obviously $\underline{\alpha}\mathscr{W}$ is dense in it, hence the kernel of $u_{\mathscr{A}}$ is $\underline{\alpha}\mathscr{W}^\wedge$, as required. Lastly, since $\mathrm{gr}_\bullet u_{\mathscr{A}}$ is an open map, the same holds for $u_{\mathscr{A}}$, and the proof is concluded. □

Example 16.6.12. In the situation of (16.6.7), let $\varphi^\flat_U : \mathbf{E}_U \to A_U$ be the continuous morphism of topological monoids furnished by proposition 16.4.34(i). Let also $\beta_\bullet := (\beta_\lambda \mid \lambda \in \Lambda)$ be any bounded system of elements of $\mathbf{E}_U$. We consider the unique morphism of monoids

$$\varphi_{\mathbf{E}} : P := \mathbb{N}[1/p]^{(\Lambda)} \to \mathbf{E}_U \qquad e_\lambda \mapsto \beta_\lambda \qquad \text{for every } \lambda \in \Lambda$$

where $e_\bullet := (e_\lambda \mid \lambda \in \Lambda)$ is the standard minimal set of generators of $\mathbb{N}^{(\Lambda)}$. Let also $I \subset P$ be the ideal generated by $e_\bullet$. The composition $\varphi_A : \varphi^\flat_U \circ \varphi_{\mathbf{E}} : P \to A$ is also a morphism of monoids, and we let $I^{\langle\delta\rangle}\overline{\mathbf{E}}$ (resp. $I^{\langle\delta\rangle}\overline{A}$) be the $\overline{\mathbf{E}}$-submodule of $\mathbf{E}_U$ generated by $\varphi_{\mathbf{E}}(I^{\langle\delta\rangle})$ (resp. the $\overline{A}$-submodule of A_U generated by $\varphi_A(I^{\langle\delta\rangle})$), for every $\delta \in \Delta := \mathbb{N}[1/p]$ (notation of (9.3.68)). We denote by $\mathrm{gr}_\delta\mathscr{E}$ (resp. $\mathrm{gr}_\delta\mathscr{A}$) the topological closure of $I^{\langle\delta\rangle}\overline{\mathbf{E}}$ in $\mathbf{E}_U$ (resp. of $I^{\langle\delta\rangle}\overline{A}$ in A_U) for every $\delta \in \Delta$ (notation of remark 9.3.70(i)). We set

$$\mathscr{E}(\beta_\bullet) := \bigoplus_{\delta\in\Delta} \mathrm{gr}_\delta\mathscr{E} \qquad \mathscr{A}(\beta_\bullet) := \bigoplus_{\delta\in\Delta} \mathrm{gr}_\delta\mathscr{A}.$$

Hence, $\mathscr{E}(\beta_\bullet)$ is a Δ-graded $\mathbf{E}$-algebra, and $\mathscr{A}(\beta_\bullet)$ is a Δ-graded A-algebras. We endow $\mathscr{E}(\beta_\bullet)$ with the $\mathscr{J}$-adic topology and $\mathscr{A}(\beta_\bullet)$ with the J-adic topology, and let $\mathscr{E}(\beta_\bullet)^\wedge$ and $\mathscr{A}(\beta_\bullet)^\wedge$ be the respective separated completion. It is easily seen that $\mathrm{gr}_\delta\mathscr{E}$ is 1-taut and bounded in $\mathbf{E}_U$, and moreover $\mathrm{gr}_{p\delta}\mathscr{E} = (\mathrm{gr}_\delta\mathscr{E})^p$ for every $\delta \in \Delta$; furthermore, $\mathrm{gr}_\delta\mathscr{A} = \{\mathrm{gr}_\delta\mathscr{E}\}$ for every such δ. Then proposition 16.6.9 shows that $(\mathscr{E}(\beta_\bullet)^\wedge, \mathscr{E}(\beta_\bullet))$, and $(\mathscr{A}(\beta_\bullet)^\wedge, \mathscr{A}(\beta_\bullet))$ are perfectoid rings with Δ-graded structures, and we have a natural isomorphism of topological rings with Δ-graded structures :

$$\mathbf{E}(\mathscr{A}(\beta_\bullet)^\wedge, \mathscr{A}(\beta_\bullet)) \xrightarrow{\sim} (\mathscr{E}(\beta_\bullet)^\wedge, \mathscr{E}(\beta_\bullet)).$$

Example 16.6.13. In the situation of (16.5.23), let $\Gamma := \mathbb{Z}[1/p]$; the family $(\mathrm{Fil}^\gamma\mathbf{E}_U \mid \gamma \in \Gamma)$ fulfills conditions (a)–(c) of (16.6.7), and taking into account corollary 16.5.42 and proposition 16.6.9, we get perfectoid rings with Γ-graded structures $(\mathscr{E}^\wedge_U, \mathscr{E}_U)$ and $(\mathscr{A}^\wedge_U, \mathscr{A}_U)$, by setting

$$\mathscr{E}_U := \bigoplus_{\gamma\in\Gamma} \mathrm{Fil}^\gamma\mathbf{E}_U \qquad \mathscr{A}_U := \bigoplus_{\gamma\in\Gamma} \mathrm{Fil}^\gamma A_U$$

as well as a natural isomorphism of topological rings with Γ-graded structures

$$\mathbf{E}(\mathscr{A}^\wedge_U, \mathscr{A}_U) \xrightarrow{\sim} (\mathscr{E}^\wedge_U, \mathscr{E}_U). \tag{16.6.14}$$

Moreover, by inspecting the proof of proposition 16.6.9 it is easily seen that – under the identification (16.6.14) – the restriction $\mathrm{gr}_\gamma\mathscr{E}_U \to \mathrm{gr}_\gamma\mathscr{A}_U$ of the map $\overline{u}_{\mathscr{A}^\wedge_U} : \mathscr{E}^\wedge_U \to \mathscr{A}^\wedge_U$ agrees with the restriction $\mathrm{Fil}^\gamma\mathbf{E}_U \to \mathrm{Fil}^\gamma A_U$ of the map $\varphi^\flat_U : \mathbf{E}_U \to A_U$, for every $\gamma \in \Gamma$.

16.6.15. Let Γ be a p-perfect monoid, $(A^\wedge, A)$ a perfectoid ring with Γ-graded structure, set $(\mathbf{E}^\wedge, \mathbf{E}) := \mathbf{E}(A^\wedge, A)$ and let $\underline{\alpha} \in W(\mathrm{gr}_0\mathbf{E})$ be a distinguished element of $\mathrm{Ker}\, u_A$ (see proposition 16.6.1(iii)). We denote by $\overline{u}_A : \mathbf{E} \to A$ the restriction of the map $u_{A^\wedge} : \mathbf{E}^\wedge \to A^\wedge$. For every integer $n > 0$ let

$$\lambda_n := \sum_{i=0}^{n-1} p^{-i} \qquad S_n := \{(i,j) \in \mathbb{N}[1/p]^{\oplus 2} \mid \lambda_n \leq i < n \quad \text{and} \quad 1 > j > 1 - i/n\}$$

and for every $\gamma \in \Gamma$ and every $e \in \mathrm{gr}_\gamma\mathbf{E}$, define the $\mathrm{gr}_0 A$-module

$$\mathscr{I}(e, n, \gamma) := \sum_{(i,j)\in S_n} \mathrm{gr}_{(1-j)\gamma} A \cdot \overline{u}_A(\alpha_0^i \cdot e^j).$$

Proposition 16.6.16. *With the notation of* (16.6.15)*, let $\gamma \in \Gamma$ and $a \in \mathrm{gr}_\gamma A$ be any elements. Then, for every integer $n > 0$ there exists $e \in \mathrm{gr}_\gamma\mathbf{E}$ such that*

$$a - \overline{u}_A(e) \in \mathscr{I}(e, n, \gamma) + p^n \cdot \mathrm{gr}_\gamma A.$$

Proof. Notice that the assertion is independent of the topology $\mathscr{T}_{A^\wedge}$ of $A^\wedge$, so we may assume that $\mathscr{T}_{A^\wedge}$ is the p-adic topology of $A^\wedge$ (proposition 16.3.8(i)). We argue by induction on $n \in \mathbb{N}$. For $n = 1$, we have $S_1 = \varnothing$, and the assertion means that there exists $e \in \mathrm{gr}_\gamma\mathbf{E}$ such that $a - \overline{u}_A(e) \in p \cdot \mathrm{gr}_\gamma A$. Hence, let $\pi : A \to A/pA$ be the projection; it suffices to remark :

Claim 16.6.17. The map $\pi \circ \overline{u}_A : \mathbf{E} \to A/pA$ is surjective.

Proof of the claim. The assertion follows easily from claim 16.6.2(i). ◊

Thus, suppose that the proposition has already been proven for some $n \geq 1$, for every $\gamma \in \Gamma$ and every $a \in \mathrm{gr}_\gamma A$. We notice :

Claim 16.6.18. (i) For every $\delta \in \Gamma$, every $b \in \mathrm{gr}_\delta A$ and every $k \in \mathbb{N}$ there exist a sequence $(\beta_0, \dots, \beta_k)$ of elements of $\mathrm{gr}_\delta\mathbf{E}$, and an element $d \in \mathrm{gr}_\delta A$ such that

$$b = \sum_{i=0}^{k} p^i \cdot \overline{u}_A(\beta_i) + p^{k+1} d. \qquad (16.6.19)$$

(ii) There exist elements $c \in \mathrm{gr}_\gamma A$, $e_n \in \mathrm{gr}_\gamma\mathbf{E}$, a finite set Λ, a system of positive integers $(k_\lambda \mid \lambda \in \Lambda)$, a mapping $\Lambda \to S_n : \lambda \mapsto (i_\lambda, j_\lambda)$, a system $(f_\lambda \mid \lambda \in \Lambda)$ with $f_\lambda \in \mathrm{gr}_{(1-j_\lambda)\gamma}\mathbf{E}$ for every $\lambda \in \Lambda$, such that

$$a = \overline{u}_A(e_n) + \sum_{\lambda\in\Lambda} k_\lambda \cdot \overline{u}_A(f_\lambda \cdot \alpha_0^{i_\lambda} \cdot e_n^{j_\lambda}) + p^n c. \qquad (16.6.20)$$

(iii) There exists $f \in \mathrm{gr}_0\mathbf{E}$ such that $p^n - \overline{u}_A(\alpha_0 \cdot f)^n \in p^{n+1}\mathrm{gr}_0 A$ for every $n \in \mathbb{N}$.

Proof of the claim. (i): We argue by induction on k, and notice that the assertion for $k = 0$ follows from the case $n = 1$ of the proposition, which is already known. Thus, suppose that $k \in \mathbb{N}$, and that we have already found a sequence $(\beta_0, \dots, \beta_k)$ such that (16.6.19) holds. Then we may also find $\beta_{k+1} \in \mathrm{gr}_\delta\mathbf{E}$ and $d' \in \mathrm{gr}_\delta A$ such that $d = \overline{u}_A(\beta_{k+1}) + pd'$, and replacing this expression for d in (16.6.19) we get the sought identity for $k + 1$.

(ii): By inductive assumption, there exist a finite subset $T \subset S_n$ and for every $(i,j) \in T$ an element $b_{(i,j)} \in \mathrm{gr}_{(1-j)\gamma} A$ such that

$$a = \overline{u}_A(e_n) + \sum_{(i,j)\in T} b_{(i,j)} \cdot \overline{u}_A(\alpha_0^i \cdot e_n^j) + p^n d \qquad \text{for some } e_n \in \mathrm{gr}_\gamma\mathbf{E} \text{ and } d \in \mathrm{gr}_\gamma A.$$

By (i), we may then find, for every $(i,j) \in T$, a system $(f_{(i,j),0}, \dots, f_{(i,j),n-1})$ of elements of $\mathrm{gr}_{(1-j)\gamma}\mathbf{E}$ and an element $c_{(i,j)} \in \mathrm{gr}_{(1-j)\gamma}A$ such that $b_{(i,j)} = \sum_{i=0}^{n-1} p^i \cdot \overline{u}_A(f_{(i,j),i}) + p^n c_{(i,j)}$. Hence, the sought identity holds with

$$c := d + \sum_{(i,j)\in T} c_{(i,j)} \cdot \overline{u}_A(\alpha_0^i \cdot e_n^j) \qquad \Lambda := T \times \{0, \dots, n-1\} \qquad k_{(t,s)} := p^s \quad \text{for every } (t,s) \in \Lambda$$

and with the mapping $\Lambda \to S_n : (t,k) \mapsto t$.

(iii): By lemma 16.2.7(iii), there exists $x \in A^\wedge$ such that $p = \overline{u}_A(\alpha_0) \cdot x$. Let $\pi_0^\wedge : A^\wedge \to \mathrm{gr}_0 A$ be the canonical 0-projection (see remark 8.5.2(iii)); it follows that $p = \overline{u}_A(\alpha_0) \cdot \pi_0^\wedge(x)$, so we may assume that $x \in \mathrm{gr}_0 A$. By (i), we have $y_0 := x - \overline{u}_A(f) \in p \cdot \mathrm{gr}_0 A$ for some $f \in \mathbf{E}$, and we check, by induction on n, that such f will do. Indeed, for $n = 0$ the assertion is trivial, and for $n = 1$ we have

$$p = \overline{u}_A(\alpha_0) \cdot (y_0 + \overline{u}_A(f)) = \overline{u}_A(\alpha_0 \cdot f) + y_0 \cdot \overline{u}_A(\alpha_0)$$

and $y_1 := y_0 \cdot \overline{u}_A(\alpha_0) = p y_0 \cdot \pi_0^\wedge(x^{-1}) \in p^2 \cdot \mathrm{gr}_0 A$, again by lemma 16.2.7(iii). Suppose now that $n \geq 1$, and that we have already shown that $y_n := p^n - \overline{u}_A(\alpha_0 \cdot f)^n \in p^{n+1}\mathrm{gr}_0 A$. We compute

$$\begin{aligned} p y_n &= p^{n+1} - p \cdot \overline{u}_A(\alpha_0 \cdot f)^n \\ &= p^{n+1} - (y_1 + \overline{u}_A(\alpha_0 \cdot f)) \cdot \overline{u}_A(\alpha_0 \cdot f)^n \\ &= p^{n+1} - \overline{u}_A(\alpha_0 \cdot f)^{n+1} - y_1 \cdot \overline{u}_A(\alpha_0 \cdot f)^n \end{aligned}$$

Since both $p y_n$ and $y_1 \cdot \overline{u}_A(\alpha_0 \cdot f)^n = p^n y_1 \cdot \overline{u}_A(f)^n \cdot \pi_0^\wedge(x^{-n})$ lie in $p^{n+2}\mathrm{gr}_0 A$, the assertion follows for $n+1$. ◊

Pick any identity (16.6.20) as provided by claim 16.6.18(ii), and any $f \in \mathrm{gr}_0\mathbf{E}$ such that claim 16.6.18(iii) holds; by claim 16.6.18(i) we may also find $g \in \mathrm{gr}_\gamma \mathbf{E}$ such that $c - \overline{u}_A(g) \in p \cdot \mathrm{gr}_\gamma A$, and notice that, after replacing the set Λ by $\bigcup_{\lambda\in\Lambda} \{\lambda\} \times \{1, \dots, k_\lambda\}$, we may also assume that $k_\lambda = 1$ for every $\lambda \in \Lambda$, so that

$$a = \overline{u}_A(e_n) + \sum_{\lambda\in\Lambda} \overline{u}_A(f_\lambda \cdot \alpha_0^{i_\lambda} \cdot e_n^{j_\lambda}) + \overline{u}_A(g \cdot \alpha_0^n \cdot f^n) + p^{n+1} d \qquad \text{for some } d \in \mathrm{gr}_\gamma A.$$

We let $S'_n := \{(i,j) \in \mathbb{N}[1/p]^{\oplus 2} \mid \lambda_{n+1} \leq i < n+1, \ nj + i \geq 1 + n \ \text{ and } \ j < 1\}$ and we set

$$\delta := \sum_{\lambda\in\Lambda} f_\lambda \cdot \alpha_0^{i_\lambda} \cdot e_n^{j_\lambda} \qquad \text{and} \qquad e_{n+1} := e_n + \delta + g \cdot \alpha_0^n \cdot f^n.$$

Claim 16.6.21. There exists a finite subset Λ' with a mapping $\Lambda' \to S'_n : \lambda \mapsto (i'_\lambda, j'_\lambda)$, and for every $\lambda \in \Lambda'$ an element $z_\lambda \in \mathrm{gr}_{(1-j'_\lambda)\gamma} A$ such that

$$a = \overline{u}_A(e_{n+1}) + \sum_{\lambda\in\Lambda'} z_\lambda \cdot \overline{u}_A(\alpha_0^{i'_\lambda} \cdot e_n^{j'_\lambda}) + p^{n+1} d' \qquad \text{for some } d' \in \mathrm{gr}_\gamma A.$$

Proof of the claim. For every $r = 1, \dots, n$, let Λ'_r be the subset of all sequences $\underline{\sigma} := (\sigma_0, \sigma_1, \sigma_\lambda \mid \lambda \in \Lambda)$ of elements of $p^{-r}\mathbb{N} \setminus p^{1-r}\mathbb{N}$ such that $\sigma_0 + \sigma_1 + \sum_{\lambda\in\Lambda} \sigma_\lambda = 1$, and set $\Lambda' := \bigcup_{r=1}^n \Lambda'_r$. Let also $x := a - \overline{u}_A(e_{n+1})$; according to proposition 9.3.62, there exist a mapping $\Lambda' \to \mathbb{Z}_p : \underline{\sigma} \mapsto z'_{\underline{\sigma}}$ and an element $d' \in \mathrm{gr}_\gamma A$ such that

$$\begin{aligned} x &= \sum_{r=1}^n p^r \cdot \sum_{\underline{\sigma}\in\Lambda'_r} z'_{\underline{\sigma}} \cdot \overline{u}_A\Big(e_n^{\sigma_0} \cdot g^{\sigma_1} \cdot f^{n\sigma_1} \cdot \alpha_0^{n\sigma_1} \cdot \prod_{\lambda\in\Lambda} f_\lambda^{\sigma_\lambda} \cdot \alpha_0^{\sigma_\lambda i_\lambda} \cdot e_n^{\sigma_\lambda j_\lambda}\Big) + p^{n+1} d' \\ &= \sum_{r=1}^n p^r \cdot \sum_{\underline{\sigma}\in\Lambda'_r} z'_{\underline{\sigma}} \cdot \overline{u}_A(f'_{\underline{\sigma}} \cdot \alpha_0^{i''_{\underline{\sigma}}} \cdot e_n^{j'_{\underline{\sigma}}}) + p^{n+1} d' \end{aligned}$$

where

$$f'_{\underline{\sigma}} := g^{\sigma_1} \cdot f^{n\sigma_1} \cdot \prod_{\lambda\in\Lambda} f_\lambda^{\sigma_\lambda} \qquad i''_{\underline{\sigma}} := n\sigma_1 + \sum_{\lambda\in\Lambda} \sigma_\lambda i_\lambda \qquad j'_{\underline{\sigma}} := \sigma_0 + \sum_{\lambda\in\Lambda} \sigma_\lambda j_\lambda \qquad \text{for every } \underline{\sigma} \in \Lambda'.$$

Let us remark that

$$(16.6.22)\quad j'_{\underline{\sigma}} + \frac{i''_{\underline{\sigma}}}{n} = \sigma_0 + \sigma_1 + \sum_{\lambda\in\Lambda} \sigma_\lambda \cdot \Big(j_\lambda + \frac{i_\lambda}{n}\Big) \geq \sigma_0 + \sigma_1 + \sum_{\lambda\in\Lambda} \sigma_\lambda = 1 \quad \text{for every } \underline{\sigma} \in \Lambda'.$$

Moreover, we notice that

$$(16.6.23)\qquad 1 > j'_{\underline{\sigma}} \qquad \text{and} \qquad n > i''_{\underline{\sigma}} \geq \frac{\lambda_n}{p^r} \qquad \text{for every } r = 1, \dots, n \text{ and every } \underline{\sigma} \in \Lambda'_r.$$

Indeed, the first inequality is immediate, since $\sigma_0 < 1$; the second inequality is clear if $\sigma_\lambda \neq 0$ for at least one index $\lambda \in \Lambda$, since in this case $\sigma_\lambda \geq p^{-r}$ and $i''_{\underline{\sigma}} < n\sigma_1 + n\sum_{\lambda\in\Lambda} \sigma_\lambda < n$. If $\sigma_\lambda = 0$ for every $\lambda \in \Lambda$, we must have $1 > \sigma_1 > 0$, since otherwise we would get $\sigma_0, \sigma_1 \in \mathbb{N}$, which is absurd; hence, in this case $1 > \sigma_1 \geq p^{-r}$, so $n > i''_{\underline{\sigma}} \geq n/p^r \geq \lambda_n/p^r$.

Next, for every $r = 1, \dots, n$ and every $\underline{\sigma} \in \Lambda'_r$, we may find $z_{\underline{\sigma}} \in \mathrm{gr}_{(1-j'_{\underline{\sigma}})\gamma} A$ such that

$$p^r \cdot z'_{\underline{\sigma}} \cdot \overline{u}_A(f'_{\underline{\sigma}}) = z_{\underline{\sigma}} \cdot \overline{u}_A(\alpha_0^r)$$

(cp. the proof of claim 16.6.18(iii)). Hence, if we set

$$i'_{\underline{\sigma}} := i''_{\underline{\sigma}} + r \qquad \text{for every } r = 1, \dots, n \text{ and every } \underline{\sigma} \in \Lambda'_r$$

we get an expression for a of the sought type, and it remains only to check that $(i'_{\underline{\sigma}}, j'_{\underline{\sigma}}) \in S'_n$ for every $\underline{\sigma} \in \Lambda'$. However, from (16.6.23) we see that $i'_{\underline{\sigma}} \geq 1 + \lambda_n/p = \lambda_{n+1}$ if $\underline{\sigma} \in \Lambda'_1$, and $i'_{\underline{\sigma}} \geq 2 + \lambda_n/p^2 > \lambda_{n+1}$ if $\underline{\sigma} \in \Lambda'_r$ for some $r > 1$. Lastly, from (16.6.22) we get $i''_{\underline{\sigma}} + j'_{\underline{\sigma}} \cdot n \geq n$ for every $\underline{\sigma} \in \Lambda'$, whence $i'_{\underline{\sigma}} + j'_{\underline{\sigma}} \cdot n \geq n + 1$, and the proof is complete. ◊

Let I (resp. J) be the ideal of $\mathbf{E}$ generated by the system (α_0^n, e_n) (resp. by $(\alpha_0^n, e_n + \delta)$) and set $q := \min(j + i/n \mid (i, j) \in \Lambda)$; then $\delta \in \mathrm{i.c.}(I, \mathbf{E}, q)$, and the radical of I equals the radical of J. Since $q > 1$, lemma 9.3.74(ii) shows therefore that

$$I^{\langle 1\rangle}\mathbf{E} = J^{\langle 1\rangle}\mathbf{E}$$

and consequently $e_n^t \in J^{\langle t\rangle}\mathbf{E}$ for every $t \in \mathbb{N}[1/p]$. Notice that (α_0^n, e_{n+1}) is another system of generators for J. Since the topology of A is p-adic, it follows that for every $t \in \mathbb{N}[1/p]$ there exist a finite subset $T_t \subset \mathbb{N}[1/p]$ with $0 \leq \sigma \leq t$ for every $\sigma \in T_t$, and a system $(h'_\sigma \mid \sigma \in T_t)$ of elements of $A^\wedge$ such that

$$\overline{u}_A(e_n^t) = \sum_{\sigma\in T_t} h'_\sigma \cdot \overline{u}_A(\alpha_0^{n\sigma} \cdot e_{n+1}^{t-\sigma})$$

(corollary 16.3.40(ii)); after replacing h'_σ with its canonical $\sigma\gamma$-projection, we may also assume that $h'_\sigma \in \mathrm{gr}_{\sigma\gamma} A$ for every $\sigma \in T_t$. Now, pick an expression for a as in claim 16.6.21; to conclude the proof, it suffices to show that $\overline{u}_A(\alpha_0^{i'_\lambda} \cdot e_n^{j'_\lambda}) \in \mathscr{I}(e_{n+1}, n+1, \gamma) + p^{n+1} \cdot \mathrm{gr}_{j'_\lambda\gamma} A$ for every $\lambda \in \Lambda'$. To ease notation, set $(s, t) := (i'_\lambda, j'_\lambda)$; we see that

$$\overline{u}_A(\alpha_0^s \cdot e_n^t) = \sum_{\sigma\in T_t} h'_\sigma \cdot \overline{u}_A(\alpha_0^{s+n\sigma} \cdot e_{n+1}^{t-\sigma}).$$

Now, since $(s, t) \in S'_n$, we have $s + n\sigma \geq s \geq \lambda_{n+1}$ for every $\sigma \in T'_t$. Moreover :

$$s + n\sigma + (t - \sigma) \cdot (n + 1) = s + nt + t - \sigma \geq n + 1 + t - \sigma.$$

Recall also that $s + nt \geq n + 1$; therefore, if $s + n\sigma < n + 1$, we must have $t - \sigma > 0$, so the pair $(s + n\sigma, t - \sigma)$ lies in S_{n+1}; lastly, if $s + n\sigma \geq n + 1$, the term $\overline{u}_A(\alpha_0^{s+n\sigma} \cdot e_{n+1}^{t-\sigma})$ lies in $p^{n+1} \cdot \mathrm{gr}_{(t-\sigma)\gamma} A$, whence $h'_\sigma \cdot \overline{u}_A(\alpha_0^{s+n\sigma} \cdot e_{n+1}^{t-\sigma}) \in p^{n+1} \cdot \mathrm{gr}_{t\gamma} A$ and the assertion follows. □

Corollary 16.6.24. *Let A be a perfectoid ring, and $a \in A$ such that $p^k \in Aa$ for some $k \in \mathbb{N}$. Then there exist $t \in A^\times$, $s \in A$, and $e \in \mathbf{E}(A)$ such that $a = t \cdot \overline{u}_A(e)$ and $p = s \cdot \overline{u}_A(e^{1/p^k})$.*

Proof. In view of proposition 16.3.8(ii), we may assume that the topology of A is p-adic, and then the topology of $\mathbf{E} := \mathbf{E}(A)$ is α_0-adic, where $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N}) \in W(\mathbf{E})$ is a distinguished element of $\mathrm{Ker}(u_A)$ (remark 16.3.7(iii)). Also, the case $k = 0$ is trivial, so we may assume that $k > 0$. We apply proposition 16.6.16 to A (graded with by the trivial monoid $\Gamma = \{0\}$), its element a, and with $n := p^{4k}$. With the notation of (16.6.15), notice that for every $(i,j) \in S_n$ we have either $i \in [p^k, n[$, in which case $i \geq k+1$ and $\overline{u}_A(\alpha_0^i) \in p^{k+1}A$ (lemma 16.2.7(iii)), or else $i \in [\lambda_n, p^k[$, in which case $j > 1 - p^{-3k}$. Consequently, we get $e \in \mathbf{E}$ and $b, c \in A$ with :

$$a - \overline{u}_A(e) \in \overline{u}_A(\alpha_0^{1+p^{-k}} e^{1-p^{-3k}})b + p^{k+1}c.$$

By assumption, $p^k = ad$ for some $d \in A$, so that $a - p^{k+1}c = a(1 - cdp)$, and notice that $x := 1 - cdp \in A^\times$; hence $a = x^{-1} \cdot \overline{u}_A(e^{1-p^{-3k}}) \cdot (\overline{u}_A(\alpha_0^{1+p^{-k}}) + \overline{u}_A(e^{p^{-3k}}))$, and in particular :

$$p^k \in \overline{u}_A(e^{1-p^{-3k}})A.$$

Notice also that $p^k A = \overline{u}_A(\alpha_0^k)$; combining with corollary 16.3.51(ii), it follows that

$$\alpha_0^k \in e^{1-p^{-3k}}\mathbf{E} \qquad \text{and therefore} \qquad \alpha_0^{kp^{-2k}} \in e^{p^{-2k}-p^{-5k}}\mathbf{E}.$$

Clearly $r := p^{-k} - kp^{-2k} > 0$, and $p^{-2k} - p^{-5k} - p^{-3k} \geq 0$, so that :

$$\alpha_0^{1+p^{-k}} e^{1-p^{-3k}} \in \alpha_0^{1+r} e$$

and finally we get, for some $y \in \mathbf{E}$:

$$ax = \overline{u}_A(e) \cdot z \qquad \text{where} \qquad z := 1 + \overline{u}_A(\alpha_0^{1+r}y).$$

Clearly $z \in A^\times$, so the first sought identity holds with $t := z/x$. It follows that $\overline{u}_A(\alpha_0^k) \in \overline{u}_A(e)A$, so that $\alpha_0^k \in e\mathbf{E}$, again by corollary 16.3.51(ii); thus, $\alpha_0 \in e^{1/p^k}\mathbf{E}$, whence the second identity. ☐

Remark 16.6.25. (i) One can show by a direct computation that the element e_n appearing in the proof of proposition 16.6.16 is integral over the ideal generated by e_{n+1} and α_0^n; as a consequence, the proof of *loc. cit.* can be made in principle completely effective, so that one can extract from it an algorithm that exhibits an element e with the sought properties, for any given $a \in \mathrm{gr}_\gamma A$.

(ii) In [149], Scholze proves theorem 16.5.52 (for his perfectoid rings, that are a special case of our perfectoid quasi-affinoid rings) by means of his "approximation lemma" (see [149, Lemma 6.5]). With proposition 16.6.16, we can give an alternative proof of theorem 16.5.52 that generalizes to quasi-affinoid perfectoid rings, along the lines of Scholze's original argument. The first step is the following extension of proposition 16.5.46 to quasi-affinoid perfectoid rings.

Lemma 16.6.26. *In the situation of* (16.5.23)*, let v be any continuous valuation on A_U. Then :*

(i) *The mapping $v \circ \varphi_U^\flat$ is a continuous valuation of $\mathbf{E}_U$.*

(ii) *The rule : $v \mapsto v \circ \varphi_U^\flat$ defines a continuous map*

$$\mathrm{Cont}(\varphi_U^\flat) : \mathrm{Cont}(A_U) \to \mathrm{Cont}(\mathbf{E}_U).$$

Proof. (i): Since both v and $\varphi_U^\flat$ are morphisms of pointed monoids, the same holds for $v \circ \varphi_U^\flat$. Thus, it remains only to check that

$$v(\varphi_U^\flat(x+y)) \leq M(x,y) := \max(v \circ \varphi_U^\flat(x), v \circ \varphi_U^\flat(y)) \qquad \text{for every } x, y \in \mathbf{E}_U.$$

However, from proposition 16.4.34(ii) we know that $\varphi_U^\flat(x+y)$ is the sum of $\varphi_U^\flat(x) + \varphi_U^\flat(y)$ and a p-adically convergent series, whose n-th term can be written as $p^n \cdot z_n$, where z_n is in turn a finite $\mathbb{Z}_p$-linear combination of elements of the form $\varphi^\flat_U(x^\sigma y^{1-\sigma})$, with σ ranging over the elements of $\Sigma_n := p^{-n}\mathbb{N} \cap [0,1]$. It follows that

$$v(z_n) \leq \max(\sigma \cdot v(\varphi^\flat_U(x)) + (1-\sigma) \cdot v(\varphi^\flat_U(y)) \mid \sigma \in \Sigma_n) \leq M(x,y).$$

On the other hand, $v(p)$ is cofinal in the value group of v, since the latter is continuous (see (15.3.1)). The assertion is an immediate consequence.

The proof of (ii) is similar to that of proposition 16.5.46(ii) : details left to the reader. □

Next, we remark the following corollary of proposition 16.6.16, that generalizes and improves slightly Scholze's "approximation lemma" in [149, Lemma 6.5]. The same improvement appears in [114, Cor.3.6.7].

Corollary 16.6.27. *Resume the notation of* (16.5.23). *For every* $\gamma \in \mathbb{Z}[1/p]$, *every* $a \in \mathrm{Fil}^\gamma A_U$, *every* $m \in \mathbb{N}$ *and every* $\beta \in \mathbb{N}[1/p]$ *with* $\beta < p/(p-1)$ *there exists* $e \in \mathrm{Fil}^\gamma \mathbf{E}_U$ *such that*

$$v(a - \varphi^\flat_U(e)) \leq v(p)^\beta \cdot \max(v(\varphi^\flat_U(e)), v(p)^m) \qquad \textit{for every } v \in \mathrm{Cont}(A_U).$$

Proof. (Notice that the value group Γ_v is p-divisible, due to theorem 16.5.52(iv), but even discounting *loc.cit.*, the term $v(p)^\beta$ is still well defined as an element of $(\mathbb{Q} \otimes_\mathbb{Z} \Gamma_v)_\circ$, so the above inequality makes sense in any case.) Fix v, m, β as in the corollary, and a distinguished element $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N}) \in \mathrm{Ker}\, u_A$, and define the sequence of rational numbers $(\lambda_{n+1} \mid n \in \mathbb{N})$ as in (16.6.15), as well as the subset $S_n \subset \mathbb{N}[1/p]^{\oplus 2}$ and the $\overline{A}$-submodule $\mathscr{I}(e,n,\gamma)$ of $\mathrm{Fil}^\gamma A_U$, for every $e \in \mathrm{Fil}^\gamma \mathbf{E}_U$ and every integer $n > 0$. Notice that

$$\lim_{n \to +\infty} \lambda_n = p/(p-1). \tag{16.6.28}$$

We apply proposition 16.6.16 to the perfectoid rings with $\mathbb{Z}[1/p]$-graded structure $\mathscr{E}_U$ and $\mathscr{A}_U$ given by example 16.6.13 : for every integer $n > 0$ we then get $e_n \in \mathrm{Fil}^\gamma \mathbf{E}_U$, $d_n \in \mathrm{Fil}^\gamma A_U$, a finite subset $T_n \subset S_n$, and for every $(i,j) \in T_n$ an element $b_{i,j,n} \in \mathrm{Fil}^{(1-j)\gamma} A_U$ such that

$$a = \varphi^\flat_U(e_n) + \sum_{(i,j) \in T_n} b_{i,j,n} \cdot \varphi^\flat_U(\alpha_0^i \cdot e_n^j) + p^n d_n.$$

Pick also $\varepsilon \in \mathbb{N}[1/p] \setminus \{0\}$ such that $\alpha_0 \in \mathrm{Fil}^\varepsilon \mathbf{E}_U$, and $k \in \mathbb{N}$ large enough so that $\gamma + k\varepsilon > 0$.

Claim 16.6.29. We have $v(p^n d_n) \leq v(p)^{\beta+m}$ for every sufficiently large $n \in \mathbb{N}$.

Proof of the claim. We have $p^k d_n \in \mathrm{Fil}^{\gamma+k\varepsilon} A_U$, and notice that $\mathrm{Fil}^\delta A_U \subset A_U^{\circ\circ}$ for every $\delta > 0$. It follows that $v(p^k d_n) < 1$, so the claim holds for every $n \geq k + m + \beta$. ◊

Recall that $pu = \varphi^\flat_U(\alpha_0)$ for some $u \in \overline{A}^\times$; suppose first that there exists $n_0 \in \mathbb{N}$ such that $v(\varphi^\flat_U(e_n)) \leq v(p)^m$ for every $n \geq n_0$. Then we have

$$v(b_{i,j,n} \cdot \varphi^\flat_U(\alpha_0^i \cdot e_n^j)) \leq v(b_{i,j,n}) \cdot v(u)^i \cdot v(p)^{i+mj} \qquad \text{for every } n \geq n_0 \text{ and every } (i,j) \in T_n$$

and on the other hand $b_{i,j,n} \cdot \varphi^\flat_u(\alpha_0^{(1-j)k}) \in \mathrm{Fil}^{(1-j)(\gamma+k\varepsilon)} \subset A_U^{\circ\circ}$, and $v(u)^i \cdot v(x) < 1$ for every $x \in A_U^{\circ\circ}$, whence

$$v(u)^i \cdot v(b_{i,j,n} \cdot \varphi^\flat_u(\alpha_0^{(1-j)k})) < 1 \qquad \text{for every } n \in \mathbb{N} \text{ and every } (i,j) \in T_n.$$

By the same token, we have $v(u)^{-(1-j)k} \cdot v(p)^\delta < 1$ for every $\delta > 0$, whence

$$v(p)^\delta \leq v(\varphi^\flat_U(\alpha_0^{(1-j)k})) \qquad \text{for every } \delta > (1-j)k.$$

Summing up we obtain, for every $(i,j) \in T_n$, the inequality

$$v(b_{i,j,n} \cdot \varphi^\flat_U(\alpha_0^i \cdot e_n^j)) \leq v(p)^{\beta+m} \qquad \text{whenever} \qquad i + mj - (1-j)k > m + \beta.$$

The latter condition is the same as the inequality $i > (1-j)(m+k)+\beta$. However, notice that $1-j < i/n$, so this inequality holds provided $i > i \cdot (m+k)/n + \beta$, *i.e.* when

$$i \cdot (1-(m+k)/n) > \beta. \qquad (16.6.30)$$

Lastly, from (16.6.28) we see that $\beta < \lambda_n$ for every sufficiently large n, and since $i \geq \lambda_n$, we may find n large enough so that (16.6.30) is verified for every $(i,j) \in T_n$; taking into account claim 16.6.29, we get the corollary, in this case.

Thus, we may assume that there exists an infinite subset $\Sigma \subset \mathbb{N}$ such that $v(p)^m < v(\varphi_U^\flat(e_s))$ for every $s \in \Sigma$, and taking into account claim 16.6.29, we are reduced to checking that

$$v(b_{i,j,s} \cdot \varphi_U^\flat(\alpha_0^i \cdot e_s^j)) \leq v(p)^\beta \cdot v(\varphi_U^\flat(e_s)) \qquad \text{for some } s \in \Sigma \text{ and every } (i,j) \in T_s.$$

However, arguing as in the foregoing we easily see that

$$v(\varphi_U^\flat(\alpha_0^i)) \leq v(p)^\delta \qquad \text{for every } \delta < i.$$

Hence, after replacing β by some $\beta' \in \mathbb{N}[1/p]$ with $p/(p-1) > \beta' > \beta$, we reduce to checking that there exists $s \in \Sigma$ such that

$$v(b_{i,j,s}) \cdot v(p)^{i-\beta} \leq v(p)^{(1-j)m} \qquad \text{for every } (i,j) \in T_s.$$

On the other hand, we have $b_{i,j,n} \cdot \varphi_U^\flat(\alpha_0^{(1-j)k}) \in A_U^{\circ\circ}$, and $v(u)^{(1-j)k} \cdot v(x) < 1$ for every $x \in A_U^{\circ\circ}$, whence

$$v(b_{i,j,n}) \cdot v(p)^{(1-j)k} < 1 \qquad \text{for every } n \in \mathbb{N} \text{ and every } (i,j) \in T_n.$$

Thus, it suffices to show that there exists $s \in \Sigma$ such that

$$i - \beta > (1-j)k + (1-j)m = (1-j)(m+k) \qquad \text{for every } (i,j) \in T_s.$$

This condition is equivalent to (16.6.30), so we may argue as in the foregoing to conclude. □

16.6.31. Now, in the situation of corollary 16.6.27, let

$$C(f_\bullet) := \mathrm{Cont}(A_U) \cap R_{A_U}\big(\tfrac{f_1}{f_0}, \cdots, \tfrac{f_n}{f_0}\big) \qquad \text{and} \qquad S(f_\bullet) := C(f_\bullet) \cap \mathrm{Spa}\,\underline{A}$$

for a sequence $f_\bullet := (f_0, \dots, f_n)$ of elements of A_U that generates an open ideal. There exist $a_0, \dots, a_n \in A_U$ and an integer $m > 0$ such that $p^{m-1} = \sum_{i=0}^n a_i f_i$, and after replacing each a_i by $p^n a_i$ for a suitable $n \in \mathbb{N}$, and m by $m+n$, we may even assume that $a_0, \dots, a_n \in \overline{A}$ (recall that $\overline{A}$ is the image of A in A_U, and $\overline{\mathbf{E}}$ is the image of $\mathbf{E}$ in $\mathbf{E}_U$) whence

$$v(p)^m \leq \max(v(pa_i) \cdot v(f_i) \mid i = 0, \dots, n) \leq \max(v(f_i) \mid i = 0, \dots, n) \qquad (16.6.32)$$

for every $v \in \mathrm{Cont}(A_U)$. It follows that

$$v(f_0) \geq v(p)^m \qquad \text{for every } v \in C(f_\bullet). \qquad (16.6.33)$$

By corollary 16.6.27 we may find $e_0, \dots, e_n \in \mathbf{E}_U$ such that for every $i = 1, \dots, n$ we have :

$$v(f_i - \varphi_U^\flat(e_i)) \leq v(p) \cdot \max(v(\varphi_U^\flat(e_i)), v(p)^m) \qquad \text{for every } v \in \mathrm{Cont}(A_U). \qquad (16.6.34)$$

We may now state the announced generalization of theorem 16.5.52 :

Proposition 16.6.35. *With the notation of* (16.6.31)*, we have :*

(i) *The map* $\mathrm{Cont}(\varphi_U^\flat)$ *of lemma* 16.6.26(ii) *is a homeomorphism.*
(ii) *The system* $e_\bullet := (e_0, \dots, e_n)$ *generates an open ideal of* $\mathbf{E}_U$.
(iii) $C(f_\bullet) = \mathrm{Cont}(\varphi_U^\flat)^{-1} C(e_\bullet)$*, where* $C(e_\bullet) := R_{\mathbf{E}_U}(\frac{e_1}{e_0}, \cdots, \frac{e_n}{e_0}) \cap \mathrm{Cont}(\mathbf{E}_U)$.
(iv) $\varphi_U^\flat(e_0) \in \mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{A}}(S(f_\bullet))^\times$ *and* $f_i/f_0 - \varphi_U^\flat(e_i)/\varphi_U^\flat(e_0) \in \mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{A}}(S(f_\bullet))^{\circ\circ}$ *for* $i = 1, \dots, n$ *(notation of* (15.5.11)*).*

Proof. (ii): Set $\varphi_U^\flat(e_\bullet) := (\varphi_U^\flat(e_0), \dots, \varphi_U^\flat(e_n))$; to begin with, we remark :

Claim 16.6.36. (ii) holds if and only if the system $\varphi_U^\flat(e_\bullet)$ generates an open ideal of A_U.

Proof of the claim. Let $b_1, \dots, b_r$ be a finite system of elements of $\overline{\mathbf{E}}$ that generates an ideal of definition. Then we may find $k \in \mathbb{N}$ large enough so that $b_i^k e_j \in \overline{\mathbf{E}}$ for every $i = 1, \dots, r$ and every $j = 1, \dots, n$. Clearly the system $b_\bullet^k e_\bullet := (b_i^k e_j \mid i \leq r, \ j \leq n)$ generates an open ideal of $\mathbf{E}_U$ if and only if the same holds for $e_\bullet$; likewise; $\varphi^\flat(e_\bullet)$ generates an open ideal of A_U if and only if the same holds for $\varphi_U^\flat(b_\bullet^k e_\bullet)$. So we may replace $e_\bullet$ by $b_\bullet^k e_\bullet$, and assume from start that $e_i \in \overline{\mathbf{E}}$ for $i = 1, \dots, n$, in which case $\varphi_U^\flat(e_i) = \overline{u}_{\overline{A}}(e_i) \in \overline{A}$ for $i = 1, \dots, n$. Now, let $I_\mathbf{E} \subset \overline{\mathbf{E}}$ be the ideal generated by $e_\bullet$; then $I_\mathbf{E}$ is open in $\overline{\mathbf{E}}$ if and only if $Z := \operatorname{Spec} \overline{\mathbf{E}}/I_\mathbf{E}$ lies in the non-analytic locus X of $\operatorname{Spec} \overline{\mathbf{E}}$; likewise, $I_\mathbf{E}\mathbf{E}_U$ is open in $\mathbf{E}_U$ if and only if $Z' := \operatorname{Spec} \mathbf{E}_U/I_\mathbf{E}\mathbf{E}_U$ lies in the non-analytic locus X' of $\operatorname{Spec} \mathbf{E}_U$ (lemma 8.3.29(v)). On the other hand, let $j : \overline{\mathbf{E}} \to \mathbf{E}_U$ be the inclusion map; then $Z' = (\operatorname{Spec} j)^{-1}Z$, and lemma 8.3.29(iii) implies that Z lies in X if and only if Z' lies in X'. Summing up, we see that $I_\mathbf{E}$ is open in $\overline{\mathbf{E}}$ if and only if $I_\mathbf{E}\mathbf{E}_U$ is open in $\mathbf{E}_U$. Likewise, let $I_A \subset \overline{A}$ be the ideal generated by $\varphi_U^\flat(e_\bullet)$; then I_A is open in $\overline{A}$ if and only if $I_A A_U$ is open in A_U. Thus, we are further reduced to showing that $e_\bullet$ generates an open ideal of $\overline{\mathbf{E}}$ if and only if $\varphi_U^\flat(e_\bullet)$ generates an open ideal of $\overline{A}$. The latter assertion follows from corollary 16.3.40(ii). $\diamondsuit$

By claim 16.6.36, it suffices to show that the system $\varphi_U^\flat(e_\bullet)$ generates an open ideal of A_U. To this aim, we apply the criterion of lemma 15.3.25, which reduces to checking that for every $v \in \operatorname{Cont}(A_U)_\mathrm{a}$ there exists $i \in \{0, \dots, n\}$ such that $v(\varphi_U^\flat(e_i)) \neq 0$. However, from (16.6.34) we deduce that for every $i = 0, \dots, n$ and every such v we have :

- either $v(f_i) = v(\varphi_U^\flat(e_i))$
- or else $v(p) > 0$ and $v(f_i), v(\varphi_U^\flat(e_i)) < v(p)^m$.

Now, since the system $f_\bullet$ generates an open ideal of A_U, lemma 15.3.25 implies that $v(f_i) \neq 0$ for some $i \leq n$. If $v(p) = 0$ we deduce that $v(\varphi_U^\flat(e_i)) \neq 0$, as required.

Thus, suppose $v(p) > 0$; from (16.6.32) we know that $v(f_i) \geq v(p)^m > 0$ for some $i \leq n$, whence $v(\varphi_U^\flat(e_i)) = v(f_i) \neq 0$, again as needed.

(iii): In view of (16.6.33) and the foregoing, it follows that

$$v(f_0) = v(\varphi_U^\flat(e_0)) \geq v(p)^m \qquad \text{for every } v \in C(f_\bullet). \tag{16.6.37}$$

Now, let $v \in C(f_\bullet)$ and $i \in \{0, \dots, n\}$; if $v(f_i) \geq v(p)^m$, the foregoing also implies that

$$v(\varphi_U^\flat(e_i)) = v(f_i) \leq v(f_0) = v(\varphi_U^\flat(e_0)).$$

If $v(f_i) < v(p)^m$, likewise we get $v(\varphi_U^\flat(e_i)) < v(p)^m \leq v(\varphi_U^\flat(e_0))$, so $v \in \operatorname{Cont}(\varphi_U^\flat)^{-1}C(e_\bullet)$.

Lastly, let $v \in \operatorname{Cont}(A_U) \setminus C(f_\bullet)$; if $v(p) = 0$, we know that $v(f_i) = v(\varphi_U^\flat(e_i))$ for every $i = 0, \dots, n$, whence $v \notin \operatorname{Cont}(\varphi_U^\flat)^{-1}C(e_\bullet)$. Otherwise, (16.6.32) says that $v(f_j) \geq v(p)^m$ for some $j \leq n$, whence $v(\varphi_U^\flat(e_j)) \geq v(p)^m$. If now $v(f_0) < v(p)^m$, we get $v(\varphi_U^\flat(e_0)) < v(p)^m$, so $v \notin \operatorname{Cont}(\varphi_U^\flat)^{-1}C(e_\bullet)$. Hence, suppose $v(\varphi_U^\flat(e_0)) = v(f_0) \geq v(p)^m > 0$. Then there exists $k \leq n$ such that $v(f_k) > v(f_0)$, whence $v(f_k) = v(\varphi_U^\flat(e_k))$, and again we conclude that $v \notin \operatorname{Cont}(\varphi_U^\flat)^{-1}C(e_\bullet)$.

(i): First, let us show that the continuous map $\operatorname{Cont}(\varphi_U^\flat)$ is bijective. Indeed, a simple inspection yields a commutative diagram of continuous maps

$$\begin{array}{ccc}
\operatorname{Cont}(A_U) & \xrightarrow{\operatorname{Cont}(\varphi_U^\flat)} & \operatorname{Cont}(\mathbf{E}_U) \\
\downarrow & & \downarrow \\
\operatorname{Cont}(\overline{A}) & \xrightarrow{\operatorname{Cont}(\overline{u}_{\overline{A}})} & \operatorname{Cont}(\overline{\mathbf{E}})
\end{array}$$

where the vertical arrows are induced by the open inclusion maps $\overline{A} \to A_U$ and $\overline{\mathbf{E}} \to \mathbf{E}_U$ (notation of (16.5.2)). Therefore, combining theorem 16.5.52(iii) and proposition 15.3.18(ii) we already see that $\operatorname{Cont}(\varphi_U^\flat)$ restricts to a bijection $\operatorname{Cont}(A_U)_\mathrm{a} \xrightarrow{\sim} \operatorname{Cont}(\mathbf{E}_U)_\mathrm{a}$. On the other hand, proposition 16.5.4(iv) implies easily that $\mathrm{Cont}(\varphi^\flat_U)$ restricts as well to a bijection $\mathrm{Cont}(A_U)_{\mathrm{na}} \stackrel{\sim}{\to} \mathrm{Cont}(\mathbf{E}_U)_{\mathrm{na}}$, whence the contention. Lastly, (ii) and (iii) imply easily that the topology of $\mathrm{Cont}(A_U)$ is induced by the topology of $\mathrm{Cont}(\mathbf{E}_U)$, via the map $\mathrm{Cont}(\varphi^\flat_U)$; the assertion follows.

(iv): Since f_0 is invertible in $\mathscr{O}^{\mathrm{loc}}_{\mathrm{Spa}\,\underline{A}}(S(f_\bullet))$, combining (16.6.37) and proposition 15.4.30 we see that the same holds for $\varphi^\flat_U(e_0)$. For the second assertion, in view of corollary 15.4.27(ii) it suffices to show :

Claim 16.6.38. $v(f_i/f_0 - \varphi^\flat_U(e_i)/\varphi^\flat_U(e_0)) < 1$ for every $i = 1, \dots, n$ and every $v \in C(f_\bullet)$.

Proof of the claim. From (16.6.34) we easily deduce that

$$v(1/f_0 - 1/\varphi^\flat_U(e_0)) \leq v(p/f_0) \qquad \text{for every } v \in C(f_\bullet)$$

whence $v(f_i/f_0 - f_i/\varphi^\flat_U(e_0)) \leq v(pf_i/f_0) < 1$ for every $v \in C(f_\bullet)$ and every $i = 1, \dots, n$. We are then reduced to checking that $v(f_i/\varphi^\flat_U(e_0) - \varphi^\flat_U(e_i)/\varphi^\flat_U(e_0)) < 1$, or equivalently, that $v(f_i - \varphi^\flat_U(e_i)) < v(\varphi^\flat_U(e_0))$ for every such v and i. Now, if $v(f_i) < v(p)^m$, we know already that $v(\varphi^\flat_U(e_i)) < v(p)^m$, whence $v(f_i - \varphi^\flat_U(e_i)) < v(p)^m$, and the assertion follows from (16.6.37) in this case. Otherwise, we have $v(f_i) = v(\varphi^\flat_U(e_i))$, whence $v(\varphi^\flat_U(e_i)) \leq v(f_0) = v(\varphi^\flat_U(e_0))$, and thus $v(f_i - v(\varphi^\flat_U(e_i))) \leq v(p) \cdot \max(\varphi^\flat_U(e_0), v(p)^m) = v(p \cdot \varphi^\flat_U(e_0)) < v(\varphi^\flat_U(e_0))$. ☐

16.6.39. Let Γ, Δ be two monoids and $(A, \underline{B})$ a topological ring with Δ-graded structure. Then we may form the complete topological ring with $\Delta \oplus \Gamma$-graded structure

$$(A, \underline{B})[\Gamma]^\wedge$$

by combining the constructions of example 8.5.7(i) and remark 8.5.2(iv). Explicitly, a direct inspection shows that $(A, \underline{B})[\Gamma]^\wedge$ is the pair $(A[\Gamma]^\wedge, \underline{B}^c[\Gamma])$, where $\underline{B}^c$ is the Δ-graded ring such that $\mathrm{gr}_\delta B^c$ is the topological closure of $\mathrm{gr}_\delta B$ in the completion $A^\wedge$ of A, and $A[\Gamma]^\wedge$ is the completion of $A[\Gamma]$, for the unique topology on the latter ring such that the inclusion map $A \to A[\Gamma]$ is adic. Notice that if A is complete and separated, then $B^c = B$, hence in this case $(A, \underline{B})[\Gamma]^\wedge = (A[\Gamma]^\wedge, \underline{B}[\Gamma])$.

Lemma 16.6.40. *In the situation of* (16.6.39)*, suppose furthermore that A is perfectoid, and Γ, Δ are both p-perfect, and let*

$$A \xrightarrow{j_A} A[\Gamma]^\wedge \xleftarrow{i_A} \Gamma \qquad \textit{and} \qquad \mathbf{E}(A) \xrightarrow{j_{\mathbf{E}}} \mathbf{E}(A)[\Gamma]^\wedge \xleftarrow{i_{\mathbf{E}}} \Gamma$$

be the natural inclusion maps. Then we have :

(i) *$A[\Gamma]^\wedge$ is perfectoid.*

(ii) *There exists a natural isomorphism of topological rings with $\Delta \oplus \Gamma$-graded structures*

$$\omega : \mathbf{E}(A, \underline{B})[\Gamma]^\wedge \stackrel{\sim}{\to} \mathbf{E}((A, \underline{B})[\Gamma]^\wedge)$$

fitting into a commutative diagram

$$\begin{array}{ccccc} \mathbf{E}(A) & \xrightarrow{j_{\mathbf{E}}} & \mathbf{E}(A)[\Gamma]^\wedge & \xleftarrow{i_{\mathbf{E}}} & \Gamma \\ & \searrow^{\mathbf{E}(j_A)} & \downarrow{\scriptstyle\omega} & \swarrow_{\mathbf{E}(i_A)} & \\ & & \mathbf{E}(A[\Gamma]^\wedge). & & \end{array}$$

Proof. (Here Γ is identified with the source $\mathbf{E}(\Gamma)$ of the morphism $\mathbf{E}(i_A)$, via $\overline{u}_\Gamma$.)

(i): Indeed, by remark 16.3.58 we may find an ideal of definition $I \subset A$ fulfilling the conditions of (16.3.55), and we let $J := I^{(p)}$; by proposition 16.3.59(ii), the corresponding map $\Phi_I : \mathrm{gr}^\bullet_I A \to \mathrm{gr}^\bullet_J A$ is a ring isomorphism. Set $I' := IA[\Gamma]^\wedge$ and $J' := JA[\Gamma]^\wedge$; by construction, the topology of $A[\Gamma]^\wedge$ agrees with the I'-adic topology, and the natural map

$(A/I^2)[\Gamma] \to A[\Gamma]^\wedge/I'^2$ is an isomorphism (remark 8.3.3(ii) and lemma 8.3.32(iv)). Since Γ is p-perfect, it follows easily that the Frobenius endomorphism of $A[\Gamma]^\wedge/I'^2$ is surjective, so $A[\Gamma]^\wedge$ is a P-ring. On the other hand, notice the natural identifications :

$$\mathrm{gr}^\bullet_{I'}(A[\Gamma]^\wedge) \xrightarrow{\sim} (\mathrm{gr}^\bullet_I A)[\Gamma] \qquad \mathrm{gr}^\bullet_{J'}(A[\Gamma]^\wedge) \xrightarrow{\sim} (\mathrm{gr}^\bullet_J A)[\Gamma]$$

which identify the ring homomorphism $\Phi_{I'}$ of proposition 16.3.59(i) with the map induced by Φ_I and the p-Frobenius endomorphism of Γ. Especially, $\Phi_{I'}$ is an isomorphism, so the assertion follows from theorem 16.3.64.

(ii): According to proposition 16.6.1(i), we may find a Δ-graded ideal I_B of B such that $I_A := I_B A$ is an ideal of definition of A; then notice that the topological closure $I_B^\wedge$ of I_B in A lies in I_A and $I_B^\wedge \cap B$ is the topological closure I_B^c of I_B in B, therefore $I_B^\wedge = I_A$ and $I_B^c = B \cap I_A$, which says especially that I_B^c is open in B. Set $A_0 := A/I_A$ and $B_0 := B/I_B^c$; since I_B^c is a Δ-graded ideal as well (remark 8.5.2(i)), we may form the quotient of $(A, \underline{B})[\Gamma]^\wedge$ by the open ideal $I_B^c[\Gamma]$ of $B[\Gamma]$ as in example 8.5.4(), and get a natural isomorphism :

$$(A, \underline{B})[\Gamma]^\wedge \otimes_B B_0 \xrightarrow{\sim} (A_0[\Gamma], B_0[\Gamma]). \tag{16.6.41}$$

However, the projections $(A, \underline{B}) \to (A_0, \underline{B}_0)$ and $(A, \underline{B})[\Gamma]^\wedge \to (A, \underline{B})[\Gamma]^\wedge \otimes_B B_0$ induce morphisms (see (9.4.24))

$$\mathbf{E}(A, \underline{B}) \to \mathbf{E}(A_0, \underline{B}_0) \qquad \mathbf{E}((A, \underline{B})[\Gamma]^\wedge) \to \mathbf{E}((A, \underline{B})[\Gamma]^\wedge \otimes_B B_0). \tag{16.6.42}$$

On the other hand, the projections $A \to A_0$ and $A[\Gamma]^\wedge \to A_0[\Gamma]$ induce isomorphisms

$$\mathbf{E}(A) \xrightarrow{\sim} \mathbf{E}_0 := \mathbf{E}(A_0) \qquad \text{and} \qquad \mathbf{E}(A[\Gamma]^\wedge) \xrightarrow{\sim} \mathbf{E}(A_0[\Gamma])$$

of topological rings (see (16.1)). Denote

$$A_0 \xrightarrow{j_{A_0}} A_0[\Gamma]^\wedge \xleftarrow{i_{A_0}} \Gamma \qquad \text{and} \qquad \mathbf{E}_0 \xrightarrow{j_{\mathbf{E}_0}} \mathbf{E}_0[\Gamma]^\wedge \xleftarrow{i_{\mathbf{E}_0}} \Gamma$$

the natural inclusion maps; taking into account example 8.5.7(iii), it follows that (16.6.42) are isomorphisms of topological rings with graded structures, and in view of (16.6.41) it suffices to exhibit an isomorphism $\omega_0 : (\mathbf{E}_0[\Gamma], \mathbf{E}(\underline{B}_0)[\Gamma])^\wedge \xrightarrow{\sim} \mathbf{E}(A_0[\Gamma], B_0[\Gamma])$ such that

$$\omega_0 \circ j_{\mathbf{E}_0} = \mathbf{E}(j_{A_0}) \qquad \text{and} \qquad \omega_0 \circ i_{\mathbf{E}_0} = \mathbf{E}(i_{A_0})$$

(where again, Γ is identified with the source $\mathbf{E}(\Gamma)$ of $\mathbf{E}(i_{A_0})$ via $\overline{u}_\Gamma$). To this aim, set

$$J := \mathrm{Ker}\,(\overline{u}_{A_0}[\Gamma] : \mathbf{E}_0[\Gamma] \to A_0[\Gamma])$$

and notice that, since A_0 is a discrete topological ring, the topology of $\mathbf{E}_0[\Gamma]$ agrees with the J-adic topology (remark 9.4.9(ii)); moreover, J is finitely generated, since A is perfectoid (details left to the reader). By corollary 9.4.14 and remark 9.4.9(v) we deduce a natural isomorphism of topological rings

$$\omega_0 : \mathbf{E}_0[\Gamma]^\wedge \xrightarrow{\sim} \mathbf{E}(A_0[\Gamma]) \qquad \text{such that} \qquad \overline{u}_{A_0[\Gamma]} \circ \omega_0 = \overline{u}_{A_0}[\Gamma]^\wedge$$

where $\overline{u}_{A_0}[\Gamma]^\wedge : \mathbf{E}_0[\Gamma]^\wedge \to A_0[\Gamma]$ is the completion of $\overline{u}_{A_0}[\Gamma]$, and a simple inspection shows that ω_0 is a morphism $(\mathbf{E}_0[\Gamma], \mathbf{E}(\underline{B}_0)[\Gamma])^\wedge \to \mathbf{E}(A_0[\Gamma], \underline{B}_0[\Gamma])$, which then must be an isomorphism, again by example 8.5.7(iii). Let us check that $\omega_0 \circ i_{\mathbf{E}_0} = \mathbf{E}(i_{A_0})$. Indeed, we have

$$\overline{u}_{A_0[\Gamma]} \circ \omega_0 \circ i_{\mathbf{E}_0} = \overline{u}_{A_0}[\Gamma]^\wedge \circ i_{\mathbf{E}_0} = i_{A_0} = \overline{u}_{A_0[\Gamma]} \circ \mathbf{E}(i_{A_0})$$

whence the sought identity, by adjunction. A similar argument proves the remaining sought identity. □

We conclude this section with a sample of other graded perfectoid rings that are analogous to certain constructions found in [149], and might be interesting for other purposes, but shall not be needed in the rest of this treatise.

Example 16.6.43. (i) Let $(\Delta, 0, +)$ be a monoid, $(A, \underline{B})$ a topological ring with Δ-graded structure, and consider two morphisms of Δ-graded monoids

$$\Gamma_2 \xleftarrow{\varphi} \Gamma_1 \xrightarrow{\psi} B^*$$

where B^* is the Δ-graded monoid defined as in (9.4.21). Hence, $B[\Gamma_2]$ is a $\Delta \oplus \Gamma_2$-graded $\mathbb{Z}$-algebra, and we may form the Δ-graded $\mathbb{Z}$-algebra $B[\Gamma_2]_{/\Delta}$ corresponding to the morphism

$$\eta : \Delta \oplus \Gamma_2 \to \Delta \qquad (\delta, \gamma) \mapsto \delta + |\gamma| \qquad \text{for every } \delta \in \Delta \text{ and } \gamma \in \Gamma_2$$

where $|\cdot| : \Gamma_2 \to \Delta$ is the Δ-grading of Γ_2. It follows easily that

$$I := \mathrm{Ker}\,(B[\Gamma_2] \to \Gamma_2 \otimes_{\Gamma_1} B)$$

is a Δ-graded ideal of $B[\Gamma_2]_{/\Delta}$, and by combining the constructions of examples 8.5.4(i) and 8.5.7(i,ii) we may define the topological ring with Δ-graded structure

$$\Gamma_2 \otimes_{\Gamma_1} (A, \underline{B}) := (A, \underline{B})[\Gamma_2]_{/\Delta}/I.$$

Explicitly, this is the pair $(A', \underline{B}')$, such that A' (resp. B') is the maximal separated quotient of $\Gamma_2 \otimes_{\Gamma_1} A$ (resp. of $\Gamma_2 \otimes_{\Gamma_1} B$), where the latter is endowed with the unique linear topology such that the natural map

$$A \to \Gamma_2 \otimes_{\Gamma_1} A \qquad (\text{resp. } B \to \Gamma_2 \otimes_{\Gamma_1} B)$$

is adic. Then, $\mathrm{gr}_\delta B'$ is the topological closure of the image of $\mathrm{gr}_\delta(B[\Gamma_2]_{/\Delta})$ in A', for each $\delta \in \Delta$. By construction, we have a natural morphism of topological rings with Δ-graded structures (resp. of monoids)

$$j_{(A,\underline{B})} : (A, \underline{B}) \to \Gamma_2 \otimes_{\Gamma_1} (A, \underline{B}) \qquad (\text{resp. } i_{(A,\underline{B})} : \Gamma_2 \to \Gamma_2 \otimes_{\Gamma_1} A\,).$$

(ii) Suppose now that Δ is p-perfect, and the topology of A is complete, separated and coarser than the p-adic topology. Then the topological ring with Δ-graded structure $\mathbf{E}(A, \underline{B})$ is well defined as in (9.4.24). Moreover, from the morphisms φ and ψ we derive two morphisms of monoids

$$\mathbf{E}(\Gamma_2) \xleftarrow{\varphi_{\mathbf{E}}} \mathbf{E}(\Gamma_1) \xrightarrow{\psi_{\mathbf{E}}} \mathbf{E}(B^*) \qquad \text{where } \varphi_{\mathbf{E}} := \mathbf{E}(\varphi) \text{ and } \psi_{\mathbf{E}} := \mathbf{E}(\psi)$$

so the considerations of (i) can be repeated on $\mathbf{E}(A, \underline{B})$, and we get a topological ring with $\mathbf{E}(\Delta)$-graded structure

$$\mathbf{E}(\Gamma_2) \otimes_{\mathbf{E}(\Gamma_1)} \mathbf{E}(A, \underline{B}).$$

Proposition 16.6.44. *In the situation of example* 16.6.43*, suppose moreover that A is perfectoid, and Δ, Γ_1, Γ_2 are p-perfect. We have :*

(i) *The completion $(\Gamma_2 \otimes_{\Gamma_1} A)^\wedge$ of $\Gamma_2 \otimes_{\Gamma_1} A$ is perfectoid.*

(ii) *There exists a natural isomorphism of topological rings with Δ-graded structures :*

$$\omega : \mathbf{E}((\Gamma_2 \otimes_{\Gamma_1} (A, \underline{B}))^\wedge) \xrightarrow{\sim} (\Gamma_2 \otimes_{\Gamma_1} \mathbf{E}(A, \underline{B}))^\wedge$$

(notation of (9.4.24)*) fitting into the commutative diagrams*

$$\begin{array}{ccc} \mathbf{E}(A, \underline{B}) & \xrightarrow{\mathbf{E}(j_{(A,\underline{B})})} & \mathbf{E}((\Gamma_2 \otimes_{\Gamma_1} (A, \underline{B}))^\wedge) \\ & \searrow^{j_{\mathbf{E}(A,\underline{B})}} & \downarrow \omega \\ & & (\Gamma_2 \otimes_{\Gamma_1} \mathbf{E}(A, \underline{B}))^\wedge \end{array} \qquad \begin{array}{ccc} \Gamma_2 & \xrightarrow{\mathbf{E}(i_{(A,\underline{B})})} & \mathbf{E}((\Gamma_2 \otimes_{\Gamma_1} A)^\wedge) \\ & \searrow^{i_{\mathbf{E}(A,\underline{B})}} & \downarrow \omega \\ & & (\Gamma_2 \otimes_{\Gamma_1} \mathbf{E}(A))^\wedge. \end{array}$$

Proof. (Here we identify Γ_1 and Γ_2 with $\mathbf{E}(\Gamma_1)$ and $\mathbf{E}(\Gamma_2)$, via the isomorphisms $\overline{u}_{\Gamma_1}$ and $\overline{u}_{\Gamma_2}$.) Let us form as well the topological ring with Δ-graded structure

$$(A', \underline{D}) := ((A, \underline{B})[\Gamma_2]^\wedge)_{/\Delta}.$$

Explicitly, A' is the completion of $A[\Gamma_2]$, where the latter is endowed with the unique linear topology such that the natural map $A \to A[\Gamma_2]$ is adic; then $\mathrm{gr}_\delta D$ is the topological closure in A' of $\mathrm{gr}_\delta(B[\Gamma_2]_{/\Delta})$, for every $\delta \in \Delta$. Here, as in example 16.6.43(i), the Δ-graded $\mathbb{Z}$-algebra $B[\Gamma_2]_{/\Delta}$ is obtained from the $\Delta \oplus \Gamma_2$-graded $\mathbb{Z}$-algebra $B[\Gamma_2]$ via the morphism η. With this notation, from proposition 8.2.13(i,v) and a simple inspection we get a natural identification

(16.6.45) $$(\Gamma_2 \otimes_{\Gamma_1} (A, \underline{B}))^\wedge \xrightarrow{\sim} (A', \underline{D})/ID.$$

Set $(\mathbf{E}, \underline{B}_\mathbf{E}) := \mathbf{E}(A, \underline{B})$; from lemma 16.6.40 and proposition 9.4.22(iii), we know already that A' is perfectoid, and there exists an isomorphism

(16.6.46) $$(\mathbf{E}', \underline{D}_\mathbf{E}) := \mathbf{E}(A', \underline{D}) \xrightarrow{\sim} ((\mathbf{E}, \underline{B}_\mathbf{E})[\Gamma_2]^\wedge)_{/\Delta}$$

of topological rings with Δ-graded structures. Set

$$\mathscr{I} := \mathrm{Ker}\,(B_\mathbf{E}[\Gamma_2] \to \Gamma_2 \otimes_{\Gamma_1} B_\mathbf{E}).$$

Claim 16.6.47. (i) $\Phi_{\mathbf{E}'}(\mathscr{I}\mathbf{E}') = \mathscr{I}\mathbf{E}'$.

(ii) $\{\mathscr{I}\mathbf{E}'\} = (IA')^c$.

Proof of the claim. Let $\overline{\psi}_\mathbf{E} := \mathbf{E}(i) \circ \psi_\mathbf{E} : \Gamma_1 \to \mathbf{E}$ where $i : B^* \to A$ is the natural map. Clearly, the ideals IA' and $\mathscr{I}\mathbf{E}'$ are generated respectively by the systems

$$\mathscr{S}_A := (\varphi(\gamma) - \psi(\gamma) \mid \gamma \in \Gamma_1) \qquad \text{and} \qquad \mathscr{S}_\mathbf{E} := (\varphi_\mathbf{E}(\gamma) - \overline{\psi}_\mathbf{E}(\gamma) \mid \gamma \in \Gamma_1).$$

Since Γ_1 is perfect, assertion (i) follows already, and for (ii) we come down to showing that the topological closure of the ideal generated by the system $\overline{u}_{A'}(\mathscr{S}_\mathbf{E})$ equals the topological closure of the ideal generated by $\mathscr{S}_A$. Now, proposition 9.3.62 says that each generator $\overline{u}_{A'}(\varphi_\mathbf{E}(\gamma) - \overline{\psi}_\mathbf{E}(\gamma))$ can be written as a p-adically convergent series $\sum_{n\in\mathbb{N}} p^n c_{\gamma,n}$ where

(16.6.48) $$c_{\gamma,0} = \overline{u}_{A'}(\varphi_\mathbf{E}(\gamma)) - \overline{u}_{A'}(\overline{\psi}_\mathbf{E}(\gamma))$$

and for every $n > 0$, the term $c_{\gamma,n}$ is a finite $\mathbb{Z}_p$-linear combination of elements of the form

$$\overline{u}_{A'}(\varphi_\mathbf{E}(\gamma)^s \cdot \overline{\psi}_\mathbf{E}(\gamma)^{s'}) - \overline{u}_{A'}(\varphi_\mathbf{E}(\gamma)^{s'} \cdot \overline{\psi}_\mathbf{E}(\gamma)^s)$$

where $s, s' \in p^{-n}\mathbb{N}$ and $s + s' = 1$. However, lemma 16.6.40(ii) implies that

$$\overline{u}_{A'}(\varphi_\mathbf{E}(\gamma)) = \varphi(\gamma) \qquad \text{and} \qquad \overline{u}_{A'}(\overline{\psi}_\mathbf{E}(\gamma)) = \psi(\gamma) \qquad \text{for every } \gamma \in \Gamma_1.$$

Thus $\{\mathscr{I}\mathbf{E}'\}$ lies in the topological closure of the ideal generated by the elements

$$t_{\gamma,s} := \varphi(\gamma)^s \cdot \psi(\gamma)^{s'} - \varphi(\gamma)^{s'} \cdot \psi(\gamma)^s \qquad \text{for every } \gamma \in \Gamma_1 \text{ and } s, s' \in \mathbb{N}[1/p] \text{ with } s + s' = 1.$$

To ease notation, set $\lambda := \varphi(\gamma)$ and $\mu := \psi(\gamma)$; we notice that

$$(\lambda^s - \mu^s) \cdot (\mu^{1-s} + \lambda^{1-s}) - (\lambda - \mu) = t_{\gamma,s}$$

and since $\lambda^s - \mu^s, \lambda - \mu \in \mathscr{S}_A$, we conclude that $t_{\gamma,s} \in IA'$. By the same token, from (16.6.48) we get $c_0 = \lambda - \mu$, so finally $(IA')^c = \{\mathscr{I}\mathbf{E}'\} + p(IA')^c$. From this, an easy induction yields

$$(IA')^c = \{\mathscr{I}\mathbf{E}'\} + p^n(IA')^c \qquad \text{for every } n \in \mathbb{N}$$

whence the claim, since $\{\mathscr{I}\mathbf{E}'\}$ is a closed ideal. ◊

From claim 16.6.47 and corollary 16.3.38 we deduce that $A'/(IA')^c$ is perfectoid and there exists an isomorphism of topological rings $\omega' : \mathbf{E}(A'/(IA')^c) \xrightarrow{\sim} \mathbf{E}'/(\mathscr{I}\mathbf{E}')^c$ such that

$$\omega' \circ \mathbf{E}(\pi_{A'}) = \pi_{\mathbf{E}'}$$

where $\pi_{A'} : A' \to A'/(IA')^c$ and $\pi_{\mathbf{E}'} : \mathbf{E}' \to \mathbf{E}'/(\mathscr{I}\mathbf{E}')^c$ are the projections. This completes the proof of (i), and we also see that the projection $(\mathbf{E}', \underline{D}_\mathbf{E}) \to (\mathbf{E}', \underline{D}_\mathbf{E})/\mathscr{I}\underline{D}_\mathbf{E}$ factors through a morphism

(16.6.49) $$\mathbf{E}((A', \underline{D})/ID) \to (\mathbf{E}', \underline{D}_\mathbf{E})/\mathscr{I}\underline{D}_\mathbf{E}$$

which must be an isomorphism, by example 8.5.7(iii). On the other hand, from (16.6.46) we get a natural identification

$$(16.6.50)\qquad (\mathbf{E}', \underline{D}_{\mathbf{E}})/\mathscr{I}\underline{D}_{\mathbf{E}} \xrightarrow{\sim} (\Gamma_2 \otimes_{\Gamma_1} \mathbf{E}(A, \underline{B}))^{\wedge}.$$

Lastly, combining (16.6.49), (16.6.50) and (16.6.45) we get the sought isomorphism ω. The commutativity of the diagrams in (ii) follows by direct inspection, taking into account the corresponding properties of the isomorphism (16.6.46) stated in lemma 16.6.40(ii) : details left to the reader. □

16.6.51. Let Λ be any (small) set and $(\Delta, +, 0, \leq)$ any ordered abelian group; we set

$$\Delta^+ = \{\delta \in \Delta \mid \delta \geq 0\} \qquad P := \Delta^{+(\Lambda)} \qquad Q := \Delta^{+(\Lambda\times\Lambda)}$$

(cp. definition 9.1.1(i)). Denote by $I \subset P$ the ideal generated by the canonical system of generators $e_\bullet := (e_\lambda \mid \lambda \in \Lambda)$ for P, *i.e.* $e_\lambda := (\delta_{\lambda\mu} \mid \mu \in \Lambda)$, where $\delta_{\lambda\mu} := 1$ for $\lambda = \mu$, and $\delta_{\lambda\mu} := 0$ otherwise, for every $\lambda, \mu \in \Lambda$. Likewise, we let

$$(f_\lambda, f'_\lambda \mid \lambda \in \Lambda) \qquad (\text{resp. } (e_{\lambda,\lambda'} \mid \lambda, \lambda' \in \Lambda))$$

be the canonical system of generators of $P \times P$ (resp. of Q).

- With this notation, we define Δ-gradings on P, $P \times P$ and Q by the rules :

$$|\delta e_\lambda|_P := \delta \qquad |\delta f_\lambda + \delta' f'_\lambda|_{P\times P} := \delta \qquad |\delta e_{\lambda,\lambda'}|_Q := \delta$$

for every $\lambda, \lambda' \in \Lambda$ and every $\delta, \delta' \in \Delta$ (see definition 4.8.8(i)), and we set

$$I^{\langle\delta\rangle} := \{x \in P \mid |x|_P \geq \delta\} \qquad \text{for every } \delta \in \Delta.$$

Notice that, in case $\Delta = \mathbb{Z}[1/p]$, the ideals $I^{\langle\delta\rangle}$ of P are the same as the ones introduced in (9.3.68), so the notation does not conflict with *loc.cit.* Lastly, we define

$$\Gamma_I^+ := \bigcup_{\delta\in\Delta^+} I^{\langle\delta\rangle} \times \{\delta\} \qquad \Gamma_I := \bigcup_{\delta\in\Delta} I^{\langle\delta\rangle} \times \{\delta\}$$

and notice that Γ_I^+ (resp. Γ_I) is a submonoid of $P \times \Delta^+$ (resp. of $P \times \Delta$), so it inherits a natural Δ-grading, given by the projection on the factor Δ. We have morphisms of Δ-graded monoids

$$(16.6.52)\qquad Q \underset{\psi'}{\overset{\psi}{\rightrightarrows}} P \times P \xrightarrow{\varphi} \Gamma_I^+$$

such that

$$\varphi(\delta f_\lambda + \delta' f'_\lambda) := ((\delta + \delta')e_\lambda, \delta) \qquad \psi(\delta e_{\lambda,\lambda'}) := \delta(f_\lambda + f'_{\lambda'}) \qquad \psi'(\delta e_{\lambda,\lambda'}) := \delta(f'_\lambda + f_{\lambda'})$$

for every $\lambda, \lambda' \in \Lambda$ and every $\delta, \delta' \in \Delta$.

Lemma 16.6.53. *With the notation of* (16.6.51)*, we have :*

(i) (16.6.52) *is a presentation for* Γ_I^+, i.e. φ *identifies* Γ_I^+ *with the coequalizer of* ψ *and* ψ'.

(ii) *Define a* Δ*-grading of* $P \times \Delta^+$ *by the rule :* $(x, \delta) \mapsto |x|_P - \delta$ *for every* $x \in P$ *and* $\delta \in \Delta^+$. *Then the mapping*

$$P \times \Delta^+ \to \Gamma_I \qquad (x, \delta) \mapsto (x, |x|_P - \delta)$$

is an isomorphism of Δ*-graded monoids.*

Proof. (i): Indeed, say that

$$g := \sum_{\lambda\in\Lambda}(r_\lambda f_\lambda + r'_\lambda f'_\lambda) \qquad \text{and} \qquad h := \sum_{\lambda\in\Lambda}(s_\lambda f_\lambda + s'_\lambda f'_\lambda)$$

are two elements of $P \times P$ whose images agree in Γ_I^+, so that $r_\lambda, r'_\lambda, s_\lambda, s'_\lambda \in \Delta^+$ and

$$r_\lambda + r'_\lambda = s_\lambda + s'_\lambda \qquad \text{for every } \lambda \in \Lambda \qquad \text{and} \qquad \sum_{\lambda\in\Lambda} r_\lambda = \sum_{\lambda\in\Lambda} s_\lambda. \tag{16.6.54}$$

Let $\sim$ be the equivalence relation defined by the pair (ψ, ψ'); we have to check that $g \sim h$. Now, consider any $\lambda \in \Lambda$, and suppose that $r_\lambda \leq s_\lambda$; then we may write $g = g' + r_\lambda f_\lambda$, $h = h' + r_\lambda f_\lambda$ for elements $g', h' \in P \times P$ such that $\varphi(g') = \varphi(h')$; it then suffices to check that $g' \sim h'$, and we are reduced to the case where $r_\lambda = 0$. In case $r_\lambda > s_\lambda$, we argue symmetrically, to reduce to the case where $s_\lambda = 0$. Likewise, we can reduce to the case where either $r'_\lambda = 0$ or $s'_\lambda = 0$. Repeating the argument for every $\lambda \in \Lambda$, and taking (16.6.54) into account, we may suppose from start that

$$g = \sum_{\lambda\in A} r_\lambda f_\lambda + \sum_{\mu\in B} r_\mu f'_\mu \qquad h = \sum_{\lambda\in A} r_\lambda f'_\lambda + \sum_{\mu\in B} r_\mu f_\mu$$

for some finite subsets $A, B \in \Lambda$ with $A \cap B = \varnothing$, and a system $(r_\lambda \mid \lambda \in A \cup B)$ of elements of $\Delta^+ \setminus \{0\}$ such that

$$\sum_{\mu\in B} r_\mu = \sum_{\lambda\in A} r_\lambda. \tag{16.6.55}$$

Next, we argue by induction on the cardinality c of $A \cup B$. If $c = 0$, there is nothing to prove. Suppose then that $c > 0$ and that the assertion is already known whenever the cardinality of $A \cup B$ is strictly smaller than c. Notice that $A \neq \varnothing$, since otherwise (16.6.55) would imply that $B = \varnothing$, contradicting the assumption that $c > 0$; likewise, we must have $B \neq \varnothing$. Thus, pick any $\lambda \in A$ and $\mu \in B$, set $A' := A \setminus \{\lambda\}$, $B' := B \setminus \{\mu\}$, and suppose first that $r_\lambda \leq r_\mu$; we set

$$g' := \sum_{\lambda\in A'} r_\lambda f_\lambda + \sum_{\mu\in B'} r_\mu f'_\mu + (r_\mu - r_\lambda)\cdot f'_\mu \qquad h' := \sum_{\lambda\in A'} r_\lambda f'_\lambda + \sum_{\mu\in B'} r_\mu f_\mu + (r_\mu - r_\lambda)\cdot f_\mu$$

so that $g = g' + r_\lambda \cdot (f_\lambda + f'_\mu)$ and $h = h' + r_\lambda \cdot (f'_\lambda + f_\mu)$. However, $r_\lambda \cdot (f_\lambda + f'_\mu) \sim r_\lambda \cdot (f'_\lambda + f_\mu)$, so we are reduced to checking that $g' \sim h'$. The latter is known by our inductive assumption. A symmetric argument will do, in case $r_\lambda > r_\mu$.

(ii) shall be left to the reader. □

16.6.56. In the situation of (16.6.51), take $\Delta := \mathbb{Z}[1/p]$ with its standard ordering, so that $\Delta^+ = \mathbb{N}[1/p]$. In this case, it is easily seen that P, Γ_I^+ and Γ_I are p-perfect monoids. In this paragraph, it will be convenient to switch to a multiplicative notation for the composition laws of these monoids : in other words, we shall hereafter replace $(P, +, 0)$ by $(\exp P, \cdot, 1)$, and likewise for Γ_I^+ and Γ_I (notation of (6.1)). Correspondingly, the product $\delta \cdot x$ of an element $\delta \in \Delta^+$ and an element $x \in P$ shall be replaced by the exponential x^δ.

Let also A be any perfectoid ring, set $\mathbf{E} := \mathbf{E}(A)$ and denote by $\underline{A}$ the topological ring with Δ-graded structure (A, A, Δ), such that $\mathrm{gr}_0 A = A$ and $\mathrm{gr}_\delta A = 0$ for every $\delta \neq 0$ in Δ; define likewise the topological ring with Δ-graded structure $\underline{\mathbf{E}} := (\mathbf{E}, \mathbf{E}, \Delta)$. Choose an ideal of definition J for A, and set $\mathscr{J} := \overline{u}_{A/pA}^{-1}(J/pA)$, which is an ideal of definition for $\mathbf{E}$. Let $\beta_\bullet := (\beta_\lambda \mid \lambda \in \Lambda)$ be any system of elements of $\mathbf{E}$; then $\beta_\bullet$ determines a unique morphism of monoids

$$\varphi_{\mathbf{E}} : P \to \mathbf{E} \qquad \text{such that} \qquad e_\lambda^\delta \mapsto \beta_\lambda^\delta \qquad \text{for every } \lambda \in \Lambda \text{ and } \delta \in \Delta$$

and composing with the map $\overline{u}_A : \mathbf{E} \to A$ we get also a morphism $\varphi_A : P \to A$. Moreover, notice that $I^{\langle 0\rangle} = P$, so we have as well a morphism $i_0 : P \to \Gamma_I^+$, and we can define the rings

$$\mathscr{E}_+ := \Gamma_I^+ \otimes_P \mathbf{E} \subset \mathscr{E} := \Gamma_I \otimes_P \mathbf{E} \qquad \text{and} \qquad \mathscr{A}_+ := \Gamma_I^+ \otimes_P A \subset \mathscr{A} := \Gamma_I \otimes_P A$$

as well as the topological rings with Δ-graded structures

$$(\mathscr{E}_+^\wedge, \underline{\mathscr{E}}^c_+) := (\Gamma_I^+ \otimes_P \underline{\mathbf{E}})^\wedge \quad \subset \quad (\mathscr{E}^\wedge, \underline{\mathscr{E}}^c_+) := (\Gamma_I \otimes_P \underline{\mathbf{E}})^\wedge$$
$$(\mathscr{A}_+^\wedge, \underline{\mathscr{A}}^c_+) := (\Gamma_I^+ \otimes_P \underline{A})^\wedge \quad \subset \quad (\mathscr{A}, \underline{\mathscr{A}}^c) := (\Gamma_I \otimes_P \underline{A})^\wedge$$

(notation of (6.1.33) and example 16.6.43). We endow $\mathscr{E}$ and $\mathscr{E}_+$ with their $\mathscr{J}$-adic topologies, and $\mathscr{A}$, $\mathscr{A}_+$ with their J-adic topologies; then $\mathscr{E}_+^\wedge$ (resp. $\mathscr{E}^\wedge$) is the completion of $\mathscr{E}_+$ (resp. of $\mathscr{E}$) and $\mathscr{A}_+^\wedge$ (resp. $\mathscr{A}^\wedge$) is the completion of $\mathscr{A}_+$ (resp. of $\mathscr{A}$). Furthermore, the rings $\mathscr{A}$ and $\mathscr{E}$ inherit natural Δ-gradings from Γ_I, such that

$$I^{\langle\delta\rangle} \otimes_P \mathbf{E} = \mathrm{gr}_\delta \mathscr{E} \qquad I^{\langle\delta\rangle} \otimes_P A = \mathrm{gr}_\delta \mathscr{A} \qquad \text{for every } \delta \in \Delta$$

and by restricting to Δ^+, we get corresponding Δ^+-gradings on $\mathscr{A}_+$ and $\mathscr{E}_+$. Then, a direct inspection shows that $\mathrm{gr}_\delta \mathscr{E}^c$ (resp. $\mathrm{gr}_\delta \mathscr{A}^c$) is the separated completion of $\mathrm{gr}_\delta \mathscr{E}$ (resp. of $\mathrm{gr}_\delta \mathscr{A}$), for every $\delta \in \Delta$. Let $i_\Gamma : \Gamma_I^+ \to \Gamma_I$ be the inclusion map; as in example 16.6.43(i), we point out the commutative diagram of monoids and of topological rings with Δ-graded structures :

$$\begin{array}{ccccccccc}
\underline{\mathbf{E}} & \xrightarrow{j^+_{\mathbf{E}}} & (\mathscr{E}_+^\wedge, \underline{\mathscr{E}}^c_+) & \xleftarrow{i^+_{\mathbf{E}}} & \Gamma_I^+ & \xrightarrow{i^+_A} & (\mathscr{A}_+^\wedge, \underline{\mathscr{A}}^c_+) & \xleftarrow{j^+_A} & \underline{A} \\
& \searrow^{j_{\mathbf{E}}} & \downarrow{\scriptstyle (i_\Gamma \otimes_P \mathbf{E})^\wedge} & & \downarrow{\scriptstyle i_\Gamma} & & \downarrow{\scriptstyle (i_\Gamma \otimes_P A)^\wedge} & \swarrow_{j_A} & \\
& & (\mathscr{E}^\wedge, \underline{\mathscr{E}}^c) & \xleftarrow{i_{\mathbf{E}}} & \Gamma_I & \xrightarrow{i_A} & (\mathscr{A}^\wedge, \underline{\mathscr{A}}^c). & &
\end{array}$$

Remark 16.6.57. In the situation of (16.6.56), suppose furthermore that the system $\beta_\bullet$ generates an open ideal of $\mathbf{E}$. Then, combining corollaries 8.6.40(ii) and 16.3.40(ii) together with proposition 16.6.5(ii), we deduce that $\Gamma_I^+ \otimes_P \mathbf{E}$ and $\Gamma_I \otimes_P \mathbf{E}$ are already $\mathscr{J}$-adically complete and separated, and $\Gamma_I^+ \otimes_P A$ and $\Gamma_I \otimes_P A$ are J-adically complete and separated.

Corollary 16.6.58. *With the notation of* (16.6.56)*, the rings $\mathscr{E}_+^\wedge$, $\mathscr{E}^\wedge$, $\mathscr{A}_+^\wedge$ and $\mathscr{A}^\wedge$ are perfectoid, and we have natural isomorphisms of topological rings with Δ-graded structures*

$$\omega_+ : \mathbf{E}(\mathscr{A}_+^\wedge, \underline{\mathscr{A}}^c_+) \xrightarrow{\sim} (\mathscr{E}_+^\wedge, \underline{\mathscr{E}}^c_+) \qquad \omega : \mathbf{E}(\mathscr{A}^\wedge, \underline{\mathscr{A}}^c) \xrightarrow{\sim} (\mathscr{E}^\wedge, \underline{\mathscr{E}}^c)$$

fitting into the commutative diagrams

$$\begin{array}{ccccc}
\underline{\mathbf{E}} & \xrightarrow{\mathbf{E}(j^+_A)} & \mathbf{E}(\mathscr{A}_+^\wedge, \underline{\mathscr{A}}^c_+) & \xleftarrow{\mathbf{E}(i^+_A)} & \Gamma_I^+ \\
& \searrow^{j^+_{\mathbf{E}}} & \downarrow{\scriptstyle \omega_+} & \swarrow_{i^+_{\mathbf{E}}} & \\
& & (\mathscr{E}_+^\wedge, \underline{\mathscr{E}}^c_+) & &
\end{array}
\qquad
\begin{array}{ccccc}
\underline{\mathbf{E}} & \xrightarrow{\mathbf{E}(j_A)} & \mathbf{E}(\mathscr{A}^\wedge, \underline{\mathscr{A}}^c) & \xleftarrow{\mathbf{E}(i_A)} & \Gamma_I \\
& \searrow^{j_{\mathbf{E}}} & \downarrow{\scriptstyle \omega} & \swarrow_{i_{\mathbf{E}}} & \\
& & (\mathscr{E}^\wedge, \underline{\mathscr{E}}^c). & &
\end{array}$$

Proof. Clearly we have $\mathbf{E}(\underline{A}) = \underline{\mathbf{E}}$. The corollary then becomes a special case of proposition 16.6.44, after we have shown

Claim 16.6.59. $\varphi_{\mathbf{E}} \circ \overline{u}_P = \mathbf{E}(\overline{u}_A \circ \varphi_{\mathbf{E}})$.

Proof of the claim. Clearly $\varphi_{\mathbf{E}} \circ \overline{u}_P = \overline{u}_{\mathbf{E}} \circ \mathbf{E}(\varphi_{\mathbf{E}})$, so we are reduced to checking the identity $\overline{u}_{\mathbf{E}} = \mathbf{E}(\overline{u}_A)$, and the latter holds by remark 9.4.5(ii). ☐

16.6.60. From lemma 16.6.53(i) we deduce a corresponding coequalizer presentation for $\mathscr{E}_+$ in the category of Δ-graded $\mathbb{Z}$-algebras :

$$\mathbb{Z}[Q] \rightrightarrows \mathbb{Z}[P \times P] \otimes_{\mathbb{Z}[P]} \mathbf{E} = \mathbf{E}[P] \longrightarrow \mathbb{Z}[\Gamma_I^+] \otimes_{\mathbb{Z}[P]} \mathbf{E} = \mathscr{E}_+$$

where $\mathbf{E}$ and $\mathbb{Z}[P \times P]$ are regarded as $\mathbb{Z}[P]$-algebras via $\varphi_{\mathbf{E}}$ and respectively via the morphism of monoids $P \to P \times P$ given by the rule $e^\delta_\lambda \mapsto f'^\delta_\lambda$ for every $\lambda \in \Lambda$ and every $\delta \in \Delta^+$. Likewise we may present $\mathscr{A}_+$, and there follow natural isomorphisms

$$\mathscr{E}_+ \xrightarrow{\sim} \mathbf{E}[P]/\mathscr{I}_{\mathbf{E}} \qquad \mathscr{A}_+ \xrightarrow{\sim} A[P]/\mathscr{I}_A$$

where $\mathscr{I}_{\mathbf{E}} \subset \mathbf{E}[P]$ is the ideal generated by the system

$$(\beta^r_\lambda \cdot e^r_\mu - \beta^r_\mu \cdot e^r_\lambda \mid \lambda, \mu \in \Lambda;\ r \in \mathbb{N}[1/p]).$$

and $\mathscr{I}_A \subset A[P]$ is the ideal generated by the system

$$(\overline{u}_A(\beta^r_\lambda) \cdot e^r_\mu - \overline{u}_A(\beta^r_\mu) \cdot e^r_\lambda \mid \lambda, \mu \in \Lambda;\ r \in \mathbb{N}[1/p]).$$

Especially, notice that $\mathscr{I}_{\mathbf{E}}$ (resp. $\mathscr{I}_A$) is a graded ideal of the Δ-graded ring $\mathbf{E}[P]_{/\Delta}$ (resp. $A[P]_{/\Delta}$), arising via the grading $|\cdot|_P : P \to \Delta$, and

$$\mathrm{gr}_\delta \mathscr{E}_+ = (\mathrm{gr}_\delta \mathbf{E}[P]_{/\Delta})/\mathrm{gr}_\delta \mathscr{I}_{\mathbf{E}} = \mathbf{E}[\mathrm{gr}_\delta P]/\mathrm{gr}_\delta \mathscr{I}_{\mathbf{E}} \qquad \text{for every } \delta \in \Delta.$$

We can then form the topological rings with Δ-graded structure

$$(\mathscr{E}^s_+, \underline{\mathscr{E}}^s_+) := (\underline{\mathbf{E}}[P]_{/\Delta})/\mathscr{I}_{\mathbf{E}} \qquad (\mathscr{A}^s_+, \underline{\mathscr{A}}^s_+) := (\underline{A}[P]_{/\Delta})/\mathscr{I}_A$$

that are the maximal separated quotients $\mathscr{E}^s_+$ of $\mathscr{E}_+$ and $\mathscr{A}^s_+$ of $\mathscr{A}_+$, endowed with the Δ-graded $\mathbb{Z}$-algebra structures

$$\underline{\mathscr{E}}^s_+ := \bigoplus_{\delta \in \Delta^+} (I^{\langle \delta \rangle} \otimes_P \mathbf{E})^s \qquad \text{and} \qquad \underline{\mathscr{A}}^s_+ := \bigoplus_{\delta \in \Delta^+} (I^{\langle \delta \rangle} \otimes_P A)^s$$

where $(I^{\langle \delta \rangle} \otimes_P \mathbf{E})^s$ denotes the maximal separated quotient of $I^{\langle \delta \rangle} \otimes_P \mathbf{E}$, for every $\delta \in \Delta$, and likewise for $(I^{\langle \delta \rangle} \otimes_P A)^s$. It is now straightforward that the completion maps $\mathscr{E}^s_+ \to \mathscr{E}^\wedge_+$ and $\mathscr{A}^s_+ \to \mathscr{A}^\wedge_+$ factor through natural isomorphisms

$$(\mathscr{E}^s_+, \underline{\mathscr{E}}^s_+)^\wedge \xrightarrow{\sim} (\mathscr{E}^\wedge_+, \underline{\mathscr{E}}^c_+) \qquad \text{and} \qquad (\mathscr{A}^s_+, \underline{\mathscr{A}}^s_+)^\wedge \xrightarrow{\sim} (\mathscr{A}^\wedge_+, \underline{\mathscr{A}}^c_+).$$

16.7. **Perfectoid spaces.** Some basic verifications concerning perfectoid spaces will employ a certain amount of formal algebraic geometry, that we collect hereafter.

16.7.1. Quite generally, let R be any $\mathbb{Q}_+$-graded ring. We associate with R a projective scheme

$$\mathrm{Proj}\, R$$

as follows. For every $\gamma \in \mathbb{Q}_{>0}$, let $R^{(\gamma)} := \bigoplus_{k \in \mathbb{N}} R_{k\gamma}$, which we regard as an $\mathbb{N}$-graded ring, whose k-graded direct summand is $R_{k\gamma}$, for every $k \in \mathbb{N}$. Set $Y^{(\gamma)} := \mathrm{Proj}\, R^{(\gamma)}$ for every such γ. If $n > 0$ is any integer, the discussion of (10.6.11) yields a natural isomorphism

$$Y^{(\gamma)} \xrightarrow{\Omega^{(\gamma)}_n} Y^{(n\gamma)}$$

of R_0-schemes, and it is easily seen that

$$\Omega^{(n\gamma)}_p \circ \Omega^{(\gamma)}_n = \Omega^{(\gamma)}_{pn} \qquad \text{for every integers } n, p > 0.$$

Thus, the rule $\gamma \mapsto Y^{(\gamma)}$ yields a well defined filtered system of isomorphisms, and we let $\mathrm{Proj}\, R$ be any choice of an R_0-scheme representing the colimit of this system; *e.g.* $\mathrm{Proj}\, R := Y^{(\gamma_0)}$, for some fixed $\gamma_0 \in \mathbb{Q}_{>0}$, together with the cocone $(\Omega^{(\gamma)} : Y^{(\gamma)} \to \mathrm{Proj}\, R \mid \gamma \in \mathbb{Q}_{>0})$ resulting from the filtered system of morphisms $\Omega^{(\bullet)}_\bullet$.

16.7.2. To ease notation, we shall let $Y := \mathrm{Proj}\, R$. For every $\gamma \in \mathbb{Q}_{>0}$, every $n \in \mathbb{N}$, and every $f \in R_{n\gamma}$ we have the open subset $D_+(f) \subset Y^{(\gamma)}$ defined as in (10.6.1), and we denote also $D_+(f) \subset Y$ the image of this open subset under $\Omega^{(\gamma)}$. It is easily seen that the resulting open subset of Y is independent of the choice of γ. We also set $\mathscr{O}_Y(0) := \mathscr{O}_Y$ and

$$\mathscr{O}_Y(\gamma) := \Omega^{(|\gamma|)}_* \mathscr{O}_{Y^{(|\gamma|)}}(\gamma/|\gamma|) \qquad \text{for every } \gamma \in \mathbb{Q} \setminus \{0\}$$

and we notice that – according to (10.6.16) – the quasi-coherent $\mathscr{O}_Y$-module $\mathscr{O}_Y(\gamma)$ restricts to an invertible $\mathscr{O}_Y$-module on the open subset

$$U_\gamma(R) := \bigcup_{f \in R_{|\gamma|}} D_+(f) \qquad \text{for every } \gamma \in \mathbb{Q} \setminus \{0\}.$$

Remark 16.7.3. Let $\Gamma \subset \mathbb{Q}_+$ be any submonoid, and suppose that $R = \mathbb{Q}_+ \times_\Gamma R'$ for a Γ-graded ring R'. Then it is easily seen that $\mathscr{O}_Y(\gamma) = 0$ and $U_\gamma(R) = \varnothing$ for every $\gamma \in \mathbb{Q} \setminus \Gamma^{\mathrm{gp}}$.

16.7.4. In view of the isomorphisms (10.6.14), we get natural identifications

$$\mathscr{O}_Y(n\gamma) \xrightarrow{\sim} \Omega_*^{(\gamma)}\mathscr{O}_{Y^{(\gamma)}}(n) \qquad \text{for every } n \in \mathbb{Z} \text{ and every } \gamma \in \mathbb{Q}_{>0}. \tag{16.7.5}$$

For every $\gamma, \gamma' \in \mathbb{Q}$ there exists as well a natural morphism

$$\mathscr{O}_Y(\gamma) \otimes_{\mathscr{O}_Y} \mathscr{O}_Y(\gamma') \to \mathscr{O}_Y(\gamma + \gamma') \tag{16.7.6}$$

that generalizes (10.6.21). Namely, pick a common divisor, *i.e.* a rational number $\delta \in \mathbb{Q}_{>0}$ and integers $p, q \in \mathbb{N}$ such that $p\delta = \gamma$ and $q\delta = \gamma'$; we have first a natural identification

$$\mathscr{O}_Y(\gamma) \otimes_{\mathscr{O}_Y} \mathscr{O}_Y(\gamma') \xrightarrow{\sim} \Omega_*^{(\delta)}\mathscr{O}_{Y^{(\delta)}}(p) \otimes_{\mathscr{O}_Y} \Omega_*^{(\delta)}\mathscr{O}_{Y^{(\delta)}}(q) \xrightarrow{\sim} \Omega_*^{(\delta)}(\mathscr{O}_{Y^{(\delta)}}(p) \otimes_{\mathscr{O}_Y^{(\delta)}} \mathscr{O}_{Y^{(\delta)}}(q))$$

which we combine with the map

$$\Omega_*^{(\delta)}(\mathscr{O}_{Y^{(\delta)}}(p) \otimes_{\mathscr{O}_Y^{(\delta)}} \mathscr{O}_{Y^{(\delta)}}(q)) \to \Omega_*^{(\delta)}\mathscr{O}_{Y^{(\delta)}}(p+q) \xrightarrow{\sim} \mathscr{O}_Y(\gamma + \gamma')$$

deduced from (10.6.21) and the inverse of the isomorphism (16.7.5), to obtain (16.7.6), and it is easily seen that the resulting map is independent of the choice of δ : details left to the reader. Especially, (16.7.6) restricts to an isomorphism on $U_{\gcd(\gamma,\gamma')}(R)$, where $\gcd(\gamma, \gamma')$ is the greatest common divisor of γ and γ' (here we let $\gcd(0,0) := 0$; actually, it is not difficult to show that (16.7.6) is an isomorphism on the open subset $U_\gamma(R) \cup U_{\gamma'}(R)$). Furthermore, let

$$\pi^{(\gamma)} : Y^{(\gamma)} \to \operatorname{Spec} R_0 \qquad \text{and} \qquad \pi : Y \to \operatorname{Spec} R_0$$

be the structure morphisms; the morphism (10.6.22) induces a natural map

$$\pi^* R_\gamma^\sim \xrightarrow{\sim} \Omega_*^{(\gamma)}\pi^{(\gamma)*}R_1^{(\gamma)} \to \Omega_*^{(\gamma)}\mathscr{O}_{Y^{(\gamma)}}(1) = \mathscr{O}_Y(\gamma) \qquad \text{for every } \gamma \in \Gamma \setminus \{0\}$$

which restricts to an epimorphism on $U_\gamma(R)$.

16.7.7. Let R' be another $\mathbb{Q}_+$-graded ring, and $\varphi : R \to R'$ a morphism of $\mathbb{Q}_+$-graded rings; set $Y' := \operatorname{Proj} R'$, $Y'^{(\gamma)} := \operatorname{Proj} R'^{(\gamma)}$, and denote by $\Omega'^{(\gamma)} : Y^{(\gamma)} \to Y'$ and $\Omega_n'^{(\gamma)} : Y^{(\gamma)} \to Y'^{(n\gamma)}$ the induced morphism, for every $\gamma \in \mathbb{Q}_{>0}$ and every integer $n > 0$. The restriction of φ

$$\varphi^{(\gamma)} : R^{(\gamma)} \to R'^{(\gamma)} \qquad \text{for every } \gamma \in \mathbb{Q}_{>0}$$

is a morphism of $\mathbb{N}$-graded rings, whence a morphism $\operatorname{Proj} \varphi^{(\gamma)} : G(\varphi^{(\gamma)}) \to Y^{(\gamma)}$ (notation of (10.6.5)). Moreover, it is easily seen that

$$\Omega_n'^{(\gamma)} G(\varphi^{(\gamma)}) = G(\varphi^{(n\gamma)}) \qquad \text{for every } \gamma \in \mathbb{Q}_{>0} \text{ and every integer } n > 0.$$

Furthermore, the resulting diagram of schemes

$$\begin{array}{ccc} G(\varphi^{(\gamma)}) & \xrightarrow{\operatorname{Proj} \varphi^{(\gamma)}} & Y^{(\gamma)} \\ {\scriptstyle \Omega_n'^{(\gamma)}} \downarrow & & \downarrow {\scriptstyle \Omega_n^{(\gamma)}} \\ G(\varphi^{(n\gamma)}) & \xrightarrow{\operatorname{Proj} \varphi^{(n\gamma)}} & Y^{(n\gamma)} \end{array}$$

commutes for every such γ and n. Thus, we may set

$$G(\varphi) := \Omega^{(\gamma)}(G(\varphi^{(\gamma)})) \qquad \text{for any } \gamma \in \mathbb{Q}_{>0}$$

and the colimit of the system $(\operatorname{Proj} \varphi^{(\gamma)} \mid \gamma \in \mathbb{Q}_+)$ is a well defined morphism

$$\operatorname{Proj} \varphi : G(\varphi) \to Y.$$

Remark 16.7.8. (i) Set $R_+ := \bigoplus_{\gamma\in\mathbb{Q}_{>0}} R_\gamma$, and define likewise R'_+. Let also $f' \in R'_+$ be any homogeneous element; we claim that $D_+(f') \subset G(\varphi)$ if and only if f' lies in the radical J of the ideal of R' generated by $\varphi(R_+)$. Indeed, say that $f' \in R'_\gamma$ for some $\gamma \in \mathbb{Q}_{>0}$; if $D_+(f') \subset G(\varphi)$, then $D_+(f') \subset G(\varphi^{(\gamma)})$ as well, so f' lies in the radical of the ideal of $R'^{(\gamma)}$ generated by $\varphi^{(\gamma)}(R_+^{(\gamma)})$ (see the discussion of (10.6.5)), and therefore f' lies in J as well. Conversely, if $f' \in J$, we may find $n, k \in \mathbb{N}$, and elements $\nu(i) \in \mathbb{Q}_{>0}$, $a_i \in R_{\nu(i)}$, $f'_i \in R'_{\gamma-\nu(i)}$ for $i = 1, \dots, k$, such that $f'^n = \sum_{i=1}^k f_i \cdot \varphi(a_i)$. Then, pick any common divisor δ of $\gamma, \nu(1), \dots, \nu(k)$ in $\mathbb{Q}_{>0}$; it follows that f' lies in the radical of the ideal of $R'^{(\delta)}$ generated by $\varphi^{(\delta)}(R_+^{(\delta)})$, whence $D_+(f') \subset G(\varphi^{(\delta)})$, and finally $D_+(f') \in G(\varphi)$.

(ii) Especially, if $\varphi(R_+)$ generates the ideal R'_+ of R', then $G(\varphi) = Y'$.

16.7.9. We shall apply the foregoing constructions to the situation contemplated in (16.4.4) : we let (A, u_0) be a pair consisting of a ring A, and a ring homomorphism

$$u_0 : R_{r,0} := \mathbb{Z}[T_1^{1/p^\infty}, \dots, T_r^{1/p^\infty}] \to A.$$

Also, we denote by $T_\bullet P_r \subset P_r := \mathbb{N}[1/p]^{\oplus r}$ the ideal generated by $\mathbb{N}^{\oplus r}$, we set $\Gamma := \mathbb{N}[1/p]$, and we consider the Γ-graded *angular Rees algebra*

$$\mathsf{R}\langle A\rangle := \bigoplus_{\gamma\in\Gamma} T_\bullet^{\langle\gamma\rangle} A.$$

Hence, for every $\gamma \in \Gamma$, the direct summand $\mathsf{R}\langle A\rangle_\gamma$ is the ideal of A generated by all products of the form $u_0(T_1^{a_1} \cdots T_r^{a_r})$, where $(a_1, \dots, a_r) \in P_r$ is any sequence of exponents such that $a_1 + \cdots + a_r = \gamma$. The *angular blowing up* of the ideal $T_\bullet A_0$ is the morphism

$$Y := \mathrm{Proj}\,(\mathsf{R}\langle A\rangle_{/\mathbb{Q}_+}) \to X := \mathrm{Spec}\, A$$

(notation of definition 7.6.1(v)). Notice that $U_\gamma(\mathsf{R}\langle A\rangle_{/\mathbb{Q}_+}) = Y$ for every $\gamma \in \Gamma \setminus \{0\}$.

Theorem 16.7.10. *In the situation of* (16.7.9)*, suppose furthermore that the ring A fulfills the condition of lemma* 16.4.5*. Then, for every $s \in \mathbb{R}_+$ we have :*

(i) *The natural maps $T_\bullet^{\lceil s\rceil} A \to T_\bullet^{\lceil s\rceil} \cdot H^0(Y, \mathscr{O}_Y) \to H^0(Y, T_\bullet^{\lceil s\rceil}\mathscr{O}_Y)$ are isomorphisms.*
(ii) $H^p(Y, T_\bullet^{\lceil s\rceil}\mathscr{O}_Y) = 0$ *for every $p > 0$.*
(iii) *The ring $\mathsf{R}\langle A\rangle$ fulfills the condition of lemma* 16.4.5.
(iv) *For every $t \in \mathbb{R}_+$ the natural map*

$$T_\bullet^{\lceil s\rceil} A \otimes_A T_\bullet^{\lceil t\rceil} A \to T_\bullet^{\lceil t+s\rceil} A$$

is an isomorphism.

Proof. Notice first that $T_\bullet^{\lceil s\rceil} \cdot H^0(Y, \mathscr{O}_Y)$ and $H^0(Y, T_\bullet^{\lceil s\rceil}\mathscr{O}_Y)$ are A-submodules of $H^0(Y, \mathscr{O}_Y)$; hence, the map $T_\bullet^{\lceil s\rceil} \cdot H^0(Y, \mathscr{O}_Y) \to H^0(Y, T_\bullet^{\lceil s\rceil}\mathscr{O}_Y)$ is injective, and in order to show (i), it suffices to prove that the composition $T_\bullet^{\lceil s\rceil} A \to H^0(Y, T_\bullet^{\lceil s\rceil}\mathscr{O}_Y)$ is an isomorphism.

Now, for every $k \in \mathbb{N}$ we set $\Gamma_k := \{n/p^k \mid n \in \mathbb{N}\} \subset \Gamma$, and consider the Γ_k-graded ring

$$S_k := \bigoplus_{\gamma\in\Gamma_k} I_k^{p^k\gamma} A \qquad \text{and the } \mathbb{Q}_+\text{-graded ring} \qquad S'_k := (S_k)_{/\mathbb{Q}_+}$$

where $I_k \subset R_{r,0}$ denotes the ideal generated by $(T_1^{1/p^k}, \dots, T_k^{1/p^k})$. The natural inclusion map is a morphism of $\mathbb{Q}_+$-graded rings $S'_k \to S'_{k+1}$ for every $k \in \mathbb{N}$, and the colimit of the resulting system $(S'_k \mid k \in \mathbb{N})$ is $\mathsf{R}(A)_{/\mathbb{Q}_+}$. Set as well

$$Y_k := \mathrm{Proj}\, S'_k \qquad \text{for every } k \in \mathbb{N}.$$

There follows a system of affine morphisms of X-schemes $(Y_k \mid k \in \mathbb{N})$, and in view of [65, Ch.IV, Prop.8.2.3] it is easily seen that its limit is Y. For every $k \in \mathbb{N}$, let $\pi_k : Y \to Y_k$ be the natural projection. Notice that the direct summand $S'_{k,\gamma}$ of S' is an ideal of A, and

$$\bigcup_{k\in\mathbb{N}} S'_{k,\gamma} = T^{\langle\gamma\rangle}_\bullet A \qquad \text{for every } \gamma \in \Gamma.$$

We deduce natural identifications as in remark 10.6.39(iv) for every $\gamma \in \Gamma$ and every $k \in \mathbb{N}$

$$\mathscr{O}_{Y_k}(\gamma) \xrightarrow{\sim} S'_{k,\gamma}\mathscr{O}_{Y_k} \qquad \operatorname*{colim}_{i\in\mathbb{N}} \pi_i^{-1}\mathscr{O}_{Y_i}(\gamma) \xrightarrow{\sim} \mathscr{O}_Y(\gamma) \xrightarrow{\sim} T^{\langle\gamma\rangle}_\bullet \mathscr{O}_Y$$

whence, by proposition 10.1.10(ii), a natural isomorphism of A-modules :

$$H^p(Y, T^{\langle\gamma\rangle}_\bullet \mathscr{O}_Y) \xrightarrow{\sim} \operatorname*{colim}_{i\in\mathbb{N}} H^p(Y_i, \mathscr{O}_{Y_i}(\gamma)) \qquad \text{for every } p \in \mathbb{N} \text{ and every } \gamma \in \Gamma. \tag{16.7.11}$$

By the same token, we have as well a natural isomorphism

$$H^p(Y, T^{[s]}_\bullet \mathscr{O}_Y) \xrightarrow{\sim} \operatorname*{colim}_{\gamma>s} H^p(Y, T^{\langle\gamma\rangle}_\bullet \mathscr{O}_Y) \qquad \text{for every } p \in \mathbb{N} \text{ and every } s \in \mathbb{R}_+. \tag{16.7.12}$$

Claim 16.7.13. There exists an integer $c > 0$ such that for every $k \in \mathbb{N}$ and every $\gamma \in \Gamma_k$, the inclusion map $i : S'_{k,\gamma+c/p^k}\mathscr{O}_{Y_k} \to S'_{k,\gamma}\mathscr{O}_{Y_k}$ induces the zero map in cohomology :

$$0 = H^p(Y_k, i) : H^p(Y_k, \mathscr{O}_{Y_k}(\gamma + c/p^k)) \to H^p(Y_k, \mathscr{O}_{Y_k}(\gamma)) \qquad \text{for every } p > 0$$

and moreover the kernel and cokernel of the natural morphism of inverse systems

$$(S'_{k,n/p^k} \to H^0(Y_k, \mathscr{O}_{Y_k}(n/p^k)) \mid n \in \mathbb{N})$$

is uniformly essentially zero with step $\leq c$.

Proof of the claim. Recall that Y_k is the colimit of the filtered system $(Y^{(\gamma)}_k \mid \gamma \in \Gamma_k)$ defined as in (16.7.1). By inspecting the construction, it is easily seen that $Z_k := Y^{(1/p^k)}_k$ is the blowing up morphism of the ideal of $\mathscr{O}_X$ generated by the sequence $\mathbf{f}^{(k)} := (u_0(T_1^{1/p^k}), \dots, u_0(T_k^{1/p^k}))$. Say now that $\gamma = a/p^k$; according to (16.7.5), we have a natural identification

$$\mathscr{O}_{Y_k}(\gamma + d/p^k) \xrightarrow{\sim} \Omega^{(1/p^k)}_* \mathscr{O}_{Z_k}(a + d) \qquad \text{for every } d \in \mathbb{N}.$$

On the other hand, lemma 16.4.5(i) implies that the ring A satisfies condition $(\mathrm{a})^{\mathrm{un}}_{\mathbf{f}^{(k)}}$ with step $\leq r$. Then, by theorem 10.6.50 and remark 10.6.57, there exists a constant $c \in \mathbb{N}$ independent of k and a, such that the inclusion map $\mathscr{O}_{Z_k}(a) \to \mathscr{O}_{Z_k}(a+c)$ induces the zero map in cohomology

$$H^p(Z_k, \mathscr{O}_{Z_k}(a + c)) \to H^p(Z_k, \mathscr{O}_{Z_k}(a)) \qquad \text{for every } p > 0$$

and moreover, the kernel and cokernel of the morphism of inverse systems

$$(I^n_k A \to H^0(Z_k, \mathscr{O}_{Z_k}(n)) \mid n \in \mathbb{N})$$

are uniformly essentially zero with step $\leq c$. Both assertions of the claim are an immediate consequence. ◊

Now, in view of (16.7.12), in order to prove (ii), it suffices to show that for every $\gamma > s$ there exists $\gamma' \in \mathbb{Q}_+$ with $s < \gamma' < \gamma$, and such that the natural map

$$H^p(Y, T^{\langle\gamma\rangle}_\bullet \mathscr{O}_Y) \to H^p(Y, T^{\langle\gamma'\rangle}_\bullet \mathscr{O}_Y)$$

vanishes. To this aim, pick any $k \in \mathbb{N}$ such that $c/p^k < \gamma - s$, where $c \in \mathbb{N}$ is as in claim 16.7.13; by virtue of (16.7.11), we get the sought vanishing with $\gamma' := \gamma - c/p^k$. A similar argument proves also assertion (i) : details left to the reader.

(iii): It suffices to check that for every $\gamma' < \gamma$ in $\mathbb{N}[1/p]$ the inclusion $I^{\langle\gamma\rangle}_{r,0} \subset I^{\langle\gamma'\rangle}_{r,0}$ induces the zero morphism

$$\mathrm{Tor}^{R_{r,0}}_i(R_{r,0}/I^{\langle\gamma\rangle}_{r,0}, \mathsf{R}\langle A\rangle) \to \mathrm{Tor}^{R_{r,0}}_i(R_{r,0}/I^{\langle\gamma'\rangle}_{r,0}, \mathsf{R}\langle A\rangle) \qquad \text{for every } i > 0.$$

However, for every $k \in \mathbb{N}$ set $A_{r,k} := \mathbb{Z}[T_1^{1/p^k}, \dots, T_r^{1/p^k}]$ and let $J_{r,k} \subset A_{r,k}$ be the ideal generated by $(T_1^{1/p^k}, \dots, T_r^{1/p^k})$; we regard A as an $A_{r,k}$-algebra for every $k \in \mathbb{N}$, via restriction of scalars along the inclusion map $A_{r,k} \to R_{r,0}$, and we let $R_k(A)$ be the Rees A-algebra associated with the $J_{r,k}A$-adic filtration of A. Now, say that $\gamma = c/p^n$ and $\gamma' = c'/p^n$ for some $c, c', n \in \mathbb{N}$; in view of claim 7.11.37(i) it suffices to show that for every $i > 0$ there exists $k_0 \in \mathbb{N}$ such that the inclusion $J_{r,n+k}^{cp^k} \subset J_{r,n+k}^{c'p^k}$ induces the zero morphism

$$\mathrm{Tor}_i^{A_{r,n+k}}(A_{r,n+k}/J_{r,n+k}^{cp^k}, R_{n+k}(A)) \to \mathrm{Tor}_i^{A_{r,n+k}}(A_{r,n+k}/J_{r,n+k}^{c'p^k}, R_{n+k}(A))$$

for every $k \geq k_0$. However, for every $k \in \mathbb{N}$ let $\mathbf{f}_\bullet^{(k)} := (u_0(T_1^{1/p^k}), \dots, u_0(T_r^{1/p^k}))$, and denote by $\mathbf{g}_\bullet^{(k)}$ the image of $\mathbf{f}_\bullet^{(k)}$ under the natural ring homomorphism $A \to R_k(A)$. By lemma 16.4.5(i) we know that A fulfills condition $(\mathrm{a})^{\mathrm{un}}_{\mathbf{f}_\bullet^{(k)}}$ with step $\leq r$; then corollary 7.9.22(ii) and remark 7.9.27 imply that $R_k(A)$ fulfills condition $(\mathrm{a})^{\mathrm{un}}_{\mathbf{g}_\bullet^{(k)}}$ with a step independent of k; explicitly, the latter means that the inverse system $(\mathrm{Tor}_i^{A_{r,k}}(A_{r,k}/J_{r,k}^t, R_k(A)) \mid t \in \mathbb{N})$ is uniformly essentially zero for every $k \in \mathbb{N}$ and every $i > 0$, with a step independent of k. The assertion is an immediate consequence.

(iv): It suffices to show that the natural map

$$T_\bullet^{\lceil s \rceil} A \otimes_A T_\bullet^{\langle t \rangle} A \to T_\bullet^{\lceil t+s \rceil} A \qquad (16.7.14)$$

is an isomorphism for every $t \in \mathbb{R}_+$. However, (iii) easily implies that the natural map

$$T_\bullet^{\lceil s \rceil} R_{r,0} \otimes_{R_{r,0}} T_\bullet^{\langle t \rangle} A \to T_\bullet^{\lceil t+s \rceil} A$$

is an isomorphism, and the latter factors through (16.7.14) and a surjection $T_\bullet^{\lceil s \rceil} R_{r,0} \otimes_{R_{r,0}} T_\bullet^{\langle t \rangle} A \to T_\bullet^{\lceil s \rceil} A \otimes_A T_\bullet^{\langle t \rangle} A$, whence the contention. □

16.7.15. In the situation of (16.7.9), suppose that A fulfills the condition of lemma 16.4.5, and is endowed with a $\mathbb{Q}_+$-grading which makes it an A_0-subalgebra of $A_0[\mathbb{Q}_+]$ (where $A_0 \subset A$ is the subring of homogeneous elements of degree zero), and moreover suppose that the image of u_0 lies in A_0. In this case, the foregoing considerations apply to A_0 as well, and we get a well defined Γ-graded subring $\mathsf{R}\langle A_0 \rangle$ of $\mathsf{R}\langle A \rangle$, as well the angular blowing up morphism

$$Y_0 := \mathrm{Proj}\,(\mathsf{R}\langle A_0 \rangle_{/\mathbb{Q}_+}) \to X_0 := \mathrm{Spec}\, A_0.$$

Notice also that $\mathsf{R}\langle A \rangle$ carries a natural $(\Gamma \times \mathbb{Q}_+)$-graded ring structure : namely,

$$\mathrm{gr}_{(\gamma,t)}\mathsf{R}\langle A \rangle := T_\bullet^{\langle \gamma \rangle} A_t \qquad \text{for every } (\gamma, t) \in \Gamma \times \mathbb{Q}_+$$

which is an ideal in A_0, for every such (γ, t), and we set

$$\mathsf{R}\langle A_t \rangle := \bigoplus_{\gamma \in \Gamma} T_\bullet^{\langle \gamma \rangle} A_t = A_t \mathsf{R}\langle A_0 \rangle \qquad \text{for every } t \in \mathbb{Q}_+.$$

Corollary 16.7.16. *In the situation of* (16.7.15)*, for every $s \in \mathbb{R}_+$ and every $t \in \mathbb{Q}_+$ we have :*

(i) *The natural maps $T_\bullet^{\lceil s \rceil} A_t \to T_\bullet^{\lceil s \rceil} A_t \cdot H^0(Y_0, \mathscr{O}_{Y_0}) \to H^0(Y_0, T_\bullet^{\lceil s \rceil} A_t \mathscr{O}_{Y_0})$ are isomorphisms.*

(ii) *$H^p(Y_0, T_\bullet^{\lceil s \rceil} A_t \mathscr{O}_{Y_0}) = 0$ for every $p > 0$.*

Proof. Let $i : A_0 \to A$ and $\mathsf{R}\langle i \rangle : \mathsf{R}\langle A_0 \rangle \to \mathsf{R}\langle A \rangle$ be the inclusion maps; since $i(\mathsf{R}\langle A_0 \rangle_+)$ generates the ideal $\mathsf{R}\langle A \rangle_+$ of $\mathsf{R}\langle A \rangle$, then i induces a morphism of schemes $\mathrm{Proj}\, \mathsf{R}\langle i \rangle : Y \to Y_0$

(remark 16.7.8(ii)) fitting into the commutative diagram

$$\begin{array}{ccc} Y & \xrightarrow{\mathrm{Proj}\,\mathsf{R}\langle i\rangle} & Y_0 \\ {\scriptstyle\pi}\downarrow & & \downarrow{\scriptstyle\pi_0} \\ X & \xrightarrow{\mathrm{Spec}\, i} & X_0. \end{array}$$

To ease notation, we let $\varphi_X := \mathrm{Spec}\, i$ and $\varphi_Y := \mathrm{Proj}\,\mathsf{R}\langle i\rangle$. Notice that

$$T_\bullet^{\lceil s\rceil}\mathsf{R}\langle A\rangle_{(f)} = T_\bullet^{\lceil s\rceil}\Big(\bigoplus_{t\in\mathbb{Q}_+}\mathsf{R}\langle A_t\rangle\Big)_{(f)} = \bigoplus_{t\in\mathbb{Q}_+} T_\bullet^{\lceil s\rceil}A_t\mathsf{R}\langle A_0\rangle_{(f)}$$

for every homogeneous element $f\in\mathsf{R}\langle A_0\rangle$, which shows that

$$\varphi_{Y*}T_\bullet^{\lceil s\rceil}\mathscr{O}_Y = \bigoplus_{t\in\mathbb{Q}_+} T_\bullet^{\lceil s\rceil}A_t\mathscr{O}_{Y_0}.$$

Since φ_Y is an affine morphism, we deduce

$$H^p(Y, T_\bullet^{\lceil s\rceil}\mathscr{O}_Y) = H^p(Y_0, \varphi_{Y*}T_\bullet^{\lceil s\rceil}\mathscr{O}_Y) = \bigoplus_{t\in\mathbb{Q}_+} H^p(Y_0, T_\bullet^{\lceil s\rceil}A_t\mathscr{O}_{Y_0})$$

and combining with theorem 16.7.10 we get the corollary. □

Example 16.7.17. (i) According to proposition 16.4.10(i), theorem 16.7.10 applies especially to the case where A is perfectoid. In this case there exist unique $\beta_1,\dots,\beta_r\in\mathbf{E}:=\mathbf{E}(A)$ such that $u_0(T_i^{1/p^k}) = \overline{u}_A(\beta_i^{1/p^k})$ for every $i=1,\dots,r$ and every $k\in\mathbb{N}$, so we may regard as well $\mathbf{E}$ as an $R_{r,0}$-algebra via the unique ring homomorphism

$$R_{r,0}\to\mathbf{E} \qquad : \qquad T_i\mapsto\beta_i \qquad \text{for every } i=1,\dots,r.$$

(ii) More generally, proposition 16.6.5 shows that theorem 16.7.10 applies to the case where A is the graded subring of a perfectoid ring $(A^\wedge, A)$ with Δ-graded structure, where Δ is an integral p-perfect monoid, provided the elements $\beta_1,\dots,\beta_r$ as in (i) are homogeneous elements of the Δ-graded subring of $\mathbf{E}(A)$.

(iii) A ring A as in (ii) is given by example 16.6.12 : we take a perfectoid ring A_0, a second finite family $\beta'_\bullet := (\beta'_1,\dots,\beta'_{r'})$ of elements of $\mathbf{E}_0 := \mathbf{E}(A_0)$, we set $I := \beta'_\bullet\mathbf{E}_0$, and let A_t be the topological closure in A_0 of $I^{\langle t\rangle}A_0$ for every $t\in\Delta := \mathbb{N}[1/p]$. Then, clearly corollary 16.7.16 shall apply to the $\mathbb{Q}_+$-graded ring $A_{/\mathbb{Q}_+}$.

(iv) Let A_0, $\mathbf{E}_0$, $\beta'_\bullet$ and A be as in (iii), and suppose that also the sequence $\beta_\bullet$ lies in $\mathbf{E}(A_0)$. Suppose moreover that I is an ideal of adic definition for $\mathbf{E}_0$. In this case, the ideal $I^{\langle t\rangle}A_0$ is also open in A_0 (corollary 16.3.40(ii)), and therefore it coincides with A_t for every $t\in\mathbb{N}[1/p]$. Especially, $\mathrm{gr}_{(\gamma,t)}\mathsf{R}\langle A\rangle = T_\bullet^{\langle\gamma\rangle}I^{\langle t\rangle}A_0$ for every $(\gamma,t)\in\Gamma\times\mathbb{N}[1/p]$.

(v) In the situation of (iv), suppose furthermore that the ideal $T_\bullet\mathbf{E}_0\subset\mathbf{E}_0$ generated by $\beta_\bullet$ is open. Notice that $T_\bullet^{\lceil 0\rceil}\mathbf{E}_0$ is the radical of $T_\bullet\mathbf{E}_0$ (details left to the reader). It follows that for every $s\in\mathbb{N}[1/p]\setminus\{0\}$ there exists $s'>0$ such that $I^{\langle s\rangle}\mathbf{E}_0\subset T_\bullet^{\langle s'\rangle}\mathbf{E}_0$, whence $I^{\langle s\rangle}A_0\subset T_\bullet^{\langle s'\rangle}A_0$ (corollary 16.3.51(ii)). Therefore :

$$I^{\langle t+s\rangle}A_0\subset I^{\langle t\rangle}T_\bullet^{\lceil 0\rceil}A_0\subset I^{\langle t\rangle}A_0 \qquad \text{for every } t,s\in\mathbb{N}[1/p] \text{ with } s>0.$$

Corollary 16.7.18. *In the situation of* (16.7.9)*, suppose that A is perfectoid, and let I be any finitely generated ideal of adic definition of $\mathbf{E} := \mathbf{E}(A)$. With the notation of example* 16.7.17(v)*, for every $t\in\mathbb{R}_+$ we have :*

(i) *The natural maps $I^{\lceil t\rceil}A\to I^{\lceil t\rceil}\cdot H^0(Y,\mathscr{O}_Y)\to H^0(Y, I^{\lceil t\rceil}\mathscr{O}_Y)$ are isomorphisms.*

(ii) $H^p(Y, I^{\lceil t\rceil}\mathscr{O}_Y)=0$ *for every $p>0$.*

Proof. With the notation of example 16.7.17(v), notice that

$$H^p(Y, I^{\lceil t\rceil}T_\bullet^{\lceil 0\rceil}\mathscr{O}_Y) = \operatorname*{colim}_{s>t} H^p(Y, I^{\langle s\rangle}T_\bullet^{\lceil 0\rceil}\mathscr{O}_Y).$$

On the other hand, example 16.7.17(v) implies that $I^{\lceil t\rceil}A = I^{\lceil t\rceil}T_\bullet^{\lceil 0\rceil}A$ for every $t \in \mathbb{R}_+$. To conclude, it suffices to invoke corollary 16.7.16 as in example 16.7.17(iii,iv) : *i.e.* with A_0 and Y_0 replaced by the current A and respectively Y, and with A replaced by the $\mathbb{Q}_+$-graded ring $A'_{/\mathbb{Q}_+}$, where $A'_s := I^{\langle s\rangle}A$ for every $s \in \mathbb{N}[1/p]$. □

Definition 16.7.19. We say that a topological ring $(A, \mathscr{T})$ is a *formal P-ring* (resp. a *formally perfectoid ring*) if it is adic with a finitely generated ideal of adic definition, and the separated completion of $(A, \mathscr{T})$ is a P-ring (resp. a perfectoid ring).

Remark 16.7.20. Let $(A, \mathscr{T})$ be any topological ring.

(i) Suppose that $(A, \mathscr{T})$ is a P-ring. Then, any ideal of definition of the P-ring A is also an ideal of adic definition of the adic ring A. Remark 16.2.4 implies that the converse holds if and only if A is an $\mathbb{F}_p$-algebra. Indeed, if I is any ideal of adic definition of A, then any power I^n is also an ideal of adic definition, but if p does not vanish in A, then one such power will not contain p, whence the contention.

(ii) Let $\varphi : (A, \mathscr{T}) \to (A', \mathscr{T}')$ be an adic morphism of topological rings, and suppose that φ is a weakly étale ring homomorphism. Then [75, Lemma 3.1.2(i)] implies that φ is adically weakly étale (see definition 8.3.23(iii)).

Theorem 16.7.21. *Let $f : A \to B$ be a c-adically weakly étale morphism of topological rings.*

- (i) *If A and B are f-adic and A is a formal P-ring (resp. a formally perfectoid ring), the same holds for B.*
- (ii) *If f is c-adically faithfully flat, the following holds :*
  - (a) *If B is f-adic and A and B are complete and separated, A is f-adic and f is adic.*
  - (b) *If B is a formal P-ring (resp. a formally perfectoid ring), the same holds for A.*

Proof. (i): In light of lemma 8.3.32(iii,iv), we may assume that A and B are complete and separated, in which case A is a P-ring (resp. a perfectoid ring), f is adically weakly étale (lemma 8.3.24(i.c)), and we have to show that B is a P-ring (resp. is perfectoid).

Suppose first that A is a P-ring, and let I be any ideal of definition of A. It suffices to check that IB is an ideal of definition for B. However, the natural map $B/I^2B \to B^\wedge/I^2B^\wedge$ is an isomorphism, by remark 8.3.3(ii), so we come down to checking that the Frobenius endomorphism of B/I^2B is surjective. However, the induced ring homomorphism $A/I^2 \to B/I^2B$ is weakly étale by assumption; since the Frobenius endomorphism of A/I^2 is surjective by assumption, the assertion then follows easily from [75, Th.3.5.13(ii)].

Next, suppose that A is perfectoid. Due to remark 16.3.58, we may assume that $p \in I^t$, where $t \in \mathbb{N}$ is defined as in (16.3.55), in terms of the length of a system of generators for I. Set $J := I^{(p)}$; taking into account (i) and theorem 16.3.64, we are then reduced to checking that the morphism of graded rings

$$\Phi_{IB} : \mathrm{gr}^\bullet_{IB}B \to \mathrm{gr}^\bullet_{JB}B$$

is an isomorphism. However, since $f \otimes_A A/I^n$ is flat for every $n \in \mathbb{N}$, we get induced graded ring isomorphisms

$$\varphi_I : B \otimes_A \mathrm{gr}^\bullet_I A \xrightarrow{\sim} \mathrm{gr}^\bullet_{IB}B \qquad \varphi_J : B \otimes_A \mathrm{gr}^\bullet_J A \xrightarrow{\sim} \mathrm{gr}^\bullet_{JB}B$$

and φ_I identifies the map

$$\mathrm{gr}^\bullet_I f : \mathrm{gr}^\bullet_I A \to \mathrm{gr}^\bullet_{IB}B$$

with the base change $f \otimes_A \mathrm{gr}^\bullet_I A$. Especially, since $f \otimes_A A/I$ is weakly étale, the same holds for $\mathrm{gr}^\bullet_I f$ ([75, Lemma 3.1.2(i)]). Moreover, denote by $(\mathrm{gr}^\bullet_I A)_{(\Phi)}$ the $\mathrm{gr}^\bullet_I A$-algebra whose underlying ring is $\mathrm{gr}^\bullet_I A$ and whose structure map is the Frobenius endomorphism $\Phi_{\mathrm{gr}^\bullet_I A}$, and define likewise $(\mathrm{gr}^\bullet_{IB} B)_{(\Phi)}$; by [75, Th.3.5.13(ii)], the maps φ_J and $\mathrm{gr}^\bullet_J f$ induce an isomorphism

$$\psi_J : B \otimes_A (\mathrm{gr}^\bullet_J A)_{(\Phi)} \xrightarrow{\sim} \mathrm{gr}^\bullet_{JB} B \otimes_{\mathrm{gr}^\bullet_J A} (\mathrm{gr}^\bullet_J A)_{(\Phi)} \xrightarrow{\sim} (\mathrm{gr}^\bullet_{JB} B)_{(\Phi)} \qquad b \otimes a \mapsto b^p \cdot \mathrm{gr}_I f(a).$$

Summing up, we get a commutative diagram of ring homomorphisms

$$(16.7.22)\qquad \begin{array}{ccc} B \otimes_A \mathrm{gr}^\bullet_I A & \xrightarrow{B\otimes_A \Phi_I} & B \otimes_A (\mathrm{gr}^\bullet_J A)_{(\Phi)} \\ {\scriptstyle\varphi_I}\downarrow & & \downarrow{\scriptstyle\psi_J} \\ \mathrm{gr}^\bullet_{IB} B & \xrightarrow{\Phi_{IB}} & (\mathrm{gr}^\bullet_{JB} B)_{(\Phi)} \end{array}$$

whose vertical arrows are isomorphisms. Lastly, since A is a formally perfectoid ring, Φ_I is an isomorphism as well (theorem 16.3.64), whence the assertion.

(ii.a): Let J be any finitely generated ideal of adic definition of B, and $(I_\lambda \mid \lambda \in \Lambda)$ a cofiltered system of ideals that defines the linear topology of A. By assumption, $(I_\lambda B)^c$ is open in B, hence $I_\lambda B = (I_\lambda B)^c$ for every $\lambda \in \Lambda$ (lemma 8.3.21(ii.b)); then the induced map

$$f_\lambda : A_\lambda := A/I_\lambda \to B_\lambda := B/I_\lambda B$$

is weakly étale and faithfully flat for every $\lambda \in \Lambda$. Also by assumption, we may find $\mu \in \Lambda$ such that $I_\mu B \subset J^2$. Hence, JB_μ is contained in the nilradical $\mathrm{nil}(B_\mu)$ of B_μ, and it follows easily from claim 14.3.27(i) that

$$\mathrm{nil}(B_\mu) = \mathrm{nil}(A_\mu) \cdot B_\mu.$$

Therefore, we may find a finitely generated ideal $K' \subset \mathrm{nil}(A_\mu)$ such that $JB_\mu \subset K'B_\mu$. Pick a finitely generated ideal $K \subset A$ such that $KA_\mu = K'$. It follows easily that $J \subset KB + J^2$. However, B is complete and J is topologically nilpotent in B, so J lies in the Jacobson radical of B, and consequently $J \subset KB$, by Nakayama's lemma. On the other hand, by construction, we may find $n \in \mathbb{N}$ such that $K'^n = 0$, whence $K^n \subset I_\mu$, and therefore $K^n B \subset J^2$. Summing up, we conclude that KB is an ideal of adic definition of B. For every $n \in \mathbb{N}$, pick $\nu(n) \in \Lambda$ such that $I_{\nu(n)} B \subset J^n$; then $I_{\nu(n)} B_\lambda \subset K^n B_\lambda$ for every $\lambda \in \Lambda$, so that $I_{\nu(n)} A_\lambda \subset K^n A_\lambda$, as f_λ is faithfully flat. We deduce that the topological closure $(K^n)^c$ of K^n contains $I_{\nu(n)}$, and especially, it is an open ideal of A, for every $n \in \mathbb{N}$. On the other hand, for every $\lambda \in \Lambda$ we may find $k(\lambda) \in \mathbb{N}$ such that $J^{2k(\lambda)} \subset I_\lambda B$, so that $K^{n \cdot k(\lambda)} B_\nu \subset I_\lambda B_\nu$ for every $\nu \geq \lambda$. It follows that $K^{n \cdot k(\lambda)} A_\nu \subset I_\lambda A_\nu$, again since f_ν is faithfully flat; then, since I_λ is closed in A, we deduce that $K^{n \cdot k(\lambda)} \subset I_\lambda$, for every $\lambda \in \Lambda$. Summing up, we see that the topology of A is c-adic, hence f-adic, by lemma 8.3.21(ii.a). Then f is adic, by lemma 8.3.24(i.c).

(ii.b): In light of lemma 8.3.32(iii), we may replace f by $f^\wedge$, and assume from start that A and B are complete and B is a P-ring (resp. is perfectoid), and we need to show that the same holds for A. However, (ii.a) already says that A is f-adic, and f is adic. Suppose first that B is a P-ring, and pick any finitely generated ideal of adic definition for A; without loss of generality we may assume that J is an ideal of definition for the P-ring B, and that $IB \subset J$. Set $A_n := A/I^{n+1}$ and $B_n := B/I^{n+1}B$ for every $n \in \mathbb{N}$, and notice that JB_0 is nilpotent ideal of B_0; arguing as in the proof of (ii.a), we deduce that there exists a finitely generated ideal

$$(16.7.23)\qquad K_0 \subset \mathrm{nil}(A_0)$$

such that $JB_0 \subset K_0 B_0$. Then, the preimage K of K_0 in A is a finitely generated ideal such that $JB \subset KB$; hence $p^2 \in K^2 B_n$ for every $n \in \mathbb{N}$. Since the induced map $A_n \to B_n$ is faithfully flat, it follows that $p \in K^2 A_n$ for every $n \in \mathbb{N}$, so p lies in the topological closure of K^2 in A; but $(K^2)^c = K^2$, since K is open in A by construction. Lastly, (16.7.23) implies that $K^n \subset I$

for some sufficiently large $n \in \mathbb{N}$; thus, K is also an ideal of adic definition of A, and we are reduced to checking that the Frobenius endomorphism Φ_{A/J^2} of A/J^2 is surjective. However, by lemma 16.2.3(iv) the Frobenius endomorphism Φ_{B/J^2B} is surjective; by [75, Th.3.5.13(ii)], it follows that $\Phi_{A/J^2} \otimes_{A/J^2} B/J^2B$ is also surjective. But the induced map $A/J^2 \to B/J^2B$ is faithfully flat, whence the contention.

Lastly, suppose that B is perfectoid; by the foregoing, we know already that A is a P-ring, and by remark 16.3.58 we may find an ideal of definition I of A such that $p \in I^t$, where $t \in \mathbb{N}$ is defined as in (16.3.55). We set $J := I^{(p)}$; arguing as in the proof of (i), we get a commutative diagram (16.7.22), whose vertical arrows are isomorphisms. Now, notice that, since f is adic, IB is an ideal of definition of B, so the bottom horizontal arrow of (16.7.22) is an isomorphism; hence the same holds for $B \otimes_A \Phi_I = (B/IB) \otimes_{A/I} \Phi_I$. But by assumption, f induces a faithfully flat map $A/I \to B/IB$, so Φ_I is an isomorphism, and therefore A is perfectoid, by theorem 16.3.64. □

16.7.24. Let $\underline{U} := (U, \mathscr{T}_A, A_U^+)$ be any perfectoid quasi-affinoid scheme, and set $\underline{U}_{\mathbf{E}} := \mathbf{E}(\underline{U})$ (notation of (16.5.20)), so that $\underline{U}_{\mathbf{E}} = (\mathbf{E}(U), \mathscr{T}_{\mathbf{E}}, \mathbf{E}_U^+)$, where $\mathbf{E}_U^+ := \mathbf{E}(A_U^+)$. Let as well

$$A_U := \mathscr{O}_U(U) \qquad \mathbf{E}_U := \mathscr{O}_{\mathbf{E}(U)}(\mathbf{E}(U))$$

and pick a perfectoid subring of definition A of A_U *such that A_U^+ is the integral closure of $A \cap A_U^+$ in A_U and such that the induced map $U \to \operatorname{Spec} A$ is an open immersion* (by theorem 16.5.13(i) and lemma 15.6.10(i), the ring A_U° is one such subring of definition), and recall that $\mathbf{E} := \mathbf{E}(A)$ is a ring of definition of $\mathbf{E}_U$. We denote as usual by $\varphi_U^\flat : \mathbf{E}_U \to A_U$ the continuous map of monoids provided by proposition 16.4.34(i), and recall that $\varphi_U^\flat$ restricts to a continuous map $\overline{u}_A : \mathbf{E} \to A$. Now, let $e_0, \dots, e_n$ be a finite system of elements of $\mathbf{E}_U$ that generates an open ideal; according to claim 16.6.36, the system $(a_i := \varphi_U^\flat(e_i) \mid i = 0, \dots, n)$ generates an open ideal of A_U, so we may consider the rational subset

$$R := R_{A_U}\Big(\frac{a_1}{a_0}, \dots, \frac{a_n}{a_0}\Big) \cap \operatorname{Spa} \underline{U}$$

and the corresponding topological rings $\mathscr{O}^\wedge_{\operatorname{Spa} U}(R)$ and $\mathscr{O}^{\wedge +}_{\operatorname{Spa} U}(R)$, defined as in (15.5.11). Recall the construction of $\mathscr{O}^\wedge_{\operatorname{Spa} U}(R)$: first, there is a natural f-adic topology on the localization $A_R := A_U[1/a_0]$ such that the localization map $A_U \to A_R$ is f-adic, and the subring

$$B_R := A[a_i/a_0 \mid i = 1, \dots, n] \subset A_R$$

is a ring of definition of A_R; hence A_R induces on B_R the unique linear topology such that the natural map $A \to B_R$ is adic. We let A_R^+ be the integral closure of $A_U^+[a_i/a_0 \mid i = 1, \dots, n]$ in A_R, set $U_R := U \cap \operatorname{Spec} A_R$, and define

$$\underline{A}_R := (A_R, A_R^+, U_R) \qquad \text{and} \qquad \underline{U}_R^\wedge := (\mathsf{Spec}\, \underline{A}_R)^\wedge.$$

Then (up to natural isomorphism) we have

$$\Gamma(\underline{U}_R^\wedge) = (\mathscr{O}^\wedge_{\operatorname{Spa} U}(R), \mathscr{O}^{\wedge +}_{\operatorname{Spa} U}(R), U_R^\wedge) \qquad \text{where} \qquad U_R^\wedge := U_R \times_{\operatorname{Spec} A_R} \operatorname{Spec} \mathscr{O}^\wedge_{\operatorname{Spa} U}(R).$$

Notice that A_R contains also the subrings

$$C_R := A\Big[\varphi_U^\flat(e_i^{1/p^k})/\varphi_U^\flat(e_0^{1/p^k}) \mid (i,k) \in \{1, \dots, n\} \times \mathbb{N}\Big]$$
$$D_R := A_U^+\Big[\varphi_U^\flat(e_i^{1/p^k})/\varphi_U^\flat(e_0^{1/p^k}) \mid (i,k) \in \{1, \dots, n\} \times \mathbb{N}\Big]$$

and endow C_R and D_R with the topologies induced by the inclusion into A_R. Let also $C_R^+ := C_R \cap A_R^+$. The first observation is the following :

Proposition 16.7.25. *With the notation of* (16.7.24)*, the following holds :*

(i) *The natural morphism $\underline{A}_R^\wedge \to \Gamma(\underline{U}_R^\wedge)$ is an isomorphism.*

(ii) *The datum* $\underline{C}_R := (C_R, C_R^+, U_R)$ *is a quasi-affinoid ring, and the natural morphism* $\mathsf{Spec}\,\underline{A}_R \to \mathsf{Spec}\,\underline{C}_R$ *is an isomorphism.*
(iii) $\underline{C}_R^\wedge$ *is a perfectoid quasi-affinoid ring, and* $\underline{U}_R^\wedge$ *is a perfectoid quasi-affinoid scheme.*
(iv) *Suppose moreover that* $\beta_{\underline{U}}(U_R) \subset \Omega_{\underline{U}}$ *(notation of definition* 15.6.1*). Then the datum* $\underline{D}_R := (D_R, D_R, U_R)$ *is a quasi-affinoid ring, and* $\underline{D}_R^\wedge$ *is perfectoid.*

Proof. (ii): We consider the natural morphisms of schemes

$$U_R \xrightarrow{f} \mathrm{Spec}\,A_R \xrightarrow{g} \mathrm{Spec}\,C_R \xrightarrow{h} \mathrm{Spec}\,A$$

whose composition is also the composition of the open immersion $U_R \to U$ with the natural morphism $i : U \to \mathrm{Spec}\,A$. By assumption, i is an open immersion, and its image contains the analytic locus of $\mathrm{Spec}\,A$ (lemma 8.3.29(iii)). It follows that $h \circ g \circ f$ is an open immersion; moreover, by construction, both f and g have schematically dense images. From claim 15.6.5, we deduce that $g \circ f$ is an open immersion, and $f(U_R) = (h \circ g)^{-1} i(U_R) = (h \circ g)^{-1} i(U)$. Now, U contains the analytic locus of $\mathrm{Spec}\,A$, and the natural map $A \to A_R$ is f-adic; taking into account lemma 8.3.29(iv), it follows that $f(U_R)$ contains the analytic locus of $\mathrm{Spec}\,A_R$. Lastly, g identifies the analytic locus of $\mathrm{Spec}\,A_R$ with that of $\mathrm{Spec}\,C_R$ (lemma 8.3.29(iii)), so $g \circ f(U_R)$ contains the analytic locus of $\mathrm{Spec}\,C_R$. Summing up, this shows that $\underline{C}_R$ is a quasi-affinoid ring. Then, a simple inspection shows that the inclusion map $C_R \to A_R$ induces an isomorphism $\mathsf{Spec}\,\underline{A}_R \to \mathsf{Spec}\,\underline{C}_R$.

(i): To begin with, we remark :

Claim 16.7.26. C_R and D_R are subrings of definition of A_R.

Proof of the claim. Clearly C_R and D_R are open in A_R, and $D_R \subset C_R$; by virtue of proposition 8.3.18(ii), we have then only to check that C_R is bounded in A_R. To this aim, since B_R is open and bounded in A_R, it suffices to show that there exists an open ideal J of B_R such that $J \cdot C_R \subset B_R$. However, pick any finite system $f_1, \dots, f_r$ of generators for an ideal of definition of $\mathbf{E}$; since the system $e_0, \dots, e_n$ generates an open ideal of $\mathbf{E}_U$, we may find an integer $k \in \mathbb{N}$ large enough so that the $f_i^r e_j \in \mathbf{E}$ for every $i = 1, \dots, r$ and every $j = 0, \dots, n$, and then it is clear that the system $(f_i^r e_j \mid i \leq r,\ j \leq n)$ generates an open ideal of $\mathbf{E}$. By claim 16.6.36, it follows that the system $(\varphi_U^\flat(f_i^r e_j) \mid i \leq r,\ j \leq n)$ generates an open ideal J_0 of A, and therefore $J := J_0 B_R$ is open in B_R. To conclude, it suffices to show that $\varphi_U^\flat(f_i^r e_j e_s^\nu e_0^{-\nu}) \in B_R$ for every $i = 1, \dots, r$ every $j, s = 0, \dots, n$, and every $\nu \in \mathbb{N}[1/p]$. Moreover, we may easily reduce to the case where $0 < \nu < 1$. Then we see that

$$f_i^r e_j e_s^\nu e_0^{-\nu} = \frac{e_j}{e_0} \cdot (f_i^{r\nu} e_s^\nu) \cdot (f_i^{r(1-\nu)} e_0^{1-\nu})$$

where both $f_i^{r\nu} e_s^\nu$ and $f_i^{r(1-\nu)} e_0^{1-\nu}$ lie in $\mathbf{E}$, since the latter is a perfect $\mathbb{F}_p$-algebra. The assertion follows. ◊

Pick a finite system $\beta_\bullet := (\beta_1, \dots, \beta_s)$ of elements of $\mathbf{E}$ that generates an ideal of adic definition, and set $f_i := \overline{u}_A(\beta_i)$ for $i = 1, \dots, s$, so that the system $\mathbf{f}_\bullet := (f_1, \dots, f_s)$ generates an ideal of adic definition of A. By claim 16.7.26, it then follows that the system $\mathbf{f}_\bullet$ also generates an ideal of adic definition J for C_R. Denote by $C_R^\wedge$ the separated completion of C_R; we notice :

Claim 16.7.27. The ring C_R fulfills condition $(\mathrm{a})_{\mathbf{f}}^{\mathrm{un}}$ of (7.8.21), and $C_R^\wedge$ is perfectoid.

Proof of the claim. Set $\Delta := \mathbb{N}[1/p]$; recall that example 16.6.12 attaches to the sequence $e_\bullet := (e_0, \dots, e_n)$ of elements of $\mathbf{E}_U$, two perfectoid rings with Δ-graded structure

$$(\mathscr{E}(e_\bullet)^\wedge, \mathscr{E}(e_\bullet)) \qquad \text{and} \qquad (\mathscr{A}(e_\bullet)^\wedge, \mathscr{A}(e_\bullet)).$$

Moreover, $\mathrm{gr}_0\mathscr{E}(e_\bullet) = \mathbf{E}$, $\mathrm{gr}_0\mathscr{A}(e_\bullet) = A$, and we have a natural isomorphism

$$\mathbf{E}(\mathscr{A}(e_\bullet)^\wedge, \mathscr{A}(e_\bullet)) \xrightarrow{\sim} (\mathscr{E}(e_\bullet)^\wedge, \mathscr{E}(e_\bullet)).$$

Furthermore, since $e_\bullet$ generates an open ideal of $\mathbf{E}_U$, the $\mathbf{E}$-module $\mathrm{gr}_\delta\mathscr{E}(e_\bullet)$ (resp. the A-module $\mathrm{gr}_\delta\mathscr{A}(e_\bullet)$) is the submodule of $\mathbf{E}_U$ (resp. of A_U) generated by the elements of the form $e_0^{\nu_0}\cdots e_n^{\nu_n}$ (resp. $\varphi_U^\flat(e_0^{\nu_0}\cdots e_n^{\nu_n})$), where $(\nu_0,\dots,\nu_n)$ ranges over all elements of $\Delta^{\oplus n+1}$ such that $\nu_0+\cdots+\nu_n=\delta$ (see remark 16.3.28(viii)). Especially, we may regard $\beta_\bullet$ as a sequence of elements of $\mathrm{gr}_0\mathscr{E}(e_\bullet)$, whose image under the map $\overline{u}_{\mathscr{A}(e_\bullet)} : \mathscr{E}(e_\bullet) \to \mathscr{A}(e_\bullet)$ is (naturally identified with) the sequence $\mathbf{f}_\bullet$. Next, let us endow $\mathscr{A}' := \mathscr{A}(e_\bullet)[a_0^{-1}]$ with its $J\mathscr{A}'$-adic topology; since we are inverting an element $a_0 \in \mathrm{gr}_1\mathscr{A}(e_\bullet)$, the A-algebra $\mathscr{A}'$ is also Δ-graded, and a simple inspection yields a natural isomorphism of $C_R \xrightarrow{\sim} \mathrm{gr}_0\mathscr{A}'$ of topological rings, which identifies the sequences $\mathbf{f}_\bullet$ in these two rings. Lastly, by virtue of proposition 16.6.5(ii), we deduce that $\mathscr{A}(e_\bullet)$ satisfies condition $(\mathrm{a})^{\mathrm{un}}_{\mathbf{f}}$ of (7.8.21), and then the same holds for $\mathrm{gr}_0\mathscr{A}'$, whence the first assertion.

In order to show that $C_R^\wedge$ is perfectoid, notice that $J^n\mathscr{A}' = \bigoplus_{\delta\in\Delta} J^n\mathrm{gr}_\delta\mathscr{A}'$ for every $n \in \mathbb{N}$. It follows easily that the maximal separated quotient $\mathscr{A}''$ of $\mathscr{A}'$ is also a Δ-graded ring (so that the projection $\mathscr{A}' \to \mathscr{A}''$ is a homomorphism of Δ-graded rings), and $\mathrm{gr}_0\mathscr{A}''$ is the maximal separated quotient of $\mathrm{gr}_0\mathscr{A}'$: details left to the reader. Hence $(\mathscr{A}'', \mathscr{A}'')$ is a topological ring with Δ-pre-graded structure, and therefore $(\mathscr{C}^\wedge, \mathscr{C}) := (\mathscr{A}'', \mathscr{A}'')^\wedge$ is a topological ring with Δ-graded structure (proposition 8.5.3(iii)), and the induced map $C_R^\wedge \to \mathrm{gr}_0\mathscr{C}$ is an isomorphism of topological rings. On the other hand, since $\mathscr{A}(e_\bullet)^\wedge$ is perfectoid, and since the localization map $\mathscr{A}(e_\bullet) \to \mathscr{A}'$ is an adic ring homomorphism, theorem 16.7.21(i) implies that $\mathscr{C}^\wedge$ is perfectoid as well. To conclude, it suffices now to invoke proposition 16.6.1(ii). ◊

As the morphism $i : U \to \mathrm{Spec}\, A$ is an open immersion whose image contains the analytic locus of $\mathrm{Spec}\, A$, we may find an open ideal $I \subset A$ such that $\mathrm{Spec}\, A \setminus U = \mathrm{Spec}\, A/I$, and we pick a finite system $\mathbf{g}_\bullet := (g_1,\dots,g_r)$ of generators of I. On the other hand, i factors through the natural open immersion $j : U \to \mathrm{Spec}\, A_U$ and the morphism $\varphi : \mathrm{Spec}\, A_U \to \mathrm{Spec}\, A$ induced by the inclusion map $A \to A_U$; by claim 15.6.5(ii), it follows that $\varphi^{-1}i(U) = j(U)$, whence $\mathrm{Spec}\, A_U/IA_U = \mathrm{Spec}\, A_U \setminus j(U)$, and therefore

$$Z := \mathrm{Spec}\, A_R/IA_R = \mathrm{Spec}\, A_R \setminus U_R.$$

In view of claim 16.7.26, remark 15.4.13(ii) and proposition 8.3.33(iii), we are then reduced to showing that

$$\mathrm{depth}_Z A_R \otimes_{C_R} C_R^\wedge > 1.$$

However, set $Q^\bullet := \mathrm{Cone}(C_R[0] \to C_R^\wedge[0])$; clearly we have $\mathrm{depth}_{IA_U} A_U > 1$, whence $\mathrm{depth}_Z A_R > 1$, and thus it suffices to check that

$$R\Gamma_Z(A_R \otimes_{C_R} Q^\bullet) = 0.$$

In light of proposition 10.4.32(i), we are then reduced to showing that the Koszul complex $\mathbf{K}^\bullet(\mathbf{g}_\bullet, A_R \otimes_{C_R} Q^\bullet)$ is acyclic. We remark :

Claim 16.7.28. The natural map $A_R \overset{\mathbf{L}}{\otimes}_{C_R} Q^\bullet \to A_R \otimes_{C_R} Q^\bullet$ is an isomorphism in $\mathsf{D}(C_R\text{-}\mathbf{Mod})$.

Proof of the claim. We have a natural morphism of distinguished triangles

$$\begin{array}{ccccccc}
A_R[0] & \longrightarrow & A_R[0] \overset{\mathbf{L}}{\otimes}_{C_R} C_R^\wedge[0] & \longrightarrow & A_R \overset{\mathbf{L}}{\otimes}_{C_R} Q^\bullet & \longrightarrow & A_R[1] \\
\| & & \downarrow & & \downarrow & & \| \\
A_R[0] & \longrightarrow & A_R \otimes_{C_R} C_R^\wedge[0] & \longrightarrow & A_R[0] \otimes_{C_R} Q^\bullet & \longrightarrow & A_R[1]
\end{array}$$

in light of which, we are reduced to checking that $T_i := \mathrm{Tor}_i^{C_R}(A_R, C_R^\wedge) = 0$ for every $i > 0$. However, clearly the natural map $T_i \to \mathrm{Tor}_i^{C_R}(A_R/C_R, C_R^\wedge)$ is an isomorphism for $i > 1$, and is injective for $i = 1$, and moreover $A_R/C_R = \bigcup_{n\in\mathbb{N}} \mathrm{Ann}_{A_R/C_R}(J^n)$. Hence, the assertion follows from claims 8.6.36 and 16.7.27. $\diamondsuit$

Taking into account lemma 7.8.2(v) and claim 16.7.28, we are further reduced to showing that $\mathbf{K}_\bullet(\mathbf{g}_\bullet) \overset{\mathbf{L}}{\otimes}_{C_R} A_R \overset{\mathbf{L}}{\otimes}_{C_R} Q^\bullet$ is acyclic, and to this aim it suffices to check that the same holds for the complex $\mathbf{K}_\bullet(\mathbf{g}_\bullet) \otimes_{C_R} Q^\bullet$. The latter follows easily from lemma 7.8.2(ii), claim 16.7.27 and corollary 8.6.34(i).

(iii): From claim 16.7.27 we know already that $\underline{C}_R^\wedge$ is perfectoid, and from (i) and (ii) we get isomorphisms of quasi-affinoid schemes

$$\underline{U}_R^\wedge \overset{\sim}{\to} \mathsf{Spec}\,(\underline{A}_R^\wedge) \overset{\sim}{\to} \mathsf{Spec}\,(\underline{C}_R^\wedge)$$

whence the contention.

(iv): We consider the natural morphisms of schemes :

$$U_R \xrightarrow{f} \mathrm{Spec}\, A_R \xrightarrow{g} \mathrm{Spec}\, D_R \to \mathrm{Spec}\, A_U^+$$

whose composition is the same as the restriction of $\beta_{\underline{U}}$ to U_R, hence it is an open immersion. Notice also that $\beta_{\underline{U}}$ is in turn the composition of the open immersion $i : U \to \mathrm{Spec}\, A$ and the natural morphism $\mathrm{Spec}\, A \to \mathrm{Spec}\, A_U^+$; the latter identifies the analytic locus of $\mathrm{Spec}\, A$ with that of $\mathrm{Spec}\, A_U^+$ (lemma 8.3.29(iii)), hence the image of $\beta_{\underline{U}}$ contains the analytic locus of $\mathrm{Spec}\, A_U^+$. We may then argue as in the proof of (ii) to conclude that $g \circ f$ is an open immersion and $g \circ f(U_R)$ contains the analytic locus of $\mathrm{Spec}\, D_R$. Together with claim 16.7.26, this already shows that $\underline{D}_R$ is a quasi-affinoid ring. Moreover, we also know that A_U^+ is a perfectoid ring (theorem 16.5.13(iii)), and our assumptions imply that $\underline{A}' := (A_U^+, A_U^+, U)$ is another perfectoid quasi-affinoid ring with $\mathsf{Spec}\, \underline{A}' = \underline{U}$. We may then argue as in the proof of claim 16.7.27 to see that the separated completion $D_R^\wedge$ of D_R is perfectoid, and the proof is complete. $\square$

Remark 16.7.29. (i) Let $\underline{X}$ be any perfectoid quasi-affinoid scheme; taking into account proposition 16.6.35(iii) we deduce that the continuous map $\mathrm{Spa}(\overline{u}_{\underline{X}})$ of (16.5.59) induces a natural isomorphism of sites (notation of (15.5.34)) :

$$\mathbf{E} : \mathscr{R}(\underline{X}) \overset{\sim}{\to} \mathscr{R}(\mathbf{E}(\underline{X})) \qquad R \mapsto \mathrm{Spa}(\overline{u}_{\underline{X}})(R).$$

(ii) Moreover, proposition 16.7.25(iii) says that for every $R \in \mathrm{Ob}(\mathscr{R}(\underline{X}))$ the sub-presheaf h''_R of $h''_{\underline{X}}$ is represented by a perfectoid quasi-affinoid scheme $\underline{Y}$ (notation of remark 15.5.9(i)), and taking into account (16.5.60) together with the equivalence of categories

$$\underline{X}\text{-}\mathsf{q.Afd.Sch}_{\mathrm{perf}} \overset{\sim}{\to} \mathbf{E}(\underline{X})\text{-}\mathsf{q.Afd.Sch}_{\mathrm{perf}}$$

described in (16.5.20), we deduce easily that $\mathbf{E}(\underline{Y})$ represents the sub-presheaf $h''_{\mathbf{E}(R)}$ of $h''_{\mathbf{E}(\underline{X})}$ (details left to the reader).

Theorem 16.7.30. *For every perfectoid quasi-affinoid scheme $\underline{X}$, the following holds :*

(i) *The presheaves $\mathscr{O}^\wedge_{\mathrm{Spa}\underline{X}}$, $\mathscr{O}^{\wedge\circ}_{\mathrm{Spa}\underline{X}}$ and $\mathscr{O}^{\wedge+}_{\mathrm{Spa}\underline{X}}$ are sheaves of topological rings on the site $\mathscr{R}(\underline{X})$ (notation of (15.5.34)).*

(ii) *For every rational subset R of $\mathrm{Spa}\,\underline{X}$ and every finite covering $\mathfrak{U}$ of R consisting of rational subsets, the augmented alternating Čech complex $C^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}})$ has strict differentials, and its cohomology has the discrete topology.*

Proof. (i): By virtue of corollary 15.4.27(i) and proposition 16.5.4(i), if $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}$ is a sheaf, the same holds for $\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}$ and $\mathscr{O}^{\wedge\circ}_{\mathrm{Spa}\,\underline{X}}$, so it suffices to check the assertion for $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}$. Now, say that $\underline{X} = (X, \mathscr{T}_X, A_X^+)$. Notice first that, for every rational subset R of $\mathrm{Spa}\,\underline{X}$, and every morphism $\varphi_{\underline{Y}/\underline{X}} : \underline{Y} \to \underline{X}$ representing the sub-presheaf h_R of $h_{\underline{X}}$, the quasi-affinoid scheme

$\underline{Y}^\wedge$ is also perfectoid (proposition 16.7.25(iii)). Moreover, lemmata 15.4.17(iv) and 15.5.10 and proposition 16.7.25(i) imply that $\varphi_{\underline{Y}/\underline{X}}$ induces equivalences of categories

$$\mathscr{R}(\underline{Y}^\wedge) \stackrel{\sim}{\to} \mathscr{R}(\underline{Y}) \stackrel{\sim}{\to} \mathscr{R}(\underline{X})/R. \tag{16.7.31}$$

Hence, let $A_X := \mathscr{O}_X(X)$ and $A := A_X^\circ$, so that $\Gamma^\circ(\underline{X}) = (A, A_X^+, X)$ (notation of (16.5.19)); according to lemma 15.5.21, every open covering of $\operatorname{Spa}\underline{X}$ can be refined by the standard covering $R_\bullet := (R_0, \dots, R_n)$ attached to a given sequence $a_\bullet := (a_0, \dots, a_n)$ of elements of A that generates an (open) ideal $J \subset A$ such that $\operatorname{Spec} A/J \subset \operatorname{Spec} A \setminus X$; for every subset $\Lambda \subset \{0, \dots, n\}$ we define the rational subset $R_\Lambda \subset R$ and the quasi-affinoid ring $\underline{A}_{X,\Lambda} := (A_{X,\Lambda}, A^+_{X,\Lambda}, X_\Lambda)$ as in remark 15.5.26(i), so that $R_\Lambda = \operatorname{Spa}\underline{A}_{X,\Lambda}$ for every such Λ. As in the proof of theorem 15.5.27, we are then reduced to checking that the natural map

$$\mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}}(\operatorname{Spa}\underline{X}) \to \operatorname{Equal}\Big(\prod_{i=0}^n \mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}}(R_i) \rightrightarrows \prod_{i,j=0}^n \mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}}(R_{\{i,j\}})\Big) \tag{16.7.32}$$

is an isomorphism of topological rings. To this aim, set $\mathbf{E} := \mathbf{E}(A)$; by proposition 16.6.35, we may assume that there exists a sequence $e_\bullet := (e_0, \dots, e_n)$ of elements of $\mathbf{E}$ such that $a_i = \overline{u}_A(e_i)$ for $i = 0, \dots, n$. Then, for every subset $\Lambda \subset \{0, \dots, n\}$, we consider the subring

$$C_{R,\Lambda} := A\Big[\overline{u}_A(e_j^{1/p^k})/\overline{u}_A(e_i^{1/p^k}) \mid (j, i, k) \in \{0, \dots, n\} \times \Lambda \times \mathbb{N}\Big] \subset A_{X,\Lambda}.$$

Claim 16.7.33. For every $\Lambda \subset \{0, \dots, n\}$ the following holds :

(i) $C_{R,\Lambda}$ is a ring of definition of $A_{X,\Lambda}$.
(ii) The natural map $\omega^\wedge_\Lambda : A^\wedge_{X,\Lambda} \to \mathscr{O}^\wedge_{\operatorname{Spa}\underline{X}}(R_\Lambda)$ of remark 15.5.26(ii) is an isomorphism of topological A-algebras.

Proof of the claim. Both assertions are clear when $\Lambda = \{i\}$, for any $i = 0, \dots, n$, due to proposition 16.7.25(i) and claim 16.7.26. We reduce to this case as follows. Let r be the cardinality of Λ, and set

$$\Sigma := \{e_{i_1} \cdots e_{i_r} \mid 0 \leq i_1 \leq i_2 \leq \dots \leq i_r \leq n\}.$$

It is easily seen that the family $(\overline{u}_A(e) \mid e \in \Sigma)$ generates an open ideal of A whose radical equals the radical of J. Set also $e_\Lambda := \prod_{i\in\Lambda} e_i \in \Sigma$, and notice that

$$R_\Lambda = R_A\Big(\frac{\overline{u}_A(e)}{\overline{u}_A(e_\Lambda)} \mid e \in \Sigma\Big) \qquad C_{R,\Lambda} = A\Big[\overline{u}_A(e^{1/p^k})/\overline{u}_A(e_\Lambda^{1/p^k}) \mid e \in \Sigma,\ k \in \mathbb{N}\Big].$$

After replacing e_0 by e_Λ, and the system $(e_0, \dots, e_n)$ by Σ, we are therefore reduced to the case where $R = R_0$, to which proposition 16.7.25(i) and claim 16.7.26 apply. ◊

In view of claim 16.7.33, we may now proceed as in remark 15.5.26(iv) : we set

$$B := A[T_0^{1/p^\infty}, \dots, T_n^{1/p^\infty}]$$

and consider the homomorphism of $\mathbb{N}[1/p]$-graded A-algebras

$$u : B \to A_X[Y^{1/p^\infty}] \qquad T_i^{1/p^k} \mapsto \overline{u}_A(e_i^{1/p^k}) \cdot Y^{1/p^k} \qquad \text{for } i = 0, \dots, n \text{ and every } k \in \mathbb{N}.$$

Set also $S := \operatorname{Spec} A_X^\circ$; according to (16.7.7), the map u induces a well defined morphism of S-schemes

$$\operatorname{Proj}(u) : X \to \operatorname{Proj} B.$$

Recall also that the inclusion map $A[T_0, \dots, T_n] \to B$ induces an affine morphism of schemes $\psi : \operatorname{Proj} B \to \mathbb{P}^n_S$. Let $\mathbb{P}^n_S = \Omega_0 \cup \dots \cup \Omega_n$ be the standard affine covering by complements of hyperplanes, as in remark 15.5.26(iv), set $\Omega'_i := \psi^{-1}\Omega_i$ and $U_i := (\operatorname{Proj} u)^{-1}\Omega'_i$ for $i = 0, \dots, n$; there follows an affine open covering of $\operatorname{Proj} B$ and an open covering of X :

$$\operatorname{Proj} B = \Omega'_0 \cup \dots \cup \Omega'_n \qquad X = U_0 \cup \dots \cup U_n.$$

Set also $U_\Lambda := \bigcap_{i\in\Lambda} U_i$ for every non-empty $\Lambda \subset \{0,\dots,n\}$; by remark 15.5.26(i) we have

$$\mathscr{O}_X(U_\Lambda) = A_{X,\Lambda} \qquad \text{for every non-empty } \Lambda \subset \{0,\dots,n\}. \tag{16.7.34}$$

Let V be the schematic image of $\mathrm{Proj}\, u$ (see remark 15.5.26(v)); a simple inspection shows that

$$V = \mathrm{Proj}\, \mathscr{A}(e_\bullet)$$

where $\mathscr{A}(e_\bullet)$ is the $\mathbb{N}[1/p]$-graded algebra associated with the sequence $e_\bullet$ via example 16.6.12 (cp. the proof of claim 16.7.27). Especially, we see that

$$V_\Lambda := V \cap \bigcap_{i\in\Lambda} \Omega'_i = \mathrm{Spec}\, C_{R,\Lambda} \qquad \text{for every non-empty subset } \Lambda \subset \{0,\dots,n\}.$$

Fix a finitely generated ideal I of adic definition for $\mathbf{E}$, and for every $t \in \mathbb{R}_+$, denote by $C_t^\bullet$ the augmented alternating Čech complex of $I^{\lceil t\rceil}\mathscr{O}_V$, relative to the open covering $(V_i \mid i = 0,\dots,n)$. Notice that if $\Lambda \neq \varnothing$, the scheme V_Λ is affine, hence we have $I^{\lceil t\rceil} C_{R,\Lambda} = H^0(V_\Lambda, I^{\lceil t\rceil}\mathscr{O}_V)$. Moreover, by corollary 16.7.18 (and theorem 10.2.28(ii)), the complex $C_t^\bullet$ is acyclic, and the natural map $I^{\lceil t\rceil}A \to C_t^{-1}$ is an isomorphism, for every $t \in \mathbb{R}_+$. It follows that

$$I^{\lceil s\rceil} C_t^i = C_{t+s}^i \qquad \text{for every } i \in \mathbb{Z} \text{ and every } s,t \in \mathbb{R}_+$$

and we endow C_t^i with the I-adic topology, so that $(C_{s+t}^i \mid s \in \mathbb{R}_+)$ is a fundamental system of open submodules of C_t^i, for every $i \in \mathbb{Z}$ and every $t \in \mathbb{R}_+$.

Furthermore, denote by $A_X^\bullet$ the augmented alternating Čech complex of $\mathscr{O}_X$ relative to the open covering $(U_i \mid i = 0,\dots,n)$, and for every $i \in \mathbb{Z}$ endow A_X^i with the topology deduced from the topologies of the rings $A_{X,\Lambda}$, via the identifications (16.7.34), as in (15.5.34). There follows a natural monomorphism of complexes of topological A-modules

$$C_t^\bullet \to A_X^\bullet \qquad \text{for every } t \in \mathbb{R}_+$$

and the image of C_t^i is open in A_X^i, for every $i \in \mathbb{Z}$. Denote by $(A_X^{\wedge\bullet}, d_X^\bullet)$ and $(C_t^{\wedge\bullet}, d_t^\bullet)$ the complexes obtained by termwise completion of $A_X^\bullet$ and $C_t^\bullet$; for every $t \in \mathbb{R}_+$ the induced map

$$C_t^{\wedge\bullet} \to A_X^{\wedge\bullet}$$

is still a monomorphism. By the foregoing, we have a natural isomorphism of complexes

$$C_t^{\wedge\bullet} \xrightarrow{\sim} \lim_{s\in\mathbb{R}_+} C_t^\bullet / C_{s+t}^\bullet \qquad \text{for every } t \in \mathbb{R}_+$$

and moreover $C_t^\bullet / C_{s+t}^\bullet$ is acyclic for every $s,t \in \mathbb{R}_+$. By virtue of [163, Th.3.5.8], it follows that $C_t^{\wedge\bullet}$ is acyclic for every $t \in \mathbb{R}_+$. Next, notice that the induced morphism

$$A_X^\bullet / C_t^\bullet \to A_X^{\wedge\bullet} / C_t^{\wedge\bullet}$$

is an isomorphism of complexes, for every $t \in \mathbb{R}_+$; we conclude that

$$H^n A_X^{\wedge\bullet} = H^n(A_X^{\wedge\bullet}/C_t^{\wedge\bullet}) = H^n(A_X^\bullet/C_t^\bullet) = H^n A_X^\bullet \qquad \text{for every } n \in \mathbb{Z}.$$

On the other hand, claim 16.7.33(ii) and remark 15.5.26(iii) yield an isomorphism of complexes of topological A-modules

$$A_X^{\wedge\bullet} \xrightarrow{\sim} C^\bullet_{\mathrm{alt}}(R_\bullet, \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}). \tag{16.7.35}$$

Since $H^0 A_X^\bullet = 0$, we conclude that (16.7.32) is a ring isomorphism. Lastly, let E be the equalizer appearing in (16.7.32), and endow it with the topology induced by the inclusion into $\prod_{i=0}^n \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(R_i)$; we have to check that the resulting map $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(\mathrm{Spa}\,\underline{X}) \to E$ is open. In view of the isomorphism (16.7.35), the assertion will follow from the following :

Claim 16.7.36. The differentials of the complex $(A_X^{\wedge\bullet}, d_X^\bullet)$ are strict and its cohomology has the discrete topology.

Proof of the claim. For every $i \in \mathbb{Z}$, the family $(\mathrm{Ker}\, d^i_t \mid t \in \mathbb{R}_+)$ yields a fundamental system of open submodules of $\mathrm{Ker}\, d^i_X$. But we have already noticed that $C^{\wedge\bullet}_t$ is acyclic, so this system is the image of $(C^{\wedge i}_t \mid t \in \mathbb{R}_+)$, which is a fundamental system of open subgroups of $A^{\wedge i}_X$, whence the contention. ◊

(ii): We may argue as in the proof of theorem 15.5.35(ii) : we choose a standard covering $\mathfrak{U}'$ that refines $\mathfrak{U}$ and we apply lemma 8.6.15(i) and corollary 8.6.12 to the double complex $C^\bullet_{\mathrm{alt}}(\mathfrak{U}, \mathfrak{U}')$ (details left to the reader). □

16.7.37. Let $\underline{X} := (X, \mathscr{T}_X, A^+_X)$ be any perfectoid quasi-affinoid scheme; in light of theorem 16.7.30, we may now argue as in (15.5.44) to first extend $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}$ to a sheaf of topological rings on the topological space $\mathrm{Spa}\,\underline{X}$, and then show that the stalks of the latter sheaf are local rings. There follows a well defined morphism of locally ringed spaces

$$\sigma_{\underline{X}} : (\mathrm{Spa}\,\underline{X}, \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}) \to (X, \mathscr{O}_X)$$

whose induced map on global sections is the identity map $\mathscr{O}_X(X) \to \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(\mathrm{Spa}\,\underline{X})$, and whose underlying continuous map $\mathrm{Spa}\,\underline{X} \to X$ is the restriction of the support map of remark 9.2.4(iii). Also corollary 15.5.46 extends to the perfectoid case :

Corollary 16.7.38. *With the notation of* (16.7.37)*, the morphism $\sigma_{\underline{X}}$ induces an isomorphism*

$$H^i(X, \mathscr{O}_X) \xrightarrow{\sim} H^i(\mathrm{Spa}\,\underline{X}, \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}) \qquad \textit{for every } i \in \mathbb{N}.$$

Proof. We proceed as in the proof of corollary 15.5.46 : first we show the following

Claim 16.7.39. In the situation of the corollary, suppose moreover that $\underline{X}$ is affinoid. Then $H^i(\mathrm{Spa}\,\underline{X}, \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}) = 0$ for every $i > 0$.

Proof of the claim. Arguing as in the proof of claim 15.5.47, we reduce to checking that for every standard covering $\mathfrak{U}$ of $\mathrm{Spa}\,X$ the Čech cohomology $H^i := H^i_{\mathrm{alt}}(\mathfrak{U}, \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}})$ vanishes for every $i > 0$; but the proof of theorem 16.7.30(i) shows that H^i is naturally isomorphic to the Čech cohomology $H^i_{\mathrm{alt}}(U_\bullet, X)$, relative to a certain affine open covering $U_\bullet$ of X. Then the assertion follows from theorem 10.2.28. ◊

Now, set $A_X := \mathscr{O}_X(X)$, say that $X = \mathrm{Spec}\, A_X \setminus \mathrm{Spec}\, A_X/J$ for some finitely generated ideal $J \subset A_X$, and pick a finite system of generators $f_\bullet := (f_0, \dots, f_n)$ for J. Let $R_\bullet := (R_0, \dots, R_n)$ be the standard covering of $\mathrm{Spa}\,\underline{X}$ associated with $f_\bullet$, and set as well $U_i := \mathrm{Spec}\, A_X[f_i^{-1}]$ for every $i = 0, \dots, n$, so that $U_\bullet := (U_0, \dots, U_n)$ is an affine open covering of X, and moreover $R_i = \sigma^{-1}_{\underline{X}}(U_i)$ for every $i = 0, \dots, n$. There follows a commutative diagram

$$\begin{array}{ccc} H^i_{\mathrm{alt}}(U_\bullet, \mathscr{O}_X) & \longrightarrow & H^i_{\mathrm{alt}}(R_\bullet, \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}) \\ \downarrow & & \downarrow \\ H^i(X, \mathscr{O}_X) & \longrightarrow & H^i(\mathrm{Spa}\,\underline{X}, \mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}) \end{array}$$

where the vertical arrows are isomorphisms, by virtue of claim 16.7.39 and corollary 10.2.21(ii). We are then reduced to checking that the top horizontal arrow is an isomorphism; but as already pointed out, the latter assertion was shown in the proof of theorem 16.7.30(i). □

16.7.40. Let again $\underline{X}$ be as in (16.7.37); set $A_X := \mathscr{O}_X(X)$, and let $V \subset X^+ := \mathrm{Spec}\, A^+_X$ be any quasi-compact open subset containing the analytic locus of X^+, and such that $\underline{X}$ spreads over V (see definition 15.6.1(i)). Let also $J_V \subset A^+_X$ be the unique radical ideal such that $\mathrm{Spec}\, A^+_X/J_V = X^+ \setminus V$. We consider the sheaf of ideals

$$\mathscr{J}_V \subset \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}} \qquad \text{on } \mathscr{R}(\underline{X})$$

defined as the sheaf associated to the presheaf given by the rule : $R \mapsto J_V \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}(R)$ for every rational subset $R \subset \mathrm{Spa}\,\underline{X}$.

Theorem 16.7.41. *In the situation of* (16.7.40)*, we have :*

(i) $\mathscr{J}_V(R) = J_V \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}(R)$ *for every* $R \in \mathrm{Ob}(\mathscr{R}_V(\underline{X}))$ *(notation of* (15.6.7)*).*

(ii) $H^i(X, \mathscr{J}_V) = 0$ *for every* $i > 0$.

Proof. To begin with, we remark :

Claim 16.7.42. Let $R \in \mathrm{Ob}(\mathscr{R}_V(\underline{X}))$, and $\underline{Y}$ any topologically local quasi-affinoid scheme representing the sub-presheaf h_R of $h_{\mathrm{Spa}\,\underline{X}}$. Say that $\underline{Y}^\wedge := (Y^\wedge, \mathscr{T}^\wedge_Y, A^{\wedge+}_Y)$. We have :

(i) The completion $\underline{Y}^\wedge$ spreads over the preimage W of V in $Y^{\wedge+} := \mathrm{Spec}\, A^{\wedge+}_Y$.

(ii) Let $J_W \subset A^{\wedge+}_Y$ be the unique radical ideal such that $\mathrm{Spec}\, A^{\wedge+}_Y / J_W = Y^{\wedge+} \setminus W$. Then $J_W = J_V A^{\wedge+}_Y$.

Proof of the claim. (i): Since $\underline{Y}$ spreads over V, the assertion follows from proposition 15.6.6(i).

(ii): We may find a finitely generated open ideal $J_{\mathbf{E}} \subset \mathbf{E}^+$ such that $J^{\lceil 0 \rceil}_{\mathbf{E}} A^+_X = J_V$ (see (16.5.16)); then we have $\mathrm{Spec}\, A^{\wedge+}_Y / J_V A^{\wedge+}_Y = Y^{\wedge+} \setminus W$, and on the other hand, arguing as in (16.5.16) we see that $J^{\lceil 0 \rceil}_{\mathbf{E}} A^{\wedge+}_Y$ is a radical ideal of $A^{\wedge+}_Y$, whence the claim. ◊

Claim 16.7.43. In order to prove the theorem it suffices to show that for every $\underline{X}$ and V as in (16.7.40) we have $\check{H}^0(\mathscr{R}(\underline{X}), J_V \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}) = J_V$ and $\check{H}^i(\mathscr{R}(\underline{X}), J_V \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}) = 0$ for every $i > 0$.

Proof of the claim. Indeed, in light of proposition 15.6.8(i,ii), both (i) and (ii) will follow once we show that the presheaf $J_V \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}$ is a sheaf on the site $\mathscr{R}_V(\underline{X})$, and $H^i(\mathscr{R}_V(\underline{X}), J_V \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}) = 0$ for every $i > 0$. Next, in view of theorem 10.2.24, in order to prove the latter assertions it suffices to show that for every $R \in \mathrm{Ob}(\mathscr{R}_V(\underline{X}))$ we have $\check{H}^0(\mathscr{R}_V(\underline{X})/R, J_V \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}) = J_V \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}(R)$ and $\check{H}^i(\mathscr{R}_V(\underline{X})/R, J_V \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}) = 0$ for every $i > 0$. Proposition 15.6.8(iii) then further reduces to showing both identities, with $\mathscr{R}_V(\underline{X})$ replaced by $\mathscr{R}(\underline{X})$. Lastly, for such a rational subset R, define $\underline{Y}$ and W as in claim 16.7.42(i); in light of claim 16.7.42(ii), and taking into account the equivalences (16.7.31), we may then replace $\underline{X}$ by $\underline{Y}^\wedge$, and V by W, and reduce to prove the foregoing identities for $R = \mathrm{Spa}\,\underline{X}$, whence the claim. ◊

We consider first the case where the induced morphism $\beta_{\underline{X}} : X \to X^+ := \mathrm{Spec}\, A^+_X$ is an open immersion, so that $\Omega_{\underline{X}}$ is the image of $\beta_{\underline{X}}$ (notation of definition 15.6.1), and we take $V := \Omega_{\underline{X}}$. By theorem 16.5.13(iii) we have the perfectoid quasi-affinoid ring

$$\Gamma^+(\underline{X}) := (A^+_X, A^+_X, V)$$

and clearly $\mathsf{Spec}\,(\Gamma^+(\underline{X}))$ is isomorphic to $\underline{X}$. In view of lemma 15.5.21, we deduce that every open covering of $\mathrm{Spa}\,\underline{X}$ can be refined by the standard covering $\mathfrak{U}_\bullet := (\mathfrak{U}_0, \dots, \mathfrak{U}_n)$ associated to some sequence $(a_0, \dots, a_n)$ of elements of A^+_X that generates an ideal K with $\mathrm{Spec}\, A^+_X/K \subset X^+ \setminus V$, and notice that $\mathfrak{U}_\bullet$ is a covering family of the site $\mathscr{R}_V(\underline{X})$, due to proposition 15.6.6(ii). We shall show more precisely that the augmented alternating Čech complex $C^\bullet_{\mathrm{alt}}(\mathfrak{U}_\bullet, J_V \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}})$ is acyclic. To this aim, set $\mathbf{E}^+ := \mathbf{E}(A^+_X)$; in view of proposition 16.6.35, we may assume that there exists a sequence $e_\bullet := (e_0, \dots, e_n)$ of elements of $\mathbf{E}^+$ such that $a_i = \overline{u}_{A^+_X}(e_i)$ for $i = 0, \dots, n$, and we let $K_{\mathbf{E}} \subset \mathbf{E}^+$ be the open ideal generated by $e_\bullet$ (proposition 16.6.35(ii)). Notice that $J^{\lceil 0 \rceil}_{\mathbf{E}}$ and $K^{\lceil 0 \rceil}_{\mathbf{E}}$ are the radicals of $J_{\mathbf{E}}$ and respectively $K_{\mathbf{E}}$; we deduce that

$$J^{\lceil 0 \rceil}_{\mathbf{E}} = J^{\lceil 0 \rceil}_{\mathbf{E}} J^{\lceil 0 \rceil}_{\mathbf{E}} \subset K^{\lceil 0 \rceil}_{\mathbf{E}} J^{\lceil 0 \rceil}_{\mathbf{E}} \subset J^{\lceil 0 \rceil}_{\mathbf{E}}. \tag{16.7.44}$$

We consider the $\mathbb{N}[1/p]$-graded A^+_X-algebra $\mathscr{A}$ associated as in example 16.6.12 to the sequence $e_\bullet$, *i.e.* such that

$$\mathscr{A}_0 := A^+_X \qquad \text{and} \qquad \mathscr{A}_\gamma := [e_\bullet]^{\langle \gamma \rangle} A^+_X \qquad \text{for every } \gamma \in \mathbb{N}[1/p] \setminus \{0\}$$

(with multiplication induced by that of A_X^+). We have then a ring homomorphism as in (16.7.9)

$$\varphi : \mathbb{Z}[T_0^{1/p^\infty}, \dots, T_n^{1/p^\infty}] \to \mathscr{A} \qquad T_i^{1/p^r} \mapsto \overline{u}_{A_X^+}(e_i^{1/p^r}) \qquad \text{for } i = 0, \dots, n \text{ and every } r \in \mathbb{N}$$

whose image lies in $\mathscr{A}_0 = A_X^+$, whence corresponding angular Rees algebras $\mathsf{R}\langle A_X^+\rangle$ and $\mathsf{R}\langle\mathscr{A}\rangle$. Set $Y_0 := \mathrm{Proj}\,\mathsf{R}\langle A_X^+\rangle$; the map φ induces a morphism of schemes

$$\mathrm{Proj}\,\varphi : Y_0 \to \mathbb{P}^n := \mathrm{Proj}\,\mathbb{Z}[T_0^{1/p^\infty}, \dots, T_n^{1/p^\infty}].$$

Let $\mathbb{P}^n = \Omega_0 \cup \dots \cup \Omega_n$ be the standard affine open covering by complements of hyperplanes, set $U_i := (\mathrm{Proj}\,\varphi)^{-1}\Omega_i$ for $i = 0, \dots, n$, and let

$$C^\bullet := C^\bullet_{\mathrm{alt}}(U_\bullet, \mathscr{O}_{Y_0})$$

be the augmented alternating Čech complex relative to the covering $U_\bullet := (U_0, \dots, U_n)$. Taking into account (16.7.44) and corollary 16.7.16 (as well as theorem 10.2.28(ii)), we deduce that

$$C^\bullet_{\mathrm{alt}}(U_\bullet, J_V\mathscr{O}_{Y_0}) = J_V C^\bullet$$

and moreover this second augmented alternating Čech complex is acyclic. Furthermore, let $I_{\mathbf{E}}$ be any finitely generated ideal of adic definition for $\mathbf{E}^+$; corollary 16.7.18 shows likewise that

$$C^\bullet_{\mathrm{alt}}(U_\bullet, I_{\mathbf{E}}^{[t]}\mathscr{O}_{Y_0}) = I_{\mathbf{E}}^{[t]}C^\bullet \qquad \text{for every } t \in \mathbb{R}_+$$

and also these complexes are acyclic. We may describe the terms of $C^\bullet$ as in the proof of theorem 16.7.30 : for every $i = 0, \dots, n$, the A_X^+-module C^i is a direct sum $\bigoplus_{\Lambda\subset\{0,\dots,n\}} \mathscr{O}_{Y_0}(U_\Lambda)$, where Λ ranges over the set of subsets of cardinality equal to $i+1$, and $U_\Lambda := \bigcap_{j\in\Lambda} U_j$ for every such Λ. Then

$$\mathscr{O}_{Y_0}(U_\Lambda) = A_X^+[\overline{u}_{A_X^+}(e_i^{1/p^\infty})/\overline{u}_{A_X^+}(e_j^{1/p^\infty}) \mid (i,j) \in \{0,\dots,n\}\times\Lambda] \subset A_X^+[a_j^{-1} \mid j \in \Lambda]$$

for every non-empty $\Lambda \subset \{0, \dots, n\}$. If we set likewise $\mathfrak{U}_\Lambda := \bigcap_{j\in\Lambda}\mathfrak{U}_j$ for every such Λ, we see that $\mathscr{O}_{Y_0}(U_\Lambda) \subset \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}(\mathfrak{U}_\Lambda)$. Set as usual $A_X := \mathscr{O}_X(X)$; in light of claim 16.7.33 we see that there exists for every $\Lambda \neq \varnothing$ a (unique) f-adic topology on $A_X[a_j^{-1} \mid j \in \Lambda]$ for which the localization map $A_X \to A_X[a_j^{-1} \mid j \in \Lambda]$ is f-adic and $\mathscr{O}_{Y_0}(U_\Lambda)$ is a subring of definition. Especially, the induced topology on $\mathscr{O}_{Y_0}(U_\Lambda)$ is adic, and the natural map $A_X^+ \to \mathscr{O}_{Y_0}(U_\Lambda)$ is an adic ring homomorphism. Let us endow C^i with the corresponding product topology, for every $i = 0, \dots, n$; then $(I_{\mathbf{E}}^{[t]}C^i \mid t \in \mathbb{R}_+)$ is a fundamental system of open submodules of C^i, and hence also of J_VC^i, for every such i. Moreover, we know that the natural maps $J_VA_X^+ \to J_VC^{-1}$ and $I_{\mathbf{E}}^{[t]}A_X^+ \to I_{\mathbf{E}}^{[t]}C^{-1}$ are isomorphisms (again, by corollaries 16.7.16(i) and 16.7.18(i)), so $(I_{\mathbf{E}}^{[t]}C^{-1} \mid t \in \mathbb{R}_+)$ is a fundamental system of open submodules of J_VC^{-1}. Taking into account [163, Th.3.5.8], we conclude that the termwise completion of $J_VC^\bullet$ is still acyclic. Furthermore, the latter is isomorphic to $J_VC^{\wedge\bullet}$, where $C^{\wedge\bullet}$ is the termwise completion of $C^\bullet$: indeed, $J_VC^{\wedge i}$ is dense and open in the completion of J_VC^i for every $i = 0, \dots, n$, so the assertion is clear.

Claim 16.7.45. Set $W_\Lambda := U_\Lambda \cap \mathrm{Spec}\,\mathscr{O}_{Y_0}(U_\Lambda)[a_j^{-1} \mid j \in \Lambda]$ for every non-empty $\Lambda \subset \{0, \dots, n\}$. The datum $(\mathscr{O}_{Y_0}(U_\Lambda), \mathscr{O}_{Y_0}(U_\Lambda), W_\Lambda)$ is a quasi-affinoid ring, and its completion is a perfectoid quasi-affinoid ring

$$\underline{R}_\Lambda := (\mathscr{O}_{Y_0}(U_\Lambda)^\wedge, \mathscr{O}_{Y_0}(U_\Lambda)^\wedge, W_\Lambda^\wedge := W_\Lambda \times_{U_\Lambda} \mathrm{Spec}\,\mathscr{O}_{Y_0}(U_\Lambda)^\wedge).$$

Proof of the claim. Arguing as in the proof of claim 16.7.33, we may assume that $\Lambda = \{i\}$, for some $i \in \{0, \dots, n\}$, in which case it suffices to invoke proposition 16.7.25(iv). ◊

With the notation of claim 16.7.45, we see that

$$\Gamma(\mathsf{Spec}\,\underline{R}_\Lambda) = (\mathscr{O}_{Y_0}(U_\Lambda)^\wedge[a_j^{-1} \mid j \in \Lambda], \mathscr{O}_{Y_0}(U_\Lambda)^{\wedge+}, W_\Lambda^\wedge)$$

where $\mathscr{O}_{Y_0}(U_\Lambda)^\wedge[a_j^{-1} \mid j \in \Lambda]$ carries the unique f-adic topology such that the localization map $\mathscr{O}_{Y_0}(U_\Lambda)^\wedge \to \mathscr{O}_{Y_0}(U_\Lambda)^\wedge[a_j^{-1} \mid j \in \Lambda]$ is open (proposition 8.3.30(ii)), and $\mathscr{O}_{Y_0}(U_\Lambda)^{\wedge+}$ is the integral closure of $\mathscr{O}_{Y_0}(U_\Lambda)^\wedge$ in $\mathscr{O}_{Y_0}(U_\Lambda)^\wedge[a_j^{-1} \mid j \in \Lambda]$. In other words, $\mathscr{O}_{Y_0}(U_\Lambda)^\wedge[a_j^{-1} \mid j \in \Lambda]$ is the completion of $\mathscr{O}_{Y_0}(U_\Lambda)[a_j^{-1} \mid j \in \Lambda] = A_X^+[a_j^{-1} \mid j \in \Lambda]$, where the latter is endowed with the unique f-adic topology such that the localization map $\mathscr{O}_{Y_0}(U_\Lambda) \to A_X^+[a_j^{-1} \mid j \in \Lambda]$ is open (proposition 8.3.33). It follows that $\mathscr{O}_{Y_0}(U_\Lambda)^{\wedge+}$ is also the completion of the integral closure of $\mathscr{O}_{Y_0}(U_\Lambda)$ in $A_X^+[a_j^{-1} \mid j \in \Lambda]$ (lemma 8.3.6), which is the same as the completion of the integral closure of $A_X^+[a_i/a_j \mid (i,j) \in \{0,\dots,n\} \times \Lambda]$ in $A_X^+[a_j^{-1} \mid j \in \Lambda]$. This means that

$$\Gamma(\mathsf{Spec}\,\underline{R}_\Lambda) = (\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{X}}(\mathfrak{U}_\Lambda), \mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}(\mathfrak{U}_\Lambda), W^\wedge_\Lambda).$$

We have already observed that $J_V\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}(\mathfrak{U}_\Lambda)$ is a radical ideal of $\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}(\mathfrak{U}_\Lambda)$; combining with corollary 16.5.17 we conclude that

$$J_V\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}(\mathfrak{U}_\Lambda) = J_V\mathscr{O}_{Y_0}(U_\Lambda)^\wedge \qquad \text{for every non-empty } \Lambda \subset \{0,\dots,n\}$$

which implies that the natural map of complexes $J_VC^{\wedge\bullet} \to C^\bullet_{\mathrm{alt}}(\mathfrak{U}_\bullet, J_V\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}})$ is an isomorphism, so the proof of the theorem is complete in this case.

For the general case, let us set

$$(X_{\mathbf{E}}, \mathscr{T}_{\mathbf{E}}, \mathbf{E}_X^+) := \mathbf{E}(\underline{X}) \qquad X' := \beta_{\underline{X}}^{-1}(V) \qquad A_{X'} := \mathscr{O}_{X'}(X') \qquad \underline{X}' := X' \times_X \underline{X}$$

(see example 15.4.4). Say that $\underline{X}' = (X', \mathscr{T}_{X'}, A^+_{X'})$; then $\underline{X}'$ spreads over the preimage V' of V in $X'^+ := \mathrm{Spec}\,A^+_{X'}$ (proposition 15.6.6(iv)); on the other hand, by construction the image of $\beta_{\underline{X}'} : X' \to X'^+$ lies in V', so $\beta_{\underline{X}'}$ is an open immersion and $V' = \Omega_{\underline{X}'}$. Therefore we have as well the perfectoid quasi-affinoid ring $\Gamma(\underline{X}') := (A_X^+, A_X^+, V')$, and $\mathsf{Spec}\,\Gamma^+(\underline{X}')$ is isomorphic to $\underline{X}'$; especially, the latter is a perfectoid quasi-affinoid scheme of the type considered in the foregoing case. Next, since the natural morphism $\pi : \underline{X}' \to \underline{X}$ is f-adic, proposition 15.4.22(iii.a) says that $\mathrm{Spa}\,\pi : \mathrm{Spa}\,\underline{X}' \to \mathrm{Spa}\,\underline{X}$ induces a functor

$$\mathscr{R}(\underline{X}) \to \mathscr{R}(\underline{X}') \qquad R \mapsto (\mathrm{Spa}\,\pi)^{-1}R$$

which restricts to a functor

$$\mathscr{R}_V(\underline{X}) \to \mathscr{R}_{V'}(\underline{X}').$$

Indeed, let R be any rational subset of $\mathrm{Spa}\,\underline{X}$, and say that the corresponding sub-presheaf h_R of $h_{\mathrm{Spa}\,\underline{X}}$ is represented by an f-adic morphism $\underline{Y} \to \underline{X}$ of quasi-affinoid schemes. Then $(\mathrm{Spa}\,\pi)^{-1}R$ is represented by the induced morphism $\underline{Y}' := (\underline{Y} \times_{\underline{X}} \underline{X}')_{\mathrm{loc}} \to \underline{X}'$ (see remark 15.5.9(iii)). Now, if $\underline{Y}$ spreads over V, proposition 15.6.6(i,iii,iv) implies that $\underline{Y}'$ spreads over V', whence the contention. Furthermore, let $J_{V'} \subset A^+_{X'}$ be the unique radical ideal such that $\mathrm{Spec}\,A^+_{X'}/J_{V'} = X'^+ \setminus V'$; we have :

Claim 16.7.46. For every $R \in \mathrm{Ob}(\mathscr{R}_V(\underline{X}))$, the induced map

$$J_V\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}}(R) \to J_{V'}\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}'}((\mathrm{Spa}\,\pi)^{-1}R) \tag{16.7.47}$$

is an isomorphism.

Proof of the claim. We consider first the case where $R = \mathrm{Spa}\,\underline{X}$: arguing as in the proof of claim 16.7.42(ii) we easily see that $J_{V'} = J_VA^+_{X'}$. Therefore, let $\overline{A}{}^+_X$ be the image of A^+_X in $A^+_{X'}$; combining with corollary 16.5.17, it follows that

$$J_{V'} = J_V\overline{A}{}^+_X$$

which already shows that the natural ring homomorphism $\rho : A^+_X \to A^+_{X'}$ restricts to a surjection $J_V \to J_{V'}$. Next, notice that the support of $\mathrm{Ker}\,\rho$ lies in the closed subset $X^+ \setminus V$, and therefore $J_V \cap \mathrm{Ker}\,\rho$ is contained in the nilradical of A^+_X; but A^+_X is reduced (corollary 16.3.63(i)), whence the claim, in this case. Next, let $R \in \mathrm{Ob}(\mathscr{R}_V(\underline{X}))$ be a general rational subset; to ease notation, set $R' := (\mathrm{Spa}\,\underline{\pi})^{-1}R$, and let $\underline{Z}$ be any topologically local quasi-affinoid scheme representing the sub-presheaf $h_{R'}$ of $h_{\mathrm{Spa}\,\underline{X}'}$. Define $\underline{Y}^\wedge$, $Y^\wedge$, $Y^{\wedge+}$, $W \subset Y^{\wedge+}$ and J_W as in claim 16.7.42. Let also $Y' := \beta^{-1}_{\underline{Y}^\wedge}(W)$ and $\underline{Y}' := Y' \times_{Y^\wedge} \underline{Y}^\wedge$. Say that $\underline{Y}' = (Y', \mathscr{T}_{Y'}, A^+_{Y'})$, and let moreover W' be the preimage of W in $Y'^+ := \mathrm{Spec}\, A^+_{Y'}$, and $J_{W'} \subset A^+_{Y'}$ the unique radical ideal such that $\mathrm{Spec}\, A^+_{Y'}/J_{W'} = Y'^+ \setminus W'$; arguing as in the foregoing, we see that $\underline{Y}'$ is a perfectoid quasi-affinoid scheme that spreads over W', and a direct inspection of the constructions shows that $\underline{Y}'$ is the completion of $\underline{Z}$. Thus, the image of $\mathrm{Spa}\,\underline{Y}^\wedge$ (resp. of $\mathrm{Spa}\,\underline{Y}'$) in $\mathrm{Spa}\,\underline{X}$ (resp. in $\mathrm{Spa}\,\underline{X}'$) agrees with R (resp. with R'), and taking into account claim 16.7.42(ii) we conclude that (16.7.47) is naturally identified with the map

$$J_W \to J_{W'}$$

induced by the projection $\underline{Y}' \to \underline{Y}^\wedge$. By the previous case, we know already that this map is bijective, whence the claim. ◊

We may now conclude the proof of the theorem : indeed, we have already remarked that every covering family of $\mathscr{R}(\underline{X})$ can be refined by a standard covering $\mathfrak{U}_\bullet := (\mathfrak{U}_0, \dots, \mathfrak{U}_n)$ which is also a covering family of $\mathscr{R}_V(\underline{X})$. It follows that $\mathfrak{U}'_\bullet := ((\mathrm{Spa}\,\pi)^{-1}\mathfrak{U}_i \mid i = 0, \dots, n)$ is a standard covering of $\mathrm{Spa}\,\underline{X}'$ which is also a covering family of $\mathscr{R}_{V'}(\underline{X}')$. By the previous case, we know already that $\check{H}^0(\mathfrak{U}'_\bullet, J_{V'}\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}'}) = J_{V'}$ and $\check{H}^i(\mathfrak{U}'_\bullet, J_{V'}\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}'}) = 0$ for every $i > 0$. In view of claim 16.7.46, it follows that $\check{H}^0(\mathfrak{U}_\bullet, J_V\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}'}) = J_V$ and $\check{H}^i(\mathfrak{U}_\bullet, J_V\mathscr{O}^{\wedge+}_{\mathrm{Spa}\,\underline{X}'}) = 0$ for every $i > 0$, and taking into account claim 16.7.43, the theorem follows. □

16.8. **Almost purity.** To begin with, let p be a prime integer; we consider a perfect $\mathbb{F}_p$-algebra V and a radical ideal $\mathfrak{m} \subset V$. Since V is perfect, $(V, \mathfrak{m})$ is clearly a basic setup, in the sense of [75, §2.1.1]. Our first observation is the following :

Lemma 16.8.1. *In the situation of* (16.8)*, let $A \subset B$ be an inclusion of perfect V-algebras, and $\mathfrak{m}_0 \subset \mathfrak{m}$ a subideal whose radical is $\mathfrak{m}$. We set*

$$A' := \{x \in B \mid \mathfrak{m} \cdot x \subset A\} \qquad B' := \{x \in B \mid \text{there exists } n \in \mathbb{N} \text{ with } \mathfrak{m}_0^n \cdot x \subset A\}.$$

Then A' and B' are perfect V-algebras, and A' is integrally closed in B'.

Proof. It is easily seen that A' and B' are V-subalgebras of B, and obviously $A \subset A' \subset B'$. Next, let $x \in B$, and say that $x^p \in A'$; thus, $\mathfrak{m} \cdot x^p \subset A$, and therefore $(ax)^p \in A$ for every $a \in \mathfrak{m}$. Since A is perfect, it follows that $ax \in A$ for every such a, so that $x \in A'$; this show that A' is perfect. Likewise one checks that B' is perfect.

Next, let $x \in B'$, and suppose that $x^n + a_1x^{n-1} + \cdots + a_n = 0$ for some $a_1, \dots, a_n \in A'$. Then $A'[x] = A' + A'x + \cdots + A'x^{n-1} \subset B'$. By assumption, there exists $k \in \mathbb{N}$ with $\mathfrak{m}_0^k \cdot x \subset A$, and $\mathfrak{m}_0 A' \subset \mathfrak{m}A' \subset A$; it follows easily that $\mathfrak{m}_0^{nk}A'[x] \subset A$. Now, let $a \in \mathfrak{m}$; by assumption, there exists $M \in \mathbb{N}$ such that $a^{p^M} \in \mathfrak{m}_0^{nk}$, whence $(ax)^{p^M} \in A$, and since A is perfect, we conclude that $ax \in A$ for every such a, *i.e.* $x \in A'$. This shows that A' is integrally closed in B'. □

We may now state the following generalization of [75, Th.3.5.28] :

Theorem 16.8.2. *In the situation of* (16.8)*, set $S := \mathrm{Spec}\, V$ and $Z := \mathrm{Spec}\, V/\mathfrak{m}$. Then :*

(i) *The pair (S, Z) is almost pure, relative to the basic setup* $(V, \mathfrak{m})$.
(ii) *If Z is constructible in S, the pair (S, Z) is normal, for the basic setup* $(V, \mathfrak{m})$.

Proof. (ii): Denote by $j : U \to S$ the open immersion; the kernel $\mathscr{K}$ of the natural map $\mathscr{O}_S \to j_*\mathscr{O}_U$ is the largest $\mathscr{O}_S$-submodule such that $\mathfrak{m}\mathscr{K} = 0$, so the induced morphism $\mathscr{O}^a_S \to j_*\mathscr{O}^a_U$ is a monomorphism. It remains to check that the image of $\mathscr{O}^a_S$ is integrally closed in $j_*\mathscr{O}^a_U$, and since Z is constructible, we are reduced to showing that V^a is integrally closed in $\mathscr{O}_S(U)^a$ ([59, Ch.I, Prop.9.2.1]). The latter follows from lemma 16.8.1 and [75, Lemma 8.2.28].

(i): Let $(Z_\lambda \mid \lambda \in \Lambda)$ be the cofiltered system of closed constructible subsets of S containing Z, and for every $\lambda \in \Lambda$ let $\mathfrak{m}_\lambda \subset \mathfrak{m}$ be the unique radical ideal such that $\mathrm{Spec}\, V/\mathfrak{m}_\lambda = Z_\lambda$. Set also $U := S \setminus Z$ and $U_\lambda := S \setminus Z_\lambda$ for every $\lambda \in \Lambda$. Then $\mathfrak{m}_\lambda = \mathfrak{m}_\lambda^2$ and notice that both $\mathfrak{m}_\lambda$ (for every $\lambda \in \Lambda$) and $\mathfrak{m}$ trivially fulfill condition $(\mathbf{B})$ of [75, §2.1.6], since V is perfect. We then get an essentially commutative diagram

$$\begin{array}{ccc} (\mathscr{O}_S, \mathfrak{m}\mathscr{O}_S)^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} & \xrightarrow{\ \rho\ } & \mathscr{O}_U\text{-}\mathbf{\acute{E}t} \\ \downarrow & & \downarrow \\ (\mathscr{O}_S, \mathfrak{m}_\lambda\mathscr{O}_S)^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} & \xrightarrow{\ \rho_\lambda\ } & \mathscr{O}_{U_\lambda}\text{-}\mathbf{\acute{E}t} \end{array} \qquad \text{for every } \lambda \in \Lambda.$$

However, on the one hand, proposition 14.2.3 and corollary 14.2.5(ii,iv,v) imply that the category $(\mathscr{O}_S, \mathfrak{m}\mathscr{O}_S)^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}}$ is equivalent to the 2-limit of the system $((\mathscr{O}_S, \mathfrak{m}_\lambda\mathscr{O}_S)^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} \mid \lambda \in \Lambda)$; on the other hand, it is clear that $\mathscr{O}_U\text{-}\mathbf{\acute{E}t}$ is equivalent to the 2-limit of the system $(\mathscr{O}_{U_\lambda}\text{-}\mathbf{\acute{E}t} \mid \lambda \in \Lambda)$. Thus, we are reduced to checking that ρ_λ is an equivalence for every $\lambda \in \Lambda$, and we may therefore assume from start that Z is constructible. In view of (ii) and lemma 14.4.5(ii), we are then reduced to showing that for every finite étale $\mathscr{O}_U$-algebra $\mathscr{B}$ there exists an étale $\mathscr{O}_S^a$-algebra $\mathscr{A}$ of almost finite rank such that $\rho(\mathscr{A})$ is isomorphic to $\mathscr{B}$. Now, by applying proposition 14.3.30 with $X := S$ and $\mathfrak{m}_0 = \mathfrak{m} := V$ (so, we consider here the "classical limit" almost ring structure) we obtain a quasi-coherent $\mathscr{O}_S$-algebra $\mathscr{R}_0$ which is finitely presented as an $\mathscr{O}_S$-module, with an isomorphism $\mathscr{B} \xrightarrow{\sim} \mathscr{R}_{0|U}$ of $\mathscr{O}_U$-algebras.

Let $\Phi_S : S \to S$ be the Frobenius endomorphism, and consider the directed system of quasi-coherent $\mathscr{O}_S$-algebras $(\mathscr{R}_n \mid n \in \mathbb{N})$ with $\mathscr{R}_n := \Phi_S^{-n}\mathscr{R}_0$ for every $n \in \mathbb{N}$; explicitly, $\mathscr{R}_n(U') = \mathscr{R}_0(U')$ for every open subset $U' \subset S$, and the $\mathscr{O}_S(U')$-algebra structure on $\mathscr{R}_n(U')$ is given by the composition of the Frobenius endomorphism $\mathscr{O}_S(U') \to \mathscr{O}_S(U')$ with the structure morphism $\mathscr{O}_S(U') \to \mathscr{R}_0(U')$. The transition maps $\varphi_n : \mathscr{R}_n \to \mathscr{R}_{n+1}$ are given on each such U' by the Frobenius endomorphism $\mathscr{R}_0(U') \to \mathscr{R}_0(U')$, for every $n \in \mathbb{N}$. We let

$$\mathscr{R} := \operatorname*{colim}_{n \in \mathbb{N}} \mathscr{R}_n.$$

Since V is perfect, [75, Th.3.5.13] (applied again in the "classical limit" case with $\mathfrak{m} = V$) implies that $\varphi_{n|U}$ is an isomorphism for every $n \in \mathbb{N}$, so the natural morphism $\mathscr{R}_0 \to \mathscr{R}$ induces an isomorphism of $\mathscr{O}_U$-algebras

$$\mathscr{B} \xrightarrow{\sim} \mathscr{R}_{|U}.$$

Claim 16.8.3. There exists a subideal $\mathfrak{m}_0 \subset \mathfrak{m}$ whose radical is $\mathfrak{m}$, and with

$$\mathfrak{m}_0 \cdot \mathrm{Ker}\, \varphi_0 = \mathfrak{m}_0 \cdot \mathrm{Coker}\, \varphi_0 = 0.$$

Proof of the claim. Since Z is constructible, there exist finitely many elements $x_1, \dots, x_n \in \mathfrak{m}$ such that $U = \bigcup_{i=1}^n \mathrm{Spec}\, V[x_i^{-1}]$. Notice that both $\mathscr{R}_0$ and $\mathscr{R}_1$ are finitely presented $\mathscr{O}_S$-modules : indeed, this holds for assumption for $\mathscr{R}_0$, and then it follows also for $\mathscr{R}_1$, since Φ_S is an automorphism of S. Thus, since moreover $\varphi_{0|U}$ is an isomorphism, after replacing each x_i by a power x_i^N for some suitable $N \in \mathbb{N}$, we may assume already that $x_i \cdot \mathrm{Coker}\, \varphi_0 = 0$ for every $i = 1, \dots, n$. Next, let $R_i := \mathscr{R}_i(S)$ for $i = 0, 1$, and denote by $f : R_0 \to R_1$ the Frobenius map; the natural map

$$V[x_i^{-1}] \otimes_V \mathrm{Hom}_V(R_1, R_0) \to \mathrm{Hom}_{V[x_i^{-1}]}(R_1[x_i^{-1}], R_0[x_i^{-1}])$$

is bijective ([75, Lemma 2.4.29(i.a)]) and $V[x_i^{-1}] \otimes_V f$ is an isomorphism, hence we may find for every $i = 1, \dots, n$ a V-linear map $g_i : R_1 \to R_0$ such that $V[x_i^{-1}] \otimes_V (g \circ f) = \mathbf{1}_{R_0}$. Then there exists $N \in \mathbb{N}$ such that $x_i^N \cdot (g \circ f) = x_i^N \cdot \mathbf{1}_{R_0}$ for every $i = 1, \dots, n$, whence $x_i^N \cdot \mathrm{Ker}\, f = 0$ for every $i = 1, \dots, n$. The claim follows. ◊

Let $\mathfrak{m}_0$ be as in claim 16.8.3, and for every $n \in \mathbb{N}$ set $\mathfrak{m}_n := \Phi_V^{-n}(\mathfrak{m}_0)$, where $\Phi_V : V \to V$ denotes the Frobenius automorphism; then $\mathfrak{m}_n \cdot \mathrm{Ker}\,\varphi_n = \mathfrak{m}_n \cdot \mathrm{Coker}\,\varphi_n = 0$ for every $n \in \mathbb{N}$. Notice that

$$\mathfrak{m}_n^2 \subset \mathfrak{m}_n \cdot \mathfrak{m}_{n+1} \cdots \mathfrak{m}_{n+k} \qquad \text{for every } n, k \in \mathbb{N}$$

and therefore $\mathfrak{m}_n^2$ annihilates the kernel and cokernel of the transition map $\mathscr{R}_n \to \mathscr{R}_{n+k}$, for every $n, k \in \mathbb{N}$; we conclude that

$$\mathfrak{m}_n^2 \cdot \mathrm{Ker}\,(\mathscr{R}_n \to \mathscr{R}) = \mathfrak{m}_n^2 \cdot \mathrm{Coker}\,(\mathscr{R}_n \to \mathscr{R}) = 0 \qquad \text{for every } n \in \mathbb{N}. \tag{16.8.4}$$

Especially, $\mathscr{A} := \mathscr{R}^a$ is an almost finitely presented and uniformly almost finitely generated $\mathscr{O}_S^a$-module ([75, Cor.2.3.13]). Next, pick again elements $x_1, \dots, x_n \in \mathfrak{m}$ such that U is the union of the affine open subsets $U_i := \mathrm{Spec}\, V[x_i^{-1}]$ for $i = 1, \dots, n$; since $\mathscr{B}$ is a projective $\mathscr{O}_U$-module of finite rank, for every $i = 1, \dots, n$ there exist $N_i \in \mathbb{N}$ and $\mathscr{O}_U$-linear morphisms

$$\mathscr{B}_{|U_i} \xrightarrow{f_i} \mathscr{O}_{U_i}^{\oplus N_i} \xrightarrow{g_i} \mathscr{B}_{|U_i} \qquad \text{such that} \qquad g_i \circ f_i = \mathbf{1}_{\mathscr{B}|U_i}.$$

Then, arguing as in the proof of claim 16.8.3 we find for every $i = 1, \dots, n$, an integer $M_i \in \mathbb{N}$ and $\mathscr{O}_S$-linear morphisms

$$\mathscr{R}_0 \xrightarrow{f_{0,i}} \mathscr{O}_S^{\oplus N_i} \xrightarrow{g_{0,i}} \mathscr{R}_0 \qquad \text{such that} \qquad g_{0,i} \circ f_{0,i} = x_i^{M_i} \cdot \mathbf{1}_{\mathscr{R}_0}$$

whence, for every $k \in \mathbb{N}$, and every $i = 1, \dots, n$, a pair of $\mathscr{O}_S$-linear morphisms

$$\mathscr{R}_k \xrightarrow{f_{k,i}} \mathscr{O}_S^{\oplus N_i} \xrightarrow{g_{k,i}} \mathscr{R}_k \qquad \text{such that} \qquad g_{k,i} \circ f_{k,i} = x_i^{M_i/p^k} \cdot \mathbf{1}_{\mathscr{R}_0}.$$

It follows easily that $x_i^{M_i/p^k} \cdot \mathrm{Tor}_j^{\mathscr{O}_S}(\mathscr{R}_k, \mathscr{N}) = 0$ for every $j > 0$, every $i = 1, \dots, n$, every $k \in \mathbb{N}$ and every quasi-coherent $\mathscr{O}_S$-module $\mathscr{N}$. After taking colimits, we conclude that $\mathscr{A}$ is a flat $\mathscr{O}_S^a$-module; then $\mathscr{A}$ is also an almost projective $\mathscr{O}_S$-module of finite rank, in light of [75, Prop.2.4.18(ii) and Rem.4.3.10(i)]. Next, let e be the diagonal idempotent of the étale $\mathscr{O}_U$-algebra $\mathscr{B}$ (see remark 14.3.10(i)). Pick a finite system of elements $\varepsilon_1, \dots, \varepsilon_k \in \mathfrak{m}$ such that $\mathfrak{m}$ is the radical of the ideal $\sum_{i=1}^k V\varepsilon_i$; we may then find $N \in \mathbb{N}$ and for every $i = 1, \dots, k$ an element $e_i \in R_0 \otimes_V R_0$ such that

$$(\varepsilon_i^N \cdot e_i)_{|\mathrm{Spec}\, V[\varepsilon^{-1}]} = (\varepsilon_i^N \cdot e)_{|\mathrm{Spec}\, V[\varepsilon^{-1}]} \qquad \text{and} \qquad \mu_0(e_i) = \varepsilon_i^N \tag{16.8.5}$$

where $\mu_n : \mathscr{R}_n \otimes_{\mathscr{O}_S} \mathscr{R}_n \to \mathscr{R}_n$ is the multiplication map, for every $n \in \mathbb{N}$. Next, let $a_1, \dots, a_n$ be a finite system of generators for the V-module R_0; we may find $N' \in \mathbb{N}$ such that

$$\varepsilon_i^{N'} \cdot (a_j \otimes 1 - 1 \otimes a_j) \cdot e_i = 0 \qquad \text{for every } i = 1, \dots, k \text{ and every } j = 1, \dots, n$$

and after replacing e_i by $\varepsilon_i^{N'} e_i$ and N by $N + N'$ we may therefore assume that (16.8.5) still holds, and additionally :

$$e_i \cdot \mathrm{Ker}\,\mu_0 = 0 \qquad \text{for every } i = 1, \dots, k.$$

The same $e_1, \dots, e_k$ can also be regarded as elements of $R_n \otimes_V R_n$, and we deduce that

$$\mu_n(e_i) = \varepsilon_i^{N/p^n} \qquad \text{and} \qquad e_i \cdot \mathrm{Ker}\,\mu_n = 0 \qquad \text{for } i = 1, \dots, k \text{ and every } n \in \mathbb{N}. \tag{16.8.6}$$

Set $R := \mathscr{R}(S)$ and denote by $e_{n,i} \in R \otimes_V R$ the image of e_i under the natural morphism $\mathscr{R}_n \to \mathscr{R}$, for $i = 1, \dots, k$. Say that $\varepsilon_i^{N''} \in \mathfrak{m}_0$ for $i = 1, \dots, k$ (where $\mathfrak{m}_0$ is as in claim 16.8.3); then $\varepsilon_i^{N''/p^n} \in \mathfrak{m}_n$ for every $n \in \mathbb{N}$ and $i = 1, \dots, k$. Recall that the kernel of the multiplication map $\mu : \mathscr{R} \otimes_{\mathscr{O}_S} \mathscr{R} \to \mathscr{R}$ is generated, as a $\mathscr{R} \otimes_{\mathscr{O}_S} \mathscr{R}$-module, by the system $(a \otimes 1 - 1 \otimes a \mid a \in R)$; in light of (16.8.4) and (16.8.6) we deduce that

$$\varepsilon_i^{2N''/p^n} \cdot e_{n,i} \cdot \mathrm{Ker}\,\mu = 0 \qquad \text{for } i = 1, \dots, k$$

where $\mu : \mathscr{R} \otimes_{\mathscr{O}_S} \mathscr{R} \to \mathscr{R}$ is the multiplication map. After replacing $e_{n,i}$ by $\varepsilon_i^{2N''/p^n} \cdot e_{n,i}$ and N by $N + 2N''$, we then obtain $\mathscr{R} \otimes_{\mathscr{O}_S} \mathscr{R}$-linear morphisms

$$\nu_{n,i} : \mathscr{R} \to \mathscr{R} \otimes_{\mathscr{O}_S} \mathscr{R} \qquad x \mapsto (x \otimes 1) \cdot e_{n,i} \qquad \text{for every } n \in \mathbb{N} \text{ and } i = 1, \dots, k$$

such that $\mu \circ \nu_{n,i} = \varepsilon_i^{N/p^n} \cdot \mathbf{1}_{\mathscr{R}}$. Set $R := \mathscr{R}(S)$ for every $n \in \mathbb{N}$; it follows easily that $\varepsilon_i^{N/p^n} \cdot \mathrm{Ext}^j_{R \otimes_V R}(R, M) = 0$ for every $i = 1, \dots, k$, every $n \in \mathbb{N}$, every $j > 0$ and every $R \otimes_V R$-module M, so $\mathscr{A}$ is an almost projective $\mathscr{A} \otimes_{\mathscr{O}_S} \mathscr{A}$-module, and the proof is concluded. ☐

Notice next that, in the situation of (16.8), the ring V is reduced, hence every flat almost finitely presented V^a-module has almost finite rank (lemma 14.3.4(ii)). We can generalize this observation as follows :

Proposition 16.8.7. *Let* $(V, \mathfrak{m})$ *be a basic setup as in* (16.8)*, and consider ideals*

$$I \subset J \subset \mathfrak{m}$$

with J finitely generated. Let P be any flat almost finitely presented $(V/I)^a$-module. We have :

(i) *P has almost finite rank.*

(ii) *If* $\mathrm{Spec}\, V/\mathfrak{m}$ *is a constructible subset of* $S := \mathrm{Spec}\, V$*, then P has finite rank.*

Proof. In light of corollary 14.2.5(iv) we may assume that $\mathfrak{m}$ is the radical of a finitely generated subideal $\mathfrak{m}_0$ containing J, in which case $\mathrm{Spec}\, V/\mathfrak{m}$ is constructible in S, and it suffices to show assertion (ii). Then we may even replace J by $\mathfrak{m}_0$, and assume that $J^{\lceil 0 \rceil} V = \mathfrak{m}$ (notation of remark 9.3.70(i)).

Claim 16.8.8. We may assume that J lies in the Jacobson radical of V.

Proof of the claim. Indeed, let $x_1, \dots, x_k$ be a finite system of generators of J; the induced map

$$V \to (1 + J)^{-1} V \times \prod_{i=1}^{k} V[x_i^{-1}]$$

is faithfully flat, and clearly $V[x_i^{-1}] \otimes_V P$ is a projective $V[x_i^{-1}] \otimes_V V/I$-module of finite rank for every $i = 1, \dots, k$, so we are reduced to checking that $(1 + J)^{-1} V \otimes_V P$ is an almost projective $(1 + J)^{-1} V \otimes_V (V/I)^a$-module of finite rank, whence the claim. ◊

Henceforth we assume that J lies in the Jacobson radical of V. Now, suppose that we have $\Lambda^r_{(V/J)^a}(P/JP) = 0$ for some $r \in \mathbb{N}$; then $J \cdot \Lambda^r_{(V/I)^a} P = \Lambda^r_{(V/I)^a} P$, and since J is tight and $\Lambda^i_{(V/I)} P$ is almost finitely generated, we deduce that $\Lambda^r_{(V/I)^a} P = 0$, by [75, Lemma 5.1.7]. Thus, we are reduced to checking the assertion in case $I = J$. Next, notice that there exists $n \in \mathbb{N}$ such that $(J^{\langle 1 \rangle})^n V = J^{\langle n \rangle} V \subset J$ (lemma 9.3.69(ii.a,iv)), so $J^{\langle 1 \rangle} V$ is also a tight ideal contained in the Jacobson radical of V, and by the same token we are reduced to checking that $Q := P/J^{\langle 1 \rangle} P$ is a $(V/J^{\langle 1 \rangle})^a$-module of finite rank. To this aim, let us consider the S-scheme

$$Y := \mathrm{Proj}\, \mathsf{R} \qquad \text{where} \qquad \mathsf{R} := \bigoplus_{\gamma \in \mathbb{N}[1/p]} J^{\langle \gamma \rangle} V$$

as in (16.7.9), as well as the closed immersion

$$i : Y_0 := Y \times_S \mathrm{Spec}\, V/J^{\langle 1 \rangle} V = \mathrm{Proj}\, \mathsf{R}/J^{\langle 1 \rangle} \mathsf{R} \to Y.$$

Let also $\mathscr{T}$ be the discrete topology on V, and notice that $(V, \mathscr{T})$ is a perfectoid ring. Notice furthermore that $(J^{\langle 1 \rangle} V)^a = (J^{\lceil 1 \rceil} V)^a$; in light of example 16.7.9(i), theorem 16.7.10, and the short exact sequence of quasi-coherent $\mathscr{O}_Y$-modules

$$0 \to J^{\langle 1 \rangle} \mathscr{O}_Y \to \mathscr{O}_Y \to i_* \mathscr{O}_{Y_0} \to 0$$

we then deduce an isomorphism of V^a-algebras

$$(V/J^{\langle 1\rangle}V)^a \xrightarrow{\sim} H^0(Y_0, \mathscr{O}_{Y_0})^a$$

(details left to the reader). Say that J is generated by a finite system $x_1, \dots, x_k$; then Y admits a closed immersion $Y \to \mathbb{P}^{k-1}_S := \mathrm{Proj}\, V[T_1^{1/p^\infty}, \dots, T_k^{1/p^\infty}]$ (see example 4.8.55(iii)), whence an affine covering $Y = U_1 \dots, U_k$ consisting of preimages of complements of hyperplanes of $\mathbb{P}^k_S$, as usual. Set $U_{0,i} := U_i \times_Y Y_0$ for $i = 1, \dots, k$; we get an injective ring homomorphism

$$H^0(Y_0, \mathscr{O}_{Y_0}) \to A := \prod_{i=1}^k H^0(U_{0,i}, \mathscr{O}_{Y_0})$$

and on the other hand, natural identifications of V-algebras

$$A_i := \mathrm{gr}_0 \mathsf{R}[x_i^{-1}] \xrightarrow{\sim} H^0(U_i, \mathscr{O}_Y) \qquad A_i/J^{\langle 1\rangle}A_i \xrightarrow{\sim} H^0(U_{0,i}, \mathscr{O}_{Y_0}) \qquad i = 1, \dots, k.$$

Since Q is a flat $(V/J^{\langle 1\rangle}V)^a$-module, the same holds for $\Lambda^r_{(V/J^{\langle 1\rangle}V)^a}Q$, for every $r \in \mathbb{N}$; hence the induced map

$$\Lambda^r_{(V/J^{\langle 1\rangle}V)^a}Q \to A^a \otimes_{V^a} \Lambda^r_{(V/J^{\langle 1\rangle}V)^a}Q = \Lambda^r_{A^a}(A^a \otimes_{V^a} Q)$$

is a monomorphism, and we are reduced to checking that $A_i^a \otimes_{V^a} Q$ is an $(A_i/J^{\langle 1\rangle}A_i)^a$-module of finite rank for every $i = 1, \dots, k$. Now, let (B_i, JB_i) be the henselization of the pair (A_i, JA_i). The ideal $\mathfrak{m}B_i$ is generated by the system $(x_i^{1/p^n} \mid n \in \mathbb{N})$ consisting of regular elements of B_i; by [75, Th.2.1.12(ii.b)] we deduce that $\mathfrak{m}B_i$ is a B_i-module of homological dimension ≤ 1. Lastly, since $B_i/J^{\langle 1\rangle}B_i = A_i/J^{\langle 1\rangle}A_i$, we may apply [75, Th.5.5.7(i)] to find a flat almost finitely presented B_i^a-module Q' with an isomorphism $Q'/J^{\langle 1\rangle}Q' \xrightarrow{\sim} A_i^a \otimes_{V^a} Q$; since the localization $B_i \to B_i[x_i^{-1}]$ is a monomorphism, and since $B_i[x_i^{-1}] \otimes_{B_i} Q'$ is a projective $B_i[x_i^{-1}]$-module of finite rank, the B_i^a-module Q' has finite rank as well. But then obviously the same holds for the $(A_i/J^{\langle 1\rangle}A)^a$-module $A_i^a \otimes_{V^a} Q$, as required. □

16.8.9. Let A be a perfectoid ring, $\mathbf{E} := \mathbf{E}(A)$, and $\underline{\alpha} \in W(\mathbf{E})$ a distinguished element in the kernel of $u_A : W(\mathbf{E}) \to A$. Recall that $\overline{u}_A : \mathbf{E} \to A$ induces an isomorphism of topological rings $\omega : \mathbf{E}/\alpha_0\mathbf{E} \xrightarrow{\sim} A/pA$ (remark 16.3.7(ii)); hence, for every ideal $I \subset A$ containing pA, there exists a unique ideal $I_\mathbf{E} \subset \mathbf{E}$ containing $\alpha_0\mathbf{E}$ such that $\omega(I_\mathbf{E}/\alpha_0\mathbf{E}) = I/pA$.

Definition 16.8.10. In the situation of (16.8.9), let $(A, \mathfrak{m})$ and $(\mathbf{E}, \mathfrak{n})$ be two basic setups. We say that $(A, \mathfrak{m})$ and $(\mathbf{E}, \mathfrak{n})$ are *compatible* if there exists an ideal of definition $I \subset A$ such that ω induces a bijection $(\mathfrak{n} + I_\mathbf{E})/I_\mathbf{E} \xrightarrow{\sim} (\mathfrak{m} + I)/I$.

Remark 16.8.11. With the notation of definition 16.8.10, let M, N be two A/I-modules, and $h : M \to N$ an A-linear map. By assumption, $\overline{u}_A$ induces a ring isomorphism $\omega_I : \mathbf{E}/I_\mathbf{E} \xrightarrow{\sim} A/I$, and the compatibility of $(A, \mathfrak{m})$ and $(\mathbf{E}, \mathfrak{n})$ means that ω_I is an isomorphism

$$(\mathbf{E}/I_\mathbf{E}, (\mathfrak{n} + I_\mathbf{E})/I_\mathbf{E}) \xrightarrow{\sim} (A/I, (\mathfrak{m} + I)/I)$$

in the category $\mathscr{B}$ of basic setups as in [75, §3.5]. Hence h^a is an isomorphism of $(A, \mathfrak{m})^a$-modules if and only if $\omega_I^*(h^a) : \omega_I^*(M^a) \to \omega_I^*(N^a)$ is an isomorphism of $(\mathbf{E}, \mathfrak{n})^a$-modules.

Lemma 16.8.12. *In the situation of* (16.8.9)*, consider two compatible basic setups* $(A, \mathfrak{m})$ *and* $(\mathbf{E}, \mathfrak{n})$*, and let also* $f : B \to B'$ *be any continuous map in* A-Perf*. Then the morphism* $f^a : B^a \to B'^a$ *is an isomorphism in* $(A, \mathfrak{m})^a$-Alg *if and only if* $\mathbf{E}(f)^a : \mathbf{E}(B)^a \to \mathbf{E}(B')^a$ *is an isomorphism in* $(\mathbf{E}, \mathfrak{n})^a$-$\mathsf{Alg}$.

Proof. By assumption, there exists an ideal of definition $I \subset A$ such that ω induces a bijection $(\mathfrak{m}+I)/I \stackrel{\sim}{\to} (\mathfrak{n}+I_{\mathbf{E}})/I_{\mathbf{E}}$, and arguing as in the proof of lemma 16.2.7(i), we find a sequence $\beta_1,\dots,\beta_k$ of elements of $\mathbf{E}$ such that I is generated by $\overline{u}_A(\beta_1),\dots,\overline{u}_A(\beta_k)$; then, after replacing each β_i by β_i^{1/p^n} for some large $n\in\mathbb{N}$, we may also assume that $p\in I^t$, with $t:=k(p-1)+1$. In light of lemma 16.1.9(ii), it follows easily that $I_{\mathbf{E}}$ is generated by $\beta_1,\dots,\beta_k$, and $\alpha_0\in I^t_{\mathbf{E}}$. Denote by $\mathscr{T}$ and $\mathscr{T}'$ the I-adic topologies of B and B'; by lemma 8.3.12 and proposition 16.3.8, the topological rings $(B,\mathscr{T})$ and $(B',\mathscr{T}')$ are still perfectoid. Now, let $\mathrm{gr}^\bullet B$ (resp. $\mathrm{gr}^\bullet B'$) be the graded ring associated with the I-adic filtration on B (resp. on B'); likewise, let $\mathrm{gr}^\bullet\mathbf{E}(B)$ (resp. $\mathrm{gr}^\bullet\mathbf{E}(B')$) be the graded ring associated with the $I_{\mathbf{E}}$-adic filtration on $\mathbf{E}(B)$ (resp. on $\mathbf{E}(B')$). By claim 16.3.62(ii), the maps $\overline{u}_B$ and $\overline{u}_{B'}$ induce graded ring isomorphisms

$$\vartheta:\mathrm{gr}^\bullet\mathbf{E}(B)\stackrel{\sim}{\to}\mathrm{gr}^\bullet B\qquad \vartheta':\mathrm{gr}^\bullet\mathbf{E}(B')\stackrel{\sim}{\to}\mathrm{gr}^\bullet B'.$$

On the other hand, f and $\mathbf{E}(f)$ induce graded ring homomorphisms

$$\mathrm{gr}^\bullet(f):\mathrm{gr}^\bullet B\to\mathrm{gr}^\bullet B'\qquad \mathrm{gr}^\bullet\mathbf{E}(f):\mathrm{gr}^\bullet\mathbf{E}(B)\to\mathrm{gr}^\bullet\mathbf{E}(B')$$

such that :

$$\mathrm{gr}^\bullet(f)\circ\vartheta=\vartheta'\circ\mathrm{gr}^\bullet\mathbf{E}(f). \tag{16.8.13}$$

Now, if f^a is an isomorphism, then the same holds for $\mathrm{gr}^\bullet(f)^a$; conversely, if $\mathrm{gr}^\bullet(f)^a$ is an isomorphism, then we easily see that $f^a_n := (A/I^n\otimes_A f)^a : (B/I^nB)^a \to (B'/I^nB')^a$ is an isomorphism for every $n\in\mathbb{N}$, and therefore $f^a=\lim_{n\in\mathbb{N}} f^a_n$ is an isomorphism (recall that the functor $(-)^a$ commutes with limits, since it is a right adjoint). Likewise we see that $\mathbf{E}(f)^a$ is an isomorphism if and only if the same holds for $\mathrm{gr}^\bullet\mathbf{E}(f)^a$. Thus, we are reduced to checking that $\mathrm{gr}^\bullet(f)^a$ is an isomorphism of $(A,\mathfrak{m})^a$-algebras if and only if $\mathrm{gr}^\bullet\mathbf{E}(f)^a$ is an isomorphism of $(\mathbf{E},\mathfrak{n})^a$-algebras. However, notice that $\mathrm{gr}^\bullet B$ and $\mathrm{gr}^\bullet B'$ are A/I-modules, and let $\omega_I:\mathbf{E}/I_{\mathbf{E}}\stackrel{\sim}{\to}A/I$ be the ring isomorphism deduced from $\overline{u}_A$; we may then regard ϑ as an isomorphism $\mathrm{gr}^\bullet\mathbf{E}(B)\stackrel{\sim}{\to}\omega_I^*(\mathrm{gr}^\bullet B)$ of $\mathbf{E}/I_{\mathbf{E}}$-modules, and likewise for ϑ'. Also, $\mathrm{gr}^\bullet(f)$ is an isomorphism of $(A,\mathfrak{m})^a$-algebras if and only if $\omega_I^*(\mathrm{gr}^\bullet(f))$ is an isomorphism of $(\mathbf{E},\mathfrak{n})^a$-algebras, by remark 16.8.11. Taking into account (16.8.13), the assertion follows. □

16.8.14. Let now A be a perfectoid ring, and $\mathfrak{m}\subset A$ an open radical ideal. It follows easily that $A^{\circ\circ}\subset\mathfrak{m}$; moreover, if $\mathfrak{m}_{\mathbf{E}}\subset\mathbf{E}:=\mathbf{E}(A)$ is associated with $\mathfrak{m}$ as in (16.8.9), then $\overline{u}_A$ induces a ring isomorphism $\mathbf{E}/\mathfrak{m}_{\mathbf{E}}\stackrel{\sim}{\to}A/\mathfrak{m}$.

Proposition 16.8.15. *In the situation of* (16.8.14)*, let also $f:B\to B'$ be any continuous map in A-*Perf*. The following holds :*

- (i) $(A,\mathfrak{m})$ *and* $(\mathbf{E},\mathfrak{m}_{\mathbf{E}})$ *are basic setups fulfilling condition* **(B)** *of* [75, §2.1.6].
- (ii) *More precisely, the multiplication maps* $\widetilde{\mathfrak{m}}:=\mathfrak{m}\otimes_A\mathfrak{m}\to\mathfrak{m}$ *and* $\widetilde{\mathfrak{m}}_{\mathbf{E}}:=\mathfrak{m}_{\mathbf{E}}\otimes_{\mathbf{E}}\mathfrak{m}_{\mathbf{E}}\to\mathfrak{m}_{\mathbf{E}}$ *are isomorphisms.*
- (iii) *The morphism* $f^a:B^a\to B'^a$ *is an isomorphism in* $(A,\mathfrak{m})^a$-Alg *if and only if* $\mathbf{E}(f)^a:\mathbf{E}(B)^a\to\mathbf{E}(B')^a$ *is an isomorphism in* $(\mathbf{E},\mathfrak{m}_{\mathbf{E}})^a$-$\mathsf{Alg}$.
- (iv) $\mathfrak{m}B$ *is a radical ideal of* B.

Proof. (i): Let I be any ideal of definition of A. Since $A/\mathfrak{m}$ is reduced, the same holds for $\mathbf{E}/\mathfrak{m}_{\mathbf{E}}$, so $\mathfrak{m}_{\mathbf{E}}$ is a radical ideal of $\mathbf{E}$, hence $\mathfrak{m}^2_{\mathbf{E}}=\mathfrak{m}_{\mathbf{E}}$, since $\mathbf{E}$ is perfect. Now, let $\underline{\alpha}\in\mathrm{Ker}\,u_A$ be any distinguished element; by remark 16.3.7(ii), the map $\overline{u}_A$ induces a ring isomorphism $\mathbf{E}/\alpha_0\mathbf{E}\stackrel{\sim}{\to}A/pA$, and it follows easily that $\mathfrak{m}^2+pA=\mathfrak{m}$. On the other hand, we have $pA\subset I^2\subset\mathfrak{m}^2$, so $\mathfrak{m}^2=\mathfrak{m}$. Next, it is clear that $\mathfrak{m}_{\mathbf{E}}$ fulfills condition **(B)**, in particular $\mathfrak{m}_{\mathbf{E}}$ is generated by its p-th powers, therefore the same follows for the ideal $\mathfrak{m}_{\mathbf{E}}/\alpha_0\mathbf{E}$ of $\mathbf{E}/\alpha_0\mathbf{E}$, and then also for the ideal $\mathfrak{m}/pA$ of A/pA. Combining with lemma 16.2.3(iv), we deduce that $\mathfrak{m}$ is generated by its p-powers. If $l \neq p$ is any prime integer, we have $l \in A^\times$, hence $\mathfrak{m}/l\mathfrak{m} = 0$, and taking into account [75, Claim 2.1.9], it follows that $\mathfrak{m}$ fulfills condition (**B**).

(ii): Let us write $\mathfrak{m}$ as the union of a filtered system $(\mathfrak{m}_\lambda \mid \lambda \in \Lambda)$ of open radical subideals such that $\mathrm{Spec}\, A/\mathfrak{m}_\lambda$ is constructible in $\mathrm{Spec}\, A$ for every $\lambda \in \Lambda$; clearly it suffices to show that the corresponding map $\mathfrak{m}_\lambda \otimes_A \mathfrak{m}_\lambda \to \mathfrak{m}_\lambda$ is an isomorphism for every $\lambda \in \Lambda$. We may therefore assume that $\mathfrak{m}$ is the radical of an open ideal generated by finitely many elements $a_1, \dots, a_r$ of A; moreover, we may also assume that there exist $\alpha_1, \dots, \alpha_r \in \mathbf{E}$ with $a_i = \overline{u}_A(\alpha_i)$ for $i = 1, \dots, r$ (see remark 16.3.7(iii)). In this situation, we have a ring homomorphism $u_0 : R_{r,0} \to A$ such that $u_0(T_i^{1/p^k}) = \overline{u}_A(\alpha_i^{1/p^k})$ for $i = 0, \dots, r$ (notation of (16.7.9)), and it is easily seen that $\mathfrak{m} = T^{\lceil 0 \rceil} A$. Then the assertion follows from proposition 16.4.10(i) and theorem 16.7.10(iv).

(iii): It is clear that the basic setups $(A, \mathfrak{m})$ and $(\mathbf{E}, \mathfrak{m}_\mathbf{E})$ are compatible, in the sense of definition 16.8.10; then the assertion follows from lemma 16.8.12.

(iv): The map $\overline{u}_B$ induces a ring isomorphism :

$$\mathbf{E}(B)/\mathfrak{m}_\mathbf{E}\mathbf{E}(B) \xrightarrow{\sim} B/\mathfrak{m}B$$

and we need to check that $B/\mathfrak{m}B$ is reduced; so we are reduced to showing that the same holds for $\mathbf{E}(B)/\mathfrak{m}_\mathbf{E}\mathbf{E}(B)$, *i.e.* that $\mathfrak{m}_\mathbf{E}\mathbf{E}(B)$ is a radical ideal. But since $\mathbf{E}(B)$ is perfect, this is equivalent to proving that $\Phi_{\mathbf{E}(B)}(\mathfrak{m}_\mathbf{E} B) = \mathfrak{m}_\mathbf{E} B$ (where $\Phi_{\mathbf{E}(B)}$ denotes the Frobenius automorphism of $\mathbf{E}(B)$); the latter is clear, since we have already shown that $\mathfrak{m}_\mathbf{E}$ is a radical ideal of $\mathbf{E}$. □

16.8.16. Let A be a perfectoid ring, $\mathbf{E} := \mathbf{E}(A)$, and $\mathfrak{m} \subset A$ an open radical ideal; let also B be any perfectoid A-algebra, and $\mathfrak{m}_\mathbf{E} \subset \mathbf{E}$ the unique open ideal such that $\overline{u}_A : \mathbf{E} \to A$ induces a ring isomorphism $\mathbf{E}/\mathfrak{m}_\mathbf{E} \xrightarrow{\sim} A/\mathfrak{m}$ (see (16.8.9)). According to proposition 16.8.15(i), we have a well defined $(A, \mathfrak{m})^a$-algebra B^a and an $(\mathbf{E}, \mathfrak{m}_\mathbf{E})^a$-algebra $\mathbf{E}(B)^a$. We denote by

$$\eta_B : B \to B^a_* \qquad \text{and} \qquad \eta_{\mathbf{E}(B)} : \mathbf{E}(B) \to \mathbf{E}(B)^a_*$$

the units of adjunction, and endow B^a_* (resp. $\mathbf{E}(B)^a_*$) with the unique ring topology such that η_B (resp. $\eta_{\mathbf{E}(B)}$) is an adic morphism.

Corollary 16.8.17. *With the notation of* (16.8.16)*, the topological rings B^a_* and $\mathbf{E}(B)^a_*$ are perfectoid, and there exists an isomorphism of $\mathbf{E}$-algebras*

$$\omega : \mathbf{E}(B)^a_* \xrightarrow{\sim} \mathbf{E}(B^a_*) \qquad \textit{such that} \qquad \omega \circ \eta_{\mathbf{E}(B)} = \mathbf{E}(\eta_B).$$

Proof. We consider first the case where the structure map $A \to B$ is adic, and $Z := \mathrm{Spec}\, A/\mathfrak{m}$ is constructible in $X := \mathrm{Spec}\, A$. Then, set $U := \mathrm{Spec}\, B \times_X (X \setminus Z)$, $B_U := \mathscr{O}_U(U)$, and let $\overline{B} \subset B_U$ be the image of the restriction map $\rho : B \to B_U$. Notice that B is reduced, by corollary 16.3.63(i); it follows easily that

$$\mathfrak{m} \cdot \mathrm{Ker}\, \rho = 0 \tag{16.8.18}$$

(the details are left to the reader). We remark :

Claim 16.8.19. If Z is constructible in X, we have a natural identification of B-algebras :

$$B^a_* \xrightarrow{\sim} C := \{x \in B_U \mid \mathfrak{m} \cdot x \subset \overline{B}\}.$$

Proof of the claim. Let $a_1, \dots, a_n \in A$ be a finite system of elements that generate an ideal whose radical equals $\mathfrak{m}$; then :

$$B_U = \mathrm{Equal}\left(\prod_{i=1}^n B[a_i^{-1}] \rightrightarrows \prod_{i,j=1}^n B[a_i^{-1}, a_j^{-1}]\right).$$

Now, obviously $B[a_i^{-1}]^a_* = B[a_i^{-1}]$, and likewise for $B[a_i^{-1}, a_j^{-1}]$, for every $i, j = 1, \dots, n$; since the functor of almost elements is left exact, we deduce that $B^a_{U*} = B_U$. Therefore, ρ induces a map of B-algebras $\rho^a_* : B^a_* \to B_U$, and notice that ρ^a is a monomorphism, due to (16.8.18), so the same holds for ρ_*^a (proposition 1.3.18(i)). Obviously $\overline{B}^a = B^a$, hence $\mathfrak{m}\cdot\rho_*^a(B_*^a) = \mathfrak{m}\overline{B}$, *i.e.* the image of ρ_*^a lies in the subring C. Moreover, ρ induces an isomorphism $C^a \stackrel{\sim}{\to} B^a$, whence by adjunction, a unique map of B-algebras $C \to B_*^a$ whose composition with ρ_*^a agrees with the inclusion map $C \to B_U$. This shows that ρ_*^a maps B_*^a onto C, whence the claim. ◊

Recall that B_U carries a natural f-adic topology for which $\overline{B}$ is a subring of definition (lemma 16.4.32(i)), and $\mathfrak{m}\overline{B}$ is an open ideal of $\overline{B}$, since the structure map $A \to B$ is adic; from claim 16.8.19 it then follows that B_*^a is a bounded subring of B_U, and therefore its topology as defined in (16.8.16) agrees with the topology induced by the inclusion into B_U (proposition 8.3.18(i,ii)). From proposition 16.5.4(iii) we also see that $(B_*^a)^{\circ\circ} = B_U^{\circ\circ} = B^{\circ\circ}$.

Claim 16.8.20. If the structure map $A \to B$ is adic, and Z is constructible in X, we have :

(i) $B_*^a/B_U^{\circ\circ}$ is a perfect $\mathbb{F}_p$-algebra and it is integrally closed in $B_U^\circ/B_U^{\circ\circ}$.

(ii) B_*^a is perfectoid and integrally closed in B_U°.

Proof of the claim. (i): Notice that $A/A^{\circ\circ}$, $\overline{B}/B^{\circ\circ}$ and $B_U^\circ/B_U^{\circ\circ}$ are perfect $\mathbb{F}_p$-algebras; also, $\mathfrak{m}/A^{\circ\circ}$ is a radical ideal of $A/A^{\circ\circ}$, and since Z is constructible, there exists a finitely generated ideal $\mathfrak{m}_0 \subset A/A^{\circ\circ}$ whose radical is $\mathfrak{m}/A^{\circ\circ}$. With this notation, $B_U^\circ/B_U^{\circ\circ}$ is an $A/A^{\circ\circ}$-algebra, and for every $x \in B_U^\circ/B_U^{\circ\circ}$ there exists $k \in \mathbb{N}$ such that $\mathfrak{m}_0^k \cdot x \subset \overline{B}/B^{\circ\circ}$. Then the assertion follows from lemma 16.8.1.

(ii) follows from (i), claim 16.5.15, and theorem 16.5.13(iii). ◊

Next, set $Z_{\mathbf{E}} := \operatorname{Spec}\mathbf{E}/\mathfrak{m}_{\mathbf{E}}$, $X_{\mathbf{E}} := \operatorname{Spec}\mathbf{E}$, and $U_{\mathbf{E}} := \operatorname{Spec}\mathbf{E}(B)\times_{X_{\mathbf{E}}}(X_{\mathbf{E}}\setminus Z_{\mathbf{E}})$. The foregoing argument applies also to $\mathbf{E}(B)_*^a$, and shows that the latter is a perfectoid subring of $\mathbf{E}_U := \mathscr{O}_{U_{\mathbf{E}}}(U_{\mathbf{E}})$; moreover, we get cartesian diagrams of topological rings :

$$\begin{array}{ccc} B_*^a & \xrightarrow{i_B} & B_U^\circ \\ \downarrow & & \downarrow \\ B_*^a/B_U^{\circ\circ} & \longrightarrow & B_U^\circ/B_U^{\circ\circ} \end{array} \qquad \begin{array}{ccc} \mathbf{E}(B)_*^a & \xrightarrow{\iota_{\mathbf{E}}} & \mathbf{E}_U^\circ \\ \downarrow & & \downarrow \\ \mathbf{E}(B)_*^a/\mathbf{E}_U^{\circ\circ} & \longrightarrow & \mathbf{E}_U^\circ/\mathbf{E}_U^{\circ\circ}. \end{array}$$

Furthermore, according to proposition 16.5.4(iv), the morphism of topological monoids $\varphi_U^{\flat\circ} : \mathbf{E}_U^\circ \to B_U^\circ$ induces a ring isomorphism $\overline{\varphi}_U^{\flat\circ} : \mathbf{E}_U^\circ/\mathbf{E}_U^{\circ\circ} \stackrel{\sim}{\to} B_U^\circ/B_U^{\circ\circ}$, which in turn restricts to a ring isomorphism $\overline{\mathbf{E}}(B)/\mathbf{E}_U^{\circ\circ} \stackrel{\sim}{\to} \overline{B}/B_U^{\circ\circ}$, where $\overline{\mathbf{E}}(B)$ denotes the image of $\mathbf{E}(B)$ into $\mathbf{E}_U$. Notice also that claim 16.8.19 yields natural identifications :

$$B_*^a/B_U^{\circ\circ} \stackrel{\sim}{\to} \{x \in B_U^\circ/B_U^{\circ\circ} \mid \mathfrak{m}\cdot x \subset \overline{B}/B_U^{\circ\circ}\}$$
$$\mathbf{E}(B)_*^a/\mathbf{E}_U^{\circ\circ} \stackrel{\sim}{\to} \{x \in \mathbf{E}_U^\circ/\mathbf{E}_U^{\circ\circ} \mid \mathfrak{m}_{\mathbf{E}}\cdot x \subset \overline{\mathbf{E}}(B)/\mathbf{E}_U^{\circ\circ}\}.$$

But clearly $\overline{\varphi}_U^{\flat\circ}(\mathfrak{m}_{\mathbf{E}}\cdot x) = \mathfrak{m}\cdot\overline{\varphi}_U^{\flat\circ}(x)$ for every $x \in \mathbf{E}_U^\circ/\mathbf{E}_U^{\circ\circ}$, so $\overline{\varphi}_U^{\flat\circ}$ restricts as well to a ring isomorphism

$$\mathbf{E}(B)_*^a/\mathbf{E}_U^{\circ\circ} \stackrel{\sim}{\to} B_*^a/B_U^{\circ\circ}.$$

Summing up, and invoking proposition 16.3.25, we obtain a unique isomorphism of topological rings $\omega : \mathbf{E}(B)_*^a \stackrel{\sim}{\to} \mathbf{E}(B_*^a)$ fitting into the commutative diagram :

$$\begin{array}{ccc} \mathbf{E}(B)_*^a & \xrightarrow{\iota_{\mathbf{E}}} & \mathbf{E}_U^\circ \\ {\scriptstyle\omega}\downarrow & & \downarrow{\scriptstyle\omega^\circ} \\ \mathbf{E}(B_*^a) & \xrightarrow{\mathbf{E}(\iota_B)} & \mathbf{E}(B_U^\circ) \end{array}$$

where ω° is the isomorphism provided by theorem 16.5.13(i). Lastly, denote by $\rho^\circ : B \to B_U^\circ$ and $\rho_{\mathbf{E}}^\circ : \mathbf{E}(B) \to \mathbf{E}_U^\circ$ the continuous ring homomorphisms induced by the restriction maps;

the isomorphism ω° is characterized by the identity :

$$\omega^\circ \circ \rho^\circ_{\mathbf{E}} = \mathbf{E}(\rho^\circ).$$

Since ρ° and $\rho^\circ_{\mathbf{E}}$ factor through η_B and respectively $\eta_{\mathbf{E}(B)}$, we conclude that $\omega \circ \eta_{\mathbf{E}(B)} = \mathbf{E}(\eta_B)$, as stated. This completes the proof of the corollary in case Z is constructible.

Next, we consider the case where Z can be an arbitrary closed subset of X, and the structure map $A \to B$ is still adic. Let us write $\mathfrak{m}$ as the filtered union of a system $(\mathfrak{m}_\lambda \mid \lambda \in \Lambda)$ of open radical subideals such that $\mathrm{Spec}\, A/\mathfrak{m}_\lambda$ is constructible in X for every $\lambda \in \Lambda$; correspondingly, we obtain a filtered system $(\mathfrak{m}_{\mathbf{E},\lambda} \mid \lambda \in \Lambda)$ of ideals in $\mathbf{E}$ whose union is $\mathfrak{m}_{\mathbf{E}}$. For every such λ let B_λ (resp. $\mathbf{E}(B)_\lambda$) be the image of B (resp. of $\mathbf{E}(B)$) in the category $(A, \mathfrak{m}_\lambda)^a$-Alg (resp. $(\mathbf{E}, \mathfrak{m}_{\mathbf{E},\lambda})^a$-Alg); we endow $B^a_{\lambda*}$ (resp. $\mathbf{E}(B)^a_{\lambda*}$) with the unique adic topology such that the unit of adjunction $\eta_{B,\lambda} : B \to B^a_{\lambda*}$ (resp. $\eta_{\mathbf{E}(B),\lambda} : \mathbf{E}(B) \to \mathbf{E}(B)^a_{\lambda*}$) is adic. After replacing Λ by a cofinal subset, we may assume that Λ admits an initial element λ_0. The localization functors $(A, \mathfrak{m})^a$-Alg $\to (A, \mathfrak{m}_\lambda)^a$-Alg $\to (A, \mathfrak{m}_\mu)^a$-Alg induce natural maps of B-algebras

$$f_\lambda : B^a_* \to B^a_{\lambda*} \qquad \text{and} \qquad f_{\lambda\mu} : B^a_{\lambda*} \to B^a_{\mu*} \qquad \text{for every } \lambda, \mu \in \Lambda \text{ with } \lambda \geq \mu$$

which are clearly continuous. Moreover, clearly the images f^a_λ and $f^a_{\lambda\mu}$ of f_λ and $f_{\lambda\mu}$ in $(A, \mathfrak{m}_{\lambda_0})^a$-Alg are isomorphism, hence

$$\mathfrak{m}_{\lambda_0}\cdot\mathrm{Ker}\, f_\lambda = \mathfrak{m}_{\lambda_0}\cdot\mathrm{Coker}\, f_\lambda = 0 \qquad \mathfrak{m}_{\lambda_0}\cdot\mathrm{Ker}\, f_{\lambda\mu} = \mathfrak{m}_{\lambda_0}\cdot\mathrm{Coker}\, f_{\lambda\mu} = 0 \qquad \text{for every } \lambda \geq \mu.$$

Claim 16.8.21. The maps f_λ and $f_{\lambda\mu}$ induce bijections

$$\mathfrak{m}_{\lambda_0} B^a_* \stackrel{\sim}{\to} \mathfrak{m}_{\lambda_0} B^a_{\lambda*} \stackrel{\sim}{\to} \mathfrak{m}_{\lambda_0} B^a_{\mu*} \qquad \text{for every } \lambda \geq \mu.$$

Proof of the claim. By the foregoing, we see already that f_λ (resp. $f_{\lambda\mu}$) maps $\mathfrak{m}_{\lambda_0} B^a_*$ onto $\mathfrak{m}_{\lambda_0} B^a_{\lambda*}$ (resp. $\mathfrak{m}_{\lambda_0} B^a_{\lambda*}$ onto $\mathfrak{m}_{\lambda_0} B^a_{\mu*}$). Moreover, by the previous case we also know that $B^a_{\lambda*}$ is perfectoid, and under our current assumptions $\mathfrak{m}_{\lambda_0} B^a_{\lambda*}$ is an open ideal of $B^a_{\lambda*}$, hence $B^a_{\lambda*}/\mathfrak{m}_{\lambda_0} B^a_{\lambda*} = B^a_{\lambda*} \widehat{\otimes}_A A/\mathfrak{m}_{\lambda_0}$ is a discrete perfectoid $\mathbb{F}_p$-algebra (proposition 16.3.9(i)); especially, the latter is a reduced ring (corollary 16.3.63(i)). Now, let $x \in \mathfrak{m}_{\lambda_0} B^a_{\lambda*} \cap \mathrm{Ker}\, f_{\lambda\mu}$; then $\mathfrak{m}_{\lambda_0} \cdot x = 0$, whence $x^2 = 0$, and finally $x = 0$, which shows that $f_{\lambda\mu}$ is injective on $\mathfrak{m}_{\lambda_0} B^a_{\lambda*}$ for every $\lambda \in \Lambda$. Next, from corollary 14.2.5(i) we know that B^a_* is the limit of the cofiltered system of B-algebras $(B^a_{\lambda*} \mid \lambda \in \Lambda)$, hence the natural map

$$\mathfrak{m}_{\lambda_0} B^a_* \to L := \lim_{\lambda \in \Lambda} \mathfrak{m}_{\lambda_0} B^a_{\lambda*}$$

is injective. But we have also just seen that all the projections $L \to \mathfrak{m}_{\lambda_0} B^a_{\lambda*}$ are isomorphisms, so the maps $\mathfrak{m}_{\lambda_0} B^a_* \to \mathfrak{m}_{\lambda_0} B^a_{\lambda*}$ are injective as well. $\Diamond$

From claim 16.8.21 and [163, Lemma 3.5.3] we deduce that the natural map

$$B^a_*/\mathfrak{m}_{\lambda_0} B^a_* \to \lim_{\lambda \in \Lambda} B^a_{\lambda*}/\mathfrak{m}_{\lambda_0} B^a_{\lambda*}$$

is a ring isomorphism; since we have already observed that each quotient $B^a_{\lambda*}/\mathfrak{m}_{\lambda_0} B^a_{\lambda*}$ is a perfect $\mathbb{F}_p$-algebra, it follows easily that the same holds for $B^a_*/\mathfrak{m}_{\lambda_0} B^a_*$; especially, the latter is a discrete perfectoid ring. We then get for every $\lambda \in \Lambda$ a cartesian diagram of rings

$$\mathscr{D}_\lambda \quad : \quad \begin{array}{ccc} B^a_* & \xrightarrow{f_\lambda} & B^a_{\lambda*} \\ \downarrow & & \downarrow \\ B^a_*/\mathfrak{m}_{\lambda_0} B^a_* & \longrightarrow & B^a_{\lambda*}/\mathfrak{m}_{\lambda_0} B^a_{\lambda*} \end{array}$$

which is also cartesian in the category of topological rings, by lemma 8.3.11, and proposition 16.3.25 implies that B^a_* is perfectoid. The same argument applies as well to the perfectoid

$\mathbf{E}$-algebra $\mathbf{E}(B)$, and it yields a cartesian diagram of perfectoid rings :

$$\mathscr{D}_{\mathbf{E},\lambda} \quad : \quad \begin{array}{ccc} \mathbf{E}(B)^a_* & \xrightarrow{f_{\mathbf{E},\lambda}} & \mathbf{E}(B)^a_{\lambda *} \\ \downarrow & & \downarrow \\ \mathbf{E}(B)^a_*/\mathfrak{m}_{\mathbf{E},\lambda_0}\mathbf{E}(B)^a_* & \longrightarrow & \mathbf{E}(B)^a_{\lambda *}/\mathfrak{m}_{\mathbf{E},\lambda}\mathbf{E}(B)^a_{\lambda *}. \end{array}$$

By the same token, the system $(f_{\mathbf{E},\lambda} \mid \lambda \in \Lambda)$ induces a ring isomorphism

$$\mathbf{E}(B)^a_*/\mathfrak{m}_{\mathbf{E},\lambda_0}\mathbf{E}(B)^a_* \to \lim_{\lambda \in \Lambda} \mathbf{E}(B)^a_{\lambda *}/\mathfrak{m}_{\mathbf{E},\lambda_0}\mathbf{E}(B)^a_{\lambda *}.$$

Furthermore, by the previous case we already have an isomorphism of topological rings

$$\omega_\lambda : \mathbf{E}(B)^a_{\lambda *} \xrightarrow{\sim} \mathbf{E}(B^a_{\lambda *}) \qquad \text{such that} \qquad \omega_\lambda \circ \eta_{\mathbf{E}(B),\lambda} = \mathbf{E}(\eta_{B,\lambda}) \qquad \text{for every } \lambda \in \Lambda.$$

We may then identify naturally the bottom row of $\mathscr{D}_\lambda$ with that of $\mathscr{D}_{\mathbf{E},\lambda}$, and by invoking again proposition 16.3.25 we obtain a natural isomorphism of topological rings $\omega : \mathbf{E}(B)^a_* \xrightarrow{\sim} \mathbf{E}(B^a_*)$ fitting into the commutative diagrams

$$\begin{array}{ccc} \mathbf{E}(B)^a_* & \xrightarrow{f_{\mathbf{E},\lambda}} & \mathbf{E}(B)^a_{\lambda *} \\ {\scriptstyle\omega}\downarrow & & \downarrow{\scriptstyle\omega_\lambda} \\ \mathbf{E}(B^a_*) & \xrightarrow{\mathbf{E}(f_\lambda)} & \mathbf{E}(B^a_{\lambda *}) \end{array} \qquad \text{for every } \lambda \in \Lambda.$$

Then the sought identity $\omega \circ \eta_{\mathbf{E}(B)} = \mathbf{E}(\eta_B)$ follows from the corresponding ones for the isomorphisms ω_λ, after taking limits (details left to the reader). This completes the proof, in case the topologies of A and B are p-adic.

For the general case, let $\mathscr{T}_{A,p}$ (resp. $\mathscr{T}_{B,p}$) be the p-adic topology on A (resp. on B); then $(A, \mathscr{T}_{A,p})$ and $(B, \mathscr{T}_{B,p})$ are perfectoid topological rings as well (proposition 16.3.8(i)), and the rings underlying $\mathbf{E}((B, \mathscr{T}_{B,p})^a_*)$ and $\mathbf{E}(B, \mathscr{T}_{B,p})^a_*$ coincide with the rings underlying $\mathbf{E}(B^a_*)$ and respectively $\mathbf{E}(B)^a_*$, so the previous case already yields a ring isomorphism ω as sought. It remains to check that B^a_* (resp. $\mathbf{E}(B)^a_*$) is perfectoid for the topology such that η_B (resp. $\eta_{\mathbf{E}(B)}$) is adic, and that ω is also an isomorphism of topological rings for these topologies. However, let $I \subset B$ be any finitely generated ideal of definition; the natural map $B^a \to \lim_{n \in \mathbb{N}}(B/I^n)^a$ is an isomorphism, hence the same holds for the induced map $B^a_* \to \lim_{n \in \mathbb{N}}(B/I^n)^a_*$, and especially, B^a_* is complete and separated for the linear topology for which $(J_n := \mathrm{Ker}\, B^a_* \to (B/I^n)^a_* \mid n \in \mathbb{N})$ is a fundamental system of open submodules (corollary 8.2.16(i)). Clearly $I^n B^a_* \subset J_n$ for every $n \in \mathbb{N}$, so B^a_* is also complete and separated for its I-adic topology (lemma 8.3.12). Together with proposition 16.3.8(ii), this proves that B^a_* is perfectoid, and the same applies to $\mathbf{E}(B)^a_*$. Lastly, since η_B is adic, the same holds for $\mathbf{E}(\eta_B)$ (corollary 16.3.8), but then the identity $\omega \circ \eta_{\mathbf{E}(B)} = \mathbf{E}(\eta_B)$ implies easily that ω is an isomorphism of topological rings. □

16.8.22. In the situation of (16.8.16), denote also by $\varepsilon_B : B^a_{!!} \to B$ and $\varepsilon_{\mathbf{E}(B)} : \mathbf{E}(B)^a_{!!} \to \mathbf{E}(B)$ the counits of adjunction, and endow $B^a_{!!}$ (resp. $\mathbf{E}(B)^a_{!!}$) with the unique topology such that the natural map $A \to B^a_{!!}$ (resp. $\mathbf{E} \to \mathbf{E}(B)^a_{!!}$) is adic.

Corollary 16.8.23. *With the notation of* (16.8.22)*, the topological rings $B^a_{!!}$ and $\mathbf{E}(B)^a_{!!}$ are perfectoid and there exists an isomorphism of $\mathbf{E}$-algebras*

$$\omega : \mathbf{E}(B)^a_{!!} \xrightarrow{\sim} \mathbf{E}(B^a_{!!}) \qquad \textit{such that} \qquad \mathbf{E}(\varepsilon_B) \circ \omega = \varepsilon_{\mathbf{E}(B)}.$$

Proof. Notice that, by virtue of proposition 16.8.15(ii) we have cartesian diagrams of rings

$$\mathscr{D}\quad:\quad\begin{array}{ccc} B^a_{!!} & \xrightarrow{\varepsilon_B} & B \\ \downarrow & & \downarrow \\ A/\mathfrak{m} & \longrightarrow & B/\mathfrak{m}B. \end{array}\qquad\qquad \mathscr{D}_{\mathbf{E}}\quad:\quad\begin{array}{ccc} \mathbf{E}(B)^a_{!!} & \xrightarrow{\varepsilon_{\mathbf{E}(B)}} & \mathbf{E}(B) \\ \downarrow & & \downarrow \\ \mathbf{E}/\mathfrak{m}_{\mathbf{E}} & \longrightarrow & \mathbf{E}(B)/\mathfrak{m}_{\mathbf{E}}\mathbf{E}(B). \end{array}$$

Moreover, clearly we may assume that the structure map $A \to B$ is an adic ring homomorphism, in which case the same holds for the map $\mathbf{E} \to \mathbf{E}(B)$ (theorem 16.3.42(i)), and the bottom rows of $\mathscr{D}$ and $\mathscr{D}_{\mathbf{E}}$ consist of discrete perfectoid $\mathbb{F}_p$-algebras (cp. the proof of claim 16.8.21). Then $\mathscr{D}$ and $\mathscr{D}_{\mathbf{E}}$ are cartesian in the category of topological rings as well (lemma 8.3.11), and the assertion follows from proposition 16.3.25. $\square$

Lemma 16.8.24. *In the situation of* (16.8.16)*, let* $f : B \to C$ *be a morphism of perfectoid* A*-algebras,* $(b_\lambda \mid \lambda \in \Lambda)$ *a system of elements of* B*, and for every* $n \in \mathbb{N}$ *denote by* $I_n \subset B$ *the ideal generated by the system* $(b^n_\lambda \mid \lambda \in \Lambda)$*. Suppose that* $p^k B \subset I_1$ *for some* $k \in \mathbb{N}$*, and that* $(f \otimes_B B/I_1)^a : (B/I_1)^a \to (C/I_1C)^a$ *is a flat morphism of* $(A, \mathfrak{m})^a$*-algebras. Then the same holds for* $(f \otimes_B B/I_n)^a$*, for every* $n \in \mathbb{N}$*.*

Proof. Set $J_n := p^n B + I_n$ for every $n \in \mathbb{N}$; since $p^k B \subset I_1$, it is easily seen that for every $n \in \mathbb{N}$ there exists $n' \in \mathbb{N}$ such that $J_{n'} \subset I_n \subset J_n$ (details left to the reader). Hence, it suffices to show that $(f \otimes_B B/J_n)^a$ is flat for every $n \in \mathbb{N}$. Next, let $\underline{\alpha} \in \operatorname{Ker} u_B$ be a distinguished element, and pick for every $\lambda \in \Lambda$ elements $e_\lambda \in \mathbf{E}(B)$ and $c_\lambda \in B$ such that

$$b_\lambda = \overline{u}_B(e_\lambda) + \overline{u}_B(\alpha_0) \cdot c_\lambda.$$

For every $n \in \mathbb{N}$, denote by $I'_n \subset B$ the ideal generated by $(\overline{u}_B(e^n_\lambda) \mid \lambda \in \Lambda)$, and set $J'_n := \overline{u}_B(\alpha^n_0) \cdot B + I'_n$; it follows easily that

$$J_{2n-1} \subset J'_n \qquad \text{and} \qquad J'_{2n-1} \subset J_n \qquad \text{for every } n \in \mathbb{N}$$

so $(f \otimes_B B/J'_1)^a$ is flat, and we are further reduced to checking that $(f \otimes_B B/J'_n)^a$ is flat for every $n \in \mathbb{N}$. For every $n \in \mathbb{N}$, denote by $I_{\mathbf{E},n} \subset \mathbf{E}(B)$ the ideal generated by $(e^n_\lambda \mid \lambda \in \Lambda)$, and set $J_{\mathbf{E},n} := \alpha^n_0 \mathbf{E}(B) + I_{\mathbf{E},n}$; notice the natural identifications

$$B/J'_1 = \mathbf{E}(B)/J_{\mathbf{E},1} \qquad \text{and} \qquad C/J'_1C = \mathbf{E}(C)/J_{\mathbf{E},1}\mathbf{E}(C). \tag{16.8.25}$$

Denote also by Φ_{B/J'_1} and Φ_{C/J'_1C} the Frobenius endomorphism of B/J'_1 and respectively C/J'_1C. We remark :

Claim 16.8.26. The induced diagram of $\mathbf{E}$-algebras

$$\begin{array}{ccc} B/J'_1 & \xrightarrow{f\otimes_B B/J'_1} & C/J'_1C \\ {\scriptstyle \Phi_{B/J'_1}}\downarrow & & \downarrow{\scriptstyle \Phi_{C/J'_1C}} \\ B/J'_1 & \xrightarrow{f\otimes_B B/J'_1} & C/J'_1C \end{array}$$

is cocartesian.

Proof of the claim. Indeed, since $\mathbf{E}(B)$ is perfect, it is easily seen that Φ_{B/J'_1} is surjective, and its kernel is the ideal generated by the system $\{\alpha^{1/p}_0\} \cup \{e^{1/p}_\lambda \mid \lambda \in \Lambda\}$, under the identifications (16.8.25); likewise, Φ_{C/J'_1C} is surjective and its kernel is generated by the image in C/J'_1C of the same system, whence the claim. $\Diamond$

For every $n \in \mathbb{N}$, set $\mathfrak{n}_n := \{\underline{a} \in W_n\mathbf{E} \mid a_0, \dots, a_{n-1} \in \mathfrak{m}\}$; since $\mathfrak{m}_{\mathbf{E}}$ fulfills condition $(\mathbf{B})$ of [75, §2.1.6], proposition 14.7.11 says that $\mathfrak{n}_n$ is the unique ideal $\mathfrak{n}_n \subset W_n\mathbf{E}$ with $\mathfrak{n}^2_n = \mathfrak{n}_n$

and $\overline{\omega}_i(\mathfrak{n}_n) = \mathfrak{m}_{\mathbf{E}}$ for $i = 0, \dots, n-1$. From claim 16.8.26 and theorem 14.7.26(i) it follows that the induced morphism of $(W_n\mathbf{E}, \mathfrak{n}_n)^a$-algebras

$$W_n(f \otimes_B B/J'_1)^a : W_n(\mathbf{E}(B)/J_{\mathbf{E},1})^a \to W_n(\mathbf{E}(C)/J_{\mathbf{E},1}\mathbf{E}(C))^a$$

is flat for every $n \in \mathbb{N}$. Moreover, the Frobenius automorphisms of $\mathbf{E}(B)$ and $\mathbf{E}(C)$ induce isomorphisms $\mathbf{E}(B)/J_{\mathbf{E},1} \xrightarrow{\sim} \mathbf{E}(B)/J_{\mathbf{E},p^k}$ and $\mathbf{E}(C)/J_{\mathbf{E},1}\mathbf{E}(C) \xrightarrow{\sim} \mathbf{E}(C)/J_{\mathbf{E},p^k}\mathbf{E}(C)$ for every $k \in \mathbb{N}$, whence a commutative diagram of $W_n\mathbf{E}$-algebras

$$\begin{array}{ccc} W_n(\mathbf{E}(B)/J_{\mathbf{E},1}) & \xrightarrow{W_n(f\otimes_B \mathbf{E}(B)/J_{\mathbf{E},1})} & W_n(\mathbf{E}(C)/J_{\mathbf{E},1}\mathbf{E}(C)) \\ \downarrow & & \downarrow \\ W_n(\mathbf{E}(B)/J_{\mathbf{E},p^k}) & \xrightarrow{W_n(f\otimes_B \mathbf{E}(B)/J_{\mathbf{E},p^k})} & W_n(\mathbf{E}(C)/J_{\mathbf{E},p^k}\mathbf{E}(C)) \end{array} \qquad \text{for every } n,k \in \mathbb{N}$$

whose vertical arrows are isomorphisms, and where the rings on the bottom row are regarded as $W_n\mathbf{E}$-algebras via restriction of scalars along the automorphism $W_n(\Phi_{\mathbf{E}}) : W_n\mathbf{E} \to W_n\mathbf{E}$. Since we have

$$W_n(\Phi_{\mathbf{E}})(\mathfrak{n}_n) = \mathfrak{n}_n \qquad \text{for every } n \in \mathbb{N}$$

it follows that $W_n(f \otimes_B \mathbf{E}(B)/J_{\mathbf{E},p^k})^a$ is a flat morphism of $(W_n\mathbf{E}, \mathfrak{n}_n)^a$-algebras, for every $n, k \in \mathbb{N}$. We remark, quite generally :

Claim 16.8.27. Let R be any ring such that the Frobenius endomorphism $\Phi_{R/pR}$ of R/pR is surjective, $(x_\lambda \mid \lambda \in \Lambda)$ any set of elements of R, and $I \subset R$ the ideal generated by this set. Then, for every $n \in \mathbb{N}$, the kernel of the projection $\pi_n : W_nR \to W_nR/I$ is generated by

$$(V_R^i(x_\lambda) \mid \lambda \in \Lambda, \ i = 0, \dots, n-1).$$

Proof of the claim. Arguing by induction on $n \in \mathbb{N}$, we are reduced to checking that the ideal $V_nI := V_nR \cap \operatorname{Ker} \pi_{n+1}$ is generated by $(V^n x_\lambda \mid \lambda \in \Lambda)$, for every $n \in \mathbb{N}$. However, according to claim 9.3.31 we have an isomorphism of $W_{n+1}R$-modules : $I \xrightarrow{\sim} V_nI$, where I is regarded as a $W_{n+1}R$-module via restriction of scalars along the ring homomorphism $\overline{\omega}_n : W_{n+1}R \to R$. Thus, we come down to showing that $\overline{\omega}_n$ is a surjection for every $n \in \mathbb{N}$. We argue by induction on n : the assertion is trivial for $n = 0$, so suppose that $\overline{\omega}_n$ is already known to be surjective for some $n \geq 0$; since $\Phi_{R/pR}$ is surjective, the same holds for $\Phi^n_{R/pR}$, and taking into account (9.3.3) together with our inductive assumption, we easily deduce that $\overline{\omega}_{n+1}$ is surjective as well. ◊

In light of claim 16.8.27 we see that

$$W_n(\mathbf{E}(B)/J_{\mathbf{E},p^k}) = W(\mathbf{E}(B))/(p^nW(\mathbf{E}(B)) + \mathscr{I}_k)$$

where $\mathscr{I}_k$ is the ideal generated by $(p^i \cdot \tau_{\mathbf{E}(B)}(e_\lambda^{p^{k-i}}) \mid \lambda \in \Lambda, \ i = 0, \dots, k)$. Taking into account lemma 16.1.1(iv), we deduce that

$$A \otimes_{W(\mathbf{E})} W_n(\mathbf{E}(B)/J_{\mathbf{E},p^k}) = B/(p^nB + I''_k) \qquad \text{for every } n,k \in \mathbb{N}$$

where I''_k is the ideal generated by $(p^i \cdot \overline{u}_B(e_\lambda^{p^{k-i}}) \mid \lambda \in \Lambda, \ i = 0, \dots, k)$. Notice that

$$J'_{p^{2k-1}} \subset I''_{2k-1} \subset J'_k \qquad \text{for every } k \in \mathbb{N}. \tag{16.8.28}$$

We have as well $A \otimes_{W(\mathbf{E})} W_n(f \otimes_{\mathbf{E}(B)} \mathbf{E}(B)/J_{\mathbf{E},p^k}) = f \otimes_B B/(p^nB + I''_k)$, and furthermore, the ring homomorphism $W_n\mathbf{E} \to A/p^nA$ induced by u_A maps $\mathfrak{n}_n$ onto $\mathfrak{m}/p^nA$; therefore, $(f \otimes_B B/(p^nB + I''_k))^a$ is a flat morphism of $(A, \mathfrak{m})^a$-algebras, for every $n, k \in \mathbb{N}$. Combining with (16.8.28), the assertion follows. □

Proposition 16.8.29. *In the situation of* (16.8.16)*, let $f^a : B^a \to C$ be an étale morphism of $(A, \mathfrak{m})^a$-algebras such that C is an almost finitely presented B^a-module, and endow C_* with the unique ring topology such that the induced map $B \to C_*$ is adic. Then C_* is perfectoid.*

Proof. Let $I \subset B$ be any ideal of definition, and $I_{\mathbf{E}} \subset \mathbf{E}(B)$ the corresponding ideal such that $\overline{u}_A$ induces an isomorphism $\mathbf{E}(B)/I_{\mathbf{E}} \xrightarrow{\sim} B/I$ (see remark 16.3.7(iii)); then $f^a \otimes_B B/I : \mathbf{E}(B)/I_{\mathbf{E}} \to C/IC$ is an étale morphism of $(\mathbf{E}, \mathfrak{m}_{\mathbf{E}})^a$-algebras. By [75, Th.5.3.27], the latter lifts uniquely to an étale morphism $g : \mathbf{E}(B)^a \to C'$ of $(\mathbf{E}, \mathfrak{m}_{\mathbf{E}})^a$-algebras such that C' is almost finitely presented as an $\mathbf{E}(B)^a$-module. Since $\mathbf{E}(B)$ is perfect, [75, Th.3.5.13] implies that the Frobenius morphism

$$(\Phi_{\mathbf{E}}, \Phi_{C'}) : ((\mathbf{E}(B), \mathfrak{m}_{\mathbf{E}}), C') \to ((\mathbf{E}(B), \mathfrak{m}_{\mathbf{E}}), C')$$

is cartesian in the fibred category $\mathscr{B}^a$-Alg of [75, §3.5.3]. Since the functor $(-)_*$ on $\mathscr{B}^a$-algebras is cartesian (see [75, §3.5.4]), it follows that the morphism

$$(\Phi_{\mathbf{E}}, \Phi_{C'_*}) : ((\mathbf{E}(B), \mathfrak{m}_{\mathbf{E}}), C'_*) \to ((\mathbf{E}(B), \mathfrak{m}_{\mathbf{E}}), C'_*)$$

is cartesian as well, *i.e.* C'_* is a perfect $\mathbb{F}_p$-algebra. Let us endow C'_* with its $I_{\mathbf{E}}$-adic topology. We remark :

Claim 16.8.30. C'_* is perfectoid.

Proof of the claim. Since $\mathbf{E}(B)^a$ is complete and separated for its $I_{\mathbf{E}}$-adic topology, [75, Claim 5.3.25], implies that the natural morphism $C' \to \lim_{n\in\mathbb{N}} C'/I^n_{\mathbf{E}}C'$ is an isomorphism, so the same holds for the induced map $C'_* \to \lim_{n\in\mathbb{N}}(C'/I^n_{\mathbf{E}}C')_*$. Especially, C'_* is complete and separated for the linear topology defined by the system of ideals $(J_n := \mathrm{Ker}\,(C'_* \to (C'/I^n_{\mathbf{E}}C')_* \mid n \in \mathbb{N})$ (corollary 8.2.16(i)). Clearly $I^n_{\mathbf{E}}C'_* \subset J_n$ for every $n \in \mathbb{N}$, so C'_* is also complete and separated for its $I_{\mathbf{E}}$-adic topology (lemma 8.3.12), whence the claim. ◊

By claim 16.8.30 it follows that there exists a perfectoid A-algebra D with an isomorphism of perfectoid $\mathbf{E}$-algebras $C'_* \xrightarrow{\sim} \mathbf{E}(D)$. We consider the composition

$$h : \mathbf{E}(B) \xrightarrow{\eta_{\mathbf{E}(B)}} \mathbf{E}(B)^a_* \xrightarrow{g_*} C'_* \xrightarrow{\sim} \mathbf{E}(D)$$

where $\eta_{\mathbf{E}(B)}$ is the unit of adjunction; since h is an adic ring homomorphism, there exists a unique adic map of A-algebras $k : B \to D$ with $\mathbf{E}(k) = h$ (theorem 16.3.42(i)). By construction, we have also an isomorphism $(C/IC)^a \xrightarrow{\sim} (D/ID)^a$ of $(B/I)^a$-algebras; especially, $(k \otimes_B B/I)^a$ is a flat ring homomorphism, and therefore the same holds for $(k \otimes_B B/I^n)^a : (B/I^n)^a \to (D/I^nD)^a$, for every $n \in \mathbb{N}$ (lemma 16.8.24). By virtue of [75, Cor.3.2.11(ii,iii)] and remark 14.1.91, it follows that there exists a unique isomorphism of $(B/I^n)^a$-algebras

$$\omega_n : C/I^nC \xrightarrow{\sim} (D/I^nD)^a \qquad \text{for every } n \in \mathbb{N}.$$

Notice that the uniqueness of the morphisms ω_n implies that $\omega_{n+1} \otimes_B B/I^n = \omega_n$ for every $n \in \mathbb{N}$. However, D is complete and separated for its I-adic topology, since h is adic; the same holds for C, since the latter is an almost projective B-module of almost finite presentation ([75, Claim 5.3.25]). Hence, the limit of the inverse system $(\omega_n \mid n \in \mathbb{N})$ is an isomorphism $\omega : C \xrightarrow{\sim} D^a$ of B^a-algebras, whence the isomorphism $\omega_* : C_* \xrightarrow{\sim} D^a_*$ of B-algebras, and it suffices to invoke corollary 16.8.17 to conclude. □

16.8.31. Let now $\underline{A} := (A, A^+, U)$ be any perfectoid quasi-affinoid ring, and set

$$\underline{U} := \mathsf{Spec}\,\underline{A} \qquad \underline{U}_{\mathbf{E}} := \mathbf{E}(\underline{U}) \qquad X_A := \mathrm{Spec}\,A \qquad Z_A := X_A \setminus U$$

(notation of (16.5.20)). We let $\mathfrak{m} \subset A$ be the unique radical ideal such that $\mathrm{Spec}\,A/\mathfrak{m} = Z_A$. Also, set $\mathbf{E} := \mathbf{E}(A)$, $X_{\mathbf{E}} := \mathrm{Spec}\,\mathbf{E}$, and let $\mathfrak{m}_{\mathbf{E}} \subset \mathbf{E}$ be the unique ideal such that $\overline{u}_A$ induces a ring isomorphism $\mathbf{E}/\mathfrak{m}_{\mathbf{E}} \xrightarrow{\sim} A/\mathfrak{m}$ (see remark 16.3.7(iii)). According to proposition 16.8.15(i), both pairs $(A, \mathfrak{m})$ and $(\mathbf{E}, \mathfrak{m}_{\mathbf{E}})$ are basic setups.

Theorem 16.8.32. *With the notation of* (16.8.31)*, the pair* (X_A, Z_A) *is normal and almost pure, relative to the basic setup* $(A, \mathfrak{m})$.

Proof. Let $j_A : U \to X_A$ be the open immersion; since $j_{A*}\mathscr{O}_U$ is a quasi-coherent $\mathscr{O}_{X_A}$-algebra ([59, Ch.I, Prop.9.4.2(i)]), in order to check that the pair (X_A, Z_A) is normal, it suffices to show that the induced map $A \to \mathscr{O}_{X_A}(U)$ is almost injective and the image of A^a is integrally closed in $\mathscr{O}_{X_A}(U)^a$. These assertions follow from claim 16.8.20(ii).

Next, pick any ideal of definition $I \subset A$, set $\mathbf{E} := \mathbf{E}(A)$, let $I_\mathbf{E} \subset \mathbf{E}$ be the unique ideal of definition such that $\overline{u}_A$ induces a ring isomorphism $\mathbf{E}/I_\mathbf{E} \xrightarrow{\sim} A/I$, and consider the following diagram of categories :

$$\mathscr{D}_A \quad : \quad \begin{array}{ccccc} \mathsf{Cov}(U) & \xleftarrow{j_A^*} & (A,\mathfrak{m})^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} & \xrightarrow{i_A^*} & (A/I,\mathfrak{m}/I)^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} \\ \uparrow{\scriptstyle w_A} & & & & \| \\ \mathsf{Cov}(U_\mathbf{E}) & \xleftarrow{j_\mathbf{E}^*} & (\mathbf{E},\mathfrak{m}_\mathbf{E})^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} & \xrightarrow{i_\mathbf{E}^*} & (\mathbf{E}/I_\mathbf{E},\mathfrak{m}_\mathbf{E}/I_\mathbf{E})^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} \end{array}$$

where j_A^* (resp. i_A^*) is induced by the open (resp. closed) immersion $j_A : U \to X_A$ (resp. $i_A : Z_A \to X_A$) and likewise for $j_\mathbf{E}^*$ and $i_\mathbf{E}^*$. We need to show that j_A^* is an equivalence. However, according to [75, Th.5.5.7(iii)], both i_A^* and $i_\mathbf{E}^*$ are equivalences, and the same holds for $j_\mathbf{E}^*$, by virtue of theorem 16.8.2(i). Then, choose an arbitrary quasi-inverse functor $s_\mathbf{E}$ for $j_\mathbf{E}^*$ and t_A for i_A^*; we let the dotted arrow be the functor $w_A := j_A^* \circ t_A \circ i_\mathbf{E}^* \circ s_\mathbf{E} : \mathsf{Cov}(U_\mathbf{E}) \to \mathsf{Cov}(U)$, so that $\mathscr{D}_A$ is essentially commutative, and we are reduced to checking that w_A is an equivalence.

Claim 16.8.33. We may assume that $\underline{A} = \Gamma^\circ(\underline{U})$ (notation of (16.5.19)).

Proof of the claim. Say that $\Gamma^\circ(\underline{U}) = (A_U^\circ, A_U^+, U)$, set $X_U^\circ := \mathrm{Spec}\, A_U^\circ$, and denote by $\mathfrak{m}_U \subset A_U^\circ$ the unique radical ideal such that $\mathrm{Spec}\, A_U^\circ/\mathfrak{m}_U = X_U^\circ \setminus U$. Likewise, say that $\Gamma^\circ(\underline{U}_\mathbf{E}) = (\mathbf{E}_U^\circ, \mathbf{E}_U^+, U_\mathbf{E})$, set $X_\mathbf{E}^\circ := \mathrm{Spec}\, \mathbf{E}_U^\circ$ and denote by $\mathfrak{m}_{\mathbf{E},U} \subset \mathbf{E}_U^\circ$ the unique radical ideal such that $\mathrm{Spec}\, \mathbf{E}_U^\circ/\mathfrak{m}_{\mathbf{E},U} = X_\mathbf{E}^\circ \setminus U_\mathbf{E}$. It follows easily that

$$\mathfrak{m}_U \subset \mathfrak{m}A_U^\circ \qquad \mathfrak{m}_{U,\mathbf{E}} \subset \mathfrak{m}_\mathbf{E}\mathbf{E}_U^\circ.$$

Moreover, set $I_U := IA_U^\circ$ and $I_{\mathbf{E},U} := I_\mathbf{E}\mathbf{E}_U^\circ$; the map $\overline{u}_{A_U^\circ} : \mathbf{E}_U^\circ \to A_U^\circ$ induces a ring isomorphism $\mathbf{E}_U^\circ/I_{\mathbf{E},U} \xrightarrow{\sim} A_U^\circ/I_U$. Also, as in the foregoing, the projection $A_U^\circ \to A_U^\circ/I_U$ and the open immersion $j_{\mathbf{E},U} : U_\mathbf{E} \to X_\mathbf{E}^\circ$ induce equivalences of categories

$$i_U^* : (A_U^\circ, \mathfrak{m}_U)^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} \xrightarrow{\sim} (A_U^\circ/I_U, \mathfrak{m}_U/I_U)^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} \qquad j_{\mathbf{E},U}^* : (\mathbf{E}_U^\circ, \mathfrak{m}_{\mathbf{E},U})^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} \xrightarrow{\sim} \mathsf{Cov}(U_\mathbf{E}).$$

After choosing quasi-inverse functors t_U for i_U^* and $s_{\mathbf{E},U}$ for $j_{\mathbf{E},U}^*$, there follows an essentially commutative diagram of functors

$$\begin{array}{ccccc} (A,\mathfrak{m})^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} & \xleftarrow{t_A} & (A/I,\mathfrak{m}/I)^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} & \xleftarrow{i_\mathbf{E}^*} & (\mathbf{E},\mathfrak{m}_\mathbf{E})^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} \\ \downarrow{\scriptstyle j_A^*} & & & & \uparrow{\scriptstyle s_\mathbf{E}} \\ \mathsf{Cov}(U) & & \downarrow & & \mathsf{Cov}(U_\mathbf{E}) \\ \uparrow{\scriptstyle j_U^*} & & & & \downarrow{\scriptstyle s_{\mathbf{E},U}} \\ (A_U^\circ,\mathfrak{m}_U)^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} & \xleftarrow{t_U} & (A_U^\circ/I_U,\mathfrak{m}_U/I_U)^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} & \xleftarrow{i_{\mathbf{E},U}^*} & (\mathbf{E}_U^\circ,\mathfrak{m}_{\mathbf{E},U})^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} \end{array}$$

whose unmarked vertical arrows are induced by the natural ring homomorphisms $A \to A_U^\circ$, $A/I \to A_U^\circ/I_U$ and $\mathbf{E} \to \mathbf{E}_U^\circ$, and where j_U^* is induced by the open immersion $j_U : U \to X_U^\circ$. The claim follows easily. ◊

The restriction to the site $\mathscr{R}(\underline{U})$ of the stack $\mathsf{Cov}_{\underline{U}}^\wedge$ of corollary 15.7.26 along the inclusion $\mathscr{R}(\underline{U}) \subset \mathscr{Q}(\underline{U})$ is a stack that we denote again

$$\pi_{\underline{U}} : \mathsf{Cov}_{\underline{U}}^\wedge \to \mathscr{R}(\underline{U}).$$

Recall the construction : for every rational subset $R \subset \mathrm{Spa}\,\underline{U}$ we choose a complete and separated quasi-affinoid scheme $\underline{U}^\wedge_R := (U^\wedge_R, \mathscr{T}^\wedge_R, A^{\wedge+}_R)$ representing the sub-presheaf h''_R of $h''_{\underline{U}}$; then $\pi^{-1}_{\underline{U}}(R) := \mathsf{Cov}(U^\wedge_R)$. We shall consider similarly the quasi-affinoid schemes

$$\underline{X}_A := \mathsf{Spec}\,(A, A^+, X_A) \qquad \text{and} \qquad \underline{Y}_A := \mathsf{Spec}\,A/I \otimes_A (A, A^+, X_A)$$

(notation of example 15.4.7(i)) and the fibrations

$$\pi_{\underline{X}^a_A} : \mathsf{Cov}^\wedge_{(\underline{X}_A,\mathfrak{m})^a} \to \mathscr{R}(\underline{U}) \qquad \pi_{\underline{Y}^a_A} : \mathsf{Cov}^\wedge_{(\underline{Y}_A,\mathfrak{m})^a} \to \mathscr{R}(\underline{U})$$

defined as follows. For any $R \in \mathrm{Ob}(\mathscr{R}(\underline{U}))$, we know that $(A^{\wedge\circ}_R, A^{\wedge+}_R, U^\wedge_R) := \Gamma^\circ(\underline{U}^\wedge_R)$ is a perfectoid quasi-affinoid ring (proposition 16.7.25(iii) and (16.5.19)), and we set $X^\circ_R := \mathrm{Spec}\,A^{\wedge\circ}_R$; then, let $\mathfrak{m}_R \subset A^{\wedge\circ}_R$ be the unique radical ideal such that $X^\circ_R \setminus U^\wedge_R = \mathrm{Spec}\,A^{\wedge\circ}_R/\mathfrak{m}_R$. Set also $I_R := IA^{\wedge\circ}_R$; by proposition 16.8.15(i), the pair $(A^{\wedge\circ}_R, \mathfrak{m}_R)$ is a basic setup, and we let

$$\pi^{-1}_{\underline{X}^a_A}(R) := (A^{\wedge\circ}_R, \mathfrak{m}_R)^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afp}} \qquad \pi^{-1}_{\underline{Y}^a_A}(R) := (A^{\wedge\circ}_R/I_R, \mathfrak{m}_R/I_R)^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afp}}.$$

If $R' \subset R$ is another rational subset, the induced inclusion of sub-presheaves $h''_{R'} \subset h''_R$ corresponds to a morphism $\underline{U}^\wedge_{R'} \to \underline{U}^\wedge_R$ of quasi-affinoid schemes, which in turn yields a morphism $\Gamma^\circ(\underline{U}^\wedge_R) \to \Gamma^\circ(\underline{U}^\wedge_{R'})$ of perfectoid quasi-affinoid rings, and it follows easily that

$$\mathfrak{m}_{R'} \subset \mathfrak{m}_R A^{\wedge\circ}_{R'}$$

whence, finally, induced functors

$$j^*_{R'R} : \pi^{-1}_{\underline{X}^a_A}(R) \to \pi^{-1}_{\underline{X}^a_A}(R') \qquad j'^*_{R'R} : \pi^{-1}_{\underline{Y}^a_A}(R) \to \pi^{-1}_{\underline{Y}^a_A}(R').$$

Moreover, for every further inclusion of rational subset $R'' \subset R'$ we have a natural isomorphisms of functors

$$j^*_{R''R'} \circ j^*_{R'R} \xrightarrow{\sim} j^*_{R''R} \qquad j'^*_{R''R'} \circ j'^*_{R'R} \xrightarrow{\sim} j'^*_{R''R}$$

and the systems of such functors and isomorphisms of functors amount to well defined pseudo-functors $\mathscr{R}(\underline{U})^o \to \mathbf{Cat}$, whence the sought fibrations $\pi_{\underline{X}^a_A}$ and $\pi_{\underline{Y}^a_A}$. Furthermore, the system of open immersions $j_R : U^\wedge_R \to X^\circ_R$ and the projections $A^{\wedge\circ}_R \to A^{\wedge\circ}_R/I_R$ induce pseudo-natural transformations

$$(A^{\wedge\circ}_R/I_R, \mathfrak{m}_R/I_R)^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afp}} \xleftarrow{i^*_R} (A^{\wedge\circ}_R, \mathfrak{m}_R)^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afp}} \xrightarrow{j^*_R} \mathsf{Cov}(U^\wedge_R) \qquad \text{for every } R \in \mathrm{Ob}(\mathscr{R}(\underline{U}))$$

whence morphisms of fibrations

$$\mathsf{Cov}^\wedge_{(\underline{Y}_A,\mathfrak{m})^a} \xleftarrow{i^*_{\underline{U}}} \mathsf{Cov}^\wedge_{(\underline{X}_A,\mathfrak{m})^a} \xrightarrow{j^*_{\underline{U}}} \mathsf{Cov}^\wedge_{\underline{U}}.$$

Likewise, by repeating the foregoing with the quasi-affinoid schemes

$$\underline{X}_{\mathbf{E}} := \mathsf{Spec}\,(\mathbf{E}, \mathbf{E}^+, X_{\mathbf{E}}) \qquad \underline{Y}_{\mathbf{E}} := \mathsf{Spec}\,\mathbf{E}/I_{\mathbf{E}} \otimes_{\mathbf{E}} (\mathbf{E}, \mathbf{E}^+, X_{\mathbf{E}})$$

we get the following fibrations and morphisms of fibrations over the site $\mathscr{R}(\underline{U}_{\mathbf{E}})$:

$$\mathsf{Cov}^\wedge_{(\underline{Y}_{\mathbf{E}},\mathfrak{m}_{\mathbf{E}})^a} \xleftarrow{i^*_{\underline{U}_{\mathbf{E}}}} \mathsf{Cov}^\wedge_{(\underline{X}_{\mathbf{E}},\mathfrak{m}_{\mathbf{E}})^a} \xrightarrow{j^*_{\underline{U}_{\mathbf{E}}}} \mathsf{Cov}^\wedge_{\underline{U}_{\mathbf{E}}}. \tag{16.8.34}$$

However, in view of the isomorphism of sites $\mathbf{E} : \mathscr{R}(\underline{U}) \xrightarrow{\sim} \mathscr{R}(\underline{U}_{\mathbf{E}})$ of remark 16.7.29(i), we may also regard (16.8.34) as fibrations and morphisms of fibrations over the site $\mathscr{R}(\underline{U})$. Moreover, by combining remark 16.7.29(ii) and (16.5.22), we obtain natural isomorphisms

$$\underline{Y}_A \times_{\underline{X}_A} \underline{U}^\wedge_R \xrightarrow{\sim} \underline{Y}_{\mathbf{E}} \times_{\underline{X}_{\mathbf{E}}} \underline{U}^\wedge_{\mathbf{E}(R)} \qquad \text{for every } R \in \mathrm{Ob}(\mathscr{R}(\underline{U})) \tag{16.8.35}$$

and a simple inspection shows that the resulting ring isomorphism $A^\circ_R/I_R \xrightarrow{\sim} A^\circ_{\mathbf{E}(R)}/I_{\mathbf{E}(R)}$ maps $\mathfrak{m}_R/I_R$ isomorphically onto $\mathfrak{m}_{\mathbf{E}(R)}/I_{\mathbf{E}(R)}$. Summing up, we get a natural fibrewise equivalence of fibrations over $\mathscr{R}(\underline{U})$:

$$\mathsf{Cov}^\wedge_{(\underline{Y}_{\mathbf{E}},\mathfrak{m}_{\mathbf{E}})^a} \xrightarrow{\sim} \mathsf{Cov}^\wedge_{(\underline{Y}_A,\mathfrak{m})^a}. \tag{16.8.36}$$

Furthermore, both $i^*_{\underline{U}}$ and $i^*_{\underline{U}_{\mathbf{E}}}$ are fibrewise equivalences, by virtue of [75, Th.5.5.7(iii)], and the same holds for $j^*_{\underline{U}_{\mathbf{E}}}$, by theorem 16.8.2(i). We may then find morphisms of fibrations

$$s_{\underline{U}_{\mathbf{E}}} : \mathsf{Cov}^{\wedge}_{\underline{U}_{\mathbf{E}}} \to \mathsf{Cov}^{\wedge}_{(\underline{X}_{\mathbf{E}},\mathfrak{m}_{\mathbf{E}})^a} \qquad \text{and} \qquad t_{\underline{U}} : \mathsf{Cov}^{\wedge}_{(\underline{Y}_A,\mathfrak{m})^a} \to \mathsf{Cov}^{\wedge}_{(\underline{X}_A,\mathfrak{m})^a}$$

that are quasi-inverse functors for $j^*_{\underline{U}_{\mathbf{E}}}$ and $i^*_{\underline{U}}$ (corollary 3.1.28(i)). The composition of these functors yields a morphism of stacks

$$w_{\underline{U}} : \mathsf{Cov}^{\wedge}_{\underline{U}_{\mathbf{E}}} \xrightarrow{s_{\underline{U}_{\mathbf{E}}}} \mathsf{Cov}^{\wedge}_{(\underline{X}_{\mathbf{E}},\mathfrak{m}_{\mathbf{E}})^a} \xrightarrow{i^*_{\underline{U}_{\mathbf{E}}}} \mathsf{Cov}^{\wedge}_{(\underline{Y}_{\mathbf{E}},\mathfrak{m}_{\mathbf{E}})^a} \xrightarrow{\sim} \mathsf{Cov}_{(\underline{Y}_A,\mathfrak{m})^a} \xrightarrow{t_{\underline{U}}} \mathsf{Cov}^{\wedge}_{(\underline{X}_A,\mathfrak{m})^a} \xrightarrow{j^*_{\underline{U}}} \mathsf{Cov}^{\wedge}_{\underline{U}}$$

such that $(w_{\underline{U}})_{\mathrm{Spa}\,\underline{U}} : \mathsf{Cov}(U_{\mathbf{E}}) \to \mathsf{Cov}(U)$ is isomorphic to w_A.

For every $x \in \mathrm{Spa}\,\underline{U}$, let $x_{\mathbf{E}} := \mathrm{Spa}(u_{\underline{X}})(x) \in \mathrm{Spa}\,\underline{U}_{\mathbf{E}}$; by propositions 5.2.9 and 5.6.37, we are then reduced to checking that the induced functor on stalks

$$w_{\underline{U}}(x) : \mathsf{Cov}^{\wedge}_{\underline{U}_{\mathbf{E}}}(x_{\mathbf{E}}) \to \mathsf{Cov}^{\wedge}_{\underline{U}}(x)$$

is an equivalence, for every such x. To this aim, suppose first that x is analytic; in this case, the completed residue field $\kappa(x)^\wedge$ is a Tate valued field (see (15.5.12)), so that the analytic locus of $\mathrm{Spec}\,\kappa(x)^{\wedge+}$ is $\{\eta_x\}$, where η_x is the generic point. We have a well defined quasi-affinoid ring

$$\underline{\kappa}(x)^{\wedge\circ} := (\kappa(x)^{\wedge\circ}, \kappa(x)^{\wedge+}, \{\eta_x\})$$

and the natural map $A \to \kappa(x)^{\wedge\circ}$ yields a morphism of quasi-affinoid rings $\pi^{\wedge}_x : \underline{A} \to \underline{\kappa}(x)^{\wedge\circ}$. Likewise we get a morphism of quasi-affinoid rings

$$\pi^{\wedge}_{x_{\mathbf{E}}} : \mathbf{E}(\underline{A}) \to \underline{\kappa}(x_{\mathbf{E}})^{\wedge\circ} := (\kappa(x_{\mathbf{E}})^{\wedge\circ}, \kappa(x_{\mathbf{E}})^{\wedge+}, \{\eta_{x_{\mathbf{E}}}\}).$$

Moreover, by virtue of corollary 16.5.61, both $\underline{\kappa}(x)^{\wedge\circ}$ and $\underline{\kappa}(x_{\mathbf{E}})^{\wedge\circ}$ are perfectoid, and there exists a unique isomorphism of quasi-affinoid rings

$$\omega : \mathbf{E}(\underline{\kappa}(x)^{\wedge\circ}) \xrightarrow{\sim} \underline{\kappa}(x_{\mathbf{E}})^{\wedge\circ} \qquad \text{such that} \qquad \omega \circ \mathbf{E}(\pi^{\wedge}_x) = \pi^{\wedge}_{x_{\mathbf{E}}}. \tag{16.8.37}$$

We may then repeat the foregoing constructions with $\underline{A}$ replaced by $\underline{\kappa}(x)^{\wedge\circ}$ and $\underline{\kappa}(x_{\mathbf{E}})^{\wedge\circ}$: we get first the quasi-affinoid schemes

$$\underline{U}(x) := \mathsf{Spec}\,\underline{\kappa}(x)^{\wedge\circ} \qquad \underline{U}_{\mathbf{E}}(x_{\mathbf{E}}) := \mathsf{Spec}\,\underline{\kappa}(x_{\mathbf{E}})^{\wedge\circ}.$$

Then we set $\underline{A}(x) := (\kappa(x)^{\wedge\circ}, \kappa(x)^{\wedge+}, \mathrm{Spec}\,\kappa(x)^{\wedge\circ})$, and

$$\underline{X}_A(x) := \mathsf{Spec}\,\underline{A}(x) \qquad \underline{Y}_A(x) := \mathsf{Spec}\,(A/I \otimes_A \underline{A}(x))$$

and define likewise $\underline{X}_{\mathbf{E}}(x_{\mathbf{E}})$ and $\underline{Y}_{\mathbf{E}}(x_{\mathbf{E}})$. Also, let $\mathfrak{m}_x \subset \kappa(x)^{\wedge\circ}$ and $\mathfrak{m}_{\mathbf{E},x} \subset \kappa(x_{\mathbf{E}})^{\wedge\circ}$ be the maximal ideals. To these quasi-affinoid schemes we attach as in the foregoing fibrations over the sites $\mathscr{R}(\underline{U}(x))$ and $\mathscr{R}(\underline{U}_{\mathbf{E}}(x_{\mathbf{E}}))$. However, notice that the points of $\mathrm{Spa}\,\underline{U}(x)$ are (the equivalence classes of) the continuous valuations $v : \kappa(x)^\circ \to \Gamma_{v\circ}$ with $\mathrm{Ker}\,v = 0$ and $v(\kappa(x)^+) \subset \Gamma^+_{v\circ}$; it is easily seen that there is only one such valuation, *i.e.* the one corresponding to the point x of $\mathrm{Spa}\,\underline{U}$. Likewise, we have $\mathrm{Spa}\,\underline{U}_{\mathbf{E}} = \{x_{\mathbf{E}}\}$; hence, these fibrations amount to categories, or equivalently, they can be identified naturally with their stalks over the unique point x of $\mathrm{Spa}\,\underline{U}$ and the unique point $x_{\mathbf{E}}$ of $\mathrm{Spa}\,\underline{U}_{\mathbf{E}}$. Then, a simple inspection yields an essentially commutative diagram of categories :

$$\mathscr{D}'_A \quad : \quad \begin{array}{ccccc} \mathsf{Cov}^{\wedge}_{(\underline{Y}_A,\mathfrak{m})^a}(x) & \xleftarrow{i^*_{\underline{U}}(x)} & \mathsf{Cov}^{\wedge}_{(\underline{X}_A,\mathfrak{m})^a}(x) & \xrightarrow{j^*_{\underline{U}}(x)} & \mathsf{Cov}^{\wedge}_{\underline{U}}(x) \\ \downarrow & & \downarrow & & \downarrow \\ \mathsf{Cov}^{\wedge}_{(\underline{Y}_A(x),\mathfrak{m}_x)^a} & \xleftarrow{i^*_{\underline{U}(x)}} & \mathsf{Cov}^{\wedge}_{(\underline{X}_A(x),\mathfrak{m}_x)^a} & \xrightarrow{j^*_{\underline{U}(x)}} & \mathsf{Cov}^{\wedge}_{\underline{U}(x)} \end{array}$$

whose right-most vertical arrow is an equivalence, by virtue of (15.7.28). Likewise we have an essentially commutative diagram $\mathscr{D}'_{\mathbf{E}}$ for the corresponding fibrations over the site $\mathscr{R}(\underline{U}_{\mathbf{E}})$; moreover, in light of (16.8.37) we have as well an essentially commutative diagram

$$\begin{array}{ccc} \mathsf{Cov}^{\wedge}_{(\underline{Y}_{\mathbf{E}},\mathfrak{m}_{\mathbf{E}})^a}(x_{\mathbf{E}}) & \longrightarrow & \mathsf{Cov}^{\wedge}_{(\underline{Y}_A,\mathfrak{m})^a}(x) \\ \downarrow & & \downarrow \\ \mathsf{Cov}^{\wedge}_{(\underline{Y}_{\mathbf{E}}(x_{\mathbf{E}}),\mathfrak{m}_{\mathbf{E},x})^a} & \longrightarrow & \mathsf{Cov}^{\wedge}_{(\underline{Y}_A(x),\mathfrak{m}_x)^a} \end{array}$$

whose vertical arrows are the same as the left-most vertical arrows of $\mathscr{D}'_A$ and $\mathscr{D}'_{\mathbf{E}}$, and whose horizontal arrows are induced by the equivalences (16.8.36). Summing up, we are reduced to checking the following :

Claim 16.8.38. The functor $j^*_{\underline{U}(x)}$ is an equivalence.

Proof of the claim. By unwinding the definitions, we see that $\mathsf{Cov}^{\wedge}_{\underline{U}(x)}$ is the category of étale $\kappa(x)^{\wedge}$-algebras, $\mathsf{Cov}^{\wedge}_{(\underline{X}_A(x),\mathfrak{m}_x)^a}$ is the category of étale $(\kappa(x)^{\wedge\circ},\mathfrak{m}_x)^a$-algebras of almost finite rank, and $j^*_{\underline{U}(x)}$ is the natural restriction functor. In light of lemma 14.4.5(ii) and remark 14.4.3(i), it follows already that $j^*_{\underline{U}(x)}$ is fully faithful. Next, let E be any finite separable field extension of $\kappa(x)^{\wedge}$, and E° the integral closure of $\kappa(x)^{\wedge\circ}$ in E; it suffices to check that $E^{\circ a}$ is an étale $\kappa(x)^{\wedge\circ a}$-algebra of finite rank. However, notice that $\kappa(x)^{\wedge\circ}$ is a valuation ring of rank one with field of fractions $\kappa(x)^{\wedge}$; moreover, it is perfectoid for the ring topology such that the natural map $A \to \kappa(x)^{\wedge\circ}$ is adic (corollary 16.5.61(i)), and therefore it is deeply ramified, by [75, Prop.6.6.6] and lemma 16.2.3(iv). Let also E^{s} be any separable closure of E, and $E^{\mathrm{s}\circ}$ the integral closure of E° in E^{s}; by [75, Prop.6.6.2 and Rem.6.1.12(iv)] it follows that $(\Omega_{E^{\mathrm{s}\circ}/\kappa(x)^{\wedge\circ}})^a = 0$, and combining with [75, Th.6.3.23] we deduce that $(\Omega_{E^{\circ}/\kappa(x)^{\wedge\circ}})^a = 0$ (cp. the proof of [75, Prop.6.6.2]). By invoking again [75, Th.6.3.23], it follows that $\mathscr{D}_{E^{\circ}/\kappa(x)^{\wedge\circ}} = E^{\circ a}$. Then the assertion follows from [75, Prop.6.3.8 and Lemma 4.1.27]. ◊

Lastly, in case x is non-analytic, set

$$Y(x) := \mathrm{Spec}\,(A/I \otimes_A \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{U},x}) \qquad Y_{\mathbf{E}}(x_{\mathbf{E}}) := \mathrm{Spec}\,(\mathbf{E}/I_{\mathbf{E}} \otimes_{\mathbf{E}} \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{U}_{\mathbf{E}},x_{\mathbf{E}}})$$

According to (15.7.28) we have natural equivalences of categories

$$\Psi : \mathsf{Cov}^{\wedge}_{\underline{U}}(x) \xrightarrow{\sim} \mathsf{Cov}(Y(x)) \qquad \Psi_{\mathbf{E}} : \mathsf{Cov}^{\wedge}_{\underline{U}}(x_{\mathbf{E}}) \xrightarrow{\sim} \mathsf{Cov}(Y_{\mathbf{E}}(x_{\mathbf{E}})).$$

Recall the construction of these equivalences : an object of $\mathsf{Cov}_{\underline{U}}(x)$ is a pair (R,φ) where R is a rational subset of $\mathrm{Spa}\,\underline{U}$ containing x, and $\varphi : V \to U^{\wedge}_R$ is a finite étale morphism of schemes; to such an object, the equivalence Ψ assigns the finite étale morphism $Y(x) \times_{U^{\wedge}_R} \varphi$. Similarly we may describe $\Psi_{\mathbf{E}}$. We get likewise well defined functors

$$\mathsf{Cov}^{\wedge}_{(X_A,\mathfrak{m}_A)^a}(x) \xrightarrow{\Psi'} \mathsf{Cov}(Y(x)) \xleftarrow{\Psi''} \mathsf{Cov}^{\wedge}_{(\underline{Y}_A,\mathfrak{m}_A)^a}(x).$$

Namely, an object of $\mathsf{Cov}^{\wedge}_{(X_A,\mathfrak{m}_A)^a}(x)$ is a pair $(R, f : (A^{\wedge\circ}_R,\mathfrak{m}_R)^a \to B^a)$ where R is as in the foregoing and f is an étale covering of almost rings, and notice that $\mathfrak{m}_R\mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{U},x} = \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{U},x}$, so $f_x := A/I \otimes_A \mathscr{O}^{\wedge}_{\mathrm{Spa}\,\underline{U},x} \otimes_{A^{\wedge\circ}_R} f$ is a homomorphism of (usual) rings; then the functor Ψ' assigns to the pair (R,f) the finite étale covering $\mathrm{Spec}\,f_x$ of $Y(x)$. Similarly we define Ψ'', and it is easily seen that the resulting diagram of categories :

$$\mathscr{D}''_A \quad : \quad \begin{array}{ccccc} \mathsf{Cov}^{\wedge}_{(\underline{Y}_A,\mathfrak{m})^a}(x) & \xleftarrow{i^*_{\underline{U}}(x)} & \mathsf{Cov}^{\wedge}_{(\underline{X}_A,\mathfrak{m})^a}(x) & \xrightarrow{j^*_{\underline{U}}(x)} & \mathsf{Cov}^{\wedge}_{\underline{U}}(x) \\ & \searrow^{\Psi''} & \downarrow{\Psi'} & \swarrow_{\Psi} & \\ & & \mathsf{Cov}(Y(x)) & & \end{array}$$

is essentially commutative. Correspondingly, we have an essentially commutative diagram $\mathscr{D}''_{\mathbf{E}}$ for the stalks over $x_{\mathbf{E}}$, and notice that all the arrows of $\mathscr{D}''_{\mathbf{E}}$ are equivalences (details left to the reader). On the other hand, the system of isomorphisms (16.8.35) induces an isomorphism of schemes

$$Y_A(x) \xrightarrow{\sim} Y_{\mathbf{E}}(x_{\mathbf{E}})$$

whence an essentially commutative diagram

$$\begin{array}{ccc} \mathsf{Cov}^\wedge_{(\underline{Y}_{\mathbf{E}},\mathfrak{m}_{\mathbf{E}})^a}(x_{\mathbf{E}}) & \xrightarrow{\Psi''_{\mathbf{E}}} & \mathsf{Cov}(Y_{\mathbf{E}}(x_{\mathbf{E}})) \\ \downarrow & & \downarrow \\ \mathsf{Cov}^\wedge_{(\underline{Y}_A,\mathfrak{m})^a}(x) & \xrightarrow{\Psi''} & \mathsf{Cov}(Y(x)) \end{array}$$

whose left vertical arrow is induced by the equivalence (16.8.36), and the right vertical arrow is an equivalence as well. We conclude that Ψ'' is an equivalence; then the same holds for $j^*_{\underline{U}}(x)$, and finally also for $w_{\underline{U}}(x)$, as sought. The proof is complete. □

Remark 16.8.39. Theorem 16.8.32 extends results of [149] (for perfectoid algebras over perfectoid fields), as well as [114, Th.5.5.9] (for perfectoid Tate rings A with $p \in A^\times \cap A^{\circ\circ}$), and [151, Th.7.4.5].

16.8.40. *Almost purity in the formally perfectoid case.* We show now how to extend theorem 16.8.32 to the case of formally perfectoid rings. We begin with some preliminary observations:

Lemma 16.8.41. *Let A be an adic topological ring that admits a finitely generated ideal I of adic definition, $A^\wedge$ the completion of A, and $\mathfrak{m} \subset A$ an open ideal. The following holds :*

(i) $\mathfrak{m}$ *is a radical ideal of A if and only if $\mathfrak{m}A^\wedge$ is a radical ideal of $A^\wedge$.*
(ii) $\mathfrak{m} = \mathfrak{m}^2$ *if and only if* $\mathfrak{m}A^\wedge = \mathfrak{m}^2 A^\wedge$.
(iii) $\mathfrak{m}$ *fulfills condition* (**B**) *of* [75, §2.1.6] *if and only if the same holds for* $\mathfrak{m}A^\wedge$.

Proof. By assumption, $I^n \subset \mathfrak{m}$ for some integer $n > 0$; after replacing I by I^n, we may then assume that $I \subset \mathfrak{m}$.

(i): Let $\mathfrak{n}$ be the radical ideal of $\mathfrak{m}$; since $I \subset \mathfrak{m}$, it is easily seen that $\mathfrak{n}/I$ is the radical ideal of $\mathfrak{m}/I$ in the quotient A/I. Since the completion map $A \to A^\wedge$ induces an isomorphism $A/I \xrightarrow{\sim} A^\wedge/IA^\wedge$, it follows that $\mathfrak{n}A^\wedge/IA^\wedge$ is the radical ideal of $\mathfrak{m}A^\wedge/IA^\wedge$; again, this easily implies that $\mathfrak{n}A^\wedge$ is the radical ideal of $\mathfrak{m}A^\wedge$, whence the assertion.

(ii): We have $\mathfrak{m} = \mathfrak{m}^2 \Leftrightarrow \mathfrak{m}/I^2 = \mathfrak{m}^2/I^2$, and since the completion map induces an isomorphism $A/I^2 \xrightarrow{\sim} A^\wedge/I^2A^\wedge$, we have $\mathfrak{m}/I^2 = \mathfrak{m}^2/I^2 \Leftrightarrow \mathfrak{m}A^\wedge/I^2A^\wedge = \mathfrak{m}^2/I^2A^\wedge$. Again, the latter condition holds if and only if $\mathfrak{m}A^\wedge = \mathfrak{m}^2A^\wedge$, whence the assertion.

(iii): In view of (ii), it is clear that if $\mathfrak{m}$ fulfills condition (**B**), then so does $\mathfrak{m}A^\wedge$. Conversely, suppose that $\mathfrak{m}A^\wedge$ fulfills condition (**B**); by (ii), it follows already that $\mathfrak{m} = \mathfrak{m}^2$, and it remains to check that for every integer $k > 0$, the ideal $\mathfrak{m}$ is generated by the system $x^k_\bullet := (x^k \mid x \in \mathfrak{m})$. However, let $a_1, \dots, a_n$ be a finite system of generators of I, and choose $N \in \mathbb{N}$ such that I^N lies in the ideal generated by $a^k_\bullet := (a^k_1, \dots, a^k_n)$; by assumption $\mathfrak{m}A^\wedge$ is generated by the system $b^k_\bullet := (b^k \mid b \in \mathfrak{m}A^\wedge)$, hence the same holds for $\mathfrak{m}A^\wedge/I^NA^\wedge$. The completion map induces an isomorphism $\mathfrak{m}/I^N \xrightarrow{\sim} \mathfrak{m}A^\wedge/I^NA^\wedge$ and maps $x^k_\bullet$ onto the family $b^k_\bullet$, so that $\mathfrak{m}/I^N$ is generated by $x^k_\bullet$, and therefore the same holds for $\mathfrak{m}$, since the family $x^k_\bullet$ contains $a^k_\bullet$. □

Proposition 16.8.42. *Let A be a formally perfectoid ring, $I \subset A$ a finitely generated ideal of adic definition, $\mathfrak{m} \subset A$ a radical ideal with $I \subset \mathfrak{m}$, and $U := \mathrm{Spec}\, A \setminus \mathrm{Spec}\, A/\mathfrak{m}$. We have :*

(i) $(A, \mathfrak{m})$ *is a basic setup fulfilling condition* (**B**) *(see* [75, §2.1.1, §2.1.6]*).*
(ii) *For every subideal $J \subset I$, every almost finitely generated almost projective $(A/J)^a$-module P has almost finite rank, for the almost structure induced by* $(A, \mathfrak{m})$.

(iii) *In the situation of* (ii)*, if moreover U is quasi-compact, then P has finite rank.*

Proof. (i) follows from lemma 16.8.41 and proposition 16.8.15(i).

(ii): After replacing I by $I + pA$, we may assume that $p \in I$. Set $X := \mathrm{Spec}\, A/J$ and $U' := X \setminus \mathrm{Spec}\, A/I$. Let $S \subset A$ be the multiplicative subset $1 + I$, and $B := S^{-1}(A/J)$. Let also $\mathscr{P}$ be the quasi-coherent $\mathscr{O}_X$-module associated with the A/J-module $P_!$. Then $X = U' \cup \mathrm{Spec}\, B$, and U' is quasi-compact, so that $\mathscr{P}_{|U'}$ is a locally free $\mathscr{O}_{U'}$-module of finite rank. Thus, it suffices to check that $P_B := P \otimes_A B$ is almost projective B^a-module of almost finite rank. Now, the ideal $I_B := I/J$ of B is obviously tight, and by construction $I_B \subset \mathrm{rad}(B)$; moreover, the localization $A/J \to B$ induces a ring isomorphism $A/I \xrightarrow{\sim} B/I_B$, whence an isomorphism of $(A/I)^a$-modules $P_0 := P/IP \xrightarrow{\sim} P_B/I_B P_B$. By lemma 14.3.17(ii) we are then reduced to checking that P_0 is an $(A/I)^a$-module of almost finite rank. To this aim, let $\mathbf{E} := \mathbf{E}(A)$, and pick a distinguished element $\underline{\alpha} \in \mathrm{Ker}\, u_A$; by remark 16.3.7(ii), the map $\overline{u}_A$ induces a ring isomorphism $\omega : \mathbf{E}/\alpha_0\mathbf{E} \xrightarrow{\sim} A/pA$, and we let $\mathfrak{m}_\mathbf{E}$ and $I_\mathbf{E}$ be the unique ideals of $\mathbf{E}$ with

$$\alpha_0 \in \mathfrak{m}_\mathbf{E} \qquad \alpha_0 \in I \qquad \mathfrak{m}/pA \xrightarrow{\sim} \mathfrak{m}_\mathbf{E}/\alpha_0\mathbf{E} \qquad I/pA \xrightarrow{\sim} I_\mathbf{E}/\alpha_0\mathbf{E}.$$

In particular, $I_\mathbf{E}$ is finitely generated, and $(\mathbf{E}, \mathfrak{m}_\mathbf{E})$ is a basic setup, by proposition 16.8.15(i). Via the isomorphism ω, we may then regard P_0 as an almost finitely generated almost projective $(\mathbf{E}/I_\mathbf{E})^a$-module (for the almost structure given by $(\mathbf{E}, \mathfrak{m}_\mathbf{E})$), and clearly it suffices to show that P_0 is of almost finite rank, when regarded as an $(\mathbf{E}/I_\mathbf{E})^a$-module. The latter follows from proposition 16.8.7(i).

(iii): Arguing as in the proof of (ii), we reduce to showing that if U is quasi-compact, then P_0 is of finite rank, when regarded as a $(\mathbf{E}/I_\mathbf{E})^a$-module, and according to proposition 16.8.7(ii), the latter will follow, once we show that $Z := \mathrm{Spec}\, \mathbf{E}/\mathfrak{m}_\mathbf{E}$ is constructible in $\mathrm{Spec}\, \mathbf{E}$. However, $(\mathrm{Spec}\, A/pA) \setminus (\mathrm{Spec}\, A/\mathfrak{m}) = U \cap \mathrm{Spec}\, A/pA$ is quasi-compact, hence the same holds for $W := (\mathrm{Spec}\, \mathbf{E}/\alpha_0\mathbf{E}) \setminus Z$. Thus, $(\mathrm{Spec}\, \mathbf{E}) \setminus Z = W \cup \mathrm{Spec}\mathbf{E}[\alpha_0^{-1}]$ is constructible in $\mathrm{Spec}\, \mathbf{E}$, and then the same follows for Z. ☐

16.8.43. Let A be a formally perfectoid ring, $I \subset A$ a finitely generated ideal of adic definition, and $\mathfrak{m} \subset A$ a radical ideal with $I \subset \mathfrak{m}$. Set $X := \mathrm{Spec}\, A$, $Z := \mathrm{Spec}\, A/\mathfrak{m}$, and $U := X \setminus Z$. According to proposition 16.8.42(i), we may consider the almost structure associated with the basic setup $(A, \mathfrak{m})$. We then have :

Theorem 16.8.44. *In the situation of* (16.8.43)*, let also $r \in \mathbb{N}$. The following holds :*

(i) *The pair (X, Z) is almost pure.*

(ii) *Let $\mathscr{M}$ be any almost projective $\mathscr{O}_X^a$-module of almost finite rank. Then $\mathscr{M}$ is a faithfully flat $\mathscr{O}_X^a$-module (resp. is an $\mathscr{O}_X^a$-module of finite rank $\leq r$) if and only if the same holds for the $\mathscr{O}_U$-module $\mathscr{M}_{|U}$.*

Proof. (i): Suppose first that Z is constructible in X. Let A^h and $A^\wedge$ be respectively the topological henselization and the completion of A, and set $X^\mathrm{h} := \mathrm{Spec}\, A^\mathrm{h}$ and $X^\wedge := \mathrm{Spec}\, A^\wedge$. Let also $U^\mathrm{h} := X^\mathrm{h} \times_X U$ and $U^\wedge := X^\wedge \times_X U$. In light of theorem 16.8.32, it suffices to check that both square subdiagrams of the following induced diagram are 2-cartesian :

$$\begin{array}{ccccc}
\mathscr{O}_X^a\text{-}\mathbf{\acute{E}t}_\mathrm{afr} & \longrightarrow & \mathscr{O}_{X^\mathrm{h}}^a\text{-}\mathbf{\acute{E}t}_\mathrm{afr} & \longrightarrow & \mathscr{O}_{X^\wedge}^a\text{-}\mathbf{\acute{E}t}_\mathrm{afr} \\
\downarrow & & \downarrow & & \downarrow \\
\mathscr{O}_U\text{-}\mathbf{\acute{E}t}_\mathrm{fr} & \longrightarrow & \mathscr{O}_{U^\mathrm{h}}\text{-}\mathbf{\acute{E}t}_\mathrm{fr} & \longrightarrow & \mathscr{O}_{U^\wedge}\text{-}\mathbf{\acute{E}t}_\mathrm{fr}.
\end{array}$$

Now, by [75, Prop.5.5.6(i)] it follows that the natural functor

$$\mathscr{O}_X^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} \to \mathscr{O}_{X^{\mathrm{h}}}^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} \overset{2}{\underset{\mathscr{O}_{U^{\mathrm{h}}}\text{-}\mathbf{\acute{E}t}_{\mathrm{fr}}}{\times}} \mathscr{O}_U\text{-}\mathbf{\acute{E}t}_{\mathrm{fr}}$$

is fully faithful. Thus, let $(\mathscr{E}^{\mathrm{h}}, \mathscr{E}_U, \xi)$ be the datum of an object $\mathscr{E}^{\mathrm{h}}$ of $\mathscr{O}_{X^{\mathrm{h}}}^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}}$, an object $\mathscr{E}_U$ of $\mathscr{O}_U\text{-}\mathbf{\acute{E}t}_{\mathrm{fr}}$, and an isomorphism ξ in $\mathscr{O}_{U^{\mathrm{h}}}\text{-}\mathbf{\acute{E}t}_{\mathrm{fr}}$ between the images of $\mathscr{E}^{\mathrm{h}}$ and $\mathscr{E}_U$. By *loc.cit.*, there exists a quasi-coherent $\mathscr{O}_X^a$-algebra $\mathscr{E}$ whose restriction to X^{h} and to U is isomorphic to $\mathscr{E}^{\mathrm{h}}$ and respectively $\mathscr{E}_U$, and in view of proposition 16.8.42(iii), it remains to check that $\mathscr{E}$ is étale and almost finitely presented as an $\mathscr{O}_X^a$-module. Since the induced morphism $U \sqcup X^{\mathrm{h}} \to X$ is quasi-compact and faithfully flat, the assertion follows from lemmata 14.3.5(i) and 14.3.26(i). This shows that the left square subdiagram of the foregoing diagram is 2-cartesian.

Next, since both of the natural maps $A/I \to A^{\mathrm{h}}/IA^{\mathrm{h}}$ and $A/I \to A^\wedge/IA^\wedge$ are isomorphisms, [75, Th.5.5.7(iii)] implies that the top horizontal arrow of the right square subdiagram is an equivalence. To conclude the proof in this case, it then suffices to show :

Claim 16.8.45. The base change functor $\mathscr{O}_{U^{\mathrm{h}}}\text{-}\mathbf{\acute{E}t}_{\mathrm{fr}} \to \mathscr{O}_{U^\wedge}\text{-}\mathbf{\acute{E}t}_{\mathrm{fr}}$ is an equivalence.

Proof of the claim. According to proposition 8.3.30(i) there exists a unique f-adic topology on $B := \mathscr{O}_{U^{\mathrm{h}}}(U^{\mathrm{h}})$ (resp. on $C := \mathscr{O}_{U^\wedge}(U^\wedge)$) such that the restriction map $A^{\mathrm{h}} \to B$ (resp. $A^\wedge \to C$) is open. It follows easily that the induced map $B \to C$ is continuous and adic, since the same holds for the completion map $A \to A^\wedge$. Set $A^{\mathrm{h}+} := A^{\mathrm{h}\circ} \subset A^{\mathrm{h}}$ and $A^{\wedge+} := A^{\wedge\circ} \subset A^\wedge$; in view of lemma 8.3.24(iii.a), the integral closure in B (resp. in C) of the image of $A^{\mathrm{h}+}$ (resp. of $A^{\wedge+}$) is a subring of integral elements, that we denote B^+ (resp. C^+). Recall also that the natural morphism of schemes $\mathrm{Spec}\, B \to X^{\mathrm{h}}$ (resp. $X^\wedge \to \mathrm{Spec}\, C$) induces an isomorphism $U_B := U^{\mathrm{h}} \times_{X^{\mathrm{h}}} \mathrm{Spec}\, B \xrightarrow{\sim} U^{\mathrm{h}}$ (resp. $U_C := U^\wedge \times_{X^\wedge} \mathrm{Spec}\, C \xrightarrow{\sim} U^\wedge$); combining with lemma 15.4.6, we deduce that the resulting diagram

$$\begin{array}{ccc} \mathsf{Spec}(C, C^+, U_C) & \longrightarrow & \mathsf{Spec}(B, B^+, U_B) \\ {\scriptstyle\varphi}\downarrow & & \downarrow \\ \mathsf{Spec}(A^\wedge, A^{\wedge+}, U^\wedge) & \longrightarrow & \mathsf{Spec}(A^{\mathrm{h}}, A^{\mathrm{h}+}, U^{\mathrm{h}}) \end{array}$$

is cartesian in the category of quasi-affinoid schemes. Furthermore, the quasi-affinoid scheme $\mathsf{Spec}(C, C^+, U_C)$ is complete, by virtue of lemma 16.4.32(ii). By arguing with universal properties, it follows easily that the morphism φ identifies $\mathsf{Spec}(C, C^+, U_C)$ with the completion of $\mathsf{Spec}(A^\wedge, A^{\wedge+}, U^\wedge)$: the details are left to the reader. Then the claim follows from theorem 15.7.17 and proposition 16.8.42(ii). $\diamondsuit$

Lastly, we consider the case where Z is an arbitrary closed subset in X. Then, let $(I_\lambda \mid \lambda \in \Lambda)$ be the filtered system of all finitely generated ideals of A containing I and contained in $\mathfrak{m}$. For every $\lambda \in \Lambda$, let also $\mathfrak{m}_\lambda$ be the radical of I_λ; then $Z_\lambda := \mathrm{Spec}\, A/\mathfrak{m}_\lambda = \mathrm{Spec}\, A/I_\lambda$ and $U_\lambda := X \setminus Z_\lambda$ are constructible subsets of X, and $(A, \mathfrak{m}_\lambda)$ is a basic setup fulfilling condition (*B*), for every such λ (proposition 16.8.42(i)). Both natural functors :

$$(A, \mathfrak{m})^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} \to 2\text{-}\lim_{\lambda \in \Lambda} (A, \mathfrak{m}_\lambda)^a\text{-}\mathbf{\acute{E}t}_{\mathrm{afr}} \qquad \mathscr{O}_U\text{-}\mathbf{\acute{E}t}_{\mathrm{fr}} \to 2\text{-}\lim_{\lambda \in \Lambda} \mathscr{O}_{U_\lambda}\text{-}\mathbf{\acute{E}t}_{\mathrm{fr}}$$

are equivalences of categories (corollary 14.2.5(ii,iv,v)), hence we are reduced to prove the theorem for the pair (X, Z_λ), relative to the almost structure $(A, \mathfrak{m}_\lambda)$, for every $\lambda \in \Lambda$. The latter is already known by the previous case, so the proof is concluded.

(ii): Again, we assume first that Z is constructible, in which case $\mathscr{M}$ has finite rank (proposition 16.8.42(iii)). Let A_{loc} be the topological localization of A (see (8.4.8)); set also $X_{\mathrm{loc}} := \mathrm{Spec}\, A_{\mathrm{loc}}$. Then A_{loc} is a formally perfectoid ring, and the localization $A \to A_{\mathrm{loc}}$ induces an isomorphism of the respective completions $A^\wedge \stackrel{\sim}{\to} A^\wedge_{\mathrm{loc}}$ (corollary 8.4.15(i)), and an isomorphism of A-schemes $\pi : U_{\mathrm{loc}} := X_{\mathrm{loc}} \times_X U \stackrel{\sim}{\to} U$. Set $M := \mathscr{M}(X)$, $M_{\mathrm{loc}} := A_{\mathrm{loc}} \otimes_A M$, and let $\mathscr{M}_{\mathrm{loc}}$ be the almost projective $\mathscr{O}^a_{X_{\mathrm{loc}}}$-module of finite rank corresponding to M_{loc}. Then π induces a natural identification of $\mathscr{M}_{|U}$ with $(\mathscr{M}_{\mathrm{loc}})_{|U_{\mathrm{loc}}}$, so that the latter is a faithfully flat $\mathscr{O}_{U_{\mathrm{loc}}}$-module. We notice :

Claim 16.8.46. In the situation of (16.8.31), let $\mathscr{F}$ be any almost projective $\mathscr{O}^a_{X_A}$-module of finite rank. Then $\mathscr{F}$ is a faithfully flat $\mathscr{O}^a_{X_A}$-module (resp. is an $\mathscr{O}^a_{X_A}$-module of finite rank $\leq r$) if and only if the same holds for the $\mathscr{O}_U$-module $\mathscr{F}_{|U}$.

Proof of the claim. Since the pair (X, Z) is normal (theorem 16.8.32), the assertion follows immediately from lemma 14.3.18. ◊

From claim 16.8.46, it follows that $A^\wedge_{\mathrm{loc}} \otimes_{A_{\mathrm{loc}}} M_{\mathrm{loc}}$ is a faithfully flat $(A^\wedge_{\mathrm{loc}})^a$-module of finite rank; consequently $M_{\mathrm{loc}}/IM_{\mathrm{loc}}$ is a faithfully flat $A^a_{\mathrm{loc}}/IA^a_{\mathrm{loc}}$-module of finite rank. By construction, $I^a_{\mathrm{loc}} \subset \mathrm{rad}(A^a_{\mathrm{loc}})$ is a tight ideal of A^a_{loc} (relative to the basic setup $(A, \mathfrak{m})$), hence M_{loc} is a faithfully flat A^a_{loc}-module (lemma 14.3.17(i)). Lastly, let Y be the disjoint union of U and $\mathrm{Spec}\, A_{\mathrm{loc}}$; we have an obvious faithfully flat morphism of A-schemes $f : Y \to X$, and the foregoing implies that $f^*\mathscr{M}$ is a faithfully flat $\mathscr{O}^a_Y$-module, so $\mathscr{M}$ is a faithfully flat $\mathscr{O}^a_X$-module, by lemma 14.3.5(i).

Next, for a general Z, define the filtered system of subideals $(\mathfrak{m}_\lambda \mid \lambda \in \Lambda)$ of $\mathfrak{m}$, and the corresponding filtered system of open constructible subsets $(U_\lambda \mid \lambda \in \Lambda)$ of U, as in the proof of (i). Then if $\mathscr{M}_{|U}$ is a faithfully flat $\mathscr{O}_U$-module (resp. if the rank of $\mathscr{M}$ is $\leq r$), obviously the same holds for the $\mathscr{O}_{U_\lambda}$-module $\mathscr{M}_{|U_\lambda}$. For every $\lambda \in \Lambda$, denote by M_λ the image of M in the category of $(A, \mathfrak{m}_\lambda)^a$-modules; by the foregoing case, M_λ is a faithfully flat $(A, \mathfrak{m}_\lambda)^a$-module (resp. has rank $\leq r$) for every such λ. Then M is a faithfully flat $(A, \mathfrak{m})^a$-module (resp. has rank $\leq r$), by corollary 14.2.5(iii,iv). □

Remark 16.8.47. A ring A is Witt-perfect (relative to a given prime integer p) in the sense of [52, Def.1.8] if and only if the p-adic completion of A is a P-ring in our sense (for its p-adic topology). In the case where $\mathfrak{m}$ is the radical of $I := Ap$, with p regular in A, and A integrally closed in $A[1/p]$, theorem 16.8.44 is essentially the purity theorem in [52, Th.2.9]. This includes cases studied by Faltings using the technique of normalized length.

16.9. **Perfectoid Tate rings and perfectoid Abhyankar's lemma.** In this section we introduce some special classes of perfectoid quasi-affinoid rings that will play an important role in the proof of Hochster's direct summand conjecture. The main results are theorems 16.9.17 and 16.9.42, that generalize important results from Y.André's papers [5] and [6]. The following definition of perfectoid Tate ring is equivalent to the one found in [70].

Definition 16.9.1. Let $(A, \mathscr{T}_A)$ be a Tate ring (see definition 8.3.8(vi)).

(i) We say that A is a *perfectoid Tate ring* (resp. *formally perfectoid Tate ring*) if it has a subring of definition A_0 that is perfectoid (resp. formally perfectoid), for the topology induced by $\mathscr{T}_A$ via the inclusion map $A_0 \to A$.

(ii) We say that A is *uniform*, if A° is a bounded subset of A (see definition 8.3.8(ii)). We let

$$\mathsf{Tate} \qquad \text{and} \qquad \mathsf{u.Tate}$$

be the full subcategories of $\mathbb{Z}$-TopAlg (see definition 8.3.1(iii)) whose objects are the Tate rings and respectively the uniform Tate rings.

Lemma 16.9.2. (i) *Let $(A, \mathscr{T}_A)$ be a Tate ring. The following conditions are equivalent :*

(a) *A is uniform.*

(b) *The completion $A^\wedge$ of A is uniform.*

(c) *$\mathscr{T}_A$ agrees with the topology given by a power-multiplicative semi-norm $\|\cdot\| : A \to \mathbb{R}$.*

(ii) *Moreover, if the power-multiplicative semi-norm* $\|\cdot\|$ *defines the topology* $\mathscr{T}_A$*, we have :*

$$A^\circ = \{a \in A \mid \|a\| \leq 1\} \qquad \textit{and} \qquad A^{\circ\circ} = \{a \in A \mid \|a\| < 1\}.$$

(iii) *The inclusion functor* $\mathsf{u.Tate} \to \mathsf{Tate}$ *admits a left adjoint*

$$\mathsf{u} : \mathsf{Tate} \to \mathsf{u.Tate} \qquad A \mapsto \mathsf{u}(A).$$

We call $\mathsf{u}(A)$ *the* uniformization *of the Tate ring* A.

Proof. (i.a)⇒(i.b): Indeed, if A° is a bounded subset of A, then its image B in $A^\wedge$ is bounded in the latter ring; but then the same holds for the topological closure B^c of B in $A^\wedge$ (remark 8.3.9(iii)). However, $B^c = (A^\wedge)^\circ$ (corollary 8.4.15(ii) and proposition 8.2.13(iii)) whence the contention.

(i.b)⇒(i.a): Let $j : A \to A^\wedge$ be the completion map; we have $j^{-1}((A^\wedge)^\circ) = A^\circ$, by corollaries 8.4.15(ii) and 8.2.17(ii). Since the topology of A is induced by that of $A^\wedge$ via j, the assertion follows easily.

(i.a)⇒(i.c): Fix $\rho \in]0,1[$ and pick $t \in A^\times \cap A^{\circ\circ}$. Notice that A° is a subring of definition of A (proposition 8.3.18(ii)). Denote by $\nu : A \to \mathbb{Z} \cup \{+\infty\}$ the order function associated with the ideal tA° of A° (see example 9.1.9(i)), and set $|a| := \rho^{\nu(a)}$ for every $a \in A$. Moreover, let $\|\cdot\| : A \to \mathbb{R}$ be the asymptotic Samuel function of tA°, *i.e.* $\|a\| := \lim\limits_{n\to+\infty} |a^n|^{1/n}$ for every $a \in A$. Notice that $\nu(t^k a) = k + \nu(a)$ for every $k \in \mathbb{Z}$ and $a \in A$, whence :

$$\|t^k a\| = \rho^k \cdot \|a\| \qquad \text{for every } k \in \mathbb{Z} \text{ and } a \in A. \tag{16.9.3}$$

By construction, $\|a\| \leq 1$ for every $a \in A^\circ$. On the other hand, if $\|a\| > r > 1$, then there exists $k \in \mathbb{N}$ such that $|a^n| > r^n$ for every $n \geq k$, and it follows easily that $a \notin A^\circ$. Combining with (16.9.3), we conclude that $t^k A^\circ = \{a \in A \mid \|a\| \leq \rho^k\}$ for every $k \in \mathbb{N}$, whence (i.c).

(i.c)⇒(i.a): Clearly $\{a \in A \mid \|a\| < 1\} = A^{\circ\circ}$. Pick $t \in A^\times \cap A^{\circ\circ}$, so that $r := \|t\| \in]0,1[$; then $t^k A^{\circ\circ}$ is an open ideal of A° for every $k \in \mathbb{N}$, and it lies in the subset $\{a \in A \mid \|a\| < r^k\}$, whence (i.a).

(ii) follows by simple inspection of the definitions.

(iii): Let $A_0 \subset A$ be a subring of definition, $t \in A^\times \cap A^{\circ\circ}$, and $\nu : A \to \mathbb{Z} \cup \{+\infty\}$ the order function associated with the ideal tA_0 of A_0. For given $\rho \in]0,1[$, the map $|\cdot|_A : A \to \mathbb{R}$ such that $|a|_A := \rho^{\nu(a)}$ for every $a \in A$ is a semi-norm, and the topology defined by $|\cdot|_A$ agrees with $\mathscr{T}_A$. Then, let $\|\cdot\|_A : A \to \mathbb{R}$ be the asymptotic Samuel function of tA_0. Recall that $\|\cdot\|_A$ is a multiplicative semi-norm, and let $\mathscr{T}_A^{\mathsf{u}}$ be the topology on A defined by $\|\cdot\|_A$. Lemma 9.1.8(iii) implies that the identity map of A is a continuous ring homomorphism $(A, \mathscr{T}_A) \to (A, \mathscr{T}_A^{\mathsf{u}})$; also, the discussion of example 9.1.9 shows that $\mathscr{T}_A^{\mathsf{u}}$ depends only on the original topology $\mathscr{T}_A$ (and is independent of all auxiliary choices). Clearly $A^+ := \{a \in A \mid \|a\|_A \leq 1\}$ is an open subring of $(A, \mathscr{T}_A^{\mathsf{u}})$ and arguing as in the foregoing we see that (16.9.3) holds as well for the semi-norm $\|\cdot\|_A$, so that $t^k A^+ = \{a \in A \mid \|a\| \leq \rho^k\}$ for every $k \in \mathbb{Z}$; especially, $\mathscr{T}_A^{\mathsf{u}}$ induces the t-adic topology on tA^+, and $(A, \mathscr{T}_A^{\mathsf{u}})^\circ = A^+$, so $(A, \mathscr{T}_A^{\mathsf{u}})$ is a uniform Tate ring. Now, let $(B, \mathscr{T}_B)$ be any uniform Tate ring, and $f : (A, \mathscr{T}_A) \to (B, \mathscr{T}_B)$ a continuous ring homomorphism. By lemma 8.3.29(iv), the map f is f-adic, hence it restricts to an adic ring homomorphism $f_0 : A_0 \to B^\circ$ (lemma 8.3.24(iii.a,iii.b)), and the proof of (i) shows that $\mathscr{T}_B$ agrees with the topology defined by the asymptotic Samuel function $\|\cdot\|_B : B \to \mathbb{R}$ of the ideal $f(t) \cdot B^\circ$. With this notation, it follows easily that f is a morphism of normed rings $(A, |\cdot|_A) \to (B, \|\cdot\|_B)$ (see (9.1.6)), and then lemma 9.1.8(iv) shows that f is also a morphism of uniform semi-normed rings $(A, \|\cdot\|_A) \to (B, \|\cdot\|_B)$. In view of (i), we deduce that $f : (A, \mathscr{T}_A^{\mathsf{u}}) \to (B, \mathscr{T}_B)$ is a continuous ring homomorphism of uniform Tate rings. Thus the sought functor is obtained by the rule : $(A, \mathscr{T}_A) \mapsto (A, \mathscr{T}_A^{\mathsf{u}})$. □

Example 16.9.4. Let A be a Tate ring, $A_0 \subset A$ a subring of definition, and suppose there exists an integer $n > 1$ such that $\{x \in A \mid x^n \in A_0\} \subset A_0$. Then it follows easily that $A^{\circ\circ} \subset A_0$, and since $A^{\circ\circ}$ is an ideal of A°, we deduce that A is uniform.

16.9.5. Let $(A, \mathscr{T}_A)$ be a perfectoid Tate ring, and $A_0 \subset A$ a perfectoid ring of definition, so that $A = A_0[t^{-1}]$, for any $t \in A^\times \cap A_0^{\circ\circ}$; moreover, tA_0 is an ideal of adic definition for A_0 (corollary 8.3.20(iv)). Let also A^+ be the integral closure of A_0 in A; it follows that $U := \mathrm{Spec}\, A$ is the analytic locus of $\mathrm{Spec}\, A_0$, and

$$\underline{U} := (U, \mathscr{T}_A, A^+)$$

is a perfectoid affinoid scheme (see definition 16.5.1(i)). Then, according to (16.5.20), theorem 16.5.13(ii) and corollary 16.5.43(i), we get a perfectoid affinoid scheme

$$(U_{\mathbf{E}}, \mathscr{T}_{\mathbf{E}}, \mathbf{E}_U^+) := \mathbf{E}(\underline{U}) \qquad \text{with } \mathbf{E}_U := \mathscr{O}_{U_{\mathbf{E}}}(U_{\mathbf{E}})$$

so that $\mathbf{E}_U$ is a complete f-adic ring, and its open subring $\mathbf{E}_U^+$ is perfectoid and naturally isomorphic to $\mathbf{E}(A^+)$. Let $(\alpha_n \mid n \in \mathbb{N})$ be a distinguished element in $\mathrm{Ker}\, u_{A^\circ}$; then the isomorphism of topological rings $\mathbf{E}_U^\circ/\alpha_0\mathbf{E}_U^\circ \xrightarrow{\sim} A^\circ/pA^\circ$ of remark 16.3.7(ii) induces an isomorphism

$$\overline{\omega} : \mathbf{E}_U^\circ/\mathbf{E}_U^{\circ\circ} \xrightarrow{\sim} A^\circ/A^{\circ\circ}.$$

Recall also that the composition $\mathbf{E}_U^\circ \to A$ of $\overline{u}_{A^\circ} : \mathbf{E}_U^\circ \to A^\circ$ with the localization $A^\circ \to A$, factors through a continuous morphism of monoids

$$\varphi_U^\flat : \mathbf{E}_U \to A$$

(lemma 16.4.29(i) and proposition 16.4.34(i)). Let $\pi_A : A^\circ \to A^\circ/A^{\circ\circ}$ and $\pi_{\mathbf{E}} : \mathbf{E}_U^\circ \to \mathbf{E}_U^\circ/\mathbf{E}_U^{\circ\circ}$ be the projections; denote by $\mathscr{D}_A$ and $\mathscr{D}_{\mathbf{E}}$ the set of perfectoid subrings of adic definition of A and respectively $\mathbf{E}_U$, and by $\mathscr{P}_A$ the set of perfect subrings of $A^\circ/A^{\circ\circ}$.

Lemma 16.9.6. *In the situation of* (16.9.5)*, the following holds :*

(i) $(A, \mathscr{T}_A)$ *is a uniform Tate ring.*

(ii) $(\mathbf{E}_U, \mathscr{T}_{\mathbf{E}})$ *is a perfectoid Tate ring, and* $U_{\mathbf{E}}$ *is the analytic locus of* $\mathrm{Spec}\, \mathbf{E}_U^\circ$.

(iii) *The rules :* $B \mapsto \pi_A^{-1}B$ *and* $B \mapsto (\overline{\omega} \circ \pi_{\mathbf{E}})^{-1}B$ *establish natural bijections*

$$\mathscr{D}_{\mathbf{E}} \xleftarrow{\sim} \mathscr{P}_A \xrightarrow{\sim} \mathscr{D}_A.$$

Proof. (i) follows immediately from theorem 16.5.13(i).

(ii): It is easily seen that tA° is an ideal of adic definition for A°, and $A^\circ[t^{-1}] = A$, hence U is the analytic locus of $\mathrm{Spec}\, A^\circ$, and therefore $U_{\mathbf{E}}$ is the analytic locus of $\mathrm{Spec}\, \mathbf{E}_U^\circ$. Pick $m \in \mathbb{N}$ such that $p^m/t \in A^\circ$; by applying corollary 16.6.27 to the quasi-affinoid ring (A°, A°, U), we deduce that there exists $t' \in \mathbf{E}_U^\circ$ such that

$$v(t - \overline{u}_{A^\circ}(t')) \leq v(p) \cdot \max(v(\overline{u}_{A^\circ}(t')), v(p^m)) \qquad \text{for every } v \in \mathrm{Cont}(A^\circ)$$

where $\overline{u}_{A^\circ} : \mathbf{E}_U^\circ \to A^\circ$ is the natural morphism of topological monoids as in (9.4). It follows that $v(t) = v(\overline{u}_{A^\circ}(t'))$ for every $v \in \mathrm{Cont}(A^\circ)$. We have $v(t) < 1$ for every $v \in \mathrm{Cont}(A^\circ)$ and $v(t) \neq 0$ for every $v \in \mathrm{Cont}(A)$, since $t \in A^{\circ\circ} \cap A^\times$ (theorem 15.3.15(i)); hence $w(t') < 1$ for every $w \in \mathrm{Cont}(\mathbf{E}_U^\circ)$ (theorem 16.5.52(i)), and therefore $t' \in \mathbf{E}_U^{\circ\circ}$ (corollary 15.4.27(ii)). Also, combining with (16.5.59) we deduce that $w(t') \neq 0$ for every $w \in \mathrm{Spa}\, \mathbf{E}(\underline{U})$, hence $t' \in \mathbf{E}_U^\times$ (proposition 15.4.30).

(iii): For every $A' \in \mathscr{D}_A$, the inclusion map $A' \to A^\circ$ induces an open injective continuous ring homomorphism $\mathbf{E}' := \mathbf{E}(A') \to \mathbf{E}_U^\circ$, and moreover we have $A^{\circ\circ} \subset A'$ and $\mathbf{E}_U^{\circ\circ} \subset \mathbf{E}'$, by theorem 16.3.42(i,iii.a). As in (16.9.5), we deduce a ring isomorphism $\mathbf{E}'/\mathbf{E}_U^{\circ\circ} \xrightarrow{\sim} A'/A^{\circ\circ}$, which shows that $A'/A^{\circ\circ} \in \mathscr{P}_A$. Conversely, let $B \in \mathscr{P}_A$; according to proposition 16.3.25, the open subring $\pi_A^{-1}B = B \times_{A^\circ/A^{\circ\circ}} A^\circ$ of A° is perfectoid for the topology induced by the inclusion into A°, and then $\pi_A^{-1}B \in \mathscr{D}_A$. Likewise one proves that the map $\mathscr{P}_A \to \mathscr{D}_\mathbf{E}$ is a bijection. □

16.9.7. Let now $(A, \mathscr{T}_A)$ be a perfectoid Tate ring, $A_0 \subset A$ a perfectoid subring of definition, $(B, \mathscr{T}_B)$ an f-adic ring, and $f : A \to B$ a continuous ring homomorphism. Define the perfectoid affinoid schemes $\underline{U}$ and $(U_\mathbf{E}, \mathscr{T}_\mathbf{E}, \mathbf{E}_U^+)$ and the f-adic ring $\mathbf{E}_U$ as in (16.9.5); by lemma 16.9.6(ii) we find $t' \in \mathbf{E}_U^\times \cap \mathbf{E}_U^{\circ\circ}$, and we let $t := \overline{u}_{A^\circ}(t')$, which is a topologically nilpotent unit of A. Then more generally, the element $t^\gamma := \varphi_U^\flat(t'^\gamma) \in A$ is well defined for every $\gamma \in \mathbb{Z}[1/p]$. Notice that $s := f(t)$ is a topologically nilpotent unit of B, hence B is a Tate ring; especially, the non-analytic loci of both $\mathrm{Spec}\,A$ and $\mathrm{Spec}\,B$ are empty, so that f is an f-adic ring homomorphism (lemma 8.3.29(iv)). By lemma 8.3.24(iii.c) there exists a subring of definition $B_0 \subset B$ such that f restricts to a continuous ring homomorphism $f_0 : A_0 \to B_0$. Then sB_0 is an ideal of adic definition of B_0, and $B = B_0[s^{-1}]$ (corollary 8.3.20(ii.b)). Let $s^\gamma := f(t^\gamma)$ for every $\gamma \in \mathbb{Z}[1/p]$. We fix $\rho \in]0, 1[$ and consider the map

$$|\cdot|_B : B \to \mathbb{R} \cup \{+\infty\} \qquad b \mapsto \inf\{\rho^\gamma \mid b \in s^\gamma B_0\}$$

(*cp.* (16.5.23)). Let also $\|\cdot\|_B : B \to \mathbb{R} \cup \{+\infty\}$ be the asymptotic Samuel function of sB_0, as defined in example 9.1.9(i). Recall furthermore that A° is perfectoid for the topology induced by A (theorem 16.5.13(i)), and the pair $(A^\circ, A^{\circ\circ})$ is a basic setup verifying condition (**B**) of [75, §2.1.6] (proposition 16.8.15(i)). Hence, the $(A^\circ, A^{\circ\circ})^a$-algebra B^a is well defined, and in view of proposition 16.8.15(ii) we see that :

$$B_*^a = \mathrm{Hom}_{A^\circ}(A^{\circ\circ}, B) = \mathrm{Hom}_A(A \otimes_{A^\circ} A^{\circ\circ}, B) = \mathrm{Hom}_A(A, B) = B.$$

Lemma 16.9.8. (i) *For every* $b \in B$ *we have :* $\lim\limits_{n\to+\infty} |b^n|_B^{1/n} = \|b\|_B$.

(ii) $\|s^\gamma b\|_B = \rho^\gamma \cdot \|b\|_B$ *for every* $\gamma \in \mathbb{Z}[1/p]$ *and every* $b \in B$.

(iii) $B^{\circ\circ} = \{b \in B \mid \|b\|_B < 1\}$.

(iv) $(B^\circ)_*^a = \{b \in B \mid \|b\|_B \leq 1\}$.

Proof. (i): Recall that $\|b\|_B := \lim\limits_{n\to+\infty} \rho^{\nu(b^n)/n}$, where $\nu(b) := \inf\{k \in \mathbb{Z} \mid b \in s^k B_0\}$. For every $b \in B$, set $\mu(b) := \sup\{\gamma \in \mathbb{Z}[1/p] \mid b \in s^\gamma B_0\}$, so that $|b|_B = \rho^{\mu(b)}$. Clearly we have

$$\nu(b^n) < \mu(b^n) < \nu(b^n) + 1 \qquad \text{for every } b \in B \text{ and } n \in \mathbb{N}.$$

It follows that $\lim_{n\to+\infty}(|b^n|_B/\rho^{\nu(b^n)})^{1/n} = 1$, whence the contention.

(ii): It suffices to observe that $|s^\gamma b|_B = \rho^\gamma \cdot |b|_B$ for every such b and γ, and apply (i).

(iii): It suffices to remark that $\|b\|_B < 1$ if and only if $x^n \in sB_0$ for some $n \in \mathbb{N}$.

(iv): Notice that $(B^\circ)_*^a \subset B_*^a = B$. On the other hand, we have $(B^\circ)_*^a = \mathrm{Hom}_{A^\circ}(A^{\circ\circ}, B^\circ)$. It then follows that $(B^\circ)_*^a = \{b \in B \mid bA^{\circ\circ} \subset B^\circ\} = \{b \in B \mid bA^{\circ\circ} \subset B^{\circ\circ}\}$. Especially, $s^\gamma b \in B^{\circ\circ}$ for every $b \in (B^\circ)_*^a$ and $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$, whence $\rho^\gamma \cdot \|b\|_B < 1$ for every such γ, in view of (ii) and (iii); *i.e.* $\|b\|_B \leq 1$. Conversely, if $\|b\|_B \leq 1$, we get $\|f(a)b\|_B \leq \|b\|_B \cdot \|f(a)\|_B < 1$ for every $a \in A^{\circ\circ}$, due to (iii); then $f(a)b \in B^{\circ\circ}$ for every such a, again due to (iii), and finally, $b \in (B^\circ)_*^a$. □

16.9.9. Keep the situation of (16.9.7), and set $C := (B^\circ)_*^a$; lemma 16.9.8(ii,iv) implies that

$$s^\gamma C = \{b \in B \mid \|b\|_B \leq \rho^\gamma\} \qquad \text{for every } \gamma \in \mathbb{Z}[1/p].$$

In light of lemma 16.9.2(iii), we may now conclude that C is the subring of power bounded elements of the uniformization $\mathsf{u}(B)$ of $(B, \mathscr{T}_B)$, and the topology of $\mathsf{u}(B)$ is the f-adic topology such that $C \subset B$ is a subring of definition, and sC is an ideal of adic definition. Notice that $f : (A, \mathscr{T}_A) \to \mathsf{u}(B)$ is still an f-adic ring homomorphism. Moreover, from lemmata 16.9.2(ii) and 16.9.8(iii) we see that

$$\mathsf{u}(B)^{\circ\circ} = B^{\circ\circ}. \qquad (16.9.10)$$

Definition 16.9.11. (i) With the notation of (16.9.7), we say that B is a *pre-perfectoid* A*-algebra*, if $\mathsf{u}(B)$ is a formally perfectoid Tate ring.

Remark 16.9.12. (i) With the notation of (16.9.9), endow C with its sC-adic topology $\mathscr{T}_C$; from corollary 8.4.15(ii) and theorem 16.5.13(i) we see that B is a pre-perfectoid A-algebra if and only if $(C, \mathscr{T}_C)^\wedge$ is a perfectoid ring.

(ii) Let $D \subset C$ be any subring that is p-root closed in C (see definition 9.8.24(i)). From (16.9.10) we see that :

$$D \text{ is open in } (B, \mathscr{T}_B) \Leftrightarrow B^{\circ\circ} \subset D \Leftrightarrow \mathsf{u}(B)^{\circ\circ} \subset D \Leftrightarrow D \text{ is open in } \mathsf{u}(B).$$

Suppose then that D is open in $(B, \mathscr{T}_B)$, and denote by $\mathscr{T}_D$ the topology of D induced by $\mathscr{T}_C$; then we claim that B is a pre-perfectoid A-algebra if and only if $(D, \mathscr{T}_D)^\wedge$ perfectoid. Indeed, suppose that B is a pre-perfectoid A-algebra; since $B^{\circ\circ} \subset D$, we see that $D/B^{\circ\circ}$ is a subring of $C/B^{\circ\circ}$, and in view of (16.9.10) we get natural identifications :

$$C/B^{\circ\circ} = C/\mathsf{u}(B)^{\circ\circ} = \overline{C} := (C, \mathscr{T}_C)^\wedge/(\mathsf{u}(B)^\wedge)^{\circ\circ}.$$

Then, (i) implies that $C/B^{\circ\circ}$ is a perfect ring, and $D/B^{\circ\circ}$ is a perfect subring, since D is p-root closed in C. In light of (i), lemma 16.9.6(iii) and proposition 8.2.13(i,ii), we conclude that $(D, \mathscr{T}_D)^\wedge = D/B^{\circ\circ} \times_{\overline{C}} (C, \mathscr{T}_C)^\wedge$ is a perfectoid subring of definition of $\mathsf{u}(B)^\wedge$. Conversely, suppose that $(D, \mathscr{T}_D)^\wedge$ is perfectoid; we know already that D is open in $\mathsf{u}(B)$, and then $(D, \mathscr{T}_D)^\wedge$ is open in $\mathsf{u}(B)^\wedge$, and its topology is induced by the inclusion into $\mathsf{u}(B)^\wedge$ (proposition 8.2.13(i,ii)); hence, B is a pre-perfectoid A-algebra.

(iii) Lastly, let $D \subset B$ be an open subring, endow D with the topology induced by B, and suppose that D is formally perfectoid (definition 16.7.19); then D is p-root closed in B. Indeed, under these assumptions, the topology of $D^\wedge$ is adic, so $D^\wedge$ is a perfectoid subring of definition of $B^\wedge$, hence $(B^\wedge)^{\circ\circ} \subset D^\wedge$, by virtue of lemma 16.9.6(iii); especially, $s^\gamma \in D$ for every $\gamma \in \mathbb{N}[1/p]$, and $s^{-\gamma}p \in D$ for every sufficiently small $\gamma \in \mathbb{N}[1/p]$ (corollary 8.2.17(ii)). It then suffices to invoke the criterion of theorem 16.4.1, together with lemma 9.8.26(i).

Example 16.9.13. Let us return to the situation of (16.6.31) : we consider a quasi-affinoid perfectoid ring $\underline{A} := (A, A^+, U_A)$ and a sequence $f_\bullet := (f_0, \dots, f_n)$ of elements of $A_U := \mathscr{O}_{U_A}(U_A)$ that generates an open ideal (for the f-adic topology on A_U as in lemma 16.4.32(i)).

(i) Let $(\mathbf{E}, \mathbf{E}^+, U_\mathbf{E}) := \mathbf{E}(\underline{A})$ (notation of (16.5.20)), and $\mathbf{E}_U := \mathscr{O}_{U_\mathbf{E}}(U_\mathbf{E})$. As recalled in (16.9.5), the map $\overline{u}_A : \mathbf{E} \to A$ extends to a continuous morphism of topological monoids $\varphi^\flat_U : \mathbf{E}_U \to A_U$; we may then find $m \in \mathbb{N}$ and $e_0, \dots, e_n \in \mathbf{E}_U$ verifying the inequalities (16.6.33) and (16.6.34) for every $i = 1, \dots, n$. Let also $A_0 \subset A_U$ be any subring of definition, and $I_0 \subset A_0$ an ideal of adic definition; recall that the I_0-adic completion $B(f_\bullet)^\wedge$ of $B(f_\bullet) := A_0[f_1/f_0, \dots, f_n/f_0] \subset A_U[1/f_0]$ is a subring of definition of $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{A}}(S(f_\bullet))$, with $S(f_\bullet) := R_{A_U}\big(\frac{f_1}{f_0}, \cdots, \frac{f_n}{f_0}\big) \cap \mathrm{Spa}\,\underline{A}$. Moreover, the sequence $\varphi^\flat_U(e_0), \dots, \varphi^\flat_U(e_n)$ generates an open ideal of A_U as well, according to proposition 16.6.35(ii) and claim 16.6.36, and $S(f_\bullet) = R_{A_U}\big(\frac{\varphi^\flat_U(e_1)}{\varphi^\flat_U(e_0)}, \cdots, \frac{\varphi^\flat_U(e_n)}{\varphi^\flat_U(e_0)}\big) \cap \mathrm{Spa}\,\underline{A}$, by proposition 16.6.35(iii). It follows that the I_0-adic completion $B(e_\bullet)^\wedge$ of $B(e_\bullet) := A_0\big[\frac{\varphi^\flat_U(e_1)}{\varphi^\flat_U(e_0)}, \dots, \frac{\varphi^\flat_U(e_n)}{\varphi^\flat_U(e_0)}\big]$ is another subring of definition of $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{A}}(S(f_\bullet))$. Therefore, the p-root closures $D(f_\bullet)$ and $D(e_\bullet)$ of $B(f_\bullet)^\wedge$ and $B(e_\bullet)^\wedge$ in $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{A}}(S(f_\bullet))$ both contain $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{A}}(S(f_\bullet))^{\circ\circ}$. Combining with proposition 16.6.35(iv), we conclude that $D(f_\bullet) = D(e_\bullet)$.

(ii) In the situation of (i), notice that if $f_0, \dots, f_n \in A$, we may take $e_0, \dots, e_n \in \mathbf{E}$, and by construction we shall then have $f_i - \overline{u}_A(e_i) \in pA$ for $i = 0, \dots, n$.

Theorem 16.9.14. *In the situation of* (16.9.7)*, pick* $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$ *with* $pB_0 \subset s^{p\gamma}B_0$*, and suppose that the Frobenius endomorphism of* $B_0/s^{p\gamma}B_0$ *is surjective. Then* B *is pre-perfectoid.*

Proof. We exhibit an increasing chain of subrings

$$B_0 \subset B_1 \subset B_2 \subset \cdots$$

of the p-root closure of B_0 in B, verifying the following conditions for every $i \in \mathbb{N}$:

(a) The Frobenius endomorphism Φ_i of $B_i/s^{p\gamma}B_i$ is surjective.
(b) Let $\overline{\Phi}_i : B_i/s^{\gamma}B_i \to B_i/s^{p\gamma}B_i$ be the ring homomorphism induced by Φ_i. Then the kernel of the induced map $j_i : B_i/s^{\gamma}B_i \to B_{i+1}/s^{\gamma}B_{i+1}$ contains $\mathrm{Ker}\,\overline{\Phi}_i$.

To this aim, we argue by induction on $i \in \mathbb{N}$. Hence, suppose that for a given $i \in \mathbb{N}$ we have already exhibited a subring B_i fulfilling condition (a); we need to exhibit B_{i+1} so that condition (b) holds as well for B_i, and moreover such that condition (a) holds for B_{i+1}. Now, since (a) holds for B_i, for every $x \in \mathrm{Ker}\,\overline{\Phi}_i$ we may find a sequence $(a(x,n) \mid n \in \mathbb{N})$ of elements of B_i, such that the image of $a(x,0)$ in $B_i/s^{\gamma}B_i$ agrees with x, and :

$$a(x,n+1)^p - a(x,n) \in s^{p\gamma}B_i \qquad \text{for every } n \in \mathbb{N}.$$

It follows easily that $a(x,n)^{p^{n+1}} \in s^{p\gamma}B_i$, and therefore $b(x,n) := a(x,n) \cdot s^{-\gamma/p^n}$ lies in the p-root closure of B_i in B, for every $n \in \mathbb{N}$. Let us then set

$$B_{i+1} := B_i[b(x,n) \mid (x,n) \in \mathrm{Ker}(\overline{\Phi}_i) \times \mathbb{N}] \subset B.$$

Since the image of $b(x,0) \cdot s^{\gamma}$ in $B_i/s^{\gamma}B_i$ agrees with the image of x, we see that $j_i(x) = 0$ for every $x \in \mathrm{Ker}\,\overline{\Phi}_i$, hence condition (b) holds for B_i. Lastly, notice that

$$b(x,n+1)^p - b(x,n) \in B_i \qquad \text{for every } n \in \mathbb{N}.$$

Since $B_i/s^{p\gamma}B_i \subset \mathrm{Im}\,\overline{\Phi}_{i+1}$, it follows easily that condition (a) holds for B_{i+1}, as required.

Set $B_\infty := \bigcup_{i\in\mathbb{N}} B_i = B_\infty$; by construction, the Frobenius endomorphism of B_∞ induces an isomorphism $B_\infty/s^{\gamma}B_\infty \xrightarrow{\sim} B_\infty/s^{p\gamma}B_\infty$, hence B_∞ is the p-root closure of B_0 in B, by lemma 9.8.26(i). Next, let $B_\infty^\wedge$ be the completion of B_∞ for its s-adic topology; the Frobenius endomorphism of $B_\infty^\wedge$ induces an isomorphism $B_\infty^\wedge/s^{\gamma}B_\infty^\wedge \xrightarrow{\sim} B_\infty^\wedge/s^{p\gamma}B_\infty^\wedge$. Clearly $B_\infty^\wedge$ is a P-ring; by theorem 16.4.1, the ring $B_\infty^\wedge$ is then perfectoid, and the assertion follows from remark 16.9.12(ii). □

Corollary 16.9.15. *In the situation of* (16.9.7)*, let $I \subset B$ be any ideal, and endow $\overline{B} := B/I$ with the f-adic topology $\mathscr{T}_{\overline{B}}$ induced by $\mathscr{T}_B$ via the projection $B \to \overline{B}$ (see example* 8.3.27(iii)*). Then, if B is a pre-perfectoid A-algebra, the same holds for $\overline{B}$.*

Proof. Let $\mathscr{T}_B^{\mathsf{u}}$ be the topology of $\mathsf{u}(B)$, and denote by $\mathscr{T}_{\overline{B}}^{\mathsf{u}}$ the f-adic topology induced by $\mathscr{T}_B^{\mathsf{u}}$ via the projection $B \to \overline{B}$. If C is any uniform Tate ring, and $f : (\overline{B}, \mathscr{T}_B) \to C$ any continuous ring homomorphism, it is easily seen that f factors through the identity map $\mathbf{1}_{\overline{B}} : (\overline{B}, \mathscr{T}_B) \to (\overline{B}, \mathscr{T}_{\overline{B}}^{\mathsf{u}})$, which is continuous, and the continuous ring homomorphism $f : (\overline{B}, \mathscr{T}_{\overline{B}}^{\mathsf{u}}) \to C$. By the universal property of uniformization, this implies that $\mathbf{1}_{\overline{B}}$ induces an isomorphism of uniform Tate rings

$$\mathsf{u}(\overline{B}, \mathscr{T}_B) \xrightarrow{\sim} \mathsf{u}(\overline{B}, \mathscr{T}_{\overline{B}}^{\mathsf{u}})$$

(whose underlying ring homomorphism is of course again the identity map of $\overline{B}$). Thus, it suffices to check that $(\overline{B}, \mathscr{T}_{\overline{B}}^{\mathsf{u}})$ is pre-perfectoid. However, since B is pre-perfectoid, $C := \mathsf{u}(B)^\circ$ is a perfectoid ring, hence for every $\gamma \in \mathbb{N}[1/p]\setminus\{0\}$ such that $pC \subset s^{p\gamma}C$, the Frobenius endomorphism of $C/s^{p\gamma}C$ is surjective. By construction, the image $\overline{C}$ of C in $\overline{B}$ is a subring of definition for the topology $\mathscr{T}_{\overline{B}}^{\mathsf{u}}$, and it follows that the Frobenius endomorphism of $\overline{C}/s^{p\gamma}\overline{C}$ is again surjective; then the assertion follows from theorem 16.9.14. □

16.9.16. Let A be a formally perfectoid Tate ring, $A_0 \subset A$ a formally perfectoid subring of definition, $t \in A_0^{\circ\circ} \cap A^\times$, and $P \in A_0[X] \setminus A_0$ a monic polynomial. We let $\overline{P}$ be the image of P in $\overline{A}_0 := A_0/A_0^{\circ\circ}$, we define $B_0 := A_0[X^{1/p^\infty}] := \bigcup_{n\in\mathbb{N}} A_0[X^{1/p^n}]$, $B := A \otimes_{A_0} B_0$, and set

$$C_{0,n} := A_0[X^{1/p^n}]/(P) \quad \text{for every } n \in \mathbb{N} \qquad C_0 := B_0/PB_0 \qquad \text{and} \qquad C := B/PB.$$

Clearly the natural map of A_0-algebras $C_{0,m} \to C_{0,n}$ is injective for every $n, m \in \mathbb{N}$ with $n \geq m$, and $C_{0,n}$ is a free A_0-module of rank $p^n \cdot \deg_X(P)$ for every such n. Hence $C_0 = \bigcup_{n\in\mathbb{N}} C_{0,n}$ is a faithfully flat A_0-algebra, and the localization $C_0 \to C$ is injective. Lastly, let $D \subset C$ be the p-root closure of C_0 in C (see definition 9.8.24(ii)), and endow D with its t-adic topology.

The following result and its proof are a generalization and refinement of [5, Th.2.5.2] (modulo powers of p, as in [5, Rem.2.6.1(4)]); see also [23, Th.2.3]. We also borrowed from a set of lecture notes of B.Bhatt the idea of stating the theorem for a general monic polynomial P : see [24, Th.9.4.3] (whereas André's original theorem would be the special case with $P = X - a$, for any $a \in A_0$).

Theorem 16.9.17. (i) *In the situation of* (16.9.16)*, D is a faithfully flat A_0-algebra.*

(ii) *Moreover, D is a formally perfectoid ring for its t-adic topology.*

(iii) *Furthermore, there exists an isomorphism of $\overline{A}_0$-algebras (notation of* (9.8.11)*) :*

$$(\overline{A}_0[X]/(\overline{P}))^{\mathrm{perf}} \xrightarrow{\sim} \overline{A}_0 \otimes_{A_0} D.$$

Proof. Clearly $D[1/t] = C$ is a faithfully flat A-algebra, and the image of t is regular in D; by virtue of [75, Lemma 5.2.1], in order to show (i), it then suffices to check that D/tD is a faithfully flat A_0/tA_0-algebra. Recall that the completion $A_0^\wedge$ is a subring of definition for the completion $A^\wedge$ of A (proposition 8.3.33(ii)); set $C_0' := A_0^\wedge \otimes_{A_0} C_0$, $C' := A^\wedge \otimes_A C$, and let D' be the p-root closure of C_0' in C'. Endow also C_0 (resp. C_0') with its t-adic topology, and C (resp. C') with the unique f-adic topology such that C_0 (resp. C_0') is a subring of definition; let $\mathscr{T}_D$ (resp. $\mathscr{T}_{D'}$) be the topology induced by C on D (resp. by C' on D'). Taking into account proposition 8.3.33, it is easily seen that the natural maps $C_0 \to C_0'$ and $C \to C'$ induce isomorphisms on the respective completions; by virtue of lemma 9.8.26(ii), the same then holds for the induced continuous ring homomorphism $(D, \mathscr{T}_D) \to (D', \mathscr{T}_{D'})$.

Claim 16.9.18. Let $D^\wedge$ be the completion of $(D, \mathscr{T}_D)$. Then the completion map $u : D \to D^\wedge$ induces an isomorphism $D/t^k D \xrightarrow{\sim} D^\wedge/t^k D^\wedge$ for every $k \in \mathbb{N}$.

Proof of the claim. Let also $C_0^\wedge$ be the completion of C_0; since $t^k C_0$ is an open A_0-submodule of D, the map u induces an isomorphism of A_0-modules $\overline{u} : D/t^k C_0 \xrightarrow{\sim} D^\wedge/t^k C_0^\wedge$. Hence, $\overline{u}(t^k D/t^k C_0) = t^k \cdot \overline{u}(D/t^k C_0) = t^k D^\wedge/t^k C_0^\wedge$, whence the assertion. ◇

By applying claim 16.9.18 to both $D^\wedge$ and the completion $D'^\wedge$ of $(D', \mathscr{T}_{D'})$, we reduce to checking that D'/tD' is a faithfully flat A_0/tA_0-algebra, and that D' is formally perfectoid for its t-adic topology. Thus, we may replace A by $A^\wedge$, and assume that *A is a perfectoid Tate ring*.

(ii): By construction, the Frobenius endomorphism of C_0 is a surjection; hence C is a pre-perfectoid A-algebra, by theorem 16.9.14. Then the assertion follows from remark 16.9.12(ii).

(i): Define the affinoid schemes $\underline{U} := (U, \mathscr{T}_A, A^+)$ and $\underline{U}_{\mathbf{E}} := (U_{\mathbf{E}}, \mathscr{T}_{\mathbf{E}}, \mathbf{E}_U^+)$ as in (16.9.5); recall that $\mathbf{E}_0 := \mathbf{E}(A_0)$ is a subring of definition of the Tate perfectoid ring $\mathbf{E}_U := \mathscr{O}_{U_{\mathbf{E}}}(U_{\mathbf{E}})$ (lemma 16.9.6(ii,iii)). We may also assume that $t := \overline{u}_{A_0}(t') \in A$ for some $t' \in \mathbf{E}_U^\times \cap \mathbf{E}_0^{\circ\circ}$.

We endow B_0 with its t-adic topology, and B with the f-adic topology such that B_0 is a subring of definition. We have then a short exact sequence of flat A_0-modules

$$\Sigma \qquad : \qquad 0 \to PB_0 \to B_0 \xrightarrow{\pi_0} C_0 \to 0.$$

As in (16.9.7), we let $t^\gamma := \varphi_U^\flat(t'^\gamma) \in A$ for every $\gamma \in \mathbb{Z}[1/p]$. With this notation, the sequence $A_0/t^\gamma A_0 \otimes_{A_0} \Sigma$ is still short exact, for every $\gamma \in \mathbb{N}[1/p]$, which means that $t^\gamma B_0 \cap PB_0 = t^\gamma PB_0$

for every such γ. Especially, the topology of B_0 induces the t-adic topology on the ideal PB_0, and after taking completions, we still get a short exact sequence :

$$\Sigma^\wedge \qquad : \qquad 0 \to PB_0^\wedge \to B_0^\wedge \xrightarrow{\pi_0^\wedge} C_0^\wedge \to 0.$$

Recall that the completion $C^\wedge$ of C is naturally identified with $C_0^\wedge[t^{-1}]$, and $C_0^\wedge$ is a subring of definition for $C^\wedge$ (proposition 8.3.33(ii,iii)). Likewise, $B_0^\wedge$ is a subring of definition of $B^\wedge = B_0^\wedge[t^{-1}]$. We consider the affinoid ring $\underline{B}^\wedge := (B^\wedge, B^{\wedge\circ})$, and the rational subset

$$R_n := R_{B^\wedge}\left(\frac{P}{t^n}\right) \cap \operatorname{Spa} \underline{B}^\wedge \qquad \text{for every } n \in \mathbb{N}.$$

Endow the subring $B_n := B_0^\wedge[P/t^n] \subset B^\wedge$ with its t-adic topology, and let $\mathscr{T}_n$ be the f-adic topology on $B^\wedge$ such that B_n is a subring of definition; then the completion $B_n^\wedge$ of B_n is a subring of definition of $\mathscr{O}^\wedge_{\operatorname{Spa} \underline{B}^\wedge}(R_n) = (B^\wedge, \mathscr{T}_n)^\wedge$, for every $n \in \mathbb{N}$. Notice that the projection $\pi_0^\wedge$ extends to a continuous open ring homomorphism $\pi^\wedge : B^\wedge \to C^\wedge$, and for every $n \in \mathbb{N}$, the image of the induced continuous map

$$\operatorname{Spa} \pi^\wedge : \operatorname{Spa}(C^\wedge, C^{\wedge\circ}) \to \operatorname{Spa} \underline{B}^\wedge$$

lies in R_n. It follows that $\pi^\wedge$ factors uniquely through a continuous ring homomorphism

$$\psi_n : \mathscr{O}^\wedge_{\operatorname{Spa} \underline{B}^\wedge}(R_n) \to C^\wedge \qquad \text{for every } n \in \mathbb{N}$$

(see remark 15.5.9(i)). Moreover, we have $R_{n+1} \subset R_n$ for every $n \in \mathbb{N}$, and clearly the composition of ψ_{n+1} with the restriction map $\mathscr{O}^\wedge_{\operatorname{Spa} \underline{B}^\wedge}(R_n) \to \mathscr{O}^\wedge_{\operatorname{Spa} \underline{B}^\wedge}(R_{n+1})$ agrees with ψ_n. Furthermore, a direct inspection shows that $\psi_n(B_n^\wedge) = C_0^\wedge$ for every $n \in \mathbb{N}$. Summing up, we deduce a commutative diagram of rings :

$$(16.9.19) \qquad \begin{array}{ccc} B' := \operatorname*{colim}_{n \in \mathbb{N}} B_n^\wedge & \longrightarrow & \mathscr{O} := \operatorname*{colim}_{n \in \mathbb{N}} \mathscr{O}^\wedge_{\operatorname{Spa} \underline{B}^\wedge}(R_n) \\ {\scriptstyle\alpha}\downarrow & & \downarrow{\scriptstyle\beta} \\ C_0^\wedge & \longrightarrow & C^\wedge \end{array}$$

whose vertical (resp. horizontal) arrows are surjections (resp. injections).

Claim 16.9.20. The diagram (16.9.19) is cartesian.

Proof of the claim. The assertion means that the induced map $\operatorname{Ker} \alpha \to \operatorname{Ker} \beta$ is bijective. However, this map is clearly injective, so it remains to check its surjectivity. To this aim, notice that for every $n \in \mathbb{N}$ and every $g_n \in \mathscr{O}^\wedge_{\operatorname{Spa} \underline{B}^\wedge}(R_n)$ there exists $N \in \mathbb{N}$ such that

$$t^N g_n = \sum_{i=0}^{\infty} b_i \cdot \left(\frac{P}{t^n}\right)^i \qquad \text{with } b_i \in B_0^\wedge \text{ for every } i \in \mathbb{N} \text{ and } \lim_{i \to +\infty} b_i = 0.$$

With this notation, it follows easily that $g_n \in \operatorname{Ker} \psi_n$ if and only if $b_0 = 0$. Suppose then that $\psi_n(g_n) = 0$; the image g_{n+N} of g_n in $\mathscr{O}^\wedge_{\operatorname{Spa} \underline{B}^\wedge}(R_{n+N})$ can be written as :

$$g_{n+N} = \sum_{i=1}^{\infty} t^{N(i-1)} b_i \cdot \left(\frac{P}{t^{n+N}}\right)^i$$

and we have $t^{N(i-1)} b_i \in B_0^\wedge$ for every $i \geq 1$, and $\lim_{i \to +\infty} t^{N(i-1)} b_i = 0$. Hence $g_{n+N} \in B^\wedge_{n+N}$, and clearly $g_{n+N} \in \operatorname{Ker} \psi_{n+N}$, whence the contention. ◊

Let $\mathscr{D}$ be the p-root closure of B' in $\mathscr{O}$, and endow $\mathscr{D}$ with its t-adic topology; it follows easily from claim 16.9.20 that $\mathscr{D} = \beta^{-1} D$. Moreover, the induced ring homomorphism $\beta_{|\mathscr{D}} : \mathscr{D} \to D$

is surjective, and its kernel is $\mathrm{Ker}\,\beta$. The latter is clearly t-divisible, hence $\beta_{|\mathscr{D}}$ induces an isomorphism of A_0-algebras

$$\mathscr{D}/t^n\mathscr{D} \xrightarrow{\sim} D/t^nD \qquad \text{for every } n \in \mathbb{N}.$$

Thus, it suffices to check that the natural ring homomorphism $A_0 \to \mathscr{D}$ is adically faithfully flat. To this aim, let also $\mathscr{D}_n$ be the p-root closure of $B_n^\wedge$ in $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{B}^\wedge}(R_n)$, for every $n \in \mathbb{N}$, and endow $\mathscr{D}_n$ with its t-adic topology; in view of lemma 9.8.26(iii.b) we are reduced to checking that $\mathscr{D}_n$ is an adically faithfully flat A_0-algebra for every $n \in \mathbb{N}$.

Now, notice that $B_0^\wedge$ is a perfectoid ring, by virtue of lemma 16.6.40, and we have a natural identification of topological rings :

$$\mathbf{E}(B_0^\wedge) \xrightarrow{\sim} \mathbf{E}_0[X^{1/p^\infty}]^\wedge \qquad \text{such that} \qquad \overline{u}_{B_0^\wedge}(X^\gamma) = X^\gamma \qquad \text{for every } \gamma \in \mathbb{N}[1/p]$$

where $\mathbf{E}_0[X^{1/p^\infty}]^\wedge$ denotes the t'-adic completion of $\mathbf{E}_0[X^{1/p^\infty}]$. Next, let $(\alpha_n \mid n \in \mathbb{N})$ be a distinguished element in the kernel of $u_{A_0} : W(\mathbf{E}_0) \to A_0$; after replacing t' by t'^γ for some sufficiently small $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$, we may assume that $\alpha_0\mathbf{E}_0 \subset t'\mathbf{E}_0$, in which case the isomorphism ω of remark 16.3.7(ii) induces ring isomorphisms

$$\mathbf{E}_0/t'\mathbf{E}_0 \xrightarrow{\sim} A_0/tA_0 \qquad \mathbf{E}(B_0^\wedge)/t'\mathbf{E}(B_0^\wedge) \xrightarrow{\sim} B_0^\wedge/tB_0^\wedge. \tag{16.9.21}$$

On the other hand, set $U_B := \mathrm{Spec}\,B^\wedge$; then $(B_0^\wedge, B_0^\wedge, U_B)$ is a perfectoid quasi-affinoid ring, and by example 16.9.13 we may then find $e_n \in \mathbf{E}(B_0^\wedge)$ such that the $\mathscr{D}_n$ is the p-root closure in $\mathscr{O}^\wedge_{\mathrm{Spa}\,\underline{B}^\wedge}(R_n)$ of the t-adic completion of $B_0^\wedge[\overline{u}_{B_0^\wedge}(e_n)/t^n]$, and moreover – after replacing again t' by t'^γ for some small $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$ – we may assume that $P - \overline{u}_{B_0^\wedge}(e_n) \in tB_0^\wedge$. Hence, there exist a monic polynomial $Q_n \in \mathbf{E}_0[X]$ and $g_n \in \mathbf{E}_0[X^{1/p^\infty}]^\wedge$ with

$$e_n = Q_n + t'g_n. \tag{16.9.22}$$

According to proposition 16.7.25(iii), the subring

$$D_n := B_0^\wedge[\overline{u}_{B_0^\wedge}(e_n^{1/p^k})/t^{n/p^k} \mid k \in \mathbb{N}] \subset B^\wedge$$

is formally perfectoid for the topology $\mathscr{T}'_n$ induced by $\mathscr{T}_n$. Then $\mathscr{T}'_n$ is the t-adic topology, and combining with remark 16.9.12(iii) and lemma 9.8.26(ii), we deduce that

$$(D_n, \mathscr{T}'_n)^\wedge = \mathscr{D}_n.$$

Thus, we are further reduced to checking that the A_0-algebra $D_{n,k} := B_0^\wedge[\overline{u}_{B_0^\wedge}(e_n^{1/p^k})/t^{n/p^k}]$ is adically faithfully flat for every $n, k \in \mathbb{N}$ with $n > 0$ and $n/p^k \leq 1$. Since t is a regular element of $D_{n,k}$, the local flatness criterion ([126, Th.22.3]) further reduces to showing that $D_{n,k}/(t^{n/p^k})$ is a faithfully flat $A_0/(t^{n/p^k})$-algebra, for every such n and k. To this aim, notice that (16.9.21) induces an isomorphism $E_{n,k} := \mathbf{E}_0/(t'^{n/p^k}) \xrightarrow{\sim} A_0/(t^{n/p^k})$, and $B_0^\wedge/(t^{n/p^k})$ is isomorphic to the A_0-algebra $E_{n,k}[X^{1/p^\infty}]$ (as $n/p^k \leq 1$). Also, the image of $\overline{u}_{B_0^\wedge}(e_n^{1/p^k})$ in $E_{n,k}[X^{1/p^\infty}]$ is the regular element Q_n^{1/p^k}, due to (16.9.22). Thus, the sequence $(t^{n/p^k}, \overline{u}_{B_0^\wedge}(e_n^{1/p^k}))$ is regular in the ring $B_0^\wedge$; in particular, this sequence is completely secant (proposition 7.8.7), so the natural map

$$B_0^\wedge[Y]/(\overline{u}_{B_0^\wedge}(e_n^{1/p^k}) - t^{n/p^k}Y) \to D_{n,k}$$

is an isomorphism of A_0-algebras (lemma 7.8.17). We are then furter reduced to checking that for every $n, k, r \in \mathbb{N}$ with $n > 0$, $r \geq k$ and $n/p^k \leq 1$, the $E_{n,k}$-algebra

$$E_{n,k}[X^{1/p^r}, Y]/(Q_n^{1/p^k})$$

is faithfully flat. The latter follows from [65, Ch.IV, Prop.11.3.7].

(iii): The proof of (i) yields an isomorphism of $\overline{A}_0$-algebras :

$$\overline{A}_0 \otimes_{A_0} D \xrightarrow{\sim} \operatorname*{colim}_{n \in \mathbb{N}} \overline{A}_0 \otimes_{A_0} D_n$$

with $D_n = B_0^\wedge[Y^{1/p^\infty}]/((t^nY)^{1/p^k} - \overline{u}_{B_0^\wedge}(e_n^{1/p^k}) \mid k \in \mathbb{N})$ for every $n \in \mathbb{N}$, and the transition map $D_n \to D_{n+1}$ is the map of $B_0^\wedge$-algebras such that $Y^{1/p^k} \mapsto (tY)^{1/p^k}$ for every $k, n \in \mathbb{N}$. Set $\overline{B}_0 := \overline{A}_0 \otimes_{A_0} B_0$; it follows that $\overline{A}_0 \otimes_{A_0} D_n = \overline{B}_0[Y^{1/p^\infty}]/(\overline{P}^{1/p^k} \mid k \in \mathbb{N})$ for every $n \in \mathbb{N}$, and the induced map $\overline{A}_0 \otimes_{A_0} D_n \to \overline{A}_0 \otimes_{A_0} D_{n+1}$ is the map of $\overline{B}_0$-algebras such that $Y^{1/p^k} \mapsto 0$ for every $n, k \in \mathbb{N}$. Therefore, we get an isomorphism $\overline{A}_0 \otimes_{A_0} D \xrightarrow{\sim} \overline{B}_0/(\overline{P}^{1/p^k} \mid k \in \mathbb{N})$, whence the assertion. ☐

16.9.23. Let (A, a) be a pair consisting of a ring A and an element $a \in A$ such that $p^n A \subset aA$ for some $n \in \mathbb{N}$, and denote by $\mathscr{C}(A, a)$ the category of all formally perfectoid A-algebras B whose topology is a-adic, and *whose a-torsion is bounded*, *i.e.* there exists $k \in \mathbb{N}$ with $\mathrm{Ann}_B(a^k) = \mathrm{Ann}_B(a^{k+1})$. The morphisms of $\mathscr{C}(A, a)$ are all the maps of A-algebras. Moreover, let $P \in A[X]$ be a non-constant monic polynomial; we associate with P the functor

$$F_P : \mathscr{C}(A, a) \to \mathbf{Set} \qquad B \mapsto \{(\beta_n \mid n \in \mathbb{N}) \in \mathbf{E}(B) \mid P(\beta_0) = 0\}.$$

Every morphism $f : B \to B'$ of $\mathscr{C}(A, a)$ induces a map $\mathbf{E}(f) : \mathbf{E}(B) \to \mathbf{E}(B')$, and we let $F_P(f) : F_P B \to F_P B'$ be the restriction of $\mathbf{E}(f)$.

Lemma 16.9.24. *With the notation of* (16.9.23)*, let $B \in \mathrm{Ob}(\mathscr{C}(A, a))$, set $B_0 := B/\mathrm{Ann}_B(a)$, $B_1 := B/B^{\circ\circ}$, and $B_2 := B_0 \otimes_B B_1$. Then we have :*

(i) *B_1 and B_2 are perfect $\mathbb{F}_p$-algebras, and B_0 is formally perfectoid for its a-adic topology.*

(ii) *The image of a is regular in B_0, and B_0 is p-root closed in $B_0[a^{-1}]$.*

(iii) *The resulting commutative diagram of rings :*

$$\begin{array}{ccc} B & \longrightarrow & B_0 \\ \downarrow & & \downarrow \\ B_1 & \longrightarrow & B_2 \end{array}$$

is cartesian (and cocartesian).

(iv) *$B_0, B_1, B_2 \in \mathrm{Ob}(\mathscr{C}(A, a))$, and $F_P B = F_P B_0 \times_{F_P B_2} F_P B_1$.*

Proof. We begin with the following observation :

Claim 16.9.25. Let M be any A-module; endow M with its a-adic topology, and denote by $M^\wedge$ the completion of M. Then, $\mathrm{Ann}_{M^\wedge}(a^k)$ is the topological closure of the image of $\mathrm{Ann}_M(a^k)$ in $M^\wedge$, for every $k \in \mathbb{N}$.

Proof of the claim. Set $N := a^k M$, and consider the induced exact sequence :

$$0 \to \mathrm{Ann}_M(a^k) \to M \xrightarrow{f} N \to 0.$$

Endow N with its a-adic topology, and $\mathrm{Ann}_M(a^k)$ with the topology induced by M; after taking a-adic completions, we get the exact sequence :

$$0 \to \mathrm{Ann}_M(a^k)^\wedge \to M^\wedge \xrightarrow{f^\wedge} N^\wedge \to 0$$

and $\mathrm{Ann}_M(a^k)^\wedge$ is the topological closure in $M^\wedge$ of the image of $\mathrm{Ann}_M(a^k)$ in $M^\wedge$ (proposition 8.2.13(i,iii,v)). Moreover, $N^\wedge = a^k M^\wedge$, and under this identification, $f^\wedge$ corresponds to the scalar multiplication by a^k on $M^\wedge$ (remark 8.3.3(iv)), whence the assertion. ◊

Now, notice that $\mathrm{Ann}_B(a^i) \cap a^k B = a^k \cdot \mathrm{Ann}_B(a^{k+i})$ for every $i, k \in \mathbb{N}$; if $\mathrm{Ann}_B(a^k) = \mathrm{Ann}_B(a^{k+1})$, it follows that $\mathrm{Ann}_B(a^i) \cap a^k B = a^k \cdot \mathrm{Ann}_B(a^k) = 0$ for every $i > 0$. In particular, the a-adic topology of B induces the discrete topology on $\mathrm{Ann}_B(a^i)$, for every $i \in \mathbb{N}$, and taking into account claim 16.9.25, we see that the natural map $\mathrm{Ann}_B(a^i) \to \mathrm{Ann}_{B^\wedge}(a^i)$ is an isomorphism, for every $i \in \mathbb{N}$. Next, according to corollary 16.6.24, there exists $\beta := (b_k \mid k \in \mathbb{N}) \in \mathbf{E}(B^\wedge)$ such that $a/b_0 \in (B^\wedge)^\times$ and $p \in b_n B^\wedge$; then the a-adic topology of $B^\wedge$ agrees with its b_k-adic topology, for every $k \in \mathbb{N}$, and by corollary 16.3.71, $B_0^\wedge := B^\wedge/\mathrm{Ann}_{B^\wedge}(b_n)$ is perfectoid for its b_n-adic topology; moreover, $B^\wedge$ is reduced (corollary 16.3.63(i)), so $\mathrm{Ann}_{B^\wedge}(b_n) = \mathrm{Ann}_{B^\wedge}(b_0)$. By claim 16.9.25 and proposition 8.2.13(i,v), $B_0^\wedge$ is then naturally identified with the a-adic completion of B_0, *i.e.* B_0 is formally perfectoid for its a-adic topology. Recall as well that $(B^\wedge)^{\circ\circ} = (B^{\circ\circ})^\wedge$, and $B^{\circ\circ}$ is a radical ideal of B (remark 8.3.10(iv) and corollary 8.4.15(ii)); since $B^\wedge$ is perfectoid, it follows easily that B_1 is a perfect $\mathbb{F}_p$-algebra. Also, obviously the a-adic topology is discrete on B_2; in light of proposition 16.3.9(i) we deduce that B_2 is a perfect $\mathbb{F}_p$-algebra, and this completes the proof of (i).

(ii): The ring $B^\wedge$ is reduced (corollary 16.3.63(i)), so $\mathrm{Ann}_{B^\wedge}(a) = \mathrm{Ann}_{B^\wedge}(a^k)$ for every $k > 0$, and in view of the foregoing, we deduce that $\mathrm{Ann}_B(a) = \mathrm{Ann}_B(a^k)$ for every $k > 0$, so the image of a is regular in B_0. Let us endow $B_0[a^{-1}]$ with the f-adic topology such that B_0 is a subring of definition, and $aB_0 \subset B_0$ is an ideal of adic definition; then, let C be the p-root closure of B_0 in $B_0[a^{-1}]$, endow B_0 and C with the topologies induced by $B_0[a^{-1}]$, and denote by $B_0^\wedge$, $C^\wedge$ and $B_0[a^{-1}]^\wedge$ the respective completions. Notice that the quotient topology on C/B_0 is discrete, so the completion map $C/B_0 \to (C/B_0)^\wedge$ is an isomorphism; we need to check that $C = B_0$, and taking into account proposition 8.2.13(i,v), we are then reduced to showing that $B_0^\wedge = C^\wedge$. To this aim, let $(b_k \mid k \in \mathbb{N})$ be as in the proof of (i); we have already noticed that the topology of $B^\wedge$ is b_{n+1}-adic, so the same holds for the topology of $B_0^\wedge$, and clearly $B_0^\wedge[a^{-1}] = B_0^\wedge[b_{n+1}^{-1}]$. On the other hand, $C^\wedge$ is the p-root closure of $B_0^\wedge$ in $B_0[a^{-1}]^\wedge$ (lemma 9.8.26(ii)), and $B_0[a^{-1}]^\wedge = B_0^\wedge[a^{-1}]$ (proposition 8.3.33(iii)), so finally $C^\wedge$ is the p-root closure of $B_0^\wedge$ in $B_0^\wedge[b_{n+1}^{-1}]$. Since $B_0^\wedge$ is perfectoid, the assertion then follows from lemma 9.8.26(i) and theorem 16.4.1.

(iii): By the foregoing, we see that the natural map

$$\mathrm{Ann}_B(a) \cap B^{\circ\circ} \to J := \mathrm{Ann}_{B^\wedge}(b_0) \cap (B^\wedge)^{\circ\circ}$$

is injective. However $J = 0$: indeed, if $x \in J$, we have $x^n = b_0 c$ for some $n \in \mathbb{N}$ and some $c \in B^\wedge$, and on the other hand $b_0 x = 0$, whence $x^{n+1} = 0$, so $x = 0$, as $B^\wedge$ is reduced (corollary 16.3.63(i)). So finally $\mathrm{Ann}_B(a) \cap B^{\circ\circ} = 0$, and the assertion follows easily.

(iv): Since B_1 and B_2 are perfect, they are reduced, so their a-torsion is bounded. The same holds trivially for the a-torsion of B_0, due to (ii). This shows that $B_0, B_1, B_2 \in \mathrm{Ob}(\mathscr{C}(A,a))$. The remaining identity follows easily from the definitions. □

Proposition 16.9.26. *In the situation of* (16.9.23)*, suppose that* $A \in \mathrm{Ob}(\mathscr{C}(A,a))$*. Then the functor* F_P *is represented by a faithfully flat* A*-algebra* $D_P \in \mathrm{Ob}(\mathscr{C}(A,a))$.

Proof. Let J be the radical of the ideal aA, and $I := \mathrm{Ann}_A(a)$; set $A_1 := A/J$ and $A_2 := A/(I+J)$. By lemma 16.9.24 we get a cartesian diagram of rings :

$$\begin{array}{ccc} A & \longrightarrow & A_0 \\ \big\downarrow & & \big\downarrow \\ A_1 & \longrightarrow & A_2 \end{array}$$

whose arrows are the natural projections, where A_1 and A_2 are perfect $\mathbb{F}_p$-algebras, and A_0 is formally perfectoid for its a-adic topology; moreover, a is regular in A_0. Let $\overline{P}$ denote the image of P in $A_2[X]$; according to theorem 16.9.17, the polynomial P acquires a root in a faithfully flat A_0-algebra D_0 that is formally perfectoid for its a-adic topology, and such that we have an isomorphism $A_2 \otimes_{A_0} D_0 \xrightarrow{\sim} D_2 := (A_2[X]/(\overline{P}))^{\mathrm{perf}}$ of $\overline{A}_0$-algebras. Let then also $Q \in A_1[X]$ be the image of P, and $D_1 := (A_1[X]/(Q))^{\mathrm{perf}}$; we notice :

Claim 16.9.27. (i) The natural map $A_2 \otimes_{A_1} D_1 \to D_2$ is an isomorphism.

(ii) D_1 is a faithfully flat A_1-algebra.

Proof of the claim. (i): The functor $(-)^{\mathrm{perf}}$ of (9.8.11) commutes with all colimits, since it is a left adjoint; in particular, the natural map $A_2^{\mathrm{perf}} \otimes_{A_1^{\mathrm{perf}}} D_1 \to D_2$ is an isomorphism. But $A_2 = A_2^{\mathrm{perf}}$ and $A_1 = A_1^{\mathrm{perf}}$, whence the assertion.

(ii): Let $j_0 : A_1 \to D_{1,0}$ be the structure map, and say that $Q = X^k + a_1 X^{k-1} + \cdots + a_k$ with $a_1, \dots, a_k \in A_1$; it suffices to show that the composition $j_n : A_1 \to D_{1,n}$ of j_0 with $\varphi_{n-1} \circ \cdots \circ \varphi_0 : D_{1,0} \to D_{1,n}$ is faithfully flat for every $n \in \mathbb{N}$. But since A_1 is a perfect $\mathbb{F}_p$-algebra, j_n identifies $D_{1,n}$ with the A_1-algebra $A_1[X]/(Q_n)$, where $Q_n := X^k + a_1^{1/p^n} X^{k-1} + \cdots + a_k^{1/p^n}$, whence the assertion. ◊

In view of claim 16.9.27 and [75, Prop.3.4.21] the A-algebra $D_P := D_0 \times_{D_2} D_1$ is flat, and the projections $D_P \to D_i$ induce isomorphisms $A_i \otimes_A D_P \xrightarrow{\sim} D_i$ of A_i-algebras, for $i = 0, 1, 2$. Hence, $\mathrm{Ann}_{D_P}(a^n) = D_P \otimes_A \mathrm{Ann}_A(a^n)$ for every $n \in \mathbb{N}$, and since the a-torsion of A is bounded, the same then holds for the a-torsion of D_P. We endow D_P with the topology $\mathscr{T}$ of the fibre product of the formally perfectoid ring D_0 with the discrete topological $\mathbb{F}_p$-algebra D_1, over the discrete topological $\mathbb{F}_p$-algebra D_2. It is easily seen that $\mathscr{T}$ coincides with the a-adic topology, and the completion $(D, \mathscr{T})^\wedge$ of $(D, \mathscr{T})$ is the fibre product $D_0^\wedge \times_{D_2} D_1$, where $D_0^\wedge$ denotes the completion of D_0. Hence, D_P is formally perfectoid, by proposition 16.3.25; this shows that $D_P \in \mathrm{Ob}(\mathscr{C}(A, a))$. In order to check that D_P is faithfully flat, let M be any non-zero A-module, and set $M_i := A_i \otimes_A M$ for $i = 0, 1$; it suffices to show that $D_P \otimes_A M \neq 0$ ([126, Th.7.2]), and according to [75, Lemma 3.4.18], we have either $M_0 \neq 0$ or $M_1 \neq 0$, so either $D_0 \otimes_A M \neq 0$ or $D_1 \otimes_A M \neq 0$, since D_i is a faithfully flat A_i-algebra for $i = 0, 1$, whence the assertion.

It remains to check that D_P represents the functor F_P. To this aim, recall first that D_0 is the p-root closure of $C_0 := A_0[X^{1/p^\infty}]/(P)$ in $C_0[a^{-1}]$; hence the image of $\delta := (X^{1/p^n} \mid n \in \mathbb{N})$ in $\mathbf{E}(D_0)$ is an element $\delta_0 \in F_P D_0$. Likewise, the image of δ in $\mathbf{E}(D_1)$ is an element $\delta_1 \in F_P D_1$, and clearly the images of δ_0 and δ_1 coincide in $F_P D_2$, so the pair (δ_0, δ_1) is a well defined element $\delta_P \in F_P D_P$ (lemma 16.9.24(iv)). Now, let B be any object of $\mathscr{C}(A, a)$, and define B_0, B_1, B_2 as in lemma 16.9.24; we easily get a natural identification :

$$\mathrm{Hom}_{A\text{-}\mathsf{Alg}}(D_P, B) \xrightarrow{\sim} \mathrm{Hom}_{A_0\text{-}\mathsf{Alg}}(D_0, B_0) \times_{\mathrm{Hom}_{A_2\text{-}\mathsf{Alg}}(D_2, B_2)} \mathrm{Hom}_{A_1\text{-}\mathsf{Alg}}(D_1, B_1)$$

(detail left to the reader). Taking into account lemma 16.9.24(iv), we are then reduced to checking that for $i = 0, 1$, and every $\beta_i \in F_P B_i$, there exists a unique map of A_i-algebras $f_i : D_i \to B_i$ such that $F_P(f_i)(\delta_i) = \beta_i$. This is clear for $i = 1$, since B_1 is perfect and D_1 is the perfection of $A_1[X]/(Q)$. Lastly, say that $\beta_0 = (b_n \mid n \in \mathbb{N})$, so that $b_{n+1}^p = b_n$ for every $n \in \mathbb{N}$. Then there is a unique map of A_0-algebras $g : A_0[X^{1/p^\infty}] \to B_0$ such that $g(X^{1/p^n}) = b_n$ for every $n \in \mathbb{N}$; since $P(b_0) = 0$, the map g factors uniquely through a map $h : C_0 \to B_0$. But according to lemma 16.9.25(ii), B_0 is p-root closed in $B_0[a^{-1}]$; in view of remark 9.8.25(ii), the map h then extends to a map $f_0 : D_0 \to B_0$, which is necessarily the unique map whose restriction to C_0 agrees with h, since $A_0[a^{-1}] \otimes_{A_0} h = A_0[a^{-1}] \otimes_{A_0} f_0$, and since the localization $B_0 \to B_0[a^{-1}]$ is injective. □

Remark 16.9.28. (i) In the situation of proposition 16.9.26, let $f : (A, a) \to (A', a')$ be any morphism of $\mathscr{C}(A, a)$, and denote by $f(P)$ the image of P in $A'[X]$. Then we can consider as well the category $\mathscr{C}(A', a')$, the corresponding functor $F_{f(P)} : \mathscr{C}(A', a) \to \mathbf{Set}$, and the representing A'-algebra $D_{f(P)}$. Let also $\delta \in F_P D_P$ and $\delta' \in F_{f(P)} D_{f(P)}$ be the respective universal elements. Notice that $A' \otimes_A D_P$ is formally perfectoid for its a'-adic topology (proposition 16.3.9(i)), and $\mathrm{Ann}_{A' \otimes_A D_P}(a'^n) = D_P \otimes_A \mathrm{Ann}_{A'}(a'^n)$ for every $n \in \mathbb{N}$, since D_P is a faithfully flat A-algebra; hence $A' \otimes_A D_P \in \mathrm{Ob}(\mathscr{C}(A', a'))$, and by comparing the respective universal properties, it follows easily that there exists a unique isomorphism of A'-algebras

$$\omega : D_{f(P)} \xrightarrow{\sim} A' \otimes_A D_P \qquad \text{such that} \qquad (F_{f(P)}\omega)(\delta') = 1 \otimes \delta.$$

(ii) We may also consider the following variant of the situation of (16.9.23). Let A be a ring, $I \subset A$ an ideal of finite type, and suppose that A is perfectoid for its I-adic topology; let also $P \in A[X]$ be a non-constant monic polynomial. We associate with P the functor

$$G_P : A\text{-Perf} \to \mathbf{Set} \qquad B \mapsto \{(\beta_n \mid n \in \mathbb{N}) \in \mathbf{E}(B) \mid P(\beta_0) = 0\}$$

defined just as F_P. Then we claim that G_P is represented by an adic and adically faithfully flat map $A \to D_P^\wedge$ of perfectoid rings (see definition 8.3.23(i,iii)). Indeed, recall that there exists $a \in A^{\circ\circ}$ such that $pA = a^p A$ (lemma 16.2.3(iv)), and A is perfectoid for its a-adic topology (which is just the p-adic topology : proposition 16.3.8(i)), hence we may consider the category $\mathscr{C}(A, a)$ and the functor $F_P : \mathscr{C}(A, a) \to \mathbf{Set}$; moreover, $A \in \mathrm{Ob}(\mathscr{C}(A, a))$ (corollary 16.3.75) so F_P is represented by a faithfully flat A-algebra $D_P \in \mathrm{Ob}(\mathscr{C}(A, a))$, and its I-adic completion $D_P^\wedge$ is perfectoid, by proposition 16.3.8(ii). Now, if $A \to B$ is any continuous map of perfectoid rings, then $B \in \mathrm{Ob}(\mathscr{C}(A, a))$, by proposition 16.3.8(i) and corollary 16.3.75, and on the other hand, every map of A-algebras $D_P \to B$ extends uniquely to a continuous map $D_P^\wedge \to B$; it follows easily that $D_P^\wedge$ represents G_P.

The following result strenghtens [25, Th.7.12].

Proposition 16.9.29. *For every perfectoid $\mathbb{F}_p$-algebra E there exists an adic and adically faithfully flat map $E \to D$ of perfectoid rings such that the following holds. For every non-constant monic polynomial $P \in W(D)[X]$ and every distinguished ideal $\mathscr{I} \subset W(D)$ there exists $\underline{w} \in W(D)$ such that $P(\underline{w}) \in \mathscr{I}$.*

Proof. Let $I \subset E$ be an adic ideal of definition; let $\mathscr{F}$ be the set of all non-constant monic polynomials in $W(E)[X]$, and $\mathscr{G}$ the set of all distinguished ideals of $W(E)$. For every $(P, \mathscr{I}) \in \mathscr{F} \times \mathscr{G}$, let $A_\mathscr{I} := W(E)/\mathscr{I}$, define the functor $G_P : A_\mathscr{I} \to \mathbf{Set}$ as in remark 16.9.28(ii) (so here we identify P with its image in $A_\mathscr{I}[X]$), and denote by $D_{P,\mathscr{I}}^\wedge$ the adic and adically faithfully flat perfectoid $A_\mathscr{I}$-algebra that represents G_P. We have a natural identification $E \xrightarrow{\sim} \mathbf{E}(A_\mathscr{I})$ for every $\mathscr{I} \in \mathscr{G}$ (example 16.3.2(ii)), so $\mathbf{E}(D_{P,\mathscr{I}}^\wedge)$ is naturally an E-algebra, for every $(P, \mathscr{I}) \in \mathscr{F} \times \mathscr{G}$; moreover, the structure map $E \to \mathbf{E}(D_{P,\mathscr{I}}^\wedge)$ is adic and adically faithfully flat, by remark 16.4.20(i). We denote by $\mathscr{E}(A)$ the coproduct of the family of E-algebras $(\mathbf{E}(D_{P,\mathscr{I}}^\wedge) \mid (P, \mathscr{I}) \in \mathscr{F} \times \mathscr{G})$, and we let $\mathscr{E}(A)^\wedge$ be the I-adic completion of $\mathscr{E}(A)$. Since each $\mathbf{E}(D_{P,\mathscr{I}}^\wedge)$ is a perfect ring, it is easily seen that the same holds for $\mathscr{E}(A)$, and then the induced map $E \to \mathscr{E}(A)^\wedge$ is an adic and adically flat ring homomorphism of perfectoid $\mathbb{F}_p$-algebras (remark 9.4.9(v)). Next, by transfinite induction we define, for every ordinal, a perfectoid E-algebra as follows : $\mathscr{E}_0(A) := E$, $\mathscr{E}_{\alpha+1}(A) := \mathscr{E}(\mathscr{E}_\alpha(A))^\wedge$ for every successor ordinal $\alpha + 1$, and $\mathscr{E}_\alpha(A)$ is the I-adic completion of $\mathrm{colim}_{\beta<\alpha}\, \mathscr{E}_\beta(A)$, for every limit ordinal α. We observe :

Claim 16.9.30. Let $(\Lambda, \leq)$ be a partially ordered set such that the following holds : for every finite or countable subset $S \subset \Lambda$ there exists $\lambda \in \Lambda$ such that $\lambda \geq \mu$ for every $\mu \in S$. We have :

(i) Let R be a ring, $J \subset R$ an ideal, $M_\bullet := (M_\lambda \mid \lambda \in \Lambda)$ a system of J-adically complete and separated R-modules. Then the colimit M of $M_\bullet$ is J-adically complete and separated.

(ii) Let $R_\bullet := (R_\lambda \mid \lambda)$ be a system of rings, and R the colimit of $R_\bullet$. Then the natural map $\tau : \mathrm{colim}_{\lambda\in\Lambda}\, W(R_\lambda) \to W(R)$ is a ring isomorphism.

Proof of the claim. (i): To check that M is separated, let $x \in M$ such that $x \in J^n M$ for every $n \in \mathbb{N}$; then x is represented by an element $y \in M_\lambda$, for some $\lambda \in \Lambda$, and the condition means that for every $n \in \mathbb{N}$ there exists $\lambda(n) \in \Lambda$ such that $\lambda(n) \geq \lambda$, and the image of y in $M_{\lambda(n)}$ lies in $I^n M_{\lambda(n)}$. By assumption, there exists $\mu \in \Lambda$ such that $\mu \geq \lambda(n)$ for every $n \in \mathbb{N}$, so the image y_μ of y in M_μ lies in $\bigcap_{n\in\mathbb{N}} J^n M_\mu$. Since M_μ is separated, we get $y_\mu = 0$, whence $x = 0$, as required. Next, let $x_\bullet := (x_n \mid n \in \mathbb{N})$ be a Cauchy sequence in M; after replacing $x_\bullet$ by a subsequence, we may assume that $x_{n+1} - x_n \in J^n M$ for every $n \in \mathbb{N}$. Each x_n is represented by an element $y_n \in M_{\mu(n)}$ for some $\mu(n) \in \Lambda$; then we find $\mu \in \Lambda$ such that $\mu \geq \mu(n)$ for every $n \in \mathbb{N}$, and after replacing each y_n by its image in M_μ, we may assume that $x_\bullet$ is the image of a sequence $y_\bullet$ in M_μ. For every $n \in \mathbb{N}$ and every $\lambda \in \Lambda$ with $\lambda \geq \mu$, let us denote by $y_{n,\lambda}$ the image of y_n in M_λ. With this notation, for every $n \in \mathbb{N}$ we can then find $\lambda(n) \in \Lambda$ such that $\lambda(n) \geq \mu$, and such that $y_{n+1,\lambda(n)} - y_{n,\lambda(n)} \in J^n M_{\lambda(n)}$. Pick $\lambda \in \Lambda$ such that $\lambda \geq \lambda(n)$ for every $n \in \mathbb{N}$; then $y_{n+1,\lambda} - y_{n,\lambda} \in J^n M_\lambda$ for every $n \in \mathbb{N}$, so the sequence $(y_{n,\lambda} \mid n \in \mathbb{N})$ is Cauchy in M_λ, and therefore it admits a limit y. Clearly, the image of y in M is a limit for $x_\bullet$.

(ii): Let $\lambda \in \Lambda$, and $\underline{w} := (w_n \mid n \in \mathbb{N}) \in W(R_\lambda)$ whose image in $\mathscr{W} := \mathrm{colim}_{\lambda \in \Lambda} W(R_\lambda)$ lies in $\mathrm{Ker}(\tau)$; then for each $n \in \mathbb{N}$ there exists $\lambda(n) \in \Lambda$ such that $\lambda(n) \geq \lambda$, and the image of w_n vanishes in $R_{\lambda(n)}$. Pick $\mu \in \Lambda$ such that $\mu \geq \lambda(n)$ for every $n \in \mathbb{N}$; then clearly the image of $\underline{w}$ vanishes in $W(R_\mu)$, so also in $\mathscr{W}$. This shows that τ is injective. Lastly, let $\underline{u} := (u_n \mid n \in \mathbb{N}) \in W(R)$; then for every $n \in \mathbb{N}$ there exists $\lambda(n) \in \Lambda$ and an element in $R_{\lambda(n)}$ whose image in R agrees with u_n. Pick again $\lambda \in \Lambda$ with $\lambda \geq \lambda(n)$ for every $n \in \mathbb{N}$; then clearly $\underline{u}$ is the image of an element of $W(R_\lambda)$, so τ is surjective. ◊

Let ω_1 be the smallest uncountable ordinal; we claim that $D := \mathscr{E}_{\omega_1}(A)$ will do. Indeed, let $P \in W(D)[X]$ be a non-constant monic polynomial, and $\underline{\alpha} := (\alpha_n \mid n \in \mathbb{N}) \in W(D)$ a distinguished element; according to claim 16.9.30(i), D represents the direct limit of the system of E-algebras $(\mathscr{E}_\beta(A) \mid \beta < \omega_1)$, so we may assume that $P \in \mathscr{E}_\beta(A)[X]$ for some $\beta < \omega_1$. Moreover, $W(D) = \mathrm{colim}_{\beta<\omega_1} W(\mathscr{E}_\beta(A))$, by claim 16.9.30(ii), so that we may also assume that $\underline{\alpha} \in W(\mathscr{E}_\beta(A))$. Since the topology of D is I-adic, we have $\alpha_0^k \in ID$ for some $k \in \mathbb{N}$, and $\alpha_1 \in D^\times$; then, up to replacing β by a larger ordinal, we may assume as well that $\alpha_0^k \in I\mathscr{E}_\beta(A)$ and $\alpha_1 \in \mathscr{E}_\beta(A)^\times$, so that $\underline{\alpha}$ is distinguished in $W(\mathscr{E}_\beta(A))$. By construction, there exists therefore $\underline{w} \in W(\mathscr{E}_{\beta+1}(A))$ such that $P(\underline{w}) \in \underline{\alpha} W(\mathscr{E}_{\beta+1}(A))$, and since $\beta + 1 < \omega_1$, the proposition follows. □

16.9.31. Let A be a perfectoid Tate ring, $A_0 \subset A$ a perfectoid subring of definition, and $(A_0, \mathfrak{m})$ a basic setup in the sense of [75, §2.1.1], such that $\mathfrak{m}$ is the filtered union of a countable system of principal subideals. If $\mathfrak{m}$ is an open radical ideal of A_0, then we have attached to $\mathfrak{m}$ an open radical ideal $\mathfrak{m}_\mathbf{E}$ of $\mathbf{E}_0 := \mathbf{E}(A_0/pA_0)$, so that $(\mathbf{E}_0, \mathfrak{m}_\mathbf{E})$ is a basic setup as well (see proposition 16.8.15). One can show that here $\mathfrak{m}$ is still a radical ideal; however, it is not necessarily open, but nevertheless we can construct a useful basic setup $(\mathbf{E}_0, \mathfrak{m}_\mathbf{E})$ as follows. By assumption, $\mathfrak{m}$ is the filtered union of a countable system of principal ideals; hence, we may find a generating system $(a_n \mid n \in \mathbb{N})$ for $\mathfrak{m}$ such that for every $n \in \mathbb{N}$ there exists an element $c_n \in A$ with $a_n = c_n a_{n+1}^p$. For every $x \in A_0$, let $\overline{x} \in A_0/pA_0$ be the class of x; since A_0 is perfectoid, for every $n \in \mathbb{N}$ there exists $(\overline{x}_{n,k} \mid k \in \mathbb{N}) \in \mathbf{E}_0$ with $\overline{x}_{n,0} = \overline{c}_n$ (recall that $\overline{x}_{n,k+1}^p = \overline{x}_{n,k}$ for every $k \in \mathbb{N}$). Set

$$\alpha_{n,k} := \overline{a}_{n+k} \cdot \overline{x}_{n,k} \cdot \overline{x}_{n+1,k-1} \cdots \overline{x}_{n+k-1,1} \qquad \text{for every } n \in \mathbb{N}.$$

Thus, $\alpha_{n,0} = \overline{a}_n$ and it is easily seen that $\alpha_{n,\bullet} := (\alpha_{n,k} \mid k \in \mathbb{N}) \in \mathbf{E}_0$ for every $n \in \mathbb{N}$; moreover, $\alpha_{n,\bullet} \in \alpha_{n+1,\bullet}^p \mathbf{E}_0$ for every $n \in \mathbb{N}$. Let then $\mathfrak{m}_\mathbf{E} \subset \mathbf{E}_0$ be the ideal generated by the system $(\alpha_{n,\bullet} \mid n \in \mathbb{N})$; it follows that $(\mathbf{E}_0, \mathfrak{m}_\mathbf{E})$ is a basic setup.

Remark 16.9.32. (i) In the situation of (16.9.31), we have :

$$\bigcap_{n\in\mathbb{N}} (\overline{u}_{A_0}(\mathfrak{m}_\mathbf{E}) \cdot A_0 + p^n A_0) = \bigcap_{n\in\mathbb{N}} (\mathfrak{m} + p^n A_0). \tag{16.9.33}$$

Indeed, on the one hand, $\overline{u}_{A_0}(\alpha_{n,\bullet})$ is the limit of the p-adically convergent sequence

$$((a_{n+k} x_{n,k} \cdots x_{n+k-1,1})^{p^k} \mid k \in \mathbb{N})$$

hence it lies in the p-adic topological closure of $\mathfrak{m}$. On the other hand, by construction for every $x \in \mathfrak{m}$ there exists $y \in \overline{u}_{A_0}(\mathfrak{m}_E)$ such that $x - y \in pA_0$; then $x^{p^n} - y^{p^n} \in p^n A_0$ for every $n \in \mathbb{N}$ (lemma 9.3.4(i)), and since $\mathfrak{m}$ is generated by $(x^{p^n} \mid x \in \mathfrak{m})$, we deduce the converse inclusion.

(ii) Quite generally, let $(V, \mathfrak{m})$ be a basic setup in the sense of [75, §2.1.1], such that $\mathfrak{m}$ is a filtered countable union of principal subideals; then it is easily seen that we may write $\mathfrak{m} = \bigcup_{n \in \mathbb{N}} V a_n$ for a system $(a_n \mid n \in \mathbb{N})$ of elements of A such that $Va_n \subset \mathfrak{m} \cdot a_{n+1}$ for every $n \in \mathbb{N}$: the details are left to the reader. Hence, for every $n \in \mathbb{N}$ let $c_n \in \mathfrak{m}$ such that $a_n = c_n a_{n+1}$. We consider the inductive system $L_\bullet := (L_n \mid n \in \mathbb{N})$ with $L_n := V$ for every $n \in \mathbb{N}$, with V-linear transition map $\varphi_n : L_n \to L_{n+1}$ such that $\varphi_n(1) := c_n$ for every $n \in \mathbb{N}$. The inductive limit L of $L_\bullet$ is the set of equivalence classes $[x, n]$ of all pairs (x, n) with $n \in \mathbb{N}$ and $x \in L_n$. We have an obvious V-linear surjection

$$\psi : L \to \mathfrak{m} \qquad [x, n] \mapsto xa_n.$$

Notice that if $[x, n] \in \operatorname{Ker} \psi$, then $a_n \cdot [x, n] = [a_n x, n] = 0$; on the other hand, for every $k \geq n$ there exists $y \in V$ such that $[x, n] = [y, k]$, whence $a_k \cdot [x, n] = a_k \cdot [y, k] = 0$ as well. This shows that $\mathfrak{m} \cdot \operatorname{Ker} \psi = 0$. Therefore, $\mathfrak{m} \otimes_V \psi : \mathfrak{m} \otimes_V L \to \widetilde{\mathfrak{m}} := \mathfrak{m} \otimes_V \mathfrak{m}$ is an isomorphism. But by construction, L is a flat V-module, hence the natural map $\mathfrak{m} \otimes_V L \to \mathfrak{m}L$ is an isomorphism; lastly, for every $[x, n] \in L$ we have $[x, n] = c_n[x, n+1]$, so $\mathfrak{m}L = L$. Summing up, $\mathfrak{m} \otimes_V \psi$ is naturally identified with the isomorphism :

$$L \xrightarrow{\sim} \widetilde{\mathfrak{m}} \qquad [x, n] \mapsto x \otimes a_n.$$

(iii) Furthermore, the functor $\mathbf{E}$ induces a functor on almost algebras

$$\mathbf{E}^a : (A_0, \mathfrak{m})^a\text{-}\mathsf{Alg} \to (\mathbf{E}_0, \mathfrak{m}_\mathbf{E})^a\text{-}\mathsf{Alg} \qquad R^a \mapsto \mathbf{E}(R/pR)^a.$$

Indeed, let $f : R \to S$ be a homomorphism of A_0-algebras such that $f^a : R^a \to S^a$ is an isomorphism of $(A_0, \mathfrak{m})^a$-algebras, and set $f_0 := f \otimes_\mathbb{Z} \mathbb{Z}/p\mathbb{Z}$; we need to check that $\mathbf{E}(f_0)^a$: $\mathbf{E}(R/pR)^a \to \mathbf{E}(S/pS)^a$ is an isomorphism of $(\mathbf{E}_0, \mathfrak{m}_\mathbf{E})^a$-algebras. However, $\mathbf{E}(f_0)$ is the limit of the system of rings $(R_n \mid n \in \mathbb{N})$, with $R_n := R/pR$ for every $n \in \mathbb{N}$, and with transition map $R_{n+1} \to R_n$ given by the Frobenius endomorphism $\Phi_{R/pR}$. Now, if $g : A_0 \to R$ is the structure map of the A_0-algebra R, then R_0 is naturally an $\mathbf{E}_0$-algebra, via the composition $g' : \mathbf{E}_0 \to R_0$ of the projection $\overline{u}_{A_0/pA_0} : \mathbf{E}_0 \to A_0/pA_0$ and $g \otimes_\mathbb{Z} \mathbb{Z}/p\mathbb{Z} : A_0/pA_0 \to R_0$. Let $\Phi_{\mathbf{E}_0}$ be the Frobenius automorphism of $\mathbf{E}_0$; then for every $n \in \mathbb{N}$, the ring R_n is an $\mathbf{E}_0$-algebra with structure morphism $g' \circ \Phi_{\mathbf{E}_0}^{-n} : \mathbf{E}_0 \to R_n$, *i.e.* $R_n = (R_0)_{(\Phi_{\mathbf{E}_0}^{-n})}$, and $\Phi_{R/pR} : R_{n+1} \to R_n$ is a homomorphism of $\mathbf{E}_0$-algebras, for these $\mathbf{E}_0$-algebra structures. Likewise, $\mathbf{E}(S/pS)$ is the limit of a system of $\mathbf{E}_0$-algebras $(S_n \mid n \in \mathbb{N})$, and f induces a system of maps of $\mathbf{E}_0$-algebras $f_n := f_0 : R_n \to S_n$, whose inverse limit is $\mathbf{E}(f_0)$. Since f^a is an isomorphism, and since $\Phi_{\mathbf{E}_0} : (\mathbf{E}_0, \mathfrak{m}_\mathbf{E}) \xrightarrow{\sim} (\mathbf{E}_0, \mathfrak{m}_\mathbf{E})$ is an isomorphism of basic setups, it is easily seen that $f_n^a : R_n^a \to S_n^a$ is an isomorphism of $(\mathbf{E}_0, \mathfrak{m}_\mathbf{E})^a$-algebras, for every $n \in \mathbb{N}$; on the other hand, the functor $(-)^a$ commutes with limits, since it has a left adjoint, whence the contention.

16.9.34. Let A be a Tate ring, $A_0 \subset A$ a subring of definition, $p \in \mathbb{N}$ a prime integer, and $A_1 \subset A$ the p-root closure of A_0 in A (see definition 9.8.24(ii)). Moreover, suppose there exists $b \in A_0^{\circ\circ} \cap A^\times$ with $pA_0 \subset b^p A_0$, and let $A_0^\wedge$ and $A_1^\wedge$ be the b-adic completions of A_0 and A_1. Notice that the Frobenius endomorphism Φ_{A_i} of $A_i/b^p A_i$ induces a ring homomorphism

$$\overline{\Phi}_{A_i} : A_i/bA_i \to A_i/b^p A_i \qquad \text{for } i = 0, 1.$$

Furthermore, let $(A_0, \mathfrak{m})$ be a basic setup, such that $\mathfrak{m}$ is the filtered union of a countable system of principal subideals, and denote by $\overline{\mathfrak{m}}$ the image of $\mathfrak{m}$ in $\overline{A}_0 := A_0/pA_0$. Then $\mathfrak{m}$ is generated by the system $(x^p \mid x \in \mathfrak{m})$ ([75, Prop.2.17]), and therefore the Frobenius endomorphism Φ of $\overline{A}_0$ is a morphism of basic setups in the sense of [75, §3.5]

$$\Phi : (\overline{A}_0, \overline{\mathfrak{m}}) \to (\overline{A}_0, \overline{\mathfrak{m}}).$$

As detailed in [75, §3.5.7], the latter induces a pull-back functor

$$(\overline{A}_0, \overline{\mathfrak{m}})^a\text{-}\mathsf{Alg} \to (\overline{A}_0, \overline{\mathfrak{m}})^a\text{-}\mathsf{Alg} \qquad B \mapsto B_{(\Phi)}.$$

Definition 16.9.35. In the situation of (16.9.34), we say that the basic setup $(A_0, \mathfrak{m})$ is *almost perfectoid* if A_0 is complete and separated, and the Frobenius endomorphism of A_0/b^pA_0 induces an isomorphism of $(A_0, \mathfrak{m})^a$-algebras $\overline{\Phi}^a_{A_0} : (A_0/bA_0)^a \xrightarrow{\sim} (A_0/b^pA_0)^a_{(\Phi)}$.

Remark 16.9.36. The following proposition 16.9.37(i) implies in particular that definition 16.9.35 is independent of the choice of the element $b \in A_0$ such that $p \in b^pA_0$: if $b' \in A_0$ is another such element, and if the b-adic topology on A_0 agrees with the b'-adic topology, then $\overline{\Phi}^a_{A_0}$ is an isomorphism if and only if the same holds for the corresponding morphism of $(A_0, \mathfrak{m})^a$-algebras $(A_0/b'A_0)^a \xrightarrow{\sim} (A_0/b'^pA_0)^a_{(\Phi)}$. See also lemma 17.5.10.

Proposition 16.9.37. (i) *In the situation of* (16.9.34)*, the following conditions are equivalent :*

(a) *The basic setup* $(A_0^\wedge, \mathfrak{m}A_0^\wedge)$ *is almost perfectoid.*

(b) *The basic setup* $(A_1^\wedge, \mathfrak{m}A_1^\wedge)$ *is almost perfectoid, and the inclusion map* $j : A_0 \to A_1$ *induces isomorphisms of* $(A_0, \mathfrak{m})^a$*-algebras* $j^a : A_0^a \xrightarrow{\sim} A_1^a$*.*

(c) *The topological closure* $\overline{C} \subset A_0$ *of the subring* $C := \mathbb{Z}[a^p \mid a \in A_0]$ *contains* $\mathfrak{m}$*, and* j *induces an isomorphism of* $(A_0, \mathfrak{m})^a$*-algebras* $j^a : A_0^a \xrightarrow{\sim} A_1^a$*.*

(ii) *If* A_0 *is integrally closed (resp.* p*-root closed) in* A*, then* A^a_{0*} *is integrally closed (resp.* p*-root closed) in* $A^a_{0*}[b^{-1}]$*.*

(iii) *If* $(A_0, \mathfrak{m})$ *is an almost perfectoid basic setup, the same holds for* $(A^a_{0*}, \mathfrak{m}A^a_{0*})$*.*

(iv) *If* $(A_0, \mathfrak{m})$ *is an almost perfectoid basic setup, and the unit of adjunction* $A_0 \to (A_0)^a_*$ *is an isomorphism, then* $A_0 = A_1$*.*

Proof. By simple inspection we see that (i.b)⇒(i.a). Conversely, suppose that (i.a) holds, and let also $j^\wedge : A_0^\wedge \to A_1^\wedge$ be the b-adic completion of j; in order to show (i.b), it suffices to check :

Claim 16.9.38. $\mathrm{Ker}\, \overline{\Phi}^a_{A_0} = 0 \Leftrightarrow j^a$ is an isomorphism $\Leftrightarrow (j^\wedge)^a$ is an isomorphism.

Proof of the claim. Suppose first that $\mathrm{Ker}\, \overline{\Phi}^a_{A_0} = 0$. We can construct A_1 as the increasing union of the ascending chain $(A_{0,n} \mid n \in \mathbb{N})$ of subrings of A defined inductively as follows: $A_{0,0} := A_0$, and $A_{0,n} := A_{0,n-1}[\Sigma_n]$, with $\Sigma_n := \{x \in A \mid x^p \in A_{0,n-1}\}$, for every $n > 0$. Thus, we are reduced to showing that the inclusion $A_0 \to A_{0,n}$ induces an isomorphism $A_0^a \xrightarrow{\sim} A^a_{0,n}$ for every $n \in \mathbb{N}$. However, if for some $n > 0$ the inclusion $j_{n-1} : A_{0,n-1} \to A_{0,n}$ induces an isomorphism $j^a_{n-1} : A^a_{0,n-1} \xrightarrow{\sim} A^a_{0,n}$, then the same holds for $j_n : A_{0,n} \to A_{0,n+1}$: indeed, let $x \in \Sigma_{n+1}$; since $x^p \in A_{0,n}$, by assumption we have $(ax)^p \in A_{0,n-1}$ for every $a \in \mathfrak{m}$, whence $ax \in \Sigma_n \subset A_{0,n}$. Thus, we are further reduced to checking that j_0 induces an isomorphism $j_0^a : A_0^a \xrightarrow{\sim} A^a_{0,1}$, *i.e.* that $(\mathrm{Coker}\, j_0)^a = 0$. We argue as in the proof of lemma 9.8.26(i) : let $x \in A_1 \setminus A_0$, and denote by $m \in \mathbb{N}$ the smallest integer such that $b^m x \cdot \mathfrak{m} \not\subset A_0$. Hence, $y := b^{mp}x^p \in A_0$, and $(b^{m+1}x)^p = b^p y^p \in b^pA_0$. By assumption, for every $a \in \mathfrak{m}$ we then have $z \in A_0$ such that $ab^{m+1}x = bz$, whence $ab^m x \in A_0$, contradicting the choice of m.

Conversely, suppose that j^a is an isomorphism, and let $x \in A_0$ be an element whose class $\overline{x} \in A_0/bA_0$ lies in $\mathrm{Ker}\, \overline{\Phi}_{A_0}$; then $x^p \in b^pA_0$, so $(x/b)^p \in A_0$, and our assumption implies that $\mathfrak{m} \cdot x \in bA_0$, *i.e.* $\mathfrak{m} \cdot \overline{x} = 0$.

Next, if j^a is an isomorphism, the same holds for $j^a_k := A_0^a/b^kA_0 \otimes_{A_0^a} j^a : A_0^a/b^kA_0^a \to A_1^a/b^kA_1^a$, for every $k \in \mathbb{N}$, and then also for the limit of the inverse system $(j^a_k \mid k \in \mathbb{N})$. But the functor $(-)^a$ commutes with limits, since it has a left adjoint, so $(j^\wedge)^a$ is an isomorphism.

Conversely, if $(j^\wedge)^a$ is an isomorphism, the induced map $A_0^\wedge[b^{-1}]/A_0^\wedge \to A_1^\wedge[b^{-1}]/A_1^\wedge$ is an almost isomorphism of A_0-modules. But proposition 8.3.33(iii) easily implies that the natural map $A_0[b^{-1}]/A_0 \to A_0^\wedge[b^{-1}]/A_0^\wedge$ is bijective, and similarly for A_1; hence j induces isomorphisms $A_0^a[b^{-1}]/A_0^a \xrightarrow{\sim} A_1^a[b^{-1}]/A_1^a$ and $A_0[b^{-1}] \xrightarrow{\sim} A_1[b^{-1}]$. By the 5-lemma, it follows easily that j^a is an isomorphism. ◊

Next, let $\mathfrak{m}_{\overline{C}} \subset \overline{C}$ be the ideal generated by $(a^p \mid a \in \mathfrak{m})$. Since $\mathfrak{m}$ is the filtered union of a countable system of principal subideals, the same holds for $\overline{\mathfrak{m}}_C$; by the same token, since $\mathfrak{m} = \mathfrak{m}^2$, for every $a \in \mathfrak{m}$ there exist $b, c \in \mathfrak{m}$ such that $a = bc$, whence $a^p = b^p c^p$, which shows that $\mathfrak{m}_{\overline{C}} = \mathfrak{m}_{\overline{C}}^2$. Hence, $(\overline{C}, \mathfrak{m}_{\overline{C}})$ is a basic setup; moreover, we have already remarked that $\mathfrak{m} = \mathfrak{m}_{\overline{C}} A_0$, hence the inclusion $\overline{C} \to A_0$ is a morphism of basic setups $(\overline{C}, \mathfrak{m}_{\overline{C}}) \to (A_0, \mathfrak{m})$.

Notice then that the $\overline{C}$-module $A_0/\overline{C}$ is the limit of the inverse system

$$(M_n := A_0/(b^n A_0 + C) \mid n \in \mathbb{N}).$$

Hence, $\mathfrak{m} \subset \overline{C}$ if and only if the $(\overline{C}, \mathfrak{m}_{\overline{C}})^a$-module $(A_0/\overline{C})^a$ vanishes, if and only if $M_n^a = 0$ for every $n \in \mathbb{N}$. Now, for given $n \in \mathbb{N}$, consider the b^p-adic filtration on M_n, and let $\mathrm{gr}_\bullet M_n$ be the associated graded $\overline{C}$-module; clearly $\mathrm{gr}_i M_n$ is a quotient of M_p, for every $i \in \mathbb{N}$. Hence, $\mathfrak{m} \subset \overline{C}$ if and only if $M_p^a = 0$; the latter in turns holds if and only if $\mathrm{Coker}\,\overline{\Phi}_{A_0}^a = 0$. This already shows that (a),(b)⇒(c). Conversely, if (c) holds, in order to deduce (a), it suffices to check that $\mathrm{Ker}\,\overline{\Phi}_{A_0}^a = 0$; since j^a is an isomorphism, the latter holds by claim 16.9.38.

(ii): Notice first that since $b \cdot \mathbf{1}_{A_0}$ is an injective map, the same holds for $(b \cdot \mathbf{1}_{A_0})_*^a = b \cdot \mathbf{1}_{A_{0*}^a}$, since the functor $(-)_*^a$ commutes with all limits. Thus, A_{0*}^a is naturally a subring of $A_{0*}^a[b^{-1}]$. Now, let $x \in A_{0*}^a[b^{-1}]$ be integral over A_{0*}^a; hence there exist $n, k \in \mathbb{N}$ and $y, a_1, \dots, a_k \in A_{0*}^a$ such that $x = y/b^n$ and

$$(y/b^n)^k + a_1 \cdot (y/b^n)^{k-1} + \cdots + a_k = 0.$$

Recall that $A_{0*}^a = \mathrm{Hom}_{A_0}(\widetilde{\mathfrak{m}}, A_0)$, with $\widetilde{\mathfrak{m}} := \mathfrak{m} \otimes_{A_0} \mathfrak{m}$. Then we get $(y(t)/b^n)^k + a_1(t) \cdot (y(t)/b^n)^{k-1} + \cdots + a_k(t) = 0$ for every $t \in \widetilde{\mathfrak{m}}$, and if A_0 is integrally closed in A, it follows that $y(t)/b^n \in A_0$ for every such t, *i.e.* $x \in A_{0*}^a$. One shows likewise that if A_0 is p-root closed in A, then A_{0*}^a is p-root closed in $A_{0*}^a[b^{-1}]$.

(iii): By assumption, $b \cdot \mathbf{1}_{A_0}$ is an injective map, so the same holds for $b \cdot \mathbf{1}_{A_{0*}^a}$, because the functor $(-)_*^a$ commutes with limits. This shows that A_{0*}^a has no b-torsion; next, we need to check that A_{0*}^a is b-adically complete and separated. This follows from the more general :

Claim 16.9.39. Let $(V, \mathfrak{m}_V)$ be a basic setup, A a V-algebra, $I \subset A$ an ideal of finite type, M an A-module whose I-adic topology is complete and separated. Then the same holds for the I-adic topology of M_*^a.

Proof of the claim. Both functors $(-)^a$ and $(-)_*$ commute with limits, since they are right adjoints, hence M_*^a is the limit of the inverse system $((M/I^n M)_*^a \mid n \in \mathbb{N})$. For every $n \in \mathbb{N}$, let M_n be the image of the natural map $\pi_n : M_*^a \to (M/I^n M)_*^a$; it follows that M_*^a is also the limit of the induced inverse system $(M_n \mid n \in \mathbb{N})$, and therefore M_*^a is complete and separated for the linear topology that admits the fundamental system of open submodules $(\mathrm{Ker}\,\pi_n = (I^n M)_*^a \mid n \in \mathbb{N})$ (corollary 8.2.16(i)). Since $I^n M_*^a \subset (I^n M)_*^a$ for every $n \in \mathbb{N}$, the claim now follows from lemma 8.3.12. ◊

It remains to check that the Frobenius endomorphism of $R := A_{0*}^a$ induces an isomorphism $(R/bR)^a \xrightarrow{\sim} (R/b^p R)_{(\Phi)}^a$; the latter is clear, since the same holds by assumption for the Frobenius endomorphism of A_0, and the natural map $A_0 \to A_{0*}^a$ is an almost isomorphism.

(iv): Under the stated assumptions, j induces an isomorphism $A_0 \xrightarrow{\sim} (A_0)_*^a \xrightarrow{\sim} (A_1)_*^a$, by (i), and on the other hand, $(A_1)_*^a$ is p-root closed in $A_{0*}^a[b^{-1}] = A$, by (ii), hence A_0 is p-root closed in A, *i.e.* $A_0 = A_1$. □

16.9.40. Let A be a perfectoid Tate ring, $A_0 \subset A$ a perfectoid subring of definition, and $b \in A_0^{\circ\circ} \cap A^\times$, so that the topology of A_0 is b-adic. Let also $g_\bullet := (g_n \mid n \in \mathbb{N}) \in \mathbf{E}_0 := \mathbf{E}(A_0)$, and set $g := g_0 = \overline{u}_{A_0}(g_\bullet)$. Hence, g^γ is well defined in A_0 for every $\gamma \in \mathbb{N}[1/p]$, and set

$$\mathfrak{m} := \bigcup_{n\in\mathbb{N}} g_n A_0 \qquad A'_0 := \mathrm{Im}(A_0 \to A_0[1/g]) \qquad \text{and} \qquad A_1 := \{a \in A_0[1/g] \mid \mathfrak{m}\cdot a \subset A'_0\}.$$

Clearly $(A_0, \mathfrak{m})$ is a basic setup fulfilling the conditions of (16.9.34).

Lemma 16.9.41. *With the notation of* (16.9.40)*, let A_0^a be the $(A_0, \mathfrak{m})^a$-algebra associated with A_0. Then the natural map $A_0 \to A_1$ factors through the unit of adjunction $A_0 \to A_{0*}^a$ and an isomorphism of A_0-algebras $A_{0*}^a \xrightarrow{\sim} A_1$.*

Proof. We claim that the induced surjection $\pi : A_0 \to A'_0$ induces an isomorphism of $(A_0, \mathfrak{m})^a$-algebras $\pi^a : A_0^a \xrightarrow{\sim} A_0'^a$. Indeed, if $a \in \mathrm{Ker}\,\pi$, there exists $n \in \mathbb{N}$ such that $g^n a = 0$ in A_0; then $(g^{n/p^k}a)^{p^k} = 0$ in A_0, and consequently $g^{n/p^k}a = 0$ in A_0 for every $k \in \mathbb{N}$, due to corollary 16.3.63(i), whence the contention. Since the natural map $A_0 \to A_1$ factors through π and the inclusion $i : A'_0 \to A_1$, and since π^a is an isomorphism we are reduced to checking that i factors through the unit of adjunction $A'_0 \to A_{0*}'^a$ and an isomorphism $A_{0*}'^a \xrightarrow{\sim} A_1$.

Next, we claim that the surjection $\mathfrak{m} \to \mathfrak{m}A'_0$ is bijective. Indeed, say that $x \in \mathfrak{m}$ and $\pi(x) = 0$; we may write $x = g^\gamma y$ for some $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$, and then clearly $\pi(y) = 0$. But by the foregoing, it follows that $g^\gamma y = 0$, whence the contention.

Set $\widetilde{\mathfrak{m}} := \mathfrak{m} \otimes_{A_0} \mathfrak{m}$; by the foregoing, the isomorphism π^a induces identifications :

$$A_{0*}^a = \mathrm{Hom}_{A_0}(\widetilde{\mathfrak{m}}, A_0) \xrightarrow{\sim} A_{0*}'^a = \mathrm{Hom}_{A_0}(\widetilde{\mathfrak{m}}, A'_0) = \mathrm{Hom}_{A'_0}(\mathfrak{m}A'_0 \otimes_{A'_0} \mathfrak{m}A'_0, A'_0).$$

Notice that the multiplication map $\mathfrak{m}A'_0 \otimes_{A'_0} \mathfrak{m}A'_0 \to \mathfrak{m}A'_0$ is the colimit of the system of isomorphisms $(g^\gamma A'_0 \otimes_{A'_0} g^\gamma A'_0 \xrightarrow{\sim} g^{2\gamma}A'_0 \mid \gamma \in \mathbb{N}[1/p]\setminus\{0\})$, and it is therefore an isomorphism. So, finally, we get a natural identification

$$A_{0*}^a \xrightarrow{\sim} \mathrm{Hom}_{A'_0}(\mathfrak{m}A'_0, A'_0) = A_1$$

from which the lemma follows easily : details left to the reader. □

The following result generalizes the "perfectoid Abhyankar's lemma" of [6].

Theorem 16.9.42. *In the situation of* (16.9.40)*, let B be a finite étale $A_0[1/g]$-algebra, B_1 the integral closure of A_1 in B, and endow A_1 and B_1 with their b-adic topologies. For the almost structure given by $(A_0, \mathfrak{m})$, we have :*

- (i) *The basic setup $(B_1, \mathfrak{m}B_1)$ is almost perfectoid, and B_1 is p-root closed in $B_1[1/b]$.*
- (ii) *$(B_1/b^n B_1)^a$ is an étale $(A_0/b^n A_0)^a$-algebra of finite rank, for every $n \in \mathbb{N}$.*
- (iii) *If B is a faithfully flat $A_0[1/g]$-algebra, then $(B_1/b^n B_1)^a$ is a faithfully flat $(A_0/b^n A_0)^a$-algebra, for every $n \in \mathbb{N}$.*
- (iv) *A_1 is complete and separated, and is integrally closed in $A_0[1/g]$.*
- (v) *The unit of adjunction $B_1 \to B_{1*}^a$ is an isomorphism.*

Proof. Arguing as in (16.9.7), we may assume that $pA_0 \subset b^p A_0$, and $b = \overline{u}_{A_0}(b_\bullet)$ for some $b_\bullet \in \mathbf{E}(A_0)$, so that b^γ is well defined in A for every $\gamma \in \mathbb{Z}[1/p]$. We let $I := A_0 b + A_0 g$, and $U := \mathrm{Spec}\,A_0 \setminus \mathrm{Spec}\,A/I$; consider the quasi-affinoid ring $\underline{A}_0 := (A_0, A_0, U)$, and the rational subsets of $X := \mathrm{Spa}\,\underline{A}_0$

$$R_n := R_{A_0}\big(\tfrac{b^n}{g}\big) \cap X \qquad R'_n := R_{A_0}\big(\tfrac{g}{b^n}\big) \cap X \qquad \text{for every } n \in \mathbb{N}$$

(definition 15.4.14(iv)). Set $\mathsf{A}_n := \mathscr{O}_X^{\wedge+}(R_n)$ and $\mathsf{A}'_n := \mathscr{O}_X^{\wedge+}(R'_n)$ for every $n \in \mathbb{N}$; since $R_n \subset R_{n+1}$ for every $n \in \mathbb{N}$, we deduce a well defined inverse system of A_0-algebras $(\mathsf{A}_n \mid n \in \mathbb{N})$.

Claim 16.9.43. (i) The natural map $A_0 \to \mathscr{O}^{\wedge+}_X(X)$ induces an isomorphism $A^a_0 \xrightarrow{\sim} \mathscr{O}^{\wedge+}_X(X)^a$ of $(A_0, \mathfrak{m})^a$-algebras.

(ii) For every $i \in \mathbb{N}$, the following holds :

(a) The induced inverse system $(\mathsf{A}_n/b^i\mathsf{A}_n \mid n \in \mathbb{N})$ is almost essentially constant, relative to the basic setup $(A_0, \mathfrak{m})$ (see definition 14.2.11(iii)).

(b) The natural cone $(\rho_n : A_0 \to \mathsf{A}_n \mid n \in \mathbb{N})$ induces a universal cone $((A_0/b^iA_0)^a \to (\mathsf{A}_n/b^i\mathsf{A}_n)^a \mid n \in \mathbb{N})$ in the category of $(A_0, \mathfrak{m})^a$-algebras.

Proof of the claim. (i): By construction, $\mathscr{O}^{\wedge+}_X(X)$ is the integral closure of the image of A_0 in $A_U := \mathscr{O}_U(U)$. On the other hand, A^a_{0*} is integrally closed in A°_U (claim 16.8.20(ii)), and recall that A°_U is integrally closed in A_U (remark 8.3.10(iv)). It follows that the unit of adjunction $\eta : A_0 \to A^a_{0*}$ factors through the inclusion map $\mathscr{O}^{\wedge+}_X(X) \to A^a_{0*}$. Since η^a is an isomorphism, the assertion follows.

(ii): In light of (i) and theorem 16.7.41, the following sequence of $(A_0, \mathfrak{m})^a$-modules is short exact for every $n \in \mathbb{N}$:

$$0 \to A^a_0 \to \mathsf{A}^a_n \oplus \mathsf{A}'^a_n \to \mathscr{O}^+_X(R_n \cap R'_n)^a \to 0.$$

Moreover, clearly the image of b is a regular element in $\mathscr{O}^+_X(R_n \cap R'_n)$; by the snake lemma, we easily deduce, for every $n, i \in \mathbb{N}$, a short exact sequence of $(A_0, \mathfrak{m})^a$-modules

$$0 \to A^a_0/b^iA^a_0 \xrightarrow{r_n} A_0/b^iA_0 \otimes_{A_0} (\mathsf{A}_n \oplus \mathsf{A}'_n)^a \xrightarrow{s_n} A_0/b^iA_0 \otimes_{A_0} \mathscr{O}^+_X(R_n \cap R'_n)^a \to 0.$$

Let us show that for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$, every $n \in \mathbb{N}$ with $n\gamma \geq i$ and every $a \in A_0$ with $\rho_n(a) \in b^i\mathsf{A}_n$, we have $g^{2\gamma}a \in b^iA_0$. Indeed, let $\overline{a} \in A_0/b^iA_0$ be the image of a; then $r_n(\overline{a}) = (0, \overline{x})$ for some $\overline{x} \in \mathsf{A}'_n$, and we notice that $g^\gamma \cdot \overline{x} = b^{n\gamma} \cdot (g/b^n)^\gamma \cdot \overline{x}$, whence $g^\gamma \cdot \overline{x} = 0$, since $(g/b^n)^\gamma \in \mathsf{A}'_n$. It follows that $r_n(g^\gamma \cdot \overline{a}) = 0$, whence $g^{2\gamma} \cdot \overline{a} = 0$, as required. Lastly, let us check that for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$, every $n \in \mathbb{N}$ with $n\gamma \geq i$ and every $\overline{x} \in \mathsf{A}_n/b^i\mathsf{A}_n$ there exists $\overline{a} \in A_0/b^iA_0$ with $\rho_n(\overline{a}) = g^{2\gamma} \cdot \overline{x}$. To this aim, set $\overline{y} := s_n(\overline{x}, 0)$; again, we notice that $g^\gamma \cdot \overline{y} = b^{n\gamma} \cdot (g/b^n)^\gamma \cdot \overline{y} = 0$, so that $(g^\gamma\overline{x}, 0) \in \operatorname{Ker} s_n = \operatorname{Im} r_n$, whence the contention. This completes the proof of (ii.a). Assertion (ii.b) follows from the proof of (ii.a) and lemma 14.2.14(iii). ◊

Recall that $\mathscr{O}^\wedge_X(R_n) = \mathsf{A}_n[1/g]$, and set $\mathsf{B}_n := \mathsf{A}_n[1/g] \otimes_{A_0} B$ for every $n \in \mathbb{N}$; recall as well that A_n is perfectoid for its b-adic topology (proposition 16.7.25(iii) and theorem 16.5.13(iii)). Since the functor $(-)^a$ commutes with limits, from claim 16.9.43 we deduce that also the cone $(\rho_n \mid n \in \mathbb{N})$ is universal, *i.e.* we have an isomorphism of $(A_0, \mathfrak{m})^a$-algebras :

$$A^a_0 \xrightarrow{\sim} \lim_{i\in\mathbb{N}} \lim_{n\in\mathbb{N}} \mathsf{A}^a_n/b^i\mathsf{A}^a_n \xrightarrow{\sim} \lim_{n\in\mathbb{N}} \mathsf{A}^a_n. \tag{16.9.44}$$

Claim 16.9.45. $\mathfrak{m}\mathsf{A}_n$ is an open radical ideal of A_n, for every $n \in \mathbb{N}$.

Proof of the claim. Clearly $\mathfrak{m}\mathsf{A}_n$ is an open ideal of A_n, since $(b^n/g)^\gamma \in \mathsf{A}_n$ for every $\gamma \in \mathbb{N}[1/p]$. Moreover, set $J := \bigcup_{\gamma\in\mathbb{N}[1/p]\setminus\{0\}} b^\gamma\mathsf{A}_n$; by corollary 16.3.71, the quotient A_n/J is a perfect $\mathbb{F}_p$-algebra; it follows easily that $\mathfrak{m}/J$ is a radical ideal of A_n/J, whence the claim. ◊

Say that B is a projective $A_0[1/g]$-module of rank $\leq r$; from claim 16.9.45 and theorem 16.8.44, we deduce that for every $n \in \mathbb{N}$ there exists an étale A^a_n-algebra C_n of rank $\leq r$, unique up to unique isomorphism, with an isomorphism of $\mathsf{A}_n[1/g]$-algebras $C_n[1/g] \xrightarrow{\sim} \mathsf{B}_n$. From the uniqueness property of C_n, there follows a unique isomorphism of A^a_n-algebras :

$$\mathsf{A}^a_n \otimes_{\mathsf{A}^a_{n+1}} C_{n+1} \xrightarrow{\sim} C_n \qquad \text{for every } n \in \mathbb{N}. \tag{16.9.46}$$

Denote by D (resp. by E) the inverse limit of the resulting system $(C_n \mid n \in \mathbb{N})$ of A^a_0-algebras (resp. $(\mathsf{B}_n \mid n \in \mathbb{N})$ of A_0-algebras), and for every $i \in \mathbb{N}$ let as well D_i be the limit of the induced system $(C_n/b^iC_n \mid n \in \mathbb{N})$ of $A^a_0/b^iA^a_0$-algebras. By proposition 14.2.32(ii,iii),

$(C_n/b^iC_n \mid n \in \mathbb{N})$ is almost essentially constant, and the projection $D_i \to C_n/b^iC_n$ induces an isomorphism of $A_0^a/b^iA_0^a$-algebras :

$$\mathsf{A}_n^a \otimes_{A_0^a} D_i \xrightarrow{\sim} C_n/b^iC_n \qquad \text{for every } n \in \mathbb{N}. \tag{16.9.47}$$

Notice that b and g are regular elements of A_n, and then they are also regular elements of C_{n*}, since C_n is a flat A_n^a-algebra; in view of the induced isomorphism

$$D_* \xrightarrow{\sim} \lim_{n\in\mathbb{N}} C_{n*} \tag{16.9.48}$$

(proposition 1.3.25(iii)) it follows easily that b and g are regular elements of D_*.

Claim 16.9.49. (i) For every $n \in \mathbb{N}$, the ring C_{n*} is perfectoid for its b-adic topology.

(ii) D_* is p-root closed in $D_*[1/b]$ and is integrally closed in $D_*[1/g]$.

(iii) The A_0^a/b^iA_0-algebra D_i is étale of rank $\leq r$ for every $i \in \mathbb{N}$.

(iv) If B is a faithfully flat $A_0[1/g]$-algebra, then D_i is a faithfully flat A_0^a/b^iA_0-algebra for every $i \in \mathbb{N}$.

(v) B and D_* are integrally closed in E.

(vi) The basic setup $(D_*, \mathfrak{m}D_*)$ is almost perfectoid for the b-adic topology of D_*, and the projection $D \to D_i$ factors through an isomorphism $D/b^iD \xrightarrow{\sim} D_i$ for every $i \in \mathbb{N}$.

Proof of the claim. (i) follows from proposition 16.8.29 and claim 16.9.45, since we have already recalled that A_n is perfectoid for its b-adic topology. Together with corollary 16.3.75 and lemma 9.8.26(i) we deduce that C_{n*} is p-root closed in $C_{n*}[1/b]$, for every $n \in \mathbb{N}$. Then lemma 9.8.26(iii.a) and the isomorphism (16.9.48) imply that D_* is p-root closed in the limit L of the system $(C_{n,*}[1/b] \mid n \in \mathbb{N})$. However, the induced map $D_* \to L$ factors through an injective map $D_*[1/b] \to L$, so D_* is also p-root closed in $D_*[1/b]$.

Similarly, C_{n*} is integrally closed in $C_{n*}[1/g] = B_n$ for every $n \in \mathbb{N}$, due to claim 16.8.20(ii); it follows easily that D_* is integrally closed in E. But the induced map $D_* \to E$ factors through an injective map $D_*[1/g] \to E$, so D_* is also integrally closed in $D_*[1/g]$.

(iii) follows from theorem 14.2.39(iii,iv).

(iv): If B is a faithfully flat $A_0[1/g]$-algebra, C_n is a faithfully flat A_n^a-algebra for every $n \in \mathbb{N}$ (theorem 16.8.44(ii)); then the assertion follows from theorem 14.2.39(ii)).

(v): We have already observed that D_* is integrally closed in E. Next, by construction, $\mathsf{B}_n = B \otimes_{A_0[1/g]} \mathsf{A}_n[1/g]$ for every $n \in \mathbb{N}$. Since B is a projective $A_0[1/g]$-module of finite rank, there follows a natural identification :

$$E \xrightarrow{\sim} B \otimes_{A_0[1/g]} \lim_{n\in\mathbb{N}} \mathsf{A}_n[1/g].$$

Since B is an étale $A_0[1/g]$-algebra, by proposition 14.3.25 we are then reduced to showing that $A_0[1/g]$ is integrally closed in the limit L of the system of A_0-algebras $(\mathsf{A}_n[1/g] \mid n \in \mathbb{N})$. However, invoking again claim 16.8.20(ii) we see that A_{n*}^a is integrally closed in $\mathsf{A}_n[1/g]$ for every $n \in \mathbb{N}$, hence the limit L' of the system $(\mathsf{A}_{n*}^a \mid n \in \mathbb{N})$ is integrally closed in L, and therefore $L'[1/g]$ is integrally closed in L. But in view of (16.9.44), we have a natural identification of A_0-algebras : $A_0[1/g] \xrightarrow{\sim} A_{0*}^a[1/g] \xrightarrow{\sim} L'[1/g]$, whence the assertion.

(vi): Since C_n is the limit of the inverse system $(C_n/b^iC_n \mid i \in \mathbb{N})$ for every $n \in \mathbb{N}$, we obtain a natural isomorphism of A_0^a-algebras :

$$D \xrightarrow{\sim} \lim_{i\in\mathbb{N}} D_i.$$

On the other hand, in view of (16.9.47) we have a natural isomorphism of A_0^a-algebras

$$(D_{i+1} \otimes_{A_0^a} A_0^a/b^iA_0^a) \otimes_{A_0^a} \mathsf{A}_n^a \xrightarrow{\sim} C_n/b^iC_n \qquad \text{for every } n, i \in \mathbb{N}$$

whence, again by theorem 14.2.39(i), an induced isomorphism of A_0^a-algebras :

$$D_{i+1} \otimes_{A_0^a} A_0^a/b^i A_0^a \xrightarrow{\sim} D_i \qquad \text{for every } i \in \mathbb{N}. \tag{16.9.50}$$

For every $i \in \mathbb{N}$, let $\pi_i : D \to D_i$ be the projection; notice that $I := \operatorname{Ker} \pi_1 = bD + \operatorname{Ker} \pi_{i+1}$ for every $i \in \mathbb{N}$, in light of the isomorphism $D_{i+1}/bD_{i+1} \xrightarrow{\sim} D_1$ deduced from (16.9.50). By [75, Lemma 5.3.5(i)], it follows that $I = \bigcap_{i\in\mathbb{N}}(bD + \overline{I^{i+1}}) = \overline{bD}$ (where $\overline{J}$ denotes the closure of J, for every ideal $J \subset D$: see [75, Def.5.3.1(iii)]). By [75, Lemma 5.3.8(iii)] we deduce that $I = bD$, and more generally $b^i D = \operatorname{Ker} \pi_i$ for every $i \in \mathbb{N}$. On the other hand, π_i is an epimorphism for every $i \in \mathbb{N}$, by lemma 14.2.24(i), so it induces an isomorphism $D/b^i D \xrightarrow{\sim} D_i$, for every $i \in \mathbb{N}$. Hence, the natural morphism $D \to \lim_{i\in\mathbb{N}} D/b^i D$ is an isomorphism of A_0^a-algebras, so we have an induced isomorphism of A_1-algebras $D_* \xrightarrow{\sim} \lim_{i\in\mathbb{N}}(D/b^i D)_*$ (lemma 16.9.41). As we have already noticed, b is regular in D_*, so for every $i \in \mathbb{N}$ we get a short exact sequence of A_0^a-modules $0 \to D \xrightarrow{b^i \cdot \mathbf{1}_{D_*}} D \to D/b^i D \to 0$ and since the functor $(-)_*$ is left exact, we deduce an injective A_1-linear map

$$D_*/b^i D_* \to (D/b^i D)_* \qquad \text{for every } i \in \mathbb{N}$$

from which it follows easily that also the induced map $D_* \to \lim_{i\in\mathbb{N}} D_*/b^i D_*$ is an isomorphism, hence D_* is b-adically complete and separated. In order to show that $(D_*, \mathfrak{m}D_*)$ is almost perfectoid, it remains only to check that the Frobenius endomorphism of D_*/pD_* induces an isomorphism $D/bD \xrightarrow{\sim} (D/b^p D)_{(\Phi)}$ of A_0^a/bA_0^a-algebras (where Φ denotes the Frobenius endomorphism of A_0/pA_0). But we have already seen that $D/b^i D$ is the inverse limit of the system $(C_n/b^i C_n \mid n \in \mathbb{N})$, for every $i \in \mathbb{N}$, hence we are reduced to checking that the Frobenius endomorphism of C_{n*}/pC_{n*} induces an isomorphism $C_n/bC_n \xrightarrow{\sim} (C_n/b^p C_n)_{(\Phi)}$ of A_0^a/bA_0^a-algebras, for every $n \in \mathbb{N}$. The latter is clear, since we know already that C_{n*} is perfectoid (corollary 16.3.3). ◊

Next, recall that for every $n \in \mathbb{N}$ we have A_0^a-algebras $\mathsf{A}_{n,0}, \dots, \mathsf{A}_{n,r}$, and an isomorphism of A_0^a-algebras $\mathsf{A}_n^a \xrightarrow{\sim} \mathsf{A}_{n,0} \times \cdots \times \mathsf{A}_{n,r}$ such that $C_{n,k} := \mathsf{A}_{n,k} \otimes_{\mathsf{A}_n^a} C_n$ is an $\mathsf{A}_{n,k}$-module of constant rank k, for every $k = 0, \dots, r$ ([75, Prop.4.3.27]). For every $n \in \mathbb{N}$ and $k = 0, \dots, r$ consider the map of sets :

$$\chi^{(n,k)} : C_{n,k*} \to \mathsf{A}_{n,k*}^a[X] \qquad c \mapsto \chi_c(X)$$

which associates with every $c \in C_{n,k*}$ the characteristic polynomial $\chi_c(X)$ of the $\mathsf{A}_{n,k}^a$-linear endomorphism $c \cdot \mathbf{1}_{C_{n,k}}$ of $C_{n,k}$ (see [75, §4.4.29]); by [75, Prop.4.4.30] we have $\chi_c(c) = 0$ for every such c. By virtue of (16.9.46), we see that the restriction map $\mathsf{A}_{n+1} \to \mathsf{A}_n$ induces isomorphisms of A_0^a-algebras

$$\mathsf{A}_n^a \otimes_{\mathsf{A}_{n+1}^a} \mathsf{A}_{n+1,k} \xrightarrow{\sim} \mathsf{A}_{n,k} \qquad \text{for every } k = 0, \dots, r$$

and from the compatibility of traces with ring extensions ([75, Prop.4.1.8(ii)]), we deduce for every $n \in \mathbb{N}$ and $k = 0, \dots, r$ a commutative diagram :

$$\begin{array}{ccc} C_{n+1,k*} & \xrightarrow{\chi^{(n+1,k)}} & \mathsf{A}_{n+1,k*}^a[X] \\ \downarrow & & \downarrow \\ C_{n,k*} & \xrightarrow{\chi^{(n,k)}} & \mathsf{A}_{n,k*}^a[X] \end{array}$$

whose vertical arrows are induced by the induced projection $\mathsf{A}_{n+1,k} \to \mathsf{A}_{n,k}$. For every $k = 0, \dots, r$, let $\mathsf{A}^{(k)}$ be the limit of the induced inverse system of A_0^a-algebras $(\mathsf{A}_{n,k} \mid n \in \mathbb{N})$, and set $D^{(k)} := \mathsf{A}^{(k)} \otimes_{A_0^a} D$; in view of (16.9.44), there follows an isomorphism of A_0^a-algebras $D \xrightarrow{\sim} D^{(0)} \times \cdots \times D^{(r)}$. Notice as well that $\chi_c(X)$ is a monic polynomial of degree k, for every

$n \in \mathbb{N}$, every $k = 0, \dots, r$ and and every $c \in C_{n,k*}$; in light of (16.9.48), it follows easily that the limit of the system of maps $(\chi^{(n,k)} \mid n \in \mathbb{N})$ is a well defined map of sets

$$\chi^{(k)} : D_*^{(k)} \to \mathsf{A}_*^{(k)}[X] \qquad d \mapsto \chi_d(X) \qquad \text{for every } k = 0, \dots, r.$$

Moreover, $\chi_d(X)$ is a monic polynomial with $\chi_d(d) = 0$ for every $k = 0, \dots, r$ and every $d \in D_*^{(k)}$. Taking into account lemma 16.9.41, it follows that D_* is an integral A_1-algebra. Since both D_* and B are integrally closed subrings of E (claim 16.9.49(v)), and since $A_1 \subset A_0[1/g]$, we deduce that $D_* \subset B$, and hence D_* is also the integral closure of A_1 in B, *i.e.* $D_* = B_1$. Then assertions (i), (ii) and (iii) of the theorem follow from claim 16.9.49.

(iv): By construction, A_1 is an open bounded subring of A, hence it is complete and separated for the topology induced by A, which agrees with the b-adic topology (proposition 8.3.18(i,ii)). In order to show that A_1 is integrally closed in $A_0[1/g]$, consider the case where $B = A_0[1/g]$; then $C_n = A_{0,n}$ for every $n \in \mathbb{N}$, so that $B_1 = D_* = A_{0*}^a = A_1$, whence the assertion. □

Remark 16.9.51. (i) In the situation of theorem 16.9.42, let $g'_\bullet := (g'_n \mid n \in \mathbb{N}) \in \mathbf{E}_0$ be another element, and $g' := g'_0 = \overline{u}_{A_0}(g'_\bullet)$. Let also $A''_0 := \mathrm{Im}(A_0 \to A_0[1/(gg')])$ and set

$$\mathfrak{m}' := \bigcup_{n\in\mathbb{N}} g'_n A_0 \qquad \mathfrak{m}'' := \mathfrak{m} \cdot \mathfrak{m}' \qquad A_2 := \{a \in A_0[1/(gg')] \mid \mathfrak{m}'' \cdot a \subset A''_0\}.$$

Clearly $(A_0, \mathfrak{m}')$ and $(A_0, \mathfrak{m}'')$ are two other basic setups; for every A_0-module M, let $(M, \mathfrak{m})^a \in (A_0, \mathfrak{m})^a$-**Mod** (resp. $(M, \mathfrak{m}')^a \in (A_0, \mathfrak{m}')^a$-**Mod**, resp. $(M, \mathfrak{m}'')^a \in (A_0, \mathfrak{m}'')^a$-**Mod**) be the image of M. We may apply theorem 16.9.42 with $(A_0, \mathfrak{m})$ and B replaced respectively by $(A_0, \mathfrak{m}'')$, and $B[1/g']$: hence, let B_2 be the integral closure of A_2 in $B[1/g']$; then $B_2 = (B_2, \mathfrak{m}'')_*^a$ is an almost perfectoid A_0-algebra relative to $(A_0, \mathfrak{m}'')$, and $(B_2/b^n B_2, \mathfrak{m}'')^a$ is an étale $(A_0/b^n A_0, \mathfrak{m}'')^a$-algebra of finite rank, for every $n \in \mathbb{N}$. The localizations $A_0[1/g] \to A_0[1/(gg')]$ and $B \to B[1/g']$ clearly restrict to ring homomorphisms $A_1 \to A_2$ and $B_1 \to B_2$.

Now, $(A_0, \mathfrak{m}'')^a$ is integrally closed in $(A_0[1/(gg')], \mathfrak{m}'')^a$ (theorem 16.9.42(iv) and lemma 16.9.41), hence the same holds for $(A_0[1/g], \mathfrak{m}'')^a$; since B is a finite étale $A_0[1/g]$-algebra, it follows that $(B, \mathfrak{m}'')^a$ is integrally closed in $(B[1/g'], \mathfrak{m}'')^a$ (proposition 14.3.25). Taking into account theorem 16.9.42(v), remark 14.2.7(ii) and [75, Lemma 8.2.28] we deduce :

$$\begin{aligned}
B_2 = (B_2, \mathfrak{m}'')_*^a &= \text{i.c.}((A_0, \mathfrak{m}'')^a, (B[1/g'], \mathfrak{m}'')^a)_* \\
&= \text{i.c.}((A_0, \mathfrak{m}'')^a, (B, \mathfrak{m}'')^a)_* \\
&= (\text{i.c.}((A_0, \mathfrak{m}'')_*^a, (B, \mathfrak{m}'')_*^a), \mathfrak{m}'')_*^a \\
&= (\text{i.c.}((A_1, \mathfrak{m}')_*^a, (B, \mathfrak{m}')_*^a), \mathfrak{m}'')_*^a \\
&= ((\text{i.c.}(A_1, B), \mathfrak{m}')_*^a, \mathfrak{m}'')_*^a \\
&= ((B_1, \mathfrak{m}')_*^a, \mathfrak{m}'')_*^a \\
&= (B_1, \mathfrak{m}'')_*^a \\
&= (B_1, \mathfrak{m}')_*^a.
\end{aligned}$$

(ii) As a special case of (i), we may take $g'_\bullet := b_\bullet$ such that $b := b_0 \in A^\times \cap A_0^{\circ\circ}$. Then, endow B_1 with its b-adic topology, so that B_1 is a subring of definition of the Tate ring $B_1[1/b]$, and by theorem 16.9.42(i) it is p-root closed in $B_1[1/b]$, hence $B_1[1/b]^{\circ\circ} \subset B_1$ (example 16.9.4). It follows easily that $(B_1[1/b]^\circ, \mathfrak{m}')^a = (B_1, \mathfrak{m}')^a$, so we have inclusions of rings :

$$B_1 \subset B^\circ \subset (B_1, \mathfrak{m}')_*^a = (B_1[1/b]^\circ, \mathfrak{m}')_*^a \subset B_1[1/b].$$

On the other hand, it is easily seen that $(B_1, \mathfrak{m}')_*^a \subset B_1[1/b]^\circ$, so $B_2 = (B_1, \mathfrak{m}')_*^a = B_1[1/b]^\circ$.

(iii) In the situation of theorem 16.9.42, suppose that A is an $\mathbb{F}_p$-algebra; then $A_0 = \mathbf{E}_0$ is a perfect $\mathbb{F}_p$-algebra, and it follows easily that the same holds for A_1. Then, set $X := \operatorname{Spec} A_1$

and $Z := \mathrm{Spec}\, A_1/gA_1$; by theorem 16.8.2, the pair (X, Z) is normal and almost pure, hence B_1^a is an étale A_1^a-algebra of finite rank (proposition 14.4.8).

(iv) If A is not an $\mathbb{F}_p$-algebra, we know neither whether A_1 is perfectoid, nor whether B_1^a is an étale A_1^a-algebra. However, by theorem 16.9.42(ii) and lemma 14.3.15(ii), for every $n \in \mathbb{N}$ we have a well defined map

$$\chi_{B_1/b^nB_1} : (B_1/b^nB_1)^a_* \to (A_0/b^nA_0)^a_*[T] \qquad b \mapsto \det((1+bT)\cdot \mathbf{1}_{B_1^a/b^nB_1^a})$$

and clearly the inverse system of maps $(\chi_{B_1/b^nB_1} \mid n \in \mathbb{N})$ amounts to a well defined map

$$\chi_{B_1} : B_1 \to A_1[T].$$

By the same token, we may associate to the finite étale $A_0[1/g]$-algebra B the map

$$\chi_B : B \to A_0[1/g, T] \qquad b \mapsto \det((1+bT)\cdot \mathbf{1}_B)$$

and we claim that

$$\chi_B(b) = \chi_{B_1}(b) \qquad \text{for every } b \in B_1.$$

For the proof, define the inverse system of A_0-algebras $\mathsf{A}_\bullet := (\mathsf{A}_n \mid n \in \mathbb{N})$, and for every $n \in \mathbb{N}$ the étale A_n^a-algebra C_n of rank $\leq r$, as in the proof of theorem 16.9.42; recall that A_1 (resp. B_1) is the limit of $\mathsf{A}_\bullet$ (resp. of $(C_{n*} \mid n \in \mathbb{N})$). It follows easily that χ_{B_1} is also the inverse limit of the system of similar maps $(\chi_{C_n} \mid n \in \mathbb{N})$. On the other hand, $A_0[1/g]$ is integrally closed in the limit L of the induced inverse system $(\mathsf{A}_n[1/g] \mid n \in \mathbb{N})$, and B is the integral closure of $A_0[1/g]$ in the inverse system E of the induced inverse system $(C_n[1/g] \mid n \in \mathbb{N})$; also, the natural map $E \to B \otimes_{A_0[1/g]} L$ is an isomorphism (see the proof of claim 16.9.49). Thus, both χ_B and χ_{B_1} are restrictions of the corresponding map $\chi_E : E \to L$, whence the assertion.

(v) Furthermore, set $R := B_1 \otimes_{A_1} B_1$, let $R^\wedge$ be the b-adic completion of R, and

$$e_{B/A_0[1/g]} \in R[1/g] = B \otimes_{A_0[1/g]} B$$

the diagonal idempotent of the $A_0[1/g]$-algebra B; we notice :

Corollary 16.9.52. *In the situation of theorem* 16.9.42*, we have :*

(i) *The following conditions are equivalent:*

- (a) $g^\gamma \cdot e_{B/A_0[1/g]} \in R' := \mathrm{Im}(R \to R[1/g])$ *for every* $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$.
- (b) *For every* $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$ *there exists* $N_\gamma \in \mathbb{N}$ *such that* $b^{N_\gamma} g^\gamma \cdot e_{B/A_0[1/g]} \in R'$.
- (c) B_1^a *is an étale* A_1^a*-algebra.*
- (d) B_1^a *is a weakly unramified* A_1^a*-algebra.*
- (e) B_1^a *is an almost finitely generated* A_1^a*-module.*
- (f) B_1^a *is an almost finite projective* A_1^a*-module.*
- (g) $B_1^a[1/b]$ *is a weakly unramified* $A_1^a[1/b]$*-algebra.*
- (h) $B_1^a[1/b]$ *is an almost finitely generated* $A_1^a[1/b]$*-module.*

(ii) *There exists* $n \in \mathbb{N}$ *such that* g^n *annihilates the kernel and cokernel of the completion map* $R \to R^\wedge$*. Also,* $\mathrm{Ann}_{R^\wedge}(g)^a = 0$.

Proof. Obviously (c)⇒(a),(d); also (d)⇒(g), (a)⇒(b) and (f)⇒(e)⇒(h).

(a)⇒(c),(f): The assumption implies that $e_{B/A_0[1/g]}$ lies in the image of the induced map

$$R^a_* \to B \otimes_{A_0[1/g]} B.$$

Then the assertion follows from proposition 14.3.21 and theorem 16.9.42(iv)).

(f)⇒(c): We consider the commutative diagram of A_1^a-algebras :

(16.9.53)
$$\begin{array}{ccc} R^a & \xrightarrow{\ \varphi\ } & \lim_{n\in\mathbb{N}} R^a/b^nR^a \\ {\scriptstyle \mu^a}\downarrow & & \downarrow \\ B_1^a & \longrightarrow & \lim_{n\in\mathbb{N}} B_1^a/b^nB_1^a \end{array}$$

where μ^a is the multiplication law, and the right vertical arrow is the inverse limit of the system of multiplication laws $(R^a/b^nR \to B_1^a/b^nB_1^a \mid n \in \mathbb{N})$. According to theorem 16.9.42(i), B_1 is b-adically complete and separated; then by lemma 14.2.24(iii) the morphism φ is an isomorphism. By theorem 16.9.42(ii), for each $n \in \mathbb{N}$ we have a diagonal idempotent $e_n \in (R/b^nR)_*$, and it is easily seen that the system $(e_n \mid n \in \mathbb{N})$ corresponds, under the isomorphism φ, to an idempotent element $e_{B_1^a/A_1^a} \in R^a_*$ such that $\mu(_{B_1^a/A_1^a}) = 1$ and $x \cdot e_{B_1^a/A_1^a} = 0$ for every $x \in (\mathrm{Ker}\,\mu^a)_*$. Then the assertion follows from [75, Prop.3.1.4].

(d)⇒(a): Let $J := \bigcup_{n\in\mathbb{N}} \mathrm{Ann}_R(g^n)$ and $\overline{R} := R/J$. By construction, g is a regular element of B_1, so that $JB_1 = 0$, for the R-algebra structure on B_1 given by the multiplication map $\mu : R \to B_1$. On the other hand, by assumption μ^a is a flat morphism of A_1^a-algebras; hence $\mu^a \otimes_R \overline{R} : \overline{R} \to B_1$ is still flat. Also, the localisation $R \to R[1/g]$ factors through a monomorphism $\overline{R} \to R[1/g]$ of A_1^a-algebras, and since B is an étale $A_0[1/g]$-algebra, $B = B_1[1/g]$ is a projective $R[1/g]$-module of finite rank. By [75, Prop.2.4.19] it follows that B_1 is an almost finite projective $\overline{R}$-module, and therefore $\mathrm{Ker}\,(\mu^a \otimes_R \overline{R})$ is generated by an idempotent almost element $d \in \overline{R}_*$ ([75, Rem.3.1.8]). For every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$, we then find $e_\gamma \in R$ whose image in $(R/J)_*$ agrees with $g^\gamma \cdot (1-d)$. It follows easily that the image of e_γ in $R[1/g]$ agrees with $g^\gamma e_{B/A_0[1/g]}$, whence the contention.

(g)⇒(b): The assumption means that $\mu^a \otimes_{A_1} A_1[1/b] : R[1/b]^a \to B_1[1/b]^a$ is a flat morphism, hence the same holds for $\mu^a \otimes_R \overline{R}[1/b]$, and arguing as in the foregoing we find for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$ an integer $N_\gamma \in \mathbb{N}$ and $e_\gamma \in R$ whose image in $R[1/(gb)]$ agrees with the image of $g^\gamma b^{N_\gamma} e_{B/A_0[1/g]}$. Notice that, since $B_1[1/g] = B$ is a flat $A_1[1/g]$-algebra, and since b is regular in A_1, it follows that b is regular also in $R[1/g]$, hence the localization $R[1/g] \to R[1/(gb)]$ is injective, and we deduce that the image of e_γ agrees with $g^\gamma b^{N_\gamma} e_{B/A_0[1/g]}$ *already in* $R[1/g]$, as required.

(b)⇒(a): Define the inverse system of A_0-algebras $(\mathsf{A}_n \mid n \in \mathbb{N})$ as in the proof of theorem 16.9.42, and for every $n \in \mathbb{N}$ let C_n be the unique étale A_n^a-algebra up to unique isomorphism, such that $C_n[1/g]$ is isomorphic to $\mathsf{A}_n[1/g] \otimes_{A_0} B$. By claim 16.9.43(ii), for every $i \in \mathbb{N}$ the induced inverse system $(\mathsf{A}_n/b^i\mathsf{A}_n \mid n \in \mathbb{N})$ is almost essentially constant relative to the basic setup $(A_0, \mathfrak{m})$. In view of (16.9.46) the same follows for the inverse system $(C_n^a/b^iC_n^a \mid n \in \mathbb{N})$, for every $i \in \mathbb{N}$; but the proof of theorem 16.9.42 also shows that the inverse limit of the latter system is naturally isomorphic to $B_1^a/b^iB_1^a$, for every $i \in \mathbb{N}$. Thus, set $R_n := C_n \otimes_{\mathsf{A}_n^a} C_n$ for every $n \in \mathbb{N}$; we deduce that for every $i \in \mathbb{N}$ and there exists $n(i,\gamma) \in \mathbb{N}$ such that g^γ annihilates the kernel of the induced morphism

$$R^a/b^iR^a \to R_{n(i,\gamma)}/b^iR_{n(i,\gamma)}.$$

Notice also that, since g is regular in A_n, and C_n is a flat A_n^a-algebra, then g is regular in C_n, and the localization $R_n \to R_n[1/g]$ is a monomorphism of A_n^a-modules, for every $n \in \mathbb{N}$. Moreover, the image of $e_{B/A_0[1/g]}$ in $R_n[1/g]$ is the diagonal idempotent of the étale $\mathsf{A}_n[1/g]$-algebra $C_n[1/g]$, and the latter agrees with the image of the diagonal idempotent $e_n \in R_{n*}$ of the étale A_n^a-algebra C_n. Summing up, we conclude that for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$, the image of e_γ vanishes in $R_{n(N_\gamma,\beta)}/b^{N_\gamma}R_{n(N_\gamma,\gamma)}$, and hence $g^{2\gamma}e_\gamma$ vanishes in $R/b^{N_\gamma}R$, *i.e.* $g^{2\gamma}e_\gamma = b^{N_\gamma}e'_\gamma$ for some $e'_\gamma \in R$. Since b is regular in $R[1/g]$, it follows that the image of e'_γ in $R[1/g]$ agrees with $g^{3\gamma}e_{B/A_0[1/g]}$, as required.

(h)⇒(b): By assumption, for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$ there exists $n(\gamma) \in \mathbb{N}$ and an A_1-linear map $f_\gamma : A_1^{\oplus n(\gamma)} \to B_1$ such that

$$g^\gamma \cdot \mathrm{Coker}(A_1[1/b] \otimes_{A_1} f_\gamma) = 0. \qquad (16.9.54)$$

Then, let E_γ be the fibre product in the cartesian diagram of A_1-modules :

$$\mathscr{D}_\gamma \quad : \quad \begin{array}{ccc} E_\gamma & \xrightarrow{f'_\gamma} & B_1 \\ \downarrow & & \downarrow {\scriptstyle g^\gamma \mathbf{1}_{B_1}} \\ A_1^{\oplus n(\gamma)} & \xrightarrow{f_\gamma} & B_1. \end{array}$$

By virtue of (16.9.54), the image of $A_1[1/b] \otimes_{A_1} g^\gamma \mathbf{1}_{B_1}$ lies in the image of $A_1[1/b] \otimes_{A_1} f_\gamma$; on the other hand, the diagram $A_1[1/b] \otimes_{A_1} \mathscr{D}_\gamma$ is still cartesian, so the map $A_1[1/b] \otimes_{A_1} f'_\gamma$ *is surjective*. Recall that b is regular in both A_1 and B_1, therefore also in E_γ; then endow $A_1[1/b]$ (resp. $B_1[1/b]$) with the f-adic topology $\mathscr{T}_{A_1}$ (resp. $\mathscr{T}_{B_1}$) such that A_1 (resp. B_1) is a subring of definition, with ideal of definition bA_1 (resp. $b_1 B_1$); since A_1 and B_1 are b-adically complete and separated (theorem 16.9.42(i)), then $\mathscr{T}_{A_1}$ and $\mathscr{T}_{B_1}$ are complete and separated (proposition 8.3.33). Endow also $A_1[1/b]^{\oplus n(\gamma)}$ with the product topology $\mathscr{T}_{A_1} \times \cdots \times \mathscr{T}_{A_1}$; it is easily seen that all the maps of $A_1[1/b] \otimes_{A_1} \mathscr{D}_\gamma$ are continuous for these topologies, hence $A_1[1/b] \otimes_{A_1} E_\gamma$ is a closed subset of $A_1[1/b] \otimes_{A_1} (A_1^{\oplus n(\gamma)} \oplus B_1)$, and is therefore complete and separated for the topology induced by the inclusion in this A_1-module; moreover, since $A_1^{\oplus n(\gamma)}$ is open in $A_1[1/b]^{\oplus n(\gamma)}$ and B_1 is open in $B_1[1/b]$, we see that E_γ *is open in* $A_1[1/b] \otimes_{A_1} E_\gamma$. By the Banach open mapping theorem ([100, Lemma 2.4]), there exists therefore $N_\gamma \in \mathbb{N}$ such that $b^{N_\gamma} B_1 \subset \mathrm{Im}(f'_\gamma)$. It follows easily that

$$g^\gamma b^{N_\gamma} B_1 \subset \mathrm{Im}(f_\gamma). \tag{16.9.55}$$

By virtue of lemma 14.2.24(iv), we deduce that

$$g^\gamma b^{N_\gamma} \mathrm{Coker}\, \varphi = 0 \tag{16.9.56}$$

where φ is as in (16.9.53). On the other hand, since $A_1[1/(gb)] \otimes_{A_1} f_\gamma : A[1/g]^{\oplus n(\gamma)} \to B[1/b]$ is surjective, and since $B[1/b]$ is a projective $A[1/g]$-module, there exists an $A[1/g]$-linear map $h : B[1/b] \to A[1/g]^{\oplus n(\gamma)}$ such that $f_\gamma \circ h = \mathbf{1}_{B[1/b]}$. Let $\varepsilon_1, \dots, \varepsilon_{n(\gamma)}$ be the canonical basis of the free $A[1/g]$-module $A[1/g]^{\oplus n(\gamma)}$, and pick $k \in \mathbb{N}$ such that $h \circ f_\gamma(b^k g^k \varepsilon_i) \in A_1^{\oplus n(\gamma)}$ for every $i = 1, \dots, n(\gamma)$. In view of (16.9.55), we deduce an A_1-linear map :

$$h' : B_1 \to A_1^{\oplus n(\gamma)} \qquad x \mapsto b^{N_\gamma + k} g^{k+\gamma} h(x)$$

and by construction we have $f_\gamma \circ h' = b^{N_\gamma + k} g^{k+\gamma} \mathbf{1}_{B_1}$. Then lemma 14.2.24(iv) implies that

$$b^{N_\gamma + k} g^{k+\gamma} \mathrm{Ker}\, \varphi = 0. \tag{16.9.57}$$

Now, let $e_\bullet := (e_n \mid n \in \mathbb{N}) \in \lim_{n \in \mathbb{N}} (R^a / b^n R^a)_*$ be the compatible system of diagonal idempotents of the étale $(A_0/b^n A_0)^a$-algebras $B_1^a / b^n B_1^a$, for every $n \in \mathbb{N}$; by (16.9.56) there exists $e' \in R$ such that $\varphi(e') = g^{2\gamma} b^{N_\gamma} e_\bullet$. Then we have

$$\varphi(x \cdot e') = 0 \qquad \text{for every } x \in \mathrm{Ker}\, \mu.$$

Combining with (16.9.57), it follows that $b^{N_\gamma + k} g^{k+\gamma} x \cdot e' = 0$ in R, for every $x \in \mathrm{Ker}\, \mu$. But we have already observed that b is regular in $R[1/g]$; we then easily conclude that the image of e' in $R[1/g]$ agrees with $g^{2\gamma} b^{N_\gamma} e_{B_1/A_0[1/g]}$.

(ii): Pick $n \in \mathbb{N}$ such that $g^n e_{B/A_0[1/g]}$ lies in the image of the localization $B_1 \otimes_{A_1} B_1 \to B \otimes_{A_0[1/g]} B$. Arguing as in the proof of claim 14.3.23, we then find $k \in \mathbb{N}$ and A_1-linear maps $B_1 \to A_1^{\oplus k} \to B_1$ whose composition is $g^k \cdot \mathbf{1}_{B_1}$. Recall now that $R^\wedge$ is the limit of the inverse system $(B_1 \otimes_{A_1} B_1 / b^i B_1 \mid i \in \mathbb{N})$; then the first assertion follows from lemma 14.2.24(iv).

In order to show the second assertion of (ii), let C_n be the étale A_n^a-algebra of finite rank as in the proof of theorem 16.9.42, for every $n \in \mathbb{N}$. Since A_n is b-adically complete and separated, the almost projective A_n^a-module of finite rank $S_n := C_n \otimes_{\mathsf{A}_n} C_n$ is b-adically complete and separated as well, for every $n \in \mathbb{N}$, by [75, Claim 5.3.25], and moreover $\mathrm{Ann}_{S_n}(g) = 0$, since $\mathrm{Ann}_{\mathsf{A}_n}(g) = 0$; then we are easily reduced to checking :

Claim 16.9.58. $(R^\wedge)^a$ represents the limit of the inverse system of A_0-algebras $(S_n \mid n \in \mathbb{N})$.

Proof of the claim. It suffices to show that the $A_0^a/b^k A_0^a$-algebra $(B_1/b^k B_1 \otimes_{A_1/b^k A_1} B_1/b^k B_1)^a$ represents the limit of the induced inverse system $(C_n/b^k C_n \otimes_{\mathsf{A}_n^a/b^k \mathsf{A}_n^a} C_n/b^k C_n \mid n \in \mathbb{N})$, for every $k \in \mathbb{N}$. However, the proof of theorem 16.9.42 shows that the inverse system $(C_n/b^k C_n \mid n \in \mathbb{N})$ is almost essentially constant for every $k \in \mathbb{N}$, and the same holds fo the inverse system $(\mathsf{A}_n^a/b^k \mathsf{A}_n^a \mid n \in \mathbb{N})$, by claim 16.9.43(ii). Then the assertion follows from proposition 14.2.38. $\square$

We conclude with a discussion of some further constructions that we do not need (though, see remark 17.5.17), but may be useful for other questions, and are related to some recent work of Y.André and others as well.

16.9.59. Let A be a perfectoid Tate ring, $A_0 \subset A$ a perfectoid subring of definition, $p \in \mathbb{N}$ a prime integer, and $b \in A_0^{\circ\circ} \cap A^\times$ with $pA_0 \subset b^p A_0$. We consider the categories :

$$A_0\text{-}\mathsf{cp.Adic} \qquad A_0\text{-}\mathsf{Tate} \qquad A_0\text{-}\mathsf{Perf.Adic} \qquad A_0\text{-}\mathsf{Perf.Tate}$$

such that :

- the objects of A_0-$\mathsf{cp.Adic}$ are the adic ring homomorphisms $A_0 \to B_0$ of complete separated topological rings, and the morphisms are the maps of A_0-algebras
- A_0-Tate is the full subcategory of A_0-$\mathsf{cp.Adic}$ whose objects are the A_0-algebras B_0 such that the localisation $B_0 \to B_0[b^{-1}]$ is injective
- A_0-$\mathsf{Perf.Adic}$ (resp. A_0-$\mathsf{Perf.Tate}$) is the full subcategory of A_0-$\mathsf{cp.Adic}$ (resp. of A_0-Tate) whose objects are the perfectoid A_0-algebras.

Notice that every morphism in these categories is adic. We wish to exhibit right adjoints for the inclusion functors

(16.9.60) $$A_0\text{-}\mathsf{Perf.Adic} \to A_0\text{-}\mathsf{cp.Adic} \qquad A_0\text{-}\mathsf{Perf.Tate} \to A_0\text{-}\mathsf{Tate}.$$

Thus, consider any $B_0 \in \mathrm{Ob}(A_0\text{-}\mathsf{cp.Adic})$, set $\overline{A}_0 := A_0/pA_0$, $\overline{B}_0 := B_0/pB_0$, and let $\overline{\beta}_\bullet := (\overline{\beta}_n \mid n \in \mathbb{N}) \in \mathbf{E}_0 := \mathbf{E}(\overline{A}_0)$ be any element such that $\overline{\beta}_0 \in \overline{A}_0$ is the class of b. Endow $\mathbf{E}(\overline{B}_0)$ with its $\overline{\beta}_\bullet$-adic topology $\mathscr{T}_{\mathbf{E}(\overline{B}_0)}$; let also $\mathscr{T}_{\overline{B}_0}$ be the b-adic topology of $\overline{B}_0$. Then the topology of $\mathbf{E}(\overline{B}_0, \mathscr{T}_{\overline{B}_0})$ is complete, separated, adic, and coarser than $\mathscr{T}_{\mathbf{E}(\overline{B}_0)}$ (remark 9.4.9(ii)). By lemma 8.3.12, it follows that $\mathscr{T}_{\mathbf{E}(\overline{B}_0)}$ is complete and separated. Then the A_0-algebra

$$B_0^\natural := A_0 \otimes_{W(\mathbf{E}_0)} W(\mathbf{E}(\overline{B}_0), \mathscr{T}_{\mathbf{E}(\overline{B}_0)})$$

is a perfectoid ring for its b-adic topology (example 16.3.2(ii)). The structure map $A_0 \to B_0$ of B_0, and the map $u_{B_0} : W(\mathbf{E}(\overline{B}_0)) \to B_0$ induce an adic map

$$\varepsilon_{B_0} : B_0^\natural \to B_0 \qquad 1 \otimes (x_n \mid n \in \mathbb{N}) \mapsto \sum_{n\in\mathbb{N}} p^n \cdot \overline{u}_A(x_n^{p^{-n}})$$

and notice that ε_{B_0} is an isomorphism if B_0 is perfectoid. Next, let $\beta_\bullet := (\beta_n \mid n \in \mathbb{N}) \in \mathbf{E}(A_0)$ be the preimage of $\overline{\beta}_\bullet$ under the isomorphism $\mathbf{E}(A_0) \xrightarrow{\sim} \mathbf{E}_0$ induced by the projection $A_0 \to \overline{A}_0$. Hence $\beta_0 - b \in pA_0$, so that $\beta_0/b \in A_0^\times$; if $B_0 \in \mathrm{Ob}(A_0\text{-}\mathsf{Tate})$, then the image of b is regular in B_0, so the same holds for the image of β_0, and finally, the image of $\beta_\bullet$ is a regular element of $\mathbf{E}(\overline{B}_0)$ (proposition 16.4.17); by the same token, the image of β_0 in $B_0^\natural$ is then regular, and hence the same holds for the image of b. Hence, in this case $B_0^\natural$ is an object of A_0-$\mathsf{Perf.Tate}$. Moreover, every morphism $g : B_0 \to C_0$ of A_0-Tate induces an adic map of A_0-algebras

$$g^\natural : B_0^\natural \to C_0^\natural \qquad 1 \otimes (\overline{x}_n \mid n \in \mathbb{N}) \mapsto 1 \otimes (\mathbf{E}(\overline{g})(\overline{x}_n) \mid n \in \mathbb{N})$$

with $\overline{g} := g \otimes_{\mathbb{Z}} \mathbb{Z}/p\mathbb{Z} : \overline{B}_0 \to \overline{C}_0$. We have therefore well defined functors

$$(-)^\natural : A_0\text{-}\mathsf{cp.Adic} \to A_0\text{-}\mathsf{Perf.Adic} \qquad (-)^\natural : A_0\text{-}\mathsf{Tate} \to A_0\text{-}\mathsf{Perf.Tate}.$$

Now, let $C \in \mathrm{Ob}(A_0\text{-}\mathsf{Perf})$; to every adic map $f : C \to B_0^\natural$ let us attach $f^* := \varepsilon_{B_0} \circ f : C \to B_0$, and to every adic map $h : C \to B_0$ let us attach $h^* := h^\natural \circ \varepsilon_C^{-1} : C \to B_0^\natural$. By a simple inspection we get $h^{**} = h$. In order to check that $f^{**} = f$, it suffices to show that $\varepsilon_{B_0^\natural} = \varepsilon_{B_0}^\natural$. Thus, let $\overline{x}_\bullet := (x_n \mid n \in \mathbb{N}) \in W(\mathbf{E}(\overline{B}_0^\natural))$ be any element; via the natural identification $\mathbf{E}(B_0^\natural) \xrightarrow{\sim} \mathbf{E}(\overline{B}_0^\natural)$, we may view $\overline{x}_\bullet$ as a system $x_{\bullet\bullet} := (x_{n,k} \mid n,k \in \mathbb{N})$ of elements of $B_0^\natural$ such that $x_{n,k+1}^p = x_{n,k}$ for every $n, k \in \mathbb{N}$; then we have :

$$\varepsilon_{B_0^\natural}(1 \otimes x_{\bullet\bullet}) = \sum_{n\in\mathbb{N}} p^n x_{n,n} \qquad \varepsilon_{B_0}^\natural(1 \otimes \overline{x}_\bullet) = 1 \otimes (\mathbf{E}(\overline{\varepsilon}_{B_0})(\overline{x}_n) \mid n \in \mathbb{N}).$$

But we have $\sum_{n\in\mathbb{N}} p^n \cdot \tau(\mathbf{E}(\overline{\varepsilon}_{B_0})(\overline{x}_n)^{p^{-n}}) = (\mathbf{E}(\overline{\varepsilon}_{B_0})(\overline{x}_n) \mid n \in \mathbb{N})$ in $W(\mathbf{E}(B_0^\natural))$, by virtue of (9.3.46), where τ denotes the Teichmüller representative. Hence, let $\overline{y}_\bullet := (\overline{y}_k \mid k \in \mathbb{N}) \in \mathbf{E}(\overline{B}_0^\natural)$ be any element, which we identify with a unique element $(y_k \mid k \in \mathbb{N}) \in \mathbf{E}(B_0^\natural)$; we come down to showing that $1 \otimes \tau(\overline{y}_\bullet) = y_0 = \overline{u}_{B_0^\natural}(y_\bullet)$ in $B_0^\natural$. But we have $1 \otimes \tau(\overline{y}_\bullet) = u_{B_0^\natural}(\tau(\overline{y}_\bullet))$, so the assertion follows from lemma 16.1.1(iv). This shows that the rule $f \mapsto f^*$ yields the sought adjunctions between (16.9.60) and the functors $(-)^\natural$.

16.9.61. In the situation of (16.9.59), let also $(A_0, \mathfrak{m})$ be a basic setup, such that $\mathfrak{m}$ is the filtered union of a countable system of principal subideals, and consider as well the categories

$$(A_0, \mathfrak{m})^a\text{-}\mathsf{Perf.Adic} \qquad (A_0, \mathfrak{m})^a\text{-}\mathsf{Perf.Tate}$$

with the same objects as A_0-Perf.Adic (resp. as A_0-Perf.Tate), and whose morphisms $B_0 \to C_0$ are the morphisms $B_0^a \to C_0^a$ of $(A_0, \mathfrak{m})^a$-algebras. We have obvious forgetful functors :

$$\text{(16.9.62)} \qquad \begin{aligned} A_0\text{-}\mathsf{Perf.Adic} &\to (A_0, \mathfrak{m})^a\text{-}\mathsf{Perf.Adic} \\ A_0\text{-}\mathsf{Perf.Tate} &\to (A_0, \mathfrak{m})^a\text{-}\mathsf{Perf.Tate} \end{aligned} \qquad B_0 \mapsto B_0^a.$$

As explained in (16.9.31), we may attach to $\mathfrak{m}$ an ideal $\mathfrak{m}_\mathbf{E} \subset \mathbf{E}_0$, and remark 16.9.32(i) implies that $(\mathbf{E}_0, \mathfrak{m}_\mathbf{E})$ is a basic setup compatible with $(A_0, \mathfrak{m})$, in the sense of definition 16.8.10. For every $B_0 \in \mathrm{Ob}(A_0\text{-}\mathsf{cp.Adic})$, we then let B_0^a (resp. $\mathbf{E}(B_0)^a$) be the $(A_0, \mathfrak{m})^a$-algebra attached to B (resp. the $(\mathbf{E}_0, \mathfrak{m}_\mathbf{E})^a$-algebras attached to $\mathbf{E}(B_0)$).

Theorem 16.9.63. *Let $B_0 \in \mathrm{Ob}(A_0\text{-}\mathsf{cp.Adic})$, and endow $C := (B_0)^a_{!!}$ with its b-adic topology, and $D := \mathbf{E}(B_0)^a_{!!}$ with its $\overline{\beta}_\bullet$-adic topology, as in* (16.9.59). *We have :*

(i) $(B_0)^a_* \in \mathrm{Ob}(A_0\text{-}\mathsf{cp.Adic})$, *and if* $B_0 \in \mathrm{Ob}(A_0\text{-}\mathsf{Tate})$, *then* $(B_0)^a_* \in \mathrm{Ob}(A_0\text{-}\mathsf{Tate})$.
(ii) *There exists a natural isomorphism* $\mathbf{E}(B^a_{0*}) \xrightarrow{\sim} (\mathbf{E}(B_0))^a_*$ *of* $\mathbf{E}_0$*-algebras.*
(iii) *Suppose moreover that the basic setup* $(B_0, \mathfrak{m}B_0)$ *is almost perfectoid; then we have :*
  (a) $\varepsilon^a_{B_0} : (B_0^\natural)^a \to B_0^a$ *is an isomorphism.*
  (b) *The completions* $C^\wedge$ *and* $D^\wedge$ *of* C *and* D *are perfectoid.*
  (c) $C^\wedge/\mathrm{Ann}_{C^\wedge}(b) \in \mathrm{Ob}(A_0\text{-}\mathsf{Perf.Tate})$.
  (d) *There exists a natural isomorphism* $\mathbf{E}(C^\wedge) \xrightarrow{\sim} D^\wedge$.
(iv) *The natural morphisms* $(C^\wedge)^a \to B_0^a$ *and* $(D^\wedge)^a \to \mathbf{E}(B_0)^a$ *are isomorphisms.*
(v) *If* B_0 *is perfectoid, the same holds for* $C^\wedge$ *and* $D^\wedge$.
(vi) *The functors* (16.9.62) *admit both left and right adjoints.*

Proof. (i): If $b \cdot \mathbf{1}_{B_0}$ is an injective map, the same holds for $b \cdot \mathbf{1}_{B^a_{0*}}$, because the functor $(-)^a_*$ commutes with limits; the assertion then follows from claim 16.9.39.

(ii): By remark 16.9.32(iii), the natural map $B_0 \to B^a_{0*}$ induces an isomorphism $\mathbf{E}(B_0)^a_* \xrightarrow{\sim} \mathbf{E}(B^a_{0*})^a_*$; in light of (i), we may then replace B_0 by B^a_{0*}, and assume from start that $B_0 = B^a_{0*}$, in which case we show that the natural map $\mathbf{E}(B_0) \to \mathbf{E}(B_0)^a_*$ is an isomorphism. To this aim, consider the system of sets and maps of sets $S_{\bullet\bullet} := (S_{ij}, \varphi^v_{ij}, \varphi^h_{ij} \mid i, j \in \mathbb{N})$ with $S_{ij} := (B_0/b^j B_0)^a_*$ for every $i, j \in \mathbb{N}$, and where :

- $\varphi^h_{ij} : S_{i+1,j} \to S_{ij}$ is given by the rule : $x \mapsto x^p$ for every $x \in (B_0/b^j B_0)^a_*$
- $\varphi^v_{ij} : S_{i,j+1} \to S_{ij}$ is induced by the projection $B_0/b^{j+1}B_0 \to B_0/b^j B_0$.

We compute the inverse limit L of the system $S_{\bullet\bullet}$ in two different ways :

$$L = \lim_{i\in\mathbb{N}} \lim_{j\in\mathbb{N}} S_{ij} \xrightarrow{\sim} \lim_{j\in\mathbb{N}} \lim_{i\in\mathbb{N}} S_{ij}.$$

Notice that, for fixed $i \in \mathbb{N}$, the system $S_{i\bullet} := (S_{ij}, \varphi^v_{ij} \mid j \in \mathbb{N})$ consists of rings and ring homomorphisms, and since the functor $(-)^a_*$ commutes with limits, the limit of $S_{i\bullet}$ represents $L_i := B^a_{0*} = B$; then, the system of maps $(\varphi^h_{ij} \mid j \in \mathbb{N})$ is a natural transformation $S_{i+1\bullet} \to S_{i\bullet}$ whose limit $\varphi^h_i : L_{i+1} \to L_i$ is obviously the map given by the rule : $x \mapsto x^p$ for every $x \in B$. Thus $L := \lim_{i\in\mathbb{N}}(S_{i\bullet}, \varphi^h_i)$ represents the set underlying $\mathbf{E}(B)$. Next, for every $j \in \mathbb{N}$, let L'_j be the limit of the system of sets $S_{\bullet j} := (S_{ij}, \varphi^h_{ij} \mid i \in \mathbb{N})$; again, the system $(\varphi^v_{ij} \mid i \in \mathbb{N})$ is a natural transformation $S_{\bullet j+1} \to S_{\bullet j}$, inducing a map $\varphi^v_j : L'_{j+1} \to L_j$ and L is also $\lim_{j\in\mathbb{N}}(L'_j, \varphi^v_j)$. Notice now that L'_0 is the set underlying $\mathbf{E}(B_0/bB_0)^a_*$, since the functor $(-)^a_*$ commutes with limits. We are therefore reduced to checking that φ^v_j is bijective for every $j \in \mathbb{N}$. To this aim, it suffices to exhibit a system of maps $(s_{ij} : S_{i+1,j} \to S_{i,j+1} \mid i \in \mathbb{N})$ such that

$$s_{ij} \circ \varphi^v_{i+1,j} = \varphi^h_{i,j+1} \qquad \varphi^v_{ij} \circ s_{ij} = \varphi^h_{ij} \qquad \text{for every } i, j \in \mathbb{N}$$

(details left to the reader). This in turn is achieved by the following more general :

Claim 16.9.64. Let $(V, \mathfrak{m}_V)$ be a basic setup such that $\widetilde{\mathfrak{m}}_V := \mathfrak{m}_V \otimes_V \mathfrak{m}_V$ is a flat V-module, R a V-algebra, $I \subset R$ an ideal with $pI = 0$ and $x^p = 0$ for every $x \in I$. Denote by $\pi : R \to R/I$ the projection. Then there exists a map s that makes commute the diagram of sets :

$$\begin{array}{ccc} R^a_* & \xrightarrow{\Phi} & R^a_* \\ {\scriptstyle \pi^a_*}\downarrow & \overset{s}{\nearrow} & \downarrow{\scriptstyle \pi^a_*} \\ (R/I)^a_* & \xrightarrow{\overline{\Phi}} & (R/I)^a_* \end{array}$$

where Φ is the map given by the rule : $x \mapsto x^p$ for every $x \in R^a_*$, and likewise for $\overline{\Phi}$.

Proof of the claim. For every V-algebra S, denote by $\sigma_S : R/I \otimes_V S \to R \otimes_V S$ the map defined as follows. For every $\overline{x} \in R/I \otimes_V S$, pick $x \in R \otimes_V S$ such that $\pi(x) = \overline{x}$, and set $\sigma_S(x) := x^p$; it is easily seen that this map is independent of the choice of representatives, and moreover the rule : $S \mapsto \sigma_S$ yields a homogeneous polynomial law $\sigma : R/I \rightsquigarrow R$ of degree p (see definition 9.5.1(ii)). Thus, σ factors through the universal homogeneous polynomial law $\boldsymbol{\lambda}^p_{R/I} : R/I \rightsquigarrow \Gamma^p_V(R/I)$ and a unique R-linear map $\sigma^* : \Gamma^p_V(R/I) \to R$ (see (9.5.19)). On the other hand, since $\widetilde{\mathfrak{m}}_V$ is a flat V-module, we have a V-linear isomorphism $\omega : \widetilde{\mathfrak{m}}_V \xrightarrow{\sim} \Gamma^p_V(\widetilde{\mathfrak{m}}_V)$ ([75, (2.1.11)]); then the map given by the rule :

$$\mathrm{Hom}_V(\widetilde{\mathfrak{m}}_V, R/I) \to \mathrm{Hom}_V(\widetilde{\mathfrak{m}}_V, R) \qquad \varphi \mapsto (\widetilde{\mathfrak{m}}_V \xrightarrow{\omega} \Gamma^p_V(\widetilde{\mathfrak{m}}_V) \xrightarrow{\Gamma^p_V(\varphi)} \Gamma^p_V(R/I) \xrightarrow{\sigma^*} R)$$

fulfills the required conditions : details left to the reader. ◊

(iii.a): Let B_1 be the p-root closure of B_0 in $B_0[b^{-1}]$, endow B_1 with its b-adic topology, and let $B_1^\wedge$ be the completion of B_1. Since $b \cdot \mathbf{1}_{B_1}$ is injective, the same holds for $(b \cdot \mathbf{1}_{B_1})^\wedge = b \cdot \mathbf{1}_{B_1^\wedge}$ (proposition 8.2.13(i)). Then, according to claim 16.9.38 and proposition 16.9.37(i), the basic setup $(B_1^\wedge, \mathfrak{m}B_1^\wedge)$ is almost perfectoid and the induced map $i : B_0 \to B_1^\wedge$ is an almost isomorphism. Moreover, $B_1^\wedge$ is p-root closed in $B_1^\wedge[b^{-1}]$, by lemma 9.8.26(ii) and proposition 8.3.33(iii). We consider the commutative diagram

$$\begin{array}{ccc} B_0^\natural & \xrightarrow{\varepsilon_{B_0}} & B_0 \\ {\scriptstyle i^\natural}\downarrow & & \downarrow{\scriptstyle i} \\ (B_1^\wedge)^\natural & \xrightarrow{\varepsilon_{B_1^\wedge}} & B_1^\wedge. \end{array}$$

By remark 16.9.32(iii), i induces an isomorphism $\mathbf{E}(i)^a : \mathbf{E}(B_0)^a \to \mathbf{E}(B_1^\wedge)^a$ of $(\mathbf{E}, \mathfrak{m}_\mathbf{E})^a$-algebras. Let $\mathfrak{n} \subset A_0$ be the ideal generated by $\overline{u}_{A_0}(\mathfrak{m}_\mathbf{E})$; it is easily seen that $(A_0, \mathfrak{n})$ is a basic setup, and then $i^\natural := A_0 \otimes_{W(\mathbf{E}_0)} W(\mathbf{E}(i))$ is an almost isomorphism relative to the almost structure furnished by $(A_0, \mathfrak{n})$. Now, $i^\natural$ is the inverse limit of the system of maps $(i_n := i^\natural \otimes_\mathbb{Z} \mathbb{Z}/p^n \mid n \in \mathbb{N})$, and in view of (16.9.33) we deduce that i_n is an almost isomorphism also relative to the original almost structure $(A_0, \mathfrak{m})$, for every $n \in \mathbb{N}$, and finally, the same holds for $i^\natural$. Summing up, we are therefore reduced to checking that $\varepsilon^a_{B_1^\wedge}$ is an isomorphism of $(A_0, \mathfrak{m})^a$-algebras, so we may assume from start that B_0 is p-root closed. Denote by $\mathrm{gr}_\bullet B_1$ the graded ring associated with the b-adic filtration on B_0, and likewise define $\mathrm{gr}_\bullet B_0^\natural$; since both B_0 and $B_0^\natural$ are b-adically complete and separated, we are further reduced to showing that the induced map $\mathrm{gr}_\bullet \varepsilon_{B_0} : \mathrm{gr}_\bullet B_0^\natural \to \mathrm{gr}_\bullet B_0$ is an almost isomorphism, and since b is regular in both B_0 and $B_0^\natural$, it suffices to prove that the same holds for

$$\mathrm{gr}_0 \varepsilon_{B_0} : B_0^\natural / bB_0^\natural \to B_0/bB_0.$$

Claim 16.9.65. Define $\beta_\bullet \in \mathbf{E}(A_0)$ as in (16.9.59). Then we have :

(i) The Frobenius endomorphism of $B_0/\beta_n B_0$ induces an injective map

$$B_0/\beta_{n+1}B_0 \to B_0/\beta_n B_0 \qquad \text{for every } n \in \mathbb{N}.$$

(ii) The kernel of the projection $\mathbf{E}(B_0) \to B_0/bB_0$ is $\beta_\bullet \mathbf{E}(B_0)$.

(iii) We have a natural identification $B_0^\natural/bB_0^\natural \xrightarrow{\sim} \mathbf{E}(B_0)/\beta_\bullet \mathbf{E}(B_0)$.

Proof of the claim. (i) follows straightforwardly from the assumption that B_0 is p-root closed in $B_0[b^{-1}]$, and (ii) follows easily from (i) : the details are left to the reader.

(iii): Let $\alpha_\bullet \in W(\mathbf{E}_0)$ be a distinguished element in the kernel of $u_A : W(\mathbf{E}_0) \to A_0$; we have $p \in b^p$ by assumption, and $\alpha_0 \in \beta_\bullet^p \mathbf{E}_0$, by lemma 16.1.9(ii). But the natural isomorphism

$$\mathbf{E}(B_0)/\alpha_0\mathbf{E}(B_0) \xrightarrow{\sim} \mathbf{E}_0/\alpha_0\mathbf{E}_0 \otimes_{\mathbf{E}_0} \mathbf{E}(B_0) \xrightarrow{\sim} A_0 \otimes_{W(\mathbf{E}_0)} \mathbf{E}(B_0) \xrightarrow{\sim} B_0^\natural/pB_0^\natural$$

maps the class of $\beta_\bullet$ to the class of b, whence the contention. ◊

By claim 16.9.65(ii), the projection $\overline{u}_{B_0/pB_0} : \mathbf{E}(B_0) \xrightarrow{\sim} \mathbf{E}(B_0/pB_0) \to B_0/bB_0$ induces an injective map

$$j : \mathbf{E}(B_0)/\beta_\bullet \mathbf{E}(B_0) \to B_0/bB_0$$

and claim 16.9.65(iii) yields a natural identification of j with $\mathrm{gr}_0\varepsilon_{B_0}$. Thus, it remains only to check that $\overline{u}^a_{B_0/pB_0}$ is an epimorphism of $(\mathbf{E}_0, \mathfrak{m}_\mathbf{E})^a$-algebras. However, recall that $\mathbf{E}(B_0)$ is the limit of the system of rings $(R_n \mid n \in \mathbb{N})$, with $R_n := B_0/bB_0$ for every $n \in \mathbb{N}$, and with transition maps given by the Frobenius endomorphism Φ_{B_0/bB_0}. Thus, $\overline{u}_{B_0/pB_0}$ is the inverse limit of the system of maps $(\Phi^n_{B_0/bB_0} : R_n \to B_0/bB_0 \mid n \in \mathbb{N})$, each of which is almost surjective, since $(B_0, \mathfrak{m}B_0)$ is almost perfectoid (as usual, we regard $(\Phi^n_{B_0/bB_0})^a$ as a morphism of $(\mathbf{E}_0, \mathfrak{m}_\mathbf{E})^a$-algebras $R^a_{n,(\Phi^{-n}_{\mathbf{E}_0})} \to B_0^a/bB_0^a$: cp. remark 16.9.32(iii)). To conclude, it suffices now to invoke lemma 14.2.24(i).

(iii.b): We consider first the assertion for $C^\wedge$: set $\overline{A}_0 := A_0/bA_0$, and $\overline{\mathfrak{m}} := \mathfrak{m}\overline{A}_0$; by assumption, the Frobenius endomorphism of B_0/b^pB_0 induces an isomorphism $\overline{\Phi}^a_{B_0} : (B_0/bB_0)^a \xrightarrow{\sim} (B_0/b^pB_0)^a_{(\Phi)}$ of $(\overline{A}_0, \overline{\mathfrak{m}})^a$-algebras, whence the isomorphism of $\overline{A}_0$-algebras

$$(\overline{\Phi}_{B_0})^a_{!!} : (B_0/bB_0)^a_{!!} \xrightarrow{\sim} ((B_0/b^pB_0)^a_{(\Phi)})_{!!}$$

where $(-)_{!!}$ denotes the left adjoint of the localization functor $(-)^a : \overline{A}_0\text{-}\mathsf{Alg} \to (\overline{A}_0, \overline{\mathfrak{m}})^a\text{-}\mathsf{Alg}$. On the other hand, by a direct inspection of the construction of these left adjoints, one gets natural identifications

$$C/bC \xrightarrow{\sim} (B_0/bB_0)^a_{!!} \qquad C/b^pC \xrightarrow{\sim} ((B_0/b^pB_0)^a_{(\Phi)})_{!!}$$

where, however, the construction of $C := (B_0)^a_{!!}$ refers to the left adjoint of the corresponding localization $(-)^a : A_0\text{-}\mathsf{Alg} \to (A_0, \mathfrak{m})^a\text{-}\mathsf{Alg}$. It is then easily seen that, under these identifications, the map $(\overline{\Phi}_{B_0})^a_{!!}$ corresponds to the ring homomorphism $\overline{\Phi}_C : C/bC \to C/b^pC$ induced by the Frobenius endomorphism of C/b^pC. The latter is therefore an isomorphism, and so the same holds for the corresponding ring homomorphism $\overline{\Phi}_{C^\wedge} : C^\wedge/bC^\wedge \to C^\wedge/b^pC^\wedge$. Then, according to corollary 16.3.75, in order to check that $C^\wedge$ is perfectoid, it remains only to show that $\mathrm{Ann}_{C^\wedge}(b^p) = \mathrm{Ann}_{C^\wedge}(b^{p-1})$, and in light of remark 8.6.39(iii), we are reduced to proving that $\mathrm{Ann}_C(b^p) = \mathrm{Ann}_C(b^{p-1})$. Let $\mu : \widetilde{\mathfrak{m}} \to A_0$ be the A_0-linear map such that $\mu(x \otimes y) := xy$ for every $x, y \in \mathfrak{m}$; we notice :

Claim 16.9.66. $\mathrm{Ann}_C(b^n)$ is a quotient of $\mathrm{Ker}(\widetilde{\mathfrak{m}}/b^n\widetilde{\mathfrak{m}} \xrightarrow{A_0/b^nA_0 \otimes_{A_0} \mu} A_0/b^nA_0)$, for all $n \in \mathbb{N}$.

Proof of the claim. We consider the commutative diagram of A_0-modules with exact rows :

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \mathfrak{n} & \longrightarrow & A_0 \oplus (\widetilde{\mathfrak{m}} \otimes_{A_0} B_0) & \longrightarrow & (B_0)^a_{!!} & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & \mathfrak{n} & \longrightarrow & A_0 \oplus (\widetilde{\mathfrak{m}} \otimes_{A_0} B_0) & \longrightarrow & (B_0)^a_{!!} & \longrightarrow & 0
\end{array}$$

whose vertical arrows are scalar multiplication by b^n, and where $\mathfrak{n}$ denotes the image of the map $\widetilde{\mathfrak{m}} \to A_0 \oplus (\widetilde{\mathfrak{m}} \otimes_{A_0} B_0)$ given by the rule : $z \mapsto (\mu(z), z \otimes 1)$ for every $z \in \widetilde{\mathfrak{m}}$. By assumption, b is a regular element in both A_0 and B_0, and $\widetilde{\mathfrak{m}}$ is a flat A_0-module, by [75, Prop.2.1.7(i)]. Hence, the central vertical arrow is injective, and the assertion follows easily from the snake lemma. ◊

In view of claim 16.9.66, we are reduced to showing that $b \cdot \mathrm{Ker}(A_0/b^nA_0 \otimes_{A_0} \mu) = 0$ for every $n \in \mathbb{N}$. To this aim, write $\mathfrak{m} = \bigcup_{n\in\mathbb{N}} A_0a_i$ for a system $(a_i \mid i \in \mathbb{N})$ of elements of A_0 such that for every $i \in \mathbb{N}$ we have $a_i = c_ia^p_{i+1}$ for some $c_i \in A_0$ (see (16.9.31)); by remark 16.9.32(ii), the A_0-module $\widetilde{\mathfrak{m}}$ is then isomorphic to the inductive limit L of a system $(F_i \mid i \in \mathbb{N})$ of free rank one A_0-modules $F_i = A_0e_i$, with transition maps $f_i : F_i \to F_{i+1}$ such that $f_i(e_i) = c_ia^{p-1}_{i+1}e_{i+1}$ for every $i \in \mathbb{N}$. Hence L is the set of equivalence classes $[x, i]$ of pairs (x, i) with $i \in \mathbb{N}$ and $x \in F_i$, and with this notation, μ corresponds to the A_0-linear map $L \to A_0$ given by the rule : $[ye_i, i] \mapsto ya_i$ for every $i \in \mathbb{N}$ and $y \in A_0$. Hence, let $[ye_i, i] \in L$ and suppose that $ya_i \in b^nA_0$; we need to show that $[ye_i, i] \in b^{n-1}L$. Pick $k \in \mathbb{N}$ with $p^k \geq n$; by a simple induction, we see that :

$$[ye_i, i] = y_k[e_{i+k}, i + k] \qquad \text{with} \qquad y_k := yc_ic^p_{i+1} \cdots c^{p^{k-1}}_{i+k-1}a^{p^k-1}_{i+k}.$$

We are then reduced to checking that $y_k \in b^{n-1}A_0$, and by theorem 16.3.64, the latter is equivalent to the condition : $y^{p^k}_k \in b^{(n-1)p^k}A_0$. But we have :

$$y^{p^k}_k = y^{p^k}c_ic^p_{i+1} \cdots c^{p^{k-1}}_{i+k-1}a^{p^k-1}_i = yc_ic^p_{i+1} \cdots c^{p^{k-1}}_{i+k-1} \cdot (ya_i)^{p^k-1} \in b^{n(p^k-1)}A_0 \subset b^{(n-1)p^k}A_0.$$

Next, we consider the assertion concerning $D^\wedge$: the discussion of (16.9.59) already shows that $\mathbf{E}(B_0)$ is a perfectoid ring, when endowed with its $\overline{\beta}_\bullet$-adic topology, and moreover the image of $\overline{\beta}_\bullet$ is regular in $\mathbf{E}(B_0)$. Hence, the assertion for $D^\wedge$ follows from the foregoing case, after replacing the basic setup $(A_0, \mathfrak{m})$ by $(\mathbf{E}, \mathfrak{m}_\mathbf{E})$.

(iii.c): Arguing as in the proof of corollary 16.3.75, we may assume that $b = b_0$ for some $(b_n \mid n \in \mathbb{N}) \in \mathbf{E}(A_0)$; notice also that $C^\wedge$ is reduced, due to (iii.b) and corollary 16.3.63(i), hence $\mathrm{Ann}_{C^\wedge}(b) = \bigcup_{n\in\mathbb{N}} \mathrm{Ann}_{C^\wedge}(b^n)$, so scalar multiplication by b is an injective endomorphism of $C^\wedge/\mathrm{Ann}_{C^\wedge}(b)$. Then the assertion follows from corollary 16.3.71.

(iv): The counit of adjunction for the pair of functors $((-)_{!!}, (-)^a)$ is an almost isomorphism $\varepsilon_{B_0} : C \to B_0$, hence the same for its b-adic completion (cp. the proof of claim 16.9.38). Likewise, recall that $\mathbf{E}(B_0)$ is $\overline{\beta}_\bullet$-adically complete and separated (see (16.9.59)); then the same argument shows that the counit of adjunction $\varepsilon_{\mathbf{E}(B_0)} : D \to \mathbf{E}(B_0)$ induces, after taking $\overline{\beta}_\bullet$-adic completions, an almost isomorphism $D^\wedge \to \mathbf{E}(B_0)$.

(v): We may assume that $b = \beta_0$, where $\beta_\bullet \in \mathbf{E}(A_0)$ is as in (16.9.59); also, arguing as in the proof of (iii.b), we see that $\overline{\Phi}_{C^\wedge}$ is an isomorphism, and then claim 16.3.76 and remark 8.6.39(iii) reduce to showing that $\mathrm{Ann}_C(b^p) = \mathrm{Ann}_C(b^p/\beta_1) = \mathrm{Ann}_C(\beta_1^{p^2-1})$. But, arguing as in the proof of claim 16.9.66 we obtain, for every $n \in \mathbb{N}$, an exact sequence of A_0-modules

$$\widetilde{\mathfrak{m}} \otimes_{A_0} \mathrm{Ann}_{B_0}(b^n) \to \mathrm{Ann}_C(b^n) \to M$$

where M is a quotient of $\mathrm{Ker}(A_0/b^n A_0 \otimes_{A_0} \mu)$. The proof of (iii.b) then shows that $bM = 0$, and on the other hand $\beta_1 \cdot \mathrm{Ann}_{B_0}(b^n) = 0$, by corollary 16.3.71; thus $\beta_1^{p+1} \cdot \mathrm{Ann}_C(b^n) = 0$, and since $p^2 - 1 \geq p + 1$, the assertion follows.

(vi): Let $X \in \mathrm{Ob}(A_0\text{-}\mathsf{Perf.Tate})$ and $Y \in \mathrm{Ob}((A_0, \mathfrak{m})^a\text{-}\mathsf{Perf.Tate})$, and set $Z := (Y^a_{!!})^\wedge$; we know already from (i) and (iii.c) that $Y^a_* \in \mathrm{Ob}(A_0\text{-}\mathsf{Tate})$ and $Z/\mathrm{Ann}_Z(b) \in \mathrm{Ob}(A_0\text{-}\mathsf{Perf.Tate})$. Then, in view of the discussion of (16.9.59) we get natural bijections

$$\mathrm{Hom}_{(A_0,\mathfrak{m})^a\text{-}\mathsf{Perf.Tate}}(X^a, Y^a) \xrightarrow{\sim} \mathrm{Hom}_{A_0\text{-}\mathsf{Tate}}(X, Y^a_*) \xrightarrow{\sim} \mathrm{Hom}_{A_0\text{-}\mathsf{Perf.Tate}}(X, (Y^a_*)^\natural)$$
$$\mathrm{Hom}_{(A_0,\mathfrak{m})^a\text{-}\mathsf{Perf.Tate}}(Y^a, X^a) \xrightarrow{\sim} \mathrm{Hom}_{A_0\text{-}\mathsf{-Alg}}(Y^a_{!!}, X) \xrightarrow{\sim} \mathrm{Hom}_{A_0\text{-}\mathsf{Perf.Tate}}(Z/\mathrm{Ann}_Z(b), X)$$

so the rule $Y \mapsto (Y^a_*)^\natural$ (resp. $Y \mapsto Z/\mathrm{Ann}_Z(b)$) yields the sought right (resp. left) adjoint for the functor A_0-$\mathsf{Perf.Tate} \to (A_0, \mathfrak{m})^a$-$\mathsf{Perf.Tate}$. The same argument shows that the rule $Y \mapsto (Y^a_*)^\natural$ also provides a right adjoint for the forgetful functor A_0-$\mathsf{Perf.Adic} \to (A_0, \mathfrak{m})^a$-$\mathsf{Perf.Adic}$, and using (v) we easily see that the rule $Y \mapsto Z$ yields a left adjoint for the same functor.

(iii.d): To begin with, let us notice :

Claim 16.9.67. The functors (16.9.62) induce equivalences between $(A_0, \mathfrak{m})^a$-$\mathsf{Perf.Adic}$ (resp. $(A_0, \mathfrak{m})^a$-$\mathsf{Perf.Tate}$) and the localization of A_0-$\mathsf{Perf.Adic}$ (resp. A_0-$\mathsf{Perf.Tate}$) obtained by inverting all almost isomorphisms.

Proof of the claim. Recall that $\varepsilon_{B_0} : B_0^\natural \to B_0$ is an isomorphism if B_0 is perfectoid (see (16.9.59)); we deduce for every $Y \in \mathrm{Ob}(A_0\text{-}\mathsf{Perf.Adic})$ an isomorphism $((Y^a_*)^\natural)^a \xrightarrow{\sim} (Y^a_*)^a \xrightarrow{\sim} Y^a$ in the category $(A_0, \mathfrak{m})^a$-$\mathsf{Perf.Adic}$. Combining with (vi) and proposition 1.1.20(iii), we deduce that the right adjoints to both of the forgetful functors (16.9.62) are fully faithful. Then the claim follows from proposition 1.6.13. ◊

From (vi) and remark 16.9.32(iii) we get a diagram of categories :

$$\begin{array}{ccc} A_0\text{-}\mathsf{Perf.Adic} & \xrightarrow{\mathbf{E}(-)} & \mathbf{E}_0\text{-}\mathsf{Perf.Adic} \\ \uparrow\downarrow (-)^a & & (-)^a \downarrow\uparrow \\ (A_0, \mathfrak{m})^a\text{-}\mathsf{Perf.Adic} & \xrightarrow{\mathbf{E}(-)} & (\mathbf{E}_0, \mathfrak{m}_\mathbf{E})^a\text{-}\mathsf{Perf.Adic} \end{array}$$

whose upward arrows are left adjoints to the downward arrows, and whose top horizontal arrow is an equivalence; in light of claim 16.9.67, it follows easily that the bottom horizontal arrow is an equivalence as well. Clearly the horizontal arrows commute with the downward arrows; then the horizontal arrows also commute with the upward arrows, up to isomorphism of functors (example 1.2.7(ii)). Hence, if $R \in \mathrm{Ob}(A_0\text{-}\mathsf{Perf.Adic})$, we have a natural ring isomorphism

$$\omega_R : \mathbf{E}((R^a_{!!})^\wedge) \stackrel{\sim}{\to} (\mathbf{E}(R)^a_{!!})^\wedge.$$

Next, if $(B_0, \mathfrak{m}B_0)$ is almost perfectoid, from (iv) and remark 16.9.32(iii) we deduce an almost isomorphism $\mathbf{E}((B_0)^a_{!!})^\wedge) \to \mathbf{E}(B_0)$, whence a ring isomorphism

$$\tau_{B_0} : (\mathbf{E}((B^a_{0!!})^\wedge)^a_{!!})^\wedge \stackrel{\sim}{\to} (\mathbf{E}(B_0)^a_{!!})^\wedge.$$

Lastly, $R := (B^a_{0!!})^\wedge$ is perfectoid, by (v), whence the isomorphism

$$\tau_{B_0} \circ \omega_R : \mathbf{E}((R^a_{!!})^\wedge) \stackrel{\sim}{\to} (\mathbf{E}(B_0)^a_{!!})^\wedge.$$

Thus, we are reduced to checking that the natural map $(((B^a_{0!!})^\wedge)^a_{!!})^\wedge \to (B^a_{0!!})^\wedge$ is an isomorphism. This in turn will follow, once we have shown that the natural map $((B^a_{0!!})^\wedge)^a_{!!} \to B^a_{0!!}$ is an isomorphism. But the latter is a straightforward consequence of (iv). □

17. Applications

17.1. **Model algebras.** We let $(K, |\cdot|)$ be a valued field of characteristic 0 with value group Γ_K of rank one, such that the residue field κ of K^+ has characteristic $p > 0$.

Definition 17.1.1. The category MA_K of *model K^+-algebras* consists of all the pairs (A, Γ), where $(\Gamma, +)$ is an integral monoid, and A is a Γ-graded K^+-algebra A, fulfilling the following conditions :

(MA1) $\mathrm{gr}_\gamma A$ is a torsion-free K^+-module, with $\dim_K \mathrm{gr}_\gamma A \otimes_{K^+} K = 1$, for every $\gamma \in \Gamma$.
(MA2) $\mathrm{gr}_\alpha A \cdot \mathrm{gr}_\beta A \neq 0$ for every $\alpha, \beta \in \Gamma$, and $(\mathrm{gr}_\gamma A)^n = \mathrm{gr}_{n\gamma} A$ for every $n \in \mathbb{N}$ and $\gamma \in \Gamma$.
(MA3) $\mathrm{gr}_0 A = K^+$.
(MA4) Γ is saturated and Γ^{gp} is a $\mathbb{Z}[1/p]$-module.

The morphisms $(A, \Gamma) \to (A', \Gamma')$ in MA_K are the pairs (f, φ), where $\varphi : \Gamma \to \Gamma'$ is a morphism of monoids, and $f : A \to \Gamma \times_{\Gamma'} A'$ is a morphism of Γ-graded K^+-algebras (see (7.6.19)).

Example 17.1.2. Let M be an integral monoid, $N \to M$ an exact and injective morphism of monoids, $N \to K^+ \setminus \{0\}$ a morphism of monoids, and suppose that :

- M is *divisible*, *i.e.* the k-Frobenius endomorphism of M is surjective for every $k > 0$
- $M^{\mathrm{gp}}/N^{\mathrm{gp}}$ is a $\mathbb{Q}$-vector space.

Let $(\Gamma, +)$ be the image of M in $M^{\mathrm{gp}}/N^{\mathrm{gp}}$, and denote by I the nilradical of the K^+-algebra $A := M \otimes_N K^+$; then A is a Γ-graded K^+-algebra, and I is a Γ-graded ideal (proposition 7.6.28(ii)). We claim that $I \otimes_{K^+} K = 0$ and $(A/I, \Gamma)$ is a model K^+-algebra. Indeed, (MA4) is immediate, and it is easily seen that $\mathrm{gr}_{n\gamma} A = (\mathrm{gr}_\gamma A)^n$ for every $\gamma \in \Gamma$ and $n \in \mathbb{N}$. Moreover, since the map $N \to M$ is exact, the kernel of the map $M \to M^{\mathrm{gp}}/N^{\mathrm{gp}}$ equals N, so $(A/I)_0 = K^+$, *i.e.* (MA3) holds as well. The remaining assertions can be checked after tensoring with K : namely, we have to show that the Γ-graded K-algebra $A_K := M \otimes_N K$ is reduced, with $\dim_K \mathrm{gr}_\gamma A_K = 1$ for every $\gamma \in \Gamma$, and $\mathrm{gr}_\alpha A_K \cdot \mathrm{gr}_\beta A_K \neq 0$ for every $\alpha, \beta \in \Gamma$. However, the morphism $N \to K^+$ extends uniquely to a group homomorphism $N^{\mathrm{gp}} \to K^\times$, and $A_K = (N^{-1}M) \otimes_{N^{\mathrm{gp}}} K$; hence, we may assume that N is a group, in which case Γ is the set-theoretic quotient of M by the translation action of N (lemma 4.8.31(iii)). In this case, choose a representative $\gamma^* \in M$ for every $\gamma \in \Gamma$; it follows easily that $(\gamma^* \otimes 1 \mid \gamma \in \Gamma)$ is a basis of the K-vector space A_K, whence (MA1), and $(\alpha^* \otimes 1) \cdot (\beta^* \otimes 1)$ is a non-zero multiple of $(\alpha+\beta)^* \otimes 1$, which yields (MA2). Lastly, since the nilradical I_K of A_K is Γ-graded (proposition 7.6.28(ii)), we also deduce that $I_K = 0$, as sought.

Remark 17.1.3. (i) The category MA_K admits a tensor product, defined by the rule :

$$(A, \Gamma) \otimes (A', \Gamma') := (A \otimes_{K^+} A', \Gamma \oplus \Gamma').$$

(ii) Let (A, Γ) be any model K^+-algebra, and suppose that $\Gamma = \Gamma_1 \oplus \Gamma_2$ is a given decomposition of Γ as direct sum of monoids. Then it is easily seen that Γ_1 and Γ_2 are integral and saturated, and they fulfill axiom (MA4). There follows a morphism of model K^+-algebras :

$$(\Gamma_1 \times_\Gamma A, \Gamma_1) \otimes (\Gamma_2 \times_\Gamma A, \Gamma_2) \to (A, \Gamma) \tag{17.1.4}$$

(iii) In the situation of (ii), set $A_K := A \otimes_{K^+} K$. Then it is easily seen that (17.1.4) induces an isomorphism of K-algebras

$$(\Gamma_1 \times_\Gamma A_K) \otimes_K (\Gamma_2 \times_\Gamma A_K) \xrightarrow{\sim} A_K.$$

In general, (17.1.4) need not be an isomorphism. However, (17.1.4) is an isomorphism, if either Γ_1 or Γ_2 is a torsion abelian group. Indeed, in any case the induced maps

$$\mathrm{gr}_\alpha A \otimes_{K^+} \mathrm{gr}_\beta A \to \mathrm{gr}_{\alpha+\beta} A \qquad a_1 \otimes a_2 \mapsto a_1 a_2$$

will be injective for every $\alpha \in \Gamma_1$ and $\beta \in \Gamma_2$. To check surjectivity, let $a \in \mathrm{gr}_{\alpha+\beta} A$ be any element, and say that $n\beta = 0$; then $a^n \in \mathrm{gr}_{n\alpha} A$, and by (MA2) we know that there exist $a_1 \in \mathrm{gr}_\alpha A$ and $x \in K^+$ such that $a^n = a_1^n x$. It follows that $a = a_1 a_2$ for some $a_2 \in \mathrm{gr}_\beta A_K$ such that $a_2^n \in K^+$. Then $a_2 \in \mathrm{gr}_\beta A$, whence the claim.

(iv) Let $(E, |\cdot|_E)$ be any valued field extension of $(K, |\cdot|)$, such that $|\cdot|_E$ is also a valuation of rank one. Then we have an obvious base change functor :

$$\mathsf{MA}_K \to \mathsf{MA}_E \quad : \quad (A, \Gamma) \mapsto (A \otimes_{K^+} E^+, \Gamma).$$

17.1.5. Let (A, Γ) be any model K^+-algebra. For any subset $\Delta \subset \Gamma$, set

$$A_\Delta := \Delta \times_\Gamma A \qquad A_{\Delta,K} := A_\Delta \otimes_{K^+} K \qquad \Delta[1/p] := \bigcup_{n\in\mathbb{N}} \{\gamma \in \Gamma \mid p^n\gamma \in \Delta\}.$$

Clearly, if Δ is a submonoid of Γ, then A_Δ is a K^+-subalgebra of A, and (A_Δ, Δ) is a subobject of (A, Γ), provided Δ satisfies (MA4). On the other hand, if Δ is saturated, it is easily seen that the same holds for $\Delta[1/p]$, and then the latter does satisfy (MA4).

Also, if Δ is an ideal of Γ, then clearly A_Δ is an ideal of A.

Set $K^* := K^+ \setminus \{0\}$ and let $A^*_\gamma := \mathrm{gr}_\gamma A \setminus \{0\}$ for every $\gamma \in \Gamma$; for any submonoid $\Delta \subset \Gamma$, we deduce a sequence of morphisms of integral monoids :

$$1 \to K^* \xrightarrow{\varphi_\Delta} A^*_\Delta \to \Delta \to 1 \qquad \text{where } A^*_\Delta := \bigoplus_{\gamma\in\Delta} A^*_\gamma \tag{17.1.6}$$

(and where the direct sum is formed in the category of K^*-modules), such that $(17.1.6)^{\mathrm{gp}}$ is a short exact complex of abelian groups; then (MA2) implies that φ_Δ is saturated (proposition 6.2.31). Also, (MA1) implies that each A^*_γ is a filtered union of free cyclic K^*-modules, hence φ_Δ is also integral. Furthermore, (MA1) and (MA2) imply that $A^{*\mathrm{gp}}_\Delta$ is Δ^{gp}-graded, and

$$\mathrm{gr}_\gamma A^{*\mathrm{gp}}_\Delta = A^*_\gamma \otimes_{K^*} K^\times \qquad \text{for every } \gamma \in \Delta. \tag{17.1.7}$$

(details left to the reader). We shall just write A^* and A_K instead of A^*_Γ, and respectively $A_{\Gamma,K}$.

17.1.8. Let now (A, Γ) be any model K^+-algebra; set $S := \mathrm{Spec}\, K^+$, $X := \mathrm{Spec}\, A$, and let $\overline{x}$ be any geometric point of X, localized on the closed subset $Z := X \times_S \mathrm{Spec}\, \kappa$. Let $\mathscr{T}_{A,p}$ be the p-adic topology on A. Suppose furthermore, that K^+ is deeply ramified (see [75, Def.6.6.1]), and let $(K^+, \mathfrak{m}_K)$ be the standard setup associated with K^+ (see [75, §6.1.15]); then we have the corresponding sheaf $\mathscr{O}^a_{X(\overline{x})}$ of K^{+a}-algebras on $X(\overline{x})$, and we may state the following *almost purity* theorem :

Theorem 17.1.9. *With the notation of* (17.1.8)*, the following holds :*

(i) $(A, \mathscr{T}_{A,p})$ *is a formally perfectoid ring.*
(ii) *The pair* $(X(\overline{x}), Z(\overline{x}))$ *is almost pure.*

Proof. (i): Let $\pi \in K^+$ be any element such that $\pi^p K^+ = pK^+$; denote by $A^\wedge$ the completion of $(A, \mathscr{T}_{A,p})$, and set $I := \pi A^\wedge$. Then the topology of $A^\wedge$ agrees with the I-adic topology (remark 8.3.3(iv)), and the image of π is a regular element in $A^\wedge$, by proposition 8.2.13(i) (the details shall be left to the reader). Moreover we have $pA^\wedge = I^{(p)}$ (notation of definition 16.2.1); by theorem 16.4.1, it then suffices to check that the Frobenius endomorphism $\Phi_{A/pA}$ of $A^\wedge/pA^\wedge = A/pA$ induces an isomorphism $A/\pi A \xrightarrow{\sim} A/pA$. We are then further reduced to showing that $\Phi_{A/pA}$ restricts to a bijection

$$\mathrm{gr}_\gamma A/\pi \cdot \mathrm{gr}_\gamma A \xrightarrow{\sim} \mathrm{gr}_{p\gamma} A/p \cdot \mathrm{gr}_{p\gamma} A \qquad \text{for every } \gamma \in \Gamma.$$

However, since Γ_K is of rank one, there exists a sequence $(a_n \mid n \in \mathbb{N})$ of elements of $\mathrm{gr}_\gamma A$ such that $K^+ a_n \subset K^+ a_{n+1}$ for every $n \in \mathbb{N}$ and $\mathrm{gr}_\gamma A = \bigcup_{n\in\mathbb{N}} K^+ a_n$. Then $\mathrm{gr}_{p\gamma} A = \bigcup_{n\in\mathbb{N}} K^+ a_n^p$. By [75, Prop.6.6.6] the Frobenius endomorphism of K^+ induces an isomorphism $K^+/\pi K^+ \xrightarrow{\sim} K^+/pK^+$. It follows that $\Phi_{A/pA}$ induces a bijection $(K^+ a_n)/\pi(K^+ a_n) \xrightarrow{\sim} (K^+ a_n^p)/p(K^+ a_n^p)$ for every $n \in \mathbb{N}$, whence the contention.

(ii) follows from (i), and theorems 16.7.21(i) and 16.8.44. □

17.1.10. The inclusion map $A^* \to A$ is a morphism of (multiplicative) monoids, hence induces a log structure on $X := \operatorname{Spec} A$ (see (12.1.15)). We shall denote

$$\mathbb{S}(A, \Gamma) := (X, (A^*_X)^{\log})$$

the resulting log scheme. Clearly, every morphism $(f, \varphi) : (A, \Gamma) \to (A', \Gamma')$ of model algebras induces a morphism of log schemes

$$\mathbb{S}(f, \varphi) : \mathbb{S}(A', \Gamma') \to \mathbb{S}(A, \Gamma).$$

Especially, by lemma 12.1.13(iv), the map φ_Γ yields a saturated morphism

$$\mathbb{S}(A, \Gamma) \to \mathbb{S}(K^+) := \mathbb{S}(K^+, \{1\}). \tag{17.1.11}$$

Also, if $(K, |\cdot|) \to (E, |\cdot|_E)$ is an extension of rank one valued fields, the inclusion $A^* \subset (A \otimes_{K^+} E^+)^*$ induces a morphism of log schemes

$$\mathbb{S}(A \otimes_{K^+} E^+, \Gamma) \to \mathbb{S}(A, \Gamma)$$

for any model K^+-algebra (A, Γ), and we remark that the resulting diagram of log schemes

$$\begin{array}{ccc} \mathbb{S}(A \otimes_{K^+} E^+, \Gamma) & \longrightarrow & \mathbb{S}(A, \Gamma) \\ \big\downarrow & & \big\downarrow \\ \mathbb{S}(E^+) & \longrightarrow & \mathbb{S}(K^+) \end{array}$$

is cartesian. Indeed, since (12.1.16) is right exact, it suffices to check that the natural map

$$A^* \otimes_{K^*} E^* \to (A \otimes_{K^+} E^+)^*$$

is an isomorphism, which is clear.

Remark 17.1.12. (i) Let (A, Γ) be any model K^+-algebra, and suppose that $\Delta_0 \subset \Gamma$ is a fine and saturated submonoid, such that Δ_0^{gp} is torsion-free. In this case, Δ_0^{gp} is a free abelian group of finite rank, hence $(17.1.6)^{\mathrm{gp}}$ admits a splitting $\sigma : \Delta_0^{\mathrm{gp}} \to A^{*\mathrm{gp}}$. Then, using (17.1.7) and (MA1), it is easily seen that the rule $\gamma \mapsto \sigma(\gamma)$ extends to an isomorphism of Δ_0-graded K-algebras

$$K[\Delta_0] \xrightarrow{\sim} A_{\Delta_0, K}.$$

(ii) In the situation of (i), suppose furthermore, that K is algebraically closed. Pick any $x \in K^\times$ such that $\gamma := |x| \neq 1$, and let $\langle\gamma\rangle \subset \Gamma_K$ be the subgroup generated by γ; we define a group homomorphism $\langle\gamma\rangle \to K^\times$ by the rule : $\gamma^k \mapsto x^k$ for every $k \in \mathbb{Z}$. Since $K^\times$ is divisible, the latter map extends to a group homomorphism

$$\Gamma_K \to K^\times \tag{17.1.13}$$

and since Γ_K is a group of rank one, it is easily seen that (17.1.13) is a right inverse for the valuation map $|\cdot| : K^\times \to \Gamma_K$, whence a decomposition :

$$K^\times \stackrel{\sim}{\to} (K^+)^\times \oplus \Gamma_K.$$

On the other hand, set $A^*_{\Delta_0,K} := A^*_{\Delta_0} \otimes_{K^*} K^\times$; from (i) we deduce an isomorphism of Δ_0-graded monoids :

$$A^*_{\Delta_0,K} \stackrel{\sim}{\to} \Delta_0 \oplus K^\times.$$

Combining these two isomorphisms, we deduce a surjection $\tau : A^*_{\Delta_0,K} \to (K^+)^\times$ which is a left inverse to the inclusion $(K^+)^\times \to A^*_0$. Then, for every $\gamma \in \Delta_0$, let us set $C_\gamma := A^*_\gamma \cap \mathrm{Ker}\,\tau$; there follows a (non-canonical) isomorphism of Δ-graded monoids :

$$A^*_{\Delta_0} \stackrel{\sim}{\to} (K^+)^\times \oplus C \qquad \text{where} \quad C := \bigoplus_{\gamma\in\Delta_0} C_\gamma \subset A^*_{\Delta_0} \quad \text{and} \quad C^{\mathrm{gp}} \simeq \Delta_0^{\mathrm{gp}} \oplus \Gamma_K$$

(details left to the reader).

(iii) Suppose that Γ^{gp} is torsion-free, and K is still algebraically closed. Let us set :

$$\Delta_n := \{\gamma \in \Gamma \mid p^n\gamma \in \Delta_0\} \qquad \text{for every } n \in \mathbb{N}.$$

It is easily seen that Δ_n is still fine and saturated, and since $K^\times$ is divisible, we may extend inductively the splitting σ of (i) to a system of homomorphisms

$$\sigma_n : \Delta_n^{\mathrm{gp}} \to A^{*\mathrm{gp}} \qquad \text{such that} \quad \sigma_{n+1|\Delta_n^{\mathrm{gp}}} = \sigma_n \quad \text{for every } n \in \mathbb{N}$$

whence a compatible system of isomorphisms

$$K[\Delta_n] \stackrel{\sim}{\to} A_{\Delta_n,K} \qquad \text{for every } n \in \mathbb{N}. \tag{17.1.14}$$

Proceeding as in (ii), we deduce a compatible system of isomorphisms of Δ_n-graded monoids

$$A^*_{\Delta_n} \stackrel{\sim}{\to} (K^+)^\times \oplus C^{(n)} \qquad \text{such that } C^{(n)} \subset C^{(n+1)} \text{ for every } n \in \mathbb{N}.$$

In this situation, notice that the p-Frobenius automorphism of Γ^{gp} restricts to an isomorphism

$$\Delta_{n+1} \stackrel{\sim}{\to} \Delta_n \qquad \text{for every } n \in \mathbb{N}.$$

Likewise, since Γ_K is p-divisible, taking p-th powers induces isomorphisms

$$C^{(n+1)} \stackrel{\sim}{\to} C^{(n)} \qquad \text{for every } n \in \mathbb{N}.$$

Definition 17.1.15. Let (B, Δ) be model K^+-algebra. We say that (B, Δ) is *small*, if the following conditions hold :

(a) $\mathrm{gr}_\gamma B$ is a finitely generated K^+-module for every $\gamma \in \Delta$.
(b) $\Delta = \Delta_0[1/p]$ for some fine and saturated submonoid Δ_0.
(c) $\Delta_0 \times_\Delta B$ is a finitely generated K^+-algebra.

Remark 17.1.16. Notice that condition (a) of definition 17.1.15 and axiom (MA1) imply that $\mathrm{gr}_\gamma B$ is a free K^+-module of rank one, for every small model algebra (B, Δ) and every $\gamma \in \Delta$. Moreover, actually conditions (b) and (c) (together with axioms (MA1) and (MA2)) imply condition (a). Indeed, (c), (MA1) and proposition 7.6.11(ii) imply that $\mathrm{gr}_\gamma B$ is a free K^+-module of rank one, for every $\gamma \in \Delta_0$. Now, in case $n\gamma \in \Delta_0$, (MA2) implies that $\mathrm{gr}_{n\gamma} B$ is generated by an element of the form $z = x_1 \cdots x_n$, for certain $x_1, \dots, x_n \in \mathrm{gr}_\gamma B$. Suppose that $x_1 = ay$ for some $a \in K^+$ and $y \in \mathrm{gr}_\gamma B$; then z is divisible by a in $\mathrm{gr}_{n\gamma} B$, so $a \in (K^+)^\times$, *i.e.*

x_1 generates $\mathrm{gr}_\gamma B$. In view of (b), for every $\gamma \in \Delta$ we may find $k \geq 0$ such that $p^k\gamma \in \Delta_0$, so (a) follows.

Remark 17.1.17. Let (B, Δ) be any small model algebra, so that conditions (b) and (c) of definition 17.1.15 are satisfied for some submonoid $\Delta_0 \subset \Delta$.

(i) Choose a decomposition $\Delta_0^\times = G \oplus H$, where G is a free abelian group, and H is the torsion subgroup of Δ_0; we have an isomorphism

$$\Delta_0 \simeq \Lambda \oplus H \qquad \text{with } \Lambda := \Delta_0^\sharp \oplus G$$

(lemma 6.2.10), which induces a decomposition :

$$\Delta \simeq \Lambda[1/p] \oplus H$$

inducing, in turn, an isomorphism of model K^+-algebras :

$$(B, \Delta) \xrightarrow{\sim} (B_{\Lambda[1/p]}, \Lambda[1/p]) \otimes (B_H, H)$$

(remark 17.1.3(iii)). Notice that both B_Λ and B_H are finitely generated K^+-algebras (proposition 7.6.11(i)). In other words, every small model algebra can be written as the tensor product of two small model algebras (B', Δ') and (B'', Δ''), such that Δ'^{gp} is torsion-free, and Δ'' is a finite abelian group whose order is not divisible by p.

(ii) For every $n \in \mathbb{N}$, set $\Delta_n := \{\gamma \in \Delta \mid p^n\gamma \in \Delta_0\}$. Then $B_n := \Delta_n \times_\Delta B$ is a finitely generated K^+-algebra for every $n \in \mathbb{N}$. Indeed, in view of (i), it suffices to check the assertion in case Δ^{gp} is a torsion-free abelian group. Now, pick a system $x_1, \dots, x_k$ of homogeneous generators of the K^+-algebra B_0; by (MA2), for every $i = 1, \dots, k$ there exist a homogeneous element $y_i \in B_n$ and $u_i \in (K^+)^\times$ such that $u_i y_i^{p^n} = x_i$. Let $z \in B_n$ be any homogeneous element; then $z^{p^n} = v x_1^{t_1} \cdots x_k^{t_k}$ for some $v \in K$ and $t_1, \dots, t_k \in \mathbb{N}$. Set $y := y_1^{t_1} \cdots y_k^{t_k}$ and $u := u_1^{t_1} \cdots u_k^{t_k} \in K^\times$; then $y^{p^n} uv = z^{p^n}$, and since Δ^{gp} is torsion-free, we deduce that $yw = z$ for some $w \in K^+$, *i.e.* the system $y_1, \dots, y_k$ generates the K^+-algebra B_n.

(iii) Suppose that Δ is a finite group whose order is not divisible by p. Then we claim that B is a finite étale K^+-algebra. Indeed, in view of remark 17.1.3(iii), it suffices to verify the assertion for Δ a cyclic finite group, say of order n, with $(n, p) = 1$; in the latter case, (MA2) implies that $B \simeq K^+[X]/(X^n - u)$ for some $u \in (K^+)^\times$, whence the contention.

(iv) Let $F \subset \Delta$ be any face. Then (B_F, F) is a small model algebra as well. Indeed, by (i), it suffices to consider the case where Δ^{gp} is a torsion-free abelian group. In this case, set $F_0 := F \cap \Delta_0$; it is easily seen that $F = F_0[1/p]$, and F_0 is a fine and saturated monoid, by lemma 6.1.20(ii) and corollary 6.2.33(ii). Moreover, $B_{F_0} = F_0 \times_F B_{\Delta_0}$ is a finitely generated K^+-algebra, by proposition 7.6.11(i), whence the contention.

(v) Suppose moreover, that K is algebraically closed, and let (B, Δ) be any small model K^+-algebra. Then we have a (non-canonical) isomorphism :

$$K[\Delta] \xrightarrow{\sim} B_K.$$

To exhibit such an isomorphism, we may – in light of (i) – assume that Δ^{gp} is either torsion-free, or a finite group of order not divisible by p. In the latter case, the assertion follows easily from (iii). In case Δ^{gp} is torsion-free, the sought isomorphism is the colimit of the system of isomorphisms (17.1.14).

Lemma 17.1.18. *Let (A, Γ) be a model K^+-algebra, and denote by $\mathscr{F}(\Gamma)$ the filtered family of all fine and saturated submonoids of Γ. We have :*

(i) $A = \mathrm{colim}_{\Delta \in \mathscr{F}(\Gamma)} A_\Delta$.

(ii) *Suppose that Γ^{gp} is a torsion-free abelian group. Then A is a normal domain.*

Proof. (i) is an immediate consequence of corollary 6.4.1(ii).

(ii): We show first the following :

Claim 17.1.19. Suppose that $\Gamma^{\rm gp}$ is a torsion-free abelian group. Then A_K is a normal domain.

Proof of the claim. In view of (i), it suffices to show that $A_{\Delta,K}$ is a normal domain, when $\Delta \subset \Gamma$ is fine and saturated. The latter assertion follows from remark 17.1.12(i) and theorem 6.4.18(iii). ◊

Let A^ν be the integral closure of A in A_K; in view of claim 17.1.19 we are reduced to showing that $A = A^\nu$. By proposition 7.6.29(ii), A^ν is Γ-graded. Suppose now that $x \in A^\nu$; we need to show that $x \in A$, and we may assume that $x \in \mathrm{gr}_\gamma A^\nu$ for some $\gamma \in \Gamma$. Hence, let

$$x^n + a_1 x^{n-1} + \cdots + a_n = 0 \qquad \text{with } a_1, \dots, a_n \in A$$

be an integral equation for x over A. If we replace each a_i by its homogeneous component in degree $i\gamma$, we still obtain an integral equation for x, so we may assume that $a_i \in \mathrm{gr}_{i\gamma} A$ for every $i = 1, \dots, n$. Then, (MA2) implies that, for every $i = 1, \dots, n$ there exist $u_i \in K^+$ and $b_i \in \mathrm{gr}_\gamma A$, such that $|u_i| = 1$ and $a_i = u_i b_i^i$. Also, from (MA1) we deduce that there exists $b \in \mathrm{gr}_\gamma A$ such that $b_1, \dots, b_n \in K^+ b$. Set $y := b^{-1}x \in \mathrm{gr}_0 A \otimes_{K^+} K$; clearly y is integral over the subring $\mathrm{gr}A_0$. Lastly, (MA3) shows that $y \in K^+$, whence $x \in \mathrm{gr}_\gamma A$, which proves the contention. □

Proposition 17.1.20. *Let* (A, Γ) *be a model* K^+*-algebra, and suppose that* Γ_K *is divisible. Then* (A, Γ) *is the filtered union of its small model* K^+*-subalgebras.*

Proof. In view of lemma 17.1.18(i), we see that (A, Γ) is the colimit of the filtered system of its subobjects $(A_{\Delta[1/p]}, \Delta[1/p])$, for Δ ranging over the fine and saturated submonoids of Γ. We may then assume from start that $\Gamma = \Gamma_0[1/p]$ for some fine and saturated submonoid Γ_0.

Next, in view of remark 17.1.17(i), we may consider separately the cases where $\Gamma_0^{\rm gp}$ is a torsion-free abelian group, and where $\Gamma = \Gamma_0$ is a finite abelian group.

Suppose first that $\Gamma_0^{\rm gp}$ is torsion-free, and let $\underline{\gamma} := (\gamma_1, \dots, \gamma_n)$ be a finite system of generators for Γ_0. For every $i = 1, \dots, n$, choose $a_i \in A^*_{\gamma_i}$, and let $B(\underline{\gamma}, \underline{a}) \subset A$ be the K^+-subalgebra generated by $\underline{a} := (a_1, \dots, a_n)$. Clearly the grading of A induces a Γ_0-grading on $B(\underline{\gamma}, \underline{a})$, and $\mathrm{gr}_\beta B(\underline{\gamma}, \underline{a})$ is a finitely generated K^+-module for every $\beta \in \Gamma_0$ (proposition 7.6.11(ii)); by virtue of (MA1), we know that $\mathrm{gr}_\beta B(\underline{\gamma}, \underline{a})$ is then even a free rank one K^+-module, for every $\beta \in \Gamma_0$. Furthermore, $\underline{a}$ generates a fine submonoid of A^*, so – by proposition 6.6.35(ii) – there exists an integer $k > 0$ such that

$$(\mathrm{gr}_{k\beta} B(\underline{\gamma}, \underline{a}))^n = \mathrm{gr}_{nk\beta} B(\underline{\gamma}, \underline{a}) \qquad \text{for every } \beta \in \Gamma_0 \text{ and every integer } n > 0.$$

Now, for any $\beta \in \Gamma$, let $t > 0$ be an integer such that $p^t\beta \in \Gamma_0$, and pick a generator b of the K^+-module $\mathrm{gr}_{kp^t\beta} B(\underline{\gamma}, \underline{a})$; in light of (MA2) we may find $x \in K^+$ and $c \in \mathrm{gr}_\beta A$, such that $b = c^{kp^t} x$. Since Γ_K is divisible, we may write $x = y^{kp^t} u$ for some $y, u \in K^+$ with $|u| = 1$.

It is easily seen that the K^+-submodule of $\mathrm{gr}_\beta A$ generated by cy does not depend on the choices of c, y, t and k; hence we denote $\mathrm{gr}_\beta C(\underline{\gamma}, \underline{a})$ this submodule; a simple inspection shows that the resulting Γ-graded K^+-module

$$C(\underline{\gamma}, \underline{a}) := \bigoplus_{\beta \in \Gamma} \mathrm{gr}_\beta C(\underline{\gamma}, \underline{a})$$

is actually a Γ-graded K^+-subalgebra of A, for which (MA2) holds, and therefore $(C(\underline{\gamma}, \underline{a}), \Gamma)$ is a small model algebra. Lastly, it is clear that the family of all such $(C(\underline{\gamma}, \underline{a}), \Gamma)$, for $\underline{\gamma}$ ranging over all finite sets of generators of Γ, and $\underline{a}$ ranging over all the finite sequences of elements of A as above, form a cofiltered system of subobjects, whose colimit is (A, Γ). This concludes the proof of the proposition in this case.

Next, suppose that $\Gamma = \Gamma_0$ is a finite abelian group. In view of remark 17.1.3(iii), we are reduced to the case where Γ is cyclic, say $\Gamma = \mathbb{Z}/n\mathbb{Z}$. Fix any generator γ of Γ, and for every

$a \in \mathrm{gr}_\gamma A$, let $C(a)$ be the K^+-subalgebra of A generated by a; it is easily seen that the colimit of the filtered family $((C(a), \Gamma) \mid a \in \mathrm{gr}_\gamma A)$ equals (A, Γ). (Details left to the reader.) □

17.1.21. Suppose now that K is algebraically closed, let (B, Δ) be a small model K^+-algebra, with Δ^{gp} torsion-free, and write $\Delta = \Delta_0[1/p]$ for some fine and saturated submonoid Δ_0 such that the K^+-algebra $B_0 := B_{\Delta_0}$ is finitely generated. Let us set

$$\Delta_n := \{\gamma \in \Delta \mid p^n\gamma \in \Delta_0\} \qquad B_n := B_{\Delta_n} \qquad Y_n := \mathrm{Spec}\, B_n \qquad \text{for every } n \in \mathbb{N}.$$

We wish to construct a ladder of log schemes

$$(17.1.22)\qquad \begin{array}{ccccccccc} \cdots \xrightarrow{g_{n+1}} & (Y_{n+1}, \underline{M}_{n+1}) & \xrightarrow{g_n} & (Y_n, \underline{M}_n) & \xrightarrow{g_{n-1}} \cdots \xrightarrow{g_0} & (Y_0, \underline{M}_0) \\ & \downarrow{\scriptstyle \varphi_{n+1}} & & \downarrow{\scriptstyle \varphi_n} & & \downarrow{\scriptstyle \varphi_0} \\ \cdots \xrightarrow{h_{n+1}} & (S, \underline{N}_{n+1}) & \xrightarrow{h_n} & (S, \underline{N}_n) & \xrightarrow{h_{n-1}} \cdots \xrightarrow{h_0} & (S, \underline{N}_0) \end{array}$$

such that, for every $n \in \mathbb{N}$:

- φ_n is smooth and saturated, and $\underline{M}_n$ admits a chart, given by a Δ_n-graded fine monoid $P^{(n)}$, such that $P_0^{(n)}$ is sharp, and the inclusion map $P_0^{(n)} \to P^{(n)}$ is flat and saturated, and gives a chart for φ_n
- the morphism of schemes underlying h_n (resp. g_n) is the identity of S (resp. is induced by the inclusion $B_n \subset B_{n+1}$)
- the morphism g_n admits a chart, given by an injective map $P^{(n)} \to \Delta_n \times_{\Delta_{n+1}} P^{(n+1)}$ of Δ_n-graded monoids, whose restriction $P_0^{(n)} \to P_0^{(n+1)}$ gives a chart for h_n.

This will be achieved in several steps, as follows :

• First, let $b_1, \dots, b_k$ be a finite system of generators for B_0. By remark 17.1.12(ii), we have a decomposition $B_0^* = (K^+)^\times \oplus C$ for some submonoid $C \subset B_0^*$, and we may suppose that each b_i lies in C. Let $P^{(0)} \subset B_0^*$ be the submonoid generated by $b_1, \dots, b_k$. The restriction of the surjection $B_0^* \to \Delta_0$ is then still a surjection $\pi : P^{(0)} \to \Delta_0$. Notice that, for every $x \in \mathrm{Ker}\,\pi^{\mathrm{gp}}$, we have either $x \in K^+$ or $x^{-1} \in K^+$; especially, we may find a finite system $x_1, \dots, x_n$ of generators for $\mathrm{Ker}\,\pi^{\mathrm{gp}}$, such that $x_i \in K^+$ for every $i = 1, \dots, n$. Now, let $\Sigma \subset P^{(0)\mathrm{gp}}$ be the submonoid generated by $x_1, \dots, x_n$; after replacing $P^{(0)}$ by $P^{(0)} \cdot \Sigma$, we may assume that $\mathrm{Ker}\,\pi^{\mathrm{gp}} = P_0^{(0)\mathrm{gp}}$, where $P_0^{(0)} := \mathrm{Ker}\,\pi^{\mathrm{gp}} \cap P^{(0)} \subset K^+$ is a fine submonoid.

• Next, by theorem 6.6.45, we may find a finitely generated submonoid $\Sigma' \subset P_0^{(0)\mathrm{gp}} \cap K^+$ such that the induced morphism $P_0^{(0)} \cdot \Sigma' \to P^{(0)} \cdot \Sigma'$ is flat. Clearly

$$P_0^{(0)} \cdot \Sigma' = \mathrm{Ker}\,\pi^{\mathrm{gp}} \cap (P^{(0)} \cdot \Sigma')$$

hence, we may replace $P^{(0)}$ by $P^{(0)} \cdot \Sigma'$, and assume that the morphism $P_0^{(0)} \to P^{(0)}$ is also flat.

• We claim that the map $P_0^{(0)} \to P^{(0)}$ is also saturated. We shall apply the criterion of proposition 6.2.31 : indeed, for given $\gamma \in \Delta_0$ and integer $n > 0$, let x (resp. y) be a generator of the $P_0^{(0)}$-module $P_\gamma^{(0)}$ (resp. $P_{n\gamma}^{(0)}$). Then x (resp. y) is also a generator of the K^+-module $\mathrm{gr}_\gamma B$ (resp. $\mathrm{gr}_{n\gamma} B$), and (MA2) implies that there exists $u \in (K^+)^\times$ such that $uy = x^n$; but since $x, y \in C$, we must have $u = 1$ therefore $(P_\gamma^{(0)})^n = P_{n\gamma}^{(0)}$, as required.

• Next, we claim that the induced map of Δ_0-graded K^+-algebras

$$(17.1.23)\qquad P^{(0)} \otimes_{P_0^{(0)}} K^+ \to B_0$$

is an isomorphism. Indeed, since $P^{(0)}$ contains a set of generators for the K^+-algebra B, the map (17.1.23) is obviously surjective. However, for every $\gamma \in \Delta_0$, the $P_0^{(0)}$-module $P_\gamma^{(0)}$ is free of rank one (remark 6.2.5(iv)), therefore $(P^{(0)} \otimes_{P_0^{(0)}} K^+)_\gamma$ is a free K^+-module of rank one. It follows easily that (17.1.23) is also injective.

• Now, denote by $\underline{N}_0$ (resp. $\underline{M}_0$) the fine log structure on S (resp. on X_0) deduced from the inclusion map $P_0^{(0)} \to K^+$ (resp. $P^{(0)} \to B_0$). By lemma 12.1.13(iv), the inclusion $P_0^{(0)} \to P^{(0)}$ yields a chart for a morphism $\varphi_0 : (Y_0, \underline{M}_0) \to (S, \underline{N}_0)$ that is saturated, as sought. Lastly, since (17.1.23) is an isomorphism, theorem 12.3.37 shows that φ_0 is also smooth.

• Next, according to remark 17.1.12(iii), we have a compatible system of decompositions

$$B_n^* = (K^+)^\times \oplus C^{(n)} \qquad \text{for every } n \in \mathbb{N}$$

with $C^{(0)} = C$, and such that the p-Frobenius induces an isomorphism $\tau_n : C^{(n+1)} \xrightarrow{\sim} C^{(n)}$ for every $n \in \mathbb{N}$. Hence, define inductively an increasing sequence of submonoids

$$P^{(0)} \subset P^{(1)} \subset P^{(2)} \subset \cdots \subset B^* \quad \text{by letting} \quad P^{(n+1)} := \tau_n^{-1} P^{(n)} \text{ for every } n \in \mathbb{N}.$$

Clearly, the grading of B^* restricts to a Δ_n-grading on $P^{(n)}$, and induces a Δ-grading on P. We deduce isomorphisms of Δ_{n+1}-graded monoids :

$$P^{(n+1)} \xrightarrow{\sim} \Delta_{n+1} \times_{\Delta_n} P^{(n)} \qquad \text{for every } n \in \mathbb{N}. \tag{17.1.24}$$

Especially, the induced maps of monoids $P_0^{(n)} \to P^{(n)}$ are still flat and saturated, and $P_0^{(n)}$ is still sharp (remark 17.1.26). The inclusion maps $P^{(n)} \to B_n$ and $P_0^{(n)} \to K^+$ determine an isomorphism of Δ_n-graded K^+-algebras

$$P^{(n)} \otimes_{P_0^{(n)}} K^+ \xrightarrow{\sim} B_n \qquad \text{for every } n \in \mathbb{N} \tag{17.1.25}$$

as well as fine log structures $\underline{M}_n$ on Y_n, and $\underline{N}_n$ on S, whence a morphism of log schemes $\varphi_n : (Y_n, \underline{M}_n) \to (S, \underline{N}_n)$ which is again smooth and saturated. This completes the construction of (17.1.22).

Remark 17.1.26. (i) With the notation of (17.1.21), notice that, by construction, $P^{(n)\mathrm{gp}} \subset C^{(n)\mathrm{gp}}$; especially, since Δ^{gp} is torsion-free, the same holds for $P^{(n)\mathrm{gp}}$. Likewise, the construction shows that the induced map $P_0^{(n)\mathrm{gp}} \to \Gamma_K$ is always injective; especially, $P_0^{(n)\mathrm{gp}}$ is a free abelian group of finite rank, and $P_0^{(n)}$ is sharp. It follows that the $P_0^{(n)}$-module $P_\gamma^{(n)}$ admits a unique generator g_γ, for every $\gamma \in \Delta_n$, and the saturation condition for the inclusion $P_0^{(n)} \to P^{(n)}$ translates as the system of identities :

$$g_\gamma^k = g_{k\gamma} \qquad \text{for every } k \in \mathbb{N} \text{ and every } \gamma \in \Delta_n.$$

(ii) Moreover, set $P := \bigcup_{n \in \mathbb{N}} P^{(n)}$. Notice that the colimit of the maps (17.1.25) is an isomorphism of Δ-graded K^+-algebras

$$P \otimes_{P_0} K^+ \xrightarrow{\sim} B. \tag{17.1.27}$$

Furthermore, since the natural map $P^{(n)}/P_0^{(n)} \to \Delta$ is an isomorphism for every $n \in \mathbb{N}$, we deduce that the grading of P induces an isomorphism :

$$P/P_0 \xrightarrow{\sim} \Delta. \tag{17.1.28}$$

(iii) We also obtain a commutative diagram of log schemes :

$$\begin{array}{ccc} \mathbb{S}(B_n, \Delta_n) & \longrightarrow & (Y_n, \underline{M}_n) \\ \downarrow & & \downarrow{\scriptstyle \varphi_n} \\ \mathbb{S}(K^+) & \longrightarrow & (S, \underline{N}_n) \end{array} \qquad \text{for every } n \in \mathbb{N} \tag{17.1.29}$$

whose left vertical arrow is the saturated morphism (17.1.11), and whose bottom (resp. top) arrow is the identity of S (resp. of Y_n) on the underlying schemes, and is induced by the inclusion map $P_n^{(0)} \to K^*$ (resp. $P^{(n)} \to B_n^*$). It is easily seen that (17.1.29) is cartesian : indeed, since the functor (12.1.16) is right exact, it suffices to check that the natural map

$$P^{(n)} \otimes_{P_0^{(n)}} K^* \to B_n^*$$

is an isomorphism, which is clear from (17.1.25).

(iv) Notice that the inclusion map $i_0 : P_0^{(0)} \to P^{(0)}$ is also local; then corollary 6.4.7 yields a decomposition

$$\vartheta_0 : P^{(0)} \xrightarrow{\sim} P^{(0)\times} \oplus P^{(0)\sharp}$$

such that $\vartheta_0 \circ i_0 = \iota_0 \circ \lambda_0^\sharp$, where $\iota_0 : P^{(0)\sharp} \to P^{(0)\times} \oplus P^{(0)\sharp}$ is the natural inclusion map. By means of the isomorphisms (17.1.24), we may then inductively construct decompositions

$$\vartheta_n : P^{(n)} \xrightarrow{\sim} P^{(n)\times} \oplus P^{(n)\sharp} \qquad \text{for every } n \in \mathbb{N}$$

fitting into a commutative diagram

$$\begin{array}{ccccc} P_0^{(n)} & \xrightarrow{i_n} & P^{(n)} & \xrightarrow{j_n} & P^{(n+1)} \\ \downarrow{\scriptstyle i_n^\sharp} & & \downarrow{\scriptstyle \vartheta_n} & & \downarrow{\scriptstyle \vartheta_{n+1}} \\ P^{(n)\sharp} & \xrightarrow{\iota_n} & P^{(n)\times} \oplus P^{(n)\sharp} & \xrightarrow{j_n^\times \oplus j_n^\sharp} & P^{(n+1)\times} \oplus P^{(n+1)\sharp} \end{array}$$

where i_n, j_n and ι_n are the natural inclusion maps. Now, set

$$B'_n := K^+[P^{(n)\times}] \qquad B''_n := P^{(n)\sharp} \otimes_{P_0^{(n)}} K^+ \qquad \text{for every } n \in \mathbb{N}$$

and let Δ'_n (resp. Δ''_n) be the image of $P^{(n)\times}$ (resp. of $\vartheta_n^{-1} P^{(n)\sharp}$) in Δ_n; since the grading of $P^{(n)}$ induces an isomorphism $P^{(n)}/P_0^{(n)} \xrightarrow{\sim} \Delta_n$, we see that $\Delta_n = \Delta'_n \oplus \Delta''_n$, and by construction, for every $n \in \mathbb{N}$ we have isomorphisms

$$(B_n, \Delta_n) \xrightarrow{\sim} (B'_n, \Delta'_n) \otimes (B''_n, \Delta''_n)$$

of model K^+-algebras, which identify the inclusions $B_n \to B_{n+1}$ with the tensor product of the induced inclusion maps $B'_n \to B'_{n+1}$ and $B''_n \to B''_{n+1}$. Furthermore, set $Y'_n := \operatorname{Spec} B'_n$ and $Y''_n := \operatorname{Spec} B''_n$ for every $n \in \mathbb{N}$. The induced map of monoids $P^{(n)\sharp} \to B''_n$ determines a fine log structure $\underline{M}''_n$ on Y''_n, the map $i_n^\sharp$ gives a chart for a smooth and saturated morphism of log schemes

$$\varphi''_n : (Y''_n, \underline{M}''_n) \to (S, \underline{N}_n)$$

and there follows an isomorphism of $(S, \underline{N}_n)$-schemes (lemma 12.1.4)

$$(17.1.30) \qquad (Y_n, \underline{M}_n) \xrightarrow{\sim} Y'_n \times_S (Y''_n, \underline{M}''_n) \qquad \text{for every } n \in \mathbb{N}.$$

(v) Starting with (17.1.31), we shall consider the strict henselization B^{sh} of B at a given geometric point $\overline{x}$ of $\operatorname{Spec} B \otimes_{K^+} \kappa$. In this situation, let $x \in Y := \operatorname{Spec} B$ be the support of $\overline{x}$, and $\mathfrak{p}_x \subset B$ the corresponding prime ideal. Let also P be as in (ii), denote by $\beta : P \to B$ the natural map deduced from (17.1.27), and set $\mathfrak{p} := \beta^{-1}\mathfrak{p}_x$. Moreover, set $\mathfrak{p}_n := \mathfrak{p} \cap P^{(n)}$ and $Q^{(n)} := P^{(n)}_{\mathfrak{p}_n}$ for every $n \in \mathbb{N}$; clearly $\mathfrak{p}_n \subset \mathfrak{p}_{n+1}$ (so the isomorphism (17.1.24) maps $\mathfrak{p}_{n+1}$ onto $\mathfrak{p}_n$), and therefore

$$Q^{(n)} \subset Q^{(n+1)} \qquad \text{for every } n \in \mathbb{N}.$$

Furthermore, the image of $Q^{(n)}$ in Δ_n^{gp} is a localization Γ_n of Δ_n, especially it is still saturated, and the maps (17.1.24) extend to isomorphisms of Γ_{n+1}-graded monoids

$$Q^{(n+1)} \xrightarrow{\sim} \Gamma_{n+1} \times_{\Gamma_n} Q^{(n)} \qquad \text{for every } n \in \mathbb{N}.$$

It is also clear that the p-Frobenius of Γ_{n+1} factors through an isomorphism $\Gamma_{n+1} \xrightarrow{\sim} \Gamma_n$, for every $n \in \mathbb{N}$. Set $F_n := P^{(n)} \setminus \mathfrak{p}_n$ for every $n \in \mathbb{N}$; notice that, by construction, $F_n \cap P_0^{(n)} = \{1\}$, hence $F_n \cap P_\gamma^{(n)}$ is either empty or else it contains exactly one element, namely the generator g_γ

of $P_\gamma^{(n)}$, by virtue of (i). It follows that $Q_0^{(n)} = P_0^{(n)}$ for every $n \in \mathbb{N}$, and therefore the inclusion map $Q_0^{(n)} \to Q^{(n)}$ is still flat and saturated (lemma 6.2.12(ii)). Let $\Gamma := \bigcup_{n\in\mathbb{N}} \Gamma_n$; we conclude that $Q := P_\mathfrak{p}$ is a Γ-graded monoid with $Q_0 = P_0$, and we may define

$$B_\mathfrak{p} := Q \otimes_{Q_0} K^+.$$

The foregoing shows that $(B_\mathfrak{p}, \Gamma)$ is still a small model algebra, and we also obtain a ladder of log schemes with the properties listed in (17.1.21) : namely, set $B_{\mathfrak{p},n} := B_{\mathfrak{p},\Gamma_n} = Q^{(n)} \otimes_{Q_0^{(n)}} K^+$ for every $n \in \mathbb{N}$, and endow $Y_{\mathfrak{p},n} := \operatorname{Spec} B_{\mathfrak{p},n}$ with the log structure $\underline{M}_{\mathfrak{p},n}$ determined by the induced map $Q^{(n)} \to B_{\mathfrak{p},n}$. Clearly the geometric point $\overline{x}$ lifts uniquely to a geometric point $\overline{x}_\mathfrak{p}$ of $Y_\mathfrak{p} := \operatorname{Spec} B_\mathfrak{p}$, and the localization map $B \to B_\mathfrak{p}$ induces an isomorphism

$$Y_\mathfrak{p}(\overline{x}_\mathfrak{p}) \xrightarrow{\sim} Y(\overline{x}).$$

Hence, for the study of the scheme $Y(\overline{x})$, it shall be usually possible to replace the original small algebra B by its localization $B_\mathfrak{p}$ thus constructed. In so doing, we gain one more property: indeed, notice that the new chart $Q^{(n)} \to B_{\mathfrak{p},n}$ is local at the geometric point $\overline{x}$, for every $n \in \mathbb{N}$. Now, choose a compatible system of decompositions

$$(Y_{\mathfrak{p},n}, \underline{M}_{\mathfrak{p},n}) \xrightarrow{\sim} Y'_{\mathfrak{p},n} \times_S (Y''_{\mathfrak{p},n}, \underline{M}''_{\mathfrak{p},n})$$

as in (iv), and denote by $\overline{x}_{\mathfrak{p},n}$ (resp. $\overline{x}''_{\mathfrak{p},n}$) the image of $\overline{x}_\mathfrak{p}$ in $Y_{\mathfrak{p},n}$ (resp. in $Y''_{\mathfrak{p},n}$), for every $n \in \mathbb{N}$. By inspecting the construction, it is easily seen that the chart $Q^{(n)\sharp} \to B''_{\mathfrak{p},n} := Q^{(n)\sharp} \otimes_{Q_0^{(n)}} K^+$ is also local at $\overline{x}''_{\mathfrak{p},n}$.

17.1.31. Let us return to the situation of (17.1.21). Fix a geometric point $\overline{x}$ of $Y := \operatorname{Spec} B$, localized on $Y \times_S \operatorname{Spec} \kappa$, and for every $n \in \mathbb{N}$, let $\overline{x}_n$ be the image of $\overline{x}$ in Y_n. Set

$$B^{\mathrm{sh}} := \mathscr{O}_{Y(\overline{x}),\overline{x}} \qquad \text{and} \qquad B_n^{\mathrm{sh}} := \mathscr{O}_{Y_n(\overline{x}_n),\overline{x}_n} \quad \text{for every } n \in \mathbb{N}.$$

For the next step, we shall apply the method of (14.5.60), to construct a normalized length function for B^{sh}-modules. To this aim, we need an auxiliary model K^+-algebra, defined as follows. First, notice that the grading $P \to \Delta$ extends to a morphism of monoids

$$\pi_\mathbb{Q} : P_\mathbb{Q} \to \Delta_\mathbb{Q}$$

(notation of (6.3.20)); *i.e.* $P_\mathbb{Q}$ is a $\Delta_\mathbb{Q}$-graded monoid. Since $K^\times$ is a divisible group, the inclusion map $P_0 \to K^*$ extends to a group homomorphism $P_{\mathbb{Q},0}^{\mathrm{gp}} \to K^\times$, and it is easily seen that the latter restricts to a morphism of monoids

$$P_{\mathbb{Q},0} \to K^*.$$

So finally, we may set

$$A := P_\mathbb{Q} \otimes_{P_{\mathbb{Q},0}} K^+.$$

Taking into account (17.1.27), we deduce an isomorphism of Δ-graded K^+-algebras

$$B \xrightarrow{\sim} A_\Delta. \tag{17.1.32}$$

Moreover, arguing as in remark 17.1.12(iii), we get an isomorphism

$$K[\Delta_\mathbb{Q}] \xrightarrow{\sim} A_K \tag{17.1.33}$$

fitting into a commutative diagram of K-algebras

$$\begin{array}{ccc} K[\Delta] & \xrightarrow{\sim} & B_K \\ \downarrow & & \downarrow \\ K[\Delta_\mathbb{Q}] & \xrightarrow{\sim} & A_K \end{array}$$

whose top horizontal arrow is the isomorphism of remark 17.1.17(v), and whose right (resp. left) vertical arrow is deduced from (17.1.32) (resp. is induced by the natural inclusion $\Delta \subset \Delta_{\mathbb{Q}}$).

Lemma 17.1.34. *With the notation of* (17.1.31)*, we have :*

(i) *$P_{\mathbb{Q},\gamma}$ is a free $P_{\mathbb{Q},0}$-module of rank one, for every $\gamma \in \Delta_{\mathbb{Q}}$.*
(ii) *$P_{\mathbb{Q},0}$ is a sharp monoid, and the inclusion map $P_{\mathbb{Q},0} \to P_{\mathbb{Q}}$ is flat and saturated.*

Proof. (i): We can write $P_{\mathbb{Q}}$ as the colimit of the system of monoids

$$(P_{[n]};\ \mu_{P,n,m} : P_{[n]} \to P_{[nm]} \mid n, m \in \mathbb{N})$$

such that $P_{[n]} := P^{(0)}$ for every $n \in \mathbb{N}$, and $\mu_{P,n,m}$ is the m-Frobenius map of $P^{(0)}$, for every $n, m \in \mathbb{N}$. Likewise, we may write $\Delta_{\mathbb{Q}}$ as colimit of a system of Frobenius endomorphisms $(\Delta_{0,[n]};\ \mu_{\Delta,n,m} \mid n, m \in \mathbb{N})$, and $\pi_{\mathbb{Q}}$ is the colimit of the corresponding system of maps $(\pi_{[n]} : P_{[n]} \to \Delta_{0,[n]} \mid n \in \mathbb{N})$ where $\pi_{[n]} := \pi$ for every $n \in \mathbb{N}$. Hence, for any $\gamma \in \Delta_0$ there exists $n \in \mathbb{N}$ such that γ is the image of some $\gamma_n \in \Delta_{0,[n]}$, and

$$P_{\mathbb{Q},\gamma} = \operatorname*{colim}_{k \in \mathbb{N}} P_{[nk],k\gamma_n} = \operatorname*{colim}_{k \in \mathbb{N}} P_{k\gamma_n}.$$

However, we know that $P_{k\gamma_n}$ is free of rank one, generated by a unique element $g_{k\gamma_n}$; moreover, the transition maps $\mu_{P,n,k}$ send g_{γ_n} onto $g_{k\gamma_n}$, for every $k \in \mathbb{N}$ (remark 17.1.26). This implies that $P_{\mathbb{Q},\gamma}$ is generated by the image of g_{γ_n}, whence (i).

(ii): The flatness follows from (i). Since the inclusion map $P_0^{(0)} \to P^{(0)}$ is saturated, it is easily seen that the same holds for the inclusion $P_{\mathbb{Q},0} \to P_{\mathbb{Q}}$. Lastly, the sharpness of $P_{\mathbb{Q},0}$ is likewise deduced from the sharpness of $P_0^{(0)}$ (details left to the reader). ☐

17.1.35. Lemma 17.1.34(ii) implies that the pair $(A, \Delta_{\mathbb{Q}})$ fulfills axiom (MA2), and we have thus our sought auxiliary model K^+-algebra. Since $P_{\mathbb{Q},0}$ is sharp, the $P_{\mathbb{Q},0}$-module $P_{\mathbb{Q},\gamma}$ admits a unique generator g_γ, for every $\gamma \in \Delta_{\mathbb{Q}}$. The image $g_\gamma \otimes 1$ of g_γ in A is a generator of the direct summand A_γ, which is a free K^+-module of rank one; hence, there exists a unique $a_\gamma \in K$ such that $\gamma \otimes a_\gamma$ gets mapped to $g_\gamma \otimes 1$, under the isomorphism (17.1.33).

After choosing an order-preserving isomorphism (14.5.63), we may define a function

$$f_A : \Delta_{\mathbb{Q}} \to \mathbb{R} \quad : \quad \gamma \mapsto \log |a_\gamma|.$$

The inclusion $A_\gamma \cdot A_\delta \subset A_{\gamma+\delta}$ translates as the inequality

$$f_A(\gamma) + f_A(\delta) \geq f_A(\gamma + \delta) \qquad \text{for every } \gamma, \delta \in \Delta_{\mathbb{Q}}.$$

Likewise, the saturation condition of axiom (MA2) translates as the identity

$$f_A(n\gamma) = n \cdot f_A(\gamma) \qquad \text{for every } \gamma \in \Delta_{\mathbb{Q}} \text{ and every } n \in \mathbb{N}.$$

We also fix a (Banach) norm

$$\Delta^{\mathrm{gp}}_{\mathbb{R}} \to \mathbb{R} \qquad \gamma \mapsto \|\gamma\|.$$

We can then state the following

Lemma 17.1.36. *With the notation of* (17.1.35)*, we have :*

(i) *There exists a Δ_0^{gp}-rational subdivision Θ of the convex polyhedral cone $(\Delta^{\mathrm{gp}}_{\mathbb{R}}, \Delta_{\mathbb{R}})$, such that*

$$f_A(\gamma + \delta) = f_A(\gamma) + f_A(\delta) \qquad \textit{for every } \sigma \in \Theta \textit{ and every } \gamma, \delta \in \sigma \cap \Delta_{\mathbb{Q}}.$$

(ii) *Especially, the function f_A is of* Lipschitz type, i.e. *there exists a real constant $C_A > 0$ such that*

$$|f_A(\gamma) - f_A(\gamma')| \leq C_A \cdot \|\gamma - \gamma'\| \qquad \textit{for every } \gamma, \gamma' \in \Delta^{\mathrm{gp}}_{\mathbb{Q}}.$$

Proof. (Here, $\Delta^{\mathrm{gp}}_{\mathbb{R}} := \Delta^{\mathrm{gp}}_0 \otimes_{\mathbb{Z}} \mathbb{R}$ and $\Delta_{\mathbb{R}} \subset \Delta^{\mathrm{gp}}_{\mathbb{R}}$ is the cone spanned by Δ_0.) Combining proposition 6.3.28 and lemma 6.3.33, we find a Δ^{gp}_0-rational subdivision Θ of $\Delta_{\mathbb{R}}$ such that

$$P_{\mathbb{Q},\gamma+\delta} = P_{\mathbb{Q},\gamma} + P_{\mathbb{Q},\delta} \qquad \text{for every } \sigma \in \Theta \text{ and every } \gamma, \delta \in \sigma \cap \Delta_{\mathbb{Q}}.$$

This means that $g_\gamma \cdot g_\delta = g_{\gamma+\delta}$ for every $\sigma \in \Theta$ and every $\gamma, \delta \in \sigma \cap \Delta_{\mathbb{Q}}$, whence (i).

(ii): Clearly, for every $\sigma \in \Theta$ we may find a constant C_σ such that the stated inequality holds – with C_A replaced by C_σ – for every $\gamma, \gamma' \in \sigma \cap \Delta_{\mathbb{Q}}$. It is easily seen that $C_A := \max(C_\sigma \mid \sigma \in \Theta)$ will do (details left to the reader). □

17.1.37. Fix $n \in \mathbb{N}$, pick a subdivision Θ of $(\Delta^{\mathrm{gp}}_{\mathbb{R}}, \Delta_{\mathbb{R}})$ as in lemma 17.1.36, and let $\Theta^s \subset \Theta$ be the subset of all $\sigma \in \Theta$ that span $\Delta^{\mathrm{gp}}_{\mathbb{R}}$. Also, for every $\gamma \in \Delta^{\mathrm{gp}}_{\mathbb{Q}}$, denote by $[\gamma]$ the class of γ in $\Delta^{\mathrm{gp}}_{\mathbb{Q}}/\Delta^{\mathrm{gp}}_n$. For any subset $\Sigma \subset \Delta^{\mathrm{gp}}_{\mathbb{R}}$ we let

$$A_\Sigma := A_{\Sigma \cap \Delta_{\mathbb{Q}}}$$

(where the right-hand side is defined as in (17.1.5)). In light of lemma 6.3.26 we obtain a decomposition of $B_n = A_{\Delta_n} = A_{[0]}$ as sum of K^+-subalgebras :

$$B_n = \sum_{\sigma \in \Theta^s} A_{[0] \cap \sigma}$$

and a corresponding decomposition of the B_n-module $A_{[\gamma]}$ as sum of $A_{[0]\cap\sigma}$-modules

$$A_{[\gamma]} = \sum_{\sigma \in \Theta^s} A_{[\gamma] \cap \sigma} \qquad \text{for every } \gamma \in \Delta^{\mathrm{gp}}_{\mathbb{Q}}.$$

Lemma 17.1.38. *With the notation of* (17.1.37) *and* (17.1.21)*, there exists $N \in \mathbb{N}$ such that for every $n \in \mathbb{N}$ and every $\gamma \in \Delta^{\mathrm{gp}}_{\mathbb{Q}}$, the B_n-module $A_{[\gamma]}$ admits a system of generators of cardinality at most N.*

Proof. According to proposition 6.3.22(ii), for every $\sigma \in \Theta^s$ and every $\gamma \in \Delta^{\mathrm{gp}}_{\mathbb{Q}}$, the subset $\Sigma_{\sigma,\gamma} := \Delta^{\mathrm{gp}}_n \cap (\sigma - \gamma)$ is a finitely generated $(\Delta^{\mathrm{gp}}_n \cap \sigma)$-module; hence, let us fix a finite system of generators $G_{\sigma,\gamma}$ for $\Sigma_{\sigma,\gamma}$. In light of lemma 17.1.36(i) we see that the finite set

$$G'_{\sigma,\gamma} := \{g_{\gamma+\delta} \otimes 1 \mid \delta \in G_{\sigma,\gamma}\} \subset A$$

generates the $A_{[0]\cap\sigma}$-module $A_{[\gamma]\cap\sigma}$. Consequently, the finite set $\bigcup_{\sigma\in\Theta^s} G'_{\sigma,\gamma}$ generates the B_n-module $A_{[\gamma]}$. On the other hand, since $\mathscr{S}_{\Delta^{\mathrm{gp}}_n,\sigma}$ is a finitely generated Δ^{gp}_n-module (proposition 6.3.35(ii)) it is clear that the cardinality of $G_{\sigma,\gamma}$ is bounded by a constant N_σ that is independent of γ, and then $A_{[\gamma]}$ is generated by at most $N_n := \sum_{\sigma\in\Theta^s} N_\sigma$ elements. It remains to show that the estimate for N_n is independent of n. However, notice that, for every $\sigma \in \Theta^s$, the automorphism of $\Delta^{\mathrm{gp}}_{\mathbb{Q}}$ given by multiplication by p^n, induces a natural bijection

$$\mathscr{S}_{\Delta^{\mathrm{gp}}_n,\sigma} \xrightarrow{\sim} \mathscr{S}_{\Delta^{\mathrm{gp}}_0,\sigma}$$

that sends each Δ_n-module $\Delta^{\mathrm{gp}}_n \cap (\sigma - v)$ onto the Δ_0-module

$$\Delta^{\mathrm{gp}}_0 \cap (\sigma - p^n v) = \Delta_0 \otimes_{\Delta_n} (\Delta^{\mathrm{gp}}_n \cap (\sigma - v))$$

(where the extension of scalars $\Delta_n \to \Delta_0$ is the isomorphism given by the rule : $\gamma \mapsto p^n\gamma$ for every $\gamma \in \Delta_n \cap \sigma$). Thus, we see that $N := N_0$ will already do. □

17.1.39. Let us choose N as in lemma 17.1.38, and endow the set $\mathscr{M}_N(B_n^a)$ with the uniform structure defined in (14.5.85) (relative to the standard setup attached to K^+); we consider the mapping

$$\Delta_{\mathbb{Q}}^{\mathrm{gp}} \to \mathscr{M}_N(B_n^a) \qquad \gamma \mapsto A_{[\gamma]}^a.$$

Lemma 17.1.40. *Keep the notation of* (6.3.34) *and* (14.5.85)*, and let also* $C_A > 0$ *be the constant appearing in lemma* 17.1.36(ii)*. Then :*

$$(A_{[\gamma]}^a, A_{[\gamma']}^a) \in E_{C_A \cdot \|\gamma - \gamma'\| \cdot 2}$$

for every $\Sigma \in \mathscr{S}_{\Delta_n^{\mathrm{gp}}, \Delta_{\mathbb{R}}}$ *and every* $\gamma, \gamma' \in \Omega(\Delta_{\mathbb{R}}, \Sigma) \cap \Delta_{\mathbb{Q}}^{\mathrm{gp}}$.

Proof. By inspecting the definitions, we get an isomorphism of B_n-modules

$$A_{[\gamma]} \xrightarrow{\sim} \bigoplus_{\delta \in \Sigma} \{\delta \otimes a \in K[\Delta_n^{\mathrm{gp}}] \mid \log|a| \geq f_A(\gamma + \delta)\} \tag{17.1.41}$$

for every $\Sigma \in \mathscr{S}_{\Delta_n^{\mathrm{gp}}, \Delta_{\mathbb{R}}}$ and every $\gamma \in \Omega(\Delta_{\mathbb{R}}, \Sigma) \cap \Delta_{\mathbb{Q}}^{\mathrm{gp}}$. Hence, suppose more generally that Σ, Σ' are two elements of $\mathscr{S}_{\Delta_n^{\mathrm{gp}}, \Delta_{\mathbb{R}}}$ such that $\Sigma \subset \Sigma'$, and let $\gamma \in \Omega(\Delta_{\mathbb{R}}, \Sigma) \cap \Delta_{\mathbb{Q}}^{\mathrm{gp}}$, $\gamma' \in \Omega(\Delta_{\mathbb{R}}, \Sigma') \cap \Delta_{\mathbb{Q}}^{\mathrm{gp}}$ be any two elements; from lemma 17.1.36(ii) we get, for any $b \in K^+$ with $\log|b| \geq C_A \|\gamma' - \gamma\|$, a B_n-linear map

$$\tau_{b,\gamma'-\gamma} : A_{[\gamma]} \to A_{[\gamma']}$$

which, under the identifications (17.1.41), corresponds to the map given by the rule : $\delta \otimes a \mapsto \delta \otimes ba$ for every $\delta \in \Sigma$ and every $a \in K$ such that $\log|a| \geq f(\gamma + \delta)$. In case $\Sigma = \Sigma'$, also $\tau_{b,\gamma-\gamma'}$ is well defined, and clearly

$$\tau_{b,\gamma'-\gamma} \circ \tau_{b,\gamma-\gamma'} = b^2 \cdot \mathbf{1}_{A_{[\gamma']}} \qquad \tau_{b,\gamma-\gamma'} \circ \tau_{b,\gamma'-\gamma} = b^2 \cdot \mathbf{1}_{A_{[\gamma]}}$$

whence the contention. ☐

Remark 17.1.42. Let $\gamma_1, \gamma_2, \gamma'_1, \gamma'_2 \in \Delta_{\mathbb{Q}}^{\mathrm{gp}}$ be four elements, and set $\gamma_3 := \gamma_1 + \gamma_2$, $\gamma'_3 := \gamma'_1 + \gamma'_2$; suppose that

$$\Delta_n^{\mathrm{gp}} \cap (\Delta_{\mathbb{R}} - \gamma_i) \subset \Delta_n^{\mathrm{gp}} \cap (\Delta_{\mathbb{R}} - \gamma'_i) \qquad \text{for } i = 1, 2, 3.$$

With the notation of the proof of lemma 17.1.40, for every $b_1, b_2 \in K^+$ such that

$$\log|b_i| \geq C_A \|\gamma'_i - \gamma_i\| \qquad (i = 1, 2)$$

we obtain a commutative diagram of B_n-linear maps

$$\begin{array}{ccc} A_{[\gamma_1]} \otimes_{B_n} A_{[\gamma_2]} & \longrightarrow & A_{[\gamma_3]} \\ {\scriptstyle \tau_{b_1,\gamma'_1-\gamma_1} \otimes \tau_{b_2,\gamma'_2-\gamma_2}} \downarrow & & \downarrow {\scriptstyle \tau_{b_1 b_2,\gamma'_3-\gamma_3}} \\ A_{[\gamma'_1]} \otimes_{B_n} A_{[\gamma'_2]} & \longrightarrow & A_{[\gamma'_3]} \end{array}$$

whose horizontal arrows are the restrictions of the multiplication map of the B_n-algebra B : the detailed verification shall be left as an exercise for the reader.

Theorem 17.1.43. *In the situation of* (17.1.31)*, the* K^+*-algebra* B^{sh} *is ind-measurable.*

Proof. First, notice that, for every $k \geq 0$, the inclusion map $B_n \to B_{n+k}$ induces a radicial morphism $B_n \otimes_{K^+} \kappa \to B_{n+k} \otimes_{K^+} \kappa$, and therefore also an isomorphism of B_{n+k}-algebras

$$B_n^{\mathrm{sh}} \otimes_{B_n} B_{n+k} \xrightarrow{\sim} B_{n+k}^{\mathrm{sh}} \tag{17.1.44}$$

([66, Ch.IV, Prop.18.8.10]). Notice as well, that B_n^{sh} is a measurable K^+-algebra (see definition 14.5.3(ii)), hence we have a well defined normalized length function λ_n on isomorphism classes of B_n^{sh}-modules, characterized as in theorem 14.5.43. Thus, our task is to exhibit a sequence $(d_n \mid n \in \mathbb{N})$ of normalizing factors fulfilling conditions (a) and (b) of definition 14.5.64, for the directed system $(B_n^{\rm sh} \mid n \in \mathbb{N})$, whose colimit is $B^{\rm sh}$. To this aim, let M be any object of $B_n^{\rm sh}\text{-}\mathbf{Mod}_{{\rm coh},\{s\}}$; in view of (17.1.44), we need to estimate

$$\lambda_{k+n}(B_{k+n} \otimes_{B_n} M) = \lambda_{k+n}\left(\bigoplus_{[\gamma]\in\Delta^{\rm gp}_{k+n}/\Delta^{\rm gp}_n} A_{[\gamma]} \otimes_{B_n} M\right).$$

To this aim, let us introduce the function

$$l_M : \Delta^{\rm gp}_{\mathbb{Q}} \to \mathbb{R} \qquad \gamma \mapsto \lambda_n(A_{[\gamma]} \otimes_{B_n} M).$$

Claim 17.1.45. Let Σ be as in lemma 17.1.40, set $J := \mathrm{Ann}_{B_0^{\rm sh}}(M/\mathfrak{m}M)$, and suppose that M admits a generating set of cardinality k. Then the restriction of l_M to $\Omega(\Delta_{\mathbb{R}},\Sigma) \cap \Delta^{\rm gp}_{\mathbb{Q}}$ is *of Lipschitz type*, *i.e.* there exists a real constant $C'_A > 0$ independent of n, Σ and M such that

$$|l_M(\gamma) - l_M(\gamma')| \leq C'_A \cdot k \cdot \mathrm{length}_{B_n^{\rm sh}}(B_n^{\rm sh}/JB_n^{\rm sh}) \cdot \|\gamma - \gamma'\|$$

for every $\gamma, \gamma' \in \Omega(\Delta_{\mathbb{R}},\Sigma) \cap \Delta^{\rm gp}_{\mathbb{Q}}$.

Proof of the claim. Let $I \subset B_0^{\rm sh}$ be any finitely generated $\mathfrak{m}_{B_n^{\rm sh}}$-primary ideal contained in the annihilator of M. Also, let N' be the cardinality of a finite set of generators for the $B_n^{\rm sh}$-module M, and N the constant provided by lemma 17.1.38; clearly $A_{[\gamma]} \otimes_{B_n} M$ admits a system of generators of cardinality $\leq NN'$, for every $\gamma \in \Delta^{\rm gp}_{\mathbb{Q}}$. Furthermore, an argument as in the proof of [75, Lemma 2.3.7(iv)] shows that the induced mapping

$$\mathscr{M}_N(B_n) \to \mathscr{M}_{NN'}(B_n^{\rm sh}/IB_n^{\rm sh}) \qquad L \mapsto L \otimes_{B_0} M$$

is of Lipschitz type; more precisely, it sends the entourage E_r into E_{2r}, for every $r \in \mathbb{R}_{>0}$ (details left to the reader). Then the claim follows by combining lemmata 14.5.86 and 17.1.40. ◊

From proposition 6.3.35(iv), we see that, for every $\Sigma \in \mathscr{S}_{\Delta_n^{\rm gp},\Delta_{\mathbb{R}}}$, the subset $\Omega(\Delta_{\mathbb{R}},\Sigma) \cap \Delta^{\rm gp}_{\mathbb{Q}}$ is dense in $\Omega(\Delta_{\mathbb{R}},\Sigma)$; taking into account claim 17.1.45, it follows that l_M extends (uniquely) to a function $l_{M,\mathbb{R}} : \Delta^{\rm gp}_{\mathbb{R}} \to \mathbb{R}$, whose restriction to every $\Omega(\Delta_{\mathbb{R}},\Sigma)$ is continuous and still satisfies the same Lipschitz type estimate. Notice that $l_{M,\mathbb{R}}$ descends to a function on the torus

$$\bar{l}_M : \mathbf{T}_n := \Delta^{\rm gp}_{\mathbb{R}}/\Delta^{\rm gp}_n \to \mathbb{R}.$$

Hence, set $r := \mathrm{rk}_{\mathbb{Z}}\Delta^{\rm gp}_0$, let us fix a basis $e_1,\dots,e_r$ for the free $\mathbb{Z}$-module $\Delta^{\rm gp}_0$, and define

$$\Omega_n := \left\{\sum_{i=1}^r t_i e_i \mid -\frac{1}{2p^n} \leq t_i < \frac{1}{2p^n} \text{ for } i = 1,\dots,r\right\}$$

so $\Omega_n \subset \Delta^{\rm gp}_{\mathbb{R}}$ is a *fundamental domain* for the lattice $\Delta^{\rm gp}_n$; in view of theorem 14.5.43(ii.b), we reach the following identity :

$$\lambda_{k+n}(B_{k+n} \otimes_{B_n} M) = \frac{1}{[\kappa(B^{\rm sh}_{k+n}) : \kappa(B^{\rm sh}_n)]} \cdot \sum_{\gamma\in\Delta^{\rm gp}_{k+n}\cap\Omega_n} l_M(\gamma).$$

Now, set

$$d_n := p^{nr} \cdot [\kappa(B^{\rm sh}_n) : \kappa(B^{\rm sh}_0)]^{-1} \qquad \text{for every } n \in \mathbb{N}. \tag{17.1.46}$$

We claim that $(d_n \mid n \in \mathbb{N})$ is a suitable sequence of normalizing factors for $B^{\rm sh}$. Indeed, recall that $\Omega(\Delta_{\mathbb{R}},\Sigma)$ is linearly constructible for every $\Sigma \in \mathscr{S}_{\Delta_0^{\rm gp},\Delta_{\mathbb{R}}}$ (proposition 6.3.35(iii)), especially, the bounded function l_M is continuous outside a subset of $\Delta^{\rm gp}_{\mathbb{R}}$ of measure zero, hence it is integrable on every bounded measurable subset of $\Delta_{\mathbb{R}}$. It follows that $\bar{l}_M$ is integrable relative to the invariant measure $d\mu_n$ on $\mathbf{T}_n$ of total volume equal to 1; lastly, a simple inspection (comparison of Riemann and Lebesgue integrals) yields

$$\lambda(B \otimes_{B_n} M) := \lim_{k \to +\infty} d_{k+n}^{-1} \cdot \lambda_{k+n}(B_{k+n} \otimes_{B_n} M) = d_n^{-1} \int_{\mathbf{T}_n} \bar{l}_M d\mu_n$$

which shows that condition (a) of definition 14.5.64 holds for this choice of normalizing factors.

In order to check condition (b), set $\Delta_{\mathbb{R}}(\rho) := \{v \in \Delta_{\mathbb{R}} \mid \|v\| \leq \rho\}$ for every $\rho > 0$. Notice that the automorphism of $\Delta_{\mathbb{R}}^{\mathrm{gp}}$ given by multiplication by p^n restricts to a bijection

$$\Omega(\Delta_{\mathbb{R}}, \Delta_n) \stackrel{\sim}{\to} \Omega(\Delta_{\mathbb{R}}, \Delta_0) \qquad \text{for every } n \in \mathbb{N}.$$

Then, by claim 6.3.40, we see that there exists ρ_0 such that

$$(17.1.47) \qquad \Delta_{\mathbb{R}}(p^{-n}\rho_0) \subset \Omega_n \cap \Omega(\Delta_{\mathbb{R}}, \Delta_n) \qquad \text{for all } n \in \mathbb{N}.$$

Especially, for every $\rho \leq \rho_0$ we may regard $\Delta_{\mathbb{R}}(p^{-n}\rho)$ as a measurable subset of $\mathbf{T}_n$, whose measure $\mathrm{Vol}(\rho)$ is strictly positive and independent of n.

Claim 17.1.48. Let $I \subset B_0^{\mathrm{sh}}$ be any finitely generated $\mathfrak{m}_{B_0^{\mathrm{sh}}}$-primary ideal. Then there exists a real constant $C_I > 0$ such that

$$d_n^{-1} \cdot \mathrm{length}_{B_n^{\mathrm{sh}}}(B_n^{\mathrm{sh}}/(I + \mathfrak{m})B_n^{\mathrm{sh}}) \leq C_I \qquad \text{for every } n \in \mathbb{N}.$$

Proof of the claim. On the one hand, we may write B_n^{sh} as the direct sum of the B_0^{sh}-modules $A_{[\gamma]\cap\Delta_{\mathbb{Q}}} \otimes_{B_0} B_0^{\mathrm{sh}}$, for γ ranging over the elements of $\Delta_n^{\mathrm{gp}}/\Delta_0^{\mathrm{gp}}$. There are p^{rn} such direct summands, and each of them admits a generating system of cardinality $\leq N$, where N is the constant provided by lemma 17.1.38. It follows that

$$\mathrm{length}_{B_0^{\mathrm{sh}}}(B_n^{\mathrm{sh}}/(I + \mathfrak{m})B_n^{\mathrm{sh}}) \leq Np^{rn} \cdot \mathrm{length}_{B_0^{\mathrm{sh}}}(B_0^{\mathrm{sh}}/(I + \mathfrak{m}B_0^{\mathrm{sh}})).$$

On the other hand, say that $l := \mathrm{length}_{B_n^{\mathrm{sh}}}(B_n^{\mathrm{sh}}/(I+\mathfrak{m})B_n^{\mathrm{sh}})$; this means that may find a filtration of $B_n^{\mathrm{sh}}/(I + \mathfrak{m})B_n^{\mathrm{sh}}$ of length l, consisting of B_n^{sh}-submodules, whose graded subquotients are all isomorphic to $\kappa(B_n^{\mathrm{sh}})$. Given such a filtration, we easily obtain a filtration of $B_n^{\mathrm{sh}}/(I+\mathfrak{m})B_n^{\mathrm{sh}}$ of length $l \cdot [\kappa(B_n^{\mathrm{sh}}) : \kappa(B_0^{\mathrm{sh}})]$, consisting of B_0^{sh}-submodules, whose graded subquotients are all isomorphic to $\kappa(B_0^{\mathrm{sh}})$. Therefore

$$l \cdot [\kappa(B_n^{\mathrm{sh}}) : \kappa(B_0^{\mathrm{sh}})] = \mathrm{length}_{B_0^{\mathrm{sh}}}(B_n^{\mathrm{sh}}/(I + \mathfrak{m})B_n^{\mathrm{sh}})$$

whence the claim. ◊

Now, fix $\varepsilon > 0$, and suppose there is given a finitely generated $\mathfrak{m}_{B_0^{\mathrm{sh}}}$-primary ideal $I \subset B_0^{\mathrm{sh}}$, and a surjection of finitely presented $B_n^{\mathrm{sh}}/IB_n^{\mathrm{sh}}$-modules $M \to M'$, generated by k elements, such that

$$d_n^{-1} \cdot (\lambda_n(M) - \lambda_n(M')) > \varepsilon.$$

Set $C(I,k) := 2kC'_A C_I$, where C'_A and C_I are as in claims 17.1.45 and 17.1.48; since

$$l_M(0) - l_{M'}(0) = \lambda_n(M) - \lambda_n(M')$$

we may estimate :

$$\begin{aligned}|\lambda(B^{\mathrm{sh}} \otimes_{B_n^{\mathrm{sh}}} M) - \lambda(B^{\mathrm{sh}} \otimes_{B_n^{\mathrm{sh}}} M')| &\geq d_n^{-1} \cdot \int_{\Delta_{\mathbb{R}}(p^{-n}\rho)} (\bar{l}_M - \bar{l}_{M'}) d\mu_n \\ &\geq \mathrm{Vol}(\rho) \cdot (d_n^{-1}(l_M(0) - l_{M'}(0)) - C(I,k) \cdot p^{-n}\rho) \\ &\geq \mathrm{Vol}(\rho) \cdot (\varepsilon - C(I,k) \cdot \rho)\end{aligned}$$

for every $\rho \leq \rho_0$. Therefore, if we set

$$\rho(k, \varepsilon, I) := \min\{\rho_0, 2^{-1}C(I,k)^{-1}\varepsilon\}$$

it is easily seen that the sought condition (b) holds with $\delta(k, \varepsilon, I) := 2^{-1} \cdot \mathrm{Vol}(\rho(k, \varepsilon, I)) \cdot \varepsilon$. □

17.2. **Almost purity : the log regular case.** In this section, we prove an almost purity theorem for certain towers of regular log schemes.

17.2.1. Let $\underline{M}_0$ be a log structure on the Zariski site of a local scheme X_0, such that $(X_0, \underline{M}_0)$ is regular at the closed point $x_0 \in X_0$, and say that $X_0 = \operatorname{Spec} B_0$ for a local ring B_0 which is necessarily noetherian, normal and Cohen-Macaulay (corollary 12.5.13). Let also $\beta_0 : P \to B_0$ be a chart for $\underline{M}_0$ that is sharp at x_0. Especially, P is a fine and saturated monoid, and $A := B_0/\mathfrak{m}_P B_0$ is a regular local ring; we denote by $\mathfrak{m}_A$ (resp. $\mathfrak{m}_{B_0}$) the maximal ideal of A (resp. of B_0). We assume furthermore that :

(a) The characteristic p of the residue field $\kappa(x_0)$ of A is positive.
(b) The Frobenius endomorphism Φ_{B_0} of B_0/pB_0 is a finite ring homomorphism.

Notice that (b) implies that B_0/pB_0 is excellent (theorem 9.7.26(i)) and also that $\Omega^1_{A/\mathbb{Z}} \otimes_A \kappa(x_0)$ is a finite dimensional $\kappa(x_0)$-vector space. Moreover, $(X_0, \underline{M}_0)$ is a regular log scheme, by theorem 12.5.31.

Example 17.2.2. Let (B, β) be a pair consisting of

(a) a local ring B whose residue field κ_B has positive characteristic
(b) a local morphism of monoids $\beta : P \to B$ from a fine, sharp and saturated monoid P.

Denote by $\mathfrak{m}_B$ the maximal ideal of B, by $\underline{M}$ the logarithmic structure on the Zariski site of $X := \operatorname{Spec} B$ induced by β, and suppose that $(X, \underline{M})$ is regular at the closed point of X.

(i) If moreover, B is complete for the $\mathfrak{m}_B$-adic topology and κ_B is perfect, then the Frobenius endomorphism of B/pB is a finite map. Indeed, in this case, for a suitable $d \in \mathbb{N}$ we have a surjective ring homomorphism

$$R[[P \times \mathbb{N}^{\oplus d}]] \to B$$

where R is either κ_B, or a discrete valuation ring with an isomorphism $R/pR \xrightarrow{\sim} \kappa_B$ (remark 12.5.12). The assertion is an immediate consequence.

(ii) It follows that for any such pair (B, β) we may find a local ring B_0 and a local and flat ring homomorphism $f : B \to B_0$ such that the log scheme

$$(X_0, \underline{M}_0) := \operatorname{Spec} B_0 \times_X (X, \underline{M})$$

and its chart $\beta_0 := \beta \circ f : P \to B_0$ fulfill the conditions of (17.2.1). Indeed, according to [61, Ch.0, Prop.10.3.1] there exists a flat and local B-algebra C such that $\kappa_B \otimes_B C$ is a perfect field, and we take B_0 to be the completion of C. By proposition 12.5.30(ii), the resulting log scheme $(X_0, \underline{M}_0)$ is regular at the closed point of X_0, so the assertion follows from (i).

17.2.3. In the situation of (17.2.1), set

$$P^{(n)} := \{\gamma \in P_{\mathbb{Q}} \mid \gamma^{p^n} \in P\} \qquad \text{for every } n \in \mathbb{N}.$$

The p^n-Frobenius map of $P^{(n)}$ identifies $P^{(n)}$ with its submonoid P; in other words, the inclusion map $P \to P^{(n)}$ is naturally identified with the p^n-Frobenius endomorphism of P. Fix a sequence $(f_1, \dots, f_r)$ of elements of B_0 whose image in A is maximal in the sense of remark 9.6.35(iii), in which case we say that $(f_1, \dots, f_r)$ is *maximal in* B_0. Notice that $\dim_{\kappa(x_0)} \mathfrak{m}_A/\mathfrak{m}_A^2 = \dim A$, since A is regular; it follows that

$$r = \dim A + \dim_{\kappa(x_0)} \Omega^1_{\kappa(x_0)/\mathbb{Z}}$$

by virtue of the short exact sequence (9.6.5), if $p \in \mathfrak{m}_A^2$, and otherwise, by virtue of proposition 9.6.17. Denote also by $\overline{f}_i \in A$ the image of f_i, for every $i = 1, \dots, r$. According to corollary 9.6.34, the ring

$$A_n := A[T_1, \dots, T_r]/(T_1^{p^n} - \overline{f}_1, \dots, T_r^{p^n} - \overline{f}_r)$$

is regular. For every $n \in \mathbb{N}$, we set :

$$B'_n := P^{(n)} \otimes_P B_0 \qquad B''_n := B_0[T_1, \dots, T_r]/(T_1^{p^n} - f_1, \dots, T_r^{p^n} - f_r) \qquad B_n := B'_n \otimes_{B_0} B''_n.$$

Lemma 17.2.4. *The induced maps*

$$B_n \to B_{n+1} \qquad \textit{and} \qquad B_n/pB_n \to B_{n+1}/pB_{n+1}$$

are injective, for every $n \in \mathbb{N}$.

Proof. The natural map $B_n \to B_{n+1}$ factors as the composition

$$B'_n \otimes_{B_0} B''_n \to B'_{n+1} \otimes_{B_0} B''_n \to B'_{n+1} \otimes_{B_0} B''_{n+1} \qquad \text{for every } n \in \mathbb{N}.$$

Notice that $B_0 = B''_0$, and B''_{n+1} is a free B''_n-module (of rank p^r) for every $n \in \mathbb{N}$; we are then reduced to checking that the maps $B'_n \to B'_{n+1}$ and $B'_n/pB'_n \to B'_{n+1}/pB'_{n+1}$ are injective for every $n \in \mathbb{N}$. However, set $G := P^{(n+1)}/P^{(n)}$, and notice that $P^{(n+1)}$ is a G-graded monoid, with $P_0^{(n+1)} = P^{(n)}$, hence B'_{n+1} is a G-graded B'_n-algebra with $(B'_{n+1})_0 = B'_n$ for every $n \in \mathbb{N}$. The assertion follows. □

17.2.5. In view of lemma 17.2.4, we may set

$$B'' := \bigcup_{n\in\mathbb{N}} B''_n \qquad B := \bigcup_{n\in\mathbb{N}} B_n \qquad P^{(\infty)} := \bigcup_{n\in\mathbb{N}} P^{(n)}$$

and clearly

$$B = P^{(\infty)} \otimes_P B'' \qquad \text{for every } n \in \mathbb{N}$$

from which we see that B is naturally a $P^{(\infty)}/P^{(n)}$-graded B_n-algebra, for every $n \in \mathbb{N}$. Also, the induced morphism $\operatorname{Spec} B_{n+1}/pB_{n+1} \to \operatorname{Spec} B_n/pB_n$ is radicial and surjective, so $\operatorname{Spec} B_n/pB_n$ is a local scheme for every $n \in \mathbb{N}$; on the other hand, the map $B_0 \to B_n$ is finite, so every point of $\operatorname{Spec} B_n$ specializes to a point of $\operatorname{Spec} B_n/pB_n$. We conclude that B_n is a local ring, and we denote by $\mathfrak{m}_{B_n}$ its maximal ideal, for every $n \in \mathbb{N}$. Let $\underline{M}_n$ be the log structure on the Zariski site of $X_n := \operatorname{Spec} B_n$ deduced from the natural map $\beta_n : P^{(n)} \to B_n$; notice that $B_n/\mathfrak{m}_{P^{(n)}}B_n = A_n$ is a regular local ring of dimension equal to $\dim A$. Since we have as well $\dim P^{(n)} = \dim P$, it follows that $(X_n, \underline{M}_n)$ is regular at the closed point $x_n \in X_n$. Then theorem 12.5.31 shows that $(X_n, \underline{M}_n)$ is a regular log scheme. Thus, we have obtained a tower of finite morphisms of regular log schemes

$$(17.2.6) \qquad \cdots \to (X_{n+1}, \underline{M}_{n+1}) \to (X_n, \underline{M}_n) \to \cdots \to (X_0, \underline{M}_0)$$

which we call the *maximal tower* associated with the chart $\beta_0 : P \to B_0$ and the maximal sequence $(f_1, \dots, f_r)$. The limit of the tower (17.2.6) is a log scheme $(X, \underline{M})$ whose log structure admits a chart $P^{(\infty)} \to B$ which is sharp at the closed point.

Remark 17.2.7. Keep the notation of (17.2.5), and let $s \in \mathbb{N}$ be any integer; from remark 9.6.35(iii) it is easily seen that the sequence $((X_{n+s}, \underline{M}_{n+s}) \mid n \in \mathbb{N})$, obtained by removing from (17.2.6) the first s terms, is the maximal tower associated with the chart β_n and the maximal sequence $(f_1^{1/p^s}, \dots, f_r^{1/p^s})$.

17.2.8. Let now $y \in (X_0, \underline{M}_0)_{\mathrm{tr}}$ be any point, and $n \in \mathbb{N}$ any integer. The chart β_0 extends uniquely to a morphism of monoids $\beta_0^{\mathrm{gp}} : P^{\mathrm{gp}} \to B_{0,y} := \mathscr{O}_{X_0,y}$, and we have a natural isomorphism

$$B_n \otimes_{B_0} B_{0,y} \xrightarrow{\sim} P^{(n)\mathrm{gp}} \otimes_{P^{\mathrm{gp}}} B_{0,y} \otimes_{B_0} B''_n.$$

Especially, $B_n \otimes_{B_0} B_{0,y}$ is a free $B_{0,y}$-module of rank p^{nd}, where

$$d := \dim P + r = \dim P + \dim A + \dim_{\kappa(x_0)} \Omega^1_{\kappa(x_0)/\mathbb{Z}}.$$

However, since $(X_0, \underline{M}_0)$ is regular, we have $\dim A + \dim P = \dim B_0$. Summing up, we find

$$d = \dim B_0 + \dim_{\kappa(x_0)} \Omega^1_{\kappa(x_0)/\mathbb{Z}}.$$

Next, let $z \in \operatorname{Spec} B_0/pB_0 \subset X_0$ be any point, and $\mathfrak{p}_z \subset B_0$ the corresponding prime ideal; as in the foregoing, the chart β_0 extends uniquely to a morphism $\beta_\mathfrak{p} : P_\mathfrak{p} \to B_{0,z} := \mathscr{O}_{X_0,z}$, where $\mathfrak{p} := \beta_0^{-1}\mathfrak{p}_z$. As already remarked, the point z lifts uniquely to a point $z_n \in X_n$, and on the other hand, there exists a unique prime ideal $\mathfrak{p}^{(n)} \subset P^{(n)}$ containing $\mathfrak{p}$, and the inclusion map $j_\mathfrak{p} : P_\mathfrak{p} \to P^{(n)}_{\mathfrak{p}^{(n)}}$ is naturally identified with the p^n-Frobenius endomorphism of $P_\mathfrak{p}$. By lemma 6.2.10, there exists an isomorphism of monoids $P_\mathfrak{p} \xrightarrow{\sim} G \times Q$, with $G := P_\mathfrak{p}^\times$ and $Q := P_\mathfrak{p}^\sharp$; we may then find a corresponding decomposition $P^{(n)}_{\mathfrak{p}^{(n)}} = G^{(n)} \times Q^{(n)}$ that identifies $j_\mathfrak{p}$ with the product of maps of monoids $G \to G^{(n)}$ and $Q \to Q^{(n)}$. Summing up, there follows an isomorphism of B_0-algebras

$$\mathscr{O}_{X_n,z_n} \xrightarrow{\sim} P^{(n)}_{\mathfrak{p}^{(n)}} \otimes_{P_\mathfrak{p}} B_{0,z} \otimes_{B_0} B''_n \xrightarrow{\sim} (Q^{(n)} \otimes_Q B_{0,z}) \otimes_{B_{0,z}} (G^{(n)} \otimes_G B_{0,z}) \otimes_{B_0} B''_n.$$

Fix a basis $g_1, \dots, g_s$ of the free $\mathbb{Z}$-module G, and set $f_{r+i} := \beta_\mathfrak{p}(g_i)$ for $i = 1, \cdots, s$; clearly

$$(G^{(n)} \otimes_G B_{0,z}) \otimes_{B_0} B''_n = B_{0,z}[T_1, \dots, T_{r+s}]/(T_1^{p^n} - f_1, \dots, T_{r+s}^{p^n} - f_{r+s}).$$

On the other hand, set $A_z := B_{0,z}/\mathfrak{m}_Q B_{0,z}$; we have

$$\begin{aligned} \dim P &= \dim Q + s && \text{(corollary 6.4.12(i))} \\ \dim B_{0,z} &= \dim Q + \dim A_z && \text{(since } (X_0, \underline{M}_0) \text{ is regular)} \\ \dim B_{0,z} &= d - \dim_{\kappa(z)} \Omega^1_{\kappa(z)/\mathbb{Z}} && \text{(proposition 9.7.20).} \end{aligned}$$

Therefore $r + s = \dim A_z + \dim_{\kappa(z)} \Omega^1_{\kappa(z)/\mathbb{Z}}$. However, $A_{z_n} := \mathscr{O}_{X_n,z_n}/\mathfrak{m}_{Q^{(n)}}\mathscr{O}_{X_n,z_n}$ is a regular local ring, since $(X_n, \underline{M}_n)$ is regular, and by inspecting the construction we see that

$$A_{z_n} = A_z[T_1, \dots, T_{r+s}]/(T_1^{p^n} - f_1, \dots, T_{r+s}^{p^n} - f_{r+s})$$

hence the image of the system $(f_1, \dots, f_{r+s})$ yields a basis of either $\Omega^1_{A_z/\mathbb{Z}} \otimes_{A_z} \kappa(z)$ or $\boldsymbol{\Omega}_{A_z}$, depending on whether or not $p \in \mathfrak{m}^2_{A_z}$ (corollary 9.6.34). In conclusion, we see that the induced sequence of morphisms of log schemes

$$\cdots \to (X_{n+1}(z_n), \underline{M}_{n+1}(z_n)) \to (X_n(z_n), \underline{M}_n(z_n)) \to \cdots \to (X_0(z), \underline{M}_0(z))$$

(notation of (12.7.11)) is the maximal tower associated with the induced chart $Q \to \mathscr{O}_{X_0,z}$ and the maximal sequence $(f_1, \dots, f_{r+s})$.

Remark 17.2.9. (i) Let $\overline{x}_0$ be any geometric point of X_0, localized at x_0, and denote by B_0^{sh} the strict henselization of B_0 at the point $\overline{x}_0$. In light of [75, Th.3.5.13(ii)], we see that the log scheme $(X_0(\overline{x}_0), \underline{M}_0(\overline{x}_0))$ still fulfills the conditions of (17.2.1). Moreover, the image in B_0^{sh} of the maximal sequence $(f_1, \dots, f_n)$ is still maximal (remark 9.6.35(iv)). It follows easily that the induced tower of regular log schemes

$$\cdots \to X_0(\overline{x}_0) \times_{X_0} (X_{n+1}, \underline{M}_{n+1}) \to X_0(\overline{x}_0) \times_{X_0} (X_n, \underline{M}_n) \to \cdots \to (X_0(\overline{x}_0), \underline{M}_0(\overline{x}_0))$$

is (naturally isomorphic to) the maximal tower associated with the induced chart $P_0 \to B_0^{\mathrm{sh}}$ and the maximal sequence $(f_1, \dots, f_n)$ of B_0^{sh}.

(ii) In the same vein, let $I \subset B_0$ be any proper ideal, $B_{0,I}^\wedge$ the I-adic completion of the local ring B_0, and set $X_0^\wedge := \operatorname{Spec} B_{0,I}^\wedge$; according to claim 9.7.21(i), the log scheme $(X_0^\wedge, \underline{M}_0^\wedge) := X_0^\wedge \times_{X_0} (X_0, \underline{M}_0)$ still fulfills the conditions of (17.2.1), and the image in $B_{0,I}^\wedge$ of the maximal sequence $(f_1, \dots, f_n)$ of B_0 is still maximal (remark 9.6.35(iv)). It follows that the induced tower of log schemes

$$\cdots \to X_0^\wedge \times_{X_0} (X_{n+1}, \underline{M}_{n+1}) \to X_0^\wedge \times_{X_0} (X_n, \underline{M}_n) \to \cdots \to (X_0^\wedge, \underline{M}_0^\wedge)$$

is (naturally isomorphic to) the maximal tower associated with the induced chart $P_0 \to B^{\wedge}_{0,I}$ and the maximal sequence $(f_1, \dots, f_n)$ of $B^{\wedge}_{0,I}$.

17.2.10. Let $\Phi_{B_n} : B_n/pB_n \to B_n/pB_n$ be the Frobenius endomorphism of B_n/pB_n; taking into account lemma 17.2.4, we see that $\Phi_{B_{n+1}}$ factors through a unique ring homomorphism

$$\Psi_{B_{n+1}} : B_{n+1}/pB_{n+1} \to B_n/pB_n \qquad \text{for every } n \in \mathbb{N}.$$

Lemma 17.2.11. *The map $\Psi_{B_{n+1}}$ is surjective for every $n \in \mathbb{N}$.*

Proof. Let us start out with the following general :

Claim 17.2.12. Let $\varphi : R \to S$ be an injective, finite and radicial ring homomorphism. Then φ is an isomorphism if and only if $\Omega^1_{S/R} = 0$.

Proof of the claim. We may assume that $\Omega^1_{S/R} = 0$, and we show that φ is an isomorphism. To this aim, it suffices to show that

$$\varphi \otimes_R R/\mathfrak{m} : R' := R/\mathfrak{m} \to S' := S/\mathfrak{m}S$$

is an isomorphism for every maximal ideal $\mathfrak{m} \subset R$. However, $\Omega^1_{S'/R'} = \Omega^1_{S/R} \otimes_R R' = 0$, so we may replace R by R' and S by S', and assume from start that R is a field. In this case, S is a local unramified R-algebra, so S must be a finite separable field extension of R, by [66, Ch.IV, Cor.17.4.2]. But S is also a radicial extension of R, so $S = R$. ◊

Claim 17.2.13. Let $p > 0$ be a prime integer, R a local $\mathbb{F}_p$-algebra whose Frobenius endomorphism Φ_R is a finite map, k_R the residue field of R, and $\Sigma \subset R$ any subset. Set $R_0 := R/\Sigma R$, and let $(g_1, \dots, g_n)$ be a finite sequence of elements of R such that $dg_1, \dots, dg_n$ is a system of generators for the k_R-vector space $\Omega^1_{R_0/\mathbb{Z}} \otimes_R k_R$. Then $R = R^p[\Sigma, g_1, \dots, g_n]$.

Proof of the claim. Set $S := R^p[\Sigma, g_1, \dots, g_n]$. The inclusion map $S \to R$ is clearly radicial, and it is finite, since Φ_R is finite; hence claim 17.2.12 reduces to checking that $\Omega^1_{R/S}$ vanishes. By Nakayama's lemma, it then suffices to show that $\Omega^1_{R/S} \otimes_R k_R = 0$. However, let M (resp. N) be the R-submodule of $\Omega := \Omega^1_{R/\mathbb{Z}}$ generated by $\{da \mid a \in \Sigma\}$ (resp. by $\{dg_1, \dots, dg_n\}$); then $\Omega^1_{R/S} = \Omega/(M + N)$ ([63, Ch.0, Th.20.5.7(i)]) and on the other hand, the induced map $(\Omega/M) \otimes_R R_0 \to \Omega^1_{R_0/\mathbb{Z}}$ is an isomorphism ([63, Ch.0, Th.20.5.12(i)]). We deduce a right exact sequence of R-modules

$$N \xrightarrow{j} \Omega^1_{R_0/\mathbb{Z}} \otimes_R k_R \to \Omega^1_{R/S} \otimes_R k_R \to 0.$$

But our choice of the sequence $(g_1, \dots, g_n)$ implies that j is surjective, whence the contention. ◊

Finally, notice that the image of $\Psi_{B_{n+1}}$ is the subring $(B_n/pB_n)^p[\beta_n(P^{(n)}), f_1^{1/p^n}, \dots, f_r^{1/p^n}]$. For every $n > 0$, consider the exact sequence

$$\Omega^1_{A/\mathbb{Z}} \otimes_A \kappa(x_n) \xrightarrow{j} \Omega^1_{A_n/\mathbb{Z}} \otimes_{A_n} \kappa(x_n) \to \Omega^1_{A_n/A} \otimes_{A_n} \kappa(x_n) \to 0$$

([63, Ch.0, Th.20.5.7(i)]); the image of j is generated by the image of the generating system $df_\bullet := (df_1, \dots, df_r)$ of the $\kappa(x_0)$-vector space $\Omega^1_{A/\mathbb{Z}} \otimes_A \kappa(x_0)$. However, since f_i admits a p-th root in A_n for every $i = 1, \dots, r$, it is easily seen that the image of $df_\bullet$ vanishes in $\Omega^1_{A_n/\mathbb{Z}}$. Hence $\Omega^1_{A_n/\mathbb{Z}} \otimes_{A_n} \kappa(x_n) = \Omega^1_{A_n/A} \otimes_{A_n} \kappa(x_n)$ is generated by the image of the system $(df_1^{1/p^n}, \dots, df_r^{1/p^n})$. Therefore, to prove the lemma, it suffices to apply claim 17.2.13 to $R := B_n/pB_n$, $\Sigma := \beta_n(\mathfrak{m}_{P^{(n)}})$ and the sequence $(f_1^{1/p^n}, \dots, f_r^{1/p^n})$. □

Theorem 17.2.14. *With the notation of* (17.2.5)*, we have :*

(i) *If B_0 is an $\mathbb{F}_p$-algebra, Ψ_{B_n} is an isomorphism for every $n \in \mathbb{N}$.*

(ii) *If B_0 is not an $\mathbb{F}_p$-algebra, then there exist $\pi \in B_1$ and $u \in B_1^\times$ such that $\pi^p = pu$.*
(iii) *For every $\pi \in B_1$ as in* (ii) *and every integer $n > 0$, we have* $\mathrm{Ker}\,\Psi_{B_n} = \pi B_n/pB_n$.
(iv) *Let $\mathscr{T}_{p,B}$ be the p-adic topology of B. Then $(B, \mathscr{T}_{p,B})$ is a formally perfectoid ring.*

Proof. (i) is immediate from lemma 17.2.11, since in that case Φ_{B_n} is the Frobenius endomorphism of B_n, so it is injective, since the latter is a domain.

(iii): Suppose we have found π as in (ii), and let $x \in B_n$ whose image in B_n/pB_n lies in $\mathrm{Ker}\,\Psi_{B_n}$; this means that $x^p = py$ holds in B_n for some $y \in B_n$; hence $(x/\pi)^p \in B_n$, and since B_n is a normal ring (corollary 12.5.13), we deduce that $x/\pi \in B_n$, *i.e.* $x \in \pi B_n$.

(ii): Assume first that $p \in \mathfrak{m}_A^2$. Then we may write

$$p = \sum_{i=1}^{t} b_i b_i' + \sum_{j=1}^{s} b_j'' \cdot \beta_0(x_j)$$

for certain $b_1, b_1', \dots, b_t, b_t' \in \mathfrak{m}_{B_0}$, $b_1'', \dots, b_s'' \in B_0$, and $x_1, \dots, x_s \in \mathfrak{m}_P$. In light of lemma 17.2.11, we may then write

$$b_i = c_i^p + pd_i \quad b_i' = c_i'^p + pd_i' \qquad \text{where } c_i, c_i', d_i, d_i' \in \mathfrak{m}_{B_1} \text{ for every } i = 1, \dots, t$$

and likewise, $b_j'' = c_j''^p + pd_j''$ where $c_j'' \in B_1$ for $j = 1, \dots, s$. Moreover, by construction, β_0 extends to a morphism of monoids $\beta_1 : P^{(1)} \to B_1$, and we may write $x_j = y_j^p$ with $y_j \in \mathfrak{m}_{P^{(1)}}$ for $j = 1, \dots, s$. A simple computation then yields

$$(17.2.15) \qquad p \cdot (1 + e) = \sum_{i=1}^{t} c_i^p c_i'^p + \sum_{j=1}^{s} c_j''^p \cdot \beta_1(y_j)^p \qquad \text{for some } e \in \mathfrak{m}_{B_1}.$$

However, the right-hand side of (17.2.15) can be written in the form $g^p + ph$ for some $g, h \in \mathfrak{m}_{B_1}$ (details left to the reader); clearly $1 + e - h \in B_1^\times$, whence the contention, in this case.

Next, suppose that $p \notin \mathfrak{m}_A^2$. In this case, recall that

$$\dim_{\kappa(x_0)^{1/p}} \boldsymbol{\Omega}_A = 1 + \dim_{\kappa(x_0)} \Omega^1_{A/\mathbb{Z}} \otimes_A \kappa(x_0).$$

Therefore, after reordering the sequence $(f_1, \dots, f_r)$, we may assume that $df_1, \dots, df_{r-1}$ is a basis of the $\kappa(x_0)$-vector space $\Omega^1_{A/\mathbb{Z}} \otimes_A \kappa(x_0)$. Set

$$B' := (P^{(1)} \otimes_P B_0)[T_1, \dots, T_{r-1}]/(T_1^p - f_1, \dots, T_{r-1}^p - f_{r-1}).$$

Clearly B_1 is a faithfully flat B'-algebra, hence B'/pB' is a B_0/pB_0-subalgebra of B_1/pB_1, so the natural map $B_0/pB_0 \to B'/pB'$ is injective (lemma 17.2.4), and just as in (17.2.5), we deduce that the Frobenius endomorphism of B'/pB' factors through a ring homomorphism $\Psi_{B'} : B'/pB' \to B_0/pB_0$, and arguing as in the foregoing, we also see that B' is a local ring. Moreover, by applying claim 17.2.13 with $R := B'/pB'$, $\Sigma := \beta_0(\mathfrak{m}_P)$ and the sequence $(f_1, \dots, f_{r-1})$ we conclude – as in the proof of lemma 17.2.11 – that $\Psi_{B'}$ is surjective. Hence, denote by $\mathfrak{m}_{B'}$ the maximal ideal of B'; it follows that there exist $g \in \mathfrak{m}_{B'}$ and $h \in B'$ such that $f_r = g^p + ph$ in B'. Set

$$A' := B'/\mathfrak{m}_{P^{(1)}} B' = A[T_1, \dots, T_{r-1}]/(T_1^p - f_1, \dots, T_{r-1}^p - f_{r-1}).$$

Then A' is a regular local ring, by corollary 9.6.34, applied to the sequence $(\overline{f}_1, \dots, \overline{f}_{r-1})$ consisting of the images of the elements f_i in A. By the same criterion – applied to the similar sequence $(\overline{f}_1, \dots, \overline{f}_r)$ – we see that $A'[T]/(T^p - f_r)$ is regular as well. So once again the same corollary – applied to the element $\overline{f}_r$ of A' – says that the element $\boldsymbol{d}(f_r)$ of $\boldsymbol{\Omega}_{A'}$ does not vanish. However

$$\boldsymbol{d}(f_r) = \boldsymbol{d}(g^p) + \boldsymbol{d}(ph) = pg^{p-1}\boldsymbol{d}(g) + h\boldsymbol{d}(p) + p\boldsymbol{d}(h) = h\boldsymbol{d}(p) \qquad \text{in } \boldsymbol{\Omega}_{A'}$$

(see (9.6.16)). We conclude that $h \in B'^{\times}$. Lastly, notice that f_r admits a p-th root $f_r^{1/p}$ in B_1, hence $ph = f_r - g^p = (f_r^{1/p} - g)^p + pe$ in B_1 for some $e \in \mathfrak{m}_{B_1}$ (details left to the reader). Since $h - e \in B_1^{\times}$, we are done.

(iv): If B_0 is an $\mathbb{F}_p$-algebra, then $\mathscr{T}_{p,B}$ is the discrete topology, and B is a perfect $\mathbb{F}_p$-algebra, whence the assertion in this case. Suppose then that B_0 is not an $\mathbb{F}_p$-algebra, in which case the topology of the completion $B^\wedge$ of $(B, \mathscr{T}_{p,B})$ is still p-adic (remark 8.3.3(iv)). Pick $\pi \in B_1$ as in (ii), set $I := \pi B^\wedge$, and notice that π is a regular element of $B^\wedge$, by proposition 8.2.13(i) : the details shall be left to the reader. In light of (iii), it is easily seen that $B^\wedge$ is a P-ring, I is a special ideal of definition, and the Frobenius endomorphism of $B^\wedge : pB^\wedge = B/pB$ induces an isomorphism $B^\wedge/I \xrightarrow{\sim} B^\wedge/I^{(p)}$. The assertion then follows from theorem 16.4.1. □

17.2.16. Let $\beta : P^{(\infty)} \to B$ be the chart of the log structure $\underline{M}$ on X from (17.2.5), and notice that the inclusion map $P^{(n)} \to P^{(\infty)}$ induces bijections $\operatorname{Spec} P^{(\infty)} \xrightarrow{\sim} \operatorname{Spec} P^{(n)}$ for every $n \in \mathbb{N}$ (lemma 6.4.59(i)); especially, $\operatorname{Spec} P^{(\infty)}$ is a finite set. Let $I \subset B$ be any non-zero ideal; we say that I is a *branch ideal*, if there exist radical ideals $J \subset B$ and $\mathfrak{r} \subset P^{(\infty)}$ such that

$$(17.2.17) \qquad p \in J \qquad \text{and} \qquad I = J \cap \mathfrak{r}B.$$

Remark 17.2.18. (i) Notice that, in case B_0 is an $\mathbb{F}_p$-algebra, a branch ideal is just any non-zero radical ideal of B.

(ii) Let $I \subset B$ be a branch ideal, and pick radical ideals $J \subset B$ and $\mathfrak{r} \subset P^{(\infty)}$ such that (17.2.17) holds. Set $\mathfrak{r}^{(n)} := \mathfrak{r} \cap P^{(n)}$ for every $n \in \mathbb{N}$; from corollary 12.5.20(ii) we know that $\mathfrak{r}^{(n)}B_n$ is a radical ideal of B_n, hence $\mathfrak{r}B$ is a radical ideal of B, and then the same holds for I.

(iii) In the situation of (ii), let $\mathfrak{Z} \subset \operatorname{Spec} P^{(\infty)}$ be a subset such that $\mathfrak{r} = \bigcap_{\mathfrak{p} \in \mathfrak{Z}} \mathfrak{p}$ (lemma 6.1.16), and set $\mathfrak{p}^{(n)} := \mathfrak{p} \cap P^{(n)}$ for every $\mathfrak{p} \in \mathfrak{Z}$ and every $n \in \mathbb{N}$, so $\mathfrak{r}^{(n)} = \bigcap_{\mathfrak{p} \in \mathfrak{Z}} \mathfrak{p}^{(n)}$ for every $n \in \mathbb{N}$. In view of proposition 12.5.16 and lemmata 12.5.1 and 6.1.37, we see that $\mathfrak{r}^{(n)}B = \bigcap_{\mathfrak{p} \in \mathfrak{Z}} \mathfrak{p}^{(n)}B_n$, and therefore

$$(17.2.19) \qquad \mathfrak{r}B = \bigcap_{\mathfrak{p} \in \mathfrak{Z}} \mathfrak{p}B.$$

(iv) Furthermore, any branch ideal $I \subset B$ is the radical of I_0B, for some ideal $I_0 \subset B_0$. Indeed, pick J and $\mathfrak{r}$ such that (17.2.17) holds; since the projection $\operatorname{Spec} B/pB \to (X_0)_{/p}$ is radicial and surjective, it is clear that J is the radical of J_0B for some ideal $J_0 \subset B_0$, and on the other hand, $\mathfrak{r}B$ is the radical of $\mathfrak{r}^{(0)}B$.

Proposition 17.2.20. *With the notation of* (17.2.16)*, let $I \subset B$ be any branch ideal. We have :*

(i) *$I^2 = I$, and I fulfills condition* $(\mathbf{B})$ *of* [75, §2.1.6].

(ii) *Let $I_1, I_2 \subset B$ be any two branch ideals. Then $I_1 \cap I_2$ and $I_1 + I_2$ are also branch ideals, and $I_1I_2 = I_1 \cap I_2$.*

Proof. (i): By assumption, $I = J \cap \mathfrak{r}B$ for radical ideals $J \subset B$ and $\mathfrak{r} \subset P^{(\infty)}$ with $p \in J$.

Claim 17.2.21. $(\mathfrak{r}B)^2 = \mathfrak{r}B$ and $J^2 = J$, and the ideals $\mathfrak{r}B$ and J fulfill condition $(\mathbf{B})$.

Proof of the claim. Since the p-Frobenius endomorphism of $P^{(\infty)}$ is an automorphism, the first stated identity is clear. Next, set $\overline{J} := J/pB$. By lemma 17.2.11, the Frobenius endomorphism of B/pB is surjective; since $\overline{J}$ is a radical ideal, we deduce that $\overline{J}^2 = \overline{J}$. On the other hand, from theorem 17.2.14(ii) we see that $p \in J^2$, from which also the second identity follows easily.

Next, it is clear that $\mathfrak{r}B$ fulfills condition $(\mathbf{B})$, and for J we apply [75, Claim 2.1.9] which reduces checking that J/pJ is generated by the p-th powers of its elements. However, the foregoing already shows that J/pB is generated by the p-th powers of its elements; combining with theorem 17.2.14(ii), the contention follows easily. ◊

Taking into account remark 17.2.18(i), we see that claim 17.2.21 already implies the assertion, in case B_0 is an $\mathbb{F}_p$-algebra. Thus, we may assume that B_0 is not an $\mathbb{F}_p$-algebra, in which case – again by claim 17.2.21 – it suffices to show that $J \cap \mathfrak{r}B = \mathfrak{r} \cdot J$, or equivalently, that :

$$\mathrm{Tor}_1^B(B/\mathfrak{r}B, B/J) = 0.$$

Now, the chart β yields a ring homomorphism $C := \mathbb{Z}[P^{(\infty)}] \to B$, and we have a change of rings spectral sequence for Tor-functors (see [163, Th.5.6.6]) :

$$E^2_{pq} := \mathrm{Tor}_p^B(\mathrm{Tor}_q^C(C/\mathfrak{r}C, B), B/J) \Rightarrow \mathrm{Tor}_{p+q}^C(C/\mathfrak{r}C, B/J).$$

Claim 17.2.22. $\mathrm{Tor}_q^C(C/\mathfrak{r}C, B) = 0$ for every $q > 0$.

Proof of the claim. Set $\mathfrak{r}^{(n)} := \mathfrak{r} \cap P^{(n)}$ and $C_n := \mathbb{Z}[P^{(n)}]$ for every $n \in \mathbb{N}$. We have natural isomorphisms :

$$\mathrm{Tor}_q^C(C/\mathfrak{r}C, B) \xrightarrow{\sim} \operatorname*{colim}_{n\in\mathbb{N}} \mathrm{Tor}_q^{C_n}(C_n/\mathfrak{r}_n C, B_n) \qquad \text{for every } q, n \in \mathbb{N}$$

so we are reduced to showing that $\mathrm{Tor}_q^{C_n}(C_n/\mathfrak{r}_n C, B_n) = 0$ for every $q, n \in \mathbb{N}$ with $q > 0$. The latter follows from propositions 12.5.16(ii) and 6.1.40(i). ◊

From claim 17.2.22 we see that $E^2_{pq} = 0$ for every $q > 0$ and every $p \in \mathbb{N}$. Thus, we deduce a natural isomorphism :

$$\mathrm{Tor}_p^B(B/\mathfrak{r}B, B/J) \xrightarrow{\sim} \mathrm{Tor}_p^C(C/\mathfrak{r}C, B/J) \qquad \text{for every } p \in \mathbb{N}.$$

By the same token, the projection $C \to \overline{C} := C/pC$ induces a change of rings spectral sequence

$$F^2_{ij} := \mathrm{Tor}_i^{\overline{C}}(\mathrm{Tor}_j^C(C/\mathfrak{r}C, \overline{C}), B/J) \Rightarrow \mathrm{Tor}_{i+j}^C(C/\mathfrak{r}C, B/J)$$

(notice that B/J is a $\overline{C}$-algebra, since $p \in J$) and $\mathrm{Tor}_j^C(C/\mathfrak{r}C, \overline{C}) = 0$ for every $j > 0$, since $C/\mathfrak{r}C$ has no p-torsion. Hence $F^2_{ij} = 0$ whenever $j > 0$, and we get an isomorphism :

$$\mathrm{Tor}_i^{\overline{C}}(\overline{C}/\mathfrak{r}\overline{C}, B/J) \xrightarrow{\sim} \mathrm{Tor}_i^C(C/\mathfrak{r}C, B/J) \qquad \text{for every } i \in \mathbb{N}.$$

Notice now that $\overline{C}$ is a perfect $\mathbb{F}_p$-algebra, since $P^{(\infty)}$ is p-divisbile, and with $I_{\overline{C}} := \mathfrak{r}\overline{C}$ we have $\overline{C}/\mathfrak{r}\overline{C} = \overline{C}/I_{\overline{C}}^{[0]}\overline{C}$. Then $\mathrm{Tor}_i^{\overline{C}}(\overline{C}/\mathfrak{r}\overline{C}, B/J) = 0$ for every $i > 0$, by proposition 16.4.7, whence the contention.

(ii): It is clear that $I_1 \cap I_2$ is a branch ideal; we have inclusions

$$(I_1 \cap I_2)^2 \subset I_1 I_2 \subset I_1 \cap I_2$$

and from (i) we know that the first ideal in this chain coincides with the third, so $I_1 I_2 = I_1 \cap I_2$.

Next, for $k = 1, 2$ let us write $I_k = J_k \cap \mathbf{r}_k B$, where $J_k \subset B$ and $\mathfrak{r}_k \subset P^{(\infty)}$ are radical ideals and $p \in J_k$. Set $Z_k := \operatorname{Spec} B/J_k$, $Z'_k := \operatorname{Spec} B/\mathfrak{r}_k B$ for $k = 1, 2$; clearly

$$Z := \operatorname{Spec} B/(I_1 + I_2) = (Z_1 \cup Z'_1) \cap (Z_2 \cup Z'_2).$$

Now let $J \subset B$ be the largest ideal such that $\operatorname{Spec} B/J = (Z_1 \cap Z_2) \cup (Z_1 \cap Z'_2) \cup (Z'_1 \cap Z_2)$. It follows easily that

$$Z = (\operatorname{Spec} B/J) \cup (\operatorname{Spec} B/(\mathfrak{r}_1 \cup \mathfrak{r}_2)B).$$

Now, J and $\mathfrak{r}_1 \cup \mathfrak{r}_2$ are radical ideals, and $p \in J$, so we deduce that the radical of $I_1 + I_2$ is a branch ideal, and it remains only to show that $I_1 + I_2$ is a radical ideal. However, notice the inclusions

$$(\mathfrak{r}_1 J_1 + \mathfrak{r}_2 J_2)^2 \subset I := (J_1 + J_2)(J_1 + \mathfrak{r}_2 B)(\mathfrak{r}_1 B + J_2)(\mathfrak{r}_1\mathfrak{r}_2 B) \subset (\mathfrak{r}_1 J_1 + \mathfrak{r}_2 J_2).$$

Especially, $\mathfrak{r}_1 J_1 + \mathfrak{r}_2 J_2$ is contained in the radical I' of I, Since we already know that $\mathfrak{r}_k J_k = I_k$ for $k = 1, 2$, it suffices to check that each of the four factors of the middle term in this chain of inclusions is a branch ideal : indeed, in this case the same holds for I, and therefore $I = I'$, so finally $I = I_1 + I_2$.

• First, set $J := J_1 + J_2$, and let $\overline{J} \subset B/pB$ be the image of J; since $p \in J$, in order to see that J is a branch ideal, it suffices to check that J is a radical ideal; then it suffices to prove that the same holds for $\overline{J}$, and the latter assertion will follow, if we show that $\Phi_B^{-1}\overline{J} = \overline{J}$, where $\Phi_B : B/pB \to B/pB$ is the Frobenius endomorphism. Now, say that $x \in B/pB$ and $x^p \in \overline{J}$; then $x^p = x_1 + x_2$ for some $x_i \in \overline{J}_i := J_i/pB$ ($i = 1, 2$), and since Φ_B is surjective and $\overline{J}_i$ is a radical ideal, we can write $x_i = y_i^p$ for some $y_i \in \overline{J}_i$. Consequently $x^p = (y_1 + y_2)^p$, so $x - y_1 - y_2$ is nilpotent; but clearly $\overline{J}$ contains the nilradical of B/pB, whence the claim.

• Next we consider $J' := J_1 + \mathfrak{r}_2 B$; as in the previous case, since $p \in J$, we see that J' is a branch ideal, provided J'/pB is a radical ideal of B/pB. However, say that $x \in B/pB$ and $x^p = y + z$, for some $y \in \overline{J}_1$ and $z \in \mathfrak{r}_2 B/pB$; arguing as in the foregoing case, we may write $y = u^p$ for some $u \in \overline{J}_1$. Likewise, since both Φ_B and the Frobenius endomorphism of $P^{(\infty)}$ are surjective, we see that $z = w^p$ for some $w \in \mathfrak{r}_2 B/pB$, so $x - u - w$ is nilpotent, and especially, it lies in $\overline{J}_1$, whence the claim. The same argument applies as well to the factor $\mathfrak{r}_1 B + J_2$.

• Lastly, since $\mathfrak{r}_1$ and $\mathfrak{r}_2$ are both radical ideals of $P^{(\infty)}$, the same holds for $\mathfrak{r}_1\mathfrak{r}_2$, so $\mathfrak{r}_1\mathfrak{r}_2 B$ is a branch ideal. □

Proposition 17.2.20(i) says that the pair (B, I) is a basic setup, in the sense of [75, (2.1.1)], so we may consider the associated categories of almost modules and almost algebras.

17.2.23. Henceforth we shall restrict to the case where B_0 is not an $\mathbb{F}_p$-algebra, so B_0 is a local integral domain whose field of fractions has characteristic zero, and whose residue field has characteristic p. For every $n \in \mathbb{N}$, set

$$(X_n)_{/p} := \mathrm{Spec}\, B_n/pB_n \qquad V_n := X_n \setminus (X_n)_{/p} \qquad V_{n,\mathrm{tr}} := (X_n, \underline{M})_{\mathrm{tr}} \cap V_n.$$

We consider now a finite morphism $\varphi_0 : Y_0 \to X_0$ with Y_0 a normal scheme, such that φ_0 maps each connected component of Y_0 onto X_0, and such that the restriction $\varphi_0^{-1}V_{0,\mathrm{tr}} \to V_{0,\mathrm{tr}}$ is a finite étale covering. For every $n \in \mathbb{N}$, we let Y_n be the normalization of X_n in $\varphi^{-1}V_{0,\mathrm{tr}} \times_{X_0} X_n$, and denote by $\varphi_n : Y_n \to X_n$ the resulting finite morphism ([126, Lemma 1, p.262]), by

$$\varphi : Y \to X$$

the limit of the system $(\varphi_n \mid n \in \mathbb{N})$, and by $W_n \subset X_n$ the *étale locus of* φ_n, *i.e.* the largest open subset such that the restriction $\varphi_n^{-1}W_n \to W_n$ of φ_n is an étale covering (lemma 13.1.7(iii) and claim 13.1.8). Let also $(X_{n,\mathfrak{p}} \mid \mathfrak{p} \in \mathrm{Spec}\, P^{(n)})$ be the logarithmic stratification of $(X_n, \underline{M}_n)$ (see (12.5.35)) and set $V_{n,\mathfrak{p}} := X_{n,\mathfrak{p}} \cap V_n$ for every $n \in \mathbb{N}$ and every $\mathfrak{p} \in \mathrm{Spec}\, P^{(n)}$. We call $(V_{n,\mathfrak{p}} \mid \mathfrak{p} \in \mathrm{Spec}\, P^{(n)})$ the *logarithmic stratification* of V_n.

Lemma 17.2.24. *With the notation of* (17.2.23)*, the following holds :*

(i) $V_n \setminus W_n$ *is a union of strata of the logarithmic stratification of* V_n*, for every* $n \in \mathbb{N}$.

(ii) $X_n \times_{X_m} W_m = W_n$ *for every sufficiently large* $m \in \mathbb{N}$ *and every* $n \geq m$.

(iii) *For* m *as in* (ii)*, set* $W := X \times_{X_m} W_m$*, and let* $I \subset B$ *be the largest ideal such that* $\mathrm{Spec}\, B/I = X \setminus W$*. Then* I *is a branch ideal of* B.

Proof. (i): Since every $X_{n,\mathfrak{p}}$ is irreducible (corollary 12.5.37(iii)), the same holds for each $V_{n,\mathfrak{p}}$. Hence, suppose that $V_n \setminus W_n$ contains a point z of $V_{n,\mathfrak{p}}$, for some $\mathfrak{p} \in \mathrm{Spec}\, P^{(n)}$; we have to show that in this case $V_{n,\mathfrak{p}} \cap W_n = \varnothing$, and since W_n is an open subset of X_n, it suffices to check that the generic point η of $V_{n,\mathfrak{p}}$ does not lie in W_n. However, let $\overline{\eta}$ be any geometric point localized at η; then η lies in W_n if and only if the induced morphism $\varphi_n \times_{X_n} X_n(\overline{\eta})$ is étale (claim 13.1.9). Let also $\overline{z}$ be a geometric point localized at z, and denote by $\underline{M}_{n,\overline{z}}$ (resp. $\underline{M}_{n,\overline{\eta}}$) the stalk at $\overline{z}$ (resp. $\overline{\eta}$) of the logarithmic structure of $(X_n(\overline{z}), \underline{M}_n(\overline{z}))$ (resp. of $(X_n(\overline{\eta}), \underline{M}_n(\overline{\eta}))$). Any choice of a strict specialization morphism $s : X_n(\overline{\eta}) \to X_n(\overline{z})$ induces a strict specialization map $\overline{\sigma} : \underline{M}_{n,\overline{z}} \to \underline{M}_{n,\overline{\eta}}$ (see (4.9.23)) that extends the specialization map $\sigma : \underline{M}_{n,z} \to \underline{M}_{n,\eta}$. Since the natural maps $\underline{M}^\sharp_{n,z} \to \underline{M}^\sharp_{n,\overline{z}}$ and $\underline{M}^\sharp_{n,\eta} \to \underline{M}^\sharp_{n,\overline{\eta}}$ are isomorphisms (see (12.1.9)), and $\sigma^{\sharp\mathrm{gp}}$ is an isomorphism (since z and η lie in the same stratum), the same holds for $\overline{\sigma}^{\sharp\mathrm{gp}}$, and therefore the induced map $\underline{M}^{\mathrm{gp}\vee}_{n,\overline{\eta}} \to \underline{M}^{\mathrm{gp}\vee}_{n,\overline{z}}$ is bijective. Pick any geometric point ξ of $X_n(\overline{z})$ localized at the maximal point, and lift ξ to a geometric point ξ_η of $X_n(\overline{\eta})$; in light of (13.3.54), we conclude that s induces an isomorphism

$$\pi_1((X_n(\overline{\eta}), \underline{M}_n(\overline{\eta}))_{\mathrm{ét}}, \xi_\eta) \xrightarrow{\sim} \pi_1((X_n(\overline{z}), \underline{M}_n(\overline{z}))_{\mathrm{ét}}, \xi).$$

Therefore, $\varphi_n \times_{X_n} X_n(\overline{\eta})$ is étale if and only if it is a trivial covering, if and only if the same holds for $\varphi_n \times_{X_n} X_n(\overline{z})$, if and only if $z \in W_n$, whence the assertion.

(ii): For every $n \in \mathbb{N}$, set

$$\mathfrak{Z}_n := \{\mathfrak{p} \in \mathrm{Spec}\, P^{(n)} \mid V_{n,\mathfrak{p}} \neq \varnothing \quad \text{and} \quad V_{n,\mathfrak{p}} \cap W_n = \varnothing\}. \tag{17.2.25}$$

The continuous map $\omega_n : \mathrm{Spec}\, P^{(n+1)} \to \mathrm{Spec}\, P^{(n)}$ induced by the inclusion $P^{(n)} \to P^{(n+1)}$ sends $\mathfrak{Z}_{n+1}$ into $\mathfrak{Z}_n$, for every $n \in \mathbb{N}$. On the other hand, ω_n is also a bijection of finite sets (lemmata 6.1.20(iii) and 6.4.59(i)); we conclude that ω_n restricts to a bijection $\mathfrak{Z}_{n+1} \xrightarrow{\sim} \mathfrak{Z}_n$ for every sufficiently large integer $n \in \mathbb{N}$. For every $n, m \in \mathbb{N}$ with $n \geq m$, let $g_{n,m} : X_n \to X_m$ be the transition morphism in the maximal tower (17.2.6), in light of (i), it follows that

$$g^{-1}_{n,m}(V_m \cap W_m) = V_n \cap W_n \qquad \text{for every sufficiently large } m \in \mathbb{N} \text{ and every } n \geq m.$$

On the other hand, the restriction $(X_n)_{/p} \to (X_m)_{/p}$ of $g_{n,m}$ is radicial and surjective for every such $n, m \in \mathbb{N}$, so the underlying continuous map is a homeomorphism; since the underlying topological spaces are noetherian, we see as well that

$$g^{-1}_{n,m}((X_m)_{/p} \cap W_m) = (X_n)_{/p} \cap W_n \qquad \text{for every sufficiently large } m \in \mathbb{N} \text{ and every } n \geq m.$$

Summing up, the assertion follows.

(iii): The assertion follows easily from (i) and (17.2.19). □

17.2.26. Let $I \subset B$ be a fixed branch ideal, and consider a pair (X, Z) with $Z \subset \mathrm{Spec}\, B/I$ and such that Z is constructible in X. Clearly such a pair is normal (see definition 14.4.1(ii)), and we aim to show that (X, Z) is almost pure for the almost structure given by the basic setup (B, I) supplied by proposition 17.2.20. This will be achieved in several steps.

To begin with, set $U := X \setminus Z$, and let $\mathscr{A}$ be any étale almost finitely presented $\mathscr{O}^a_U$-algebra. Set also $U_I := X \setminus \mathrm{Spec}\, B/I$; then $\mathscr{A}_{|U_I}$ is a finite étale $\mathscr{O}_{U_I}$-algebra, $U_I = X \times_{X_0} U_{I,0}$ for some open subset $U_{I,0} \subset X_0$ (remark 17.2.18(iv)), and a simple inspection shows that

$$V_{0,\mathrm{tr}} \subset U_{I,0}.$$

Let $\psi : U_I \to U_{I,0}$ be the natural projection; by [66, Ch.IV, Prop.17.7.8(ii)] and [65, Ch.IV, Th.8.8.2(ii)], and by virtue of remark 17.2.7, we may assume – after replacing $(X_0, \underline{M}_0)$ by $(X_n, \underline{M}_n)$ for some sufficiently large $n \in \mathbb{N}$ – that there exists a coherent étale $\mathscr{O}_{U_{I,0}}$-algebra $\mathscr{A}_0$ with an isomorphism $\psi^*\mathscr{A}_0 \xrightarrow{\sim} \mathscr{A}_{|U_I}$ of $\mathscr{O}_{U_I}$-algebras. Denote by Y_0 the normalization of X_0 in $\mathrm{Spec}\, \mathscr{A}_0(U_{I,0})$; the resulting morphism $\varphi_0 : Y_0 \to X_0$ is finite (lemma 9.7.4(i)) and induces an isomorphism $(\varphi_{0*}\mathscr{O}_{Y_0})_{|U_{I,0}} \xrightarrow{\sim} \mathscr{A}_0$. Especially, φ_0 is a morphism of the type contemplated in (17.2.23), and the resulting morphism $\varphi : Y \to X$ induces an isomorphism $(\varphi_*\mathscr{O}_Y)_{|U_I} \xrightarrow{\sim} \mathscr{A}_{|U_I}$. However, we have as well $\mathscr{A} = (\mathscr{A}_{|U_I})^\nu$ (lemma 14.4.5(i)), and since Y is normal, there follows an isomorphism of $\mathscr{O}^a_U$-algebras $(\varphi_*\mathscr{O}^a_Y)_{|U} \xrightarrow{\sim} \mathscr{A}$. Then proposition 14.4.8 and [75, Lemma 8.2.28] show that (X, Z) is almost pure if and only if the resulting $\mathscr{O}^a_X$-algebra $\varphi_*\mathscr{O}^a_Y$ is weakly unramified, for every such φ_0.

17.2.27. Keep the notation of (17.2.26), and *suppose now that B_0 is strictly henselian*; especially, the N-torsion subgroup μ_N of $B_0^\times$ has cardinality equal to N, for every $N > 0$ such that $(N, p) = 1$. Let $k > 0$ be any integer and write $k = p^s \cdot q$, with $s, q \in \mathbb{N}$ and $(q, p) = 1$; set $Q := P$, let $\nu : P \to Q$ be the k-Frobenius map, define

$$C'_0 := Q \otimes_P B_0 \qquad C_0 := C'_0 \otimes_{B_0} B''_s$$

and endow $X'_0 := \operatorname{Spec} C_0$ with the log structure $\underline{M}'_0$ deduced from the natural map $Q \to C_0$. Notice that C_0 is strictly henselian and the Frobenius endomorphism of C_0/pC_0 is still a finite map (claim 9.7.21(i)); also, since the induced map $A \to C'_0/\mathfrak{m}_Q C'_0$ is an isomorphism, the image of the sequence $(f_1, \dots, f_r)$ in C_0 is still maximal, in the sense of (17.2.3), and therefore $C_0/\mathfrak{m}_Q C_0$ is still a regular local ring, by corollary 9.6.34. Arguing as in (17.2.5), we deduce that $(X'_0, \underline{M}'_0)$ is a regular log scheme, and we may consider the maximal tower

$$((X'_n, \underline{M}'_n) \mid n \in \mathbb{N})$$

associated with the chart $Q \to C_0$ and the maximal sequence $(f_1^{1/p^s}, \dots, f_r^{1/p^s})$ (see remark 9.6.35(iii)). So, $X'_n = \operatorname{Spec} C_n$ for a finite C_0-algebra C_n, and $\underline{M}'_n$ is given by a chart $Q^{(n)} \to C_n$, where $Q^{(n)}$ is a submonoid of $Q_\mathbb{Q}$ containing Q, for every $n \in \mathbb{N}$. For every $n \in \mathbb{N}$, we set $V'_{n,\mathrm{tr}} := V_{0,\mathrm{tr}} \times_{X_0} X'_n$, we let Y'_n be the normalization of X'_n in $Y_0 \times_{X_0} V'_{n,\mathrm{tr}}$, we denote by

$$\varphi'_n : Y'_n \to X'_n \qquad \text{and} \qquad h_n : (X'_n, \underline{M}'_n) \to (X_n, \underline{M}_n)$$

the resulting finite morphisms, and by $\varphi' : Y' \to X'$ (resp. $h : (X', \underline{M}') \to (X, \underline{M})$) the limit of the system of morphisms $(\varphi'_n \mid n \in \mathbb{N})$ (resp. the limit of the system $(h_n \mid n \in \mathbb{N})$). Recall also that the induced morphism $V'_{0,\mathrm{tr}} \to V_{0,\mathrm{tr}}$ is a torsor for the finite abelian group

$$G := \operatorname{Hom}_\mathbb{Z}(Q^{\mathrm{gp}}, \mu_k)$$

(see (13.3.32)). Set

$$C := \bigcup_{n \in \mathbb{N}} C_n \qquad Q^{(\infty)} := \bigcup_{n \in \mathbb{N}} Q^{(n)}.$$

With this notation, we have

$$Q^{(\infty)} = Q \otimes_P P^{(\infty)} \qquad \text{and} \qquad C = Q^{(\infty)} \otimes_P B''.$$

Let also write $Y = \operatorname{Spec} D$ (resp. $Y' = \operatorname{Spec} D'$) for a B-algebra D (resp. for a C-algebra D'). The morphism $h : (X', \underline{M}') \to (X, \underline{M})$ shall be called the *standard covering* of $(X, \underline{M})$ of degree k.

Lemma 17.2.28. *In the situation of* (17.2.27)*, set $U' := X' \setminus h^{-1}Z$. The induced diagram*

$$\begin{array}{ccc} \mathscr{O}_X^a\text{-}\mathbf{\acute{E}t}_{\mathrm{fr}} & \xrightarrow{\rho} & \mathscr{O}_U^a\text{-}\mathbf{\acute{E}t}_{\mathrm{fr}} \\ \downarrow & & \downarrow \\ \mathscr{O}_{X'}^a\text{-}\mathbf{\acute{E}t}_{\mathrm{fr}} & \xrightarrow{\rho'} & \mathscr{O}_{U'}^a\text{-}\mathbf{\acute{E}t}_{\mathrm{fr}} \end{array}$$

is 2-cartesian (notation of definition 14.4.2*).*

Proof. A simple inspection shows that h_0 factors through a morphism $(X'_0, \underline{M}'_0) \to (X_s, \underline{M}_s)$, and indeed we have natural isomorphisms of $(X', \underline{M}')$-schemes

$$(X'_n, \underline{M}'_n) \xrightarrow{\sim} (X'_0, \underline{M}'_0) \times_{(X_s, \underline{M}_s)} (X_{n+s}, \underline{M}_{n+s}) \qquad \text{for every } n \in \mathbb{N}$$

that identify the transition morphisms $(X'_{n+1}, \underline{M}'_{n+1}) \to (X'_n, \underline{M}'_n)$ with the base change of the corresponding morphisms for the tower $((X_{n+s}, \underline{M}_{n+s}) \mid n \in \mathbb{N})$. In view of remark 17.2.7, we may then replace $(X_0, \underline{M}_0)$ by $(X_s, \underline{M}_s)$, and P by $P^{(s)}$, and assume that $(k, p) = 1$, so also $(o(G), p) = 1$.

Suppose now that $(\varphi'_*\mathscr{O}^a_{Y'})_{|U'}$ is in the essential image of the restriction functor ρ'; by proposition 14.4.8, this means that D'^a is an étale almost finitely presented $(C, IC)^a$-algebra. Then, taking into account the discussion of (17.2.26), and recalling that ρ and ρ' are fully faithful (lemma 14.4.5(ii)), we are reduced to checking that D^a is an étale almost finitely presented $(B, I)^a$-algebra.

However, the action of G on $V'_{0,\mathrm{tr}}$ is inherited by C and D', and clearly $C^G = B$ and $D'^G = D$; by corollary 14.6.28(ii), it suffices therefore to show that the action of G on D'^a is horizontal. Denote

$$G \to \mathrm{Aut}(C) \quad : \quad \chi \mapsto \rho_\chi$$

the action of G, let $\chi \in G$ be any element, and $J_\chi \subset C$ the ideal generated by all elements of the form $\rho_\chi(c) - c$, for c ranging over all elements of C. By the discussion in (13.3.32) we get

$$\rho_\chi((q \otimes y) \otimes b) = \chi(q) \cdot (q \otimes y) \otimes b \qquad \text{for every } q \in Q, y \in P^{(\infty)} \text{ and } b \in B''.$$

Hence, J_χ is the ideal generated by all elements of the form $(1 - \chi(q)) \cdot q \otimes y \otimes 1$, for all $q \otimes y \in Q^{(\infty)}$. However, since $\chi(q) \in \mu_k$ and $(k, p) = 1$, it is easily seen that $1 - \chi(q)$ either vanishes, or else it is invertible in B_0. Thus, denote by $\mathfrak{q}_\chi \subset Q^{(\infty)}$ the ideal generated by all elements of the form $q \otimes y$, with $\chi(q) \neq 1$; it follows that

$$J_\chi = \mathfrak{q}_\chi \cdot C.$$

Claim 17.2.29. $\mathfrak{q}_\chi$ is a radical ideal.

Proof of the claim. Indeed, say that $(q \otimes y)^n \in \mathfrak{q}_\chi$, so there exist elements $q_1 \otimes y_1$ and x_1 of $Q^{(\infty)}$ such that $(q \otimes y)^n = (q_1 \otimes y_1) \cdot x_1$ and $\chi(q_1) \neq 1$. We may assume that $n = p^t$ for some integer $t \in \mathbb{N}$, and since $Q^{(\infty)}$ is uniquely p-divisible, we may write $q_1 \otimes y_1 = (q_2 \otimes y_2)^n$ and $x_1 = x_2^n$ for some elements $q_2 \otimes y_2$ and x_2 of $Q^{(\infty)}$, and then $q \otimes y = (q_2 \otimes y_2) \cdot x_2$; however, clearly $\chi(q_2) \neq 1$, whence the claim. ◊

In view of claim 17.2.29, we may write $\mathfrak{q}_\chi = \mathfrak{q}_1 \cap \cdots \cap \mathfrak{q}_s$, for certain $\mathfrak{q}_1, \dots, \mathfrak{q}_s \in \mathrm{Spec}\, Q^{(\infty)}$ (lemma 6.1.16). Set $\mathfrak{Q} := \{\mathfrak{q}_1, \dots, \mathfrak{q}_s\}$; we also know that $(\mathfrak{q} \cap Q^{(n)}) \cdot C_n$ is a prime ideal of C_n, for every $\mathfrak{q} \in \mathfrak{Q}$ and every $n \in \mathbb{N}$ (corollary 12.5.20(i)), therefore $\mathfrak{q}C$ is a prime ideal of C, for every $\mathfrak{q} \in \mathfrak{Q}$. Especially, the induced map

$$C/J_\chi \to \prod_{\mathfrak{q} \in \mathfrak{Q}} C/\mathfrak{q}C \qquad (17.2.30)$$

is injective. Since, by assumption, D'^a is a flat C^a-algebra, it follows that the map of almost modules $D'^a \otimes_C$ (17.2.30) is a monomorphism. Summing up, we are reduced to checking that χ acts trivially on $(D'/\mathfrak{q}D')^a$, for every $\mathfrak{q} \in \mathfrak{Q}$. However, set

$$X'_\mathfrak{q} := \mathrm{Spec}\, C/\mathfrak{q}C \quad \text{and} \quad U'_\mathfrak{q} := X'_\mathfrak{q} \times_X U_I \qquad \text{for every } \mathfrak{q} \in \mathfrak{Q}.$$

Suppose first that $U'_\mathfrak{q} = \varnothing$; in that case, set $\mathfrak{p} := \mathfrak{q} \cap P^{(\infty)}$, and notice that $\mathfrak{q}$ is the radical of the ideal $\mathfrak{p} \cdot Q^{(\infty)}$, so $\mathfrak{q}C$ is the radical of $\mathfrak{p}C$, and therefore $\mathrm{Spec}\,(C/\mathfrak{p}C) \times_X U_I = \varnothing$. However, the induced morphism $\mathrm{Spec}\, C/\mathfrak{p}C \to \mathrm{Spec}\, B/\mathfrak{p}B$ is surjective, so $\mathrm{Spec}\,(B/\mathfrak{p}B) \cap U_I = \varnothing$; since $\mathfrak{p}B$ is a prime ideal of B, the latter means that $I \subset \mathfrak{p}B$, whence $(B/\mathfrak{p}B)^a = 0$, so $(D'/\mathfrak{q}D')^a$ vanishes as well, and the assertion is trivial. If $U'_\mathfrak{q} \neq \varnothing$, set $Y'_\mathfrak{q} := Y' \times_{X'} X'_\mathfrak{q}$, let $\varphi'_\mathfrak{q} : Y'_\mathfrak{q} \to X'_\mathfrak{q}$ be the induced morphism, and define

$$\mathscr{D} := \varphi_*\mathscr{O}_Y \qquad \mathscr{D}' := \varphi'_*\mathscr{O}_{Y'} \qquad \mathscr{D}'_\mathfrak{q} := \varphi'_{\mathfrak{q}*}\mathscr{O}_{Y'_\mathfrak{q}}.$$

On the one hand, by assumption $\mathscr{D}'^a_\mathfrak{q}$ is a flat $\mathscr{O}^a_{X'_\mathfrak{q}}$-algebra; on the other hand, $X'_\mathfrak{q}$ is reduced and irreducible, hence the restriction map $\Gamma(X'_\mathfrak{q}, \mathscr{O}_{X'_\mathfrak{q}}) \to \Gamma(U'_\mathfrak{q}, \mathscr{O}_{X'_\mathfrak{q}})$ is injective. Consequently, the restriction map

$$(D'/\mathfrak{q}D')^a = \Gamma(X'_\mathfrak{q}, \mathscr{D}'^a_\mathfrak{q}) \to \Gamma(U'_\mathfrak{q}, \mathscr{D}'^a_\mathfrak{q})$$

is a monomorphism; so, we are reduced to checking that χ acts trivially on $\Gamma(U'_{\mathfrak q}, \mathscr{D}'^a_{\mathfrak q})$. To this aim, we remark that the open subset $U'_I := X' \times_X U_I$ is stable under the action of G, and the restriction $\mathscr{D}'_{|U'_I}$ of $\mathscr{D}'$ to the open subset U'_I is isomorphic to $(h^*\mathscr{D})_{|U'_I}$ ([66, Ch.IV, Prop.17.5.8(iii)]), so the action of G on $\mathscr{D}'_{|U'_I}$ is horizontal, and the assertion follows easily. □

17.2.31. In the situation of (17.2.27), define $\mathfrak{Z}_n$ as in (17.2.25), for every $n \in \mathbb{N}$. As already remarked, in view of lemma 17.2.24(i,ii) we may assume that the map $\operatorname{Spec} P^{(n+1)} \to \operatorname{Spec} P^{(n)}$ sends $\mathfrak{Z}_{n+1}$ bijectively onto $\mathfrak{Z}_n$, for every $n \in \mathbb{N}$. Set $V'_0 := V_0 \times_{X_0} X'_0$, and let

$$(V'_{0,\mathfrak p} \mid \mathfrak p \in \operatorname{Spec} Q) \qquad \text{and} \qquad (V_{0,\mathfrak p} \mid \mathfrak p \in \operatorname{Spec} P)$$

be the logarithmic stratifications of V'_0 and respectively V_0, defined as in (17.2.23); notice that the map $\nu^* : \operatorname{Spec} Q \to \operatorname{Spec} P$ induced by ν is bijective (lemma 6.4.59(i)), and clearly

$$V'_{0,\mathfrak p} = h_0^{-1} V_{0,\nu^*(\mathfrak p)} \qquad \text{for every } \mathfrak p \in \operatorname{Spec} Q.$$

Let $\mathfrak{Z}'_0 := \nu^{*-1}\mathfrak{Z}_0$, and for every $\mathfrak p \in \mathfrak{Z}'_0$, let $\eta'_{\mathfrak p}$ (resp. $\eta_{\mathfrak p}$) denote the generic point of $V'_{0,\mathfrak p}$ (resp. of $V_{0,\nu^*(\mathfrak p)}$), pick geometric points $\overline{\eta}'_{\mathfrak p}$ and $\xi'_{\mathfrak p}$ localized respectively at $\eta'_{\mathfrak p}$ and at a point of $V'_{0,\mathrm{tr}}(\overline{\eta}'_{\mathfrak p}) := V'_{0,\mathrm{tr}} \times_{X'_0} X'_0(\overline{\eta}'_{\mathfrak p})$. Denote by $\overline{\eta}_{\mathfrak p}$ the image of $\overline{\eta}'_{\mathfrak p}$ in $V_{0,\nu^*(\mathfrak p)}$, and by $\xi_{\mathfrak p}$ the image of $\xi'_{\mathfrak p}$ in $V_{0,\mathrm{tr}}(\overline{\eta}_{\mathfrak p}) := V_{0,\mathrm{tr}} \times_{X_0} X_0(\overline{\eta}_{\mathfrak p})$. According to (13.3.31) there follows, for every integer $N > 0$, a commutative diagram of groups

$$\begin{array}{ccc} \pi_1(V'_{0,\mathrm{tr}}(\overline{\eta}'_{\mathfrak p})_{\mathrm{ét}}, \xi'_{\mathfrak p}) & \longrightarrow & \pi_1(V_{0,\mathrm{tr}}(\overline{\eta}_{\mathfrak p})_{\mathrm{ét}}, \xi_{\mathfrak p}) \\ \downarrow & & \downarrow \\ \underline{M}'^{\mathrm{gp}\vee}_{0,\eta'_{\mathfrak p}} \otimes_{\mathbb Z} \mu_N & \longrightarrow & \underline{M}^{\mathrm{gp}\vee}_{0,\eta_{\mathfrak p}} \otimes_{\mathbb Z} \mu_N \end{array}$$

(where μ_N is the N-torsion subgroup of $\kappa(\xi_{\mathfrak p})^\times$) whose top arrow is induced by the natural morphism $V'_{0,\mathrm{tr}}(\overline{\eta}'_{\mathfrak p}) \to V_{0,\mathrm{tr}}(\overline{\eta}_{\mathfrak p})$, and whose bottom arrow is induced by $\nu^{\mathrm{gp}\vee} : Q^{\mathrm{gp}\vee} \to P^{\mathrm{gp}\vee}$, *i.e.* by the k-Frobenius map of $P^{\mathrm{gp}\vee}$, for every $\mathfrak p \in \mathfrak{Z}'_0$. Now, the restriction

$$\varphi_{\mathfrak p} : Y_0(\overline{\eta}_{\mathfrak p}) := Y_0 \times_{X_0} X_0(\overline{\eta}_{\mathfrak p}) \to X_0(\overline{\eta}_{\mathfrak p})$$

of φ is a tamely ramified covering, hence the action of $\pi_1(V_{0,\mathrm{tr}}(\overline{\eta}_{\mathfrak p})_{\mathrm{ét}}, \xi_{\mathfrak p})$ on $F_{\mathfrak p} := \varphi_{\mathfrak p}^{-1}(\xi_{\mathfrak p})$ factors through a group homomorphism

$$\rho_{\mathfrak p} : \underline{M}^{\mathrm{gp}\vee}_{0,\eta_{\mathfrak p}} \otimes_{\mathbb Z} \mu_N \to \operatorname{Aut}(F_{\mathfrak p})$$

for some sufficiently large $N \in \mathbb{N}$ (theorem 13.3.45). We may then find $k \in \mathbb{N}$ such that the image of $k \cdot P^{\mathrm{gp}\vee}$ in $\underline{M}^{\mathrm{gp}\vee}_{0,\eta_{\mathfrak p}}$ lies in the kernel of $\rho_{\mathfrak p}$, for every $\mathfrak p \in \mathfrak{Z}'_0$. Especially, for this choice of k, the image of $\underline{M}'^{\mathrm{gp}\vee}_{0,\eta'_{\mathfrak p}} \otimes_{\mathbb Z} \mu_N$ acts trivially on $\operatorname{Aut}(F_{\mathfrak p})$ via $\rho_{\mathfrak p}$, for every such $\mathfrak p$. Consequently, $\pi_1(V'_{0,\mathrm{tr}}(\overline{\eta}'_{\mathfrak p})_{\mathrm{ét}}, \xi'_{\mathfrak p})$ acts trivially on the fibres $\varphi_0'^{-1}(\xi'_{\mathfrak p})$ (by virtue of (3.6.22)); after applying lemma 17.2.24(i) to the morphism φ'_0, we conclude that the étale locus of φ'_0 contains the whole of V'_0.

Theorem 17.2.32. *In the situation of* (17.2.26)*, the pair* (X, Z) *is almost pure, relative to the basic setup* (B, I)*.*

Proof. Fix a geometric point $\overline{x}$ of X localized at the closed point x of X, and let B^{sh} denote the strict henselization of B at x. In view of proposition 14.4.10, in order to prove that (X, Z) is almost pure, it suffices to show that the pair $(X(\overline{x}), Z(\overline{x}))$ is almost pure relative to the basic setup (B, I), or – equivalently – relative to the basic setup $(B^{\mathrm{sh}}, IB^{\mathrm{sh}})$. However, it is easily seen that IB^{sh} is also a branch ideal of B^{sh}, if the latter is endowed with the chart $P^{(\infty)} \to B^{\mathrm{sh}}$ deduced from the given chart of $\underline{M}$. Taking into account remark 17.2.9(i), we may then replace B by B^{sh}, and assume that X_0 and X are strictly local.

Now, consider a finite morphism $\varphi_0 : Y_0 \to X_0$ and the resulting morphism $\varphi : Y \to X$ as in (17.2.23). The discussion of (17.2.26) shows that (X, Z) is almost pure if and only if $\varphi_* \mathscr{O}^a_Y$ is an étale $\mathscr{O}^a_X$-algebra, for every such φ_0. Set $V := \mathrm{Spec}\, B[1/p]$; in view of (17.2.31) and lemma 17.2.28, we may then assume that $V_0 \subset U_0$, and therefore $(\varphi_* \mathscr{O}_Y)_{|V}$ is a finite étale $\mathscr{O}_X$-algebra. On the other hand, let $I' \subset B$ be the radical of the ideal $I + pB$, and set $Z' := Z \setminus V$; clearly, I' is a branch ideal. It then suffices to show that $\varphi_* \mathscr{O}^a_Y$ is an étale $\mathscr{O}^a_X$-algebra, for the almost structure given by the new setup (B, I'). Thus, we may assume that $p \in I$, in which case the assertion follows from theorems 17.2.14(iii) and 16.8.44. □

Theorem 17.2.33. *In the situation of* (17.2.5)*, the ring B is ind-measurable.*

Proof. (See remark 14.5.69(i) for the definition of ind-measurable ring.) One argues as in the proof of theorem 17.1.43, with some simplifications. We have to exhibit a sequence $(d_n \mid n \in \mathbb{N})$ of normalizing factors fulfilling conditions (a) and (b) of definition 14.5.64, where the λ_n occurring in *loc.cit.* is meant to be the usual length function for finitely generated B_n-modules supported at the closed point x_n of X_n. Now, fix $n \in \mathbb{N}$, set

$$\mathbf{T}_\mathbb{R} := P^{\mathrm{gp}}_\mathbb{R} / P^{(n)\mathrm{gp}}$$

and endow $\mathbf{T}_\mathbb{R}$ with its invariant measure $d\mu_n$ of total volume equal to 1. For every $\gamma \in P^{\mathrm{gp}}_\mathbb{R}$, let $[\gamma] \in \mathbf{T}_\mathbb{R}$ be the equivalence class of γ; notice that the $P^{(n)}$-module

$$S_{[\gamma]} := \gamma P^{(n)\mathrm{gp}} \cap P_\mathbb{Q} \qquad (17.2.34)$$

is finitely generated (proposition 6.3.22(ii)) and depends only on the class $[\gamma]$, and for any given finitely generated B_n-module M supported at x_n, consider the function

$$l_M : \mathbf{T}_\mathbb{R} \to \mathbb{N} \qquad [\gamma] \mapsto \lambda_n(S_{[\gamma]} \otimes_{P^{(n)}} M).$$

Let $e_1, \dots, e_r$ be a basis of the free $\mathbb{Z}$-module P^{gp}, and define $\Omega_n \subset P^{\mathrm{gp}}_\mathbb{R}$ as in the proof of theorem 17.1.43, so that Ω_n is a fundamental domain for the lattice $P^{(n)\mathrm{gp}}$, and 0 lies in the interior of Ω_n. Denote also by $\Sigma \subset \mathbf{T}_\mathbb{R}$ the image of $P_\mathbb{R} \cap \Omega_n$.

Claim 17.2.35. There is a partition of $\mathbf{T}_\mathbb{R}$ into finitely many measurable subsets $\Theta_1, \dots, \Theta_t$, independent of M, such that :

(i) For every $\gamma, \lambda \in \Omega_n$, the classes $[\gamma], [\lambda] \in \mathbf{T}_\mathbb{R}$ lie in the same Θ_i if and only if $\gamma^{-1} S_{[\gamma]} = \lambda^{-1} S_{[\lambda]}$.
(ii) Especially, l_M restricts to a constant function on each Θ_i.
(iii) Let $\Theta \in \{\Theta_1, \dots, \Theta_t\}$ be the subset containing $[0] \in \mathbf{T}_\mathbb{R}$; then $\Theta \cap \Sigma$ has measure > 0.

Proof of the claim. According to proposition 6.3.35(i,iii), the set $\mathscr{S} := \{\gamma^{-1} S_{[\gamma]} \mid \gamma \in \Omega_n\}$ is finite, and for every non-empty $S \in \mathscr{S}$, the set $\{\gamma \in \Omega_n \mid \gamma^{-1} S_{[\gamma]} = S\}$ is the intersection of Ω_n with a $\mathbb{Q}$-linearly constructible subset. It follows that the same must hold also in case $S = \varnothing$. The image in $\mathbf{T}_\mathbb{R}$ of any such $\mathbb{Q}$-linearly constructible subset is obviously measurable, whence (i). Moreover, in view of our choice of Ω, assertion (ii) follows easily from claim 6.3.40. ◊

Let $m \geq n$ be any integer; since B''_m is a free B''_n-module of rank $p^{r(m-n)}$ (notation of (17.2.3)), we may compute :

$$\lambda_m(B_m \otimes_{B_n} M) = \frac{p^{r(m-n)}}{[\kappa(x_m) : \kappa(x_n)]} \cdot \sum_{[\gamma] \in P^{(m)\mathrm{gp}}/P^{(n)\mathrm{gp}}} l_M([\gamma]).$$

However, lemma 17.2.11 easily implies that $\kappa(x_{n+1})^p = \kappa(x_n)$ for every $n \in \mathbb{N}$, whence

$$[\kappa(x_{n+1}) : \kappa(x_n)] = p^{e_n} \qquad \text{where } e_n := \Omega^1_{\kappa(x_n)/\mathbb{Z}}$$

by virtue of [63, Ch.0, Th.21.4.5]. But by the same token, the field $\kappa(x_m)$ is isomorphic to $\kappa(x_n)$ for every $m \geq n$, so e_n is actually independent of n, and we get

$$[\kappa(x_m) : \kappa(x_n)] = p^{e_0(m-n)} \qquad \text{for every } m \geq n.$$

Therefore, set

$$d_n := p^{n \cdot \dim B_0} \qquad \text{for every } n \in \mathbb{N}.$$

We claim that $(d_n \mid n \in \mathbb{N})$ is a suitable sequence of normalizing factors for B. Indeed, claim 17.2.35(ii) says that l_M is a measurable function on $\mathbf{T}_{\mathbb{R}}$, and the foregoing, together with the discussion of (17.2.8) implies that :

$$\lambda(B \otimes_{B_n} M) := \lim_{m \to +\infty} d_m^{-1} \cdot \lambda_m(B_m \otimes_{B_n} M) = d_n^{-1} \int_{\mathbf{T}_{\mathbb{R}}} l_M d\mu_n$$

(recall that $\dim P = \mathrm{rk}_{\mathbb{Z}} P^{\mathrm{gp}}$, by corollary 6.4.12(i)), so condition (a) holds for this choice of factors. Next, fix $\varepsilon > 0$, let $N \to N'$ be a surjection of finitely generated B_n-modules supported at x_n, and suppose that $d_n^{-1}(\lambda_n(N) - \lambda_n(N')) \geq \varepsilon$. Since $\lambda_n(N) = l_N(0)$ (and likewise for N'), we deduce that

$$\lambda(B \otimes_{B_n} N) - \lambda(B \otimes_{B_n} N') \geq \varepsilon \cdot \int_{\Theta} d\mu_n$$

where $\Theta \in \{\Theta_1, \dots, \Theta_t\}$ is the unique subset of $\mathbf{T}_{\mathbb{R}}$ such that $[0] \in \Theta$, so the volume of Θ is > 0, by claim 17.2.35(iii). This shows that condition (b) holds as well, and concludes the proof of the theorem. □

17.3. **The direct summand conjecture.** In the following paragraphs we prove a generalization of the direct summand conjecture for finite injective extensions of log-regular rings.

To begin with, let A be a ring, and consider a short exact sequence of A-modules

$$\Sigma \qquad : \qquad 0 \to M' \xrightarrow{f} M \xrightarrow{g} M'' \to 0.$$

We say that Σ is *universally exact* if the sequence $X \otimes_A \Sigma$ is short exact for every A-module X.

Lemma 17.3.1. (i) *In the situation of* (17.3)*, the following conditions are equivalent :*

(a) *The sequence Σ is universally exact.*
(b) *The sequence $X \otimes_A \Sigma$ is short exact for every finitely presented A-module X.*
(c) *The sequence $\Sigma^\vee := \mathrm{Hom}_{\mathbb{Z}}(\Sigma, \mathbb{Q}/\mathbb{Z})$ splits.*
(d) *$\Sigma^\vee$ is universally exact.*
(e) *The sequence $\mathrm{Hom}_A(X, \Sigma)$ is exact for every finitely presented A-module X.*
(f) *Σ is the colimit of a filtered system of split short exact sequences of A-modules.*

(ii) *If moreover M'' is finitely presented, then conditions* (a)–(f) *are also equivalent to :*

(g) *Σ is a split short exact sequence of A-modules.*

(iii) *If furthermore, A is local and noetherian, and M, M', M'' are finitely generated, then conditions* (a)–(g) *are also equivalent to :*

(h) *The sequence $X \otimes_A \Sigma$ is short exact for every A-module X of finite length.*

Proof. Obviously (f)⇒(a)⇒(b). To see that (b)⇒(a), write any given A-module X as the filtered colimit of a system $(X_\lambda \mid \lambda \in \Lambda)$ of finitely presented A-modules; then $H^i(X \otimes_A \Sigma)$ is the colimit of the induced filtered system of A-modules $(H^i(X_\lambda \otimes_A \Sigma) \mid \lambda \in \Lambda)$, for every $i \in \mathbb{Z}$. But (b) says that each $X_\lambda \otimes_A \Sigma$ is exact, whence (a).

(a)⇒(c): Clearly $\Sigma^\vee$ is short exact, since $\mathbb{Q}/\mathbb{Z}$ is an injective $\mathbb{Z}$-module. For every A-module X, recall that $X^\vee := \mathrm{Hom}_{\mathbb{Z}}(X, \mathbb{Q}/\mathbb{Z})$ is naturally an A-module (see (14.2.26)); notice that for every pair of A-modules X, Y we have a natural isomorphism of A-modules :

$$\omega_{X,Y} : \mathrm{Hom}_A(X^\vee, Y^\vee) \xrightarrow{\sim} (X^\vee \otimes_A Y)^\vee \qquad \varphi \mapsto (h \otimes y \mapsto \varphi(h)(y)).$$

There follows a commutative diagram :

$$\begin{array}{ccc} \mathrm{Hom}_A(M'^{\vee}, M^{\vee}) & \xrightarrow{\mathrm{Hom}_A(M'^{\vee}, f^{\vee})} & \mathrm{Hom}_A(M'^{\vee}, M'^{\vee}) \\ {\scriptstyle \omega_{M',M}} \downarrow & & \downarrow {\scriptstyle \omega_{M',M'}} \\ (M'^{\vee} \otimes_A M)^{\vee} & \xrightarrow{(M'^{\vee} \otimes_A f)^{\vee}} & (M'^{\vee} \otimes_A M')^{\vee}. \end{array}$$

By assumption, $M'^{\vee} \otimes_A f$ is injective, hence $(M'^{\vee} \otimes_A f)^{\vee}$ is surjective, so the same holds for $\mathrm{Hom}_A(M'^{\vee}, f^{\vee})$, and (c) follows easily.

Obviously (c)⇒(d). In order to show that (d)⇒(e), let X be any finitely presented A-module; by assumption, $X \otimes_A g^{\vee}$ is an injection. On the other hand, for every pair of A-modules X, Y we have a natural A-linear map

$$\sigma_{X,Y} : X \otimes_A Y^{\vee} \to \mathrm{Hom}_A(X, Y)^{\vee} \qquad x \otimes t \mapsto (h \mapsto t \circ h(x))$$

and it is easily seen that $\sigma_{X,Y}$ is an isomorphism if X is finitely presented (details left to the reader). By naturality of $\sigma_{X,\bullet}$, it follows that $\mathrm{Hom}_A(X, g^{\vee})^{\vee}$ is injective, hence $\mathrm{Hom}_A(X, g^{\vee})$ is surjective, whence (e).

(e)⇒(f): Write M'' as the colimit of a filtered system $(M''_\lambda \mid \lambda \in \Lambda)$ of finitely presented A-modules, and let $(j_\lambda : M_\lambda \to M \mid \lambda \in \Lambda)$ be the universal co-cone; for every λ, set $\Sigma_\lambda := j^*_\lambda \Sigma$. Then Σ is the colimit of the resulting system of short exact sequences $(\Sigma_\lambda \mid \lambda \in \Lambda)$, and we are reduced to checking that each Σ_λ is split. However, (e) implies that for every λ there exists an A-linear map $h_\lambda : M''_\lambda \to M$ such that $g \circ h_\lambda = j_\lambda$; the assertion follows straightforwardly.

Next, if M'' is finitely presented, (e) implies that $\mathrm{Hom}_A(M'', g)$ is surjective, whence (g).

(iii): Let $(A, \mathfrak{m})$ be a local and noetherian ring, and let X be any finitely presented A-module; if (h) holds, then for every $n \in \mathbb{N}$ the map $f_n := X/\mathfrak{m}^n X \otimes_A f$ is injective. Let $t \in \mathrm{Ker}\,(X \otimes_A f) \setminus \{0\}$; since the $\mathfrak{m}$-adic topology of $X \otimes_A M'$ is separated ([126, Th.8.10(i)]), there exists $n \in \mathbb{N}$ such that the image $\bar{t}$ of t in $X/\mathfrak{m}^n X \otimes_A M'$ does not vanish, so $f_n(\bar{t}) \neq 0$ by assumption, and therefore $f(t) \neq 0$, a contradiction. So $X \otimes_A f$ is injective for every such X, whence (b). □

17.3.2. Let $\mathscr{M}$ be a regular log-structure on either the Zariski or the étale site of a noetherian and affine scheme X; say that $X = \mathrm{Spec}\, A$ for a noetherian ring A. Let also $f : A \to B$ be a finite injective ring homomorphism; we want to show that there exists an A-linear map $g : B \to A$ such that $g \circ f = \mathbf{1}_A$, or equivalently, that the short exact sequence of A-modules

$$\Sigma_f \qquad : \qquad 0 \to A \xrightarrow{f} B \to Q := \mathrm{Coker}\, f \to 0$$

splits. The latter holds if and only if the class $[\Sigma_f] \in \mathrm{Ext}^1_A(Q, A)$ of Σ_f vanishes. Let us recall:

Lemma 17.3.3. (i) *Let A be a noetherian ring, and M, N two A-modules, with M of finite type; then every flat A-algebra A' induces an isomorphism :*

$$A' \otimes_A \mathrm{Ext}^1_A(M, N) \xrightarrow{\sim} \mathrm{Ext}^1_{A'}(A' \otimes_A M, A' \otimes_A N).$$

(ii) *In the situation of* (17.3)*, suppose that A is noetherian and M'' is of finite type. Then the following conditions are equivalent :*

(a) *Σ is a split short exact sequence of A-modules.*
(b) *For every $\mathfrak{p} \in \mathrm{Spec}\, A$ there exists a faithfully flat $A_\mathfrak{p}$-algebra A' such that $A' \otimes_A \Sigma$ is a split short exact sequence of A'-module.*

Proof. (i): Pick a resolution $P^\bullet \to M$ by projective A-modules of finite type; then $\mathrm{Ext}^1_A(M, N)$ is computed by $H^1\mathrm{Hom}_A(P^\bullet, N)$, and likewise $\mathrm{Ext}^1_{A'}(A' \otimes_A M, A' \otimes_A N)$ is computed by

$H^1\mathrm{Hom}_{A'}(A'\otimes_A P^\bullet, A'\otimes_A N)$. But since A is noetherian and P^i is an A-module of finite type for every i, the induced morphism of complexes

$$A'\otimes_A \mathrm{Hom}_A(P^\bullet, N) \to \mathrm{Hom}_{A'}(A'\otimes_A P^\bullet, A'\otimes_A N)$$

is an isomorphism, whence the assertion.

(ii): It is easily seen that the class $[A'\otimes_A \Sigma] \in \mathrm{Ext}^1_{A'}(A'\otimes_A Q, A')$ corresponds – under the isomorphism of (i) – to $1\otimes[\Sigma] \in A'\otimes_A \mathrm{Ext}^1_A(Q, A')$. The assertion follows immediately. □

In view of lemma 17.3.3(ii) we are reduced to checking that $f_\mathfrak{p} : A_\mathfrak{p} \to B_\mathfrak{p}$ admits an $A_\mathfrak{p}$-linear section for every $\mathfrak{p} \in \mathrm{Spec}\, A$; hence *we may assume that* $(A, \mathfrak{m})$ *is a local noetherian ring*. Likewise, let A^{sh} be a strict henselization of A (at the closed point $\mathfrak{m}$); since the structure map $A \to A^{\mathrm{sh}}$ is faithfully flat, lemma 17.3.3(ii) implies that $[\Sigma_f] = 0$ if and only if $[A^{\mathrm{sh}}\otimes_A \Sigma_f] = 0$ in $\mathrm{Ext}^1_{A^{\mathrm{sh}}}(A^{\mathrm{sh}}\otimes_A Q, A^{\mathrm{sh}})$; also, A^{sh} is noetherian, by [66, Ch.IV, Prop.18.8.8(iv)]. Thus, it suffices to check that $A^{\mathrm{sh}}\otimes_A f$ admits an A^{sh}-linear section, and therefore *we may assume that* $\mathscr{M}$ *admits a chart* $\beta : P \to A$ *that is sharp at the point* $\mathfrak{m}$.

17.3.4. Arguing likewise, we may replace A by its $\mathfrak{m}$-adic completion, and suppose therefore that A is a complete local noetherian ring. Moreover, A is normal and Cohen-Macaulay, by corollary 12.5.13. Furthermore, the proof of theorem 12.5.10 show that there exists $r \in \mathbb{N}$ and a surjective ring homomorphism

$$\varphi : V[[Q]] \to A \qquad \text{where } Q := P \times \mathbb{N}^{\oplus r}$$

and where :

- $(V, \mathfrak{m}_V)$ is a *coefficient ring* of A, *i.e.* either a field, or a complete discrete valuation ring with $A = \varphi(V) + \mathfrak{m}$ and such that $\mathfrak{m}_V = pV$ for a prime integer p
- The kernel of φ is trivial if V is a field, and otherwise it is principal, generated by a power series $\sum_{q\in Q} a_q \cdot q$ with $a_0 \in \mathfrak{m}_V \setminus \mathfrak{m}_V^2$
- The chart β is the composition of φ with the obvious inclusion map $P \to Q \to V[[Q]]$.

Let k' be an algebraically closed field extension of the residue field k of A; by [126, Th.29.1] there exists a flat ring homomorphism $\psi : V \to V'$, where $V' = k'$ if $V = k$, and otherwise V' is a complete discrete valuation ring with maximal ideal pV' and residue field k'. The induced ring extension $\psi[Q] : V[Q] \to V'[Q]$ is again faithfully flat, hence it induces a faithfully flat ring homomorphism $V[[Q]] \to V'[[Q]]$ ([126, Th.22.4]). Set $A' := V'[[Q]] \otimes_{V[[Q]]} A$; the induced map $A \to A'$ is faithfully flat, and A' is the quotient of $V'[[Q]]$ by the principal ideal generated by the image of $\mathrm{Ker}\,\varphi$. Hence, A' is a complete local noetherian ring, and by theorems 12.5.10 and 12.5.31, the induced map of monoids $Q \to A'$ is a chart for a regular log structure on $\mathrm{Spec}\, A'$. By lemma 17.3.3(ii), we may then replace A, B, P by respectively $A', A'\otimes_A B, Q$, and *assume that* k *is algebraically closed and* $\mathfrak{m} = \mathfrak{m}_P A$ (with $\mathfrak{m}_P = P \setminus \{0\}$: see definition 6.1.10(i)).

17.3.5. Let $\mathfrak{p}_1, \dots, \mathfrak{p}_k$ be the finitely many minimal prime ideals of B; since A is reduced, $f(A)\cap\mathfrak{p}_1\cap\cdots\cap\mathfrak{p}_k = 0$, hence the composition of f with the natural map $B \to B/\mathfrak{p}_1\times\cdots\times B/\mathfrak{p}_k$ is still finite and injective, and its kernel contains the ideal $\prod_{i=1}^k f^{-1}\mathfrak{p}_i$. Then there exists $i \in \{1, \dots, k\}$ such that $f^{-1}\mathfrak{p}_i = 0$, so that the composition $\overline{f}_i : A \to B/\mathfrak{p}_i$ of f with the projection $B \to B/\mathfrak{p}_i$ is still injective; clearly it suffices to check that $\overline{f}_i$ admits an A-linear section, so *we may assume that* B *is a domain*.

Let K be the field of fractions of A, set $B_K := K\otimes_A B$, let $d := \dim_K B_K$, and denote by $\mathrm{Tr}_{B_K/K} : B_K \to K$ the trace form; since A is integrally closed in K, the composition of $\mathrm{Tr}_{B_K/K}$ with the localization $B \to B_K$ factors through an A-linear map (lemma 14.3.15(i))

$$\mathrm{Tr}_{B/A} : B \to A.$$

Then $\mathrm{Tr}_{B/A} \circ f = d \cdot \mathbf{1}_A$. In particular, if A is a $\mathbb{Q}$-algebra, the map $d^{-1} \cdot \mathrm{Tr}_{B/A}$ is a section of f as sought. Thus, *we may assume that k has characteristic* $p > 0$. Let us set

$$P^{(n)} := \{\gamma \in P_{\mathbb{Q}} \mid \gamma^{p^n} \in P\} \qquad P^{(\infty)} := \bigcup_{n\in\mathbb{N}} P^{(n)} \qquad \text{and} \qquad \Gamma := (P^{(\infty)}/P)^{\mathrm{gp}}.$$

Then $P^{(\infty)}$ is naturally a Γ-graded monoid. More precisely, for every $\gamma \in (P^{(\infty)})^{\mathrm{gp}}$, denote by $[\gamma] \in \Gamma$ the class of γ; then we have :

$$\mathrm{gr}_{[\gamma]} P^{(\infty)} = P^{(\infty)} \cap \gamma P^{\mathrm{gp}} \qquad \text{for every } \gamma \in (P^{(\infty)})^{\mathrm{gp}}.$$

Theorem 17.3.6. *In the situation of* (17.3.2)*, suppose that A is an $\mathbb{F}_p$-algebra. Then f admits an A-linear section.*

Proof. After the foregoing reductions, we may assume that $A = k[[P]]$ for a sharp, fine and saturated monoid P, and that B is a domain. For every $n \in \mathbb{N}$, set

$$A_n := k[[P^{(n)}]] \qquad B_n := A_n \otimes_A B \qquad \text{and} \qquad A_\infty := \bigcup_{n\in\mathbb{N}} A_n.$$

Notice that A_0 is a direct summand of the A_0-module A_n, hence the inclusion map $i_n : A \to A_n$ has a section $\sigma_n : A_n \to A$ for every $n \in \mathbb{N}$; we are then reduced to checking that the induced map $f_n : A_n \to B_n$ has an A_n-linear section $s_n : B_n \to A_n$, for some $n \in \mathbb{N}$: indeed, in this case let $j_n : B \to B_n$ be the induced inclusion map, and set $s := \sigma_n \circ s_n \circ j_n : B \to A$. We get:

$$s \circ f = \sigma_n \circ s_n \circ j_n \circ f = \sigma_n \circ s_n \circ f_n \circ i_n = \sigma_n \circ i_n = \mathbf{1}_A$$

as required. On the other hand, let K_n be the field of fractions of A_n, and denote by B'_n the maximal reduced quotient of B_n, for every $n \in \mathbb{N}$; since A_n is reduced, the induced map $f'_n : A_n \to B'_n$ is still injective, so it suffices to exhibit a section for f'_n. Moreover, $E_n := K_n \otimes_{A_n} B'_n$ is a finite field extension of K_n (since K_n is a purely inseparable field extension of K), and the inclusion map $K_n \to K_{n+1}$ induces a field extension $E_n \to E_{n+1}$ for every such n. Notice also that $K_\infty := \bigcup_{n\in\mathbb{N}} K_n$ is a perfect field; hence $E_\infty := \bigcup_{n\in\mathbb{N}} E_n$ is the maximal reduced quotient of $K_\infty \otimes_A B$, and is a finite *separable* field extensions of K_∞. It follows easily that for $n \in \mathbb{N}$ sufficiently large, E_n is already a *separable and finite* field extension of K_n. Summing up, we may replace A and B by A_n and B'_n for n large enough, and *assume that f is generically étale, i.e.* there exists $g \in A \setminus \{0\}$ such that $A[1/g] \otimes_A f$ is a finite, injective and étale map. Then, notice that A_∞ is a perfect $\mathbb{F}_p$-algebra, and let $\mathfrak{n} \subset A_\infty$ be the radical of the ideal $A_\infty g$; let also C_∞ be the integral closure of A_∞ in $A_\infty[1/g] \otimes_A B$. By theorems 16.8.2 and 16.8.44(ii), and proposition 14.4.8, the $(A_\infty, \mathfrak{n})^a$-algebra C^a_∞ is étale, faithfully flat and of almost finite rank. Now, let X be any A-module of finite length; by virtue of lemma 17.3.1(ii,iii), it suffices to check that the map $X \otimes_A f : X \to X \otimes_A B$ is injective. However, since A is a direct summand of the A-module A_∞, the induced map $h : X \to X \otimes_A A_\infty$ is injective, and since C^a_∞ is a faithfully flat $(A_\infty, \mathfrak{n})^a$-algebra, the kernel of the induced map $l : X \otimes_A A_\infty \to X \otimes_A C_\infty$ is annihilated by $\mathfrak{n}$. Clearly $l \circ h$ factors through $X \otimes_A f$; hence :

$$\mathfrak{n} \cdot \mathrm{Ker}(X \otimes_A f) = 0$$

(we regard $\mathrm{Ker}(X \otimes_A f)$ as a subset of $\mathrm{Ker}\, l$, via h). Now, as $P^{(\infty)}$ is Γ-graded, A_∞ is naturally a Γ-graded A-algebra, and $X \otimes_A A_\infty$ is a Γ-graded $(A_\infty, \mathrm{gr}_\bullet A_\infty)$-module (see definition 7.6.1(ii)); by definition :

$$\mathrm{gr}_{[\gamma]} A_\infty := A \otimes_{\mathbb{Z}[P]} \mathbb{Z}[\mathrm{gr}_{[\gamma]} P^{(\infty)}] \qquad \text{for every } \gamma \in P^{(\infty)}.$$

According to proposition 6.4.14(ii), there exist $\lambda_1, \ldots, \lambda_k \in P^\vee := \mathrm{Hom}_{\mathbf{Mnd}}(P, \mathbb{N})$ such that $\mathbb{R}\lambda_1, \ldots, \mathbb{R}\lambda_k$ are the extremal rays of $P^\wedge_{\mathbb{R}}$ (see (6.3.15)).

Claim 17.3.7. If $\gamma \in P^{(\infty)}$, and $0 \leq \lambda_i(\gamma) < 1$ for every $i = 1, \ldots, k$, then $\mathrm{gr}_{[\gamma]} P^{(\infty)} = \gamma P$.

Proof of the claim. By proposition 6.4.14(iv), we have

$$P^{(\infty)} = \{\gamma \in (P^{(\infty)})^{\mathrm{gp}} \mid \lambda_i(\gamma) \geq 0 \text{ for every } i = 1, \dots, k\}.$$

Hence $\mathrm{gr}_{[\gamma]} P^{(\infty)}$ is the subset of all $\gamma \cdot \beta$, with $\beta \in P^{\mathrm{gp}}$ and $\lambda_i(\gamma \cdot \beta) \geq 0$ for $i = 1, \dots, k$. But $\lambda_i(\beta) \in \mathbb{Z}$ for every such i and β; our assumption on $\lambda_i(\gamma)$ then implies that $\lambda_i(\beta) \in \mathbb{N}$ for every such i and β, whence $\beta \in P$ (again, by proposition 6.4.14(iv)), and the claim follows. $\diamondsuit$

We have $g = \sum_{\gamma \in P} g_\gamma \cdot \gamma$ for a system $(g_\gamma \mid \gamma \in P)$ of elements of k. Pick $\beta \in P$ with $g_\beta \neq 0$, and $N \in \mathbb{N}$ large enough, so that $\lambda_i(\beta^{1/p^N}) = p^{-N}\lambda_i(\beta) < 1$ for $i = 1, \dots, k$; by claim 17.3.7, we then have $\mathrm{gr}_{[\beta^{1/p^N}]} P^{(\infty)} = \beta^{1/p^N} P$. Clearly $g^{1/p^N} = \sum_{\gamma \in P} g_\gamma^{1/p^N} \cdot \gamma^{1/p^N}$; let us also write $g^{1/p^N} = \sum_{[\gamma] \in \Gamma} g_{[\gamma]}$, with $g_{[\gamma]} \in \mathrm{gr}_{[\gamma]} A_\infty$ for every $[\gamma] \in \Gamma$. It follows that $g_{[\beta^{1/p^N}]} = g_\beta^{1/p^N} \cdot \beta^{1/p^N} \cdot (1 + a)$ for some $a \in \mathfrak{m}$. Let now $x \in \mathrm{Ker}\, X \otimes_A f$; we have $x \in \mathrm{gr}_0(X \otimes_A A_\infty)$, and $g^{1/p^N} x = 0$; then $g_{[\gamma]} x = 0$ for every $[\gamma] \in \Gamma$, and especially :

$$x \otimes g_\beta^{1/p^N} \cdot \beta^{1/p^N} = 0 \quad \text{in} \quad \mathrm{gr}_{[\beta^{1/p^N}]}(X \otimes_A A_\infty) = X \otimes_A A_{[\beta^{1/p^N}]} = X \otimes_{\mathbb{Z}[P]} \mathbb{Z}[\beta^{1/p^N} P]$$

and since $g_\beta \neq 0$, we have $x \otimes \beta^{1/p^N} = 0$ in $X \otimes_{\mathbb{Z}[P]} \mathbb{Z}[\beta^{1/p^N} P]$, so finally $x = 0$, as required. $\square$

Remark 17.3.8. Theorem 17.3.6 also has a proof along the lines of [93, Rem.6.2], which proves the direct summand conjecture for regular $\mathbb{F}_p$-algebras. This alternative argument still relies on claim 17.3.7, but avoids lemma 17.3.1 and the reduction to the case where f is generically étale.

17.3.9. By theorem 17.3.6 and the foregoing reductions, we may assume that

$$A = V[[P]]/(\vartheta)$$

for a fine, sharp and saturated monoid $P \neq 0$, a complete discrete valuation ring $(V, \mathfrak{m}_V)$ with $\mathfrak{m}_V = pV$, whose residue field $k := V/pV$ is algebraically closed, and a power series $\vartheta := \sum_{\gamma \in P} a_\gamma \cdot \gamma$ with $a_0 \in pV \setminus p^2 V$. Then $\mathfrak{m}_P A = \mathfrak{m}$, the maximal ideal of A. We set

$$A_n := A \otimes_{\mathbb{Z}[P]} \mathbb{Z}[P^{(n)}] \qquad \text{and} \qquad B_n := A_n \otimes_A B \qquad \text{for every } n \in \mathbb{N}.$$

Notice that the induced map $A_n \to A_{n+1}$ is injective for every $n \in \mathbb{N}$, since $\mathbb{Z}[P^{(n)}]$ is a direct summand of the $\mathbb{Z}[P^{(n)}]$-module $\mathbb{Z}[P^{(n+1)}]$; hence, let as well $A_\infty := \bigcup_{n \in \mathbb{N}} A_n$. Moreover, notice that $A/\mathfrak{m}_P A = V/a_0 V = k$, and $\Omega^1_{k/\mathbb{Z}} = 0$, since k is perfect; then, the integer r of (17.2.3) vanishes in the current situation, hence theorem 17.2.14(iv) tells us that A_∞ *is a formally perfectoid ring, for its p-adic topology*, and clearly it is also naturally Γ-graded.

Let $\lambda_1, \dots, \lambda_k \in P^\vee := \mathrm{Hom}_{\mathbf{Mnd}}(P, \mathbb{N})$ such that $\mathbb{R}\lambda_1, \dots, \mathbb{R}\lambda_k$ are the extremal rays of $P^\vee_{\mathbb{R}}$ (see the proof of theorem 17.3.6), and $\beta_1, \dots, \beta_l \in P$ a finite system of generators of the $\mathbb{Q}_+$-module $\mathbb{Q}_+ \otimes_{\mathbb{N}} P$ (see (3.7.17)); set

$$\lambda := \lambda_1 + \cdots + \lambda_k \qquad \beta := \beta_1 \cdots \beta_l \qquad \text{and} \qquad L := \max(\lambda(\beta_1), \dots, \lambda(\beta_l)).$$

Lemma 17.3.10. *In the situation of* (17.3.9)*, let $J \subset A_\infty$ be a Γ-graded ideal, $g \in A_\infty$, and let $e, n \in \mathbb{N}$ such that*

$$g \in \mathfrak{m}^e A_\infty \setminus \mathfrak{m}^{e+1} A_\infty \qquad g \in J^{p^n} \qquad \textit{and} \qquad 1 \geq \varepsilon(e, n) := (eL + \lambda(\beta))/p^n.$$

Then there exists $\gamma \in P^{(\infty)}$ such that :

$$\mathrm{gr}_{[\gamma]} J = \mathrm{gr}_{[\gamma]} A_\infty \qquad \textit{and} \qquad \lambda(\gamma) < \varepsilon(e, n).$$

Proof. We may write $g = g_1 + \cdots + g_r$ for a finite sequence $g_1, \dots, g_r \in J^{p^n}$ such that each g_i is in turn of the form $g_i = \prod_{j=1}^{p^n} a_{ij} \otimes \gamma_{ij}$ with :

$$a_{i1}, \dots, a_{i,p^n} \in A \qquad \gamma_{i1}, \dots, \gamma_{i,p^n} \in P^{(\infty)} \qquad a_{ij} \otimes \gamma_{ij} \in \mathrm{gr}_{[\gamma_{ij}]} J \quad \text{for every } j = 1, \dots, p^n.$$

It is clear that there exists $e' \leq e$ and $i \in \{1, \dots, r\}$ such that $g_i \in \mathfrak{m}^{e'} A_\infty \setminus \mathfrak{m}^{e'+1} A_\infty$. Up to reordering the p^n factors of g_i, we may then assume that there exists $c \in \{0, \dots, p^n\}$ such that $\lambda(\gamma_{ij}) < \varepsilon(e, n)$ for $j = 1, \dots, c$, and $\lambda(\gamma_{ij}) \geq \varepsilon(e, n)$ for $j = c+1, \dots, p^n$. Suppose now that the lemma fails; then we must have $a_{ij} \in \mathfrak{m}$ for every $i = 1, \dots, c$, and therefore

$$\prod_{j=c+1}^{p^n} a_{ij} \otimes \gamma_{ij} \notin \mathfrak{m}^{e'-c+1} A_\infty. \tag{17.3.11}$$

For every $j = c+1, \dots, p^n$, write $\gamma_{ij} = \prod_{s=1}^{l} \beta_s^{d_{ijs}}$ for certain $d_{ij1}, \dots, d_{ijl} \in \mathbb{Q}_+$; then there exist unique $d'_{is} \in \mathbb{N}$ and $d''_{is} \in [0, 1[$ with

$$\sum_{j=c+1}^{p^n} d_{ijs} = d'_{is} + d''_{is} \qquad \text{for every } s = 1, \dots, l$$

and (17.3.11) then implies that $\sum_{s=1}^{l} d'_{is} \leq e' - c$, whence :

$$\sum_{j=c+1}^{p^n} \lambda(\gamma_{ij}) < (e' - c) \cdot L + \lambda(\beta') \leq p^n \cdot \varepsilon(e, n) - cL.$$

However, $\sum_{j=c+1}^{p^n} \lambda(\gamma_{ij}) \geq (p^n - c) \cdot \varepsilon(e, n)$, and since $\varepsilon(e, n) \leq 1 \leq L$, this is absurd. □

Theorem 17.3.12. *In the situation of* (17.3.2)*, the map f admits an A-linear section.*

Proof. In view of the foregoing reductions, we may assume that A and A_∞ are as in (17.3.9) and B is a domain; recall also that $B[1/g]$ is an étale and faithfully flat $A[1/g]$-algebra. Let :

$$A'_n := A_\infty[X^{1/p^n}]/(X - g) \qquad \text{for every } n \in \mathbb{N} \qquad \text{and} \qquad A'_\infty := \bigcup_{n \in \mathbb{N}} A'_n.$$

Let also D be the p-root closure of A'_∞ in $A'_\infty[1/p]$, and endow D with its p-adic topology; by theorem 16.9.17, we know that D is a faithfully flat A_∞-algebra, and that D is a formally perfectoid ring. Denote by $D^\wedge$ the p-adic completion of D, and set $B' := D^\wedge \otimes_A B[1/g]$. Hence, B' is a finite étale $D^\wedge[1/g]$-algebra. Let now $\mathfrak{n} \subset D^\wedge$ be the ideal generated by $(g^{1/p^n} \mid n \in \mathbb{N})$; then $(D^\wedge, \mathfrak{n})$ is a basic setup, and we set $D_1^\wedge := (D^\wedge, \mathfrak{n})_*^a \subset D^\wedge[1/g]$ (see lemma 16.9.41); lastly, let B'_1 be the integral closure of $D_1^\wedge$ in B'. By theorem 16.9.42(ii,iii), for every $n \in \mathbb{N}$, the $(D/p^n D)^a$-algebra $(B'_1/p^n B'_1)^a$ is faithfully flat and étale of finite rank, for the almost structure given by the basic setup $(D_1^\wedge, \mathfrak{n})$. After these preliminaries, let X be any A-module of finite length; by lemma 17.3.1(ii,iii), it suffices to show that the map $X \otimes_A f$ is injective. However, let $x \in \mathrm{Ker}(X \otimes_A f)$, and pick $m \in \mathbb{N}$ large enough, so that $p^m X = 0$. Since A_∞ is a Γ-graded A-algebra with $\mathrm{gr}_0 A_\infty = A$, the induced map $\varphi : X \to X_\infty := X \otimes_A A_\infty/p^m A_\infty$ is injective, and X_∞ is naturally a Γ-graded $(A_\infty, \mathrm{gr}_\bullet)$-module, with $\mathrm{gr}_0 X_\infty = X$. Especially, the annihilator J of $\varphi(x) = x \otimes 1 \in \mathrm{gr}_0 X_\infty$ is a Γ-graded ideal of A_∞. Next, since D is a faithfully flat A_∞-algebra, the induced map $\varphi' : X_\infty \to X_\infty \otimes_{A_\infty} D/p^m D$ is again injective, and $\mathrm{Ann}_D(\varphi'(x \otimes 1)) = JD$. Lastly, since $(B'_1/p^m B'_1)^a$ is a faithfully flat $(D/p^m D)^a$-algebra, the kernel of the induced map $\varphi'' : X_\infty \otimes_{A_\infty} D/p^m D \to X_\infty \otimes_{A_\infty} B'_1/p^m B'_1$ is annihilated by $\mathfrak{n}$. Clearly $\varphi'' \circ \varphi' \circ \varphi$ factors through $X \otimes_A f$, hence $\varphi'(x \otimes 1) \in \mathrm{Ker}\,\varphi''$, and consequently :

$$\mathfrak{n} \subset JD.$$

Thus, $g^{1/p^n} \in JD \cap A_\infty = J$ for every $n \in \mathbb{N}$ ([126, Th.7.5(ii)]), *i.e.* $g \in J^{p^n}$ for every $n \in \mathbb{N}$. Notice that the $\mathfrak{m}$-adic topology is separated on A_∞; hence, let $e \in \mathbb{N}$ such that $g \in \mathfrak{m}^e A_\infty \setminus \mathfrak{m}^{e+1} A_\infty$; by lemma 17.3.10, for every $n \in \mathbb{N}$ there exists $\gamma_n \in P^{(\infty)}$ such that $\lambda(\gamma_n) < \varepsilon(e, n)$ and $\mathrm{gr}_{[\gamma_n]} J = \mathrm{gr}_{[\gamma_n]} A_\infty$. By claim 17.3.7, it follows that for every sufficiently large $n \in \mathbb{N}$, we have $\mathrm{gr}_{[\gamma_n]} J = A \otimes_{\mathbb{Z}[P]} \mathbb{Z}[\gamma_n + P]$, a free A-module of rank one, with generator

$1 \otimes \gamma_n$. Finally, we get $x \otimes \gamma_n = 0$ in $\mathrm{gr}_{[\gamma_n]} X_\infty = X \otimes_{\mathbb{Z}[P]} \mathbb{Z}[\gamma_n + P]$ for every such n; thus, $x = 0$, and the proof is concluded. □

17.4. **Diagonal idempotents of generically étale maps.** Let $f : A \to B$ be a finite and injective ring homomorphism of noetherian rings; set $X := \mathrm{Spec}\, A$, denote by $\mathscr{B}$ the quasi-coherent $\mathscr{O}_X$-algebra associated with B, and by $\mu : \mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B} \to \mathscr{B}$ the multiplication morphism. For every affine open subset $U \subset X$ such that $\mathscr{B}_{|U}$ is an étale $\mathscr{O}_U$-algebra, we have a unique *diagonal idempotent* $e_{f,U} \in \mathscr{B}(U) \otimes_{\mathscr{O}_X(U)} \mathscr{B}(U)$ such that :

$$\mu_U(e_{f,U}) = 1 \quad \text{and} \quad x \cdot e_{f,U} = 0 \quad \text{for every } x \in \mathrm{Ker}\,(\mathscr{B}(U) \otimes_{\mathscr{O}_X(U)} \mathscr{B}(U) \xrightarrow{\mu_U} \mathscr{B}(U)).$$

We suppose moreover that f is *generically étale*, *i.e.* that the union $U_f \subset X$ of all such affine open subsets is dense in X; the uniqueness property of the diagonal idempotents then implies that there exists a unique section

$$e_f \in \Gamma(U_f, \mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B})$$

such that $e_{f|U} = e_{f,U}$ for every affine open subset $U \subset U_f$. Moreover, $\mathscr{B}_{|U_f}$ is a locally free $\mathscr{O}_{U_f}$-module of finite rank, hence we have a well defined $\mathscr{O}_{U_f}$-linear *trace map*

$$\mathrm{tr}_{\mathscr{B}/\mathscr{O}_X} : \mathscr{B}_{|U_f} \to \mathscr{O}_{U_f}$$

that assigns to every affine open subset $U \subset U_f$ and every $b \in \mathscr{B}(U)$ the trace of the $\mathscr{O}_X(U)$-linear endomorphism $b \cdot \mathbf{1}_{\mathscr{B}(U)}$. The corresponding *trace form*

$$t_{\mathscr{B}/\mathscr{O}_X} := \mathrm{tr}_{\mathscr{B}/\mathscr{O}_X} \circ \mu : (\mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B})_{|U_f} \to \mathscr{O}_{U_f}$$

is a perfect pairing ([75, Th.4.1.14]), hence it induces an $\mathscr{O}_{U_f}$-linear isomorphism

$$\omega_{\mathscr{B}/\mathscr{O}_X} : \mathscr{B}_{|U_f} \xrightarrow{\sim} (\mathscr{B}^\vee)_{|U_f} \qquad \text{where} \qquad \mathscr{B}^\vee := \mathscr{H}om_{\mathscr{O}_X}(\mathscr{B}, \mathscr{O}_X).$$

Remark 17.4.1. Let $f : A \to B$ be as in (17.4), $p \in \mathbb{N}$ a prime integer, and suppose that A is an $\mathbb{F}_p$-algebra. Let also $h \in A$ such that the localization $f_h : A_h \to B_h$ of f is étale. It is easily seen that the natural map (notation of (9.8.11))

$$B^{\mathrm{perf}} \otimes_{A^{\mathrm{perf}}} B^{\mathrm{perf}} \to (B \otimes_A B)^{\mathrm{perf}}$$

is bijective. By assumption, $h^n e_f$ is in the image of the localization $B \otimes_A B \to B_h \otimes_{A_h} B_h$, for some $n \in \mathbb{N}$. The image e_f^{perf} of e_f in $(B \otimes_A B)_h^{\mathrm{perf}}$ is the diagonal idempotent of the étale map $A_h^{\mathrm{perf}} \otimes_A f : A_h^{\mathrm{perf}} \to B_h^{\mathrm{perf}} = A_h^{\mathrm{perf}} \otimes_A B$. Since $(e_f^{\mathrm{perf}})^p = e_f^{\mathrm{perf}}$, we conclude that $h^{n/p^k} e_f^{\mathrm{perf}}$ lies in the image of the localization $(B \otimes_A B)^{\mathrm{perf}} \to (B \otimes_A B)_h^{\mathrm{perf}}$, for every $k \in \mathbb{N}$.

Definition 17.4.2. (i) A *log ring* (A, P, β) is the datum of a ring A, an integral saturated monoid P whose associated abelian group P^{gp} is *torsion-free*, and a morphism of monoids $\beta : P \to A$ from P to the multiplicative monoid $(A, \cdot)$, furnishing a chart for a *log structure* $\mathscr{P}$ on the Zariski site of $\mathrm{Spec}\, A$ (see definition 12.1.17(i)), which we call *the log structure of* (A, P, β).

(ii) We say that the log ring (A, P, β) is *regular* if A is noetherian, P is fine and saturated, and the log structure of (A, P, β) is *regular*. In this case, P^{gp} is a free abelian group of finite rank, and A is a product of finitely many normal domains (corollary 12.5.13).

17.4.3. Let (A, P, β) be any log ring, $f : A \to B$ a ring homomorphism as in (17.4), and set $X := \mathrm{Spec}\, A$. We consider the monoid $P^{(\infty)}$ associated with P as in (17.3.5), and the abelian group $\Gamma := (P^{(\infty)}/P)^{\mathrm{gp}}$. We will likewise use the monoid $P_{\mathbb{Q}} := \mathbb{Q}_+ \otimes_{\mathbb{N}} P$, and the abelian group $\Gamma_{\mathbb{Q}} := (P_{\mathbb{Q}}/P)^{\mathrm{gp}}$, and for every $\gamma \in P_{\mathbb{Q}}$, we let $[\gamma] \in \Gamma_{\mathbb{Q}}$ be the class of γ. Then the ring

$$A_\infty := A \otimes_{\mathbb{Z}[P]} \mathbb{Z}[P_{\mathbb{Q}}]$$

is naturally a $\Gamma_{\mathbb{Q}}$-graded A-algebra, with graded summands :

$$A_{[\gamma]} := A \otimes_{\mathbb{Z}[P]} \mathbb{Z}[\mathrm{gr}_{[\gamma]} P_{\mathbb{Q}}] \qquad \text{for every } \gamma \in P_{\mathbb{Q}}.$$

Likewise, set $B_\infty := A_\infty \otimes_A B$; both B_∞ and its dual A_∞-module $B^\vee_\infty := \mathrm{Hom}_{A_\infty}(B_\infty, A_\infty)$ inherit natural $\Gamma_\mathbb{Q}$-graded structures whose graded summands are respectively

$$B_{[\gamma]} := A_{[\gamma]} \otimes_A B \qquad \text{and} \qquad B^\vee_{[\gamma]} := \mathrm{Hom}_A(B, A_{[\gamma]}) \qquad \text{for every } \gamma \in P_\mathbb{Q}.$$

Let $\mathscr{O}_{X_\infty}$ and $\mathscr{B}_\infty$ be the quasi-coherent $\mathscr{O}_X$-algebras associated with A_∞ and B_∞. Hence, $\mathscr{B}_{\infty|U_f}$ is an étale $\mathscr{O}_{X_\infty|U_f}$-algebra, whose trace morphism induces the isomorphism

$$\omega_{\mathscr{B}_\infty/\mathscr{O}_{X_\infty}} := \mathscr{O}_{X_\infty|U_f} \otimes_{\mathscr{O}_{U_f}} \omega_{\mathscr{B}/\mathscr{O}_X} : \mathscr{B}_{\infty|U_f} \xrightarrow{\sim} \mathscr{B}^\vee_{\infty|U_f}.$$

Also, the corresponding diagonal idempotent $e_{f,\infty} \in \Gamma(U_f, \mathscr{B}_\infty \otimes_{\mathscr{O}_{X_\infty}} \mathscr{B}_\infty)$ is the image of e_f, under the natural morphism

$$\mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B} \to \mathscr{O}_{X_\infty} \otimes_{\mathscr{O}_X} \mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B} \xrightarrow{\sim} \mathscr{B}_\infty \otimes_{\mathscr{O}_{X_\infty}} \mathscr{B}_\infty. \tag{17.4.4}$$

More precisely, since U_f is quasi-compact, the A_∞-module $\Gamma(U_f, \mathscr{B}_\infty \otimes_{\mathscr{O}_{X_\infty}} \mathscr{B}_\infty)$ is also $\Gamma_\mathbb{Q}$-graded, and on the other hand, $\mathrm{gr}_0 P_\mathbb{Q} = P$, since P is saturated; then $\mathrm{gr}_0 B_\infty = B$, and the map (17.4.4) identifies $\Gamma(U_f, \mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B})$ with $\mathrm{gr}_0\Gamma(U_f, \mathscr{B}_\infty \otimes_{\mathscr{O}_{X_\infty}} \mathscr{B}_\infty)$.

17.4.5. Let $\underline{f} := (f, P, \beta)$ be the datum of a log ring (A, P, β) and a ring homomorphism $f : A \to B$ as in (17.4); with the notation of (17.4.3), we attach to $\underline{f}$ the composition

$$B^\vee_\infty \otimes_{A_\infty} B^\vee_\infty \xrightarrow{\rho} \Gamma(U_f, \mathscr{B}^\vee_\infty \otimes_{\mathscr{O}_{X_\infty}} \mathscr{B}^\vee_\infty) \xrightarrow{\alpha} \Gamma(U_f, \mathscr{B}_\infty \otimes_{\mathscr{O}_{X_\infty}} \mathscr{B}_\infty) \tag{17.4.6}$$

where ρ is the restriction map of the quasi-coherent $\mathscr{O}_X$-module $\mathscr{B}^\vee_\infty \otimes_{\mathscr{O}_{X_\infty}} \mathscr{B}^\vee_\infty$, and α is induced by the isomorphism $\omega^{-1}_{\mathscr{B}_\infty/\mathscr{O}_{X_\infty}} \otimes_{\mathscr{O}_{X_\infty|U_\infty}} \omega^{-1}_{\mathscr{B}_\infty/\mathscr{O}_{X_\infty}}$. Set as well :

$$\mathsf{R}(B, \Delta) := \bigoplus_{[\gamma]\in\Delta} B^\vee_{[\gamma]} \otimes_A B^\vee_{[1/\gamma]} \qquad \text{for every subset } \Delta \subset \Gamma_\mathbb{Q}.$$

Since (17.4.6) is a morphism of graded A_∞-modules, it restricts to an A-linear map

$$\vartheta_{\underline{f}} : \mathsf{R}(B, \Gamma_\mathbb{Q}) \to \mathrm{gr}_0\Gamma(U_f, \mathscr{B}_\infty \otimes_{\mathscr{O}_{X_\infty}} \mathscr{B}_\infty) \xrightarrow{\sim} \Gamma(U_f, \mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B}).$$

Remark 17.4.7. (i) In the situation of (17.4.5), let $g : A \to A'$ be a ring homomorphism; set $B' := A' \otimes_A B$, let $f' : A' \to B'$ be the induced map, and suppose that $\underline{f}' := (f', P, g \circ \beta)$ is also a datum as in (17.4.5). Set $X' := \mathrm{Spec}\, A'$, and let $h : X' \to X$ be the morphism of schemes induced by g; also, let $\mathscr{B}'$ be the quasi-coherent $\mathscr{O}_{X'}$-algebra arising from B'. For every $[\gamma] \in \Gamma_\mathbb{Q}$ we get a natural A-linear map

$$B^\vee_{[\gamma]} \to \mathrm{Hom}_A(B, A'_{[\gamma]}) \xrightarrow{\sim} B'^\vee_{[\gamma]} := \mathrm{Hom}_{A'}(B', A'_{[\gamma]}) \tag{17.4.8}$$

and a direct inspection of the definitions yields a commutative diagram :

$$\begin{array}{ccccc}
\mathsf{R}(B, \Gamma_\mathbb{Q}) & & \xrightarrow{\quad\vartheta_{\underline{f}}\quad} & & \Gamma(U_f, \mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B}) \\
\downarrow & & & & \downarrow \\
\mathsf{R}(B', \Gamma_\mathbb{Q}) & \xrightarrow{\vartheta_{\underline{f}'}} & \Gamma(U_{f'}, \mathscr{B}' \otimes_{\mathscr{O}_{X'}} \mathscr{B}') & \xrightarrow{\rho} & \Gamma(h^{-1}U_f, \mathscr{B}' \otimes_{\mathscr{O}_{X'}} \mathscr{B}')
\end{array}$$

whose left (resp. right) vertical arrow is induced by the maps (17.4.8) (resp. by the natural morphisms of quasi-coherent $\mathscr{O}_X$-algebras $\mathscr{O}_X \to h_*\mathscr{O}_{X'}$ and $\mathscr{B} \to h_*\mathscr{B}'$), and where ρ is the restriction map. Also, it is clear that the right vertical arrow maps e_f to $\rho(e_{f'})$.

(ii) Let R be any ring, S and S' two finite R-algebras whose underlying R-modules are projective (of finite rank). Then all the trace maps $\mathrm{tr}_{S/R}, \mathrm{tr}_{S'/R}$ and $\mathrm{tr}_{S\otimes_R S'/R}$ are well defined, and [75, Lemma 4.1.3] implies that :

$$\mathrm{tr}_{S\otimes_R S'/R} = \mathrm{tr}_{S/R} \otimes_R \mathrm{tr}_{S'/R} : S \otimes_R S' \to R.$$

We deduce the following alternative description of $\vartheta_{\underline{f}}$. First, we have a natural A_∞-linear map

$$B_\infty^\vee \otimes_{A_\infty} B_\infty^\vee \to (B_\infty \otimes_{A_\infty} B_\infty)^\vee := \mathrm{Hom}_A(B \otimes_A B, A_\infty) \qquad (17.4.9)$$

given by the rule : $\varphi \otimes \varphi' \mapsto (b \otimes b' \mapsto \varphi(b) \cdot \varphi'(b'))$ for every $\varphi, \varphi' \in B_\infty^\vee$ and every $b, b' \in B$. Next, the trace map of the $\mathscr{O}_{X_\infty}$-algebra $\mathscr{B}_\infty \otimes_{\mathscr{O}_X} \mathscr{B}_\infty$ induces an $\mathscr{O}_{X_\infty}$-linear map

$$\omega_{\mathscr{B}_\infty \otimes_{\mathscr{O}_{X_\infty}} \mathscr{B}_\infty / \mathscr{O}_{X_\infty}} : \mathscr{B}_\infty \otimes_{\mathscr{O}_X} \mathscr{B}_\infty \to (\mathscr{B}_\infty \otimes_{\mathscr{O}_X} \mathscr{B}_\infty)^\vee$$

whose restriction to the open subset U_f is an isomorphism. Then it is easily seen that (17.4.6) equals the composition of (17.4.9) with the map

$$(B_\infty \otimes_{A_\infty} B_\infty)^\vee \xrightarrow{\rho'} \Gamma(U_f, (\mathscr{B}_\infty \otimes_{\mathscr{O}_X} \mathscr{B}_\infty)^\vee) \xrightarrow{\alpha'} \Gamma(U_f, \mathscr{B}_\infty \otimes_{\mathscr{O}_X} \mathscr{B}_\infty)$$

where ρ' is the restriction map of the quasi-coherent $\mathscr{O}_X$-module $(\mathscr{B}_\infty \otimes_{\mathscr{O}_X} \mathscr{B}_\infty)^\vee$, and α' is induced by the isomorphism $(\omega_{\mathscr{B}_\infty \otimes_{\mathscr{O}_{X_\infty}} \mathscr{B}_\infty / \mathscr{O}_{X_\infty}})_{|U_f}$. Moreover, $(B_\infty \otimes_{A_\infty} B_\infty)^\vee$ is naturally a $\Gamma_\mathbb{Q}$-graded A_∞-module, with a natural identification :

$$\mathrm{gr}_0(B_\infty \otimes_{A_\infty} B_\infty)^\vee \xrightarrow{\sim} (B \otimes_A B)^\vee := \mathrm{Hom}_A(B \otimes_A B, A)$$

and (17.4.9) is a morphism of $\Gamma_\mathbb{Q}$-graded modules. It follows that $\vartheta_{\underline{f}}$ is the composition

$$\mathsf{R}(B, \Gamma_\mathbb{Q}) \xrightarrow{\xi_{\underline{f}}} (B \otimes_A B)^\vee \xrightarrow{\xi'_{\underline{f}}} \Gamma(U_f, \mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B})$$

where $\xi_{\underline{f}}$ is induced by the restriction of (17.4.9), and $\xi'_{\underline{f}}$ is the restriction of $\alpha' \circ \rho'$. In turn, $\xi'_{\underline{f}}$ can be described as the composition of the restriction map $(B \otimes_A B)^\vee \to \Gamma(U_f, (\mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B})^\vee)$ of the quasi-coherent $\mathscr{O}_X$-module $(\mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B})^\vee$ arising from $(B \otimes_A B)^\vee$, and the isomorphism $\Gamma(U_f, (\mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B})^\vee) \xrightarrow{\sim} \Gamma(U_f, \mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B})$ induced by the isomorphism $(\mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B})^\vee_{|U_f} \xrightarrow{\sim} (\mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B})_{U_f}$ deduced as usual from the trace map of $\mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B}$.

(iii) With the notation of (ii), notice as well that $\xi'_{\underline{f}}$ is injective if A is reduced. Indeed, if $\varphi : B \otimes_A B \to A$ restricts on U_f to the zero section of $(\mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B})^\vee$, then for every $b, b' \in B$ the element $\varphi(b \otimes b') \in A$ restricts on U_f to the zero section of $\mathscr{O}_X$; since A is reduced and U_f is dense in X, this means that $\varphi(b \otimes b') = 0$ for every such b, b', whence the contention.

Lemma 17.4.10. (i) *In the situation of* (17.4.5)*, let $\Delta \subset \Gamma_\mathbb{Q}$ be any subset. Then there exists a finite subset $\Sigma \subset \Delta$ such that $\xi_{\underline{f}}(\mathsf{R}(B, \Delta)) = \xi_{\underline{f}}(\mathsf{R}(B, \Sigma))$ (where $\xi_{\underline{f}}$ is defined as in remark* 17.4.7(ii)*). Moreover, Σ depends only on P and Δ (and neither on β nor f).*

(ii) *Suppose that $P = P_1 \times P_2$, where $P_2 = \mathbb{N}^{\oplus r} \times \mathbb{Z}^{\oplus s}$, for some $r, s \in \mathbb{N}$. For $i = 1, 2$, let $\Delta_i \subset \Gamma_{i,\mathbb{Q}} := (P_{i,\mathbb{Q}}/P_i)^{\mathrm{gp}}$ be any subset, so that $\Delta_1 \times \Delta_2 \subset \Gamma_\mathbb{Q} = \Gamma_{1,\mathbb{Q}} \oplus \Gamma_{2,\mathbb{Q}}$. Then*

$$\xi_{\underline{f}}(\mathsf{R}(B, \Delta_1 \times \Delta_2)) = \xi_{\underline{f}}(\mathsf{R}(B, \Delta_1 \times \{0\})).$$

Proof. (i): On the one hand, the multiplication law of A_∞ induces by restriction A-linear maps

$$\mu_{[\gamma]} : A_{[\gamma]} \otimes_A A_{[1/\gamma]} \to \mathrm{gr}_0 A_\infty = A \qquad (a \otimes \gamma\lambda) \otimes (a' \otimes \lambda'/\gamma) \mapsto aa' \cdot \beta(\lambda\lambda')$$

(notice that if $\gamma, \lambda, \lambda' \in P_\mathbb{Q}^{\mathrm{gp}}$ and we have both $\gamma\lambda \in \mathrm{gr}_{[\gamma]} P_\mathbb{Q}$ and $\lambda'/\gamma \in \mathrm{gr}_{[1/\gamma]} P_\mathbb{Q}$, then $\lambda\lambda' \in \mathrm{gr}_0 P_\mathbb{Q} = P$). On the other hand, we have an obvious isomorphism of P-modules :

$$Q_\gamma := P^{\mathrm{gp}} \cap \gamma^{-1} P_\mathbb{Q} \xrightarrow{\sim} \mathrm{gr}_{[\gamma]} P_\mathbb{Q} \qquad \lambda \mapsto \gamma\lambda \qquad \text{for every } \gamma \in P_\mathbb{Q}^{\mathrm{gp}}.$$

Especially, if $Q_\gamma = Q_\delta$ for some $\gamma, \delta \in P_\gamma^{\mathrm{gp}}$, we deduce an A-linear isomorphism

$$\omega_{\gamma,\delta} : A_{[\gamma]} \xrightarrow{\sim} A_{[\delta]} \qquad a \otimes \gamma\lambda \mapsto a \otimes \delta\lambda \qquad \text{for every } a \in A \text{ and } \gamma\lambda \in \mathrm{gr}_{[\gamma]} P_\mathbb{Q}$$

which induces an A-linear isomorphism

$$\omega_{\gamma,\delta *} : B_{[\gamma]}^\vee \xrightarrow{\sim} B_{[\delta]}^\vee \qquad (\varphi : B \to A_{[\gamma]}) \mapsto (\omega_{\gamma,\delta} \circ \varphi : B \to A_{[\delta]}).$$

Furthermore, if we have both $Q_\gamma = Q_\delta$ and $Q_{1/\gamma} = Q_{1/\delta}$ for some $\gamma, \delta \in P^{\mathrm{gp}}_\gamma$, a direct inspection yields a commutative diagram :

(17.4.11)
$$\begin{array}{ccc} A_{[\gamma]} \otimes_A A_{[1/\gamma]} & \xrightarrow{\omega_{\gamma,\delta}\otimes_A \omega_{1/\gamma,1/\delta}} & A_{[\delta]} \otimes_A A_{[1/\delta]} \\ & {\scriptstyle \mu_{[\gamma]}} \searrow \quad \swarrow {\scriptstyle \mu_{[\delta]}} & \\ & A. & \end{array}$$

For such γ and δ, there follows a commutative diagram :

$$\begin{array}{ccc} B^\vee_{[\gamma]} \otimes_A B^\vee_{[1/\gamma]} & \xrightarrow{\omega_{\gamma,\delta *}\otimes_A \omega_{1/\gamma,1/\delta *}} & B^\vee_{[\delta]} \otimes_A B^\vee_{[1/\delta]} \\ & \searrow \quad \swarrow & \\ & (B \otimes_A B)^\vee & \end{array}$$

whose downward arrows are the restrictions of $\xi_{\underline{f}}$: the details shall be left to the reader. Pick a section of the projection $P^{\mathrm{gp}}_{\mathbb{Q}} \to \Gamma_{\mathbb{Q}}$:

$$\Gamma_{\mathbb{Q}} \to P^{\mathrm{gp}}_{\mathbb{Q}} \subset P^{\mathrm{gp}}_{\mathbb{R}} \qquad [\gamma] \mapsto [\gamma]^*$$

whose image is contained in a *bounded* subset of the finite dimensional $\mathbb{R}$-vector space $P^{\mathrm{gp}}_{\mathbb{R}}$. Summing up, we see that if $Q_{[\gamma]^*} = Q_{[\delta]^*}$ and $Q_{[1/\gamma]^*} = Q_{[1/\delta]^*}$, then $\xi_{\underline{f}}(B^\vee_{[\gamma]} \otimes B^\vee_{[1/\gamma]}) = \xi_{\underline{f}}(B^\vee_{[\delta]} \otimes B^\vee_{[1/\delta]})$. To conclude, it suffices now to invoke proposition 6.3.35(i).

(ii): For every $(\gamma_1, \gamma_2) \in P^{\mathrm{gp}}_{\mathbb{Q}}$, let $[\gamma_i] \in \Gamma_{i,\mathbb{Q}}$ be the class of γ_i for $i = 1, 2$, and $[\gamma_1, \gamma_2] \in \Gamma_{\mathbb{Q}}$ the class of (γ_1, γ_2); also, for each $x \in \mathbb{Q}$, denote by $x^\dagger$ the smallest element of $(x + \mathbb{Z}) \cap \mathbb{Q}_+$. It is easily seen that

$$\mathrm{gr}_{[\gamma_1,\gamma_2]} P_{\mathbb{Q}} = (\mathrm{gr}_{[\gamma_1]} P_{1,\mathbb{Q}}) \times (\gamma_2^\dagger P_2) \qquad \text{where } \gamma_2^\dagger := (\gamma_{2,1}^\dagger, \dots, \gamma_{2,r}^\dagger)$$

whence a natural identification :

$$B^\vee_{[\gamma_1,0]} \otimes_{\mathbb{Z}[P]} \mathbb{Z}[\gamma_2^\dagger P_2] \xrightarrow{\sim} B^\vee_{[\gamma_1,\gamma_2]}. \tag{17.4.12}$$

Notice that for every $x \in \mathbb{Q}$ the rational number $x^\dagger + (-x)^\dagger$ equals 0 if $x \in \mathbb{Z}$, and otherwise it equals 1. Especially :

$$\gamma_2^\dagger + (-\gamma_2)^\dagger \in P_2 \qquad \text{for every } \gamma_2 \in P^{\mathrm{gp}}_{2,\mathbb{Q}}.$$

Therefore the multiplication law of $\mathbb{Z}[P_{2,\mathbb{Q}}]$ induces by restriction an A-linear map :

$$\mu_{\gamma_2} : \mathbb{Z}[\gamma_2^\dagger P_2] \otimes_{\mathbb{Z}[P]} \mathbb{Z}[(-\gamma_2)^\dagger P_2] \to \mathbb{Z}[P_2].$$

We then get a commutative diagram

$$\begin{array}{ccc} (B^\vee_{[\gamma_1,0]} \otimes_{\mathbb{Z}[P_2]} \mathbb{Z}[\gamma_2^\dagger P_2]) \otimes_A (B^\vee_{[1/\gamma_1,0]} \otimes_{\mathbb{Z}[P_2]} \mathbb{Z}[(-\gamma_2)^\dagger P_2]) & \longrightarrow & B^\vee_{[\gamma_1,\gamma_2]} \otimes_A B^\vee_{[1/\gamma_1,-\gamma_2]} \\ \Big\downarrow {\scriptstyle \xi_{\underline{f},[\gamma_1,0]} \otimes_{\mathbb{Z}[P_2]} \mathbb{Z}[\gamma_2^\dagger P_2] \otimes_{\mathbb{Z}[P_2]} \mathbb{Z}[(-\gamma_2)^\dagger P_2]} & & \Big\downarrow {\scriptstyle \xi_{\underline{f},[\gamma_1,\gamma_2]}} \\ (B \otimes_A B)^\vee \otimes_{\mathbb{Z}[P_2]} \mathbb{Z}[\gamma_2^\dagger P_2] \otimes_{\mathbb{Z}[P_2]} \mathbb{Z}[(-\gamma_2)^\dagger P_2] & \longrightarrow & (B \otimes_A B)^\vee \end{array}$$

where $\xi_{\underline{f},[\gamma_1,0]} : B^\vee_{[\gamma_1,0]} \otimes_A B^\vee_{[1/\gamma_1,0]} \to (B \otimes_A B)^\vee$ is the restriction of $\xi_{\underline{f}}$, and likewise for $\xi_{\underline{f},[\gamma_1,\gamma_2]}$. Also, the top horizontal arrow is the isomorphism induced by (17.4.12), and the bottom horizontal arrow is $(B \otimes_A B)^\vee \otimes_{\mathbb{Z}[P_2]} \mu_{\gamma_2}$. Summing up, we conclude that :

$$\xi_{\underline{f}}(B^\vee_{[\gamma_1,\gamma_2]} \otimes_A B^\vee_{[1/\gamma_1,-\gamma_2]}) \subset \xi_{\underline{f}}(B^\vee_{[\gamma_1,0]} \otimes_A B^\vee_{[1/\gamma_1,0]}) \qquad \text{for every } [\gamma_1, \gamma_2] \in P^{\mathrm{gp}}_{\mathbb{Q}}$$

whence the assertion. □

Example 17.4.13. Let V be a noetherian regular ring, P a fine and saturated monoid such that P^{gp} is torsion-free, $\psi : V[P] \to A$ a smooth ring homomorphism, and $\beta : P \to A$ the composition of ψ with the natural inclusion map $\alpha : P \to V[P]$. Set $S := \mathrm{Spec}\, V$, $X_0 := \mathrm{Spec}\, V[P]$ and $X := \mathrm{Spec}\, A$; then α is a chart for a log structure $\mathscr{P}_0$ on the Zariski site of X_0, and the induced morphism of log schemes $(X_0, \mathscr{P}_0) \to (S, \mathscr{O}_S^\times)$ is smooth, by virtue of proposition 12.3.34. Since $(S, \mathscr{O}_S^\times)$ is trivially a regular log scheme, it follows that the same holds for $(X_0, \mathscr{P}_0)$, by theorem 12.5.28; then, again by theorem 12.5.28 and corollary 12.3.27, the log scheme $(X, \mathscr{P}) := X \times_{X_0} (X_0, \mathscr{P}_0)$ is regular, and β is a chart for $\mathscr{P}$. Summing up, this shows that the datum (A, P, β) is a regular log ring.

Lemma 17.4.14. *Let A be a domain, B an A-algebra of finite type, C a B-algebra of finite type, M a B-module of finite type, and N a C-module of finite type. Set also $K := \mathrm{Frac}(A)$.*

(i) *There exists $f \in A \setminus \{0\}$ such that the following holds for every A-algebra A'. Set $B' := A' \otimes_A B$, $C' := A' \otimes_A C$, $M' := B' \otimes_B M$ and $N' := C' \otimes_C N$; then the natural map*

$$A' \otimes_A \mathrm{Hom}_B(M, N)_f \to \mathrm{Hom}_{B'}(M', N')_f$$

is an isomorphism.

(ii) *For every B-linear map $\varphi : M \to N$ there exists $f \in A \setminus \{0\}$ such that $(\mathrm{Coker}\, \varphi)_f$ is a free A-module.*

(iii) *In the situation of* (ii)*, let $x \in N$. Then $x \in \mathrm{Im}\,(K \otimes_A \varphi)$ if and only if there exists a dense subset $U \subset \mathrm{Spec}\, A$ such that $1 \otimes x \in \mathrm{Im}(\kappa(\mathfrak{p}) \otimes_A \varphi)$ for every $\mathfrak{p} \in U$.*

Proof. (i): Pick $n \in \mathbb{N}$ and a B-linear surjection $\psi : B^{\oplus n} \to M$; let also $M' \subset B^{\oplus n}$ be a finitely generated B-submodule such that $K \otimes_A M' = \mathrm{Ker}\,(K \otimes_A \psi)$. Set $M'' := B^{\oplus n}/M'$, and denote by $\overline{\psi} : M'' \to M$ the B-linear surjection induced by ψ. By [65, Ch.IV, Lemma 8.9.4.1], there exists $f \in A \setminus \{0\}$ such that the A_f-module M''_f is flat, and by construction $\mathrm{Ker}(\overline{\psi}_f : M''_f \to M_f)$ is a torsion A-module; then $\mathrm{Ker}\, \overline{\psi}_f = 0$, hence M_f is a finitely presented B_f-module. We may thus replace A, B, C, M, N by A_f, B_f, C_f, M_f, N_f, and assume that M is a B-module of finite presentation. Now, let

$$B^{\oplus m} \xrightarrow{\varphi} B^{\oplus n} \to M$$

be a finite presentation of M; there follow short exact sequences of B-modules :

$$\begin{aligned} \Sigma \quad &: \quad 0 \to \mathrm{Hom}_B(M, N) \to N^{\oplus n} \to T := \mathrm{Im}(\varphi^\vee \otimes_B N) \to 0 \\ \Sigma' \quad &: \quad 0 \to T \to N^{\oplus m} \to T' := \mathrm{Coker}(\varphi^\vee \otimes_B N) \to 0 \end{aligned}$$

where $\varphi^\vee : B^{\oplus n} \to B^{\oplus m}$ is the transpose of φ. Notice that T and T' are C-modules of finite type. By invoking again [65, Ch.IV, Lemma 8.9.4.1], we find $f \in A \setminus \{0\}$ such that T_f and T'_f are flat A_f-modules; after replacing again A, B, C, M, N and φ by their respective localizations, we may therefore assume that T and T' are flat A-modules. In this case, the induced sequences $A' \otimes_A \Sigma$ and $A' \otimes_A \Sigma'$ are again short exact, for every A-algebra A', whence a left exact sequence

$$0 \to A' \otimes_A \mathrm{Hom}_B(M, N) \to N'^{\oplus n} \xrightarrow{\varphi'^\vee \otimes_{B'} N'} N'^{\oplus m} \qquad \text{with } \varphi' := \varphi \otimes_B B'.$$

But we have a natural identification : $\mathrm{Ker}(\varphi'^\vee \otimes_{B'} N') \xrightarrow{\sim} \mathrm{Hom}_{B'}(M', N')$, and the resulting isomorphism $A' \otimes_A \mathrm{Hom}_B(M, N) \xrightarrow{\sim} \mathrm{Hom}_{B'}(M', N')$ is the natural map of (i).

(ii): Arguing as in the proof of (i), we reduce easily to the case where B and C are finitely presented A-algebras, and M (resp. N) is a finitely presented B-module (resp. C-module). Then we may find a $\mathbb{Z}$-subalgebra of finite type $A_0 \subset A$, an A_0-algebra of finite type B_0, a B_0-algebra of finite type C_0, a B_0-module M_0 of finite type, a C_0-module of finite type N_0, and a B_0-linear map $\varphi_0 : M_0 \to N_0$ with isomorphisms

$$A \otimes_{A_0} B_0 \xrightarrow{\sim} B \qquad A \otimes_{A_0} C_0 \xrightarrow{\sim} C \qquad B \otimes_{B_0} M_0 \xrightarrow{\sim} M \qquad C \otimes_{C_0} N_0 \xrightarrow{\sim} N.$$

which identify $B \otimes_{B_0} \varphi_0$ with φ. It suffices then to exhibit $f \in A_0$ such that $(\mathrm{Coker}\,\varphi_0)_f$ is a free $A_{0,f}$-module; the latter follows easily from [126, Th.24.1].

(iii): If $x \in \mathrm{Im}\,(K \otimes_A \varphi)$, we have $x \in \mathrm{Im}\,\varphi_f$ for some $f \in A \setminus \{0\}$, and then $x \otimes 1 \in \mathrm{Im}(\kappa(\mathfrak{p}) \otimes_A \varphi)$ for every $\mathfrak{p} \in \mathrm{Spec}\,A_f$. Conversely, suppose that $U \subset \mathrm{Spec}\,A$ is a dense subset such that $x \otimes 1 \in \mathrm{Im}(\kappa(\mathfrak{p}) \otimes_A \varphi)$ for every $\mathfrak{p} \in U$. We pick $f \in A \setminus \{0\}$ as in (ii), so that $(\mathrm{Coker}\,\varphi)_f$ is a free A-module. Clearly $U \cap \mathrm{Spec}\,A_f$ is still dense in $\mathrm{Spec}\,A_f$, hence we may replace A, B, C, M, N and φ by A_f, B_f, C_f, M_f, N_f and φ_f, and assume that $\mathrm{Coker}\,\varphi$ is a free A-module, say with basis $(e_i \mid i \in I)$. Suppose now that $x \notin \mathrm{Im}\,(K \otimes_A \varphi)$, so that the image $\overline{x} \in \mathrm{Coker}\,\varphi$ of x does not vanish. Then there exists a finite subset $I_0 \subset I$ and a system $(f_i \mid i \in I_0)$ of non-zero elements of A, with $\overline{x} = \sum_{i \in I_0} f_i e_i$. Pick $j \in I_0$, and any $\mathfrak{p} \in U \cap \mathrm{Spec}\,A_{f_j}$; then $\mathrm{Coker}\,(\kappa(\mathfrak{p}) \otimes_A \varphi)$ is a free $\kappa(\mathfrak{p})$-vector space with basis $(1 \otimes e_i \mid i \in I)$, and $1 \otimes x = \sum_{i \in I_0} \overline{f}_i \otimes e_i$, where $\overline{f}_i \in \kappa(\mathfrak{p})$ denotes the image of f_i, for every $i \in I$. Especially, $\overline{f}_j \neq 0$, whence $1 \otimes x \neq 0$, a contradiction. □

17.4.15. Let $(P, +, 0)$ be a fine and saturated monoid such that P^{gp} is torsion-free, and fix a Banach norm $\|\cdot\|$ on the finite dimensional $\mathbb{R}$-vector space $P^{\mathrm{gp}}_{\mathbb{R}} := \mathbb{R} \otimes_{\mathbb{Z}} P^{\mathrm{gp}}$. Let also

$$P^{\mathrm{gp}}_{\mathbb{R}}(\rho) := \{\gamma \in P^{\mathrm{gp}}_{\mathbb{R}} \mid \|\gamma\| \leq \rho\} \qquad \text{for all } \rho \in \mathbb{R}_+.$$

Define also $P^{(\infty)}$ and $P_{\mathbb{Q}}$ as in (17.4.3), as well as the polyhedral cone $P_{\mathbb{R}} := \mathbb{R}_+ \otimes_{\mathbb{Z}} P \subset P^{\mathrm{gp}}_{\mathbb{R}}$. Moreover, for every $m \in \mathbb{N} \setminus \{0\}$, let

$$P_{(m)} := \{\gamma \in P_{\mathbb{Q}} \mid m\gamma \in P^{(\infty)}\}.$$

Lemma 17.4.16. *With the notation of* (17.4.15)*, there exists an integer $m > 0$ with $(p, m) = 1$ such that the following holds. For every $\delta > 0$ there exists a real number $\varepsilon > 0$ such that for every $\beta_1, \beta_2 \in P^{\mathrm{gp}}_{\mathbb{R}}$ with $\|\beta_1 + \beta_2\| < \varepsilon$ we may find $\beta'_1, \beta'_2 \in P^{\mathrm{gp}}_{(m)}$ with :*

(i) $\beta'_1 + \beta'_2 = 0$
(ii) $\|\beta'_i - \beta_i\| < \delta$ *for* $i = 1, 2$
(iii) $(P_{\mathbb{R}} - \beta_i) \cap P^{\mathrm{gp}} \subset (P_{\mathbb{R}} - \beta'_i) \cap P^{\mathrm{gp}}$ *for* $i = 1, 2$.

Proof. Since $P^{(\infty)\mathrm{gp}}$ is p-divisible, $P^{\mathrm{gp}}_{(m)} = P^{\mathrm{gp}}_{(pm)}$ for every integer $m > 0$, so we may always arrange that $(p, m) = 1$, if all the other conditions are already fulfilled. Moreover, let $\rho > 0$ such that every class of $P^{\mathrm{gp}}_{\mathbb{R}}/P^{\mathrm{gp}}$ admits a representative $\beta \in P^{\mathrm{gp}}_{\mathbb{R}}$ with $\|\beta\| \leq \rho$. Then it is easily seen that, after replacing β_i by $\beta_i + (-1)^i\gamma$ for $i = 1, 2$, with a suitable $\gamma \in P^{\mathrm{gp}}$, we may assume that $\beta_1 \in P^{\mathrm{gp}}_{\mathbb{R}}(\rho)$. Now, for every $\gamma \in P^{\mathrm{gp}}_{\mathbb{R}}$, let $\overline{\Omega}(\gamma)$ be the topological closure of the subset $\Omega(P_{\mathbb{R}}, P^{\mathrm{gp}} \cap (P_{\mathbb{R}} - \gamma))$ in $P^{\mathrm{gp}}_{\mathbb{R}}$ (notation of (6.3.34)); in view of condition (i) and of proposition 6.3.35(v), condition (iii) is implied by :

$$\beta'_1 \in \overline{\Omega}(\beta_1) \cap (-\overline{\Omega}(\beta_2)). \tag{17.4.17}$$

Moreover, suppose that

$$\|\beta'_1 - \beta_1\| \leq \delta/2. \tag{17.4.18}$$

Then

$$\|\beta'_2 - \beta_2\| = \|\beta'_2 + \beta_1 - \beta_1 - \beta_2\| \leq \| - \beta'_1 + \beta_1\| + \|\beta_1 + \beta_2\| < \delta/2 + \varepsilon.$$

Hence condition (ii) will hold, provided $\varepsilon \leq \delta/2$. Thus, we have to exhibit $m > 0$ and $\varepsilon > 0$ such that, for every $\beta_1, \beta_2 \in P^{\mathrm{gp}}_{\mathbb{R}}$ with $\|\beta_1\| \leq \rho$ and $\|\beta_1 + \beta_2\| < \varepsilon$, there exists $\beta'_1 \in P^{\mathrm{gp}}_{(m)}$ fulfilling (17.4.17) and (17.4.18). Then, by proposition 6.3.35(i) and lemma 6.3.42, it suffices to find $\beta'_1 \in P^{\mathrm{gp}}_{\mathbb{R}}$ fulfilling these two latter conditions. By way of contradiction, suppose that such β'_1 cannot always be found : this means that there exists a sequence $\underline{\beta} := ((\beta_{1,k}, \beta_{2,k}) \mid k \in \mathbb{N})$ of pairs of elements in $P^{\mathrm{gp}}_{\mathbb{R}}$, with $\beta_{1,k} \in P^{\mathrm{gp}}_{\mathbb{R}}(\rho)$ for every $k \in \mathbb{N}$, and such that

(a) $\|\beta_{1,k} + \beta_{2,k}\| < 2^{-k}$ for every $k \in \mathbb{N}$

(b) $\overline{\Omega}(\beta_{1,k}) \cap (-\overline{\Omega}(\beta_{2,k})) \cap (P^{\mathrm{gp}}_{\mathbb{R}}(\delta/2) + \beta_{1,k}) = \varnothing$ for every $k \in \mathbb{N}$.

However, by proposition 6.3.35(i), after replacing $\underline{\beta}$ by a subsequence we may assume that both $\overline{\Omega}(\beta_{1,k})$ and $\overline{\Omega}(\beta_{2,k})$ are independent of k. Since $P^{\mathrm{gp}}_{\mathbb{R}}(\rho)$ is a compact subset, we may also assume that the sequence $(\beta_{1,k} \mid k \in \mathbb{N})$ converges to an element $\beta'_1 \in P^{\mathrm{gp}}_{\mathbb{R}}(\rho)$; then clearly $(\beta_{2,k} \mid k \in \mathbb{N})$ converges to $\beta'_2 := -\beta'_1$. Since $\beta_{i,k} \in \overline{\Omega}(\beta_{i,k})$ for $i = 1, 2$ and every $k \in \mathbb{N}$, we also have $\beta'_i \in \overline{\Omega}(\beta_{i,k})$ for $i = 1, 2$. Lastly, we have $\|\beta'_1 - \beta_{1,k}\| < \delta/2$ for every sufficiently large $k \in \mathbb{N}$; this contradicts (b), and the claim follows. □

Theorem 17.4.19. *In the situation of* (17.4.5)*, suppose that* (A, P, β) *is regular. We have :*

(i) $e_f \in \vartheta_{\underline{f}}(\mathsf{R}(B, \Gamma_{\mathbb{Q}}))$.

(ii) *Let* $J \subset A$ *be the radical ideal such that* $\mathrm{Spec}\, A/J = X \setminus U_f$*. Then* $Je_f \subset \vartheta_{\underline{f}}(\mathsf{R}(B, \Gamma))$.

Proof. For every datum $\underline{f} := (f, \beta, P)$ as in (17.4.5), let $\mathsf{X}(\underline{f}) := \Gamma(U_f, \mathscr{B} \otimes_{\mathscr{O}_X} \mathscr{B})$; denote also by $\mathsf{Y}(\underline{f}) \subset \mathsf{X}(\underline{f})$ the image of $\vartheta_{\underline{f}}$, and set $\mathsf{Z}(\underline{f}) := Ae_f \subset \mathsf{X}(\underline{f})$. We notice :

Claim 17.4.20. Let A' be a noetherian ring, $g : A \to A'$ a flat ring homomorphism; set $X' := \mathrm{Spec}\, A'$, $f' := A' \otimes_A f$ and $\underline{f}' := (f', P, g \circ \beta)$. Then $U_{f'} = X' \times_X U_f$, and we have a natural isomorphism

$$A' \otimes_A \mathsf{X}(\underline{f}) \xrightarrow{\sim} \mathsf{X}(\underline{f}')$$

that identifies $\mathsf{Y}(\underline{f}')$ and $\mathsf{Z}(\underline{f}')$ respectively with $A' \otimes_A \mathsf{Y}(\underline{f})$ and $A' \otimes_A \mathsf{Z}(\underline{f})$.

Proof of the claim. The first assertion follows from [66, Ch.IV, Prop.17.7.1]. Next, set $B' := A' \otimes_A B$; since B is an A-module of finite type, B' is an A'-module of finite presentation. Hence, the natural map $A' \otimes_A B^\vee \to B'^\vee := \mathrm{Hom}_{A'}(B', A')$ is an isomorphism (details left to the reader). Then the second assertion follows by a direct inspection of the constructions. ◇

Now, assertion (i) comes down to the inclusion $\mathsf{Z}(\underline{f}) \subset \mathsf{Y}(\underline{f})$, and it suffices to check that $\mathsf{Z}(\underline{f})_{\mathfrak{p}} \subset \mathsf{Y}(\underline{f})_{\mathfrak{p}}$ in $\mathsf{X}(\underline{f})_{\mathfrak{p}}$, for every $\mathfrak{p} \in \mathrm{Spec}\, A$. Let $j_{(\mathfrak{p})} : A \to A_{\mathfrak{p}}$ be the localization map, set $f_{\mathfrak{p}} := A_{\mathfrak{p}} \otimes_A f : A_{\mathfrak{p}} \to B_{\mathfrak{p}}$, and $\underline{f}_{\mathfrak{p}} := (f_{\mathfrak{p}}, P, \beta \circ j_{(\mathfrak{p})})$; by claim 17.4.20, we are then reduced to checking that $\mathsf{Z}(\underline{f}_{\mathfrak{p}}) \subset \mathsf{Y}(\underline{f}_{\mathfrak{p}})$ in $\mathsf{X}(\underline{f}_{\mathfrak{p}})$, for every such $\mathfrak{p}$. Thus, in order to show (i), *we may assume that* $(A, \mathfrak{m})$ *is a local noetherian ring*. Likewise we may reduce assertion (ii) to the case where $(A, \mathfrak{m})$ is local. Next, let $A^\wedge$ be the $\mathfrak{m}$-adic completion of A; since the completion map $j : A \to A^\wedge$ is faithfully flat, we are reduced to checking that $A^\wedge \otimes_A \mathsf{Z}(\underline{f}) \subset A^\wedge \otimes_A \mathsf{Y}(\underline{f})$ in $A^\wedge \otimes_A \mathsf{X}(\underline{f})$. Moreover, the log structure attached to the chart $j \circ \beta : P \to A^\wedge$ is still regular (theorems 12.5.10 and 12.5.31); after invoking again claim 17.4.20, we may thus *assume that* $(A, \mathfrak{m})$ *is a complete noetherian local ring* in order to prove (i), and a similar argument reduces the proof of (ii) as well to the complete case.

Next, let $\mathfrak{p} := \beta^{-1}(A^\times)$; then β extends uniquely to a morphism of monoids $\beta' : P_{\mathfrak{p}} \to A$ (notation of remark 6.1.15(i)); moreover, the log structures on the Zariski site of X induced by β and by β' are naturally isomorphic, so the datum $\underline{f}' := (f, P_{\mathfrak{p}}, \beta')$ still fulfills the conditions of (17.4.5) and $(A, P_{\mathfrak{p}}, \beta')$ is regular. Moreover, $(P_{\mathfrak{p}})^{\mathrm{gp}} = P^{\mathrm{gp}}$ and $(P_{\mathfrak{p}})^{\mathrm{gp}}_{\mathbb{Q}} = P^{\mathrm{gp}}_{\mathbb{Q}}$, hence $(P_{\mathfrak{p}})_{\mathbb{Q}}$ is still naturally Γ-graded. Furthermore, for every $\gamma \in P^{\mathrm{gp}}_{\mathbb{Q}}$ we have

$$\mathrm{gr}_{[\gamma]}((P_{\mathfrak{p}})_{\mathbb{Q}}) = (\mathrm{gr}_{[\gamma]}(P_{\mathbb{Q}}))_{\mathfrak{p}} \qquad \text{whence :} \qquad A \otimes_{\mathbb{Z}[P_{\mathfrak{p}}]} \mathbb{Z}[\mathrm{gr}_{[\gamma]}((P_{\mathfrak{p}})_{\mathbb{Q}})] = A_{[\gamma]}.$$

Hence, the A-modules $\mathsf{X}(\underline{f}'), \mathsf{Y}(\underline{f}'), \mathsf{Z}(\underline{f}')$ are naturally identified with $\mathsf{X}(\underline{f}), \mathsf{Y}(\underline{f}), \mathsf{Z}(\underline{f})$. Thus, in order to prove (i), it suffices to show that $\mathsf{Z}(\underline{f}') \subset \mathsf{Y}(\underline{f}')$; after replacing $\underline{f}$ by $\underline{f}'$, we may therefore *assume that the chart* β *is local at the closed point of* X (see definition 12.1.17(vi)). Arguing likewise we reduce as well the proof of (ii) to the case where β is local.

Recall now that P admits a decomposition $P \xrightarrow{\sim} Q \times P^\times$, where Q is a fine, sharp and saturated monoid, and $P^\times \subset P$ is the abelian group of invertible elements of P (lemma 6.2.10). Let $\alpha : Q \to A$ be the restriction of β; by direct inspection, we see that the inclusion $Q \to P$

induces an isomorphism between the log structures on $\mathrm{Spec}\, A$ associated with the charts (P, β) and (Q, α) : see (12.1.6); hence, the datum $\underline{f}'' := (f, Q, \alpha)$ fulfills again the conditions of (17.4), and (A, Q, α) is regular. In light of lemma 17.4.10(ii), we may then replace $\underline{f}$ by $\underline{f}''$, and thus *assume that* β *is a sharp chart at the closed point of* X (see definition 12.1.17(vi)).

After these preliminaries, we may then assume, as in (17.3.4), that there exists $r \in \mathbb{N}$, a coefficient ring $(V, \mathfrak{m}_V)$ of A, and a surjective ring homomorphism

$$\varphi : V[[P \times \mathbb{N}^{\oplus r}]] \to A$$

and β is the composition of φ with the natural inclusion map $P \to V[[P \times \mathbb{N}^{\oplus r}]]$.

Claim 17.4.21. The theorem holds if A contains a field of positive characteristic.

Proof of the claim. In this case, V is the residue field of A, and φ is an isomorphism. The induced morphism of monoids $\beta' : P \times \mathbb{N}^{\oplus r} \to V[[P \times \mathbb{N}^{\oplus r}]] \to A$ is the chart for another regular log structure on the Zariski site of X (theorems 12.5.10 and 12.5.31); in view of lemma 17.4.10(ii) we may then replace β by β', and assume that $A = V[[P]]$ and $\mathfrak{m} = \mathfrak{m}_P \cdot A$ (with $\mathfrak{m}_P := P \setminus \{1\}$). Next, let k be an algebraic closure of V; the induced map $V[P] \to k[P]$ is faithfully flat, so the same holds for its completion $A \to k[[P]]$ ([126, Th.22.4]); moreover, the inclusion map $P \to k[[P]]$ is again a chart for a regular log structure on the Zariski site of $\mathrm{Spec}\, k[[P]]$. In view of claim 17.4.20, we may then replace V by k and B by $k[[P]] \otimes_A B$, and assume that $A = k[[P]]$. In this case, notice that, with the notation of (9.8.11), we have :

$$A^{\mathrm{perf}} = \Gamma \times_{\Gamma_{\mathbb{Q}}} A_\infty.$$

Let now $h \in J$. The isomorphism (9.8.12) yields a natural identification of A^{perf}-algebras :

$$\Gamma \times_{\Gamma_{\mathbb{Q}}} B_\infty[h^{-1}] \xrightarrow{\sim} B^{\mathrm{perf}}[h^{-1}]$$

and then remark 17.4.1 shows that $h^{1/p^n} e_f$ lies in the image of the induced map

$$B^{\mathrm{perf}} \otimes_{A^{\mathrm{perf}}} B^{\mathrm{perf}} = (B \otimes_A B)^{\mathrm{perf}} \to B_\infty \otimes_{A_\infty} B_\infty[h^{-1}] \to \Gamma(U_f, \mathscr{B}_\infty \otimes_{\mathscr{O}_{X_\infty}} \mathscr{B}_\infty) \tag{17.4.22}$$

for every $n \in \mathbb{N}$. On the other hand, B^{perf} is an integral A^{perf}-algebra, and A^{perf} is a normal domain, hence the trace map of the finite étale map $A^{\mathrm{perf}}[h^{-1}] \to B^{\mathrm{perf}}[h^{-1}]$ restricts to an A^{perf}-linear map $B^{\mathrm{perf}} \to A^{\mathrm{perf}}$ (lemma 14.3.15(i)) which in turns induces an A^{perf}-linear map

$$\omega_{B^{\mathrm{perf}}/A^{\mathrm{perf}}} : B^{\mathrm{perf}} \to \mathrm{Hom}_{A^{\mathrm{perf}}}(B^{\mathrm{perf}}, A^{\mathrm{perf}}) \to B_\infty^\vee$$

such that

$$A_\infty[h^{-1}] \otimes_{A^{\mathrm{perf}}} \omega_{B^{\mathrm{perf}}/A^{\mathrm{perf}}} = \Gamma(\mathrm{Spec}\, A[h^{-1}], \omega_{\mathscr{B}_\infty/\mathscr{O}_{X_\infty}}).$$

A simple inspection then shows that (17.4.22) is the composition of $\omega_{B^{\mathrm{perf}}/A^{\mathrm{perf}}} \otimes_{A^{\mathrm{perf}}} \omega_{B^{\mathrm{perf}}/A^{\mathrm{perf}}}$ with (17.4.6). Summing up, this proves that $h^{1/p^n} e_f$ lies in the image of the map (17.4.6) for every $n \in \mathbb{N}$, and especially, $he_f \in \vartheta_{\underline{f}}(\mathsf{R}(B, \Gamma))$, whence assertion (ii).

In order to show (i), say that $h = \sum_{\gamma \in P} h_\gamma \cdot \gamma$ for a system $(h_\gamma \mid \gamma \in P)$ of elements of k, and pick $\gamma_0 \in P$ with $h_{\gamma_0} \neq 0$. According to claim 17.3.7, there exists $n \in \mathbb{N}$ such that $\mathrm{gr}_{[\gamma_0^{1/p^n}]} P_{\mathbb{Q}} = \gamma_0^{1/p^n} P$; then we have an A-linear isomorphism :

$$\mathsf{X}(\underline{f}) \xrightarrow{\sim} \mathrm{gr}_{[\gamma_0^{1/p^n}]} \Gamma(U_f, \mathscr{B}_\infty \otimes_{\mathscr{O}_{X_\infty}} \mathscr{B}_\infty) = \mathsf{X}(\underline{f}) \otimes_A A_{[\gamma_0^{1/p^n}]} \qquad x \mapsto x \otimes \gamma_0^{1/p^n}. \tag{17.4.23}$$

We have already remarked that $h^{1/p^n} e_f$ lies in the image of (17.4.6); let us write $h^{1/p^n} = \sum_{[\gamma] \in \Gamma} h_{[\gamma]}$, with $h_{[\gamma]} \in A_{[\gamma]}$ for every $[\gamma] \in \Gamma$; then $h^{1/p^n} = \sum_{\gamma \in P} h_\gamma^{1/p^n} \cdot \gamma^{1/p^n}$, and $h_{[\gamma_0^{1/p^n}]} = h_{\gamma_0}^{1/p^n} \cdot \gamma_0^{1/p^n} \cdot a$ for some $a \in 1 + \mathfrak{m}$. Hence, $h_{[\gamma_0^{1/p^n}]} e_f$ is in the image of $\mathrm{gr}_{[\gamma_0^{1/p^n}]}(B_\infty^\vee \otimes_{A_\infty} B_\infty^\vee)$, and so the same holds for $e_f \otimes \gamma_0^{1/p^n}$. Thus, there exists a finite subset $\Sigma \subset \Gamma$ and an element of

$\bigoplus_{[\gamma]\in\Sigma} B^\vee_{[\gamma]} \otimes_A B^\vee_{[\gamma_0^{1/p^n}/\gamma]}$ whose image under the map (17.4.6) equals $e_f \otimes \gamma_0^{1/p^n}$. Then, lemma 17.4.16 yields for every $[\gamma] \in \Sigma$ an element $[\gamma'] \in \Sigma_{\mathbb{Q}}$ such that :

$$\gamma^{-1}P_{\mathbb{Q}} \cap P^{\mathrm{gp}} \subset \gamma'^{-1}P_{\mathbb{Q}} \cap P^{\mathrm{gp}} \qquad \text{and} \qquad (\gamma/\gamma_0^{1/p^n})P_{\mathbb{Q}} \cap P^{\mathrm{gp}} \subset \gamma' P_{\mathbb{Q}} \cap P^{\mathrm{gp}}.$$

With $\Sigma' := \{[\gamma'] \mid [\gamma] \in \Sigma\}$, we finally deduce a commutative diagram of A-modules :

$$\begin{array}{ccc} \bigoplus_{[\gamma]\in\Sigma} B^\vee_{[\gamma]} \otimes_A B^\vee_{[\gamma_0^{1/p^n}/\gamma]} & \longrightarrow & \mathsf{X}(\underline{f}) \otimes_A A_{[\gamma_0^{1/p^n}]} \\ \downarrow & & \uparrow \\ \mathsf{R}(B, \Sigma') & \longrightarrow & \mathsf{X}(\underline{f}) \end{array}$$

whose right vertical arrow is the isomorphism (17.4.23) and whose bottom horizontal arrow is the restriction of $\vartheta_{\underline{f}}$; it follows easily that $e_f \in \vartheta_{\underline{f}}(\mathsf{R}(B, \Sigma'))$, as required. ◊

Suppose next that A is a $\mathbb{Q}$-algebra, so that V is a field of characteristic zero, and φ is an isomorphism. We pick a complete discrete valuation ring W with residue field V, and a surjective map of monoids $\pi : \mathbb{N}^{\oplus r'} \to P$; for $s := r + r'$ we get a surjective map of W-algebras $W[\mathbb{N}^{\oplus s}] \to A_0 := V[P \times \mathbb{N}^{\oplus r}]$ whose completion is a surjective map $W[[\mathbb{N}^{\oplus s}]] \to A$. According to [32, §3.6, Th.12], the completion map $W[\mathbb{N}^{\oplus s}] \to W[[\mathbb{N}^{\oplus s}]]$ is the colimit of a filtered system $(R_\lambda \mid \lambda \in \Lambda)$ of smooth $W[\mathbb{N}^{\oplus s}]$-algebras; set $A_\lambda := R_\lambda \otimes_{W[\mathbb{N}^{\oplus s}]} A_0$ for every $\lambda \in \Lambda$. Then A is the colimit of the filtered system of smooth A_0-algebras $A_\bullet := (A_\lambda \mid \lambda \in \Lambda)$. For every $\lambda \in \Lambda$, let X'_λ be the connected component of $\operatorname{Spec} A_\lambda$ containing the image of X, and let A'_λ be the quotient of A_λ with $\operatorname{Spec} A'_\lambda = X'_\lambda$. It is easily seen that the colimit of the induced system $A'_\bullet := (A'_\lambda \mid \lambda \in \Lambda)$ is still A; after replacing $A_\bullet$ by $A'_\bullet$, we may then assume that A_λ is a domain for every $\lambda \in \Lambda$. Next, after replacing Λ by a cofinal subset, we may assume that for every $\lambda \in \Lambda$ there exists an open subset $U_\lambda \subset X_\lambda$ such that $U_f = X \times_{X_\lambda} U_\lambda$, and $U_\mu = X_\mu \times_{X_\lambda} U_\lambda$ for every $\mu \in \Lambda$ with $\mu \geq \lambda$. We may then find $\lambda \in \Lambda$ and a finite morphism of schemes $\varphi_\lambda : Y_\lambda \to X_\lambda$ with an isomorphism of X-schemes $X \times_{X_\lambda} Y_\lambda \xrightarrow{\sim} \operatorname{Spec} B$. Then there exists $\mu \in \Lambda$ with $\mu \geq \lambda$ such that $U_\mu \times_{X_\lambda} Y_\lambda$ is a finite étale U_μ-scheme; set $Y_\mu := X_\mu \times_{X_\lambda} Y_\lambda$, and $B_\mu := \mathscr{O}_{Y_\mu}(Y_\mu)$. By construction, the morphism $Y_\mu \to X_\mu$ is surjective; since A_μ is a domain, it follows easily that the induced ring homomorphism $f_\mu : A_\mu \to B_\mu$ is injective. Let $\beta_\mu : P \to A_0 \to A_\mu$ be the natural map; by example 17.4.13, the datum (A_μ, P, β_μ) is a regular log ring, and $\underline{f}_\mu := (f_\mu, P, \beta_\mu)$ is a datum as in (17.4.5). In light of remark 17.4.7(i), it then suffices to prove assertions (i) and (ii) for the map $\vartheta_{\underline{f}_\mu}$; the latter is covered by the following :

Claim 17.4.24. The theorem holds if there exists a field K of characteristic zero and a smooth ring homomorphism $\psi : K[P] \to A$, such that β is the composition of ψ and the inclusion map $P \to K[P]$ (see example 17.4.13).

Proof of the claim. The field K is the colimit of the filtered system of its smooth $\mathbb{Z}$-subalgebras $(V_\lambda \mid \lambda \in \Lambda)$. Then we may find $\lambda \in \Lambda$, a smooth $V_\lambda[P]$-algebra A_λ, and a finite, injective and generically finite ring homomorphism $f_\lambda : A_\lambda \to B_\lambda$ with isomorphisms

$$K \otimes_{V_\lambda} A_\lambda \xrightarrow{\sim} A \qquad A \otimes_{A_\lambda} B_\lambda \xrightarrow{\sim} B$$

(details left to the reader). Let $\alpha : P \to V_\lambda[P] \to A_\lambda$ be the natural map; since V_λ is a regular noetherian ring, the datum (A_λ, P, α) is a regular log ring, by example 17.4.13, and in light of remark 17.4.7(i), it suffices to show assertions (i) and (ii) for the map $\vartheta_{\underline{f}_\lambda}$ corresponding to the datum $\underline{f}_\lambda := (f_\lambda, P, \alpha)$. Now, for every $\mathfrak{p} \in \operatorname{Spec} V_\lambda$, every V_λ-module M, let $M(\mathfrak{p}) := \kappa(\mathfrak{p}) \otimes_{A_\lambda} M$; also, for every homomorphism of V_λ-modules $h : M \to N$ let likewise $h_{(\mathfrak{p})} := \kappa(\mathfrak{p}) \otimes_{V_\lambda} h : M(\mathfrak{p}) \to N(\mathfrak{p})$; moreover, let $\alpha_{(\mathfrak{p})} : P \to A_\lambda(\mathfrak{p})$ be the composition of α with the natural map $A_\lambda \to A_\lambda(\mathfrak{p})$. Let also $a \in A_\lambda \setminus \{0\}$ such that $\operatorname{Spec} A_\lambda[a^{-1}] \subset U_{f_\lambda}$. According to [65, Ch.IV, Prop.9.5.3], the set $Z := \{\mathfrak{p} \in \operatorname{Spec} V_\lambda \mid \operatorname{Spec} A_\lambda[a^{-1}](\mathfrak{p}) \text{ is dense in } \operatorname{Spec} A_\lambda(\mathfrak{p})\}$

is *constructible* in $\mathrm{Spec}\, V_\lambda$; furthermore, Z contains the generic point of $\mathrm{Spec}\, V_\lambda$, so it is *dense* in $\mathrm{Spec}\, V_\lambda$. For every $\mathfrak{p} \in Z$, the datum $\underline{f}_{\lambda,(\mathfrak{p})} := (f_{\lambda,(\mathfrak{p})}, P, \alpha_{(\mathfrak{p})})$ fulfills therefore the conditions of (17.4), and moreover $(A_\lambda(\mathfrak{p}), P, \alpha_{(\mathfrak{p})})$ is still a regular log ring. Set $X_\lambda := \mathrm{Spec}\, A_\lambda$, and denote by $\mathscr{B}_\lambda$ the quasi-coherent $\mathscr{O}_{X_\lambda}$-algebra arising from B_λ. By remark 17.4.7(i), for Δ either equal to $\Gamma_\mathbb{Q}$ or to Γ we have a commutative diagram :

$$\begin{array}{ccc} \mathsf{R}(B_\lambda, \Delta) & \xrightarrow{\vartheta'_\Delta} & B_\lambda \otimes_{A_\lambda} B_\lambda[a^{-1}] \\ \downarrow & & \downarrow \\ \mathsf{R}(B_\lambda(\mathfrak{p}, \Delta)) & \xrightarrow{\vartheta'^{(\mathfrak{p})}_\Delta} & B_\lambda \otimes_{A_\lambda} B_\lambda(\mathfrak{p})[a^{-1}] \end{array}$$

whose right vertical arrow maps e_{f_λ} to $e_{f_{\lambda,(\mathfrak{p})}}$, and where ϑ'_Δ is the composition of the restriction of $\vartheta_{\underline{f}_\lambda}$ to $\mathsf{R}(B, \Delta)$ with the restriction map $\Gamma(U_{f_\lambda}, \mathscr{B}_\lambda \otimes_{\mathscr{O}_{X_\lambda}} \mathscr{B}_\lambda) \to B_\lambda \otimes_{A_\lambda} B_\lambda[a^{-1}]$, and likewise $\vartheta'^{(\mathfrak{p})}_\Delta$ is deduced from $\vartheta_{\underline{f}_{\lambda,(\mathfrak{p})}}$. Lemma 17.4.10(i) yields a finite subset $\Sigma \subset \Delta$ such that

$$\vartheta_{\underline{f}_{\lambda,(\mathfrak{p})}}(\mathsf{R}(B(\mathfrak{p}), \Sigma)) = \vartheta_{\underline{f}_{\lambda,(\mathfrak{p})}}(\mathsf{R}(B(\mathfrak{p}), \Delta)) \qquad \text{for every } \mathfrak{p} \in Z.$$

On the other hand, in view of lemma 17.4.14(i), after replacing V_λ by a suitable localization $V_\lambda[t^{-1}]$ (with $t \neq 0$), and Z by $Z \cap \mathrm{Spec}\, V[t^{-1}]$, we may assume that the natural maps

$$(B_\lambda^\vee)_{[\gamma]}(\mathfrak{p}) \to (B_\lambda(\mathfrak{p}))^\vee_{[\gamma]} \qquad (B_\lambda^\vee)_{[1/\gamma]}(\mathfrak{p}) \to (B_\lambda(\mathfrak{p}))^\vee_{[1/\gamma]}$$

are isomorphisms, for every $\mathfrak{p} \in Z$ and every $[\gamma] \in \Sigma$. Summing up, we may assume that *the image of* $\vartheta'^{(\mathfrak{p})}_\Delta$ *equals the image of* $\vartheta'_{\Delta,(\mathfrak{p})}$, *for every* $\mathfrak{p} \in Z$. Lastly, recall that the set Z' of all $\mathfrak{p} \in \mathrm{Spec}\, V_\lambda$ such that $\kappa(\mathfrak{p})$ is a finite field is *dense in the constructible topology of* $\mathrm{Spec}\, V_\lambda$, since V_λ is a $\mathbb{Z}$-algebra of finite type ([65, Ch.IV, Cor.10.4.6]). Hence, $Z \cap Z'$ is a dense subset of $\mathrm{Spec}\, V_\lambda$, and by claim 17.4.21, the image of $\vartheta'^{(\mathfrak{p})}_{\Gamma_\mathbb{Q}}$ (resp. of $\vartheta'^{(\mathfrak{p})}_\Gamma$) contains $e_{f_{\lambda,(\mathfrak{p})}} = 1 \otimes e_{f_\lambda}$ (resp. $be_{f_{\lambda,(\mathfrak{p})}} = 1 \otimes be_{f_\lambda}$) for every $\mathfrak{p} \in Z \cap Z'$ (resp. and every $b \in J$). By lemma 17.4.14(iii) it follows that the image of $\vartheta'_{\Gamma_\mathbb{Q}}$ contains e_f (resp. that the image of ϑ'_Γ contains be_f for every $b \in J$). The claim is an immediate consequence. $\diamondsuit$

It remains to deal with the case where A does not contain a field, hence $A = V[[P]]/(h)$, for a discrete valuation ring $(V, \mathfrak{m}_V)$ whose residue field k has positive characteristic, such that $\mathfrak{m}_V = pV$, and with some $h := \sum_{\gamma \in P} h_\gamma \cdot \gamma$ such that $h_0 \in pV \setminus p^2V$. Arguing as in (17.3.4), and taking into account claim 17.4.20, we may then further reduce to the case where k is algebraically closed. In this situation, let $g \in J \setminus \{0\}$, and set

$$A_\Gamma := \Gamma \times_{\Gamma_\mathbb{Q}} A_\infty \qquad \text{and} \qquad A'_\Gamma := A_\Gamma[X^{1/p^\infty}]/(X - g) = A_\Gamma[g^{1/p^\infty}].$$

We get a basic setup $(A_\Gamma, \mathfrak{n})$, where $\mathfrak{n} \subset A_\Gamma$ is the ideal generated by $(g^\delta \mid \delta \in \mathbb{N}[1/p] \setminus \{0\})$. Moreover, let D be the p-root closure of A'_Γ in $A'_\Gamma[1/p]$, and $D^\wedge$ the p-adic completion of D; also, set $D_1^\wedge := (D^\wedge)^a_*$, the ring of almost elements of the $(A_\Gamma, \mathfrak{n})^a$-algebra $(D^\wedge)^a$, and denote by B'_1 the integral closure of $D_1^\wedge$ in $B' := D^\wedge \otimes_A B[1/g]$. Pick $N \in \mathbb{N}$ and $e \in B \otimes_A B$ whose image in $B \otimes_A B[1/g]$ equals $g^N e_f$, and let $e' \in B'_1 \widehat{\otimes}_{D^\wedge} B'_1$ be the image of e.

Claim 17.4.25. For every $\delta \in \mathbb{N}[1/p] \setminus \{0\}$ we have $g^\delta e' \in g^N(B'_1 \widehat{\otimes}_{D^\wedge} B'_1)$.

Proof of the claim. For every $n \in \mathbb{N}$, the $(D/p^nD)^a$-algebra $(B'_1/p^nB'_1)^a$ is étale of finite rank, and we let $\varepsilon_n \in (B'_1/p^nB'_1 \otimes_D B'_1/p^nB')^a_*$ be the corresponding diagonal idempotent. The system $(\varepsilon_n \mid n \in \mathbb{N})$ corresponds to a unique element

$$\varepsilon \in (B'_1 \widehat{\otimes}_{D^\wedge} B'_1)^a_*$$

where $B'_1 \widehat{\otimes}_{D^\wedge} B'_1$ denotes the p-adic completion of $B'_1 \otimes_{D^\wedge} B'_1$. Let $\mu : B'_1 \otimes_{D^\wedge} B'_1 \to B'_1$ be the multiplication law of B'_1, and $\widehat{\mu}$ the p-adic completion of μ; by construction, we see that :

(17.4.26) $\qquad \widehat{\mu}(\varepsilon) = 1 \qquad$ and $\qquad \varepsilon \cdot (1 \otimes x - x \otimes 1) = 0 \quad$ for every $x \in B'_1 = (B'_1)^a_*$.

By corollary 16.9.52(ii), the completion map $B'_1 \otimes_{D^\wedge} B'_1 \to B'_1 \widehat{\otimes}_{D^\wedge} B'_1$ induces an isomorphism

$$B \otimes_A B \otimes_A D^\wedge[1/g] \xrightarrow{\sim} B'_1 \otimes_{D^\wedge} B'_1[1/g] \xrightarrow{\sim} B'_1 \widehat{\otimes}_{D^\wedge} B'_1[1/g]$$

and it follows easily from (17.4.26) that the image of $e_f \otimes 1$ in $B'_1 \widehat{\otimes}_{D^\wedge} B'_1[1/g]$ agrees with the image of ε. But g is a regular element of $(B'_1 \widehat{\otimes}_{D^\wedge} B'_1)^a_*$, due to corollary 16.9.52(ii), hence the image of e in $(B'_1 \widehat{\otimes}_{D^\wedge} B'_1)^a_*$ agrees with $g^N \varepsilon$, whence the claim. ◊

Recall that $D_1^\wedge$ is integrally closed in $D^\wedge[1/g]$ (theorem 16.9.42(iv)), and A is a normal domain; then the trace maps for the étale ring homomorphisms $D^\wedge[1/g] \to B'$ and $A[1/g] \to B[1/g]$ restrict to a $D_1^\wedge$-linear map and respectively an A-linear map

$$\mathrm{tr}_{B'_1/D_1^\wedge} : B'_1 \to D_1^\wedge \qquad \mathrm{tr}_{B/A} : B \to A$$

(lemma 14.3.15(i)) whence an A-linear map and a $D_1^\wedge$-linear map

$$\tau : B \to B^\vee := \mathrm{Hom}_A(B, A) \quad b \mapsto (b' \mapsto \mathrm{tr}_{B/A}(bb'))$$
$$\tau' : B'_1 \to \mathrm{Hom}_A(B, D_1^\wedge) \qquad b \mapsto (b' \mapsto \mathrm{tr}_{B'_1/D_1^\wedge}(bb')).$$

Let also $i : A \to A_\Gamma$ and $i_D : D^\wedge \to D_1^\wedge$ be the natural maps; since i_D^a is an isomorphism of A_Γ^a-modules, we get by adjunction a unique A_Γ-linear map $j_D : \widetilde{\mathfrak{n}} \otimes_{A_\Gamma} D_1^\wedge \to D^\wedge$ such that $i_D \circ j_D = \mu \otimes_{A_\Gamma} D_1^\wedge$, where as usual $\widetilde{\mathfrak{n}} := \mathfrak{n} \otimes_{A_\Gamma} \mathfrak{n}$, and $\mu : \widetilde{\mathfrak{n}} \to A$ is the multiplication map : $a \otimes a' \mapsto aa'$. Then, for every $\delta, \delta' \in \mathbb{N}[1/p] \setminus \{0\}$ we let $j_{\delta+\delta'} : D_1^\wedge \to D^\wedge$ be the A_Γ-linear map such that $j_{\delta+\delta'}(d) := j_D(g^\delta \otimes g^{\delta'} \otimes d)$ for every $d \in D_1^\wedge$; it is easily seen that this map depends only on the sum $\delta + \delta'$. Hence :

$$i_D \circ j_\delta = g^\delta \cdot \mathbf{1}_{D_1^\wedge} \qquad \text{and} \qquad j_{\delta+\delta'} = g^\delta \cdot j_{\delta'} \qquad \text{for every } \delta, \delta' \in \mathbb{N}[1/p] \setminus \{0\}$$

and moreover for every such δ we get a commutative diagram of A_Γ-modules :

$$\begin{array}{ccc} A_\Gamma & \xrightarrow{g^\delta \cdot \mathbf{1}_{A_\Gamma}} & A_\Gamma \\ \downarrow & & \downarrow \\ D_1^\wedge & \xrightarrow{j_\delta} & D^\wedge \end{array}$$

whose vertical arrows are the structure maps of the A_Γ-algebras $D_1^\wedge$ and $D^\wedge$. Set

$$B_\Gamma^\vee := \mathrm{Hom}_A(B, A_\Gamma) \qquad B_1'^\vee := \mathrm{Hom}_A(B, D_1^\wedge) \qquad C := \mathrm{Hom}_A(B, D^\wedge)$$

and let $i_* : B^\vee \to B_\Gamma^\vee$ (resp. $j_{\delta*} : B_1'^\vee \to C$) be the A-linear (resp. A_Γ-linear) map such that $i_*(\varphi) := i \circ \varphi$ for every A-linear map $\varphi : B \to A$ (resp. $j_{\delta*}(\varphi) := j_\delta \circ \varphi$ for every A-linear map $\varphi : B \to D_1^\wedge$). To ease notation, set as well

$$B_{\Gamma,i}^\vee := \mathrm{Hom}_A(B, A_\Gamma/p^i A_\Gamma) \qquad \text{and} \qquad C_i := \mathrm{Hom}_A(B, D/p^i D) \qquad \text{for every } i \in \mathbb{N}.$$

We then obtain a commutative diagram for every $\delta \in \mathbb{N}[1/p] \setminus \{0\}$ and every $i \in \mathbb{N}$:

$$\begin{array}{ccccccc} B \otimes_A B & \xrightarrow{\tau \otimes_A \tau} & B^\vee \otimes_A B^\vee & \xrightarrow{g^\delta \cdot i_* \otimes_A g^\delta \cdot i_*} & B_\Gamma^\vee \otimes_{A_\Gamma} B_\Gamma^\vee & \longrightarrow & B_{\Gamma,i}^\vee \otimes_{A_\Gamma} B_{\Gamma,i}^\vee \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \\ B'_1 \widehat{\otimes}_{D^\wedge} B'_1 & \xrightarrow{\tau' \widehat{\otimes}_{D^\wedge} \tau'} & B_1'^\vee \widehat{\otimes}_{D^\wedge} B_1'^\vee & \xrightarrow{j_{\delta*} \widehat{\otimes}_{D^\wedge} j_{\delta*}} & C \widehat{\otimes}_{D^\wedge} C & \longrightarrow & C_i \otimes_D C_i. \end{array}$$

For given δ, pick $\delta', \delta'' \in \mathbb{N}[1/p] \setminus \{0\}$ with $\delta = \delta' + \delta''$; then

$$(j_{\delta*} \circ \tau') \widehat{\otimes}_{D^\wedge} (j_{\delta*} \circ \tau')(e') = (j_{\delta'*} \circ \tau') \widehat{\otimes}_{D^\wedge} (j_{\delta'*} \circ \tau')(g^{2\delta''} e').$$

By claim 17.4.25, we deduce that the image of $(j_{\delta *} \circ \tau')\widehat{\otimes}_{D^\wedge}(j_{\delta *} \circ \tau')(e')$ in $C_i \otimes_D C_i$ is divisible by g^N. Recall now that D is a faithfully flat A_Γ-algebra (theorem 16.9.17); since A is noetherian, and B is a finite A-algebra, we deduce a natural isomorphism

$$B^\vee_{\Gamma,i} \otimes_{A_\Gamma} D \stackrel{\sim}{\to} C_i \qquad \text{for every } i \in \mathbb{N}.$$

Set $e'' := (i_* \circ \tau) \otimes_A (i_* \circ \tau)(e)$; it follows that the image of ge'' in $B^\vee_{\Gamma,i} \otimes_{A_\Gamma} B^\vee_{\Gamma,i}$ is divisible by g^N, for every $i \in \mathbb{N}$. Next, for every $i \in \mathbb{N}$ and every subset $\Delta \subset \Gamma_{\mathbb{Q}}$, let :

$$\mathsf{R}(B, \Delta, i) := \bigoplus_{[\gamma]\in\Delta} B^\vee_{[\gamma],i} \otimes_A B^\vee_{[1/\gamma],i} \quad \text{with } B^\vee_{[\gamma],i} := \mathrm{Hom}_A(B, A_{[\gamma]}/p^i A_{[\gamma]}) \text{ for every } [\gamma] \in \Gamma_{\mathbb{Q}}$$

and notice that we have an A-linear surjection $\mathsf{R}(B, \Gamma, i) \to \mathrm{gr}_0(B^\vee_{\Gamma,i} \otimes_{A_\Gamma} B^\vee_{\Gamma,i})$, for the natural Γ-grading on $B^\vee_{\Gamma,i} \otimes_{A_\Gamma} B^\vee_{\Gamma,i}$. Summing up, for every $i \in \mathbb{N}$ there exists $e_i \in \mathsf{R}(B, \Gamma, i)$ such that the image of ge'' in $\mathrm{gr}_0(B^\vee_{\Gamma,i} \otimes_{A_\Gamma} B^\vee_{\Gamma,i})$ equals the image of $g^N e_i$. On the other hand, as in remark 17.4.7(ii) we obtain for every $i \in \mathbb{N}$ a commutative diagram of A-linear maps

$$\begin{array}{ccccc}
A/p^iA \otimes_A \mathsf{R}(B,\Gamma) & \longrightarrow & A/p^iA \otimes_A \mathrm{gr}_0(B^\vee_\Gamma \otimes_{A_\Gamma} B^\vee_\Gamma) & \longrightarrow & A/p^iA \otimes_A (B \otimes_A B)^\vee \\
\downarrow & & \downarrow & & \downarrow \\
\mathsf{R}(B,\Gamma,i) & \longrightarrow & \mathrm{gr}_0(B^\vee_{\Gamma,i} \otimes_{A_\Gamma} B^\vee_{\Gamma,i}) & \longrightarrow & \mathrm{Hom}_A(B \otimes_A B, A/p^iA)
\end{array}$$

whose left vertical arrow is induced by the projections $A_{[\gamma]} \to A_{[\gamma]}/p^i A_{[\gamma]}$ for every $[\gamma] \in \Gamma_{\mathbb{Q}}$, and such that the composition of the top horizontal arrows is $A/p^iA \otimes_A \xi_{\underline{f}}$. Denote by $\xi_{\underline{f},i}$ the composition of the bottom horizontal arrows; arguing as in the proof of lemma 17.4.10(i) we find a finite subset $\Sigma \subset \Gamma$ such that $\xi_{\underline{f}}(\mathsf{R}(B,\Gamma)) = \xi_{\underline{f}}(\mathsf{R}(B,\Sigma))$ and $\xi_{\underline{f},i}(\mathsf{R}(B,\Gamma,i)) = \xi_{\underline{f},i}(\mathsf{R}(B,\Sigma,i))$ for every $i \in \mathbb{N}$. We notice:

Claim 17.4.27. Let R be a noetherian ring, M, N two R-modules of finite type, and $I \subset R$ an ideal. Set $H^i := \mathrm{Hom}_R(M, N/I^iN)$ for every $i \in \mathbb{N}$. Then there exists $c \in \mathbb{N}$ such that

$$\mathrm{Im}(H^{i+c} \to H^i) = \mathrm{Im}(\mathrm{Hom}_R(M,N) \to H^i) \qquad \text{for every } i \in \mathbb{N}.$$

Proof of the claim. Pick a finite presentation $R^{\oplus q} \stackrel{\varphi}{\to} R^{\oplus p} \to M$ of the R-module M; let $\varphi^\vee : R^{\oplus p} \to R^{\oplus q}$ be the transpose of φ, set $\varphi^\vee_N := \varphi^\vee \otimes_A N : N^{\oplus q} \to N^{\oplus p}$ and $N' := \mathrm{Im}\,\varphi^\vee_N$; by the Artin-Rees lemma ([126, Th.8.5]) there exists $c \in \mathbb{N}$ such that $N' \cap I^{i+c}N^{\oplus q} = I^i(N' \cap I^c N^{\oplus q})$ for every $i \in \mathbb{N}$. We consider then the induced commutative diagram :

$$\begin{array}{ccccccc}
0 & \longrightarrow & \mathrm{Hom}_R(M,N) & \longrightarrow & N^{\oplus p} & \xrightarrow{\varphi^\vee_N} & N^{\oplus q} \\
 & & \downarrow & & \downarrow & & \downarrow \\
0 & \longrightarrow & H^{i+c} & \longrightarrow & N^{\oplus p}/I^{i+c}N^{\oplus p} & \xrightarrow{\varphi^\vee_{N/I^{i+c}N}} & N^{\oplus q}/I^{i+c}N^{\oplus q} \\
 & & \downarrow & & \downarrow & & \downarrow \\
0 & \longrightarrow & H^i & \longrightarrow & N^{\oplus p}/I^iN^{\oplus p} & \xrightarrow{\varphi^\vee_{N/I^iN}} & N^{\oplus q}/I^iN^{\oplus q}
\end{array}$$

whose horizontal rows are left exact sequences. Let then $\overline{h} \in \mathrm{Ker}\,\varphi^\vee_{N/I^{i+c}N}$, and pick a representative $h \in N^{\oplus p}$ for the class $\overline{h}$. Then $\varphi^\vee_N(h) \in N' \cap I^{i+c}N^{\oplus q}$, so there exists $k \in \mathbb{N}$ such that $\varphi^\vee_N(h) = \sum_{j=1}^k a_j \varphi^\vee_N(x_j)$ for certain $a_1, \dots, a_k \in I^i$ and $x_1, \dots, x_k \in N^{\oplus p}$. Set $h' := h - \sum_{j=1}^k a_j x_j$. Then $h' \in \mathrm{Ker}\,\varphi^\vee_N$, and the image of h' in $N^{\oplus p}/I^iN^{\oplus p}$ agrees with the image of $\overline{h}$, whence the claim. ◊

By claim 17.4.27, for every $i \in \mathbb{N}$ there exists $e'_i \in \mathsf{R}(B,\Sigma)$ such that $\xi_{\underline{f},i}(e_i)$ agrees with the image of $1 \otimes \xi_{\underline{f}}(e'_i) \in A/p^iA \otimes_A (B \otimes_A B)^\vee$. Now, let $M \subset (B \otimes_A B)^\vee$ be the A-submodule generated by the system $(\xi_{\underline{f}}(e'_i) \mid i \in \mathbb{N})$; we conclude that the image of ge'' in $(B \otimes_A B)^\vee$ lies in the submodule $g^N M + p^i(B \otimes_A B)^\vee$, for every $i \in \mathbb{N}$; but then it lies already in $g^N M$, since $g^N M$ is a closed subset for the p-adic topology of the finitely generated A-module $(B \otimes_A B)^\vee$ ([126, Th.8.10(i)]). Lastly, this shows that the image of ge'' in $\mathsf{X}(\underline{f})$ lies in $g^N \cdot \vartheta_{\underline{f}}(\mathsf{R}(B,\Gamma))$; but this image equals $g^{N+1}e_f$, whence $ge_f \in \vartheta_{\underline{f}}(\mathsf{R}(B,\Gamma))$, which achieves the proof of (ii).

To show (i), let e''_i be the image of e'' in $B^\vee_{\Gamma,i} \otimes_{A_\Gamma} B^\vee_{\Gamma,i}$ for every $i \in \mathbb{N}$, and set

$$I_i := \{a \in A_\Gamma \mid ae''_i \in g^N(B^\vee_{\Gamma,i} \otimes_{A_\Gamma} B^\vee_{\Gamma,i})\} \qquad \text{and} \qquad I_{D,i} := \{d \in D \mid de''_i \in g^N(C_i \otimes_D C_i)\}.$$

As already observed in the foregoing, $g^\delta \in I_{D,i}$ for every $\delta \in \mathbb{N}[1/p] \setminus \{0\}$; then, since D is a flat A_Γ-algebra, we have $I_{D,i} = I_i D$ for every $i \in \mathbb{N}$ (details left to the reader), so that $I^k_{D,i} = I^k_i D$ for every $i, k \in \mathbb{N}$. Since D is a faithfully flat A_Γ-algebra, it follows that $I^k_i = I^k_{D,i} \cap A_\Gamma$ for every $i, k \in \mathbb{N}$ ([126, Th.7.5(ii)]), whence $g \in I^k_i$ for every $i, k \in \mathbb{N}$, and notice as well that I_i is a Γ-graded ideal of A_Γ. Let $\lambda_1, \dots, \lambda_k \in P^\vee := \mathrm{Hom}_{\mathbf{Mnd}}(P_\mathbb{R}, \mathbb{R}_+)$ such that $\mathbb{R}\lambda_1, \dots, \mathbb{R}\lambda_k$ are the extremal rays of $P^\vee_\mathbb{R}$, and set $\lambda := \lambda_1 + \cdots + \lambda_k$; by lemma 17.3.10 there exists a sequence $(\gamma_n \mid n \in \mathbb{N})$ of elements of $P^{(\infty)}$ with $\lim_{n \to +\infty} \lambda(\gamma_n) = 0$ and such that $\mathrm{gr}_{[\gamma_n]} I_i = A_{[\gamma_n]}$ for every $n \in \mathbb{N}$, and by claim 17.3.7 we may assume that $\mathrm{gr}_{[\gamma_n]} P^{(\infty)} = \gamma_n P$ for every $n \in \mathbb{N}$, so that $A_{[\gamma_n]} = A \cdot (1 \otimes \gamma_n)$, and therefore

$$(1 \otimes \gamma_n) \cdot e''_i \in g^N \cdot \mathrm{gr}_{[\gamma_n]}(B^\vee_{\Gamma,i} \otimes_{A_\Gamma} B^\vee_{\Gamma,i}).$$

On the other hand, lemma 17.4.16 yields for every $[\gamma] \in \Gamma$ an element $[\gamma'] \in \Sigma_\mathbb{Q}$ such that :

$$\gamma^{-1} P_\mathbb{Q} \cap P^{\mathrm{gp}} \subset \gamma'^{-1} P_\mathbb{Q} \cap P^{\mathrm{gp}} \qquad \text{and} \qquad (\gamma/\gamma_n) P_\mathbb{Q} \cap P^{\mathrm{gp}} \subset \gamma' P_\mathbb{Q} \cap P^{\mathrm{gp}}.$$

We then get a commutative diagram of A-modules :

$$\begin{array}{ccccc}
\mathsf{R}(B, \Gamma_\mathbb{Q}, i) & \longrightarrow & \mathrm{gr}_0(B^\vee_{\infty,i} \otimes_{A_\Gamma} B^\vee_{\infty,i}) & \longrightarrow & \mathrm{Hom}_A(B \otimes_A B, A/p^i A) \\
\uparrow & & & & \downarrow \\
\bigoplus_{[\gamma] \in \Gamma} B^\vee_{[\gamma],i} \otimes_A B^\vee_{[\gamma_n/\gamma],i} & \longrightarrow & \mathrm{gr}_{[\gamma_n]}(B^\vee_{\Gamma,i} \otimes_{A_\Gamma} B^\vee_{\Gamma,i}) & \longrightarrow & \mathrm{Hom}_A(B \otimes_A B, A_{[\gamma_n]}/p^i A_{[\gamma_n]})
\end{array}$$

whose right vertical arrow is an isomorphism induced by scalar multiplication by $1 \otimes \gamma_n$. Moreover, the composition of the top horizontal arrows is $\xi_{\underline{f},i}$. With this notation, we have $e''_i \in \mathrm{gr}_0(B^\vee_{\Gamma,i} \otimes_{A_\Gamma} B^\vee_{\Gamma,i})$, and it follows easily that the image of e''_i lies in $g^N \cdot \xi_{\underline{f},i}(\mathsf{R}(B, \Gamma_\mathbb{Q}, i))$, for every $i \in \mathbb{N}$. Arguing as in the proof of lemma 17.4.10(i), we then find a finite subset $\Delta \subset \Gamma_\mathbb{Q}$ such that the image of e''_i in $\mathrm{Hom}_A(B \otimes_A B, A/p^i A)$ lies in the A-submodule $g^N \cdot \xi_{\underline{f},i}(\mathsf{R}(B, \Delta, i))$, for every $i \in \mathbb{N}$. By invoking again claim 17.4.27, we deduce that for every $i \in \mathbb{N}$, the image of e'' in $(B \otimes_A B)^\vee$ lies in the A-submodule $g^N \cdot \xi_{\underline{f}}(\mathsf{R}(B, \Delta)) + p^i \cdot (B \otimes_A B)^\vee$. Arguing as in the foregoing proof of (ii), we conclude that the image of e'' in $(B \otimes_A B)^\vee$ lies already in $g^N \cdot \xi_{\underline{f}}(\mathsf{R}(B, \Delta))$, and finally $e_f \in \vartheta_{\underline{f}}(\mathsf{R}(B, \Gamma_\mathbb{Q}))$, as stated. □

17.4.28. Keep the notation of (17.4.5), and for every $m \in \mathbb{N}$, let $\Gamma_m := \{\gamma \in \Gamma_\mathbb{Q} \mid m\gamma = 0\}$. By theorem 17.4.19, if (A, P, β) is regular, there exists $m \in \mathbb{N}$ such that $e_f \in \vartheta_{\underline{f}}(\mathsf{R}(B, \Gamma_m))$. It turns out that a suitable integer m with this property can be exhibited purely in terms of the combinatorics of the monoid P. Indeed, let $P^\vee$ be the dual of P (see (6.4.13)); since P is fine, $P^\vee$ is fine, sharp and saturated (proposition 6.4.14(i,ii)), and we let $F_1, \dots, F_k$ be the one-dimensional faces of $P^\vee$. Then $F_i \simeq \mathbb{N}$ (theorem 6.4.18(ii)), and we denote by λ_i the unique generator of F_i, for every $i = 1, \dots, k$. Set $\Lambda := \{\lambda_1, \dots, \lambda_k\}$, and denote by $\mathscr{E}$ the set of all subsets $\Sigma \subset \Lambda$ such that $\{\lambda^{\mathrm{gp}} \otimes_\mathbb{Z} \mathbb{Q} : P^{\mathrm{gp}}_\mathbb{Q} \to \mathbb{Q} \mid \lambda \in \Sigma\}$ is a basis of $(P^{\mathrm{gp}}_\mathbb{Q})^\vee$. For every $\Sigma \in \mathscr{E}$, let $L_\Sigma \subset P^{\vee\mathrm{gp}}$ be the subgroup generated by $(\lambda^{\mathrm{gp}} \mid \lambda \in \Sigma)$, and denote by m_Σ the exponent of the finite abelian group $P^{\vee\mathrm{gp}}/L_\Sigma$. Lastly, denote by m_P the least common multiple of the finite system of integers $(m_\Sigma \mid \Sigma \in \mathscr{E})$. We may then state :

Corollary 17.4.29. *In the situation of theorem* 17.4.19*, we have* $e_f \in \vartheta_{\underline{f}}(\mathsf{R}(B, \Gamma_{m_p}))$.

Proof. For every $\Sigma \in \mathscr{E}$, let $\lambda_\Sigma : P^{\mathrm{gp}}_{\mathbb{Q}} \xrightarrow{\sim} \mathbb{Q}^\Sigma$ be the $\mathbb{Q}$-linear isomorphism given by the rule :

$$\gamma \mapsto (\lambda^{\mathrm{gp}}_{\mathbb{Q}}(\gamma) \mid \lambda \in \Sigma) \qquad \text{for every } \gamma \in P^{\mathrm{gp}}_{\mathbb{Q}}.$$

Notice that $P^{\mathrm{gp}} \subset \lambda_\Sigma^{-1}(\mathbb{Z}^\Sigma)$ for every such B, and m_Σ equals the exponent of the finite abelian group $\lambda_\Sigma^{-1}(\mathbb{Z}^\Sigma)/P^{\mathrm{gp}}$. With this notation, we have :

Claim 17.4.30. For every $\beta \in P^{\mathrm{gp}}_{\mathbb{Q}}$ there exist $\Sigma \in \mathscr{E}$ and an element $\beta^\dagger \in \lambda_\Sigma^{-1}(\mathbb{Z}^\Sigma)$ such that

$$\beta P_{\mathbb{Q}} \cap P^{\mathrm{gp}} \subset \beta^\dagger P_{\mathbb{Q}} \cap P^{\mathrm{gp}} \qquad \text{and} \qquad \beta^{-1} P_{\mathbb{Q}} \cap P^{\mathrm{gp}} \subset \beta^{\dagger -1} P_{\mathbb{Q}} \cap P^{\mathrm{gp}}. \tag{17.4.31}$$

Proof of the claim. Notice that, for every $\beta \in P^{\mathrm{gp}}_{\mathbb{R}}$, we have

$$\beta P_{\mathbb{R}} \cap P^{\mathrm{gp}} = \{x \in P^{\mathrm{gp}} \mid \lambda^{\mathrm{gp}}(x) \geq \lambda^{\mathrm{gp}}_{\mathbb{R}}(\beta) \text{ for every } \lambda \in \Lambda\}.$$

For every such β and every $\lambda \in \Lambda$, denote by $N_{\beta,\lambda}$ (resp. $N'_{\beta,\lambda}$) the largest (resp. smallest) integer which is smaller than (resp. larger than) or equal to $\lambda^{\mathrm{gp}}_{\mathbb{R}}(\beta)$. Recalling that $\lambda^{\mathrm{gp}}(P^{\mathrm{gp}}) \subset \mathbb{Z}$ for every $\lambda \in \Lambda$, it is easily seen that (17.4.31) holds if and only if

$$\lambda^{\mathrm{gp}}_{\mathbb{Q}}(\beta^\dagger) \in [N_{\beta,\lambda}, N'_{\beta,\lambda}] \qquad \text{for every } \lambda \in \Lambda. \tag{17.4.32}$$

Set $\Sigma_\beta := \{\lambda \in \Lambda \mid \lambda^{\mathrm{gp}}_{\mathbb{R}}(\beta) \in \mathbb{Z}\}$. Now, if $\beta \in P^{\mathrm{gp}}_{\mathbb{Q}}$ and Σ_β spans $(P^{\mathrm{gp}}_{\mathbb{Q}})^\vee$, obviously the claim holds with $\beta^\dagger := \beta$. Thus, a simple induction argument reduces to showing that, if $\beta \in P^{\mathrm{gp}}_{\mathbb{Q}}$ and Σ_β does not span $(P^{\mathrm{gp}}_{\mathbb{Q}})^\vee$, there exists $\gamma \in P^{\mathrm{gp}}_{\mathbb{Q}}$ such that (17.4.32) holds, and such that Σ_γ strictly contains Σ_β. To this aim, let $l : P^{\mathrm{gp}}_{\mathbb{R}} \to \mathbb{R}^\Lambda$ be the $\mathbb{R}$-linear map such that

$$l(\gamma) := (\lambda^{\mathrm{gp}}_{\mathbb{R}}(\gamma) \mid \lambda \in \Lambda) \qquad \text{for every } \gamma \in P^{\mathrm{gp}}_{\mathbb{R}}$$

and set

$$K := \prod_{\lambda \in \Lambda} [N_{\beta,\gamma}, N'_{\beta,\gamma}] \subset \mathbb{R}^\Lambda \qquad M := \bigcap_{\lambda \in \Sigma_\beta} \mathrm{Ker}\, \lambda^{\mathrm{gp}}_{\mathbb{Q}} \subset P^{\mathrm{gp}}_{\mathbb{Q}}.$$

Notice that l is a closed immersion, K is a compact subset of $\mathbb{R}^\Lambda$, and by assumption, $M \neq 0$. Clearly $\beta \in l^{-1}K$, and we pick any non-zero $\mu \in M$. It follows that the subset

$$\{a \in \mathbb{R} \mid \beta + a\mu \in l^{-1}K\}$$

is non-empty and compact, so it admits a largest element a_0. Set $\gamma := \beta + a_0\mu$; by construction, $\Sigma_\beta \subset \Sigma_\gamma$, and it is easily seen that there must exist some $\lambda \in \Lambda \setminus \Sigma_\beta$ such that $\lambda^{\mathrm{gp}}_{\mathbb{R}}(\gamma) \in \{N_{\beta,\lambda}, N'_{\beta,\lambda}\}$, since otherwise we could find a real number $a > a_0$ with $\beta + a\mu \in l^{-1}K$. Thus Σ_γ strictly contains Σ_β. Lastly, since both β and μ lie in $P^{\mathrm{gp}}_{\mathbb{Q}}$ and $\lambda^{\mathrm{gp}}_{\mathbb{R}}(\beta) \notin \mathbb{Z}$, we must have $\lambda^{\mathrm{gp}}_{\mathbb{R}}(a_0\mu) \in \mathbb{Q} \setminus \mathbb{Z}$, and since $\lambda^{\mathrm{gp}}_{\mathbb{R}}(\mu) \in \mathbb{Q}$, we conclude that $a_0 \in \mathbb{Q}$, hence $\gamma \in P^{\mathrm{gp}}_{\mathbb{Q}}$, whence the claim. ◊

Now, for every $[\beta] \in \Gamma_{\mathbb{Q}}$ pick $\beta^\dagger \in P^{\mathrm{gp}}_{\mathbb{Q}}$ fulfilling the condition of claim 17.4.30, and set $\Delta := \{[\beta^\dagger] \mid [\beta] \in \Gamma_{\mathbb{Q}}\}$. Notice that $\Delta \subset \Gamma_{m_P}$. Arguing as in the proof of lemma 17.4.10(ii) we easily deduce that $\vartheta_{\underline{f}}(\mathsf{R}(B, \Delta)) = \vartheta_{\underline{f}}(\mathsf{R}(B, \Gamma_{\mathbb{Q}}))$, whence the corollary. □

Example 17.4.33. (i) Suppose that $\dim P = 2$. Then we may find a basis (f_1, f_2) of P^{gp} and integers $a, b \in \mathbb{N}$ such that $b > a$, $(a, b) = 1$ and P is the submonoid of P^{gp} generated by f_1 and $af_1 + bf_2$ (example 6.4.19(ii)). With this notation, a simple calculation shows that $m_P = b$ (details left to the reader).

(ii) In the situation of theorem 17.4.19, suppose that $P = \mathbb{N}^{\oplus r} \times \mathbb{Z}^{\oplus s}$ for some $r, s \in \mathbb{N}$; by corollary 12.5.19, the latter holds if and only if A is a regular ring. In this case, the integer m_P of (17.4.28) equals 1, and therefore corollary 17.4.29 says that $e_f \in \vartheta_{\underline{f}}(B^\vee \otimes_A B^\vee)$. However, the latter follows also more directly from lemma 17.4.10(ii). Moreover, in case A is regular, the submodule $\vartheta_{\underline{f}}(B^\vee \otimes_A B^\vee)$ can be interpreted in terms of the *different ideal* of the finite ring extension $f : A \to B$. We conclude this section with a review of different ideals in the more general context of quasi-coherent algebras on schemes; especially, remark 17.4.44 explains the connection with theorem 17.4.19.

17.4.34. Let X be a reduced scheme, $\mathscr{A}$ a quasi-coherent and finite $\mathscr{O}_X$-algebra and $j : U \to X$ a quasi-compact open immersion with dense image, such that $j^*\mathscr{A}$ is a locally free $\mathscr{O}_U$-module. Denote by

$$\mathrm{Max}\, X$$

the set of maximal points of X, and notice that $\mathrm{Max}\, X \subset U$, by proposition 8.1.47(i). In this situation, there is a trace form as in remark 14.3.10(iii) :

$$t_{j^*\mathscr{A}} : j^*\mathscr{A} \otimes_{\mathscr{O}_U} j^*\mathscr{A} \to \mathscr{O}_U$$

whence a pairing

$$t_{\mathscr{A},U} : \mathscr{A} \otimes_{\mathscr{O}_X} j_*j^*\mathscr{A} \to j_*(j^*\mathscr{A} \otimes_{\mathscr{O}_U} j^*\mathscr{A}) \xrightarrow{j_*t_{j^*\mathscr{A}}} j_*\mathscr{O}_U$$

which in turns yields a morphism of $\mathscr{O}_X$-modules

$$\tau_{\mathscr{A},U} : j_*j^*\mathscr{A} \to \mathscr{H}om_{\mathscr{O}_X}(\mathscr{A}, j_*\mathscr{O}_U).$$

Since X is reduced, the natural morphism $\mathscr{O}_X \to j_*\mathscr{O}_U$ is injective, and therefore the same holds for the induced $\mathscr{O}_X$-linear morphism

$$\mathscr{A}^\vee \to \mathscr{H}om_{\mathscr{O}_X}(\mathscr{A}, j_*\mathscr{O}_U)$$

so we may define

$$\mathscr{D}^{-1}_{\mathscr{A},U} := \tau^{-1}_{\mathscr{A},U}(\mathscr{A}^\vee).$$

We call $\mathscr{D}^{-1}_{\mathscr{A},U} \subset j_*j^*\mathscr{A}$ the *inverse different of $\mathscr{A}$ relative to the open subset U*.

Remark 17.4.35. (i) In the situation of (17.4.34), notice that the natural isomorphism

$$\mathscr{H}om_{\mathscr{O}_X}(\mathscr{A}, j_*\mathscr{O}_U) \xrightarrow{\sim} j_*(j^*\mathscr{A})^\vee$$

(see (10.1.19)) identifies $\tau_{\mathscr{A},U}$ with $j_*\tau_{j^*\mathscr{A}}$, where $\tau_{j^*\mathscr{A}} : j^*\mathscr{A} \to j^*\mathscr{A}^\vee$ is the $\mathscr{O}_U$-linear morphism deduced from the trace pairing $t_{j^*\mathscr{A}}$.

(ii) Moreover, set $\mathscr{B} := \mathrm{Im}\,(\mathscr{A} \to j_*j^*\mathscr{A})$. Since the natural map $\mathscr{O}_X \to j_*\mathscr{O}_U$ is a monomorphism, it is easily seen that the the epimorphism $\mathscr{A} \to \mathscr{B}$ induces an isomorphism $\mathscr{B}^\vee \xrightarrow{\sim} \mathscr{A}^\vee$, and taking (i) into account, we deduce that the latter induces an isomorphism

$$\mathscr{D}^{-1}_{\mathscr{A},U} \xrightarrow{\sim} \mathscr{D}^{-1}_{\mathscr{B},U}.$$

(iii) Suppose next that $U' \subset U$ is another open subset, such that the open immersion $j' : U' \to X$ is also quasi-compact with dense image. A direct inspection of the definitions yields a commutative diagram

$$\begin{array}{ccc} j_*j^*\mathscr{A} & \xrightarrow{\tau_{\mathscr{A},U}} & \mathscr{H}om_{\mathscr{O}_X}(\mathscr{A}, j_*\mathscr{O}_U) \\ \downarrow & & \downarrow \\ j'_*j'^*\mathscr{A} & \xrightarrow{\tau_{\mathscr{A},U'}} & \mathscr{H}om_{\mathscr{O}_X}(\mathscr{A}, j'_*\mathscr{O}_{U'}) \end{array}$$

whose vertical arrows are monomorphisms, under the current assumptions. It follows easily that

$$\mathscr{D}^{-1}_{\mathscr{A},U} = \mathscr{D}^{-1}_{\mathscr{A},U'} \cap j_*j^*\mathscr{A}.$$

(iv) In the situation of (iii), suppose that $\mathscr{A}$ is generically étale, and let $U' \subset U$ be the largest open subset such that $\mathscr{A}_{|U'}$ is an étale $\mathscr{O}_{U'}$-algebra. Then the inclusion $U' \to U$ is a dense and quasi-compact open immersion. For the proof, we may assume that U is affine, say $U = \mathrm{Spec}\, R$, and that $j^*\mathscr{A}$ is the quasi-coherent $\mathscr{O}_U$-algebra associated with an R-algebra A

which is a projective R-module of finite rank; then we easily reduce to the case where A is a free R-module of finite rank. In this case, let $(e_i \mid i = 1, \dots, r)$ be a basis of the R-module A; consider the matrix $D := (t_{j^*\mathscr{A}}(e_i, e_j) \mid i, j = 1, \dots, r)$, and set $d := \det(D)$. We have $U' = \operatorname{Spec} R[d^{-1}]$, a quasi-compact dense open subset of U ([75, Th.4.1.14]), as required.

(v) In the situation of (iii), suppose additionally that $j^*\mathscr{A}$ is an étale $\mathscr{O}_U$-algebra. Then $t_{j^*\mathscr{A}}$ and $t_{j'^*\mathscr{A}}$ are perfect pairings ([75, Th.4.1.14]). Taking (i) into account, we conclude that $\tau_{\mathscr{A},U}$ is an isomorphism, and the same applies to $\tau_{\mathscr{A},U'}$, so the inclusion map $j_*j^*\mathscr{A} \to j'_*j'^*\mathscr{A}$ restricts to a natural isomorphism

$$\mathscr{D}^{-1}_{\mathscr{A},U} \xrightarrow{\sim} \mathscr{D}^{-1}_{\mathscr{A},U'}.$$

More generally, if $j : U \to X$ and $j' : U' \to X$ are any two quasi-compact dense open immersions such that $j^*\mathscr{A}$ and $j'^*\mathscr{A}$ are respectively an étale $\mathscr{O}_U$-algebra and an étale $\mathscr{O}_{U'}$-algebra, then both $\mathscr{D}^{-1}_{\mathscr{A},U}$ and $\mathscr{D}^{-1}_{\mathscr{A},U'}$ are naturally identified with $\mathscr{D}^{-1}_{\mathscr{A},U\cap U'}$, and in this sense we may say that the inverse different of a finite and generically étale $\mathscr{O}_X$-algebra is independent of the open subset U. We shall therefore henceforth denote just by $\mathscr{D}^{-1}_{\mathscr{A}}$ the inverse different of $\mathscr{A}$.

Lemma 17.4.36. *In the situation of* (17.4.34)*, denote by $\mathscr{A}^\nu$ the normalization of $j^*\mathscr{A}$ over X (see remark* 14.4.3(ii)*). The following holds :*

(i) *If X is normal, $\mathscr{A} \subset \mathscr{D}^{-1}_{\mathscr{A},U}$.*

(ii) *Suppose that $\mathscr{A}$ is a generically étale $\mathscr{O}_X$-algebra. Then :*

 (a) *There exists a dense quasi-compact open subset $U' \subset U$ such that the map $\tau_{\mathscr{A},U'}$ restricts to an $\mathscr{O}_X$-linear isomorphism $\mathscr{D}^{-1}_{\mathscr{A}} \xrightarrow{\sim} \mathscr{A}^\vee$.*

 (b) *If X is locally coherent, $\mathscr{D}^{-1}_{\mathscr{A}}$ is a reflexive $\mathscr{O}_X$-module of finite type.*

 (c) *If X is normal, $\mathscr{A}^\nu \subset \mathscr{D}^{-1}_{\mathscr{A}}$.*

(iii) *Suppose that X is normal, and $j^*\mathscr{A}$ is an étale $\mathscr{O}_U$-algebra. Let also $j' : U' \to X$ be a quasi-compact open immersion with dense image, with $U' \subset U$, and $\mathscr{A}'^\nu$ the integral closure of $\mathscr{O}_X$ in $j'^*\mathscr{A}$. Then the natural map $\mathscr{A}^\nu \to \mathscr{A}'^\nu$ is an isomorphism.*

Proof. (i) follows immediately from lemma 14.3.15(i).

(ii.a) follows immediately from the discussion of remark (17.4.35)(iv,v), and (ii.b) follows from (ii.a) and lemma 11.3.3.

(ii.c): Taking into account remark 17.4.35(ii), we may assume without loss of generality that $\mathscr{A} = \operatorname{Im}(\mathscr{A} \to j_*j^*\mathscr{A})$, in which case the natural map $\mathscr{A} \to \mathscr{A}^\nu$ is a monomorphism. Moreover, the assertion is clearly local on X, hence we may assume that X is affine, in which case $\mathscr{A}^\nu$ is the union of the filtered family of its $\mathscr{A}$-subalgebras $\mathscr{B}$ that are quasi-coherent and finite $\mathscr{O}_X$-algebras. For any such $\mathscr{B}$, the $\mathscr{O}_X$-module $\mathscr{B}/\mathscr{A}$ is supported on $X \setminus U$. It follows that $(\mathscr{B}/\mathscr{A})^\vee = 0$, so the transpose map $\mathscr{B}^\vee \to \mathscr{A}^\vee$ is a monomorphism as well; by the same token, we see that $\tau_{\mathscr{A},U} = \tau_{\mathscr{B},U}$ (notation of (17.4.34)), so $\mathscr{D}^{-1}_{\mathscr{B}} \subset \mathscr{D}^{-1}_{\mathscr{A}}$, whence $\mathscr{B} \subset \mathscr{D}^{-1}_{\mathscr{A}}$, by virtue of (i). Since $\mathscr{B}$ is arbitrary, the assertion follows.

(iii): We may assume that X is local, say $X = \operatorname{Spec} R$ for a local and normal domain R, and let K be the field of fractions of R; then $A^\nu := \mathscr{A}^\nu(X)$ (resp. A'^ν) is the integral closure of R in $\mathscr{A}(U)$ (resp. in $\mathscr{A}(U')$); but under the stated assumptions, both A^ν and A'^ν are also the integral closure of R in $K \otimes_R \mathscr{A}(X)$, whence the assertion. □

Remark 17.4.37. Let X be a reduced and quasi-separated scheme, such that $\operatorname{Max} X$ is finite.

(i) Let also $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module of finite type. Then we claim that there exists a dense and quasi-compact open immersion $j : U \to X$ such that $j^*\mathscr{F}$ is a locally free $\mathscr{O}_U$-module. Indeed, for any maximal point $\eta \in X$, pick an affine open subset $V_\eta \subset X$ such that η is the unique maximal point of V_η; hence $V_\eta = \operatorname{Spec} A$ for an integral domain A and $\mathscr{F}_{|V} = M^\sim$ for an A-module M of finite type. Set $K := \operatorname{Frac} A$; then $P := M \otimes_A K$ is a finite dimensional K-vector space, and we may find a element $f \in A \setminus \{0\}$, a free A_f-module Q of finite rank and an A_f-linear map $\varphi : Q \to M \otimes_A A_f$ such that $\operatorname{Ker} \varphi \otimes_A K = 0 = \operatorname{Coker} \varphi \otimes_A K$. However, the natural map $Q \to Q \otimes_{A_f} K$ is injective, so we see that $\mathrm{Ker}\,\varphi = 0$, and on the other hand $\mathrm{Coker}\,\varphi$ is an A_f-module of finite type, so we may find $g \in A \backslash \{0\}$ such that φ_g is surjective. Set $U_\eta := \mathrm{Spec}\,A_{fg}$; by construction $\mathscr{F}_{|U_\eta}$ is a locally free $\mathscr{O}_{U_\eta}$-module, and since η is arbitrary, the assertion follows easily.

(ii) Let $\mathscr{A}$ be a quasi-coherent and finite $\mathscr{O}_X$-algebra, and suppose that $\mathscr{A}_\eta$ is an étale $\mathscr{O}_{X,\eta}$-algebra, for every maximal point η of X. Then we claim that there exists an dense quasi-compact open immersion $j : U \to X$ such that $j^*\mathscr{A}$ is an étale $\mathscr{O}_U$-algebra. Indeed, by (i), we may already assume that $\mathscr{A}$ is a locally free $\mathscr{O}_X$-module, and then we may argue as in remark 17.4.35(iv).

17.4.38. Keep the situation of (17.4.34), let X' be another reduced scheme, and $g : X' \to X$ a quasi-compact and quasi-separated morphism of schemes which restricts to a map

$$\mathrm{Max}\,X' \to \mathrm{Max}\,X.$$

Set

$$U' := g^{-1}U \qquad \mathscr{A}' := g^*\mathscr{A}$$

and denote by $j' : U' \to X'$ the resulting open immersion. It is easily seen that j' is quasi-compact and has dense image, and clearly $j'^*\mathscr{A}'$ is a locally free $\mathscr{O}_{U'}$-module, so there is a well defined inverse different $\mathscr{D}^{-1}_{\mathscr{A}',U'}$ relative to U'. Moreover, we have a commutative diagram

(17.4.39)
$$\begin{array}{ccccc} g^*j_*j^*\mathscr{A} & \xrightarrow{g^*\tau_{\mathscr{A},U}} & g^*\mathscr{H}om_{\mathscr{O}_X}(\mathscr{A}, j_*\mathscr{O}_U) & \longleftarrow & g^*(\mathscr{A}^\vee) \\ \downarrow{\scriptstyle a} & & \downarrow{\scriptstyle b} & & \downarrow{\scriptstyle c} \\ j'_*j'^*\mathscr{A}' & \xrightarrow{\tau_{\mathscr{A}',U'}} & \mathscr{H}om_{\mathscr{O}_{X'}}(\mathscr{A}', j'_*\mathscr{O}_{U'}) & \longleftarrow & \mathscr{A}'^\vee \end{array}$$

([75, Lemma 4.1.13(iii)]). It follows that the left vertical arrow restricts to an $\mathscr{O}_{X'}$-linear map

(17.4.40)
$$g^*\mathscr{D}^{-1}_{\mathscr{A},U} \to \mathscr{D}^{-1}_{\mathscr{A}',U'}.$$

Lemma 17.4.41. *The map* (17.4.40) *is an isomorphism in the following cases :*

(a) *if $\mathscr{A}$ is a locally free $\mathscr{O}_X$-module of finite type and $j^*\mathscr{A}$ is an étale $\mathscr{O}_U$-algebra*

(b) *or if g is a flat morphism.*

Proof. For case (a), notice that when $\mathscr{A}$ is locally free, the map c is an isomorphism, and if $j^*\mathscr{A}$ is an étale $\mathscr{O}_U$-algebra, the discussion of remark 17.4.35(v) identifies (17.4.40) with the map c.

If g is flat, the map a in (17.4.39) is an isomorphism (corollary 10.3.8). The isomorphism of remark 17.4.35(i) identifies b with the composition

$$g^*j_*\mathscr{H}om_{\mathscr{O}_X}(j^*\mathscr{A}, \mathscr{O}_U) \xrightarrow{d} j'_*g^*\mathscr{H}om_{\mathscr{O}_X}(j^*\mathscr{A}, \mathscr{O}_U) \xrightarrow{e} j'_*\mathscr{H}om_{\mathscr{O}_{U'}}(j'^*\mathscr{A}', \mathscr{O}_{U'})$$

where d is an isomorphism, since g is flat (corollary 10.3.8), and the same holds for e, since $j^*\mathscr{A}$ is locally free of finite type (proposition 10.3.3(ii)). To conclude, it then suffices to show that c is an isomorphism as well. The assertion is local on X, hence we may assume that X is affine; in this case, we may find a finitely presented $\mathscr{O}_X$-module $\mathscr{G}$ and an $\mathscr{O}_X$-linear epimorphism $\varphi : \mathscr{G} \to \mathscr{A}$ such that $j^*\varphi$ is an isomorphism. Set $\mathscr{G}' := g^*\mathscr{G}$; there follows a commutative diagram

$$\begin{array}{ccc} g^*(\mathscr{A}^\vee) & \xrightarrow{g^*(\varphi^\vee)} & g^*(\mathscr{G}^\vee) \\ \downarrow & & \downarrow \\ \mathscr{A}'^\vee & \xrightarrow{(\varphi^*g)^\vee} & \mathscr{G}'^\vee \end{array}$$

whose right vertical arrows is an isomorphism, by virtue of [75, Lemma 2.4.29(i)]. Moreover $\mathrm{Ker}\,(\varphi^\vee) = 0$ and $\mathrm{Coker}\,(\varphi^\vee) \subset (\mathrm{Ker}\,\varphi)^\vee$, and since $\mathrm{Max}\,X \subset U$, we see that $\mathrm{Ker}\,\varphi_\eta = 0$ for every $\eta \in \mathrm{Max}\,X$, whence $(\mathrm{Ker}\,\varphi)^\vee = 0$, since X is reduced. Thus, the top horizontal arrow of the foregoing diagram is also an isomorphism; the same argument applies as well to the bottom horizontal arrow, and the assertion follows. □

17.4.42. In the situation of (17.4.38), suppose now that X and X' are locally coherent and $\mathscr{A}$ is generically étale. Taking into account lemma 17.4.36(ii.b), we see that (17.4.40) factors as a composition

$$g^*\mathscr{D}^{-1}_{\mathscr{A}} \xrightarrow{\beta} (g^*\mathscr{D}^{-1}_{\mathscr{A}})^{\vee\vee} \xrightarrow{\gamma} \mathscr{D}^{-1}_{\mathscr{A}'}$$

where β is the natural map as in (11.3).

Proposition 17.4.43. *With the notation of* (17.4.42)*, suppose moreover that :*

(a) *both X and X' are locally noetherian normal schemes*
(b) *g maps the points of codimension one of X' to points of codimension ≤ 1 of X.*

Then γ is an isomorphism.

Proof. Set $\mathscr{B} := \mathrm{Im}\,(\mathscr{A} \to j_*j^*\mathscr{A})$ and $\mathscr{B}' := g^*\mathscr{B}$. It is easily seen that the image of $\mathscr{B}'$ in $j'_*j'^*\mathscr{B}'$ agrees with the image of $\mathscr{A}'$; in view of remark 17.4.35(ii) we deduce that the natural maps $\mathscr{A} \to \mathscr{B}$ and $\mathscr{A}' \to \mathscr{B}'$ induce isomorphisms

$$\mathscr{D}^{-1}_{\mathscr{A}} \xrightarrow{\sim} \mathscr{D}^{-1}_{\mathscr{B}} \qquad \mathscr{D}^{-1}_{\mathscr{A}'} \xrightarrow{\sim} \mathscr{D}^{-1}_{\mathscr{B}'}.$$

We may then replace $\mathscr{A}$ by $\mathscr{B}$, and assume that the natural map $\mathscr{A} \to j_*j^*\mathscr{A}$ is a monomorphism. By lemmata 11.3.3 and 17.4.36(ii.b), both the source and target of γ are reflexive $\mathscr{O}_{X'}$-modules. Thus, denote by $V \subset X'$ the subset of all points such that γ_x is an isomorphism; then V is an open subset of X' ([126, Th.4.10]) and the inclusion map $V \to X'$ is quasi-compact, since X' is locally noetherian. In view of proposition 11.3.8(ii), it suffices to check that V contains all the points of codimension one of X'. Thus, let x' be such a point, and set $x := g(x')$; by assumption (b), the point x has codimension ≤ 1 in X, so $\mathscr{O}_{X,x}$ is either a field or a discrete valuation ring and $(j_*j^*\mathscr{A})_x$ is a torsion-free $\mathscr{O}_{X,x}$-module of finite type. Then the same holds for $\mathscr{A}_x$, so the latter is a free $\mathscr{O}_{X,x}$-module of finite rank. By lemma 17.4.41, it follows that $(17.4.40)_{x'}$ is an isomorphism. It is also clear that $\beta_{x'}$ is an isomorphism, and since $\gamma_{x'} = (17.4.40)_{x'} \circ \beta^{-1}_{x'}$, the contention follows. □

Remark 17.4.44. (i) Let us now consider a domain A, and a finite, injective, and generically étale ring homomorphism $f : A \to B$. As in (17.4), we let $X := \mathrm{Spec}\,A$, and denote by $\mathscr{B}$ the quasi-coherent $\mathscr{O}_X$-algebra arising from B. Let also K be the field of fractions of A; set $B_K := K \otimes_A B$, and let $\overline{B}$ be the image of B in B_K. We may then regard the diagonal idempotent e_f of the map f as an element in $B_K \otimes_K B_K$, and the associated trace form as a K-bilinear map $B_K \otimes_K B_K \to K$, inducing an isomorphism $\omega_f : B_K \xrightarrow{\sim} B^\vee_K$. With this notation, the inverse different $\mathscr{D}^{-1}_{\mathscr{B}}$ corresponds to $\omega_f^{-1}(\overline{B}^\vee) \subset B_K$, and the subset

$$\mathscr{D}_{\mathscr{B}} := \{b \in B \mid b\mathscr{D}^{-1}_{\mathscr{B}} \subset \overline{B}\}$$

is an ideal of B called the *different of f*. (If A and B are noetherian normal domains, then $\mathscr{D}^{-1}_{\mathscr{B}}$ is the inverse of $\mathscr{D}_{\mathscr{B}}$ in the group of reflexive fractional ideals of B : see example 6.4.38.)

(ii) Suppose moreover that B is a *projective A-module*. Then we have a natural isomorphism $B \otimes_A B^\vee \xrightarrow{\sim} \mathrm{Hom}_A(B, B)$, and we denote by ζ_f the unique element of $B \otimes_A B^\vee$ corresponding to $\mathbf{1}_B : B \to B$ under this isomorphism. According to [75, Rem.4.1.17], we have the identity :

$$(B_K \otimes_K \omega_f)(e_f) = \zeta_f$$

and it follows easily that :

$$(B \otimes_A \mathscr{D}_{\mathscr{B}}) \cdot e_f \subset \mathrm{Im}(B \otimes_A B \to B_K \otimes_K B_K).$$

(iii) If B is not a projective A-module, the inclusion of (ii) can fail; however, if A is a regular and noetherian domain, theorem 17.4.19 tells us that we have at least :

$$(\mathscr{D}_{\mathscr{B}} \otimes_A \mathscr{D}_{\mathscr{B}}) \cdot e_f \subset \mathrm{Im}(B \otimes_A B \to B_K \otimes_K B_K).$$

17.5. **Big Cohen-Macaulay algebras.** We shall use the following auxiliary construction. For every abelian group $(G, 0, +)$, set

$$G^\diamond := G^{\mathbb{N}}/G^{(\mathbb{N})}.$$

Hence, the elements of $G^\diamond$ are represented by sequences $(g_n \mid n \in \mathbb{N})$ of elements of G, and such a sequence represents the zero element of the quotient group $G^\diamond \Leftrightarrow$ the set $\{n \in \mathbb{N} \mid g_n \neq 0\}$ is finite. Especially, $G = 0 \Leftrightarrow G^\diamond = 0$. Moreover, for every group homomorphism $\varphi : G \to H$, we have $\varphi^{\mathbb{N}}(G^{(\mathbb{N})}) \subset H^{(\mathbb{N})}$, hence φ induces a group homomorphism

$$\varphi^\diamond : G^\diamond \to H^\diamond$$

and the rules : $G \mapsto G^\diamond$ and $\varphi :\mapsto \varphi^\diamond$ define an endofunctor of the category of abelian groups. Notice as well that $(\varphi + \psi)^\diamond = \varphi^\diamond + \psi^\diamond$ for every pair of group homomorphisms $\varphi, \psi : G \to H$. Lastly, we have an injective natural transformation that maps G diagonally into $G^\diamond$

$$\Delta_G : G \to G^\diamond \quad : \quad g \mapsto (g, g, \dots).$$

• If $(R, +, \cdot, 0, 1)$ is a ring, then $R^{(\mathbb{N})}$ is an ideal of the R-algebra $R^{\mathbb{N}}$ (the product in the category of rings of copies of R indexed by $\mathbb{N}$), hence $R^\diamond$ is naturally an R-algebra via the map Δ_R, and for every ring homomorphism $\varphi : R \to S$, the map $\varphi^\diamond : R^\diamond \to S^\diamond$ is a ring homomorphism such that

$$\Delta_S \circ \varphi = \varphi^\diamond \circ \Delta_R.$$

• Moreover, if M is any R-module, then $M^{\mathbb{N}}$ is obviously an $R^{\mathbb{N}}$-module, and since $R^{(\mathbb{N})} \cdot M^{\mathbb{N}} = M^{(\mathbb{N})}$, it follows that $M^\diamond$ is naturally an $R^\diamond$-module, and for every R-linear map $f : M \to N$, the map $f^\diamond : M^\diamond \to N^\diamond$ is $R^\diamond$-linear.

Lemma 17.5.1. (i) *The functor* $(-)^\diamond : R\text{-}\mathbf{Mod} \to R^\diamond\text{-}\mathbf{Mod}$ *is exact and faithful.*

(ii) *We have* $(IM)^\diamond = IM^\diamond$ *for every ideal* $I \subset R$ *of finite type, and every* R*-module* M.

Proof. (i): Since we have $M = 0 \Leftrightarrow M^\diamond = 0$, it is clear that $(-)^\diamond$ is faithful. Next, let $f : M \to N$ be an R-linear map, and $g_\bullet := (g_n \mid n \in \mathbb{N}) \in M^{\mathbb{N}}$; denote by $\overline{g}_\bullet \in M^\diamond$ the class of $g_\bullet$, and suppose that $f^\diamond(\overline{g}_\bullet) = 0$. This means that there exists $k \in \mathbb{N}$ such that $f(g_n) = 0$ for every $n \geq k$; then clearly $\overline{g}_\bullet$ is in the image of the natural map $(\mathrm{Ker}\, f)^\diamond \to M^\diamond$. In particular, if φ is injective, the same holds for $\varphi^\diamond$, and it is also clear that if φ is surjective, the same holds for $\varphi^\diamond$. It follows that the natural surjection $N \to \mathrm{Coker}\, f$ induces a surjection $N^\diamond \to (\mathrm{Coker}\, f)^\diamond$, whose kernel is $(\mathrm{Im}\, f)^\diamond$, and it is easily seen that $(\mathrm{Im}\, f)^\diamond = \mathrm{Im}(f^\diamond)$; hence $(\mathrm{Coker}\, f)^\diamond$ represents $\mathrm{Coker}(f^\diamond)$, whence the exactness of $(-)^\diamond$.

(ii): Let $a_1, \dots, a_k$ a finite system of generators of I; there follows an R-linear surjection $f : M^{\oplus k} \to IM$ whose composition with the inclusion map $j : IM \to M$ is given by the rule : $(m_1, \dots, m_k) \mapsto a_1 m_1 + \cdots + a_k m_k$. Hence $j^\diamond \circ f^\diamond = (j \circ f)^\diamond : (M^\diamond)^{\oplus k} \to M^\diamond$ is given by the same rule, and by the foregoing $f^\diamond : (M^\diamond)^{\oplus k} \to (IM)^\diamond$ is a surjection, whence the claim. □

17.5.2. Let now $(V, \mathfrak{m})$ be a basic setup (in the sense of [75, §2.1.1]), such that $\mathfrak{m}$ is the filtered union of a countable system of principal subideals. We consider the subset

$$\mathsf{S} \subset V^{\mathbb{N}}$$

of all $(a_n \mid n \in \mathbb{N})$ such that $Va_n \subset Va_{n+1}$ for every $n \in \mathbb{N}$, and $\mathfrak{m} \subset \bigcup_{n \in \mathbb{N}} Va_n$.

Remark 17.5.3. (i) Since $\mathfrak{m} = \mathfrak{m}^2$, it is easily seen that S is a multiplicative system.

(ii) Also, for every V-module M we have

$$\mathrm{Ker}(j_M : M^\diamond \to \mathsf{S}^{-1}M^\diamond) = \{x \in M^\diamond \mid \mathfrak{m}x = 0\} \qquad \text{and} \qquad \mathfrak{m} \cdot \mathrm{Coker}(j_M) = 0.$$

Especially, $j^a_M : (M^\diamond)^a \to (\mathsf{S}^{-1}M^\diamond)^a$ is an isomorphism of $(V,\mathfrak{m})^a$-modules.

(iii) Notice that S contains the multiplicative subset $\mathsf{T} := (e_{k,\bullet} \mid k \in \mathbb{N})$, where $e_{k,\bullet} := (e_{k,n} \mid n \in \mathbb{N})$, with $e_{k,n} := 0$ for every $n = 0, \dots, k-1$ and $e_{k,n} := 1$ for every $n \geq k$. Notice moreover that $e_{k,\bullet}$ is invertible in $V^\diamond$ for every $k \in \mathbb{N}$, and for every V-module M the projection $M^{\mathbb{N}} \to M^\diamond$ factors through the localization $M^{\mathbb{N}} \to \mathsf{T}^{-1}M^{\mathbb{N}}$ and an isomorphism

$$\mathsf{T}^{-1}M^{\mathbb{N}} \xrightarrow{\sim} M^\diamond.$$

Hence, we also get an isomorphism of $V^\diamond$-modules

$$\mathsf{S}^{-1}M^\diamond \xrightarrow{\sim} \mathsf{S}^{-1}M^{\mathbb{N}} \qquad \text{for every } V\text{-module } M.$$

Lemma 17.5.4. *In the situation of* (17.5.2)*, let $A \to V$ be a ring homomorphism. We have :*

(i) *$M^a = 0$ if and only if $\mathsf{S}^{-1}M^\diamond = 0$.*

(ii) *The functor V-$\mathbf{Mod} \to V^\diamond$-$\mathbf{Mod}$: $M \mapsto \mathsf{S}^{-1}M^\diamond$ factors via an exact faithful functor*

$$\mathsf{S}^{-1}(-)^\diamond : V^a\text{-}\mathbf{Mod} \to V^\diamond\text{-}\mathbf{Mod} \qquad M^a \mapsto \mathsf{S}^{-1}M^\diamond.$$

(iii) *The unit of adjunction $\mathsf{S}^{-1}M^\diamond \to (\mathsf{S}^{-1}M^\diamond)^a_*$ is an isomorphism of V-modules.*

(iv) *If A is a coherent ring, then $\mathsf{S}^{-1}M^\diamond$ is a flat A-module if and only if M^a is flat over A in the sense of definition* 14.2.40.

(v) *If A is noetherian, then $\mathsf{S}^{-1}M^\diamond$ is a faithfully flat A-module if and only if M^a is faithfully flat over A in the sense of definition* 14.2.40.

Proof. The proof of (i) shall be left to the reader.

(ii) is an immediate consequence of (i) and lemma 17.5.1(i).

(iii): Let $x \in \mathsf{S}^{-1}M^\diamond$ be an element such that $\mathfrak{m} \cdot x = 0$, and write $x = s_\bullet^{-1}m_\bullet$ for some $s_\bullet := (s_n \mid n \in \mathbb{N}) \in \mathsf{S}$ and $m_\bullet := (m_n \mid n \in \mathbb{N}) \in M^\diamond$. Let us also write $\mathfrak{m} = \bigcup_{i\in\mathbb{N}} Va_n$ for a sequence $(a_i \mid i \in \mathbb{N})$ of elements of V such that $Va_i \subset \mathfrak{m} \cdot a_{i+1}$ for every $i \in \mathbb{N}$. Then, for every $i \in \mathbb{N}$ there exist $\rho(i) \in \mathbb{N}$, $c_i \in \mathfrak{m}$, and $t_{i,\bullet} := (t_{i,n} \mid n \in \mathbb{N}) \in \mathsf{S}$ such that

$$a_i = c_i a_{i+1} \qquad \text{and} \qquad a_i m_n t_{i,n} = 0 \qquad \text{for every } n \geq \rho(i)$$

and we may assume that $\rho(i+1) > \rho(i)$ for every $i \in \mathbb{N}$. Moreover, since $\mathfrak{m} \subset \bigcup_{n\in\mathbb{N}} Vt_{i,n}$, we may also assume that $a_i \in Vt_{i,n}$ for every $n \geq \rho(i)$, in which case we get :

$$a_i^2 m_n = 0 \qquad \text{for every } i \in \mathbb{N} \text{ and } n \geq \rho(i).$$

Hence, let $b_\bullet := (b_n \mid n \in \mathbb{N}) \in V^{\mathbb{N}}$ be the element such that $b_n := 0$ for every $n < \rho(0)$, and $b_n := a_i^2$ for every $i \in \mathbb{N}$ and every $n = \rho(i), \dots, \rho(i+1)-1$. It follows easily that $b_\bullet \in \mathsf{S}$ and $b_\bullet \cdot m_\bullet = 0$ in $M^\diamond$, so finally $x = 0$. This shows that the unit of adjunction $\eta_{\mathsf{S}^{-1}M^\diamond} : \mathsf{S}^{-1}M^\diamond \to (\mathsf{S}^{-1}M^\diamond)^a_*$ is injective. Next, let $y \in (\mathsf{S}^{-1}M^\diamond)^a_*$. By remark 16.9.32(ii), the V-module $\widetilde{\mathfrak{m}}$ is the inductive limit of a system $(L_n \mid n \in \mathbb{N})$ with $L := V$ for every $n \in \mathbb{N}$, and with V-linear transition maps $\varphi_n : L_n \to L_{n+1}$ such that $\varphi_n(1) = c_n$ for every $n \in \mathbb{N}$; hence y is represented by a system $(y^{(n)} \mid n \in \mathbb{N})$ of elements of $\mathsf{S}^{-1}M^\diamond$ such that

$$(17.5.5) \qquad c_n y^{(n+1)} = y^{(n)} \qquad \text{for every } n \in \mathbb{N}.$$

Claim 17.5.6. Let $\Sigma \subset \mathsf{S}$ be any countable subset. Then $\mathsf{S} \cap \bigcap_{s_\bullet\in\Sigma} V^\diamond s_\bullet \neq \varnothing$.

Proof of the claim. Say that $\Sigma = \{s_{n,\bullet} \mid n \in \mathbb{N}\}$. Let the sequence $(a_n \mid n \in \mathbb{N})$ of generators of $\mathfrak{m}$ be as in the foregoing; then, for every $n, k \in \mathbb{N}$ there exists $\rho(n,k) \in \mathbb{N}$ such that

$$a_k \in Vs_{n,j} \qquad \text{for every } j \geq \rho(n,k).$$

Hence, for every $k \in \mathbb{N}$, we can find $\rho'(k) \in \mathbb{N}$ such that

$$a_k \in Vs_{n,j} \qquad \text{for every } n = 0, \dots, k \text{ and every } j \geq \rho'(k)$$

and moreover we may assume that $\rho'(k+1) > \rho'(k)$ for every $k \in \mathbb{N}$. Then, let $x_\bullet := (x_n \mid n \in \mathbb{N}) \in V^{\mathbb{N}}$ be the sequence such that $x_n := 0$ for every $n = 0, \dots, \rho'(0)-1$, and $x_n := a_k$

whenever $\rho'(k) \leq n < \rho'(k+1)$, for every $k \in \mathbb{N}$. It is easily seen that $x_\bullet \in \mathsf{S} \cap V^\diamond s_{n,\bullet}$ for every $n \in \mathbb{N}$, whence the claim. ◊

Now, say that $y^{(n)} = s_{n,\bullet}^{-1} m_{n,\bullet}$, with $s_{n,\bullet} \in \mathsf{S}$ and $m_{n,\bullet} \in M^\diamond$ for every $n \in \mathbb{N}$; by claim 17.5.6, we may assume that all the elements $s_{n,\bullet}$ are equal, in which case (17.5.5) amounts to the identities :

$$m_{n,\bullet} = c_n m_{n+1,\bullet} \qquad \text{in } \mathsf{S}^{-1}M^\diamond \text{ for every } n \in \mathbb{N}.$$

The latter in turns means that for every $n \in \mathbb{N}$ there exists $t_{n,\bullet} \in \mathsf{S}$ such that $t_{n,\bullet} m_{n,\bullet} = c_n t_{n,\bullet} m_{n+1,\bullet}$ in $M^\diamond$. By invoking again claim 17.5.6, we may also assume that all the $t_{n,\bullet}$ are equal; then set $m'_{n,\bullet} := t_{0,\bullet} m_{n,\bullet}$ for every $n \in \mathbb{N}$, so that $m'_{n,\bullet} = c_n m'_{n+1,\bullet}$ in $M^\diamond$ for every $n \in \mathbb{N}$. The latter means that for every $n \in \mathbb{N}$ there exists $\rho(n) \in \mathbb{N}$ such that

$$m_{n,j} = c_n m_{n+1,j} \qquad \text{for every } j \geq \rho(n)$$

and we may assume that $\rho(n+1) > \rho(n)$ for every $n \in \mathbb{N}$. Then, let $t_\bullet := (t_n \mid n \in \mathbb{N}) \in V^{\mathbb{N}}$ (resp. $l_\bullet := (l_n \mid n \in \mathbb{N}) \in M^{\mathbb{N}}$) be the element with $t_j := 0$ (resp. $l_j := 0$) for $j = 0, \dots, \rho(0) - 1$ and $t_j := a_n$ (resp. $l_j := m_{n,j}$) whenever $\rho(n) \leq j < \rho(n+1)$, for every $n \in \mathbb{N}$.

Claim 17.5.7. $t_\bullet m_{n,\bullet} = a_n l_\bullet$ in $M^\diamond$ for every $n \in \mathbb{N}$.

Proof of the claim. It suffices to show that for every $k \geq n$ and every $j = \rho(k), \dots, \rho(k+1) - 1$ we have $a_k m_{n,j} = a_n m_{k,j}$. The latter follows by a simple inspection. ◊

Set $z := t_\bullet^{-1} l_\bullet$; claim 17.5.7 implies that $m_{n,\bullet} = a_n y$ in $\mathsf{S}^{-1}M^\diamond$ for every $n \in \mathbb{N}$; hence $\eta_{\mathsf{S}^{-1}M^\diamond}(z) = y$, whence the assertion.

(iv): Suppose that M^a is flat over A, and let $I \subset A$ be an ideal of finite type; in light of lemma 17.5.1(ii), it suffices to check that the natural map

$$f : I \otimes_A \mathsf{S}^{-1}M^\diamond \to \mathsf{S}^{-1}(IM)^\diamond$$

is an isomorphism. Now, it is easily seen that for every A-module N of finite type, the natural map $N \otimes_A \mathsf{S}^{-1}M^\diamond \to \mathsf{S}^{-1}(N \otimes_A M)^\diamond$ is surjective; on the other hand, since A is coherent, there exists $k \in \mathbb{N}$ and a surjective A-linear map $A^{\oplus k} \to I$, whose kernel is an A-module N of finite type. Thus, we have the following commutative diagram

$$\begin{array}{ccccccccc}
0 & \longrightarrow & N \otimes_A \mathsf{S}^{-1}M^\diamond & \longrightarrow & A^{\oplus k} \otimes_A \mathsf{S}^{-1}M^\diamond & \longrightarrow & I \otimes_A \mathsf{S}^{-1}M^\diamond & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow{\scriptstyle f} & & \\
0 & \longrightarrow & \mathsf{S}^{-1}(N \otimes_A M)^\diamond & \longrightarrow & \mathsf{S}^{-1}(M^{\oplus k})^\diamond & \longrightarrow & \mathsf{S}^{-1}(IM)^\diamond & \longrightarrow & 0
\end{array}$$

whose first and third vertical arrows are surjections, and whose central vertical arrow is an isomorphism. Moreover, the top horizontal sequence is right exact, and since M^a is flat over A, combining (i) and lemma 17.5.1(i) it is easily seen that the bottom horizontal arrow is a short exact sequence. Then, by the snake lemma, $\operatorname{Ker} f = 0$, whence the contention.

Conversely, suppose that $\mathsf{S}^{-1}M^\diamond$ is a flat A-module, and consider any short exact sequence $\Sigma := (0 \to N' \to N \to N'' \to 0)$ of A-modules; we need to show that the induced sequence $M^a \otimes_A \Sigma$ is still exact. To this aim, notice that Σ is the filtered colimit of a system of short exact sequences $(0 \to N'_\lambda \to N_\lambda \to N''_\lambda \to 0 \mid \lambda \in \Lambda)$ such that N_λ and N''_λ are finitely presented A-modules, for every $\lambda \in \Lambda$. Thus, we may assume that N and N'' is finitely presented, in which case the same holds for N', since A is coherent, and we consider the diagram :

$$\begin{array}{ccccccccccc}
\Sigma \otimes_A \mathsf{S}^{-1}M^\diamond & \quad & 0 & \longrightarrow & N' \otimes_A \mathsf{S}^{-1}M^\diamond & \longrightarrow & N \otimes_A \mathsf{S}^{-1}M^\diamond & \longrightarrow & N'' \otimes_A \mathsf{S}^{-1}M^\diamond & \longrightarrow & 0 \\
\downarrow & & & & \downarrow & & \downarrow & & \downarrow & & \\
\mathsf{S}^{-1}((\Sigma \otimes_A M)^\diamond) & & 0 & \longrightarrow & \mathsf{S}^{-1}(N' \otimes_A M)^\diamond & \longrightarrow & \mathsf{S}^{-1}(N \otimes_A M)^\diamond & \longrightarrow & \mathsf{S}^{-1}(N'' \otimes_A M)^\diamond & \longrightarrow & 0.
\end{array}$$

Since N, N' and N'' are finitely presented, lemma 17.5.1(i) easily implies that all the vertical arrows are isomorphisms. By assumption, the top horizontal row is short exact, hence the same holds for the bottom one, and therefore the sequence of $(V, \mathfrak{m})^a$-modules $((\Sigma \otimes_A M)^\diamond)^a$ is short exact; then we conclude by invoking again lemma 17.5.1(i).

(v): Suppose that M^a is faithfully flat over A; in view of (iv), it suffices to show that for every A-module $N \neq 0$ of finite type, we have $\mathsf{S}^{-1}M^\diamond \otimes_A N \neq 0$. But then N is finitely presented, since A is noetherian, hence the natural map $\mathsf{S}^{-1}M^\diamond \otimes_A N \to \mathsf{S}^{-1}(M \otimes_A N)^\diamond$ is an isomorphism, and by assumption $M^a \otimes_A N \neq 0$; then the assertion follows from (i). One argues similarly for the converse : details left to the reader. □

Proposition 17.5.8. *In the situation of* (17.5.2)*, let $I \subset V$ be any ideal of finite type; then both $M^\diamond$ and $\mathsf{S}^{-1}M^\diamond$ are I-adically complete V-modules.*

Proof. Let $x_{\bullet\bullet} := (x_{k,\bullet} \mid k \in \mathbb{N})$ be a Cauchy sequence for the I-adic topology in $M^\diamond$. Hence, $x_{k,\bullet}$ is the class of a sequence $(x_{k,i} \mid i \in \mathbb{N})$, for every $i \in \mathbb{N}$, and after replacing $x_{\bullet\bullet}$ by a subsequence, we may assume that $x_{k,\bullet} - x_{k+1,\bullet} \in I^k M^\diamond$ for every $k \in \mathbb{N}$. In light of lemma 17.5.1(ii), the latter means that for every $k \in \mathbb{N}$ there exists $n(k) \in \mathbb{N}$ such that $x_{k,i} - x_{k+1,i} \in I^k M$ for every $i \geq n(k)$, and clearly we may assume that $n(k+1) > n(k)$ for every $k \in \mathbb{N}$. Now, let $y_\bullet := (y_i \mid i \in \mathbb{N})$ be the following element of $M^\diamond$. For every $i \leq n(0)$ we let $y_i := x_{0,i}$; then, for every $k \in \mathbb{N}$ and $n(k) < i \leq n(k+1)$ we let $y_i := x_{k+1,i}$. For every $k \geq j$ and $n(k) < i \leq n(k+1)$, we get :

$$y_i - x_{j,i} = (x_{k+1,i} - x_{k,i}) + \cdots + (x_{j+1,i} - x_{j,i}) \in I^k M + \cdots + I^j M = I^j M.$$

Hence, $y_\bullet - x_{j,\bullet} \in I^j M^\diamond$ for every $j \in \mathbb{N}$, so $y_\bullet$ is a limit of $x_{\bullet\bullet}$.

Next, let $x_{\bullet\bullet} := (x_{k,\bullet} \mid k \in \mathbb{N})$ be a Cauchy sequence for the I-adic topology in $\mathsf{S}^{-1}M^\diamond$; again, we may assume that $y_{k,\bullet} := x_{k+1,\bullet} - x_{k,\bullet} \in I^k\mathsf{S}^{-1}M^\diamond$ for every $k \in \mathbb{N}$, and then there exist $s_{k,\bullet} \in \mathsf{S}$ and $z_{k,\bullet} \in I^k M^\diamond$ with $y_{k,\bullet} = s_{k,\bullet}^{-1} \cdot z_{k,\bullet}$ for every $k \in \mathbb{N}$. Also, we may assume :

$$s_{k+1,\bullet} \in V^{\mathbb{N}} s_{k,\bullet} \qquad \text{for every } k \in \mathbb{N}. \tag{17.5.9}$$

Now, by assumption there exists a sequence $(a_n \mid n \in \mathbb{N})$ of elements of V such that $Va_n \subset Va_{n+1}$ for every $n \in \mathbb{N}$, and $\bigcup_{n \in \mathbb{N}} Va_n = \mathfrak{m}$. For every $k \in \mathbb{N}$ we define inductively a sequence of integers $(n(k,i) \mid i \in \mathbb{N})$ as follows. For $i = 0$, let $n(k,0)$ be the smallest of the integers $n \in \mathbb{N}$ such that $a_0 \in Vs_{k,n}$; then, for every $i > 0$ let $n(k,i) \in \mathbb{N}$ be the smallest of the integers $n > n(k,i-1)$ such that $a_i \in Vs_{k,n}$. Notice that (17.5.9) implies

$$n(k+1,i) \geq n(k,i) \qquad \text{for every } k,i \in \mathbb{N}.$$

Lastly, let $t_\bullet$ be the sequence such that $t_n := 0$ for every $n < n(0,0)$, and $t_n := a_i$ for every $n, i \in \mathbb{N}$ with $n(i,i) \leq n < n(i+1,i+1)$. We have $t_\bullet \in \mathsf{S}$, and $t_i \in Vs_{k,i}$ for every $k \in \mathbb{N}$ and every $i \geq n(k,k)$; thus, the class of $s_{k,\bullet}$ in $V^\diamond$ divides the class of $t_\bullet$, and we may replace $s_{k,\bullet}$ by $t_\bullet$ for every $k \in \mathbb{N}$. By the foregoing case, the series $\sum_{k \in \mathbb{N}} z_{k,\bullet}$ converges in $M^\diamond$, and let $z_\bullet$ be a limit; then $t_\bullet^{-1} z_\bullet$ is a limit for $x_{\bullet\bullet}$ in $\mathsf{S}^{-1}M^\diamond$. □

Lemma 17.5.10. *In the situation of* (16.9.34)*, let us endow $\mathsf{S}^{-1}A_0^\diamond$ with its b-adic topology, and let $A_0^\wedge$ be the b-adic completion of A_0; then the basic setup $(A_0^\wedge, \mathfrak{m}A_0^\wedge)$ is almost perfectoid if and only if the maximal separated quotient $(\mathsf{S}^{-1}A_0^\diamond)^{\mathrm{sep}}$ of $\mathsf{S}^{-1}A_0^\diamond$ is perfectoid.*

Proof. Clearly $\mathsf{S}^{-1}\overline{\Phi}_{A_0}^\diamond : \mathsf{S}^{-1}(A_0/bA_0)^\diamond \to \mathsf{S}^{-1}(A_0/b^pA_0)^\diamond$ is the ring endomorphism induced by Frobenius endomorphism of $\mathsf{S}^{-1}(A_0/b^pA_0)^\diamond$. On the other hand, by lemma 17.5.4(ii), $\overline{\Phi}_{A_0}^a$ is an isomorphism if and only if the same holds for $\mathsf{S}^{-1}\overline{\Phi}_{A_0}^\diamond$. Notice also that $C := (\mathsf{S}^{-1}A_0^\diamond)^{\mathrm{sep}}$ is b-adically complete and separated, by virtue of propositions 17.5.8 and 8.2.13(v). Then let $\overline{\Phi}_C : C/bC \to C/b^pC$ be the ring homomorphism induced by the Frobenius endomorphism of C/b^pC; in view of theorem 16.4.1, we are reduced to showing :

Claim 17.5.11. $\overline{\Phi}_C$ is an isomorphism if and only if the same holds for $\mathsf{S}^{-1}\overline{\Phi}^\diamond_{A_0}$.

Proof of the claim. By lemma 17.5.1(ii), the projection $A_0 \to A_0/bA_0$ induces a ring isomorphism $\mathsf{S}^{-1}A_0^\diamond/(b) \xrightarrow{\sim} \mathsf{S}^{-1}(A_0/bA_0)^\diamond$, and likewise $\mathsf{S}^{-1}A_0^\diamond/(b^p) \xrightarrow{\sim} \mathsf{S}^{-1}(A_0/b^pA_0)^\diamond$. Therefore, the projections $\mathsf{S}^{-1}A_0^\diamond \to C/bC$ and $\mathsf{S}^{-1}A_0^\diamond \to C/b^pC$ factor through ring isomorphisms

$$\mathsf{S}^{-1}(A_0/bA_0)^\diamond \xrightarrow{\sim} C/bC \qquad \mathsf{S}^{-1}(A_0/b^pA_0)^\diamond \xrightarrow{\sim} C/b^pC$$

whence the claim. ☐

Remark 17.5.12. As an alternative to our constructions of $G^\diamond$ and $\mathsf{S}^{-1}M^\diamond$, one could use an ultraproduct with respect to a non-principal ultrafilter of $\mathbb{N}$: this would lead to analogous results. In a similar vein, see remark 17.5.47.

17.5.13. Let A be a Tate ring, $A_0 \subset A$ a subring of definition, and $p \in \mathbb{N}$ a prime integer; suppose that there exists $b \in A_0^{\circ\circ} \cap A^\times$ with $pA_0 \subset b^pA_0$, and let $A_0^\wedge$ be the b-adic completion of A_0. Let also $g_\bullet := (g_n \mid n \in \mathbb{N}) \in \mathbf{E}(A_0)$, and set $g := g_0 \in A_0$, so that g^γ is well defined in A_0 for every $\gamma \in \mathbb{N}[1/p]$. We let $\mathfrak{m} := \bigcup_{\gamma\in\mathbb{N}[1/p]\setminus\{0\}} A_0g^\gamma$, and we suppose that the basic setup $(A_0^\wedge, \mathfrak{m}A_0^\wedge)$ is almost perfectoid (see definition 16.9.35).

Proposition 17.5.14. *In the situation of* (17.5.13)*, suppose moreover that A_0 is complete and separated, and let A_0^ν be the integral closure of the image of A_0 in $A_0[1/g]$. Then we have :*

(i) *The induced morphism $A_0^a \to (A_0^\nu)^a$ is an isomorphism of $(A_0, \mathfrak{m})^a$-algebras.*
(ii) *If moreover, the unit of adjunction $A_0 \to A_{0*}^a$ is an isomorphism, the same holds for the natural map $A_0 \to A_0^\nu$.*

Proof. (i): Let us check first that the kernel of the localization $A_0 \to A_0[1/g]$ is annihilated by $\mathfrak{m}$. Hence, let $x \in A_0$ such that $g^nx = 0$ for some $n \in \mathbb{N}$, and denote by $\overline{x}_\bullet \in B := (\mathsf{S}^{-1}A_0^\diamond)^{\mathrm{sep}}$ the image of the constant sequence $(x, x, x, \dots) \in A_0^{\mathbb{N}}$ (notation of lemma 17.5.10). Since B is reduced (corollary 16.3.63), we have $g^\gamma \cdot \overline{x} = 0$ in B for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$. The latter means that for all $i \in \mathbb{N}$ and $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$ there exists $s_\bullet := (s_n \mid n \in \mathbb{N}) \in \mathsf{S}$ such that $s_\bullet \cdot g^\gamma \cdot \overline{x} \in b^iA_0^\diamond$. In turn, this means that for every such i and γ there exists $s_\bullet$ and $n \in \mathbb{N}$ such that $s_mg^\gamma x \in b^iA_0$ for every $m \geq n$; equivalently, for every $i \in \mathbb{N}$ and $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$ we have $g^\gamma x \in b^iA_0$, and then $g^\gamma x = 0$ in A_0 for every such γ, as required.

Next, we show that the cokernel of the map $A_0 \to A_0^\nu$ is annihilated by $\mathfrak{m}$. Indeed, let $a/g^n \in A_0^\nu$ for some $a \in A_0$ and $n \in \mathbb{N}$, and denote by $\overline{a}_\bullet \in B$ the image of the constant sequence $(a, a, a, \dots) \in A_0^{\mathbb{N}}$. Hence $\overline{a}_\bullet/g^n \in B[g^{-1}]$ lies in the integral closure C of the image $\overline{B}$ of B in $B[1/g]$. Since B is perfectoid, the induced map $B^a \to C^a$ is an isomorphism of $(A_0, \mathfrak{m})^a$-algebras (theorem 16.9.42(iv)), hence $g^\gamma \cdot (\overline{a}_\bullet/g^n) \in \overline{B}$ for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$; then there exists $y_\bullet := (y_n \mid n \in \mathbb{N}) \in B$ such that

$$g^{\gamma+\gamma'} \cdot \overline{a}_\bullet = g^{n+\gamma'} \cdot y_\bullet \qquad \text{for every } \gamma, \gamma' \in \mathbb{N}[1/p].$$

Hence, for every $i \in \mathbb{N}$ there exists $s_\bullet \in \mathsf{S}$ such that $s_\bullet(g^{\gamma+\gamma'} \cdot \overline{a}_\bullet - g^{n+\gamma'} \cdot y_\bullet) \in b^iA_0^\diamond$. The latter implies that for every $i \in \mathbb{N}$ and every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$ the image $z_{\gamma,i}$ of $g^\gamma a$ in A_0/b^iA_0 lies in $J_i := g^n(A_0/b^iA_0)$. For every $i \in \mathbb{N}$, let $K_i := \mathrm{Ker}\, g^n\mathbf{1}_{A_0/b^iA_0}$; we get an exact sequence

$$K := \lim_{i\in\mathbb{N}} K_i \to A_0 = \lim_{i\in\mathbb{N}} A_0/b^iA_0 \xrightarrow{\alpha} J := \lim_{i\in\mathbb{N}} J_i \to \lim_{n\in\mathbb{N}}{}^1 K_i$$

and notice that $K = \mathrm{Ker}\, g^n\mathbf{1}_{A_0}$ lies in the kernel of the localization $A_0 \to A_0[1/g]$, hence $K^a = 0$, by the foregoing. Moreover, the system of inclusions $(J_i \to A_0/b^iA_0 \mid i \in \mathbb{N})$ induces a map $\beta : J \to A_0$ such that $\beta \circ \alpha = g^n\mathbf{1}_{A_0}$.

Claim 17.5.15. The inverse system $(K_i \mid i \in \mathbb{N})$ is almost essentially zero.

Proof of the claim. Since A_0 is almost perfectoid, the Frobenius endomorphism of A_0/b^pA_0 induces a map $A_0/bA_0 \to A_0/b^pA_0$ whose kernel is almost zero. By a simple induction on j, it follows that for every $j \in \mathbb{N}$ and every $x \in A_0$ such that $x^p \in b^{pj}A_0$, we have $g^\gamma x \in b^jA_0$ for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$. Now, fix $i, k \in \mathbb{N}$ and let $x \in A_0$ whose class in $A_0/b^{p^ki}A_0$ lies in K_{p^ki}, *i.e.* $g^nx \in b^{p^ki}A_0$. Then $(g^{n/p^k}x)^{p^k} \in b^{p^ki}A_0$, and an easy induction on j yields

$$(g^{(j+1)n/p^k}x)^{p^{k-j}i} \in b^{p^{k-j}i}A_0 \qquad \text{for every } j = 0, \dots, k.$$

For $j = k$, it follows that $g^{(k+1)n/p^k}x \in b^iA_0$. This shows that for every $i \in \mathbb{N}$ and every $\beta \in \mathbb{N}[1/p] \setminus \{0\}$ there exists $k \in \mathbb{N}$ such that the image of K_{p^ki} in K_i is annhilated by g^β, whence the contention. ♢

From proposition 14.2.25(iii) and claim 17.5.15 we get $\lim^1_{i\in\mathbb{N}} K_i^a = 0$, hence α is almost surjective. By construction, $z_{\gamma,\bullet} := (z_{\gamma,i} \mid i \in \mathbb{N}) \in \lim_{i\in\mathbb{N}} J_i$; so we find for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$ an element $a' \in A$ such that $\alpha(a') = g^\gamma z_{\gamma,\bullet}$, whence $g^na' = \beta \circ (a') = g^\gamma\beta(z_{\gamma,\bullet}) = g^{2\gamma}a$. The image of a' in A_0^ν therefore equals $g^{2\gamma}(a/g^n)$, and the proof of (i) is complete.

(ii): We have already seen that $\mathfrak{m}$ annihilates the kernel of the localization $j : A_0 \to A_0[1/g]$; on the other hand, A^a_{0*} has no $\mathfrak{m}$-torsion elements, so j is injective under the assumptions of (ii). By (i), the inclusion map $A_0 \to A_0^\nu$ induces an isomorphism $A_0 \xrightarrow{\sim} A^a_{0*} \xrightarrow{\sim} (A_0^\nu)^a_*$, and notice that $(A_0^\nu)^a_*$ is a subring of $A_0[1/g]$ containing A_0^ν; the assertion follows immediately. □

Proposition 17.5.16. *In the situation of* (17.5.13)*, let $h \in A_0$, and set $B := A_0[h^{1/p^\infty}] = A_0[X^{1/p^\infty}]/(X - h)$. Let moreover C be the p-root closure of B in $B[1/b]$, and $C^\wedge$ the b-adic completion of C. Then C^a is a faithfully flat $(A_0, \mathfrak{m})^a$-algebra, and the basic setup $(C^\wedge, \mathfrak{m}C^\wedge)$ is almost perfectoid for the b-adic topology of $C^\wedge$.*

Proof. For every A_0-module M, let $\Delta_M : M \to M^{\mathbb{N}}$ be the diagonal map, and for every $n \in \mathbb{N}$, let $\pi_{M,n} : M^{\mathbb{N}} \to M$ be the projection on the n-th factor. Let us regard $A_0^{\mathbb{N}}$ as an A_0-algebra via $\Delta_{A_0} : A_0 \to A_0^{\mathbb{N}}$, and denote by C' the p-root closure of $B' := B \otimes_{A_0} A_0^{\mathbb{N}}$ in $B'[1/b]$. By remark 9.8.25(ii), the induced map $B[1/b] \to B'[1/b]$ restricts to a ring homomorphism $j_C : C \to C'$. By the same token, $B[1/p] \otimes_{A_0} \pi_{A_0,n} : B'[1/b] \to B[1/b]$ restricts to a map $\varphi_{C,n} : C' \to C$ such that $\varphi_{C,n} \circ j_C = \mathbf{1}_C$, for every $n \in \mathbb{N}$. For every such M and every $n \in \mathbb{N}$ we then get maps of A_0-modules :

$$T_0 := \mathrm{Tor}_1^{A_0}(M, C) \xrightarrow{\alpha} T := \mathrm{Tor}_1^{A_0^{\mathbb{N}}}(M^{\mathbb{N}}, C') \xrightarrow{\beta_n} T_0$$

where α is induced by $(\Delta_{A_0}, \Delta_M, j_C)$, and β_n is induced by $(\pi_{A_0,n}, \pi_{M,n}, \varphi_{C,n})$. On the other hand, $\mathsf{S}^{-1}A_0^{\mathbb{N}}$ is a formally perfectoid ring for its b-adic topology, by lemma 17.5.10 and remark 17.5.3(iii), hence $\mathsf{S}^{-1}C'$ is a faithfully flat $\mathsf{S}^{-1}A_0^{\mathbb{N}}$-algebra, by theorem 16.9.17(i) and lemma 9.8.26(iv). Hence, $\mathsf{S}^{-1}T = 0$. Now, let $x \in T_0$; then there exists $s_\bullet := (s_n \mid n \in \mathbb{N}) \in \mathsf{S}$ with $s_\bullet \cdot \alpha(x) = 0$ in T, whence $s_n \cdot \beta_n \circ \alpha(x) = s_nx = 0$ in T_0 for every $n \in \mathbb{N}$, so $T_0^a = 0$. This shows that C^a is a flat A_0^a-algebra. Next, consider, for every $n \in \mathbb{N}$, the commutative diagram :

$$\begin{array}{ccc} M & \xrightarrow{\quad\Delta_M\quad} & M^{\mathbb{N}} \\ {\scriptstyle\gamma}\downarrow & & \downarrow{\scriptstyle\delta} \\ C \otimes_{A_0} M & \xrightarrow{j_C \otimes_{A_0} \Delta_M} & C' \otimes_{A_0^{\mathbb{N}}} M^{\mathbb{N}} \end{array}$$

and let $y \in \mathrm{Ker}\,\gamma$; then $\Delta_M(y) \in \mathrm{Ker}\,\delta$, and since $\mathsf{S}^{-1}C'$ is a faithfully flat $\mathsf{S}^{-1}A_0^{\mathbb{N}}$-algebra, it follows that there exists $s_\bullet \in \mathsf{S}$ with $s_\bullet \cdot \Delta_M(y) = 0$, *i.e.* $s_ny = 0$ for every $n \in \mathbb{N}$, so that $(\mathrm{Ker}\,\gamma)^a = 0$, which proves that C^a is a faithfully flat A_0^a-algebra.

Next, since b is a regular element of C, it is also regular in $C^\wedge$; also, we already know that the Frobenius endomorphism of $C^\wedge$ induces an injection $\overline{\Phi}_C : C/bC \to C/b^pC$ (lemma 9.8.26(i));

on the other hand, for any $n \in \mathbb{N}$, consider the commutative diagram :

$$\begin{array}{ccccc} C/bC & \xrightarrow{A_0/bA_0 \otimes_{A_0} j_C} & C'/bC' & \xrightarrow{A_0/bA_0 \otimes_{A_0} \varphi_{C,n}} & C/bC \\ \downarrow{\scriptstyle \overline{\Phi}_C} & & \downarrow{\scriptstyle \overline{\Phi}_{C'}} & & \downarrow{\scriptstyle \overline{\Phi}_C} \\ C/b^pC & \xrightarrow{A_0/b^pA_0 \otimes_{A_0} j_C} & C'/b^pC' & \xrightarrow{A_0/b^pA_0 \otimes_{A_0} \varphi_{C,n}} & C/b^pC. \end{array}$$

By theorem 16.9.17(ii), the map $\mathsf{S}^{-1}\overline{\Phi}_{C'}$ is an isomorphism. Now, let $x \in C/b^pC$, and pick $s_\bullet := (s_n \mid n \in \mathbb{N}) \in \mathsf{S}$ and $y_\bullet \in C'/bC'$ such that $\overline{\Phi}_{C'}(y_\bullet) = s_\bullet \cdot (A_0/b^pA_0 \otimes_{A_0} j_C)(x)$. Set $z_n := (A_0/bA_0 \otimes_{A_0} \varphi_{C,n})(y_\bullet)$ for every $n \in \mathbb{N}$; then $\overline{\Phi}_C(z_n) = s_n x$ for every $n \in \mathbb{N}$. This shows that $\overline{\Phi}_C$ is an almost isomorphism, so $(C^\wedge, \mathfrak{m}C^\wedge)$ is an almost perfectoid basic setup. □

Remark 17.5.17. (i) In the situation of (17.5.13), suppose moreover that there exists a perfectoid Tate ring R, with a perfectoid subring of definition R_0, and an adic ring homomorphism $R_0 \to A_0$, such that $g_\bullet$ is the image of an element $g'_\bullet := (g'_n \mid n \in \mathbb{N})$ of $\mathbf{E}(R_0)$. Then we get a basic setup $(R_0, \mathfrak{m}_R)$ with $\mathfrak{m}_R := \bigcup_{\gamma \in \mathbb{N}[1/p]\setminus\{0\}} g_0^{\prime\gamma} R_0$, and we can form as in (16.9.59) the topological R-algebra $A_0^\natural := R \otimes_{W(\mathbf{E}_0(R_0))} W(\mathbf{E}(A_0/pA_0))$, which is perfectoid and admits a natural adic map $A_0^\natural \to A_0$; the latter is an almost isomorphism relative to the basic setup $(R_0, \mathfrak{m}_R)$, by theorem 16.9.63(iii.a). Let A_0^ν (resp. $(A_0^\natural)^\nu$) be the integral closure of A_0 in $A_0[1/g]$ (resp. of $A_0^\natural$ in $A_0^\natural[1/g'_0]$). Then, on the one hand, the induced morphism $((A_0^\natural)^\nu)^a \to (A_0^\nu)^a$ is an isomorphism of $(R_0, \mathfrak{m}_R)^a$-algebras ([75, Lemma 8.2.28]); on the other hand, the same holds for the morphism $(A_0^\natural)^a \to ((A_0^\natural)^\nu)^a$, due to theorem 16.9.42(iv). In this way we thus obtain a shorter proof of proposition 17.5.14, under the stated further assumptions.

(ii) We can also give an alternative proof of the first assertion of proposition 17.5.16 along the same lines, under the assumptions of (i). Indeed, first let us remark that, since the map $A_0^\natural \to A_0$ is an almost isomorphism, there exists an almost element $l \in (A_0^\natural)^a_*$ whose image in $(A_0)^a_*$ agrees with h; by definition, $l : \mathfrak{m}_R \otimes_R \mathfrak{m}_R \to A_0^\natural$ is an R-linear map, and we set $l_{\gamma+\delta} := l(g_0^{\prime\gamma} \otimes g_0^{\prime\delta})$ for every $\gamma, \delta \in \mathbb{N}[1/p] \setminus \{0\}$. It is easily seen that $l_{\gamma+\delta}$ depends only on the sum $\gamma + \delta$, hence we get a compatible system $(l_\gamma \mid \gamma \in \mathbb{N}[1/p] \setminus \{0\})$ of elements of $A_0^\natural$ such that $g_0^{\prime\delta} \cdot l_\gamma = l_{\gamma+\delta}$ for every such γ and δ. Let D_γ (resp. E_γ) be the p-root closure of $A_{0,\gamma}^\natural := A_0^\natural[l_\gamma^{1/p^\infty}]$ in $A_{0,\gamma}^\natural[1/b]$ (resp. of $A_{0,\gamma} := A_0[(g^\gamma h)^{1/p^\infty}]$ in $A_{0,\gamma}[1/b]$) for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$; by theorem 16.9.17(i), D_γ is a faithfully flat $A_0^\natural$-algebra; moreover, for every $\gamma, \delta \in \mathbb{N}[1/p] \setminus \{0\}$, the natural map $A_{0,\gamma+\delta}^\natural \to A_{0,\gamma}^\natural$ induces a map of $A_0^\natural$-algebras $D_{\gamma+\delta} \to D_\gamma$ (remark 9.8.25(ii)). Furthermore, for every such γ we have a natural map $i_\gamma : A_{0,\gamma}^\natural \to A_{0,\gamma}$, whence an induced map $j_\gamma : D_\gamma \to E_\gamma$. Since $p \in b^pA_0$, the localization $A_{0,\gamma} \to A_{0,\gamma}[1/b]$ induces an isomorphism $A_{0,\gamma}[1/p] \xrightarrow{\sim} A_{0,\gamma}[1/b, 1/p]$, and therefore E_γ is also the weak normalization of $A_{0,\gamma}$ in $A_{0,\gamma}[1/b]$ (proposition 9.8.28); likewise we see that D_γ is the weak normalization of $A_{0,\gamma}^\natural$ in $A_{0,\gamma}^\natural[1/b]$. On the other hand, clearly i_γ^a is an isomorphism; taking into account 14.3.12(iii), we conclude that the same holds for j_γ^a. Lastly, the compatible system of ring homomorphisms $(A_0[(g^\gamma h)^{1/p^\infty}] \to A_0[h^{1/p^\infty}] \mid \gamma \in \mathbb{N}[1/p] \setminus \{0\})$ yields a compatible system of maps $(E_\gamma \to B \mid \gamma \in \mathbb{N}[1/p] \setminus \{0\})$, and it is easily seen that the induced co-cone of A_0^a-algebras $(E_\gamma^a \to B^a \mid \gamma \in \mathbb{N}[1/p] \setminus \{0\})$ is universal. Summing up, B^a is the colimit of the filtered system of faithfully flat A_0^a-algebras $(D_\gamma^a \mid \gamma \in \mathbb{N}[1/p] \setminus \{0\})$, so it is a faithfully flat A_0^a-algebra (lemma 14.3.7(ii)).

(iii) Likewise, by applying the functor $(-)^\natural$ in a similar fashion, one may show that the basic setup $(C^\wedge, \mathfrak{m}C^\wedge)$ is almost perfectoid : we leave the details as an exercise for the reader.

17.5.18. Let $(A, \mathfrak{n})$ be a noetherian local ring. The aim of this section is to exhibit an A-algebra B such that $\mathrm{depth}_A B = \dim A$ (notation of remark 10.4.29). Quite generally, we say that an

A-module M is *big Cohen-Macaulay* (or briefly, that M is *big CM*) if $\mathrm{depth}_A M = \dim A$; hence our sought B is a *big CM A-algebra*.

Remark 17.5.19. Set $d := \dim A$, and let $\mathbf{f} := (f_1, \dots, f_d)$ a *system of parameters* for A, *i.e.* a system of generators for an $\mathfrak{n}$-primary ideal of A. Let also M be an A-module.

(i) By proposition 10.4.32(i), M is a big CM A-module if and only if $H^i(\mathbf{f}, M) = 0$ for every $i = 0, \dots, d-1$, and $H^d(\mathbf{f}, M) \neq 0$, or equivalently, if and only if $\mathbf{f}$ is completely secant on M (see definition 7.8.6), and $H_0(\mathbf{f}, M) = M/\mathbf{f}M \neq 0$ (lemma 7.8.2(v)). It follows easily that M is a big CM A-module if and only if $H^i(\mathbf{f}, M) = 0$ for $i = 0, \dots, d-1$, and $M/\mathfrak{n}M \neq 0$.

(ii) Notice also that a big CM A-module is the same as a Cohen-Macaulay module whose support contains an irreducible component of $\mathrm{Spec}\, A$ of dimension d (see definition 11.3.60(ii)). The additional *big* adjective can then be somewhat justified, by remarking that the condition on the support often forces an A-algebra B to be of non-finite type : the question is discussed in B.Bhatt's article [21], which exhibits a non-trivial cohomological obstruction to the existence of *finite* CM A-algebras, when A has positive characteristic. On the other hand, it is conjectured that every complete local noetherian domain admits a faithful Cohen-Macaulay *module* of finite type : see [142, Conj.12]; moreover, sometimes a big CM-algebra can be of finite type : *e.g.* this is the case for a Nagata universally catenary local domain $(A, \mathfrak{n})$ of dimension 2. Indeed, the normalization B of A in its field of fractions is a finite A-algebra, hence noetherian, catenary and of dimension 2; so it is a Cohen-Macaulay ring, by Serre's criterion for normality ([126, Th.23.8]), and the support of B is $\mathrm{Spec}\, A$.

(iii) Let $f : (A', \mathfrak{n}') \to (A, \mathfrak{n})$ be a local ring homomorphism of local noetherian rings with $\dim A' = \dim A$, and such that $\mathfrak{n}$ is the radical of $\mathfrak{n}'A$. Let B be an A-algebra, and B' an A'-algebra. We have :

(a) B is a big CM A-algebra if and only if, by restriction of scalars, B is a big CM A'-algebra (lemma 10.4.17(ii)).

(b) If f is faithfully flat, then B' is a big CM A'-algebra if and only if $A \otimes_{A'} B'$ is a big CM A-algebra (corollary 10.4.37).

(iv) Let $B_\bullet := (B_\lambda \mid \lambda \in \Lambda)$ be a filtered system of big CM A-algebras. Then the colimit B of $B_\bullet$ is also a big CM A-algebra. Indeed, since the functor $H_i(\mathbf{f}, -)$ commutes with filtered colimits, we have $H_i(\mathbf{f}, B) = 0$ for $i = 0, \dots, d-1$, and if we had $B/\mathfrak{n}B = 0$, we would have $1 = 0$ in $B/\mathfrak{n}B$, so $1 \in \mathfrak{n}B_\lambda$ for some $\lambda \in \Lambda$, but we know from (i) that $B_\lambda/\mathfrak{n}B_\lambda \neq 0$, whence the assertion.

Lemma 17.5.20. *Let $(A, \mathfrak{m}_A)$ and $(B, \mathfrak{m}_B)$ be local noetherian rings, $f : A \to B$ a local ring homomorphism of complete intersection (see definition* 9.7.30(ii)*), and M a big CM A-module. Then the $\mathfrak{m}_B$-adic completion $B\widehat{\otimes}_A M$ of $B \otimes_A M$ is a big CM B-module.*

Proof. We establish first the following special cases :

Claim 17.5.21. (i) The $\mathfrak{m}_A$-adic completion $M^\wedge$ of M is a big CM A-module.

(ii) If f is surjective, with kernel generated by a regular sequence $\mathbf{g} := (g_1, \dots, g_r)$ of A, and M is $\mathfrak{m}_A$-adically complete and separated, then $B \otimes_A M$ is a big CM B-module.

Proof of the claim. (i): Let $\mathbf{f}$ be any system of parameters for A. Clearly the sequence $\mathbf{f}$ is M-quasi-regular if and only if it is $M^\wedge$-quasi-regular (see definition 7.8.13). Then the assertion follows from proposition 7.8.15 and remark 17.5.19(i). (The assertion is already essentially contained in [15, Th.1.7], which shows, by a different argument, that if a given system of parameters for A is M-regular, then every system of parameters for A is $M^\wedge$-regular.)

(ii): By [63, Ch.0, Prop.16.4.1] we may find a sequence $\mathbf{g}' := (g_{r+1}, \dots, g_d)$ such that $\mathbf{g}'' := (g_1, \dots, g_d)$ is a system of parameters for A, and then $H_i(\mathbf{g}'', M) = 0$ for every $i > 0$, by remark 17.5.19(i). Consequently, $\mathbf{g}''$ is a regular sequence on M (proposition 7.8.15), so that

$\mathbf{g}'$ is regular on $M/\mathbf{g}M$, and thus $H_i(\mathbf{g}', B \otimes_A M) = 0$ for every $i > 0$, again by proposition 7.8.15; in view of remark 17.5.19(i), we are then reduced to checking that $\mathbf{g}'$ is a system of parameters for B. But the latter follows immediately from [126, Th.14.1]. ◊

Now, let us pick a Cohen factorization $A \xrightarrow{g} (C, \mathfrak{m}_C) \xrightarrow{h} B^\wedge$ of f, such that $\mathrm{Ker}\, h$ is generated by a regular sequence of $\mathfrak{m}_C$. Since g is flat, and $\overline{C} := C/\mathfrak{m}_A C$ is regular, we have :

$$\dim C = \dim A + \dim \overline{C} = \mathrm{depth}_A M + \mathrm{depth}_{\overline{C}} \overline{C} = \mathrm{depth}_C (C \otimes_A M)$$

by [126, Th.15.1] and theorem 10.4.38. Combining with claim 17.5.21(i), we see that the $\mathfrak{m}_C$-adic completion $C\widehat{\otimes}_A M$ of $C \otimes_A M$ is a CM C-module. Then, claim 17.5.21(ii) says that $N := B^\wedge \otimes_C (C\widehat{\otimes}_A M)$ is a CM $B^\wedge$-module, so also a CM B-module, by remark 17.5.19(iii.a). Lastly, it is easily seen that the $\mathfrak{m}_B$-adic completion of N is naturally isomorphic to $B\widehat{\otimes}_A M$, so the latter is a big CM B-module, again by claim 17.5.21(i). □

To explain how we shall produce big CM-algebras, let us make the following :

Definition 17.5.22. Let $(A, \mathfrak{n})$ be a noetherian local ring, V an A-algebra, $\mathfrak{m} \subset V$ an ideal such that $\mathfrak{m} = \mathfrak{m}^2$, so that $(V, \mathfrak{m})$ is a basic setup, in the sense of [75, §2.1.1], and suppose moreover that $\widetilde{\mathfrak{m}} := \mathfrak{m} \otimes_V \mathfrak{m}$ is a flat V-module. Let also M be a V-module; we say that M is *big almost CM over* A if $M^a_!$ is a big Cohen-Macaulay A-module.

With this terminology, our strategy relies on the following observation, which is a replacement of Hochster's techniques of *algebra modifications*, that have been employed in previous papers, to turn almost CM algebras into CM algebras (see *e.g.* [94], [5], [7], [153]).

Lemma 17.5.23. *In the situation of definition* 17.5.22*, set* $d := \dim A$*, and suppose that the basic setup* $(V, \mathfrak{m})$ *fulfills the condition of* (17.5.2)*. The following conditions are equivalent :*

(a) *M is big almost CM over A.*
(b) $(R^i\Gamma_{\{\mathfrak{n}\}}M)^a = 0$ *for every* $i = 0, \dots, d-1$*, and* $(R^d\Gamma_{\{\mathfrak{n}\}}M)^a \neq 0$.
(c) *$M^\diamond$ is big almost CM over A.*
(d) $\mathsf{S}^{-1}M^\diamond$ *is a big Cohen-Macaulay A-module.*

Proof. (Here, $\mathsf{S} \subset V^{\mathbb{N}}$ is the multiplicative subset associated with $\mathfrak{m}$, as in (17.5.2).)
Let $Z := \mathrm{Spec}\, V/\mathfrak{n}V$; ; in view of lemma 10.4.13(v), we have a natural identification

$$R^i\Gamma_{\{\mathfrak{n}\}}M \xrightarrow{\sim} R^i\Gamma_Z M \qquad \text{for every } i \in \mathbb{N}$$

whence a natural V-module structure on $R^i\Gamma_{\{\mathfrak{n}\}}M$, so the $(V, \mathfrak{m})^a$-module $(R^i\Gamma_{\{\mathfrak{n}\}}M)^a$ is well defined, and the lemma will follow from the more general :

Claim 17.5.24. Let $I \subset V$ be a finitely generated ideal, $d \in \mathbb{N}$, and $Z := \mathrm{Spec}\, V/I \subset \mathrm{Spec}\, V$. The following conditions are equivalent :

(a) $\mathrm{depth}_I(M^a_!) = d$ (notation of (10.4.29)).
(b) $(R^i\Gamma_Z M)^a = 0$ for every $i < d$ and $(R^d\Gamma_Z M)^a \neq 0$.
(c) $\mathrm{depth}_I((M^\diamond)^a_!) = d$.
(d) $\mathrm{depth}_I(\mathsf{S}^{-1}M^\diamond) = d$.

Proof of the claim. (a)⇔(b): Since $\widetilde{\mathfrak{m}}$ is a flat V-module, we have natural identifications :

$$(R^i\Gamma_Z M)^a_! \xrightarrow{\sim} \widetilde{\mathfrak{m}} \otimes_V R^i\Gamma_Z M \xrightarrow{\sim} R^i\Gamma_Z(\widetilde{\mathfrak{m}} \otimes_V M) \xrightarrow{\sim} R^i\Gamma_Z(M^a_!) \qquad \text{for every } i \in \mathbb{N}$$

provided by lemma 10.4.17(iv), whence the contention.

(a)⇔(c)⇔(d): Let $\mathbf{f}$ be a finite system of generators of I, and $\mathbf{K}^\bullet(\mathbf{f}, M)$ the Koszul complex of M relative to the sequence $\mathbf{f}$. Let $\mathsf{S}^{-1}\mathbf{K}^\bullet(\mathbf{f}, M_!)^\diamond$ be the complex obtained by applying the functor $\mathsf{S}^{-1}(-)^\diamond$ termwise to $\mathbf{K}^\bullet(\mathbf{f}, M_!)$, and define likewise $\mathbf{K}^\bullet(M)^\diamond$ and $\mathbf{K}^\bullet(\mathbf{f}, M)^a_!$. By direct inspection (and since $\widetilde{\mathfrak{m}}$ is a flat V-module), we easily obtain natural identifications :

$$\mathbf{K}^\bullet(\mathbf{f}, M)^a_! \xrightarrow{\sim} \mathbf{K}^\bullet(\mathbf{f}, M^a_!) \quad \mathbf{K}^\bullet(\mathbf{f}, M)^\diamond \xrightarrow{\sim} \mathbf{K}^\bullet(\mathbf{f}, M^\diamond) \quad \mathsf{S}^{-1}\mathbf{K}^\bullet(\mathbf{f}, M)^\diamond \xrightarrow{\sim} \mathbf{K}^\bullet(\mathbf{f}, \mathsf{S}^{-1}M^\diamond).$$

In view of lemmata 17.5.1(i) and 17.5.4(ii), we deduce for every $i \in \mathbb{N}$ natural isomorphisms :

$$H^i(\mathbf{f}, M)^a_! \xrightarrow{\sim} H^i(\mathbf{f}, M^a_!) \qquad H^i(\mathbf{f}, M)^\diamond \xrightarrow{\sim} H^i(\mathbf{f}, M^\diamond) \qquad \mathsf{S}^{-1}H^i(\mathbf{f}, M)^\diamond \xrightarrow{\sim} H^i(\mathbf{f}, \mathsf{S}^{-1}M^\diamond)$$

and moreover, $H^i(\mathbf{f}, M)^a = 0$ if and only if $\mathsf{S}^{-1}H^i(\mathbf{f}, M)^\diamond = 0$. Combining with proposition 10.4.32(i), the assertion follows. □

Hence, we shall seek a suitable basic setup $(V, \mathfrak{m})$ as in definition 17.5.22, fulfilling the additional condition of (17.5.2), together with a V-algebra C whose underlying V-module is big almost CM over A; in this situation, lemma 17.5.23 will ensure that $\mathsf{S}^{-1}C^\diamond$ is a big CM A-algebra. Proposition 17.5.25 and theorem 17.5.28 below illustrate the method in the easier case where A is an $\mathbb{F}_p$-algebra, for some prime integer p.

Proposition 17.5.25. *Let p be a prime integer, $(A, \mathfrak{n})$ a noetherian local $\mathbb{F}_p$-algebra, and $a \in A$ a non-nilpotent element. Let also A^{perf} be the perfection of A, defined as in* (9.8.11), *and $J \subset A^{\mathrm{perf}}$ the ideal generated by $(a^{1/p^n} \mid n \in \mathbb{N})$. We have :*

(i) $J(A^{\mathrm{perf}}/\mathfrak{n}A^{\mathrm{perf}}) \neq 0$.

(ii) *If A is excellent and equidimensional, and $A[a^{-1}]$ is a Cohen-Macaulay ring, then :*

$$J \cdot R^i\Gamma_{\{\mathfrak{n}\}}A^{\mathrm{perf}} = 0 \qquad \textit{for } i = 0, \dots, \dim A - 1.$$

Proof. (i): Let $\mathfrak{q} \subset A$ be a minimal prime ideal that does not contain a, and set $B := A/\mathfrak{q}$; clearly B^{perf} is a quotient of A^{perf}, hence it suffices to check that $J(B^{\mathrm{perf}}/\mathfrak{n}B^{\mathrm{perf}}) \neq 0$. Thus, we may replace A by B, and assume that A is a domain. If $a \in A^\times$, the assertion is trivial; suppose then that $a \notin A^\times$, in which case a lies in a prime ideal $\mathfrak{p} \subset A$ of height one ([126, Th.13.5]). Set $C := A_\mathfrak{p}$; clearly C^{perf} is a localization of A^{perf}, hence it suffices to check that $J(C^{\mathrm{perf}}/\mathfrak{n}C^{\mathrm{perf}}) \neq 0$. Thus, we may replace A by C, and assume that A is a one-dimensional domain, in which case there exists a one-dimensional valuation ring V of $\mathrm{Frac}\,A$ that dominates A (claim 15.3.27). It is easily seen that V^{perf} is a one-dimensional valuation ring of $\mathrm{Frac}\,(A^{\mathrm{perf}})$ dominating A^{perf} (the details shall be left to the reader). We have to show that $JA^{\mathrm{perf}} \not\subset \mathfrak{n}A^{\mathrm{perf}}$, and it suffices to check that $JV^{\mathrm{perf}} \not\subset \mathfrak{n}V^{\mathrm{perf}}$. However, since $\mathfrak{n}$ is an ideal of finite type, $\mathfrak{n}V^{\mathrm{perf}}$ is a principal ideal lying in the maximal ideal $\mathfrak{m}_V^{\mathrm{perf}}$ of V^{perf}; on the other hand, the value group of V^{perf} is of rank one and p-divisible, and $a \in \mathfrak{m}_V^{\mathrm{perf}}$, so $JV^{\mathrm{perf}} = \mathfrak{m}_V^{\mathrm{perf}}$, whence the assertion.

(ii): Let us first notice :

Claim 17.5.26. Let $i \in \mathbb{N}$ such that $a^n R^i\Gamma_{\{\mathfrak{n}\}}A = 0$ for some $n \in \mathbb{N}$; then $J \cdot R^i\Gamma_{\{\mathfrak{n}\}}A^{\mathrm{perf}} = 0$.

Proof of the claim. Let $\Phi_A : A \to A$ be the Frobenius endomorphism, and for every $k \in \mathbb{N}$ and every A-module M, let $M_{(k)}$ be the A-module obtained from M by restriction of scalars along the map $\Phi_A^k : A \to A$. Clearly $\mathfrak{n}$ is the radical of the ideal $\Phi_A^k(\mathfrak{n})$, for every $k \in \mathbb{N}$, hence we have a natural identification of A-modules :

$$H^i_k := R^i\Gamma_{\{\mathfrak{n}\}}(A_{(k)}) = (R^i\Gamma_{\{\mathfrak{n}\}}A)_{(k)} \qquad \text{for every } i, k \in \mathbb{N}$$

(lemma 10.4.13(v)). It follows that $a^{n/k}H^i_k = 0$ for every $k \in \mathbb{N}$. But by definition, A^{perf} is the direct limit of the system of A-algebras $(A_{(k)} \mid k \in \mathbb{N})$, hence $R^i\Gamma_{\{\mathfrak{n}\}}A^{\mathrm{perf}}$ is the direct limit of the system of A-modules $(H^i_k \mid k \in \mathbb{N})$ (proposition 10.4.9), whence the claim. ◊

In light of claim 17.5.26, it suffices to check that for every $i = 0, \dots, \dim A - 1$ we have $a^n R^i\Gamma_{\{\mathfrak{n}\}}A = 0$ for some $n \in \mathbb{N}$. Let $(A^\wedge, \mathfrak{n}^\wedge)$ be the completion of A; by assumption, the induced morphism of schemes $\mathrm{Spec}\,A^\wedge \to \mathrm{Spec}\,A$ is faithfully flat and regular, hence $A^\wedge[a^{-1}]$ is again a Cohen-Macaulay ring ([126, Th.32.2(i)]), and $\dim A^\wedge = \dim A$; moreover, $A^\wedge$ is equidimensional, by [126, Th.31.7]. Furthermore, since $\mathfrak{n}^\wedge = \mathfrak{n}A^\wedge$, we have a natural identification

$$R^i\Gamma_{\{\mathfrak{n}^\wedge\}}A^\wedge = A^\wedge \otimes_A R^i\Gamma_{\{\mathfrak{n}\}}A \qquad \text{for every } i \in \mathbb{N}$$

(lemma 10.4.17(iii)). Thus, it suffices to check that for every $i = 0, \dots, \dim A^\wedge - 1$ there exists $n \in \mathbb{N}$ such that $a^n R^i\Gamma_{\{\mathfrak{n}^\wedge\}}A^\wedge = 0$; *i.e.* we may replace A by $A^\wedge$, and assume from start that A is complete, and especially, A admits a dualizing complex $\omega^\bullet$ (remark 11.3.45(iv)). Set $X := \operatorname{Spec} A$, and define the map $c_X : |X| \to \mathbb{Z}$ as in (11.3.49); since A is equidimensional, we have $c_X(\mathfrak{n}) - c_X(\mathfrak{p}) = \dim A$ for every minimal prime ideal $\mathfrak{p} \subset A$ (lemma 11.3.50). Thus, after replacing $\omega^\bullet$ by a suitable shift $\omega^\bullet[c]$, we may assume that $c_X(\mathfrak{p}) = 0$ for every minimal prime ideal $\mathfrak{p} \subset A$, and consequently $c_X(x) = \dim \mathscr{O}_{X,x}$ for every $x \in X$.

Claim 17.5.27. $H^i(\omega^\bullet) = 0$ for every $i < 0$, and $A[a^{-1}] \otimes_A H^i(\omega^\bullet) = 0$ for every $i > 0$.

Proof of the claim. Let $x \in X$ be any point; by proposition 11.3.37, the complex $\omega^\bullet(x)$ is dualizing on $X(x)$, and denote by $\mathscr{D}_x$ the corresponding dualizing functor. Recall that $\mathscr{D}_x(\mathscr{O}_{X(x)}) = \omega^\bullet_x$, and that the natural map

$$\mathscr{O}_{X(x)} \to \mathscr{D}_x \circ \mathscr{D}_x(\mathscr{O}_{X(x)}) = \mathscr{D}_x(\omega^\bullet(x))$$

is an isomorphism. Let also $A^\wedge_x$ be the completion of the local ring $A_x := \mathscr{O}_{X,x}$; by corollary 11.5.17(iii) there follow natural isomorphisms :

$$D(H^{c(x)-i}_{\{x\}}\mathscr{O}_{X(x)}) \xrightarrow{\sim} D(H^{c(x)-i}_{\{x\}}\mathscr{D}_x(\omega^\bullet(x))) \xrightarrow{\sim} A^\wedge_x \otimes_A H^i(\omega^\bullet(x)) \qquad \text{for every } i \in \mathbb{Z}$$

where the functor D is defined as in (11.5.16). By assumption, if $x \in \operatorname{Spec} A[a^{-1}]$, we have $H^{c(x)-i}_{\{x\}}\mathscr{O}_{X(x)} = 0$ for every $i > 0$, so that $H^i(\omega^\bullet(x)) = 0$ for every such i and every such x, since $A^\wedge_x$ is a faithfully flat A_x-algebra. Lastly, we have $H^{c(x)-i}_{\{x\}}\mathscr{O}_{X(x)} = 0$ for every $i < 0$ and every $x \in X$, by proposition 10.4.7(ii.b), hence $H^i(\omega^\bullet(x)) = 0$ for every such i and x. ◊

By corollary 11.5.17(ii) we have a natural isomorphism :

$$H^i_{\{\mathfrak{n}\}}(A) \xrightarrow{\sim} H^i_{\{\mathfrak{n}\}}(\mathscr{D}(\omega^\bullet)) \xrightarrow{\sim} D(H^{c(\mathfrak{n})-i}(\omega^\bullet)) \qquad \text{for every } i \in \mathbb{Z}$$

and $c(\mathfrak{n}) = \dim A$. Since $H^j(\omega^\bullet)$ is a finitely generated A-module for every $j \in \mathbb{Z}$, claim 17.5.27 implies that there exists $n \in \mathbb{N}$ such that $a^n \cdot H^j(\omega^\bullet) = 0$ for every $j > 0$. Since D is an A-linear functor, it follows that $a^n \cdot H^i_{\{\mathfrak{n}\}}(A) = 0$ for every $i < \dim A$, as required. □

Theorem 17.5.28. *Let p be a prime integer, and $(A, \mathfrak{n})$ a local noetherian $\mathbb{F}_p$-algebra. Then there exists a perfect big CM A-algebra.*

Proof. We first notice :

Claim 17.5.29. We may assume that A is an excellent and equidimensional local ring.

Proof of the claim. Let $\mathfrak{p}$ be a minimal prime ideal of the completion $A^\wedge$ of A, such that $A' := A^\wedge/\mathfrak{p}$ has dimension equal to $\dim A$; then the natural map $A \to A'$ fulfills the conditions of remark 17.5.19(ii); thus it suffices to exhibit a big CM A'-algebra, and A' is an excellent local domain ([64, Ch.IV, Sch.7.8.3(iii)]). ◊

Thus, we assume now that A is as in claim 17.5.29. Then, by [64, Ch.IV, Sch.7.8.3(iv)], the subset U of points $\mathfrak{p} \in X := \operatorname{Spec} A$ such that $A_\mathfrak{p}$ is Cohen-Macaulay, is open in X, and trivially contains all the maximal points of X, hence it is dense in X. We may therefore find $a \in A$ such that $\varnothing \neq \operatorname{Spec} A[a^{-1}] \subset U$, so that a is not nilpotent, and $A[a^{-1}]$ is a Cohen-Macaulay ring. Define A^{perf} and J as in proposition 17.5.25. Clearly $J^2 = J$, and the basic setup (A^{perf}, J) fulfills the condition of (17.5.2). By proposition 17.5.25(ii), we then have

$$(A^{\mathrm{perf}}/\mathfrak{n}A^{\mathrm{perf}})^a \neq 0 \qquad \text{and} \qquad (R^i\Gamma_{\{\mathfrak{n}\}}A^{\mathrm{perf}})^a = 0 \qquad \text{for every } i = 0, \dots, \dim A - 1.$$

It follows that $(A^{\mathrm{perf}})^a_!/\mathfrak{n}(A^{\mathrm{perf}})^a_! \neq 0$. Recall that $J^\sim := J \otimes_{A^{\mathrm{perf}}} J$ is a flat A^{perf}-module ([75, Prop.2.1.7(i)]), and let $\mathsf{S}_a \subset (A^{\mathrm{perf}})^{\mathbb{N}}$ be the multiplicative subset associated with J, as in (17.5.2); then by lemmata 17.5.23 and 17.5.4(i,ii) we conclude that $\mathsf{S}_a^{-1}(A^{\mathrm{perf}})^\diamond$ is a big CM A-algebra, and since A^{perf} is perfect, it is easily seen that the same holds for $\mathsf{S}_a^{-1}(A^{\mathrm{perf}})^\diamond$. □

It is useful to generalize theorem 17.5.28 to non-local noetherian $\mathbb{F}_p$-algebras. To this aim, let us make the following :

Definition 17.5.30. Let A be a noetherian ring, M an A-module, and B an A-algebra.

(i) We say that A is *locally equidimensional* if $A_\mathfrak{p}$ is equidimensional for every $\mathfrak{p} \in \mathrm{Spec}\, A$.

(ii) We say that M is a *big locally CM A-module*, if $M_\mathfrak{p}$ is a big CM $A_\mathfrak{p}$-module for every $\mathfrak{p} \in \mathrm{Spec}\, A$. Likewise, B is a *big locally CM A-algebra*, if it is big locally CM as an A-module.

(iii) We say that a ring homomorphism $f : A \to B$ is *maximizing*, if the continuous map $\mathrm{Spec}\, f$ is maximing (see definition 8.1.46(ii)).

Lemma 17.5.31. *Let A be a catenary noetherian ring (see definition* 9.7.3(iii)*). The following conditions are equivalent :*

(a) *A is locally equidimensional.*

(b) *$A_\mathfrak{m}$ is equidimensional for every maximal ideal $\mathfrak{m} \subset A$.*

(c) *For every two irreducible components Z and Z' of* $\mathrm{Spec}\, A$*, and every maximal point $\mathfrak{p}$ of the topological space $Z \cap Z'$, the ring $A_\mathfrak{p}$ is equidimensional.*

Proof. Trivially (a)⇒(b), and (a)⇒(c).

(b)⇒(a): Indeed, say that $\mathfrak{p} \in \mathrm{Spec}\, A$, and let $\mathfrak{q}$ and $\mathfrak{q}'$ be two minimal prime ideal contained in $\mathfrak{p}$; we need to check that two every saturated chain of prime ideals

$$\mathfrak{q} \subset \cdots \subset \mathfrak{p} \qquad \text{and} \qquad \mathfrak{q}' \subset \cdots \subset \mathfrak{p} \tag{17.5.32}$$

have the same length. To this aim, pick any maximal ideal $\mathfrak{m}$ of A containing $\mathfrak{p}$, and complete the two chains with the same saturated chain $\mathfrak{p} \subset \cdots \subset \mathfrak{m}$; the resulting chains $\mathfrak{q} \subset \cdots \subset \mathfrak{m}$ and $\mathfrak{q}' \subset \cdots \subset \mathfrak{m}$ are saturated, so by assumption they both have length equal to $\dim A_\mathfrak{m}$, whence the assertion.

(c)⇒(b): Let $\mathfrak{m} \subset A$ be a maximal ideal, and $\mathfrak{q}, \mathfrak{q}'$ two minimal prime ideals of A contained in $\mathfrak{m}$; set $Z := \mathrm{Spec}\, A/\mathfrak{q}$ and $Z' := \mathrm{Spec}\, A/\mathfrak{q}'$. Then, $\mathfrak{m} \in Z \cap Z'$, so let $\mathfrak{p}$ be any maximal generization of $\mathfrak{m}$ in $Z \cap Z'$; pick any two saturated chains as in (17.5.32), and complete them again with the same saturated chain $\mathfrak{p} \subset \cdots \subset \mathfrak{m}$, say of length l_0. Since $A_\mathfrak{p}$ is equidimensional, the chains (17.5.32) have the same length l_1; now, let $\mathfrak{q} \subset \cdots \mathfrak{m}$ and $\mathfrak{q}' \subset \cdots \mathfrak{m}$ be any other pair of saturated chains, of lengths l and respectively l'; since A is catenary, we must have $l = l_0 + l_1 = l'$, so $A_\mathfrak{m}$ is equidimensional. □

Corollary 17.5.33. *Let A be an excellent and locally equidimensional $\mathbb{F}_p$-algebra. Then there exists a big locally CM A-algebra B.*

Proof. The subset U of points $\mathfrak{p} \in X := \mathrm{Spec}\, A$ such that $A_\mathfrak{p}$ is Cohen-Macaulay is open ([64, Ch.IV, Sch.7.8.3(iv)]), and trivially contains the subset $\mathrm{Min}(A)$ of all minimal prime ideals of A, hence it is dense in X. Say that $X \setminus U = \mathrm{Spec}\, A/I$ for some ideal $I \subset A$; then I is not contained in any minimal ideal of A, and so there exists $a \in I \setminus \bigcup_{\mathfrak{p} \in \mathrm{Min}(A)} \mathfrak{p}$ ([12, Prop.1.11(i)]). Let A^{perf} be the perfection of A (see (9.8.11)), and $J \subset A^{\mathrm{perf}}$ the ideal generated by $(a^{1/p^n} \mid n \in \mathbb{N})$. Let moreover $\mathsf{S}_a \subset (A^{\mathrm{perf}})^{\mathbb{N}}$ be the multiplicative subset associated with J, as in (17.5.2). We claim that $B := \mathsf{S}_a^{-1}(A^{\mathrm{perf}})^\diamond$ will do. Indeed, let $\mathfrak{p} \subset A$ be any prime ideal, $k(\mathfrak{p})$ its residue field, $j : A \to A_\mathfrak{p}$ the localization, and $\mathsf{S}_{j(a)} \subset (A_\mathfrak{p}^{\mathrm{perf}})^{\mathbb{N}}$ the corresponding multiplicative subset, associated with the ideal $JA_\mathfrak{p}$.

Claim 17.5.34. $\mathsf{S}_{j(a)}^{-1}(A_\mathfrak{p}^{\mathrm{perf}})^\diamond$ is a big CM $A_\mathfrak{p}$-algebra; especially, $\mathsf{S}_{j(a)}^{-1}(A_\mathfrak{p}^{\mathrm{perf}})^\diamond \otimes_{A_\mathfrak{p}} k(\mathfrak{p}) \neq 0$.

Proof of the claim. By [64, Ch.IV, Sch.7.8.3(ii)], $A_{\mathfrak{p}}$ is excellent and equidimensional. Then the assertion follows from the proof of theorem 17.5.28. $\diamondsuit$

The map j induces a ring homomorphism $B \to \mathsf{S}_{j(a)}^{-1}(A_{\mathfrak{p}}^{\mathrm{perf}})^{\diamond}$; with claim 17.5.34 we then get $B \otimes_A k(\mathfrak{p}) \neq 0$ for every $\mathfrak{p} \in \operatorname{Spec} A$. In view of (10.4.30), we are then reducing to showing :

Claim 17.5.35. $\operatorname{depth}_{\mathfrak{p}} B = \dim A_{\mathfrak{p}}$ for every $\mathfrak{p} \in \operatorname{Spec} A$.

Proof of the claim. Set $I := \mathfrak{p}A^{\mathrm{perf}}$, $Z := \operatorname{Spec} A/\mathfrak{p}$ and $Z' := \operatorname{Spec} A^{\mathrm{perf}}/I$; by lemma 10.4.13(v), we have a natural identification :

$$R^i\Gamma_Z B \xrightarrow{\sim} R^i\Gamma_{Z'} B \qquad \text{for every } i \in \mathbb{N}.$$

In view of claim 17.5.24, we are then reduced to checking that :

$$\operatorname{depth}_I((A^{\mathrm{perf}})^a_!) = \dim A_{\mathfrak{p}}$$

for the almost structure attached to the basic setup (A^{perf}, J). However, recall that $(A^{\mathrm{perf}})_{\mathfrak{q}} = (A_{\mathfrak{q}})^{\mathrm{perf}}$ for every $\mathfrak{q} \in \operatorname{Spec} A$ (see (9.8.11)); also, $((A^{\mathrm{perf}})^a_!)_{\mathfrak{q}}$ agrees with $(A_{\mathfrak{q}}^{\mathrm{perf}})^a_!$, for every such $\mathfrak{q}$, where now $(A_{\mathfrak{q}}^{\mathrm{perf}})^a$ is regarded as an $(A_{\mathfrak{q}}^{\mathrm{perf}}, JA_{\mathfrak{q}}^{\mathrm{perf}})^a$-module, and $(-)_!$ refers to the left adjoint of the localization $A_{\mathfrak{q}}^{\mathrm{perf}}\text{-}\mathbf{Mod} \to (A_{\mathfrak{q}}^{\mathrm{perf}}, JA_{\mathfrak{q}}^{\mathrm{perf}})^a\text{-}\mathbf{Mod}$. It follows that :

$$\operatorname{depth}_{A_{\mathfrak{q}}}(A_{\mathfrak{q}}^{\mathrm{perf}})^a_! = \dim A_{\mathfrak{q}} \qquad \text{for every } \mathfrak{q} \in \operatorname{Spec} A$$

by virtue of lemma 17.5.23 and claim 17.5.34. We conclude by invoking again (10.4.30). $\square$

Remark 17.5.36. (i) Theorem 17.5.28 was first proved by Hochster and Huneke in [95]; more precisely, they showed that for every excellent local domain A of equicharacteristic $p > 0$, the integral closure of A in the algebraic closure of $\operatorname{Frac}(A)$ is a big CM A-algebra; this result has been recently extended to excellent local domains of mixed characteristic, in [26]. Our construction yields a different big CM A-algebra.

(ii) Our construction can be easily upgraded to a functor on the category

$$\mathscr{B}_p$$

whose objects are all the excellent and locally equidimensional $\mathbb{F}_p$-algebras, and whose morphisms are the maximizing ring homomorphisms (see definition 17.5.30(iii)). Namely, for every $A \in \operatorname{Ob}(\mathscr{B}_p)$, let $\operatorname{Min}(A)$ be the set of minimal primes of A, and endow $A^* := A \setminus \bigcup_{\mathfrak{p} \in \operatorname{Min}(A)} \mathfrak{p}$ with the partial preordering such that $a \leq b$ if and only if $bA \subset aA$, and for every $a \in A^*$, define the multiplicative subset $\mathsf{S}_a \subset (A^{\mathrm{perf}})^{\mathbb{N}}$ as in the proof of theorem 17.5.28. Clearly $(A^*, \leq)$ is a filtered category (see example 1.1.6(iii)), and we have $\mathsf{S}_a \subset \mathsf{S}_b$ for every $a, b \in A^*$ with $a \leq b$. Then, denote by $E_p(A)$ the colimit of the induced filtered system of A-algebras $(\mathsf{S}_a^{-1}(A^{\mathrm{perf}})^{\diamond} \mid a \in A^*)$. The proof of corollary 17.5.33 shows that A^* admits a cofinal subset $\Sigma \subset A^*$ such that $\mathsf{S}_a^{-1}(A^{\mathrm{perf}})^{\diamond}$ is a big locally CM A-algebra for every $a \in \Sigma$; then the same holds for $E_p(A)$ (remark 17.5.19(iv)). Now, let $f : A \to B$ be a morphism of $\mathscr{B}_p$; clearly f extends uniquely to a ring homomorphism $f^{\mathrm{perf}} : A^{\mathrm{perf}} \to B^{\mathrm{perf}}$, and restricts to a map $f^* : A^* \to B^*$, as f is maximizing. Moreover, $(f^{\mathrm{perf}})^{\mathbb{N}}(\mathsf{S}_a) \subset \mathsf{S}_{f(a)}$ for every $a \in A^*$. Hence, we obtain an induced map $\mathsf{S}^{-1}(A^{\mathrm{perf}})^{\diamond} \to \mathsf{S}_{f(a)}^{-1}(B^{\mathrm{perf}})^{\diamond} \to E_p(B)$ for every such a, and the colimit of these maps is a ring homomorphism $E_p(f) : E_p(A) \to E_p(B)$. It is easily seen that the rules : $A \mapsto E_p(A)$ and $f \mapsto E_p(f)$ yield the sought functor $E_p : \mathscr{B}_p \to \mathbb{F}_p\text{-}\mathsf{Alg}$.

(iii) Moreover, consider the functor

$$(-)^{\nu} : \mathscr{B}_p \to \mathscr{B}_p \qquad A \mapsto A^{\nu} := \prod_{\mathfrak{p} \in \operatorname{Min} A} (A/\mathfrak{p})^{\nu}$$

where, for every $\mathfrak{p} \in \operatorname{Min} A$, we denote by $(A/\mathfrak{p})^{\nu}$ the integral closure of $A/\mathfrak{p}$ in its field of fractions. Clearly, the natural map $j_A : A \to A^{\nu}$ is a morphism of $\mathscr{B}_0$. It is easily seen that every morphism $f : A \to B$ in $\mathscr{B}_p$ induces a well defined morphism $f^\nu : A^\nu \to B^\nu$, such that $f^\nu \circ j_A = j_B \circ f$; this completes the construction of the functor $(-)^\nu$, and shows that the rule : $A \mapsto j_A$ yields a natural transformation $j_\bullet : \mathbf{1}_{\mathscr{B}_p} \Rightarrow (-)^\nu$. With this notation, we have :

Proposition 17.5.37. (i) *The functor E_p factors through the functor $(-)^\nu$.*
(ii) *The functor E_p commutes with finite products.*

Proof. (i): We need to check that $E_p(j_A)$ is an isomorphism for every $A \in \mathrm{Ob}(\mathscr{B}_p)$; to this aim, let A_{red} be the maximal reduced quotient of A, and notice that j_A factors through the quotient map $j'_A : A \to A_{\mathrm{red}}$ and a unique map $j''_A : A_{\mathrm{red}} \to A^\nu$, and both maps are morphisms in $\mathscr{B}_p$. Now, clearly j'_A induces an isomorphism $(j'_A)^{\mathrm{perf}} : A^{\mathrm{perf}} \xrightarrow{\sim} (A_{\mathrm{red}})^{\mathrm{perf}}$ that identifies S_a with $\mathsf{S}_{j'_A(a)}$ for every $a \in A^*$ (notation of remark 17.5.36(ii)). Then, under these identifications, $E_p(A_{\mathrm{red}})$ is the colimit of the functor

$$F : ((A_{\mathrm{red}})^*, \leq) \to \mathbb{F}_p\text{-}\mathsf{Alg} \qquad a \mapsto \mathsf{S}_a^{-1}(A^{\mathrm{perf}})^\diamond$$

and $E_p(A)$ is the colimit of the functor $F \circ (j'_A)^* : (A^*, \leq) \to \mathbb{F}_p\text{-}\mathsf{Alg}$. But notice that the map $(j'_A)^* : A^* \to (A_{\mathrm{red}})^*$ is surjective, so it is a cofinal functor of filtered categories (lemma 1.5.7(i)), and thus $E_p(j'_A)$ is an isomorphism (proposition 1.5.2). Next, we remark :

Claim 17.5.38. (i) There exists $c \in A^*_{\mathrm{red}}$ such that $j''_A(c) \cdot A^\nu \subset j''_A(A_{\mathrm{red}})$.
(ii) For every c as in (i), and every $n \in \mathbb{N}$, we have $c^{1/p^n}(A^\nu)^{\mathrm{perf}} \subset A^{\mathrm{perf}}$.

Proof of the claim. (i): We further write j''_A as the composition of injective maps

$$A_{\mathrm{red}} \xrightarrow{i_1} B := \prod_{\mathfrak{p} \in \mathrm{Min}\, A} A/\mathfrak{p} \xrightarrow{i_2} A^\nu.$$

It then suffices to find $c_1 \in A^*_{\mathrm{red}}$ and $c_2 \in B^*$ such that $c_1 B \subset i_1(A_{\mathrm{red}})$ and $c_2 A^\nu \subset i_2(B)$, since in that case $c_3 := i_1(c_1)c_2 \in i_1(A_{\mathrm{red}}) \cap B^* = i_1(A^*_{\mathrm{red}})$, and $i_2(c_3)A^\nu \subset j''_A(A_{\mathrm{red}})$. Now, let $Z_1, \dots, Z_k$ be the irreducible components of $\mathrm{Spec}\, A_{\mathrm{red}}$, and set $Z := \bigcup_{1 \leq i < j \leq k} Z_i \cap Z_j$; pick any ideal $J \subset A_{\mathrm{red}}$ such that $Z = \mathrm{Spec}\, A/J$. Hence, J does not lie in any minimal prime ideal of A_{red}, so $J \cap A^*_{\mathrm{red}} \neq \varnothing$ ([12, Prop.1.11(i)]); let then $d \in J \cap A^*_{\mathrm{red}}$. We have $Z \cap \mathrm{Spec}\, A_{\mathrm{red}}[d^{-1}] = \varnothing$, so i_1 induces an isomorphism $A_{\mathrm{red}}[d^{-1}] \xrightarrow{\sim} B[d^{-1}]$. Since B is a finite A_{red}-algebra, it follows that $d^n B \subset i_1(A_{\mathrm{red}})$, for some $n \in \mathbb{N}$, so $c_1 := d^n$ will do. Next, notice that $B^* = \prod_{\mathfrak{p} \in \mathrm{Min}\, A}(A/\mathfrak{p})^*$ and $(A^\nu)^* = \prod_{\mathfrak{p} \in \mathrm{Min}\, A}((A/\mathfrak{p})^\nu)^*$, so in order to exhibit c_2 it suffices to find for every $\mathfrak{p} \in \mathrm{Min}\, A$ some $c_\mathfrak{p} \in (A/\mathfrak{p})^* = (A/\mathfrak{p}) \setminus \{0\}$ with $c_\mathfrak{p}(A/\mathfrak{p})^\nu \subset A/\mathfrak{p}$. To this aim, it suffices to notice that, as A is excellent, $(A/\mathfrak{p})^\nu$ is a finite $A/\mathfrak{p}$-subalgebra of $\mathrm{Frac}(A/\mathfrak{p})$.
(ii) shall be left to the reader. ◊

Pick $c \in A^*_{\mathrm{red}}$ as in claim 17.5.38(i); set $\Sigma := \{ca \mid a \in A^*_{\mathrm{red}}\} \subset A^*_{\mathrm{red}}$, and let $c_\bullet \in (A_{\mathrm{red}})^\diamond$ be the class of $(c^{1/p^n} \mid n \in \mathbb{N})$. With this notation, claim 17.5.38(i) states that the image of Σ is cofinal in the partially ordered set $((A^\nu)^*, \leq)$. Moreover, j''_A induces an injection $A^{\mathrm{perf}}_{\mathrm{red}} = A^{\mathrm{perf}} \to (A^\nu)^{\mathrm{perf}}$; combining with claim 17.5.38(ii) we deduce that j''_A induces an isomorphism

$$(A^{\mathrm{perf}})^\diamond[c_\bullet^{-1}] \xrightarrow{\sim} ((A^\nu)^{\mathrm{perf}})^\diamond[c_\bullet^{-1}]$$

and on the other hand, $c_\bullet \in \mathsf{S}_b$ for every $b \in \Sigma$. Summing up, we conclude that $E_p(j''_A)$ is naturally identified with the colimit of the system of maps

$$\mathsf{S}_b^{-1}((A^\nu)^{\mathrm{perf}})^\diamond \to \mathsf{S}_{j''_A(b)}^{-1}((A^\nu)^{\mathrm{perf}})^\diamond \qquad \text{for every } b \in \Sigma \tag{17.5.39}$$

induced by the inclusion $\mathsf{S}_b \subset \mathsf{S}_{j''_A(b)}$, for every such b (here, S_b lies in $(A^{\mathrm{perf}})^\mathbb{N}$, whereas $\mathsf{S}_{j''_A(b)}$ lies in $((A^\nu)^{\mathrm{perf}})^\mathbb{N}$). In order to check that $E_p(j''_A)$ is an isomorphism, it then suffices to prove that the same holds for the maps (17.5.39); the latter follows at once from :

Claim 17.5.40. $c_\bullet \cdot s_\bullet \in \mathsf{S}_b$, for every $s_\bullet \in \mathsf{S}_{j_A(b)}$.

Proof of the claim. Say that $s_\bullet = (s_n \mid n \in \mathbb{N}) \in ((A^\nu)^{\mathrm{perf}})^{\mathbb{N}}$ and $b = ac$ for some $a \in (A^{\mathrm{perf}})^*$; we need to check that $b^{1/p^k} \in \bigcup_{n\in\mathbb{N}} c^{1/p^n} s_n A^{\mathrm{perf}}$ for every $k \in \mathbb{N}$. However, by assumption $j''_A(b^{1/p^k}) \in \bigcup_{n\in\mathbb{N}} s_n (A^\nu)^{\mathrm{perf}}$, so say that $j''_A(b^{1/p^k}) = s_n x$ for some $n \in \mathbb{N}$ and $x \in (A^\nu)^{\mathrm{perf}}$; also, we may assume that $n > k$. By claim 17.5.38(ii), we get $c^{1/p^n} x \in A^{\mathrm{perf}}$, and it follows easily that $(ac^2)^{1/p^k} = (bc)^{1/p^k} \in c^{1/p^n} s_n A^{\mathrm{perf}}$. Then we get $b^{2/p^k} = (ac)^{2/p^k} \in \bigcup_{n\in\mathbb{N}} c^{1/p^n} s_n A^{\mathrm{perf}}$ for every $k \in \mathbb{N}$, whence the claim. ◊

(ii): First, it is easily seen that the finite products in $\mathscr{B}_p$ are represented by the usual (cartesian) products of rings (details left to the reader). Hence, say that $A = A_1 \times \cdots \times A_n$, for some $A_1, \dots, A_n \in \mathrm{Ob}(\mathscr{B}_p)$. It is easily seen that $A^* = A_1^* \times \cdots \times A_n^*$. It is also clear that $(A^{\mathrm{perf}})^\diamond = \prod_{i=1}^n (A_i^{\mathrm{perf}})^\diamond$ (lemma 17.5.1(i)). Moreover, for each $a_\bullet := (a_1, \dots, a_n) \in A^*$, we have $\mathsf{S}_{a_\bullet} = \mathsf{S}_{a_1} \times \cdots \times \mathsf{S}_{a_n}$, and thus $\mathsf{S}_{a_\bullet}^{-1} = \prod_{i=1}^n \mathsf{S}_{a_i}^{-1}(A_i^{\mathrm{perf}})\diamond$. Since finite products commute with filtered colimits in the category of rings, the assertion follows. □

17.5.41. It turns out that the construction of big CM algebras over $\mathbb{Q}$-algebras can be reduced to the case of algebras of positive characteristic. Indeed, consider first a locally equidimensional $\mathbb{Q}$-algebra A of finite type. Let $\Delta(A)$ be the set of all $\mathbb{Z}$-subalgebras $B \subset A$ of finite type with $\mathbb{Q} \otimes_{\mathbb{Z}} B = A$. Let also $\mathrm{Max}\,\mathbb{Z}$ be the maximal spectrum of $\mathbb{Z}$, *i.e.* the set of prime integers.

Lemma 17.5.42. *With the notation of* (17.5.41)*, the following holds :*

(i) *Every connected component of* $\mathrm{Spec}\,A$ *is equidimensional.*

(ii) *For every* $B \in \Delta(A)$ *there exists a finite subset* $S_B \subset \mathrm{Max}\,\mathbb{Z}$ *such that* B/pB *is excellent and locally equidimensional, for every* $p \in \mathrm{Max}\,(\mathbb{Z}) \setminus S_B$.

Proof. (i): It suffices to check that if Z and Z' are two irreducible components ot $\mathrm{Spec}\,A$ with $Z \cap Z' \neq \varnothing$, then $\dim Z = \dim Z'$. Hence, pick any maximal ideal $\mathfrak{m}$ of A that lies in $Z \cap Z'$; by assumption, $A_{\mathfrak{m}}$ is equidimensional, and $Z(\mathfrak{m}), Z'(\mathfrak{m})$ are two irreducible components of $\mathrm{Spec}\,A_{\mathfrak{m}}$ (notation of definition 8.1.44(iii)), so $\dim Z(\mathfrak{m}) = \dim Z'(\mathfrak{m})$. On the other hand, $\dim Z = \dim Z(\mathfrak{m})$, and likewise for Z' ([64, Ch.IV, Prop.5.2.1]), whence the assertion.

(ii): Since the localization $B \to \mathbb{Q} \otimes_{\mathbb{Z}} B$ is injective, the unique morphism of schemes $\varphi : \mathrm{Spec}\,B \to \mathrm{Spec}\,\mathbb{Z}$ is flat. Let $T_1, \dots, T_l$ be the connected components of $\mathrm{Spec}\,A$, and for $i = 1, \dots, l$, denote by $\overline{T}_i$ the topological closure of T_i in $\mathrm{Spec}\,B$; since φ is generizing, it follows easily that $\mathrm{Spec}\,B = \overline{T}_1 \cup \cdots \cup \overline{T}_l$. On the other hand, for every $i = 1, \dots, l$, we have also $T_i = \mathrm{Spec}\,A/e_iA$, for a unique idempotent element $e_i \in A$; we may then find $d \in \mathbb{Z} \setminus \{0\}$ such that $e_1, \dots, e_l \in B[d^{-1}]$. Set $U := \mathrm{Spec}\,B[d^{-1}]$; it follows easily that the connected components of U are $\overline{T}_1 \cap U, \dots, \overline{T}_l \cap U$. After replacing B by $B[d^{-1}]$, we may then assume that $B = B_1 \times \cdots \times B_l$, and $\mathrm{Spec}\,\mathbb{Q} \otimes_{\mathbb{Z}} B_i$ is connected for every $i = 1, \dots, l$. Thus, it suffices to prove the assertion for A replaced by $\mathbb{Q} \otimes_{\mathbb{Z}} B_i$ for every $i = 1, \dots, l$, and we may therefore assume from start that $\mathrm{Spec}\,A$ is connected, so A is equidimensional, by (i).

Let $Z_1, \dots, Z_k$ be the irreducible components of $\mathrm{Spec}\,A$, and denote by $\overline{Z}_i$ the topological closure of Z_i in $\mathrm{Spec}\,B$, for every $i = 1, \dots, k$; it follows easily that $\overline{Z}_1, \dots, \overline{Z}_k$ are the irreducible components of $\mathrm{Spec}\,B$, and we endow them with their reduced closed subscheme structures. Then the restriction $\varphi_i : \overline{Z}_i \to \mathrm{Spec}\,\mathbb{Z}$ of φ is a flat morphism of schemes, for every $i = 1, \dots, k$. According to lemma 11.4.1(i), for every $p \in \mathrm{Max}\,\mathbb{Z}$ and every $i = 1, \dots, k$, every irreducible component of $\varphi_i^{-1}(p)$ has dimension equal to $\dim Z_i$, and we know already that the latter equals $d := \dim A$. Summing up, for every $p \in \mathrm{Max}\,\mathbb{Z}$, every irreducible component of $\mathrm{Spec}\,B/pB$ has dimension d; combining with [64, Ch.IV, Prop.5.2.1], we deduce that for every maximal ideal $\mathfrak{m} \subset B/pB$, the localization $(B/pB)_{\mathfrak{m}}$ is equidimensional of dimension d. Lastly, B/pB is an excellent ring, by [64, Ch.IV, Sch.7.8.3(ii)], so we may invoke lemma 17.5.31 to conclude. □

For every $B \in \Delta(A)$, pick a finite subset $S_B \subset \mathrm{Max}\,\mathbb{Z}$ fulfilling the condition of lemma 17.5.42(ii), and set

$$F_0(A,B) := \prod_{p\in\mathrm{Max}(\mathbb{Z})\setminus S_B} E_p(B/pB) \qquad \text{and} \qquad I_0(A,B) := \bigoplus_{p\in\mathrm{Max}(\mathbb{Z})\setminus S_B} E_p(B/pB)$$

where E_p is the functor exhibited in remark 17.5.36(ii). Notice then that $F_0(A,B)$ is naturally a B-algebra, and $I_0(A,B)$ is an ideal of $F_0(A,B)$; then the quotient

$$E_0(A,B) := F_0(A,B)/I_0(A,B)$$

is again endowed with a natural B-algebra structure. Moreover, if $B, B' \in \Delta(A)$, we may find $d \in \mathbb{Z} \setminus \{0\}$ such that $B[d^{-1}] = B'[d^{-1}]$, and hence $B/pB = B'/pB'$ for every $p \in \mathrm{Max}(\mathbb{Z}) \setminus \mathrm{Spec}\,\mathbb{Z}/d\mathbb{Z}$. There follows a natural identification

$$E_0(A,B) \xrightarrow{\sim} E_0(A,B')$$

in which of which, we shall denote this ring simply by $E_0(A)$. Since $A = \bigcup_{B\in\Delta(A)} B$, we conclude that $E_0(A)$ carries a natural A-algebra structure.

17.5.43. Next, let $f : A \to A'$ be a maximizing ring homomorphism of locally equidimensional $\mathbb{Q}$-algebras of finite type. Clearly, we may find $B \in \Delta(A)$ and $B' \in \Delta(A')$ such that f restricts to a ring homomorphism $g : B \to B'$. If $h : C \to C'$ is another such restriction with $C \in \Delta(A)$ and $C' \in \Delta'$, then for any $d \in \mathbb{Z} \setminus \{0\}$ such that $B[d^{-1}] = C[d^{-1}]$ and $B'[d^{-1}] = C'[d^{-1}]$ we have $\mathbb{Z}[d^{-1}] \otimes_\mathbb{Z} g = \mathbb{Z}[d^{-1}] \otimes_\mathbb{Z} h$, so the induced maps $\mathbb{F}_p \otimes_\mathbb{Z} g : B/pB \to B'/pB'$ and $\mathbb{F}_p \otimes_\mathbb{Z} h : C/pC \to C'/pC'$ are naturally identified for every $p \in \mathrm{Max}(\mathbb{Z}) \setminus \mathrm{Spec}\,\mathbb{Z}/d\mathbb{Z}$. Moreover, we have :

Lemma 17.5.44. *With the notation of* (17.5.43)*, there exists a finite subset $S_g \subset \mathrm{Max}\,\mathbb{Z}$ such that $\mathbb{F}_p \otimes_\mathbb{Z} g$ is maximizing for every $p \in \mathrm{Max}(\mathbb{Z}) \setminus S_g$.*

Proof. Notice first that B and B' are flat $\mathbb{Z}$-algebra, so all the maximal points of $X := \mathrm{Spec}\,B$ and $X' := \mathrm{Spec}\,B'$ lie in $\mathrm{Spec}\,A$ and respectively $\mathrm{Spec}\,A'$, so $\varphi := \mathrm{Spec}\,g$ is maximizing. Let $Z_1, \dots, Z_k$ (resp. $Z'_1, \dots, Z'_l$) be the irreducible components of X (resp. of X'), which we endow with their reduced closed subscheme structures; it follows that for every $i = 1, \dots, l$ there exists a unique $t(i) \in \{1, \dots, k\}$ such that φ restricts to a dominant morphism of schemes $\varphi_i : Z'_i \to Z_{t(i)}$. By [64, Ch.IV, Lemme 6.9.2], we may then find $h \in B \setminus \{0\}$ such that, with $U := \mathrm{Spec}\,B[h^{-1}]$, the morphism φ_i restricts to a flat morphism

$$\varphi_{i|U} : \varphi_i^{-1}(U \cap Z_{t(i)}) \to U \cap Z_{t(i)} \qquad \text{for every } i = 1, \dots, l.$$

Endow likewise the irreducible components $T_1, \dots, T_n$ of $\mathrm{Spec}\,B/hB$ with their reduced closed subscheme structures; by the same token, we may find $d \in \mathbb{Z} \setminus \{0\}$ such that, with $W := \mathrm{Spec}\,\mathbb{Z}[d^{-1}]$, the unique morphism of schemes $\psi_i : T_i \to \mathrm{Spec}\,\mathbb{Z}$ restricts to a flat morphism

$$\psi_i^{-1}(W) \to W \qquad \text{for every } i = 1, \dots, n.$$

Let $\eta \in \mathrm{Spec}\,\mathbb{Z}$ be the generic point; on the one hand, we have

$$\dim \psi_i^{-1}(\eta) < \dim A \qquad \text{for every } i = 1, \dots, n$$

and on the other hand, lemma 11.4.1(i) says that for every $p \in W$ we have :

$$\dim \psi_i^{-1}(p) = \dim \psi_i^{-1}(\eta) \quad \text{for every } i = 1, \dots, n \quad \text{and} \quad \dim B/pB = \dim A.$$

Summing up, we conclude that for every $p \in W \cap \mathrm{Max}(\mathbb{Z})$, all the maximal points of $\mathrm{Spec}\,B/pB$ lie in U. Arguing likewise with the irreducible components of $\mathrm{Spec}\,B'/hB'$, we get an open subset $W' \subset \mathrm{Spec}\,\mathbb{Z}$ such that, for every $p \in W \cap \mathrm{Max}(\mathbb{Z})$, all the maximal points of $\mathrm{Spec}\,B'/pB'$ lie in $\varphi^{-1}U$. But since each $\varphi_{i|U}$ is flat, for every $p \in \mathrm{Max}(\mathbb{Z})$ the restriction of φ :

$$\varphi^{-1}(U) \cap \mathrm{Spec}\,B'/pB' \to U \cap \mathrm{Spec}\,B/pB$$

is maximizing, so the lemma holds with $S_g := \mathrm{Max}(\mathbb{Z}) \setminus (W \cap W')$. □

Using lemma 17.5.44, we may attach to any $f : A \to A'$ as in (17.5.43) a well defined map

$$E_0(f) : E_0(A) \to E_0(A').$$

Namely, pick B, B' and $g : B \to B'$ as in (17.5.43), and finite subsets $S_B, S_{B'}, S_g \subset \mathrm{Max}\,\mathbb{Z}$ as in lemmata 17.5.42 and 17.5.44; set $M := \mathrm{Max}(\mathbb{Z}) \setminus (S_B \cup S_{B'} \cup S_g)$ and

$$F_0(f, g) := \prod_{p\in M} E_p(\mathbb{F}_p \otimes_{\mathbb{Z}} g) : \prod_{p\in M} E_p(B/pB) \to \prod_{p\in M} E_p(B'/pB').$$

Clearly $F_0(f, g)$ maps the ideal $\bigoplus_{p\in M} E_p(B/pB)$ into $\bigoplus_{p\in M} E_p(B'/pB')$, so it induces a unique map $E_0(f)$ as sought. It is also easily seen that if A'' is any other locally equidimensional $\mathbb{Q}$-algebra of finite type, and $f' : A' \to A''$ is any maximizing ring homomorphism, then $E_0(f' \circ f) = E_0(f') \circ E_0(f)$: details left to the reader. Summing up, we have a well defined functor

$$E_0 : \mathscr{B}_0 \to \mathbb{Z}\text{-}\mathsf{Alg}$$

where $\mathscr{B}_0$ is the category whose objects are the locally equidimensional $\mathbb{Q}$-algebras of finite type, and whose morphisms are the maximizing ring homomorphisms. Furthermore, just as in remark 17.5.36(iii), we have a normalization functor

$$(-)^\nu : \mathscr{B}_0 \to \mathscr{B}_0 \qquad A \mapsto \prod_{\mathfrak{p}\in\mathrm{Min}\,A} (A/\mathfrak{p})^\nu$$

(where $(A/\mathfrak{p})^\nu$ denotes the integral closure of $A/\mathfrak{p}$ in $\mathrm{Frac}(A/\mathfrak{p})$, for every $\mathfrak{p} \in \mathrm{Min}\,A$), as well as a natural transformation $j_\bullet : \mathbf{1}_{\mathscr{B}_0} \Rightarrow (-)^\nu$. With this notation, we may now state :

Theorem 17.5.45. (i) *$E_0(A)$ is a big locally CM A-algebra, for every $A \in \mathrm{Ob}(\mathscr{B}_0)$.*
(ii) *The functor E_0 commutes with finite products.*
(iii) *The functor E_0 factors through the functor $(-)^\nu$.*

Proof. (ii): It is easily seen that the products in $\mathscr{B}_0$ are represented by the usual (cartesian) products of rings; then, say that $A = A_1 \times \cdots \times A_k$ for some $A_1, \dots, A_k \in \mathrm{Ob}(\mathscr{B}_0)$, and pick $B_i \in \Delta(A_i)$ for $i = 1, \dots, k$. Clearly $B := B_1 \times \cdots \times B_k \in \Delta(A)$, and in light of proposition 17.5.37(ii), we easily deduce that $E_0(A, B) = \prod_{i=1}^k E_0(A_i, B_i)$, whence the assertion.

(i): In view of (ii) and lemma 17.5.42, we may assume that A is equidimensional. Then, let $\mathfrak{p} \subset A$ be any prime ideal; set $Z := \mathrm{Spec}\,A/\mathfrak{p}$, and $c := \dim\, A_\mathfrak{p}$. We show :

Claim 17.5.46. $\mathrm{depth}_\mathfrak{p}(E_0(A)) = c$.

Proof of the claim. Pick any $B \in \Delta(A)$, and let $\overline{Z}$ be the topological closure of Z in $\mathrm{Spec}\,B$, which we endow with its reduced closed subscheme structure. Hence, $\overline{Z} = \mathrm{Spec}\,B/\mathfrak{q}$, with $\mathfrak{q} = B \cap \mathfrak{p}$, and let $\mathbf{f} := (f_1, \dots, f_r)$ be any finite system of generators of $\mathfrak{q}$. In view of (10.4.30) and proposition 10.4.32(i), it suffices to check that $H^i(\mathbf{f}, E_0(A, B)) = 0$ for every $i < c$ and $H^c(\mathbf{f}, E_0(A, B)) \neq 0$. However, pick also a finite subset $S_B \subset \mathrm{Max}\,\mathbb{Z}$ as in lemma 17.5.42(ii); moreover, notice that the image of $\overline{Z}$ in $\mathrm{Spec}\,\mathbb{Z}$ is constructible and dense ([63, Ch.IV, Th.1.8.4]), so its complement S_Z is a finite set of closed points. Set $S := S_B \cup S_Z$; a direct inspection yields a natural short exact sequence of complexes of B-modules :

$$0 \to \bigoplus_{p\in\mathrm{Max}(\mathbb{Z})\setminus S} \mathbf{K}^\bullet(\mathbf{f}, E_p(B/pB)) \to \prod_{p\in\mathrm{Max}(\mathbb{Z})\setminus S} \mathbf{K}^\bullet(\mathbf{f}, E_p(B/pB)) \to \mathbf{K}^\bullet(\mathbf{f}, E_0(A, B)) \to 0$$

so we are reduced to checking that for every $p \in \mathrm{Max}(\mathbb{Z}) \setminus S$ we have :

$$H^i(\mathbf{f}, E_p(B/pB)) = 0 \qquad \text{for every } i < c, \text{ and} \qquad H^c(\mathbf{f}, E_p(B/pB)) \neq 0.$$

But since $E_p(B/pB)$ is a big locally CM B/pB-algebra, invoking again (10.4.30) and proposition 10.4.32(i), we are further reduced to showing that $\overline{Z} \cap \mathrm{Spec}\, B/pB$ has codimension c in $\mathrm{Spec}\, B/pB$, for every $p \in \mathrm{Max}(\mathbb{Z}) \setminus S$. But the unique morphisms of schemes $\varphi : \mathrm{Spec}\, B \to \mathrm{Spec}\, \mathbb{Z}$ and $\psi : \overline{Z} \to \mathrm{Spec}\, \mathbb{Z}$ are flat, and the generic fibre of φ (resp. ψ) is the equidimensional scheme $\mathrm{Spec}\, A$ (resp. Z), so $\varphi^{-1}(p)$ is as well equidimensional of dimension $\dim A$, for every $p \in \mathrm{Max}(\mathbb{Z}) \setminus S$, by lemma 11.4.1(i). By the same token, $\psi^{-1}(p)$ is equidimensional of dimension $\dim Z$, for every such p, whence the assertion. ◇

From claim 17.5.46 and (10.4.30), we already see that $\mathrm{depth}_{A_\mathfrak{p}} E_0(A)_\mathfrak{p} \geq \dim A_\mathfrak{p}$ for every prime ideal $\mathfrak{p} \subset A$. By the same token, if $\mathfrak{p} \subsetneq \mathfrak{q}$ are two such prime ideals, we have $\mathrm{depth}_{A_\mathfrak{q}} E_0(A)_\mathfrak{q} > \dim A_\mathfrak{p}$, so, again by virtue of claim 17.5.46 and (10.4.30), we must have $\mathrm{depth}_{A_\mathfrak{p}} E_0(A)_\mathfrak{p} = \dim A_\mathfrak{p}$ for every $\mathfrak{p} \in \mathrm{Spec}\, A$, as required.

(iii): Arguing as in the proof of proposition 17.5.37(i), for every $A \in \mathrm{Ob}(\mathscr{B}_0)$ we write $j_A : A \to A^\nu$ as the composition of the projection $j'_A : A \to A_{\mathrm{red}}$ onto the maximal reduced quotient, and the natural injective map $j''_A : A_{\mathrm{red}} \to A^\nu$. It is easily seen that both maps are morphisms of $\mathscr{B}_0$, and we then need to check that $E_0(j'_A)$ and $E_0(j''_A)$ are isomorphisms. However, clearly $B_{\mathrm{red}} \in \Delta(A_{\mathrm{red}})$, for every $B \in \Delta(A)$; for such B, pick a finite subset $S_B \subset \mathrm{Max}\, \mathbb{Z}$ as in lemma 17.5.42(ii). In order to prove that $E_0(j'_A)$ is an isomorphism, it suffices to check that the induced map $j'_{B,p} : B/pB \to B_{\mathrm{red}}/pB_{\mathrm{red}}$ induces an isomorphism $E_p(j'_{B,p}) : E_p(B/pB) \xrightarrow{\sim} E_p(B_{\mathrm{red}}/pB_{\mathrm{red}})$ for every $p \in \mathrm{Max}(\mathbb{Z}) \setminus S_B$; but $j'_{B,p}$ induces an isomorphism

$$(B/pB)_{\mathrm{red}} \xrightarrow{\sim} (B_{\mathrm{red}}/pB_{\mathrm{red}})_{\mathrm{red}}$$

so the assertion follows from proposition 17.5.37(i). Next, set $B^\nu := \prod_{\mathfrak{p} \in \mathrm{Max}\, B} (B/\mathfrak{p})^\nu$, and consider the commutative diagram of schemes :

$$\begin{array}{ccc} \mathrm{Spec}\, B^\nu & \xrightarrow{\pi} & \mathrm{Spec}\, B_{\mathrm{red}} \\ {\scriptstyle\psi}\downarrow & & \downarrow{\scriptstyle\varphi} \\ \mathrm{Spec}\, \mathbb{Z} & = & \mathrm{Spec}\, \mathbb{Z}. \end{array}$$

We have a maximal open subset $U \subset \mathrm{Spec}\, B_{\mathrm{red}}$ such that π restricts to an isomorphism $\pi^{-1}U \xrightarrow{\sim} U$, and since B_{red} is reduced, U is dense in $\mathrm{Spec}\, B_{\mathrm{red}}$. Let $\eta \in \mathrm{Spec}\, \mathbb{Z}$ be the generic point; it follows that $U \cap \varphi^{-1}(\eta)$ is a dense open subset of $\varphi^{-1}(\eta)$, and then there exists an open subset $V \subset \mathrm{Spec}\, \mathbb{Z}$ such that $U \cap \varphi^{-1}(x)$ is dense in $\varphi^{-1}(x)$ for every $x \in V$ ([65, Ch.IV, Prop.9.5.3]). Therefore, for every $x \in V$, the subset $\pi^{-1}U \cap \psi^{-1}(x)$ is open and dense in $\psi^{-1}(x)$, and π induces an isomorphism

$$\pi^{-1}U \cap \psi^{-1}(x) \xrightarrow{\sim} U \cap \varphi^{-1}(x) \qquad \text{for every } x \in V.$$

On the other hand, since the $\mathbb{Q}$-schemes $\varphi^{-1}(\eta)$ and $\psi^{-1}(\eta)$ are respectively geometrically reduced and geometrically normal, there exists a dense open subset $W \subset \mathrm{Spec}\, \mathbb{Z}$ such that $\varphi^{-1}(x)$ and $\psi^{-1}(x)$ are respectively a geometrically reduced and a geometrically normal $\kappa(x)$-scheme, for every $x \in W$ ([65, Ch.IV, Prop.9.9.4]). Summing up, we conclude that, for every $x \in V \cap W$, the fibre $\psi^{-1}(x)$ is the normalization of the affine reduced scheme $\varphi^{-1}(x)$. By proposition 17.5.37(ii), we conclude that the natural map $j''_{B,p} : B_{\mathrm{red}}/pB_{\mathrm{red}} \to B^\nu/pB^\nu$ induces an isomorphism $E_p(j''_{B,p})$ for every $p \in \mathrm{Max}(\mathbb{Z}) \cap V \cap W$. Therefore, j''_A induces an isomorphism $E_0(A_{\mathrm{red}}, B_{\mathrm{red}}) \xrightarrow{\sim} E_0(A^\nu, B^\nu)$, as required. □

Remark 17.5.47. For the definition of $E_0(A)$, we could have used instead an ultraproduct with respect to a non-principal ultrafilter of $\mathbb{N}$: this would have amounted to replacing $I_0(A, B)$ by a larger ideal (and thus, $E_0(A)$ by a smaller quotient); the resulting functor would have similar properties (and some others as well). The use of ultraproducts in commutative algebra is expounded in Schoutens's monograph [152], and our construction can be viewed as a simplification of the construction of big CM algebras in characteristic zero via ultraproducts, presented in [152, (6.4.2)].

17.5.48. The functor E_0 can be extended naturally to the category

$$\mathscr{B}'_0$$

whose objects are all locally equidimensional $\mathbb{Q}$-algebras of essentially finite type, and whose morphisms are again the maximizing ring homomorphisms. Indeed, for $A \in \mathrm{Ob}(\mathscr{B}'_0)$, let $\Delta'(A)$ be the set of $\mathbb{Q}$-subalgebras of finite type $B \subset A$, such that A is a localization of B. Notice that $\Delta'(A)$ is a filtered set, for the partial order given by inclusion of $\mathbb{Q}$-subalgebras; moreover, $A = \bigcup_{B\in\Delta'(A)} B$. Let also $\Delta''(A) := \{B \in \Delta'(A) \mid B \text{ is locally equidimensional}\}$. We notice:

Lemma 17.5.49. *With the notation of* (17.5.48)*, we have :*

(i) *For every* $B \in \Delta'(A)$*, the natural map* $\mathrm{Spec}\, A \to \mathrm{Spec}\, B$ *restricts to a bijection* $\mathrm{Min}\, A \xrightarrow{\sim} \mathrm{Min}\, B$ *on the respective sets of minimal prime ideals.*

(ii) $\Delta''(A)$ *is a cofinal subset of* $\Delta'(A)$*.*

Proof. (i): This is clear, since the natural morphism of schemes $\mathrm{Spec}\, A \to \mathrm{Spec}\, B$ is flat, injective on the underlying topological spaces, and with dense image.

(ii): Let $B \in \Delta'(A)$, so that $A = S^{-1}B$ for some multiplicative subset $S \subset B$, and say that $\mathrm{Min}\, A = \{\mathfrak{p}_1, \dots, \mathfrak{p}_n\}$. Set $\mathfrak{q}_i := B \cap \mathfrak{p}_i$ for every $i = 1, \dots, n$. Also, for $1 \le i < j \le n$, set $B_{ij} := B/(\mathfrak{q}_i + \mathfrak{q}_j)$ and $A_{ij} := A/(\mathfrak{p}_i + \mathfrak{p}_j) = S^{-1}B_{ij}$. For every such i, j and every $s \in S$, the induced map $\mathrm{Spec}\, A_{ij} \to \mathrm{Spec}\, B_{ij}[s^{-1}]$ restricts to an injective map of finite sets $\mathrm{Min}\, A_{ij} \to \mathrm{Min}\, B_{ij}[s^{-1}]$, and the system of such maps yields a natural identification : $\mathrm{Min}\, A_{ij} \xrightarrow{\sim} \lim_{s\in S} \mathrm{Min}\, B_{ij}[s^{-1}]$. Hence, for a suitable $s \in S$ we get bijections

$$\mathrm{Min}\, A_{ij} \xrightarrow{\sim} \mathrm{Min}\, B_{ij}[s^{-1}] \qquad \text{for every } 1 \le i < j \le n. \tag{17.5.50}$$

Now, both A and B are excellent rings ([64, Ch.IV, Sch.7.8.3(ii)]), and A fulfills condition (c) of lemma 17.5.31, since it is locally equidimensional; but in light of (17.5.50), we see that $B[s^{-1}]$ fulfills the same condition as well, so $B[s^{-1}] \in \Delta''(A)$, by lemma 17.5.31. □

In view of lemma 17.5.49(i), for every pair $B_1 \subset B_2$ of elements of $\Delta'(A)$, the inclusion map $B_1 \to B_2$ is trivially maximizing; with lemma 17.5.49(ii), we then get a well defined ring

$$E'_0(A) := \operatorname*{colim}_{B\in\Delta''(A)} E_0(B)$$

and the B-algebra structures on each $E_0(B)$ assemble into a natural A-algebra structure for $E'_0(A)$. Then, with theorem 17.5.45 and remark 17.5.19(iv), we see that $E'_0(A)$ is a big locally CM A-algebra. If $A \in \mathrm{Ob}(\mathscr{B}_0)$, clearly A is a final object of $\Delta''(A)$, so $E'_0(A) = E_0(A)$ in this case. Furthermore, let $f : A \to A'$ be any morphism of $\mathscr{B}'_0$; for every $B \in \Delta''(A)$, we may pick $B' \in \Delta''(A')$ such that f restricts to a map of $\mathbb{Q}$-algebras $g : B \to B'$. Since f is maximizing, from lemma 17.5.49(i) it follows easily that the same holds for g. We may therefore compose $E_0(g) : E_0(B) \to E_0(B')$ with the natural map $E_0(B') \to E_0(A')$, to get a ring homomorphism $h_B : E_0(B) \to E'_0(A)$, and it is easily seen that h_B depends only on the restriction $B \to A'$ of f (and is independent of the choice of B' : details left to the reader). The colimit of the system of maps $(h_B \mid B \in \Delta''(A))$ is a well defined ring homomorphism

$$E'_0(f) : E'_0(A) \to E'_0(A')$$

and the rules : $A \mapsto E'_0(A)$ and $f \mapsto E'_0(f)$ yield the sought functor $E' : \mathscr{B}'_0 \to \mathbb{Z}\text{-}\mathsf{Alg}$. Lastly, from theorem 17.5.45 we easily deduce that E'_0 commutes with finite products, and factors through the corresponding normalization functor $(-)^\nu : \mathscr{B}'_0 \to \mathscr{B}'_0$: details left to the reader.

17.5.51. We turn now to consider the case of a noetherian local ring $(A, \mathfrak{n})$ with residue field $k := A/\mathfrak{n}$ of characteristic $p > 0$. Arguing as in the proof of theorem 17.5.28, we can assume that A is a complete domain, with field of fractions of zero characteristic. By [126, Th.29.4], there exists a complete discrete valuation ring $R \subset A$ whose maximal ideal is pR, and such that the induced map $R/pR \to k$ is an isomorphism; moreover, if $p, x_1, \dots, x_n$ is any system of parameters of A, then the inclusion of R into A extends to a finite injective map :

$$R[[X_1, \dots, X_n]] \to A \qquad X_i \mapsto x_i \qquad \text{for } i = 1, \dots, n$$

whose image we call A_0. Let $\mathfrak{n}_0 \subset A_0$ be the maximal ideal; clearly the natural map $A_0/\mathfrak{n}_0 \to k$ is an isomorphism. Pick also $g \in A_0 \setminus \{0\}$ such that $A[g^{-1}]$ is faithfully flat étale over $A_0[g^{-1}]$.

• *We consider first the case where* $[k : k^p] < +\infty$, and we pick $x_{n+1}, \dots, x_m \in A_0$ whose classes in k form a p-basis (*i.e.* a basis of the k^p-vector space k). Set $x_0 := p$, and

$$A_\infty := A_0[T_0^{1/p^\infty}, \dots, T_m^{1/p^\infty}]/(x_0 - T_0, \dots, x_m - T_m)$$

(notation as in example 4.8.55(iii)). Notice that the sequence $(p, x_{n+1}, \dots, x_m)$ is maximal in the sense of remark 9.6.35(iii); hence A_∞ is formally perfectoid for its p-adic topology, according to theorem 17.2.14(iv). Next, if $g \in \{p, x_1, \dots, x_m\}$, set $B_\infty := A_\infty$, and otherwise, let

$$B_\infty := A_\infty[T_{m+1}^{1/p^\infty}]/(g - T_{m+1}).$$

In either case, let C be the p-root closure of B_∞ in $B_\infty[1/p]$, and $C^\wedge$ the p-adic completion of C; then $C^\wedge$ is perfectoid for its p-adic topology, and C is a faithfully flat A_∞-algebra (theorem 16.9.17). Let D be the integral closure of $C^\wedge$ in $C^\wedge \otimes_{A_0} A[1/g]$, and $D^\wedge$ the p-adic completion of D. Denote also by $\mathfrak{m} \subset C$ the ideal generated by $(g^{1/p^n} \mid n \in \mathbb{N})$; clearly $(C, \mathfrak{m})$ is a basic setup (in the sense of [75, §2.1.1]), and we let $(C^\wedge)^a$ and D^a be the $(C, \mathfrak{m})^a$-algebras arising from $C^\wedge$ and respectively D.

Lemma 17.5.52. (i) *D^a is faithfully flat over A_0, in the sense of definition* 14.2.40.
(ii) *The basic setup $(D^\wedge, \mathfrak{m}D^\wedge)$ is almost perfectoid.*

Proof. Denote as usual by $(C^\wedge)^a_*$ the ring of almost elements of $(C^\wedge)^a$, and let D_1 be the integral closure of $(C^\wedge)^a_*$ in $C^\wedge \otimes_{A_0} A[1/g]$. Recall that the natural morphism $D^a \to D_1^a$ of $(C^\wedge, \mathfrak{m})^a$-algebras is an isomorphism ([75, Lemma 8.2.28]); taking into account theorem 16.9.42(i,iii), it follows that D^a is a p-adically complete C^a-algebra, that $(D/p^nD)^a$ is a faithfully flat $(C/p^nC)^a$-algebra, for every $n \in \mathbb{N}$, and that (ii) holds. By virtue of proposition 14.2.43, in order to prove that D^a is flat over A_0, it then suffices to check that $(D/p^nD)^a$ is flat over A_0/p^nA_0, for every $n \in \mathbb{N}$. But it is easily seen that A_∞ is a flat A_0-algebra, whence the assertion. By lemma 14.2.41(ii), we then come down to checking that $(D/\mathfrak{n}_0D)^a \neq 0$. Since we already know that $(D/pD)^a$ is a faithfully flat $(C/pC)^a$-algebra, and since $p \in \mathfrak{n}_0$, we are further reduced to checking that $(C/\mathfrak{n}_0C)^a \neq 0$. In turns, this amounts to showing that $g^{1/p^m} \notin \mathfrak{n}_0C$ for some $m \in \mathbb{N}$. If the latter fails, we get :

$$g \in \mathfrak{n}_0^n C \qquad \text{for every } n \in \mathbb{N}. \tag{17.5.53}$$

Now, recall that C is a faithfully flat A_∞-algebra, and A_∞ is a faithfully flat A_0-algebra, so C is a faithfully flat A_0-algebra. Then, from (17.5.53) we deduce that $g \in \bigcap_{n \in \mathbb{N}} \mathfrak{n}_0^n$. But the $\mathfrak{n}_0$-adic topology of A_0 is separated ([126, Th.8.10(i)]), hence $g = 0$, a contradiction. □

Denote by $\mathsf{S} \subset C^{\mathbb{N}}$ the multiplicative subset associated with $\mathfrak{m}$, as in (17.5.2); we endow $E := \mathsf{S}^{-1}D^\diamond$ with its p-adic topology, and denote by E^{sep} the maximal separated quotient of E. Notice that D contains the integral closure of A_0 in $A[1/g]$, which contains A, hence D is naturally an A-algebra, and therefore the same holds for E and E^{sep}. We may then state :

Theorem 17.5.54. *E and E^{sep} are big CM A-algebras, and E^{sep} is perfectoid.*

Proof. In order to show that $E^{\rm sep}$ is perfectoid, it suffices to invoke lemmata 17.5.52(ii) and 17.5.10. Next, in light of remark 17.5.19(iii), it suffices to show that E and $E^{\rm sep}$ are big CM A_0-algebras. By lemmata 17.5.52(i) and 17.5.4(v), E is a faithfully flat A_0-algebra; then, by proposition 14.2.43(i), the same holds for the A_0-algebra $E^{\rm sep}$, since the latter is the p-adic completion of E (proposition 17.5.8). Especially, $E/\mathfrak{n}_0 E \stackrel{\sim}{\to} E^{\rm sep}/\mathfrak{n}_0 E^{\rm sep} \neq 0$. Now the theorem follows from lemma 10.4.20, proposition 10.4.32(i), and remark 17.5.19(i). □

• *Next, we consider the case where $[k : k^p]$ can be infinite.* Define the regular local ring $(A_0, \mathfrak{n}_0)$, and pick $g \in A_0$ as in the foregoing case; choose also a family $(b_\lambda \mid \lambda \in \Lambda)$ of elements of A_0 whose image $(\bar{b}_\lambda \mid \lambda \in \Lambda)$ in k is a p-basis. Again, we set $x_0 := p$, and

$$A_\infty := A_0[T_0^{1/p^\infty}, \dots, T_n^{1/p^\infty}][T_\lambda^{1/p^\infty} \mid \lambda \in \Lambda]/(x_0 - T_0, \dots, x_n - T_n, b_\lambda - T_\lambda \mid \lambda \in \Lambda).$$

We endow A_∞ with its $\mathfrak{n}_0$-adic topology, and let $A_\infty^\wedge$ be the completion of A_∞.

Lemma 17.5.55. *$A_\infty^\wedge$ is perfectoid for its p-adic topology.*

Proof. With the notation of (9.8.11), set

$$B_0 := k[[T_0, \dots, T_n]] \otimes_k k^{\rm perf} \qquad B_\infty := k[[T_0^{1/p^\infty}, \dots, T_n^{1/p^\infty}]] \otimes_k k^{\rm perf}$$

and let $\bar{\mathfrak{n}}_0 \subset B_0$ be the ideal generated by $T_0, \dots, T_n$. Endow B_∞ with its $\bar{\mathfrak{n}}_0$-adic topology, and let $B_\infty^\wedge$ be the completion of B_∞. Then B_∞ is naturally an A_0-algebra, via the projection $A_0 \to k$, and by simple inspection we get an isomorphism of topological A_0-algebras

$$A_\infty/pA_\infty \stackrel{\sim}{\to} B_\infty/T_0 B_\infty \quad T_i^{1/p^k} \mapsto T_i^{1/p^k} \ (i = 0, \dots, n) \quad T_\lambda^{1/p^k} \mapsto 1 \otimes \bar{b}_\lambda^{1/p^k} \ \text{ for every } \lambda \in \Lambda$$

for the respective quotient topologies. Notice that the sequence $(p, x_1, \dots, x_n)$ is A_0-regular, hence also A_∞-regular, since A_∞ is a faithfully flat A_0-algebra; by proposition 7.8.15, we deduce that the $\mathfrak{n}_0$-topology of A_∞ induces the $\mathfrak{n}_0$-topology on the ideal pA_∞, and therefore the natural map $A_\infty^\wedge/pA_\infty^\wedge \to (A_\infty/pA_\infty)^\wedge$ is an isomorphism of topological rings (proposition 8.2.13(i,v)). Likewise, the sequence $(T_0, \dots, T_n)$ is B_0-regular, hence also B_∞-regular, since B_∞ is a faithfully flat B_0-algebra; arguing as in the foregoing, we deduce that the natural map $B_\infty^\wedge/T_0 B_\infty^\wedge \to (B_\infty/T_0 B_\infty)^\wedge$ is as well an isomorphism of topological rings. However, by direct inspection we see that $B_0^{\rm perf}$ is a dense subring of $B_\infty^\wedge$ (here it is important to work with the $\bar{\mathfrak{n}}_0$-adic topology), and the $\bar{\mathfrak{n}}_0$-adic topology of $B_\infty^\wedge$ induces the $\bar{\mathfrak{n}}_0$-adic topology on $B_0^{\rm perf}$; hence $B_\infty^\wedge$ is also the completion C of $B_0^{\rm perf}$ (theorem 8.2.8(iii)), and therefore it is a perfect topological $\mathbb{F}_p$-algebra (remark 9.4.9(v) and corollary 9.4.14). Summing up, we see that $A_\infty^\wedge/pA_\infty^\wedge$ is isomorphic to $C/T_0 C$, and clearly the Frobenius endomorphism of C induces a bijection $C/T_0^{1/p} C \stackrel{\sim}{\to} C/T_0 C$; therefore the Frobenius endomorphism of $A_\infty^\wedge$ induces a bijection $A_\infty^\wedge/p^{1/p} A_\infty^\wedge \stackrel{\sim}{\to} A_\infty^\wedge/pA_\infty^\wedge$. Moreover, $A_\infty^\wedge$ is complete and separated for its p-adic topology (lemma 8.3.12); then the lemma follows from corollary 16.3.75. □

17.5.56. We may now proceed as in the previous case : if $g \in \{x_0, \dots, x_n\} \cup \{b_\lambda \mid \lambda \in \Lambda\}$, set $B_\infty := A_\infty$, and otherwise set $B_\infty := A_\infty^\wedge[X^{1/p^\infty}]/(g - X)$. Let also C be the p-root closure of B_∞ in $B_\infty[1/p]$, and $C^\wedge$ the p-adic completion of C. Then, again by theorem 16.9.17, $C^\wedge$ is perfectoid and C is a faithfully flat $A_\infty^\wedge$-algebra. Denote by $\mathfrak{m} \subset C^\wedge$ the ideal generated by $(g^{1/p^n} \mid n \in \mathbb{N})$, by D be the integral closure of $C^\wedge$ in $C^\wedge \otimes_{A_0} A[1/g]$, and by $D^\wedge$ the p-adic completion of D. Arguing as in (17.5.51) we see that $(D/p^n D)^a$ is a faithfully flat $(C/p^n C)^a$-algebra for every $n \in \mathbb{N}$ (relative to the basic setup $(C^\wedge, \mathfrak{m})$), and $(D^\wedge, \mathfrak{m}D^\wedge)$ is an almost perfectoid basic setup. Moreover, $A_\infty^\wedge$ is the $\mathfrak{n}_0$-adic completion of a faithfully flat A_0-algebra, hence it is a faithfully flat A_0-algebra (proposition 14.2.43(i)). Thus, C is a faithfully flat A_0-algebra. After these observations, the proof of lemma 17.5.52 can be repeated in our current situation, so that D^a is still faithfully flat over A_0 (in the sense of definition 14.2.40). Lastly, we define again $E := \mathsf{S}^{-1} D^\diamond$, and let $E^{\rm sep}$ be the maximal p-adically separated quotient of E; now the proof of theorem 17.5.54 applies again *verbatim*, and we finally conclude that E and E^{sep} are big CM A-algebras, and that E^{sep} is perfectoid for its p-adic topology.

17.5.57. Next, we would like to upgrade the constructions of the previous paragraphs to a functor on a suitable category of local noetherian domains. Hence, let $(A, \mathfrak{n})$ be a local noetherian domain, complete for its $\mathfrak{n}$-adic topology, with field of fractions of zero characteristic, and residue field k of characteristic $p > 0$, and suppose first that $[k : k^p] < +\infty$. Let $\Sigma \subset A \setminus \{0\}$ be a finite subset with $p \in \Sigma$, and $\Sigma' \subset \Sigma$ a non-empty subset; we consider the category

$$\mathscr{C}^A_{\Sigma,\Sigma'}$$

whose objects are all pairs (f, Δ), where $f : A \to B$ is a ring homomorphism, and $\Delta := (\beta_{a,\bullet} \mid a \in \Sigma)$ is a family of elements of $\mathbf{E}(B)$ (notation of remark 9.4.12(ii)), fulfilling the following conditions :

(a) the projection $\beta_{a,0} \in B$ of $\beta_{a,\bullet}$ equals $f(a)$, for every $a \in \Sigma$ (especially, $\beta^p_{p,1} = p$)
(b) let $\mathfrak{m} \subset B$ be the ideal generated by the system $(\delta_n := \prod_{a\in\Sigma'} \beta_{a,n} \mid n \in \mathbb{N})$; we call $(B, \mathfrak{m})$ the *basic setup attached to* (f, Δ), and denote by $(B, \mathfrak{m})^a$ the $(B, \mathfrak{m})^a$-algebra arising from B; then the unit of adjunction $B \to (B, \mathfrak{m})^a_*$ is an isomorphism
(c) B is p-torsion free, and complete and separated for its p-adic topology
(d) B is δ_0-torsion free, integrally closed in $B[\delta_0^{-1}]$, and p-root closed in $B[p^{-1}]$.

For two such pairs $(f : A \to B, \Delta)$ and $(f' : A \to B', \Delta' := (\beta'_{a,\bullet} \mid a \in \Sigma))$, the morphisms $(f, \Delta) \to (f', \Delta')$ in $\mathscr{C}^A_{\Sigma,\Sigma'}$ are the ring homomorphisms $h : B \to B'$ with :

$$f' = h \circ f \qquad \text{and} \qquad \mathbf{E}(h)(\beta_{a,\bullet}) = \beta'_{a,\bullet} \quad \text{for every } a \in \Sigma.$$

We shall say that the object $(f : A \to B, \Delta)$ of $\mathscr{C}^A_{\Sigma,\Sigma'}$ is *almost perfectoid*, if the basic setup $(B, \mathfrak{m})$ attached to (f, Δ) is almost perfectoid for the p-adic topology of B.

Remark 17.5.58. Let $\Sigma_1 \subset \Sigma_2$ be two finite subsets of $A \setminus \{0\}$ with $p \in \Sigma_1$, and $\Sigma'_1 \subset \Sigma_1$, $\Sigma'_2 \subset \Sigma_2$ two subsets, with $\varnothing \neq \Sigma'_1 \subset \Sigma'_2$. For every object $(f : A \to B, \Delta := (\beta_{a,\bullet} \mid a \in \Sigma_2))$ of $\mathscr{C}^A_{\Sigma_2,\Sigma'_2}$ set $\Delta_{|\Sigma_1} := (\beta_{a,\bullet} \mid a \in \Sigma_2)$. By remark 14.2.7(ii), we get a well defined functor :

$$\mathscr{C}^A_{\Sigma_2,\Sigma'_2} \to \mathscr{C}^A_{\Sigma_1,\Sigma'_1} \qquad (f, \Delta) \mapsto (f, \Delta)_{|\Sigma_1,\Sigma'_1} := (f, \Delta_{|\Sigma_1}).$$

Proposition 17.5.59. *Let $\Sigma_1 \subset \Sigma_2$ be an inclusion of finite subsets of $A \setminus \{0\}$ with $p \in \Sigma_1$, and $\Sigma'_1 \subset \Sigma_1$, $\Sigma'_2 \subset \Sigma_2$ two non-empty subsets, with $\Sigma'_1 \subset \Sigma'_2$. If the category $\mathscr{C}^A_{\Sigma_1,\Sigma'_1}$ admits an almost perfectoid initial object, the same holds for the category $\mathscr{C}^A_{\Sigma_2,\Sigma'_2}$.*

Proof. Let $(f_1 : A \to D_1, \Delta_1)$ be a given almost perfectoid initial object of $\mathscr{C}^A_{\Sigma_1,\Sigma'}$, with $\Delta_1 := (\beta_{x,\bullet} \mid x \in \Sigma_1)$, and let $\mathfrak{m}_1 \subset D_1$ be the ideal generated by $(\delta_n := \prod_{x\in\Sigma'_1} \beta_{x,n} \mid n \in \mathbb{N})$.

We suppose first that $\Sigma' := \Sigma'_2 = \Sigma'_1$, and we are easily reduced to the case where $\Sigma_2 = \Sigma_1 \cup \{a\}$ for some $a \in A$. We set

$$D'_2 := D_1[T^{1/p^\infty}]/(a - T).$$

Let D''_2 be the p-root closure of D'_2 in $D'_2[1/p]$, and $D''^{\wedge}_2$ the p-adic completion of D''_2. For every $x \in \Sigma_1$, denote by $\beta'_{x,\bullet} \in \mathbf{E}(D'_2)$ the image of $\beta_{x,\bullet}$, and let likewise

$$\beta'_{a,\bullet} := (\overline{T}^{1/p^n} \mid n \in \mathbb{N}) \in \mathbf{E}(D'_2)$$

where $\overline{T}^{1/p^n} \in D'_2$ denotes the image of T^{1/p^n}, for every $n \in \mathbb{N}$. Set $D_2 := (D''^{\wedge}_2, \mathfrak{m}_1 D''^{\wedge}_2)^a_*$, and let $f_2 : A \to D_2$ be the structure map of the A-algebra D_2. Lastly, let $\beta''_{x,\bullet} \in \mathbf{E}(D_2)$ be the image of $\beta'_{x,\bullet}$, for every $x \in \Sigma_2$, and set $\Delta_2 := (\beta''_{x,\bullet} \mid x \in \Sigma_2)$. We show more precisely :

Claim 17.5.60. (f_2, Δ_2) is an almost perfectoid initial object of the category $\mathscr{C}^A_{\Sigma_2,\Sigma'}$.

Proof of the claim. By proposition 17.5.16, the basic setup $(D_2''^{\wedge}, \mathfrak{m}_1 D_2''^{\wedge})$ is almost perfectoid, hence the same holds for $(D_2, \mathfrak{m}_1 D_2)$, by proposition 16.9.37(iii); then D_2 is p-root closed in $D_2[1/p]$, by proposition 16.9.37(iv), and is integrally closed in $D_2[1/\delta_0]$, by virtue of proposition 17.5.14(ii). This shows that (f_2, Δ_2) is an almost perfectoid object of $\mathscr{C}^A_{\Sigma_2,\Sigma'}$.

Next, let $(f : A \to D, \Delta := (\delta_{x,\bullet} \mid x \in \Sigma_2))$ be any other object of $\mathscr{C}^A_{\Sigma_2,\Sigma'}$; by assumption, there exists a unique morphism $h_0 : (f_1, \Delta_1) \to (f, \Delta')_{|\Sigma_1,\Sigma'}$ in $\mathscr{C}^A_{\Sigma_1,\Sigma'}$ (notation of remark 17.5.58). Clearly h_0 extends to a unique map $h_1 : D_2' \to D$ such that $\mathbf{E}(h_1)(\beta'_{x,\bullet}) = \delta_{x,\bullet}$ for every $x \in \Sigma_2$, and arguing as in the proof of proposition 17.5.62, we see that $A_0[1/p] \otimes_{1_0} h_1 : D_2'[1/p] \to D[1/p]$ restricts to a map of A-algebras $h_2 : D_2'' \to D$. Since D is p-adically complete and separated, the completion of h_2 is a map $h_2^{\wedge} : D_2''^{\wedge} \to D$, and since $D = D^a_*$, the latter induces a map of A-algebras $h := (h_2^{\wedge})^a_* : D_2 \to D$; it is then easily seen that h is the unique morphism $(f_2, \Delta_2) \to (f, \Delta)$ in $\mathscr{C}^A_{\Sigma_2,\Sigma'}$. ◊

It remains to consider the case where $\Sigma := \Sigma_1 = \Sigma_2$. Then, let $\mathfrak{m}_2 \subset D_1$ be the ideal generated by $(\gamma_n := \prod_{x\in\Sigma_2'} \beta_{x,n} \mid n \in \mathbb{N})$; endow $D_2 := (D_1, \mathfrak{m}_2)^a_*$ with its p-adic topology, and let $\eta : D_1 \to D_2$ be the unit of adjunction. Since the basic setup $(D_1, \mathfrak{m}_1)$ is almost perfectoid, and since $\mathfrak{m}_2 \subset \mathfrak{m}_1$, it is clear that the basic setup $(D_1, \mathfrak{m}_2)$ is almost perfectoid. Then the same holds for the basic setup $(D_2, \mathfrak{m}_2 D_2)$, according to proposition 16.9.37(iii). By proposition 17.5.14(ii), it follows that D_2 is γ_0-torsion free and integrally closed in $D_2[\gamma_0^{-1}]$. For every $x \in \Sigma$, let $\beta'_{x,\bullet} \in \mathbf{E}(D_2)$ be the image of $\beta_{x,\bullet}$; set $\Delta_2 := (\beta'_{x,\bullet} \mid x \in \Sigma)$ and $f_2 := \eta \circ f_1$. The foregoing already shows that (f_2, Δ_2) is an object of $\mathscr{C}^A_{\Sigma,\Sigma_2'}$. Lastly, let $(f' : A \to D', \Delta')$ be any object of $\mathscr{C}^A_{\Sigma,\Sigma_2'}$; by assumption, there exists a unique morphism $h : (f_1, \Delta_1) \to (f', \Delta')_{|\Sigma,\Sigma_1'}$ in $\mathscr{C}^A_{\Sigma,\Sigma_1'}$, and since $D' = (D', \mathfrak{m}_2)^a_*$, it follows easily that $(h, \mathfrak{m}_2)^a_* : D_2 \to D'$ is the unique morphism $(f_2, \Delta_2) \to (f', \Delta')$ in $\mathscr{C}^A_{\Sigma,\Sigma_2'}$. □

17.5.61. Resume the notation of (17.5.51), set $x_0 := p$, and define either $t := m$ if $g \in \{x_0, \dots, x_m\}$, or else $t := m + 1$ and $x_t := g$; we take

$$\Sigma_0 := \{x_0, \dots, x_t\} \qquad \Sigma_0' := \{x_t\}.$$

Let also $f_0 : A \to D^a_* := (D, \mathfrak{m}D)^a_*$ be the structure map of the A-algebra D^a_*, and for $i = 0, \dots, t$, set $\beta_{x_i,\bullet} := (\overline{T}_i^{1/p^n} \mid n \in \mathbb{N}) \in \mathbf{E}(D^a_*)$, where $\overline{T}_i^{1/p^n} \in D^a_*$ denotes the image of T_i^{1/p^n}, for every such i and every $n \in \mathbb{N}$. Set $\Delta_0 := (\beta_{a,\bullet} \mid a \in \Sigma_0)$. Lastly, let $\Sigma_1' \subset \Sigma_1 \subset A \setminus \{0\}$ be two finite subsets with $\Sigma_0 \subset \Sigma_1$ and $\Sigma_0' \subset \Sigma_1'$.

Proposition 17.5.62. *In the situation of* (17.5.61)*, we have :*

(i) *The pair (f_0, Δ_0) is an almost perfectoid initial object of the category $\mathscr{C}^A_{\Sigma_0,\Sigma_0'}$.*

(ii) *Let $(f_1 : A \to D_1, \Delta_1)$ be an initial object of $\mathscr{C}^A_{\Sigma_1,\Sigma_1'}$, and $(D_1, \mathfrak{m}_1)$ the basic setup attached to (f_1, Δ_1). Then $(D_1, \mathfrak{m}_1)^a$ is faithfully flat over A_0, in the sense of definition* 14.2.40.

Proof. (i): From theorem 16.9.42(i,v) and lemma 16.9.41 we see that (f_0, Δ_0) is an almost perfectoid object of $\mathscr{C}^A_{\Sigma_0,\Sigma_0'}$. Now, define B_∞, C and $C^{\wedge}$ as in (17.5.51), and let

$$(f' : A \to D', \Delta' := (\beta'_{a,\bullet} \mid a \in \Sigma_0))$$

be any other object of $\mathscr{C}^A_{\Sigma_0,\Sigma'}$; clearly there exists a unique homomorphism $h_0 : B_\infty \to D'$ of A_0-algebras such that $\mathbf{E}(h_0)(\beta_{a,\bullet}) = \beta'_{a,\bullet}$ for every $a \in \Sigma_0$. Since D' is p-root closed in $D'[1/p]$, by proposition 9.8.28(i,ii) and remark 9.8.16(i), the map

$$A_0[1/p] \otimes_{A_0} h_0 : B_\infty[1/p] \to D'[1/p]$$

restricts to a map of A_0-algebras $h_1 : C \to D'$, and clearly h_1 is the unique map of A_0-algebras extending h_0. Next, h_1 extends uniquely to a map of A_0-algebras $h_1^{\wedge} : C^{\wedge} \to D'$, since by assumption D' is p-adically complete and separated. Set $h_2 := A[1/g] \otimes_{A_0} h_1^{\wedge} :$

$A[1/g] \otimes_{A_0} C^\wedge \to D'[1/g]$; by assumption, the localization $D' \to D'[1/g]$ is injective, and D' is integrally closed in $D'[1/g]$, so h_2 restricts to a map of A-algebras $h_3 : D \to D'$. Lastly, since $D' = (D')^a_*$, we get an induced map of A-algebras $h := h^a_{3*} : D^a_* \to D'$, and by construction it is easily seen that h is the unique morphism $(f_0, \Delta_0) \to (f', \Delta')$ in $\mathscr{C}^A_{\Sigma_0,\Sigma'_0}$.

(ii): Suppose first that $\Sigma'_1 = \Sigma'_0$. Recall that D_1 is p-adically complete and separated; taking into account proposition 14.2.43, in order to show that $(D_1, \mathfrak{m}_1)^a$ is flat over A_0, it then suffices to check that $(D_1/p^n D_1)^a$ is flat over $A_0/p^n A_0$ for every $n \in \mathbb{N}$. But lemma 17.5.52(i) implies that $(D/p^n D)^a$ is flat over $A_0/p^n A_0$ for every such n; hence we come down to the following :

Claim 17.5.63. In the situation of proposition 17.5.59, suppose that $\Sigma' := \Sigma'_1 = \Sigma'_2$, and let $(f_1 : A \to D_1, \Delta_1)$ (resp. $(f_2 : A \to D_2, \Delta_2)$) be an initial object of $\mathscr{C}^A_{\Sigma_1,\Sigma'}$ (resp. of $\mathscr{C}^A_{\Sigma_2,\sigma'}$). Let also $(D_1, \mathfrak{m}_1)$ be the basic setup attached to (f_1, Δ_1). Then the unique morphism $(f_1, \Delta_1) \to (f_2, \Delta_2)_{\Sigma_1,\Sigma'}$ in $\mathscr{C}^A_{\Sigma_1,\Sigma'}$ induces a faithfully flat morphism of $(D_1, \mathfrak{m}_1)^a$-algebras

$$(D_1/p^n D_1)^a \to (D_2/p^n D_2)^a \qquad \text{for every } n \in \mathbb{N}.$$

Proof of the claim. We are easily reduced to the case where $\Sigma_2 = \Sigma_1 \cup \{a\}$ for some $a \in A\setminus\{0\}$, and then the assertion follows from proposition 17.5.16, after inspecting the proof of proposition 17.5.59. ◊

By lemma 14.2.41(ii), there remains only to show that $(D_1/\mathfrak{n}_0 D_1)^a \neq 0$. Since $p \in \mathfrak{n}_0$, it suffices to check that $(D_1/pD_1)^a$ is faithfully flat over A_0/pA_0; since the morphism $(D/pD)^a \to (D_1/pD_1)^a$ is faithfully flat (claim 17.5.63), lemma 14.2.41(iii) further reduces to checking that $(D/pD)^a$ is faithfully flat over A_0/pA_0, which follows from lemma 17.5.52(i).

To deal with the general case, let $(f'_1 : A \to D'_1, \Delta'_1 := (\beta'_{a,\bullet} \mid a \in \Sigma_1))$ be an initial object of $\mathscr{C}^A_{\Sigma_1,\Sigma'_0}$, and $\mathfrak{m}'_1 \subset D'_1$ the ideal generated by $(\beta'_n := \prod_{a\in\Sigma'_1} \beta'_{a,n} \mid n \in \mathbb{N})$. By the foregoing, the $(C, \mathfrak{m})^a$-algebra $(D'_1, \mathfrak{m}D'_1)^a$ is faithfully flat over A_0, and by inspecting the proof of proposition 17.5.59, we see that the A-algebra D_1 is isomorphic to $(D'_1, \mathfrak{m}'_1)^a_*$. Hence, the two functors

$$A_0\text{-}\mathbf{Mod} \to (D_1, \mathfrak{m}_1)^a\text{-}\mathbf{Mod} \qquad N \mapsto (D_1, \mathfrak{m}_1)^a \otimes_{A_0} N \qquad N \mapsto (D'_1, \mathfrak{m}'_1)^a \otimes_{A_0} N$$

are isomorphic (notation of definition 14.2.40). However, the functor $(D'_1, \mathfrak{m}'_1)^a \otimes_{A_0} -$ is the composition of the exact functor

$$A_0\text{-}\mathbf{Mod} \to (D'_1, \mathfrak{m}D'_1)^a\text{-}\mathbf{Mod} \qquad N \mapsto (D'_1, \mathfrak{m}D'_1)^a \otimes_{A_0} N$$

and the natural functor $(D'_1, \mathfrak{m}D'_1)^a\text{-}\mathbf{Mod} \to (D'_1, \mathfrak{m}'_1)^a\text{-}\mathbf{Mod} \xrightarrow{\sim} (D_1, \mathfrak{m}_1)^a\text{-}\mathbf{Mod}$, which is obviously exact, so the same holds for the functor $(D'_1, \mathfrak{m}'_1)^a \otimes_{A_0} -$, and hence also for $(D_1, \mathfrak{m}_1)^a \otimes_{A_0} -$, *i.e.* $(D_1, \mathfrak{m}_1)^a$ is flat over A_0. Again, there remains to show that the $(D_1, \mathfrak{m}_1)^a$-module $(D_1/\mathfrak{n}_0 D_1)^a$ is not zero, or equivalently, that the same holds for the $(D'_1, \mathfrak{m}'_1)^a$-module $(D'_1/\mathfrak{n}_0 D'_1)^a$. Suppose that the latter fails; then we have $\beta'_n \in \mathfrak{n}_0 D'_1$ for every $n \in \mathbb{N}$. Set $b := \prod_{a\in\Sigma'_1} a \in A \setminus \{0\}$; it follows that $f'_1(b) \in \mathfrak{n}_0^k D'_1$ for every $k \in \mathbb{N}$.

Claim 17.5.64. (i) There exists $c \in A \setminus \{0\}$ such that $bc \in A_0$.
(ii) f'_1 induces an injective map $A_0/\mathfrak{n}_0^k \to D'_1/\mathfrak{n}_0^k D'_1$ for every $k \in \mathbb{N}$.

Proof of the claim. (i): Since A is a finite A_0-algebra, we may find a monic polynomial $P \in A_0[X]$ such that $P(b) = 0$, and since A is a domain, we may assume that $P(0) \neq 0$. Then it is easily seen that $P(0) = bc$ for some $c \in A \setminus \{0\}$.

(ii): We know already that $(D'_1, \mathfrak{m}'_1)^a$ is faithfully flat over A_0, hence $(D'_1/\mathfrak{n}_0^k D'_1)^a$ is faithfully flat over $A_0/\mathfrak{n}_0^k$ for every $k \in \mathbb{N}$. Then the assertion follows from lemma 14.2.41(i). ◊

Let c be as in claim 17.5.64(i); hence $bc \in A_0 \setminus \{0\}$, and $f'_1(bc) \in \mathfrak{n}_0^k D'_1$ for every $k \in \mathbb{N}$. By claim 17.5.64(ii), it follows that $bc \in \bigcap_{k\in\mathbb{N}} \mathfrak{n}_0^k$; but the $\mathfrak{n}_0$-adic topology of A_0 is separated ([126, Th.8.10(i)]), so $bc = 0$, a contradiction. □

17.5.65. Next, let $(A, \mathfrak{n})$ be any local noetherian domain, complete for its $\mathfrak{n}$-adic topology, with $\mathrm{Frac}\, A$ of zero characteristic, and residue field of characteristic $p > 0$. Let $\Sigma' \subset \Sigma$ be two subsets of $A \setminus \{0\}$ such that Σ' is finite and non-empty, and $p \in \Sigma$; we consider the category

$$\mathscr{D}^A_{\Sigma,\Sigma'}$$

whose objects are all pairs (f, Δ), where $f : A \to B$ is a ring homomorphism, and $\Delta := (\beta_{a,\bullet} \mid a \in \Sigma)$ is a family of elements of $\mathbf{E}(B)$, fulfilling conditions (a)–(d) of (17.5.57), as well as the following :

(e) B is complete and separated for its $\mathfrak{n}$-adic topology.

If $\Sigma_1 \subset \Sigma_2$ is an inclusion of subsets of $A \setminus \{0\}$, and $\Sigma'_1 \subset \Sigma_1$, $\Sigma'_2 \subset \Sigma_2$ are two non-empty finite subsets with $\Sigma'_1 \subset \Sigma'_2$, then clearly, remark 17.5.58 holds *verbatim* in the present situation, *i.e.* we get a well defined restriction functor :

$$\mathscr{D}^A_{\Sigma_2,\Sigma'_2} \to \mathscr{D}^A_{\Sigma_1,\Sigma'_1} \qquad (f, \Delta) \mapsto (f, \Delta)_{|\Sigma_1,\Sigma'_1} := (f, \Delta_{|\Sigma_1}).$$

Let moreover the subring $A_0 \subset A$ be as in (17.5.51); we shall say that an object $(f : A \to B, \Delta)$ of $\mathscr{D}^A_{\Sigma,\Sigma'}$ is almost flat (resp. almost faithfully flat) over A_0, if B^a is flat (resp. faithfully flat) over A_0 (as usual, we refer here to the almost structure associated with the basic setup $(B, \mathfrak{m})$ attached to (f, Δ)). We have the following variant of proposition 17.5.59 :

Proposition 17.5.66. *Let $\Sigma_1 \subset \Sigma_2$ be two subsets of $A \setminus \{0\}$ with $p \in \Sigma_1$, and $\Sigma'_1 \subset \Sigma_1$, $\Sigma'_2 \subset \Sigma_2$ two finite subsets, with $\varnothing \neq \Sigma'_1 \subset \Sigma'_2$. If the category $\mathscr{D}^A_{\Sigma_1,\Sigma'_1}$ admits an almost perfectoid initial object that is almost flat (resp. almost faithfully flat) over A_0, the same holds for $\mathscr{D}^A_{\Sigma_2,\Sigma'_2}$.*

Proof. Let $(f_1 : A \to D_1, \Delta_1 := (\beta_{a,\bullet} \mid a \in \Sigma_1))$ be an almost perfectoid initial object of $\mathscr{D}^A_{\Sigma_1,\Sigma'_1}$. Consider first the case where $\Sigma' := \Sigma'_2 = \Sigma'_1$. Say that $\Sigma_2 \setminus \Sigma_1 = (a_\lambda \mid \lambda \in \Lambda)$; we set :

$$D'_2 := D_1[T_\lambda^{1/p^\infty} \mid \lambda \in \Lambda]/(a_\lambda - T_\lambda \mid \lambda \in \Lambda).$$

Let D''_2 be the p-root closure of D'_2 in $D'_2[1/p]$; endow D''_2 with its p-adic topology, and let $D''^{\wedge}_2$ be the completion of D''_2. Let moreover $(D_1, \mathfrak{m}_1)$ be the basic setup attached to (f_1, Δ_1).

Claim 17.5.67. (i) The basic setup $(D''^{\wedge}_2, \mathfrak{m}_1 D''^{\wedge}_2)$ is almost perfectoid.

(ii) $(D''_2)^a$ is a faithfully flat D_1^a-algebra.

Proof of the claim. Let $\mathscr{P}$ be the set of all finite subsets of Λ, and for every $\Omega \in \mathscr{P}$, set

$$D'_{2,\Omega} := D_1[T_\lambda^{1/p^\infty} \mid \lambda \in \Omega]/(a_\lambda - T_\lambda \mid \lambda \in \Omega)$$

and let $D''_{2,\Omega}$ be the p-root closure of $D'_{2,\Omega}$ in $D'_{2,\Omega}[1/p]$; endow $D''_{2,\Omega}$ of its p-adic topology, and denote by $D''^{\wedge}_{2,\Omega}$ the completion of $D''_{2,\Omega}$. Clearly, every inclusion $\Omega \subset \Omega'$ of elements of $\mathscr{P}$ induces an injective map of D_1-algebras $D'_{2,\Omega} \to D'_{2,\Omega'}$, which induces in turn a map of D_1-algebras $D''_{2,\Omega} \to D''_{2,\Omega'}$ (remark 9.8.16(i) and proposition 9.8.28). Clearly D'_2 is the colimit of the filtered system of D_1-algebras $(D'_{2,\Omega} \mid \Omega \in \mathscr{P})$, and by lemma 9.8.17, D''_2 is the colimit of the filtered system $(D''_{2,\Omega} \mid \Omega \in \mathscr{P})$. Recall that, by construction, p admits a p-th root $p^{1/p}$ in D_1. Let Φ be the Frobenius endomorphism of D_1/pD_1, and suppose now that the Frobenius endomorphism of $D''_{2,\Omega}$ induces an isomorphism $(D''_{2,\Omega}/p^{1/p}D''_{2,\Omega})^a \xrightarrow{\sim} (D''_{2,\Omega}/pD''_{2,\Omega})^a_{(\Phi)}$, for every $\Omega \in \mathscr{P}$ (notation as in definition 16.9.35); then the Frobenius endomorphism of D''_2 induces an isomorphism $(D''_2/p^{1/p}D''_2)^a \xrightarrow{\sim} (D''_2/pD''_2)^a_{(\Phi)}$. We are thus reduced to checking that the basic setup $(D''^{\wedge}_{2,\Omega}, \mathfrak{m}_1 D''^{\wedge}_{2,\Omega})$ is almost perfectoid, and that $(D''_{2,\Omega})^a$ is a faithfully flat D_1^a-algebra, for every $\Omega \in \mathscr{P}$. The latter follows from proposition 17.5.16, by an easy induction on the cardinality of Ω : the details shall be left to the reader. ◊

Set $D_2 := (D''^{\wedge}_2, \mathfrak{m}_1 D''^{\wedge}_2)^a_*$; the basic setup $(D_2, \mathfrak{m}_1 D_2)$ is almost perfectoid for the p-adic topology of D_2, by claim 17.5.67(i) and proposition 16.9.37(iii). Moreover, if D_1^a is flat (resp.

faithfully flat) over A_0, the same holds for $(D''_2)^a$, by claim 17.5.67(ii) and lemma 14.2.41(iii); consequently, the same holds as well for both $(D''^{\wedge}_2)^a$ and D^a_2, by proposition 14.2.43(i).

Endow D_2 with its $\mathfrak{n}$-adic topology, let $D^{\wedge}_2$ be the completion of D_2, and $E_2 := (D^{\wedge}_2, \mathfrak{m}_1 D^{\wedge}_2)^a_*$. Notice that the $\mathfrak{n}$-adic topology agrees with the $\mathfrak{n}_0$-adic topology, on every A-module M.

Claim 17.5.68. (i) E_2 has no p-torsion and is $\mathfrak{n}$-adically complete and separated.

(ii) Let R be any D_1/pD_1-algebra, and denote by $R^{\wedge}$ and $(R_{(\Phi)})^{\wedge}$ the $\mathfrak{n}$-adic completions of R and of $R_{(\Phi)}$. Then $(R^{\wedge})_{(\Phi)} = (R_{(\Phi)})^{\wedge}$.

(iii) The basic setup $(E_2, \mathfrak{m}_1 E_2)$ is almost perfectoid for the p-adic topology of E_2.

Proof of the claim. (i): For the first assertion, it suffices to check that the endomorphism $p\cdot\mathbf{1}_{(D^{\wedge}_2)^a}$ is a monomorphism, since the functor $(-)_*$ is left exact. The latter will follow from lemma 14.2.45, after we check that the $\mathfrak{n}_0$-adic topology of D^a_2 induces the $\mathfrak{n}_0$-adic topology on the ideal pD^a_2 (see [75, §5.3] for generalities on topological almost algebras and modules). However, by the Artin-Rees lemma, there exists $c \in \mathbb{N}$ such that $\mathfrak{n}^{n+c}_0 A_0 \cap pA_0 \subset \mathfrak{n}^n_0 pA_0$ for every $n \in \mathbb{N}$. But we have already noticed that D^a_2 is flat over A_0, hence $\mathfrak{n}^{n+c}_0 D^a_2 \cap pD^a_2 \subset \mathfrak{n}^n_0 pD^a_2$ for every $n \in \mathbb{N}$, as required. The second assertion follows from claim 16.9.39.

(ii): By definition, $\mathfrak{n} \cdot R_{(\Phi)} = J \cdot R$, where $J \subset A$ is the ideal generated by $(a^p \mid a \in \mathfrak{n})$; since $\mathfrak{n}$ is finitely generated, there exists $N \in \mathbb{N}$ such that $\mathfrak{n}^N \subset J \subset \mathfrak{n}$, so the J-adic topology agrees with the $\mathfrak{n}$-adic topology on R, whence the assertion.

(iii): First, E_2 is p-adically complete and separated, by (i) and lemma 8.3.12. Next, pick $c \in \mathbb{N}$ as in the proof of (i); for every $n \in \mathbb{N}$ and every $x \in \mathfrak{n}^{n+c}_0 D_2 \cap p^{1/p} D_2$ we have $p^{(p-1)/p}x \in \mathfrak{n}^{n+c}_0 D_2 \cap pD_2$, whence $\mathfrak{m}_1 \cdot p^{(p-1)/p}x \subset \mathfrak{n}^n_0 pD_2$, and therefore $\mathfrak{m}_1 \cdot x \subset \mathfrak{n}^n_0 p^{1/p} D_2$. This shows that $\mathfrak{n}^{n+c}_0 D^a_2 \cap p^{1/p} D^a_2 \subset \mathfrak{n}^n_0 p^{1/p} D^a_2$ for every $n \in \mathbb{N}$, so the $\mathfrak{n}_0$-adic topology of D_2 induces the $\mathfrak{n}_0$-adic topology on the ideal $p^{1/p}D^a_2$. By assumption, the Frobenius endomorphism of D_2/pD_2 induces an isomorphism $D^a_2/p^{1/p}D^a_2 \xrightarrow{\sim} (D^a_2/pD^a_2)_{(\Phi)}$; the latter persists after taking $\mathfrak{n}_0$-adic completions, and in view of (ii) and lemma 14.2.45, we conclude that the Frobenius endomorphism of E_2/pE_2 induces an isomorphism $E^a_2/p^{1/p}E^a_2 \xrightarrow{\sim} (E^a_2/pE^a_2)_{(\Phi)}$, as needed. $\diamondsuit$

For every $a \in \Sigma_1$, let $\beta'_{a,\bullet} \in \mathbf{E}(D_2)$ be the image of $\beta_{a,\bullet}$, and set likewise

$$\beta'_{a_\lambda,\bullet} := (\overline{T}^{1/p^n}_\lambda \mid n \in \mathbb{N}) \in \mathbf{E}(D_2) \qquad \text{for every } \lambda \in \Lambda$$

where $\overline{T}^{1/p^n}_\lambda \in D_2$ denotes the image of T^{1/p^n}_λ, for every such λ and every $n \in \mathbb{N}$. Moreover, for every $a \in \Sigma_2$, let $\beta''_{a,\bullet} \in \mathbf{E}(E_2)$ be the image of $\beta'_{a,\bullet}$, and set $\Delta_2 := (\beta''_{a,\bullet} \mid a \in \Sigma_2)$. Let also $f_2 : A \to E_2$ be the structure map of the A-algebra E_2; by claim 17.5.68(i) the pair $(f_2 : A \to E_2, \Delta_2)$ fulfills conditions (a),(b),(c) of (17.5.57) and condition (e) of (17.5.65). Combining with propositions 16.9.37(iv) and 17.5.14(ii) we deduce that also condition (d) of (17.5.57) holds for this pair, *i.e.* (f_2, Δ_2) is an almost perfectoid object of $\mathscr{D}^A_{\Sigma_2,\Sigma'}$; moreover, if D^a_2 is flat (resp. faithfully flat) over A_0, the same holds for E^a_2, by virtue of proposition 14.2.43.

Lastly, let $(g : A \to F, \Delta := (\delta_{a,\bullet} \mid a \in \Sigma_2))$ be any other object of $\mathscr{D}^A_{\Sigma_2,\Sigma'}$; arguing as in the proof of claim 17.5.60, we see that there exists a unique map $h : D_2 \to F$ of A-algebras such that $\mathbf{E}(h')(\beta'_{a,\bullet}) = \delta_{a,\bullet}$ for every $a \in \Sigma_2$. Let $h^{\wedge} : D^{\wedge}_2 \to F$ be the $\mathfrak{n}$-adic completion of h'; it follows easily that $h := (h^{\wedge})^a_* : E_2 \to F$ is the unique morphism $(f_2, \Delta_2) \to (g, \Delta)$ in $\mathscr{D}^A_{\Sigma_2,\Sigma'}$.

It remains consider the case where $\Sigma := \Sigma_1 = \Sigma_2$. Then, let $\mathfrak{m}_2 \subset D_1$ be the ideal generated by $(\prod_{a\in\Sigma'_2} \beta_{a,n} \mid n \in \mathbb{N})$; let $D^{\wedge}_2$ be the $\mathfrak{n}$-adic completion of $D_2 := (D_1, \mathfrak{m}_2)^a_*$, and set $E_2 := (D^{\wedge}_2, \mathfrak{m}_2 D^{\wedge}_2)^a_*$. Arguing as in the proof of proposition 17.5.59, we see that the basic setup $(D_2, \mathfrak{m}_2 D_2)$ is almost perfectoid for the p-adic topology of D_2. Moreover, arguing as in the proof of proposition 17.5.62(ii), we see that if $(D_1, \mathfrak{m}_1)^a$ is flat over A_0, the same holds for $(D_1, \mathfrak{m}_2)^a$, so also for $(D_2, \mathfrak{m}_2 D_2)^a$, and then also for $(D^{\wedge}_2, \mathfrak{m}_2 D^{\wedge}_2)^a$, by proposition 16.9.37. Furthermore, if $(D_1, \mathfrak{m}_1)^a$ is faithfully flat over A_0, then arguing again as in the proof of proposition 17.5.62(ii), we check that the same holds for $(D_2, \mathfrak{m}_2 D_2)^a$, and thus, also for

$(D_2^\wedge, \mathfrak{m}_2 D_2^\wedge)^a$. Summing up, we conclude that if $(D_1, \mathfrak{m}_1)^a$ is flat (resp. faithfully flat) over A_0, the same holds for $(E_2, \mathfrak{m}_2 E_2)^a$. Then, arguing as in the proof of claim 17.5.68 we see that E_2 has no p-torsion and is $\mathfrak{n}$-adically complete and separated, and the basic setup $(E_2, \mathfrak{m}_1 E_2)$ is almost perfectoid for the p-adic topology of E_2. For every $a \in \Sigma$, let $\beta'_{a,\bullet} \in \mathbf{E}(E_2)$ be the image of $\beta_{a,\bullet}$, and set $\Delta_2 := (\beta'_{a,\bullet} \mid a \in \Sigma)$; let also $f_2 : A \to E_2$ be the structure map of the A-algebra E_2; as in the previous case, we conclude that (f_2, Δ_2) is an almost perfectoid object of $\mathscr{D}^A_{\Sigma,\Sigma'_2}$, and it is easily seen that it is the sought initial object : details left to the reader. □

17.5.69. Resume the notation of (17.5.56), and let $D^\wedge$ be the $\mathfrak{n}$-adic completion of D, and $D' := (D^\wedge, \mathfrak{m}D^\wedge)^a_*$. Set also $x_0 := p$, and let either $t := n$ if $g \in \{x_0, \dots, x_n\} \cup \{b_\lambda \mid \lambda \in \Lambda\}$, or else $t := n+1$ and $x_t := g$; we take

$$\Sigma'_0 := \{x_t\} \qquad \Sigma_0 := \{x_0, \dots, x_t\} \cup \{b_\lambda \mid \lambda \in \Lambda\}.$$

For $i = 0, \dots, t$ and for every $\lambda \in \Lambda$, let $\beta_{x_i,\bullet} := (\overline{T}_i^{1/p^k} \mid k \in \mathbb{N}) \in \mathbf{E}(D')$ and $\beta_{b_\lambda,\bullet} := (\overline{T}_\lambda^{1/p^k} \mid k \in \mathbb{N}) \in \mathbf{E}(D')$, where as usual $\overline{T}_i^{1/p^k}, \overline{T}_\lambda^{1/p^k} \in D'$ denote the image of T_i^{1/p^k} and T_λ^{1/p^k}, for every such i, every λ, and every $k \in \mathbb{N}$. Lastly, set $\Delta_0 := (\beta_{a,\bullet} \mid a \in \Sigma_0)$, and let $f_0 : A \to D'$ be the structure map of the A-algebra D'.

Proposition 17.5.70. *The pair (f_0, Δ_0) is an almost perfectoid initial object of $\mathscr{D}^A_{\Sigma_0,\Sigma'_0}$, and is almost faithfully flat over A_0.*

Proof. Let D_1 be the integral closure of $(C^\wedge, \mathfrak{m}C^\wedge)^a_*$ in $C^\wedge \otimes_{A_0} A[1/g]$, and recall that the inclusion map $j : D \to D_1$ induces an isomorphism $D^a \xrightarrow{\sim} D_1^a$ of $(C, \mathfrak{m})^a$-algebras ([75, Lemma 8.2.28]), so its $\mathfrak{n}$-adic completion $j^\wedge : D^\wedge \to D_1^\wedge$ induces an isomorphism of C-algebras $(j^\wedge)^a_* : D' \xrightarrow{\sim} (D_1^\wedge)^a_*$. By theorem 16.9.42(i,iii), $(D_1, \mathfrak{m}D_1)$ is an almost perfectoid basic setup, for the p-adic topology of D_1, and $D_1^a/p^n D_1^a$ is a faithfully flat $C^a/p^n C^a$-algebra, for every $n \in \mathbb{N}$; hence $D_1^a/p^n D_1^a$ is faithfully flat over $A_0/p^n A_0$, for every $n \in \mathbb{N}$, and therefore D_1^a is faithfully flat over A_0 (proposition 14.2.43(i)). We may now argue as in the proof of claim 17.5.68(iii), to conclude that $((D_1^\wedge)^a_*, \mathfrak{m}(D_1^\wedge)^a_*)$ is an almost perfectoid basic setup, for the p-adic topology of D_1, so the same holds for $(D', \mathfrak{m}D')$. This already shows that the pair (f_0, Δ_0) fulfills conditions (a),(b),(c) of (17.5.57) and condition (e) of (17.5.65). Combining with propositions 16.9.37(iv) and 17.5.14(ii) we deduce that also condition (d) of (17.5.57) holds for this pair, *i.e.* (f_0, Δ_0) is an almost perfectoid object of $\mathscr{D}^A_{\Sigma_0,\Sigma'_0}$. Moreover, since D_1^a is faithfully flat over A_0, the same holds for $(D_1^\wedge)^a$, again by proposition 14.2.43(i), so also for D'^a. Lastly, one verifies as in the proof of proposition 17.5.62(i) that (f_0, Δ_0) is an initial object of $\mathscr{D}^A_{\Sigma_0,\Sigma'_0}$: details left to the reader. □

17.5.71. Consider now the category

$$\mathscr{A}$$

whose objects are all local noetherian domains $(A, \mathfrak{n})$, complete for their $\mathfrak{n}$-adic topology, with $\mathrm{Frac}\, A$ of zero characteristic, residue field k of characteristic $p > 0$ and with $[k : k^p] < +\infty$. The morphisms $(A, \mathfrak{n}) \to (A', \mathfrak{n}')$ of $\mathscr{A}$ are all the *injective* ring homomorphisms $A \to A'$.

For every object $(A, \mathfrak{n})$ of $\mathscr{A}$, let $\Omega(A)$ be the set of all pairs (Σ, Σ') of finite non-empty subsets of $A \setminus \{0\}$ with $\Sigma' \subset \Sigma$ and $p \in \Sigma$, such that the corresponding category $\mathscr{C}^A_{\Sigma,\Sigma'}$ admits an initial object (notation of (17.5.57)), and for every $(\Sigma, \Sigma') \in \Omega(A)$, fix such an initial object

$$(f_{\Sigma,\Sigma'} : A \to D_{\Sigma,\Sigma'}, \Delta_{\Sigma,\Sigma'}).$$

We let $\leq$ be the partial ordering on $\Omega(A)$ such that $(\Sigma_1, \Sigma'_1) \leq (\Sigma_2, \Sigma'_2)$ if and only if $\Sigma_1 \subset \Sigma_2$ and $\Sigma'_1 \subset \Sigma'_2$. Clearly, $(\Omega(A), \leq)$ is a filtered partially ordered set, and with the notation of remark 17.5.58, we have a unique morphism

$$(f_{\Sigma_1,\Sigma'_1},\Delta_{\Sigma_1,\Sigma'_1}) \to (f_{\Sigma_2,\Sigma'_2},\Delta_{\Sigma_2,\Sigma'_2})_{|\Sigma_1,\Sigma'_1} \qquad \text{in } \mathscr{C}^A_{\Sigma_1,\Sigma'_2}, \text{ whenever } (\Sigma_1,\Sigma'_1) \leq (\Sigma_2,\Sigma'_2).$$

In other words, we get a well defined filtered system of A-algebras $(D_{\Sigma,\Sigma'} \mid (\Sigma,\Sigma') \in \Omega(A))$.

For every $(\Sigma,\Sigma') \in \Omega(A)$, let $(D_{\Sigma,\Sigma'},\mathfrak{m}_{\Sigma,\Sigma'})$ be the basic setup attached to $(f_{\Sigma,\Sigma'},\Delta_{\Sigma,\Sigma'})$, and consider the subset $\mathsf{S}_{\Sigma,\Sigma'} \subset D^{\mathbb{N}}_{\Sigma,\Sigma'}$ of all $(a_n \mid n \in \mathbb{N})$ such that $a_n \in D_{\Sigma,\Sigma'}a_{n+1}$ for every $n \in \mathbb{N}$, and $\mathfrak{m}_{\Sigma,\Sigma'} \subset \bigcup_{n\in\mathbb{N}} D_{\Sigma,\Sigma'}a_n$. We let $\Theta(A) \subset \Omega(A)$ be the subset of all (Σ,Σ') such that

$$E_{\Sigma,\Sigma'} := \mathsf{S}^{-1}_{\Sigma,\Sigma'} D^{\diamond}_{\Sigma,\Sigma'}$$

is a big CM A-algebra (see (17.5.2)).

Lemma 17.5.72. *$\Theta(A)$ is a cofinal subset of $\Omega(A)$, for every $(A,\mathfrak{n}) \in \mathrm{Ob}(\mathscr{A})$.*

Proof. Choose a subring $(A_0,\mathfrak{n}_0) \subset (A,\mathfrak{n})$ as in (17.5.51); then propositions 17.5.59 and 17.5.62 show that there exists $(\Sigma_0,\Sigma'_0) \in \Omega(A)$ such that $(D_{\Sigma,\Sigma'},\mathfrak{m}_{\Sigma,\Sigma'})^a$ is faithfully flat over A_0, for every $(\Sigma,\Sigma') \geq (\Sigma_0,\Sigma'_0)$. Then, arguing as in the proof of theorem 17.5.54 we see that $E_{\Sigma,\Sigma'}$ is a big CM A-algebra for every such (Σ,Σ'). □

Notice that whenever $(\Sigma_1,\Sigma'_1) \leq (\Sigma_2,\Sigma'_2)$, the induced map $D^{\mathbb{N}}_{\Sigma_1,\Sigma'_1} \to D^{\mathbb{N}}_{\Sigma_2,\Sigma'_2}$ sends $\mathsf{S}_{\Sigma_1,\Sigma_2}$ into $\mathsf{S}_{\Sigma_2,\Sigma'_2}$. Let then $E(A)$ be the colimit of the induced filtered system $(E_{\Sigma,\Sigma'} \mid (\Sigma,\Sigma') \in \Omega(A))$. By lemma 17.5.72 and remark 17.5.19(iv), $E(A)$ is a big CM A-algebra. Next, let $g : (A,\mathfrak{n}) \to (A',\mathfrak{n}')$ be any morphism of $\mathscr{A}$, and $(\Sigma_1,\Sigma'_1) \in \Omega(A)$, $(\Sigma_2,\Sigma'_2) \in \Omega(A')$ with

$$g(\Sigma_1) \subset \Sigma_2 \qquad \text{and} \qquad g(\Sigma'_1) \subset \Sigma'_2.$$

For every object $(f,\Delta := (\beta_{a,\bullet} \mid a \in \Sigma_2))$ of $\mathscr{C}^{A'}_{\Sigma_2,\Sigma'_2}$, set $\Delta_{|\Sigma_1} := (\beta_{g(a),\bullet} \mid a \in \Sigma_1)$; since g is injective, the pair $(f \circ g,\Delta_{|\Sigma_1})$ fulfills conditions (a),(c) and (d) of (17.5.57), defining the objects of $\mathscr{C}^A_{\Sigma_1,\Sigma'_1}$, and with remark 14.2.7(ii), we easily check that also condition (b) holds for this pair. We get therefore a well defined functor :

$$\mathscr{C}^{A'}_{\Sigma_2,\Sigma'_2} \to \mathscr{C}^A_{\Sigma_1,\Sigma'_1} \qquad (f,\Delta) \mapsto (f,\Delta)_{|\Sigma_1,\Sigma'_1} := (f \circ g,\Delta_{|\Sigma_1}).$$

Especially, notice that for every $(\Sigma,\Sigma') \in \mathrm{Ob}(A)$ we have $(g\Sigma,g\Sigma') \in \mathrm{Ob}(A')$, whence a natural morphism in $\mathscr{C}^A_{\Sigma,\Sigma'}$:

$$(f_{\Sigma,\Sigma'},\Delta_{\Sigma,\Sigma'}) \to (f_{g\Sigma,g\Sigma'},\Delta_{g\Sigma,g\Sigma'})_{|\Sigma,\Sigma'}.$$

Moreover, the induced map $D^{\mathbb{N}}_{\Sigma,\Sigma'} \to D^{\mathbb{N}}_{g\Sigma,g\Sigma'}$ sends $\mathsf{S}_{\Sigma,\Sigma'}$ into $\mathsf{S}_{g\Sigma,g\Sigma'}$, so we get a map of A-algebras :

$$E_{\Sigma,\Sigma'} \to E_{g\Sigma,g\Sigma'} \qquad \text{for every } (\Sigma,\Sigma') \in \Omega(A).$$

Finally, the colimit of this system of maps yields a well defined map $E(g) : E(A) \to E(A')$, and a simple inspection shows that the rules : $(A,\mathfrak{n}) \mapsto E(A)$ and $g \mapsto E(g)$ define a functor

$$E : \mathscr{A} \to \mathbb{Z}\text{-}\mathsf{Alg}.$$

17.5.73. Using the categories $\mathscr{D}^A_{\Sigma,\Sigma'}$ of (17.5.65) we may obtain the following variant of the functor E. Consider the category

$$\mathscr{A}'$$

whose objects are all local noetherian domains $(A,\mathfrak{n})$, complete for their $\mathfrak{n}$-adic topology, with $\mathrm{Frac}\,A$ of zero characteristic, and residue field k of characteristic $p > 0$. The morphisms $(A,\mathfrak{n}) \to (A',\mathfrak{n}')$ of $\mathscr{A}'$ are all the *injective and local* ring homomorphisms $A \to A'$.

For every object $(A,\mathfrak{n})$ of $\mathscr{A}$, let $\Omega'(A)$ be the set of all pairs (Σ,Σ') of non-empty subsets of $A \setminus \{0\}$ where Σ' is finite, and $\Sigma' \cup \{p\} \subset \Sigma$, and such that the corresponding category $\mathscr{D}^A_{\Sigma,\Sigma'}$ admits an initial object. For every $(\Sigma,\Sigma') \in \Omega(A)$, fix such an initial object

$$(f_{\Sigma,\Sigma'} : A \to D_{\Sigma,\Sigma'},\Delta_{\Sigma,\Sigma'}).$$

We define a partial ordering $\leq$ on $\Omega'(A)$ just as for $\Omega(A)$ in (17.5.71). Clearly, $(\Omega'(A), \leq)$ is a filtered partially ordered set, and with the notation of (17.5.65), we have a unique morphism

$$(f_{\Sigma_1,\Sigma'_1}, \Delta_{\Sigma_1,\Sigma'_1}) \to (f_{\Sigma_2,\Sigma'_2}, \Delta_{\Sigma_2,\Sigma'_2})_{|\Sigma_1,\Sigma'_1} \qquad \text{in } \mathscr{D}^A_{\Sigma_1,\Sigma'_2}, \text{ whenever } (\Sigma_1, \Sigma'_1) \leq (\Sigma_2, \Sigma'_2).$$

In other words, we get a well defined filtered system of A-algebras $(D_{\Sigma,\Sigma'} \mid (\Sigma, \Sigma') \in \Omega'(A))$.

For every $(\Sigma, \Sigma') \in \Omega'(A)$, let $(D_{\Sigma,\Sigma'}, \mathfrak{m}_{\Sigma,\Sigma'})$ be the basic setup attached to $(f_{\Sigma,\Sigma'}, \Delta_{\Sigma,\Sigma'})$, and define the multiplicative subset $\mathsf{S}_{\Sigma,\Sigma'} \subset D^{\mathbb{N}}_{\Sigma,\Sigma'}$ as in (17.5.71). We let $\Theta'(A) \subset \Omega'(A)$ be the subset of all (Σ, Σ') such that $E'_{\Sigma,\Sigma'} := \mathsf{S}^{-1}_{\Sigma,\Sigma'} D^{\diamond}_{\Sigma,\Sigma'}$ is a big CM A-algebra. Using propositions 17.5.66 and 17.5.70, and arguing as in the proof of lemma 17.5.72, we see that $\Theta'(A)$ is a cofinal subset of $\Omega'(A)$, for every $(A, \mathfrak{n}) \in \mathrm{Ob}(\mathscr{A}')$. Then, the colimit $E'(A)$ of the induced filtered system $(E'_{\Sigma,\Sigma'} \mid (\Sigma, \Sigma') \in \Omega'(A))$ is a big CM A-algebra (remark 17.5.19(iv)). Next, let $g : (A, \mathfrak{n}) \to (A', \mathfrak{n}')$ be any morphism of $\mathscr{A}'$, and $(\Sigma_1, \Sigma'_1) \in \Omega'(A)$, $(\Sigma_2, \Sigma'_2) \in \Omega'(A')$ with

$$g(\Sigma_1) \subset \Sigma_2 \qquad \text{and} \qquad g(\Sigma'_1) \subset \Sigma'_2.$$

For every object $(f, \Delta := (\beta_{a,\bullet} \mid a \in \Sigma_2))$ of $\mathscr{D}^{A'}_{\Sigma_2,\Sigma'_2}$, set again $\Delta_{|\Sigma_1} := (\beta_{g(a),\bullet} \mid a \in \Sigma_1)$; since g is injective, arguing as in the foregoing we see that the pair $(f \circ g, \Delta_{|\Sigma_1})$ fulfills conditions (a),(b), (c),(d) of (17.5.57). Moreover, since g is local, lemma 8.3.12 implies that also condition (e) of (17.5.65) is fulfilled. We get therefore a well defined functor :

$$\mathscr{D}^{A'}_{\Sigma_2,\Sigma'_2} \to \mathscr{D}^{A}_{\Sigma_1,\Sigma'_1} \qquad (f, \Delta) \mapsto (f, \Delta)_{|\Sigma_1,\Sigma'_1} := (f \circ g, \Delta_{|\Sigma_1}).$$

From this, arguing as in the foregoing case, we obtain a natural map of A-algebras $E'(g) : E'(A) \to E'(A')$, whence a well defined functor :

$$E' : \mathscr{A}' \to \mathbb{Z}\text{-}\mathsf{Alg}.$$

17.5.74. Next, we wish to establish a *weak funtoriality* property of big CM algebras, for not necessarily injective maps of local rings. The first step is the following :

Proposition 17.5.75. *Let A be noetherian ring, $I \subset A$ an ideal, $f_1, \dots, f_r \in I$ a finite sequence such that the following holds for every $\mathfrak{p} \in \Sigma := \mathrm{Ass}_A(A/I)$ (see definition* 10.5.1(iii)*) :*

(a) *$I_\mathfrak{p}$ is generated by the image of the sequence $f_\bullet$.*
(b) *The image of the sequence $f_\bullet$ is regular in $I_\mathfrak{p}$.*

Then we have :

(i) *There exists $g \in A \setminus \bigcup_{\mathfrak{p}\in\Sigma} \mathfrak{p}$ such that $gI \subset J := \sum_{i=1}^r f_i A$.*
(ii) *For every g as in* (i)*, the sequence $f'_\bullet := (f_1/g, \dots, f_r/g)$ is quasi-regular in the subring $A' := A[f_1/g, \dots, f_r/g]$ of $A[1/g]$.*
(iii) *With the notation of* (ii)*, let $J' \subset A'$ be the ideal generated by $f'_\bullet$. The natural map $A \to A'$ induces an isomorphism $A/I \xrightarrow{\sim} A'/J'$.*

Proof. (i): Let $L := \{x \in A \mid xI \subset J\}$; since I is finitely generated, it is easily seen that $L_\mathfrak{p} = \{x \in A_\mathfrak{p} \mid xI_\mathfrak{p} \subset J_\mathfrak{p}\}$ for every $\mathfrak{p} \in \mathrm{Spec}\, A$. Especially, $L_\mathfrak{p} = A_\mathfrak{p}$ for every $\mathfrak{p} \in \Sigma$, by assumption (a), *i.e.* $L \not\subset \mathfrak{p}$ for every such $\mathfrak{p}$; then the assertion follows from [12, Prop.1.11(i)].

(iii): Clearly the natural map $A \to A'$ induces a surjection $\varphi : A \to A'/J'$, and we need to check that $\mathrm{Ker}\,\varphi = I$. However, if $x \in I$, then $gx = \sum_{i=1} a_i f_i$ for some $a_1, \dots, a_r \in A$, whence $x = \sum_{i=1}^r a_i f_i/g \in J'$ in A', so $I \subset \mathrm{Ker}\,\varphi$. Let then $\overline{\varphi} : A/I \to A'/J'$, be the map induced by φ; notice that $A[1/g] = A'[1/g]$, and $IA[1/g] = J'A'[1/g]$, so that the localization $\overline{\varphi}_g$ of $\overline{\varphi}$ is an isomorphism. Especially, $\overline{\varphi}_\mathfrak{p}$ is an isomorphism for every $\mathfrak{p} \in \Sigma$, and it suffices then to invoke the following :

Claim 17.5.76. Let M and N be two A-modules, and $h : M \to N$ an A-linear map. Then h is injective if and only if $h_\mathfrak{p} : M_\mathfrak{p} \to N_\mathfrak{p}$ is injective for every $\mathfrak{p} \in \mathrm{Ass}_A(M)$.

Proof of the claim. To ease notation, set $\Omega := \mathrm{Ass}_A(M)$, and consider the commutative diagram

$$\begin{array}{ccc} M & \xrightarrow{\quad h \quad} & N \\ \downarrow & & \downarrow \\ \prod_{\mathfrak{p}\in\Omega} M_{\mathfrak{p}} & \xrightarrow{\prod_{\mathfrak{p}\in\Omega} h_{\mathfrak{p}}} & \prod_{i\in\Omega} N_{\mathfrak{p}} \end{array}$$

whose left vertical arrow is injective, by lemma 10.5.3(iii), and whose bottom horizontal arrow is injective if and only if $h_{\mathfrak{p}}$ is injective for every $\mathfrak{p} \in \Omega$. The assertion is an immediate consequence. $\Diamond$

(ii): Set $A_r := A/I[T_1, \dots, T_r]$, let $I_r \subset A_r$ be the ideal generated by $T_1, \dots, T_r$, and denote by $\mathrm{gr}_\bullet A_r$ the graded A/I-algebra associated with the I_r-adic filtration of A_r. Also, for every $i = 1, \dots, r$, let $\overline{T}_i \in \mathrm{gr}_1 A_r$ (resp. $x_i \in J'/J'^2$) be the image of T_i (resp. of f_i/g); we consider the map of graded A/I-algebras

$$\psi_\bullet : \mathrm{gr}_\bullet A_r \to \bigoplus_{n\in\mathbb{N}} J'^n/J'^{n+1} \qquad \overline{T}_1 \mapsto x_1, \dots, \overline{T}_r \mapsto x_r.$$

In view of (iii), we need to check that ψ is an isomorphism, and since ψ is surjective, it suffices to show that its restriction $\psi_n : \mathrm{gr}_n A_r \to J'^n/J'^{n+1}$ is injective for every $n \in \mathbb{N}$. However, by assumption (b), the image of the sequence $f_\bullet$ is regular in $I_{\mathfrak{p}} = J'_{\mathfrak{p}}$, for every $\mathfrak{p} \in \Sigma$, hence $\psi_{n,\mathfrak{p}}$ is an isomorphism for every $n \in \mathbb{N}$ and every $\mathfrak{p} \in \Sigma$ (proposition 7.8.15). Then the assertion follows from claim 17.5.76. $\square$

Remark 17.5.77. Let A be a noetherian ring, and $\mathfrak{p} \subset A$ a prime ideal such that $A_{\mathfrak{p}}$ is a regular local ring. Then $\mathrm{Ass}_A(A/\mathfrak{p}) = \{\mathfrak{p}\}$, and we may find $g_1, \dots, g_r \in \mathfrak{p}$ whose images in $A_{\mathfrak{p}}$ are a regular system of parameters (just take any regular system of parameters for $A_{\mathfrak{p}}$, and multiply by a suitable element of $A\backslash\mathfrak{p}$ to clear denominators : details left to the reader). Hence, assumptions (a) and (b) of proposition 17.5.75 hold for $I := \mathfrak{p}$ and $f_\bullet := g_\bullet$.

17.5.78. Consider now a sequence of local ring homomorphisms

$$A_0 \xrightarrow{f_0} A_1 \xrightarrow{f_1} \cdots \xrightarrow{f_{n-1}} A_n$$

of some finite length n, where $A_0, \dots, A_n$ are complete, local noetherian domains.

Proposition 17.5.79. *In the situation of* (17.5.78)*, there exists a commutative diagram of complete local noetherian domains, and local ring homomorphisms :*

$$\begin{array}{ccccccc} A_0 & \xrightarrow{f_0} & A_1 & \xrightarrow{f_1} & \cdots & \xrightarrow{f_{n-1}} & A_n \\ & \searrow^{h_0} & \downarrow{\scriptstyle j_1} & & & & \downarrow{\scriptstyle j_n} \\ & & B_1 & \xrightarrow{g_1} & \cdots & \xrightarrow{g_{n-1}} & B_n \\ & & \uparrow{\scriptstyle \pi_1} & & & & \uparrow{\scriptstyle \pi_n} \\ & & C_1 & \xrightarrow{h_1} & \cdots & \xrightarrow{h_{n-1}} & C_n \end{array} \qquad (17.5.80)$$

such that $h_0, \dots, h_{n-1}$ are injective maps, and the following holds for every $i = 1, \dots, n$:

(i) *the map j_i is finite and injective*
(ii) *the map π_i is surjective, and* $\mathrm{Ker}\, \pi_i$ *is generated by a regular sequence of C_i.*

Proof. Let us show first how to reduce to the case where $n = 1$. Indeed, suppose that $n > 1$, and B_1 and C_1 are given as required, with local ring homomorphisms $h_0 : A_0 \to C_0$, $j_1 : A_1 \to B_1$ and $\pi_1 : C_1 \to B_1$ such that h_0 is injective, and conditions (i) and (ii) hold for $i = 1$. By induction on n, we further suppose that the proposition is already known for every sequence $A_0 \to \cdots \to A_{n-1}$ of local ring homomorphisms of complete local noetherian domains.

• We construct by induction on $i = 1, \dots, n$, a commutative diagram :

$$\begin{array}{ccc} A_1 & \xrightarrow{f_1} \cdots \xrightarrow{f_{n-1}} & A_n \\ \downarrow{\scriptstyle j'_1} & & \downarrow{\scriptstyle j'_n} \\ A'_1 & \xrightarrow{f'_1} \cdots \xrightarrow{f'_{n-1}} & A'_n \end{array} \qquad (17.5.81)$$

where $A'_1, \dots, A'_n$ are complete local noetherian domains, $j'_1, \dots, j'_n$ are local, finite and injective ring homomorphisms, and $f'_1, \dots, f'_{n-1}$ are local ring homomorphisms. For $i = 1$, we take $A'_1 := B_1$ and $j'_1 := j_1$; suppose next that $i > 1$, and A'_j has already been given for every $j < i$, together with the required commutative diagram of maps $j'_1, \dots, j'_{i-1}$ and $f'_1, \dots, f'_{i-2}$. Since j'_{i-1} is finite and injective, the induced map $\mathrm{Spec}\, A'_{i-1} \to \mathrm{Spec}\, A_{i-1}$ is surjective, so the same holds for its base change $\mathrm{Spec}\, (A_i \otimes_{A_{i-1}} A'_{i-1}) \to \mathrm{Spec}\, A_i$, and hence we may pick $\mathfrak{p} \in \mathrm{Spec}(A_i \otimes_{A_{i-1}} A'_{i-1})$ whose image in $\mathrm{Spec}\, A_i$ is the generic point; we set $A'_i := (A_i \otimes_{A_{i-1}} A'_{i-1})/\mathfrak{p}$, and let $j_i : A_i \to A'_i$ be the induced map. By construction, $\mathrm{Spec}(j_i)$ is dominant with closed image, hence it is surjective, so $\mathrm{Ker}\, j_i = 0$, since A_i is a domain. Moreover, since A_i is complete and separated, j_i is local, and A'_i is a finite A_i-algebra, so it is a complete local noetherian domain, as required. Lastly, let k_{i-1}, k_i and k'_{i-1} be the residue fields of A_{i-1}, A_i and A'_{i-1}; to see that the natural map $f'_{i-1} : A'_{i-1} \to A'_i$ is local, it suffices to remark that the residue field of A'_i is a quotient of $k_i \otimes_{k_{i-1}} k'_{i-1}$.

• Next, we apply the inductive assumption to the sequence of local ring homomorphisms

$$C_1 \xrightarrow{f'_1 \circ \pi_1} A'_2 \xrightarrow{f'_2} \cdots \xrightarrow{f'_{n-1}} A'_n. \qquad (17.5.82)$$

Thus, we find a commutative diagram of complete local noetherian domains and local ring homomorphisms :

$$\begin{array}{ccccc} C_1 & \xrightarrow{f'_1 \circ \pi_1} & A'_2 & \xrightarrow{f'_2} \cdots \xrightarrow{f'_{n-1}} & A'_n \\ & \searrow^{h_1} & \downarrow{\scriptstyle j''_2} & & \downarrow{\scriptstyle j''_n} \\ & & B_2 & \xrightarrow{g_2} \cdots \xrightarrow{g_{n-1}} & B_n \\ & & \uparrow{\scriptstyle \pi_2} & & \uparrow{\scriptstyle \pi_n} \\ & & C_2 & \xrightarrow{h_2} \cdots \xrightarrow{h_{n-1}} & C_n \end{array}$$

where $h_1, \dots, h_{n-1}$ are injective, and the map j''_i (resp. π_i) fulfills the corresponding condition (i) (resp. (ii)) of the proposition, for every $i = 2, \dots, n$. Then we obtain the sought diagram with $g_1 := j''_2 \circ f'_1$ and $j_i := j''_i \circ j'_i$ for every $i = 2, \dots, n$.

• We consider now the case $n = 1$, so we are given a single local ring homomorphism $f_0 : A_0 \to A_1$ of complete local noetherian domains. We notice :

Claim 17.5.83. There exist a complete local noetherian domain D_0, and local ring homomorphisms $\varphi_0 : A_0 \to D_0$, $\psi_0 : D_0 \to A_1$ such that φ_0 is injective, ψ_0 is surjective, and $\psi_0 \circ \varphi_0 = f_0$.

Proof of the claim. By proposition 9.7.31(i) there exists a complete local noetherian ring D'_0, a faithfully flat ring homomorphism $\varphi'_0 : A_0 \to D'_0$, and a surjective map $\psi'_0 : D'_0 \to A_1$ with $\psi'_0 \circ \varphi'_0 = f_0$. Then, let $\mathfrak{p}$ be any minimal prime ideal of D'_0 contained in $\mathrm{Ker}\, \psi'_0$, and set $D_0 := D'_0/\mathfrak{p}$; since φ'_0 is flat, we have $\varphi'^{-1}_0 \mathfrak{p} = 0$, so the induced map $\varphi_0 : A_0 \to D_0$ is still injective, and ψ'_0 factors through a surjection $\psi_0 : D_0 \to A_1$, whence the claim. ◊

Let $\varphi_0 : A_0 \to D_0$ and $\psi_0 : D_0 \to A_1$ be as in claim 17.5.83, and set $\mathfrak{p} := \mathrm{Ker}\, \psi_0$; lemma 9.7.4(v) says that D_0 is excellent, so $D_{0,\mathfrak{p}}$ is quasi-excellent, by lemma 9.7.4(ii,iv).

Especially, $D_{0,\mathfrak{p}}$ is a Nagata ring, and the regular locus of $\mathrm{Spec}\, D_{0,\mathfrak{p}}$ is an open subset ([66, Ch.IV, Th.6.12.4]); by corollary 9.6.56, we may then find a regular local domain $(D_1, \mathfrak{m}_1)$, and an injective local ring homomorphism $D_{0,\mathfrak{p}} \to D_1$ of essentially finite type, inducing an isomorphism $\mathrm{Frac}(D_0) \xrightarrow{\sim} \mathrm{Frac}(D_1)$ and a finite field extension $\mathrm{Frac}(D_0/\mathfrak{p}) \to D_1/\mathfrak{m}_1$. Pick $y_1, \dots, y_n \in D_1$ and a prime ideal $\mathfrak{q} \subset D_2 := D_0[y_1, \dots, y_n]$ such that $D_1 = D_{2,\mathfrak{q}}$; we remark :

Claim 17.5.84. We can assume that the induced injective map $A_1 \xrightarrow{\sim} D_0/\mathfrak{p} \to D_2/\mathfrak{q}$ is finite.

Proof of the claim. The image $\overline{y}_i \in D_1/\mathfrak{m}_1 = \mathrm{Frac}(D_2/\mathfrak{q})$ of y_i is algebraic over $\mathrm{Frac}(D_0/\mathfrak{p})$ for every $i = 1, \dots, n$, so we may find $x \in D_0 \setminus \mathfrak{p}$ such that the images of $xy_1, \dots, xy_n$ in $\mathrm{Frac}(D_2/\mathfrak{q})$ are integral over $D_0/\mathfrak{p}$. Set $D'_2 := D_0[xy_1, \dots, xy_n]$ and $\mathfrak{q}' := \mathfrak{q} \cap D'_2$; then clearly $D'_{2,\mathfrak{q}'} = D_1$, so we may replace y_i by xy_i for $i = 1, \dots, n$, and assume that $\overline{y}_i$ is integral over $D_0/\mathfrak{p}$, for every $i = 1, \dots, n$, whence the claim. ◊

• Now we apply proposition 17.5.75 and remark 17.5.77 to $A := D_2$, $I := \mathfrak{q}$, and to a finite sequence $x_1, \dots, x_d$ of elements of $\mathfrak{q}$ whose images in the regular local ring D_1 are a regular system of parameters : we obtain $g \in D_2 \setminus \mathfrak{q}$ with $g \cdot \mathfrak{q} \subset \sum_{i=1}^d x_i D_2$, and such that the sequence $t_1 := x_1/g, \dots, t_d := x_d/g$ is quasi-regular in the subring $D'_2 := D_2[t_1, \dots, t_d] \subset D_2[1/g]$; moreover, if $\mathfrak{q}' \subset D'_2$ denotes the ideal generated by $t_1, \dots, t_d$, the inclusion map $D_2 \to D'_2$ induces an isomorphism

$$D_2/\mathfrak{q} \xrightarrow{\sim} B_1 := D'_2/\mathfrak{q}'.$$

Since A_1 is complete, claim 17.5.84 implies that $D_2/\mathfrak{q}$ is a complete local noetherian domain, so the same holds for B_1, and the resulting map $g_1 : A_1 \to B_1$ is injective and finite; then, let $\mathfrak{m} \subset B_1$ be the maximal ideal, $\mathfrak{m}' \subset D'_2$ its preimage, and C_1 the $\mathfrak{m}'$-adic completion of D'_2. Since C_1 is a flat D'_2-algebras, the image $\mathbf{t}$ in C_1 of the sequence $t_1, \dots, t_d$ is still quasi-regular, hence it is regular, by proposition 7.8.15 and [126, Th.8.10]. Also, the localization $D'_2 \to D'_{2,\mathfrak{m}'}$ is injective, since D_2 is a domain, and the same holds for the completion map $D'_{2,\mathfrak{m}'} \to C_1$, since the latter is faithfully flat; summing up, we deduce that the structure map $h_0 : A_0 \to C_1$ of the resulting A_0-algebra C_1 is injective. To conclude the proof, it now suffices to remark :

Claim 17.5.85. C_1 is a domain, and h_0 is a local ring homomorphism.

Proof of the claim. In order to show that h_0 is local, it suffices to check that the same holds for the natural map $A_0 \to D'_{2,\mathfrak{m}'}$. The latter comes down to verifying that the preimage of $\mathfrak{m}'$ under the natural map $A_0 \to D'_2$ is the maximal ideal of A_0. But in turns, this is the same as the preimage of $\mathfrak{m}$ under the composition $A_0 \to A_1 \to D_2/\mathfrak{q} \xrightarrow{\sim} B_1$, which is local, whence the assertion. Next, let $\mathrm{gr}_\bullet C_1$ be the graded ring associated with the $\mathfrak{q}'$-adic filtration on C_1; hence $\mathrm{gr}_0 C_1$ is the $\mathfrak{m}'$-adic completion of B_1. But B_1 is $\mathfrak{m}'$-adically complete and separated, so $\mathrm{gr}_0 C_1 = B_1$ and since $\mathbf{t}$ is quasi-regular, the natural map of graded B_1-algebras

$$B_1[T_1, \dots, T_d] \to \mathrm{gr}_\bullet C_1 \qquad T_1 \mapsto t_1, \dots, T_d \mapsto t_d$$

is an isomorphism. Since the $\mathfrak{q}'$-adic filtration is separated on C_1, the assertion follows. □

17.5.86. We will also need the following variant of the situation contemplated in (17.5.78) : we consider a sequence, of some finite length n, of ring homomorphisms

$$A_0 \xrightarrow{f_0} A_1 \xrightarrow{f_1} \cdots \xrightarrow{f_{n-1}} A_n$$

where $A_0, \dots, A_n$ are quasi-excellent domains, and $f_0, \dots, f_{n-1}$ are of finite type.

Proposition 17.5.87. *In the situation of* (17.5.86)*, there exists a commutative diagram* (17.5.80) *of quasi-excellent domains, such that $h_0, \dots, h_{n-1}$ are injective maps of finite type, and for every $i = 1, \dots, n$ the following holds :*

(i) *the map j_i is finite and injective*

(ii) *the map* π_i *is surjective, and* $\operatorname{Ker}\pi_i$ *is generated by a quasi-regular sequence of* C_i.

Proof. We argue as in the proof of proposition 17.5.79 : first, we show how to reduce to the case where $n = 1$. Hence, suppose that $n > 1$, and B_1 and C_1 are given as required, with local ring homomorphisms $h_0 : A_0 \to C_0$, $j_1 : A_1 \to B_1$ and $\pi_1 : C_1 \to B_1$ such that h_0 is injective, and conditions (i) and (ii) of proposition 17.5.79 hold for $i = 1$. By induction on n, we further suppose that the proposition is already known for every sequence $A_0 \to \cdots \to A_{n-1}$ consisting of maps of finite type, and quasi-excellent domains $A_0, \dots, A_{n-1}$.

• We construct by induction on $i = 1, \dots, n$, quasi-excellent domains $A'_1, \dots, A'_n$, and a commutative diagram (17.5.81), where $j'_1, \dots, j'_n$ are injective and finite ring homomorphisms, and $f'_1, \dots, f'_{n-1}$ are of finite type. For $i = 1$, we take $A'_1 := B_1$ and $j'_1 := j_1$; suppose next that $i > 1$, and A'_j has already been given for every $j < i$, together with the required commutative diagram of maps $j'_1, \dots, j'_{i-1}$ and $f'_1, \dots, f'_{i-2}$. Just as in the proof of proposition 17.5.79, we may then find $\mathfrak{p} \in \operatorname{Spec}(A_i \otimes_{A_{i-1}} A'_{i-1})$ whose image in $\operatorname{Spec} A_i$ is the generic point; we set $A'_i := (A_i \otimes_{A_{i-1}} A'_{i-1})/\mathfrak{p}$, and let $j_i : A_i \to A'_i$ and $f'_{i-1} : A'_{i-1} \to A'_i$ be the induced maps.

• Next, we apply the inductive assumption to the sequence (17.5.82), to construct the sought commutative diagram, as in the proof of proposition 17.5.79.

• We consider now the case $n = 1$, so we are given a single map of finite type $f_0 : A_0 \to A_1$ of quasi-excellent domains. Then we pick a polynomial A_0-algebra $D_0 := A_0[T_1, \dots, T_k]$ with a surjection of A_0-algebras $\psi_0 : D_0 \to A_1$. Set $\mathfrak{p} := \operatorname{Ker}\psi_0$; then $D_{0,\mathfrak{p}}$ is quasi-excellent, by lemma 9.7.4(ii,iv). Especially, $D_{0,\mathfrak{p}}$ is a Nagata ring (lemma 9.7.4(i)), and the regular locus of $\operatorname{Spec} D_{0,\mathfrak{p}}$ is an open subset ([66, Ch.IV, Th.6.12.4]); by corollary 9.6.56, we may then find a regular local domain $(D_1, \mathfrak{m}_1)$, and an injective local ring homomorphism $D_{0,\mathfrak{p}} \to D_1$ of essentially finite type, inducing an isomorphism $\operatorname{Frac}(D_0) \xrightarrow{\sim} \operatorname{Frac}(D_1)$ and a finite field extension $\operatorname{Frac}(D_0/\mathfrak{p}) \to D_1/\mathfrak{m}_1$. Pick $y_1, \dots, y_n \in D_1$ and a prime ideal $\mathfrak{q} \subset D_2 := D_0[y_1, \dots, y_n]$ such that $D_1 = D_{2,\mathfrak{q}}$. Arguing as in the proof of claim 17.5.84, we can assume that the induced injective map $A_1 \xrightarrow{\sim} D_0/\mathfrak{p} \to D_2/\mathfrak{q}$ is finite.

• Now we apply proposition 17.5.75 and remark 17.5.77 to $A := D_2$, $I := \mathfrak{q}$, and to a finite sequence $x_1, \dots, x_d$ of elements of $\mathfrak{q}$ whose images in the regular local ring D_1 are a regular system of parameters : we obtain $g \in D_2 \setminus \mathfrak{q}$ with $g \cdot \mathfrak{q} \subset \sum_{i=1}^d x_i D_2$, and such that the sequence $t_1 := x_1/g, \dots, t_d := x_d/g$ is quasi-regular in the subring $C_1 := D_2[t_1, \dots, t_d] \subset D_2[1/g]$; moreover, if $\mathfrak{q}' \subset C_1$ denotes the ideal generated by $t_1, \dots, t_d$, the inclusion map $D_2 \to C_1$ induces an isomorphism

$$D_2/\mathfrak{q} \xrightarrow{\sim} B_1 := C_1/\mathfrak{q}'.$$

By construction, the resulting map $g_1 : A_1 \to B_1$ is injective and finite, and the natural map $A_0 \to C_1$ is injective of finite type, as required. □

Corollary 17.5.88. *In the situation of* (17.5.86)*, suppose moreover that* A_0 *is a* $\mathbb{Q}$*-algebra of essentially finite type. Then there exists a commutative diagram of ring homomorphisms :*

$$\begin{array}{ccccccc}
A_0 & \xrightarrow{f_0} & A_1 & \xrightarrow{f_1} & \cdots & \xrightarrow{f_{n-1}} & A_n \\
\downarrow & & \downarrow & & & & \downarrow \\
D_0 & \longrightarrow & D_1 & \longrightarrow & \cdots & \longrightarrow & D_n
\end{array}$$

such that D_i *is a big locally CM* A_i*-algebra for every* $i = 0, \dots, n$.

Proof. Pick a commutative diagram (17.5.80) fulfilling the conditions of proposition 17.5.87. Especially, $h_0, \dots, h_n$ are maximizing, since they are injective maps of domains. Then, with the functor E'_0 of (17.5.48), we get a commutative diagram of ring homomorphisms :

$$\begin{array}{ccccccc} A_0 & \xrightarrow{h_0} & C_1 & \xrightarrow{h_1} & \cdots & \xrightarrow{h_{n-1}} & C_n \\ \downarrow & & \downarrow & & & & \downarrow \\ D'_0 & \longrightarrow & D'_1 & \longrightarrow & \cdots & \longrightarrow & D'_n \end{array} \tag{17.5.89}$$

such that D'_0 is a big locally CM A_0-algebra, and D'_i is a big locally CM C_i-algebra, for $i = 1, \dots, n$. Next, by construction, for every $i = 1, \dots, n$ the kernel $\mathfrak{p}_i$ of π_i is a prime ideal generated by a quasi-regular sequence $\mathbf{f}_i := (f_{i,1}, \dots, f_{i,r_i})$ of C_i; then, the image of the sequence $\mathbf{f}_i$ is regular in $C_{i,\mathfrak{p}_i}$ (proposition 7.8.15), so it can be completed to a system of parameters for $C_{i,\mathfrak{p}_i}$ ([63, Ch.0, Prop.16.4.1]) and hence $0 = \dim B_{i,\mathfrak{p}_i} = \dim C_{i,\mathfrak{p}_i} - r_i$ ([126, Th.14.1(i)]), *i.e.* $\mathfrak{p}_i$ is a prime of height r_i, for every $i = 1, \dots, n$. Then, by corollary 10.4.36, the ring $D_i := B_i \otimes_{C_i} D'_i$ is a big locally CM B_i-algebra, for $i = 1, \dots, n$; set as well $D_0 := D'_0$. It remains to check that D_i is a big CM A_i-algebra, for $i = 1, \dots, n$, after restriction of scalars along the map j_i. Thus, for any such i, let $\mathfrak{q}$ be any prime ideal of A_i; clearly $D_{i,\mathfrak{q}}$ is a locally CM $B_{i,\mathfrak{q}}$-algebra, and we need to show that $\mathrm{depth}_{A_{i,\mathfrak{q}}} D_{i,\mathfrak{q}} = \dim A_{i,\mathfrak{q}}$. Since $B_{i,\mathfrak{q}}$ is a finite $A_{i,\mathfrak{q}}$-algebra, taking into account [126, §9, Lemma 2], lemma 10.4.17(ii), and (10.4.30), we come down to checking that the height of every maximal ideal of $B_{i,\mathfrak{q}}$ equals the height of $\mathfrak{q}$. The latter holds by [64, Ch.IV, Prop.5.6.1]. □

We are now ready to state :

Theorem 17.5.90. *In the situation of* (17.5.78)*, there exists a commutative diagram of ring homomorphisms :*

$$\begin{array}{ccccccc} A_0 & \xrightarrow{f_0} & A_1 & \xrightarrow{f_1} & \cdots & \xrightarrow{f_{n-1}} & A_n \\ \downarrow & & \downarrow & & & & \downarrow \\ D_0 & \longrightarrow & D_1 & \longrightarrow & \cdots & \longrightarrow & D_n \end{array}$$

such that D_i is a big CM A_i-algebra for every $i = 0, \dots, n$.

Proof. Suppose first that the residue field k_i of A_i is of characteristic $p > 0$, for $i = 0, \dots, n$. Then, we pick a commutative diagram as in proposition 17.5.79. Especially, $h_0, \dots, h_{n-1}$ are injective and local maps, so if $\mathrm{Frac}\, A_0$ has characteristic zero, the same holds for $\mathrm{Frac}\, C_i$, for every $i = 1, \dots, n$, in which case the discussion of (17.5.73) yields a commutative diagram (17.5.89) such that D'_0 is a big CM A_0-algebra, and D'_i is a big CM C_i-algebra for every $i = 1, \dots, n$. Let $\mathfrak{m}_0, \mathfrak{n}_1, \dots, \mathfrak{n}_n$ be the maximal ideals of $A_0, C_1, \dots, C_n$, and endow D'_0 (resp. D'_i for $i = 1, \dots, n$) with its $\mathfrak{m}_0$-adic (resp. $\mathfrak{n}_i$-adic) topology; by claim 17.5.21(i), the completion D_0 of D'_0 (resp. $D'^{\wedge}_i$ of D'_i, for $i = 1, \dots, n$) is still a CM D_0-algebra (resp. a CM C_i-algebra). Moreover, since $f_0, \dots, f_{n-1}$ are local maps, the maps $D'_0 \to D'_1 \to \cdots \to D'_n$ are continuous, so they induce a sequence of ring homomorphisms $D_0 \to D'^{\wedge}_1 \to \cdots \to D'^{\wedge}_n$. After setting $D_i := B_i \otimes_{C_i} D'^{\wedge}_i$ for $i = 1, \dots, n$, we get a commutative diagram as sought, such that D_i is a big CM B_i-algebra for every $i = 1, \dots, n$, by claim 17.5.21(ii). Next, by restriction of scalars along the finite injective map j_i, the ring D_i is a big CM A_i-algebra for $i = 1, \dots, n$ (remark 17.5.19(iii)), whence the theorem, in this case.

Next, if A_0 is an $\mathbb{F}_p$-algebra, the same holds for $C_1, \dots, C_n$, and then we may argue likewise, using the functor E_p from remark 17.5.36(ii) (recall that all complete noetherian local rings are excellent : see lemma 9.7.4(v)).

Lastly, we consider the case where $k_0, \dots, k_n$ are of zero characteristic, in which case, notice that $H_1 \mathbb{L}_{k_i/\mathbb{Q}} = 0$ for $i = 0, \dots, n$, by proposition 9.6.1(ii). Then, invoking theorem 9.7.41, we obtain a commutative diagram of rings :

$$\begin{array}{ccccc} A'_0 & \xrightarrow{f'_0} & \cdots & \xrightarrow{f'_{n-1}} & A'_n \\ \downarrow{\scriptstyle i_0} & & & & \downarrow{\scriptstyle i_n} \\ A_0 & \xrightarrow{f_0} & \cdots & \xrightarrow{f_{n-1}} & A_n \end{array}$$

such that $A'_0, \dots, A'_n$ are local $\mathbb{Q}$-algebras of essentially finite type, the maps $f'_0, \dots, f'_{n-1}$ are local, and the maps $i_0, \dots, i_n$ are local and of complete intersection. We show :

Claim 17.5.91. There exists a commutative diagram of rings :

$$\begin{array}{ccccccc} A'_0 & \xrightarrow{f'_0} & A'_1 & \xrightarrow{f'_1} & \cdots & \xrightarrow{f'_{n-1}} & A'_n \\ \downarrow & & \downarrow & & & & \downarrow \\ D'_0 & \longrightarrow & D'_1 & \longrightarrow & \cdots & \longrightarrow & D'_n \end{array}$$

such that D'_i is a big CM A'_i-algebra for every $i = 0, \dots, n$.

Proof of the claim. We may find a further commutative diagram of rings :

$$\begin{array}{ccccc} A''_0 & \xrightarrow{f''_0} & \cdots & \xrightarrow{f''_{n-1}} & A''_n \\ \downarrow{\scriptstyle i'_0} & & & & \downarrow{\scriptstyle i'_n} \\ A'_0 & \xrightarrow{f'_0} & \cdots & \xrightarrow{f'_{n-1}} & A'_n \end{array}$$

such that A''_j is a $\mathbb{Q}$-algebra of finite type for $j = 0, \dots, n$, and i'_j is a localization map, so that $A'_j = (A''_j)_{\mathfrak{q}_j}$ for some prime ideal $\mathfrak{q}_j \subset A''_j$. Then we must have $\mathfrak{q}_j = f''^{-1}_j(\mathfrak{q}_{j+1})$ for every $j = 0, \dots, n-1$, since the maps $f'_0, \dots, f'_n$ are local. Notice that A''_0 is excellent ([64, Ch.IV, Sch.7.8.3(ii)]); then, by corollary 17.5.88 we have a commutative diagram

$$\begin{array}{ccccccc} A''_0 & \xrightarrow{f''_0} & A''_1 & \xrightarrow{f''_1} & \cdots & \xrightarrow{f''_{n-1}} & A''_n \\ \downarrow & & \downarrow & & & & \downarrow \\ D''_0 & \longrightarrow & D''_1 & \longrightarrow & \cdots & \longrightarrow & D''_n \end{array}$$

such that D''_i is a big locally CM A''_i-algebra for every $i = 0, \dots, n$. Therefore, $D'_i := (D''_i)_{\mathfrak{q}_i}$ is a big CM A'_i-algebra for $i = 0, \dots, n$, and the map $D''_i \to D''_{i+1}$ induces a map $D'_i \to D'_{i+1}$ for every $i = 0, \dots, n-1$. ◊

Let then $D'_0, \dots, D'_n$ be as in claim 17.5.91; according to lemma 17.5.20, the ring $D_i := A_i \widehat{\otimes}_{A'_i} D'_i$ is a big CM A_i-algebra for $i = 0, \dots, n$, and since each map f_i is local, we may argue as in the foregoing, to obtain the sought sequence of maps $D_0 \to \cdots \to D_n$. □

Corollary 17.5.92. *Every local noetherian ring* $(A, \mathfrak{m})$ *admits a big CM algebra.*

Proof. If the residue field k of A has characteristic $p > 0$, the assertion just summarizes theorems 17.5.28 and 17.5.54. If k has characteristic zero, we may argue as in the proof of claim 17.5.29, to reduce to the case where A is a complete local domain, and the assertion is then the special case of theorem 17.5.90 where $n = 0$. □

Remark 17.5.93. The existence of big CM algebras over rings of equicharacteristic zero was first established by Hochster and Huneke in [95, Th.8.1]; moreover, a later paper by the same authors proves for such algebras a weak functoriality property which is stronger than our theorem 17.5.90 ([96, Th.3.9]). A similar result was proved by Aschenbrenner and Schoutens in

[11, §7], using a technique that has been further developed in [57]. Theorem 17.5.90 for local rings of residue characteristic $p > 0$ has also been proved by Y.André via a different method which yields weakly functorial perfectoid big CM algebras ([7]); the recent preprint [26] gives another proof of this using p-adic completions of absolute integral closures.

17.5.94. *Further refinements.* We conclude by explaining a variant of our constructions, which has some further useful properties, and especially, it generalizes to mixed characteristic [56, Th.7.8]. Consider a complete local noetherian ring $(A, \mathfrak{n})$ of dimension d, with residue field $k := A/\mathfrak{n}$ of characteristic $p > 0$. Suppose moreover that B is a big CM A-algebra, perfectoid for its $\mathfrak{n}$-adic topology; let $\beta_\bullet := (\beta_n \mid n \in \mathbb{N})$ be any element of $\mathbf{E}(B) \setminus \{0\}$, and denote by $\mathfrak{m}_\beta \subset B$ the ideal generated by the system $(\beta_n \mid n \in \mathbb{N})$. Then $(B, \mathfrak{m}_\beta)$ is a basic setup in the sense of [75, §2.1.1], and we denote as usual by $\mathsf{S}_\beta \subset B^{\mathbb{N}}$ the multiplicative subset associated with $(B, \mathfrak{m}_\beta)$ as in (17.5.2).

Lemma 17.5.95. *In the situation of* (17.5.94)*, endow* $\mathsf{S}_\beta^{-1}B^\diamond$ *with its* $\mathfrak{n}$*-adic topology. Then the maximal separated quotient* $(\mathsf{S}_\beta^{-1}B^\diamond)^{\mathrm{sep}}$ *of* $\mathsf{S}_\beta^{-1}B^\diamond$ *is a perfectoid big CM* A*-algebra.*

Proof. Recall that $C := (\mathsf{S}_\beta^{-1}B^\diamond)^{\mathrm{sep}}$ is the $\mathfrak{n}$-adic completion of $\mathsf{S}_\beta^{-1}B^\diamond$ (proposition 17.5.8). In order to show that C is a big CM A-algebra, it then suffices to check that the same holds for $\mathsf{S}_\beta^{-1}B^\diamond$ (lemma 17.5.20), and since B is a big CM A-algebra, lemma 17.5.23 reduces to verify that $(R\Gamma^d_{\{\mathfrak{n}\}}B)^a \neq 0$, for the almost structure relative to the basic setup $(B, \mathfrak{m}_\beta)$. Arguing as in remark 17.5.19(i), we are then further reduced to checking that $(B/\mathfrak{n}B)^a \neq 0$, *i.e.* that $\mathfrak{m}_\beta B \not\subset \mathfrak{n}B$. If the latter fails, we have $\beta_k \in \mathfrak{n}B$ for every $k \in \mathbb{N}$, whence $\beta_0^k \in \mathfrak{n}^k$ for every such k; since the $\mathfrak{n}$-adic topology is separated on B, we then get $\beta_0 = 0$, so $\beta_\bullet = 0$ in $\mathbf{E}(B)$, a contradiction. Next, since B is a P-ring for its $\mathfrak{n}$-adic topology, it is easily seen that the same holds for $B^{\mathbb{N}}$, and then also for its quotient $B^\diamond$, and for C. Now, by remark 16.3.58 we may find an ideal $I \subset B$ of adic definition, fulfilling the conditions of (16.3.55), and for any given finite sequence $b_1, \dots, b_k$ of generators of I, we let J be the ideal generated by $b_1^p, \dots, b_k^p$; let moreover $\mathrm{gr}^\bullet_I B$ and $\mathrm{gr}^\bullet_J B$ be the graded rings associated with the I-adic and respectively the J-adic filtrations of B, and define likewise $\mathrm{gr}^\bullet_I C$ and $\mathrm{gr}^\bullet_J C$. According to proposition 16.3.59, the p-th power map on B (resp. on C) induces an isomorphism $\Phi_{B,I} : \mathrm{gr}^\bullet_I B \xrightarrow{\sim} \mathrm{gr}^\bullet_J B$ (resp. a ring homomorphism $\Phi_{C,I} : \mathrm{gr}^\bullet_I C \to \mathrm{gr}^\bullet_J C$); on the other hand, by lemma 17.5.1 we get natural identifications :

$$\mathrm{gr}^\bullet_I C \xrightarrow{\sim} \mathrm{gr}^\bullet_I(\mathsf{S}_\beta^{-1}B^\diamond) \xrightarrow{\sim} \mathsf{S}_\beta^{-1}(\mathrm{gr}^\bullet_I B)^\diamond \qquad \mathrm{gr}^\bullet_J C \xrightarrow{\sim} \mathrm{gr}^\bullet_J(\mathsf{S}_\beta^{-1}B^\diamond) \xrightarrow{\sim} \mathsf{S}_\beta^{-1}(\mathrm{gr}^\bullet_J B)^\diamond$$

and $\Phi_{C,I}$ corresponds to $\mathsf{S}_\beta^{-1}\Phi^\diamond_{I,B}$, under these identifications. Hence, $\Phi_{C,I}$ is an isomorphism, so C is perfectoid, by theorem 16.3.64. □

Theorem 17.5.96. *For every complete local noetherian ring* $(A, \mathfrak{n})$ *with residue field* $A/\mathfrak{n}$ *of characteristic* $p > 0$*, and every perfectoid big CM* A*-algebra* B_0 *there exists a ring homomorphism* $B_0 \to B$ *such that the following holds :*

(i) B *is a big CM* A*-algebra, and is perfectoid for its* $\mathfrak{n}$*-adic topology.*

(ii) B *is a local domain, whose maximal ideal is the radical of* $\mathfrak{n}B$*.*

(iii) *Set* $\mathbf{E} := \mathbf{E}(B)$*. Then, for every non-constant monic polynomial* $P \in W(\mathbf{E})[X]$ *and every distinguished ideal* $\mathscr{I} \subset W(\mathbf{E})$ *there exists* $\underline{w} \in W(\mathbf{E})$ *such that* $P(\underline{w}) \in \mathscr{I}$*.*

(iv) *Especially,* B *is normal, and* $\mathrm{Frac}(B)$ *is an algebraically closed field.*

(v) *For every* $\beta_\bullet \in \mathbf{E} \setminus \{0\}$*, define the basic setup* $(B, \mathfrak{m}_\beta)$ *as in* (17.5.94)*. Then the unit of adjunction* $\eta_B : B \to (B, \mathfrak{m}_\beta)^a_*$ *is an isomorphism.*

Proof. By proposition 16.3.8(ii), the $\mathfrak{n}$-adic completion of B_0 is perfectoid for its $\mathfrak{n}$-adic topology, and is still a big CM A-algebra (lemma 17.5.20); hence we may assume from start that B_0 is perfectoid for its $\mathfrak{n}$-adic topology. Set $\mathbf{E}_0 := \mathbf{E}(B_0)$. By proposition 16.9.29, we have an adic, adically faithfully flat, and perfectoid $\mathbf{E}_0$-algebra $\mathbf{E}_1$ such that for every non-constant monic polynomial $P \in W(\mathbf{E}_1)[X]$ and every distinguished ideal $\mathscr{I} \subset W(\mathbf{E}_1)$ there exists $\underline{w} \in W(\mathbf{E}_1)$ with $P(\underline{w}) \in \mathscr{I}$. Set $B_1 := B_0 \otimes_{W(\mathbf{E}_0)} W(\mathbf{E}_1)$; the induced map $B_0 \to B_1$ is then adically faithfully flat (proposition 16.4.18), so $B_1/\mathfrak{n}B_1$ is a faithfully flat $B_0/\mathfrak{n}B_0$-algebra, and especially $B_1/\mathfrak{n}B_1 \neq 0$. Moreover $\mathrm{depth}_A B_1 \geq \mathrm{depth}_A B_0$ (corollary 14.2.50(ii) and proposition 16.4.10(ii)). By remark 17.5.19(i), this shows that B_1 is a big CM A-algebra. Notice that, due to the foregoing property of $\mathbf{E}_1$, the map $\overline{u}_{B_1} : \mathbf{E}_1 \to B_1$ is surjective. Choose any minimal prime ideal $\mathfrak{p} \subset B_1$, and endow $S := \overline{u}_{B_1}^{-1}(B_1 \setminus \mathfrak{p})$ with the preordering such that $\beta_\bullet \leq \beta'_\bullet$ if and only if $\beta'_\bullet \mathbf{E}_1 \subset \beta_\bullet \mathbf{E}_1$, for every $\beta_\bullet, \beta'_\bullet \in S$. Then clearly $(S, \leq)$ is a filtered category (see example 1.1.6(iii)), and for every $\beta_\bullet := (\beta_n \mid n \in \mathbb{N})$, define the basic setup $(B_1, \mathfrak{m}_\beta)$ and the multiplicative subset $\mathsf{S}_\beta \subset B_1^{\mathbb{N}}$ as in (17.5.94), and the perfectoid big CM A-algebra $(\mathsf{S}_\beta^{-1} B_1^\diamond)^{\mathrm{sep}}$ as in lemma 17.5.95. Let B_2 be the colimit of the filtered system of B_1-algebras $((\mathsf{S}_\beta^{-1} B_1^\diamond)^{\mathrm{sep}} \mid \beta_\bullet \in S)$. Then the $\mathfrak{n}$-adic completion $B_2^\wedge$ of B_2 is again a perfectoid big CM A-algebra, by remark 17.5.19(iv), lemma 17.5.20 and corollary 16.3.46.

Claim 17.5.97. (i) The kernel of the induced map $j : B_1 \to B_2$ contains $\mathfrak{p}$.

(ii) For every $\beta \in S$ we have a commutative diagram of B_1-modules :

$$\begin{array}{ccc} B_1 & \xrightarrow{\ j\ } & B_2 \\ {\scriptstyle \eta_{B_1}} \downarrow & \nearrow & \downarrow {\scriptstyle \eta_{B_2}} \\ (B_1, \mathfrak{m}_\beta)^a_* & \xrightarrow{\ j^a_*\ } & (B_2, \mathfrak{m}_\beta)^a_* \end{array}$$

whose vertical arrows are the units of adjunctions.

Proof of the claim. (i): Recall that B_1 is reduced (corollary 16.3.63(i)), hence $B_{1,\mathfrak{p}}$ is a field, and in particular, the kernel of the localization map $B_1 \to B_{1,\mathfrak{p}}$ equals $\mathfrak{p}$. The latter means that for every $b \in \mathfrak{p}$ there exists $\beta_0 \in B_1 \setminus \mathfrak{p}$ such that $b\beta_0 = 0$ in B_1. We have already observed that $\overline{u}_{B_1}$ is surjective; then pick $\beta_\bullet \in S$ such that $\overline{u}_{B_1}(\beta_\bullet) = \beta_0$. We regard $\beta_\bullet := (\beta_n \mid n \in \mathbb{N})$ as an element of $B_1^{\mathbb{N}}$, in which case $\beta_\bullet \in \mathsf{S}_\beta$; but notice that $\beta_\bullet \cdot j(b)$ is the class of $(\beta_n b \mid n \in \mathbb{N})$, and we have $\beta_n b = 0$ for every $n \in \mathbb{N}$, since $(\beta_n b)^{p^n} = \beta_0 g^{p^n} = 0$, and since B_1 is reduced. Thus, $j(b) = 0$, as stated.

(ii): According to lemma 17.5.4(iii), the unit of adjunction $\mathsf{S}_\beta^{-1} B_1^\diamond \to (\mathsf{S}_\beta^{-1} B_1^\diamond)^a_*$ is an isomorphism (relative to the basic setup $(B_1, \mathfrak{m}_\beta)$), hence the structure map $B_1 \to \mathsf{S}_\beta^{-1} B_1^\diamond$ factors through η_{B_1}, and then the same holds for j. ◊

Next, let $\overline{\mathfrak{q}}$ be any minimal prime ideal of $B_2^\wedge/\mathfrak{n}B_2^\wedge$, and $\mathfrak{q} \subset B_2^\wedge$ the preimage of $\overline{\mathfrak{q}}$. Let B_3 be the $\mathfrak{n}$-adic completion of the localization $B_{2,\mathfrak{q}}^\wedge$. Clearly B_3 is a P-ring, for its $\mathfrak{n}$-adic topology. By remark 16.3.58 we may find an ideal $I \subset B_2^\wedge$ of adic definition, fulfilling the conditions of (16.3.55), and for any given finite sequence $b_1, \dots, b_k$ of generators of I, we let J be the ideal generated by $b_1^p, \dots, b_k^p$. Let moreover $\mathrm{gr}_I^\bullet B_2^\wedge$ and $\mathrm{gr}_J^\bullet B_2^\wedge$ be the graded rings associated with the I-adic and respectively the J-adic filtrations of B, and define likewise $\mathrm{gr}_I^\bullet B_3$ and $\mathrm{gr}_J^\bullet B_3$. According to proposition 16.3.59, the p-th power map on B induces an isomorphism $\Phi_I : \mathrm{gr}_I^\bullet B_2^\wedge \xrightarrow{\sim} \mathrm{gr}_J^\bullet B_2^\wedge$ and a ring homomorphism $\Phi_{IB_3} : \mathrm{gr}_I^\bullet B_3 \to \mathrm{gr}_J^\bullet B_3$. Clearly $\mathrm{gr}_I^j B_3 = (\mathrm{gr}_I^j B_2^\wedge)_\mathfrak{q}$ and $\mathrm{gr}_J^j B_3 = (\mathrm{gr}_J^j B_2^\wedge)_\mathfrak{q}$, for every $j \in \mathbb{N}$, and Φ_{IB_3} corresponds to the localization $(\Phi_I)_\mathfrak{q}$ under these identifications. Hence Φ_{IB_3} is an isomorphism, so B_3 is perfectoid, by theorem 16.3.64. Let us check that B_3 is a big CM A-algebra. By lemma 17.5.20, it suffices to show that the same holds for $B_{2,\mathfrak{q}}^\wedge$. But clearly $\mathrm{depth}_A B_{2,\mathfrak{q}}^\wedge \geq \mathrm{depth}_A B_2^\wedge$, and moreover $B_{2,\mathfrak{q}}^\wedge/\mathfrak{n}B_{2,\mathfrak{q}}^\wedge \neq 0$, since $B_2^\wedge/\mathfrak{n}B_2^\wedge \neq 0$, and since the preimage of $\mathfrak{q}$ in A equals $\mathfrak{n}$. Then the assertion follows from remark 17.5.19(i). Summing up, to every big CM A-algebra B_0 that is perfectoid for its $\mathfrak{n}$-adic topology, we have attached three more such algebras; we introduce the notation :

$$\mathscr{B}(B_0)_1 := B_1 \qquad \mathscr{B}(B_0)_2 := B_2^\wedge \qquad \mathscr{B}(B_0) := B_3.$$

Let also $\mathfrak{p}(B_0) \subset \mathscr{B}_0(B_0)_1$ be the minimal ideal $\mathfrak{p}$. Then we define by transfinite induction, for every ordinal α an A-algebra $\mathscr{B}_\alpha(B_0)$, as follows. First, we set $\mathscr{B}_0 := B_0$; next, $\mathscr{B}_{\alpha+1} := \mathscr{B}(\mathscr{B}_\alpha)$ for every successor ordinal $\alpha+1$, and $\mathscr{B}_\alpha$ is the $\mathfrak{n}$-adic completion of $\mathrm{colim}_{\beta<\alpha}\mathscr{B}_\beta$, for every limit ordinal α. Taking into account remark 17.5.19(iv) and lemma 17.5.20, we see easily that $\mathscr{B}_\alpha$ is a perfectoid big CM A-algebra, for every ordinal α. Lastly, let ω_1 be the smallest uncountable ordinal; we claim that $B := \mathscr{B}_{\omega_1}$ will do. Indeed, arguing as in the proof of proposition 16.9.29 we see that $B = \mathrm{colim}_{\beta<\alpha}\mathscr{B}_\beta$, and that (iii) holds. Next, let $x, y \in B$ with $xy = 0$; we find $\beta < \omega_1$ such that x and y are the images of elements x' and y' of $\mathscr{B}_\beta$, and we may assume that $x'y' = 0$. But then the image of either x' or y' in $\mathscr{B}(\mathscr{B}_\beta)_1$ lies in $\mathfrak{p}(\mathscr{B}_\beta)_1$, and then the image of either x' or y' vanishes in $\mathscr{B}(\mathscr{B}_\beta)_2$, by claim 17.5.97(i), so either $x = 0$ or $y = 0$; this shows that B is a domain. Moreover, by construction $\mathscr{B}(\mathscr{B}_\alpha)$ is a local ring, and its maximal ideal is the radical of $\mathfrak{n}\mathscr{B}(\mathscr{B}_\alpha)$, for every ordinal α; assertion (ii) follows easily. Assertion (iv) follows easily from (ii) and (iii) : the details shall be left to the reader.

(v): From corollary 16.3.46 and claim 16.9.30, we deduce that $\mathbf{E}(B)$ is the colimit of the system $(\mathbf{E}(\mathscr{B}_\alpha) \mid \alpha < \omega_1)$. Let now $\beta_\bullet \in \mathbf{E}$, so that $\beta_\bullet$ is the image of an element $\beta'_\bullet \in \mathbf{E}(\mathscr{B}_\alpha)$ for some ordinal $\alpha < \omega_1$, and the ideal $\mathfrak{m}_\beta \subset B$ equals $\mathfrak{m}B$, where $\mathfrak{m} \subset \mathscr{B}_\alpha$ is the ideal generated by $(\beta'_n \mid n \in \mathbb{N})$; let $x \in (B, \mathfrak{m}_\beta)^a_*$. We notice :

Claim 17.5.98. $(B, \mathfrak{m}_\beta)^a_* = \mathrm{colim}_{\alpha\leq\gamma<\omega_1}(\mathscr{B}_\gamma, \mathfrak{m}\mathscr{B}_\gamma)^a_*$.

Proof of the claim. Recall that for any basic setup $(V, \mathfrak{m})$ and any V-module M we have $M^a_* = \mathrm{Hom}_V(\widetilde{\mathfrak{m}}, M)$, with $\widetilde{\mathfrak{m}} := \mathfrak{m} \otimes_V \mathfrak{m}$. Moreover, for every ring homomorphism $V \to W$ we have $\mathfrak{m}W \otimes_W \mathfrak{m}W = W \otimes_V \widetilde{\mathfrak{m}}$ ([75, Rem.2.1.4(ii)]). Thus, it suffices to check that $B^a_* = \mathrm{colim}_{\alpha\leq\gamma<\omega_1}\mathscr{B}^a_{\gamma,*}$ for the almost structure given by the basic setup $(\mathscr{B}_\alpha, \mathfrak{m})$. However, according to [75, Th.2.1.12(ii.a)] we have a $\mathscr{B}_\alpha$-linear presentation

$$\mathscr{B}_\alpha^{(\mathbb{N})} \xrightarrow{f} \mathscr{B}_\alpha^{(\mathbb{N})} \to \widetilde{\mathfrak{m}} \to 0.$$

Let $(e_i \mid i \in \mathbb{N})$ be the canonical basis of the free $\mathscr{B}_\alpha$-module $\mathscr{B}_\alpha^{(\mathbb{N})}$, so that for every $i \in \mathbb{N}$ we have a finite subset $S_i \subset \mathbb{N}$ and a system $(a_{ij} \mid j \in S_i)$ of elements of $\mathscr{B}_\alpha$ such that $f(e_i) = \sum_{j\in S_i} a_{ij}e_j$. With this notation, the datum of a $\mathscr{B}_\alpha$-linear map $\varphi : \widetilde{\mathfrak{m}} \to B$ is the same as that of a system $b_\bullet := (b_i \mid i \in \mathbb{N})$ of elements of B with $\sum_{j\in S_i} a_{ij}b_j = 0$ for every $i \in \mathbb{N}$. Since $B = \mathrm{colim}_{\gamma<\omega_1}\mathscr{B}_\gamma$, for every $i \in \mathbb{N}$ the element b_i is the class $[c_i, \gamma_i]$ of a pair consisting of an ordinal $\gamma_i < \omega_1$ and some $c_i \in \mathscr{B}_{\gamma_i}$; pick any ordinal $\gamma < \omega_1$ such that $\gamma \geq \gamma_i$ for every $i \in \mathbb{N}$, and $\gamma \geq \alpha$. After replacing each c_i by its image in $\mathscr{B}_\gamma$, we may assume that $\gamma_i = \gamma$ for every $i \in \mathbb{N}$. Likewise, for every $i \in \mathbb{N}$ there exists an ordinal $\delta_i < \omega_1$ with $\delta_i \geq \gamma$, and such that the image of $\sum_{j\in S_i} a_{ij}c_j$ vanishes in $\mathscr{B}_{\delta_i}$. We pick again $\delta < \omega_1$ such that $\delta \geq \delta_i$ for every $i \in \mathbb{N}$, and let $d_i \in \mathscr{B}_\delta$ be the image of c_i in $\mathscr{B}_\delta$, for every $i \in \mathbb{N}$; then the system $(d_i \mid i \in \mathbb{N})$ corresponds to a $\mathscr{B}_\alpha$-linear map $\psi : \widetilde{\mathfrak{m}} \to \mathscr{B}^a_{\delta,*}$ whose composition with the natural map $\mathscr{B}^a_{\delta,*} \to B^a_*$ agrees with φ. This shows that the natural map $t : \mathrm{colim}_{\alpha\leq\gamma<\omega_1}\mathscr{B}^a_{\gamma,*} \to B^a_*$ is surjective. Lastly, notice that φ is the zero map if and only if $b_i = 0$ for every $i \in \mathbb{N}$; if $b_i = [c_i, \gamma_i]$ as in the foregoing, we may then find $\delta < \omega_1$ with $\delta \geq \gamma_i$ and $\delta \geq \alpha$, and such that the image of c_i vanishes in $\mathscr{B}_\delta$ for every $i \in \mathbb{N}$. This shows that t is injective, and concludes the proof. ◊

From claim 17.5.98, the almost element x is the image of some $y \in (\mathscr{B}_\gamma, \mathfrak{m}\mathscr{B}_\gamma)^a_*$, for some $\gamma < \omega_1$ with $\gamma \geq \alpha$, in which case the image of y in $(\mathscr{B}_{\gamma+1}, \mathfrak{m}\mathscr{B}_{\gamma+1})^a_*$ is also the image of some $z \in \mathscr{B}(\mathscr{B}_\gamma)_2$, by claim 17.5.97(ii); if $z' \in B$ is the image of z, we see that $\eta_B(z') = x$. This shows that η_B is surjective, and we also know that its kernel is annihilated by $\mathfrak{m}_\beta$; since B is a domain, it then follows that η_B is an isomorphism. □

Remark 17.5.99. (i) With the notation of theorem 17.5.96, let $\beta_\bullet := (\beta_n \mid n \in \mathbb{N}) \in \mathbf{E}(B)$ be any non-zero element; notice that every principal ideal of B is a free B-module, since B is a domain (theorem 17.5.96(iv)), hence $\mathfrak{m}_\beta$ is a flat B-module, since it is the filtered union of principal ideals, and therefore $\mathfrak{m}_\beta = \mathfrak{m}_\beta \otimes_B \mathfrak{m}_\beta$ ([75, Rem.2.14(i)]). It follows that

$$(B, \mathfrak{m}_\beta)^a_* = \mathrm{Hom}_B(\mathfrak{m}_\beta, B) = \bigcap_{n\in\mathbb{N}} \{x \in \mathrm{Frac}(B) \mid \beta_n x \in B\}. \tag{17.5.100}$$

(ii) Recall that an integral domain A is said to be *completely integrally closed* if the following holds for every $x \in K := \mathrm{Frac}(A)$. The subring $A[x] \subset K$ lies in a finitely generated A-submodule of K if and only if $x \in A$. Then, we claim that condition (v) of theorem 17.5.96 is equivalent to the assertion that B is completely integrally closed. Indeed, let $\beta_\bullet$ be as in (i), and $x \in (B, \mathfrak{m}_\beta)^a_*$; in light of (17.5.100), we see that $B[x] \subset \beta_0^{-1} B$. Hence, if B is completely integrally closed, we have $B = (B, \mathfrak{m}_\beta)^a_*$. Conversely, suppose the latter condition holds, and let $x \in \mathrm{Frac}(B)$ be an element such that $B[x]$ lies in a B-module of finite type; this means that $B[x] \subset b^{-1}B$ for some $b \in B \setminus \{0\}$, so that $bx^{p^n} \in B$ for every $n \in \mathbb{N}$. But by virtue of theorem 17.5.96(iii), there exists $\beta_\bullet \in \mathbf{E}(B)$ with $\beta_0 = b$; then, with (17.5.100), we deduce that $x \in (B, \mathfrak{m}_\beta)^a_*$, so $x \in B$, by assumption.

17.6. **Monomial conjectures.** The existence of big CM modules and algebras can be applied to settle some other long-standing conjectures concerning systems of parameters in local noetherian rings. In this section we prove some of these conjectures. The first result is the following:

Theorem 17.6.1 (Monomial conjecture). *Let $(A, \mathfrak{m})$ be a local noetherian ring, and $x_1, \dots, x_d$ a system of parameters for A. Then we have :*

$$x_1^t \cdots x_d^t \notin Ax_1^{t+1} + \cdots + Ax_d^{t+1} \qquad \textit{for every } t \in \mathbb{N}.$$

Proof. We reproduce the argument from [92, Prop.3.5]. Let $R := \mathbb{Z}[T_1, \dots, T_d]$, and for every $t \in \mathbb{N}$, denote by $I_t \subset R$ the ideal generated by $T_1^t, \dots, T_d^t$. We have a short exact sequence of R-modules :

$$0 \to R/I_1 \xrightarrow{\varphi_t} R/I_{t+1} \to Q := R/(I_{t+1} + Rp_t) \to 0$$

where φ_t is induced by the endomorphism $R \to R$ such that $q \mapsto qT_1^t \cdots T_d^t$ for every $q \in R$. Let also $f : R \to A$ be the ring homomorphism such that $f(T_i) = x_i$ for $i = 1, \dots, d$. Then, every A-module becomes an R-module, after restriction of scalars along f. We notice :

Claim 17.6.2. For every big CM A-module M we have $\mathrm{Tor}_1^R(Q, M) = 0$.

Proof of the claim. Notice the natural ring isomorphism $R/I_1 \xrightarrow{\sim} \mathbb{Z}$, and let $\mathrm{gr}_\bullet Q$ be the graded $\mathbb{Z}$-module associated with the I_1-adic filtration of Q; we easily see that $I^k Q = 0$ for every sufficiently large $k \in \mathbb{N}$; then the long Tor exact sequences induced by the short exact sequences of R-modules :

$$0 \to I_1^{k+1} Q \to I^k Q \to \mathrm{gr}_k Q \to 0 \qquad \text{for every } k \in \mathbb{N} \tag{17.6.3}$$

easily reduce to checking that $\mathrm{Tor}_i^R(\mathrm{gr}_k Q, M) = 0$ for every $k \in \mathbb{N}$ and every $i > 0$. Moreover, it is easily seen that $\mathrm{gr}_k Q$ is a free $\mathbb{Z}$-module, for every $k \in \mathbb{N}$ (details left to the reader), hence we are further reduced to checking that $\mathrm{Tor}_1^R(R/I_1, Q) = 0$ for every $i > 0$. The latter follows from remark 17.5.19(i) and lemma 7.8.14. ◊

By corollary 17.5.92, we may find a big CM A-module M. Then it suffices to check :

Claim 17.6.4. For every big CM A-module M, the map φ_t induces an injective map

$$\varphi_t \otimes_A M : M/I_1 M \to M/I_{t+1} M \qquad \overline{m} \mapsto \overline{x_1^t \cdots x_d^t m} \qquad \text{for every } t \in \mathbb{N}.$$

Proof of the claim. It follows immediately by combining claim 17.6.2 with the long Tor exact sequence attached to (17.6.3). □

Remark 17.6.5. (i) In the situation of theorem 17.6.1, set $X := \mathrm{Spec}\, A$ and $U_i := \mathrm{Spec}\, A[x_i^{-1}]$ for $i = 1, \dots, d$. Then, $U_\bullet := (U_i \mid i = 1, \dots, d)$ is an affine covering of $X \setminus \{\mathfrak{m}\}$, and proposition 10.4.18 yields a natural isomorphism

$$R\Gamma_{\{\mathfrak{m}\}}\mathscr{O}_X \xrightarrow{\sim} C^\bullet_{\mathrm{alt}}(U_\bullet, \mathscr{O}_X)[-1] \qquad \text{in } \mathsf{D}(A\text{-}\mathbf{Mod})$$

where $C^\bullet_{\mathrm{alt}}(U_\bullet, \mathscr{O}_X)$ denotes the alternating augmented Čech complex of the structure sheaf $\mathscr{O}_X$, relative to the covering $U_\bullet$. Set as well $y := x_1 \cdots x_d$, and $y_i := x_1 \cdots x_{i-1}x_{i+1} \cdots x_d$ for $i = 1, \dots, d$; there follows an A-linear isomorphism

$$H^d_{\{\mathfrak{m}\}}(A) \xrightarrow{\sim} \mathrm{Coker}\Big(\partial : \bigoplus_{i=1,\dots,d} A[y_i^{-1}] \to A[y^{-1}]\Big)$$

where ∂ is the sum of the localization maps $A[y_i^{-1}] \to A[y^{-1}]$. Especially, the class of y^{-1} in $\mathrm{Coker}\,\partial$ corresponds to an element $\beta \in H^d_{\{\mathfrak{m}\}}(A)$, and a simple inspection shows that theorem 17.6.1 is equivalent to the assertion that $\beta \neq 0$: the details shall be left to the reader.

(ii) Moreover, it was already known, by some early work of Hochster, that the monomial conjecture is equivalent to the direct summand conjecture (for finite extensions of regular local rings) : see [93, Th.6.1].

Theorem 17.6.6 (Strong monomial conjecture)**.** *Let $(A, \mathfrak{m})$ be a noetherian local ring, $\mathfrak{p} \subset A$ a prime ideal, and $x_1, \dots, x_d$ a system of parameters for A, such that :*

(a) $\mathfrak{p}$ *has height one, and* $\dim A/\mathfrak{p} = d - 1$.
(b) $x_1 \in \mathfrak{p}$.

Then we have : $\qquad x_1^{t+1}x_2^t \cdots x_d^t \notin \mathfrak{p} \cdot (Ax_1^{t+1} + \cdots + Ax_d^{t+1}) \qquad$ *for every $t \in \mathbb{N}$.*

Proof. We first notice :

Claim 17.6.7. We may assume that $(A, \mathfrak{m})$ is a complete local domain.

Proof of the claim. Let $A^\wedge$ and $(A/\mathfrak{p})^\wedge$ be the $\mathfrak{m}$-adic completions of A and $A/\mathfrak{p}$; recall that the $\mathfrak{m}$-adic topology of A induces the $\mathfrak{m}$-adic topology on $\mathfrak{p}A$ ([126, Th.8.6]), and $\mathfrak{p}A^\wedge$ is a closed ideal for the $\mathfrak{m}$-adic topology of $A^\wedge$ ([126, Th.8.10(i)]), hence the natural map $A^\wedge/\mathfrak{p}A^\wedge \to (A/\mathfrak{p})^\wedge$ is a ring isomorphism (proposition 8.2.13(i,v)). Especially, $\dim A^\wedge/\mathfrak{p}A^\wedge = d - 1$, *i.e.*, there exists a maximal point $\mathfrak{p}'$ of the closed subset $\mathrm{Spec}\, A^\wedge/\mathfrak{p}A^\wedge \subset \mathrm{Spec}\, A^\wedge$, such that $\dim A^\wedge/\mathfrak{q} = d - 1$. Moreover, by the going-down theorem for flat extensions, for every such $\mathfrak{p}'$ we have $\mathfrak{p} = \mathfrak{p}' \cap A$ ([126, Th.9.5]), and furthermore, $\mathfrak{p}'$ has height one ([126, Th.15.1(ii)]). Pick any minimal prime ideal $\mathfrak{q} \subset A^\wedge$ contained in $\mathfrak{p}'$. By the same token, $\mathfrak{q}$ is a closed ideal for the $\mathfrak{m}$-adic topology of $A^\wedge$, and therefore $A' := A^\wedge/\mathfrak{q}$ is still a complete local ring; since $\dim A^\wedge/\mathfrak{q} = d - 1$, we must have $\dim A' = d$, and $\mathfrak{p}'A'$ has height one. Clearly it suffices to prove the theorem for the ring A', its prime ideal $\mathfrak{p}'A'$, and the image in A' of the sequence $x_1, \dots, x_d$, which is still a system of parameters for A'. ◊

Henceforth, we assume that $(A, \mathfrak{m})$ is a complete local domain, so the same holds for $A/\mathfrak{p}$, and we may find a commutative diagram of rings :

$$\begin{array}{ccc} A & \longrightarrow & A/\mathfrak{p} \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle g} \\ B_0 & \longrightarrow & B_1 \end{array}$$

such that B_0 is a big CM A-algebra, and B_1 is a big CM $A/\mathfrak{p}$-algebra (theorem 17.5.90). For a given $t \in \mathbb{N}$, set $y := x_1^{t+1}x_2^t \cdots x_d^t$, and $I := Ax_1^{t+1} + \cdots + Ax_d^{t+1}$. Clearly it suffices to check :

Claim 17.6.8. $f(y) \notin (I\mathfrak{p} + I^2)B_0$.

Proof of the claim. The sequence $x_1, \dots, x_d$ is completely secant in B_0 (remark 17.5.19(i)), so the same holds for the sequence $x_1^{t+1}, \dots, x_d^{t+1}$ (corollary 7.8.8(ii)), and then the latter is also B_0-quasi-regular (proposition 7.8.15). The latter means that the A-linear map

$$\omega : \bigoplus_{i=1}^{d} (B_0/IB_0) \to M := IB_0/I^2B_0 \qquad (\bar{b}_1, \dots, \bar{b}_d) \mapsto \overline{x_1^{t+1}b_1 + \cdots + x_d^{t+1}b_d}$$

is an isomorphism. We have $f(y) \in IB_0$, and clearly $\omega(\overline{f(x_2^t \cdots x_d^t)}, 0, \dots, 0)$ is the class $\overline{f(y)}$ of $f(y)$ in M. Now, if the claim fails, we have $\overline{f(y)} \in \mathfrak{p}M$, and therefore

$$(17.6.9) \qquad (\overline{f(x_2^t \cdots x_d^t)}, 0, \dots, 0) \in \bigoplus_{i=1}^{d} \mathfrak{p}(B_0/IB_0) \qquad i.e. \quad f(x_2^t \cdots x_d^t) \in (\mathfrak{p} + I)B_0.$$

Now, notice that the image $\overline{x}_2, \dots, \overline{x}_d$ of the sequence $x_2, \dots, x_d$ is a system of parameters for $A/\mathfrak{p}$, since $\dim A/\mathfrak{p} = d - 1$. However, from (17.6.9) we get

$$g(\overline{x}_2^t \cdots \overline{x}_d^t) \in IB_1$$

which contradicts claim 17.6.4, since B_1 is a big CM $A/\mathfrak{p}$-algebra. □

Remark 17.6.10. (i) In the situation of theorem 17.6.6, notice that $\dim A/x_1A = d - 1$ ([126, Th.14.1]), hence $\mathfrak{p}$ must be a maximal point of the closed subset $\operatorname{Spec} A/x_1A \subset \operatorname{Spec} A$.

(ii) Conversely, if A is equidimensional and catenary, and $\mathfrak{p}$ is a maximal point of the closed subset $\operatorname{Spec} A/x_1A$, then conditions (a) and (b) of theorem 17.6.6 are clearly fulfilled.

(iii) The hypothesis on $\dim A/\mathfrak{p}$ in condition (a) of theorem 17.6.6 is incorrectly omitted from the statement of the strong monomial conjecture in the survey article [142], where it is listed as conjecture 19. To see that this hypothesis cannot be omitted, consider a local noetherian domain $(A, \mathfrak{m})$ of dimension d, with a prime ideal $\mathfrak{p}$ of height one, such that $\dim A/\mathfrak{p} \leq d - 2$. Pick any $x_1 \in \mathfrak{p} \setminus \{0\}$; then let $\Sigma \subset \operatorname{Spec} A$ be the subset of all prime ideals $\mathfrak{q}$ of A such that $x_1 \in \mathfrak{q}$ and $\dim A/\mathfrak{q} = d - 1$. Clearly every element of Σ must have height one, so Σ lies in the finite set of maximal points of $\operatorname{Spec} A/x_1A$. Moreover, for every $\mathfrak{q} \in \Sigma$ we have $\mathfrak{p} \not\subseteq \mathfrak{q}$, since $\dim A/\mathfrak{p} < d - 1$. Hence, there exists $x_2 \in \mathfrak{p} \setminus \bigcup_{\mathfrak{q} \in \Sigma} \mathfrak{q}$ ([12, Prop.1.11(i)]). Let $I := Ax_1 + Ax_2$; we have $\dim A/I \geq d - 2$ by [126, Th.13.6(ii)], and on the other hand, by construction there exists no prime ideal $\mathfrak{q} \subset A$ such that $I \subset \mathfrak{q}$ and $\dim A/\mathfrak{q} = d - 1$, so $\dim A/I = d - 2$. Now, pick $x_3, \dots, x_d \in \mathfrak{m}$ whose images in A/I are a system of parameters for the latter local ring. It follows easily that $x_1, \dots, x_d$ is a system of parameters for A, and it is easily seen that $x_1^2 x_2 \cdots x_d \in \mathfrak{p} \cdot (Ax_1^2 + \cdots + Ax_d^2)$.
